It is difficult for any man, however able, to estimate the importance of the advances which the practice of medicine has made in recent times, unless he be intimately acquainted with the history of the art, and have also that true discernment which originates in and is quickened by practical experience. The erroneous notions springing out of this difficulty Dr. Warburton Begbie has set himself to expose in the very learned and thoughtful Address in Medicine which he delivered before our Association at Edinburgh.

Sir William Hamilton asked the question, "Has the *practice* of medicine made a single step since Hippocrates?" and answered it in the negative. We are surprised that a man possessed of the knowledge and acuteness of Sir William Hamilton should have been content to deny any progress to the healing art. The facts of mortality in civilised countries show that plagues are arrested and diseases are less deadly in proportion as medicine is more scientifically studied. There are not in modern times any diseases of such terrific malignity as the Black Death and Sweating Sickness of the Middle Ages. Even cholera, we have good reason to hope, if it should visit us again, will be deprived of its intense fatality. Small-pox has been brought under control by vaccination. Should it be remarked that these maladies have not been cured or even modified in their progress by drugs, the answer is, that the true physician does not rely upon drugs alone, but summons to his aid all the resources of Nature, of which drugs are only a part. Everything in the wide domain of Nature that can attack disease, its causes, its activities, or its effects, is a constituent part of the *practice* of medicine. If any man should not understand this, or should wilfully close his eyes to it, then he does not comprehend the higher philosophy of the art, as now taught and practised by our most enlightened physicians.

In regarding Nature in this general sense in connection with the art of healing, we touch the very proposition which is at the centre of the Hippocratic philosophy—a proposition on which Sydenham delighted to insist, and which seems to have unduly swayed Sir William Hamilton in coming to his unfavourable decision. There is no phrase, probably, that is more liable to misleading interpretations than this. What do we mean by Nature? Is it the variety of phenomena and agencies external to man? is it the formative and disintegrating forces within the body of man? does it signify mere physical forces? or does it include also that mysterious influence over the animal economy which we call vital or spiritual, according to the hypothesis employed for the interpretation? We say—the whole of these; but, in view of the argument so ably expounded by Dr. Begbie, we limit it to that preservative power which was supposed by Hippocrates to be the restorer of any disorder in the bodily functions—the *vis medicatrix nature*—which was explained by Sydenham to be that Nature which “by herself determines diseases, and is of herself sufficient in all things against all of them”.

There can be little doubt that too implicit a reliance upon this assumed *vis medicatrix* would lead to a negative practice, to an indolent acquiescence in its operations, rather than to an active interposition with the intention of using and guiding them. This principle has lain at the root of many modern fallacies and empirical systems of treatment. It must not be overlooked, that Nature will cause diseases and conduct them to a fatal termination, as well as cure them; and it is the province of the skilful physician to discern the tendency of these actions, and to moderate or quicken them as may seem most expedient. In whatever he does, however, if it be done wisely and thoughtfully, is all in subordination to those forces which are moulding the living structure; and, so far, he is a pupil of the great father of medicine, who was himself, if primarily a servant of Nature, also a prompt and energetic practitioner.

Sir William Hamilton was doubtless charmed by the universality of this proposition. A philosopher himself, he recognised the importance of a law that subjected all art to Nature, and made art only an ingenious application, in special cases, of the forces already pre-existing in Nature. We have always regarded Hippocrates as the most eminent natural philosopher of his time. He was the only man of his age who inculcated as a principle the duty of observing Nature—of founding practice upon experience; and in this respect he was the forerunner of that method of research which we now call the Baconian system. We believe that this will be the conclusion to which every reader who studies the philosophy of the men of that era will come.

But is this all that is meant by the *practice* of medicine? Surely not; and here Dr. Begbie's address is rich in illustrations of the advances that have been made by modern men in all departments of medical science. The science of medicine has for its main end the saving of human life, and every improvement or gain of exact knowledge made in any one of its sections must ultimately have this application. “It might be a sufficient answer,” says Dr. Begbie, “to the query of Sir William Hamilton, to signalise the discovery in modern times of vaccination, and the introduction of sulphuric ether and chloroform as anæsthetics.” But the study of anatomy, physiology, and pathology, has wonderfully advanced, and gone far to put the treatment of disease upon a sound basis. If we cannot predict what will be the effect upon the human body of any particular drug until we try it, we are getting nearer to an exact knowledge of the effects or changes that we should aim at producing in order to correct any morbid action. If we shall succeed in the course of time in determining the “way to do it,” we shall at the same time succeed in making the practice of medicine a science; we shall be able to fix with confidence upon the drug (its operation being already known) that is qualified to produce the results we desire to attain; and we shall know how they are attained. The haphazard of a blind empiricism will be supplanted by a rational and scientific treatment. We believe that we are already far on the road to this consummation. It is quite true that we are in the dark at

present as to the mode of operation of most of our so-called specifics: how quinine cures an intermittent; how iodide of potassium cures syphilitic periostitis; how chloroform annihilates pain; how a minute speck of vaccine lymph prevents an attack of small-pox. These are among the profound mysteries of Nature that will take time to unravel. But, on the other hand, successful treatment depends in a high degree upon a correct diagnosis; and how great have been the advances made in this direction during the last thirty years by original investigation into the phenomena and structure of animal bodies! How much have the discoveries of Bell and Marshall Hall done to help the practitioner in respect of the diseases of the nervous system! Dr. Begbie alludes to these points with much felicity.

What is termed “preventive medicine,” or the study of the etiology of disease, is perhaps the most complete development of the Hippocratic theory that has been made by modern men. The system now in operation in this country transcends any idea of the scope of such a research which Hippocrates entertained. It will be the means, however, ultimately of saving countless human lives. Here, indeed, we get away from the sphere of drugs, and work through the medium of natural forces in their direct action upon the animal economy. This science must be regarded as peculiarly modern; unless, indeed, we join the sceptics, and insist that there is nothing new under the sun, because observations of facts lying on the surface of things have been made before—observations that indicated a correlation that had never been actually made and systematised.

After all, modern medicine is a very different thing from what medicine was in the days of Hippocrates. Our great Harvey, in discovering the circulation of the blood, laid its foundations so firmly, that they can never be overthrown. John Hunter, by his laborious researches, has deserved the proud title of “the father of scientific surgery.” Charles Bell was the founder of a school of investigators who are toilsomely unfolding the complex structure of the nervous system, and leading us nearer to an understanding of its mysteries. Have not the labours of these men advanced the healing art? It seems idle to ask the question. We are all indebted to Dr. Begbie for his erudite defence of modern physic, and assuredly the duty could not have fallen to abler hands.

ALLEGED MANSLAUGHTER BY A SURGEON.

A CASE of much interest to most practitioners was decided last week at the Lincolnshire Summer Assizes. Mr. W. John Haram Wood, surgeon, of Boston, was indicted for the manslaughter of one Mrs. Wright. It appeared that the patient, who had previously given birth to six children, was taken in labour early in the morning of April 6th, two months before her expected time. Mr. Wood was sent for, and attended. The patient had had two very severe labour-pains, and also some hæmorrhage, before his arrival. He found her much exhausted, and, on examination, discovered that the placenta was partially detached; whereupon he intimated to her friends that she needed help, and proceeded to deliver her by turning; one foot being brought down, to which a tape was attached, and the child, which was dead, extracted; the placenta coming away at the same time. The patient was very weak and exhausted. After giving instructions to let her lie about half an hour, he left. The patient never rallied, and sank within three hours of her delivery.

Dr. G. M. Lowe of Lincoln, who made the *post mortem* examination, and upon whose evidence, apparently, at the inquest, Mr. Wood was committed for trial, gave evidence to the effect that there was rupture of the uterus, and “he had no hesitation in saying that the rupture was the immediate cause of death. Such a rupture was a rare thing, and the position of this one was remarkable. This rupture was not the result of natural causes,” because it was below the position of the child in the uterus, and therefore must have been caused by the exit of the child from the uterus. He asserted that ruptures occurring spontaneously were most frequently transverse in direction, and were

usually situated at the fundus, as the walls of the uterus were in that situation thinner, and consequently less resistant, than elsewhere. He admitted that "no care or skill could have saved her life, owing to the rupture and the hæmorrhage, which were said to have taken place previously"; and that "it would have been certain death to have left the foetus there. It was incumbent upon the doctor to deliver the child. Assuming that it was necessary to deliver artificially, he saw nothing out of the usual course or in any way improper in the conduct of Mr. Wood."

Mr. Justice Lindley, the presiding judge, in his charge to the Grand Jury, remarked that "the case for the prosecution was, that the death did not result from natural causes, but from the criminal negligence and want of skill of the prisoner. It was not denied that, in the first instance, he might have acted properly; but it was urged that he left his patient too soon—that he ought to have stopped longer with her." His lordship, after hearing the evidence of Dr. Lowe that it was incumbent upon the practitioner to deliver the woman, and that no care or skill could have saved her life, even had he remained longer than he did, remarked that it would not be just to convict Mr. Wood, and therefore directed the jury to return a verdict of not guilty. The child was not in a proper position for delivery; and, after Mr. Wood had examined the woman, he found it necessary to deliver her at once. That was his first duty, and it could only be done by using force. Of course it sounds sad to inexperienced people that force should be used; but, had force not been used, the woman must have died; and by using force her life might possibly have been saved.

We are at a loss to understand on what grounds Dr. Lowe asserted that "ruptures occurring spontaneously were most frequently transverse in direction, and were usually situated at the fundus". Any part of the uterus may be the seat of laceration, while the rent in the tissues may take any direction. Considerably more than half the ruptures at the full time occur in the region of the cervix, generally at that part which marks the junction between the uterus and vagina. Next in point of frequency comes the body, and last of all the fundus, which is the site preferred in early pregnancy. These are the *ipsissima verba* of one of our most reliable modern authors, and the experience of most practical men will endorse the statement. In these days of frequent prosecutions for malpraxis, it behoves every man to be extremely cautious in enunciating theories, more especially when they have no foundation in facts. Non-professional people can scarcely be expected to decide when doctors disagree. The profession owe a debt of gratitude to Mr. Justice Lindley for his sensible remarks; and we feel sure that the majority of the profession will sympathise with Mr. Wood, and congratulate him upon the issue.

THE prize of 2,000 thalers for the best work in the Geneva Convention has been awarded to Professor Lüder of Erlangen.

KING ALBERT of Saxony has been nominated "Rector Magnificentissimus" of the University of Leipzig.

THE metrical system is to be used in Hungary in prescribing and dispensing, from January 1st, 1876. The quantities are to be written legibly without abbreviations. A table of the old weights and their metrical equivalents has been published for the guidance of practitioners.

WE regret to announce the death of Mr. John Churchill, the eminent medical publisher, who for many years, originally in Princes Street, Oxford Street, and subsequently in New Burlington Street, has been most intimately associated with the members of the medical profession by the publication of their works. Mr. Churchill died at Tunbridge Wells on the 3rd instant, and was within a few hours of completing his seventy-fourth year. His mantle has fallen upon his sons, who doubtless will continue the same active participation in medical literature which was initiated by their father.

THE *Vahit*, a Turkish newspaper published at Constantinople, states that the cholera in Syria is considerably increasing. According to it, during the past week, the number of cases reached 500, a great part of which were fatal.

AT the assizes at Haverfordwest last week, the trial of Dr. Adler for the murder of Lieutenant Walker, of the Royal Artillery, at Fort Hubberstone, was concluded. The jury, after deliberating an hour and a half, acquitted Dr. Adler of the charge of wilful murder; and, no evidence having been offered on the minor counts, he was discharged.

A HOSPITAL FOR INCURABLES IN VIENNA.

THE brotherhood of St. Michael has lately opened, at Währing near Vienna, a new hospital named the "House of Charity", the object of which is to receive poor incurable persons, without distinction of religion or nationality, who are unfit for treatment at other hospitals, and to maintain them entirely without charge during their life. The hospital at present has accommodation for thirty; but the number will be doubled when the building is completed.

VIVISECTION.

DR. J. CRICHTON BROWNE, Medical Superintendent of the West Riding Lunatic Asylum, writes to the *Times* as follows:—

An advertisement which appeared in your columns yesterday, under the authority of the Society for the Abolition of Vivisection, contains statements which are skilfully misleading, and which call for immediate correction. After giving an inaccurate description of the mode of experiment adopted by Professor Ferrier in his important researches into the functions of the brain, and after quoting a few of his observations adroitly selected, because to the non-professional reader they may seem to justify the unwarrantable conclusion that "intense and protracted agony" was inflicted during their progress, the advertisement proceeds to say:—"It is stated that chloroform and ether were given in some of these experiments; but it appears to have been done with the view of rendering the animals helpless." It will, I think, scarcely be credited that this is the version which the Society for the Abolition of Vivisection thinks proper to give of Professor Ferrier's distinct intimation, made at the outset of the paper in the *West Riding Asylum Medical Reports*, from which the observations are quoted:—"It may be here mentioned, once for all, that before and throughout all the following experiments ether or chloroform was administered."

Every one able to understand the meaning and purpose of Professor Ferrier's experiments will at once perceive that it was essential to their success that the animals employed in them should be unconscious and incapable of feeling pain or of making any voluntary effort. The movements and cries produced by the faradisation of the brain were not expressive of suffering, but simply of the stimulation of a motor centre, and the "intense and protracted agony" of the animals exhibiting these signs of pain was not greater than that of a pianoforte when its keys are struck. Similar signs of pain may be witnessed in an animal without a brain, or in the deepest state of anæsthesia. It is an elementary truth in physiology that the brain-tissue itself is absolutely insensitive, and may be irritated or sliced away without even discomfort being occasioned. All this must have been well known to those who concocted the advertisement referred to, and yet they have not hesitated to deceive the public by representing mere automatic movements as indications of "intense and protracted agony". To such base practices may not ill-judged enthusiasm or a thirst for subscriptions reduce even a benevolent society!

THE MEDICAL PROFESSORSHIP FOR THE AINTAB COLLEGE.

THE HON. ARTHUR KINNAIRD, M.P., speaking lately at the annual meeting of the Turkish Missions' Aid Society, held under the presidency of the Earl of Shaftesbury, at Willis's Rooms, said, that the committee of the Society wanted to raise £5,000 in Great Britain to complete the proposed endowment of a professorship in the medical department of the Christian college at Aintab, in Central Turkey. One of the most pressing wants of the East was competent native medical practitioners. The Society had recently appropriated £1,000—the half of a legacy Miss Harrison, late of Sheffield, had bequeathed to the Society—towards the endowment fund; and it was desired to complete the fund by adding £4,000, in order to place the young and

flourishing college at Aintab on a sound footing. The fund would be placed in the hands of British trustees, and the interest paid bi-annually to the college for the support of the professorship.

EDINBURGH UNIVERSITY CLUB.

The quarterly dinner of this club was held at St. James's Hall on Monday evening last—Capping Day. Dr. Lavies occupied the chair. A small but very genial party was assembled. The Chairman read a telegram which arrived in the course of the evening from Dr. Farquharson, one of the honorary secretaries, giving particulars of the graduation ceremonial of that morning. The usual toasts were proposed and responded to, and the Chairman, Dr. Boulton, Dr. Cock, and Dr. Shears, contributed much to the musical entertainment of the evening.

SCOTLAND.

CAPPING DAY IN EDINBURGH: HONORARY DEGREES.

The annual ceremony of "capping" took place in the Edinburgh University on Monday last. After an opening prayer from the Rev. Dr. Wallace, the degrees were conferred. The first business was the conferring of the degree of Doctor of Law (LL.D.) on Dr. Warburton Begbie, Dr. J. Hughes Bennett, Dr. J. Matthews Duncan, Sir William Fergusson, Bart., F.R.S., Dr. A. H. McClintock (Dublin), Professor W. Pirrie (Aberdeen), Dr. J. Burdon Sanderson, F.R.S., and Dr. Thomas Shapter (Exeter). Each of these gentlemen was introduced by Professor MacLagan, who, in a brief speech, set forth the claims of the candidate to the honour. The degrees of M.B., C.M., and M.D., were then conferred on a number of gentlemen. Degrees in Arts and Laws were also conferred; and the address to the graduates was delivered by Professor Crum-Brown. After the ceremonial, a meeting was held in the University Library, to witness the presentation of a bust of Dr. Hughes Bennett, lately Professor of the Institutes of Medicine. The presentation was made by Dr. Andrew Clark of London, on behalf of Dr. Bennett's pupils and friends. The gift was acknowledged by Principal Sir Alexander Grant. The bust is of white marble, and is the work of Mr. Brodie.

IRELAND.

The salary of Dr. Carleton, Medical Officer of the Delvin Dispensary District, Westmeath, has been increased by £20 *per annum*.

An accident, which resulted fatally, lately occurred to a medical student named Turner, son of Dr. Turner of Tuam, who, jumping off a spring-board at Blackrock, a watering-place a few miles from Dublin, struck his head with such violence (there being only three feet of water at the time at the baths), that death took place in a few hours. We understand that a monument is about to be erected at Tuam, in recognition of his services during a late epidemic of small-pox in that town, to commemorate his humane exertions during that period.

IMPROVEMENTS IN THE DUBLIN HOSPITALS.

The annual polishing up of the Dublin hospitals is going on with more than usual activity; in fact, several are making such extensive and organic changes, that considerable additional accommodation and comfort will be afforded to the inmates. The City of Dublin Hospital is reconstructing its out-patient department. Steevens's Hospital is adding largely to the cubic space of the wards on its upper floor, by raising the roof along two sides of the quadrangle. This improvement was commenced nine years ago, but funds were only available for the reconstruction of one side. The new front of the Coombe Lying-in Hospital is quickly approaching completion, and now presents a handsome façade in red brick and granite to the Coombe. The Fever Hospital in Cork Street is undergoing extensive repairs, and many modern improvements in sanitary and decorative art are being introduced.

FORTY-THIRD ANNUAL MEETING

OF THE

BRITISH MEDICAL ASSOCIATION.

Held in EDINBURGH, August 3rd, 4th, 5th, and 6th, 1875.

TUESDAY, AUGUST 3RD, 1875.

AT 11 A.M. a sermon was preached at St. Giles's Church, by the Rev. W. Lindsey Alexander, D.D., who chose as his text the words, "Honour all men". He concluded with showing how the medical profession carried out to the fullest extent the precept of the apostle.

The first general meeting of the members was held in the Free Church Assembly Rooms, and there were present, besides a very large number of members, the magistrates and Town Council of Edinburgh, who wore their robes of office.

Mr. Fowke, the General Secretary, presented the minutes of the last annual meeting, which were taken as read and unanimously confirmed.

Address of Retiring President.—Dr. COPEMAN said: Members of the British Medical Association, the Baillie, magistrates of the City of Edinburgh, and visitors, I beg to say to you that it is with much pleasure that this Association meets again in the beautiful City of Edinburgh. We have, some of us, a vivid remembrance of our last happy meeting here, and it is with pride that, in this city, I have to yield up the position which, by your kindness, I have held during the last year. I thank you most warmly for having bestowed that office upon me, and I thank the officers of the Association for the cordial attention they have bestowed upon me during my year of office, and for their courtesy towards me at all times. [*Cheers.*] Allow me to congratulate you upon the favourable circumstances under which you meet in this beautiful city—a city as famous for its University and medical school as for its picturesqueness. [*Cheers.*] My duty as President here ends, and shall not intervene between you and the important business which is to follow. I have now the pleasure of asking Sir Robert Christison to take the Chair as your President.

The retiring President then inducted Sir Robert Christison into the Presidential Chair amid the loud cheers of the whole assemblage.

Vote of Thanks to the Retiring President.—Dr. SIBSON proposed the following resolution: "That the best thanks of the Association are due and are hereby given to Dr. E. Copeman of Norwich, for the able and courteous manner in which he has filled the office of President during the year, and that he be elected a Vice-President." He said that the resolution would commend itself to every gentleman in that assemblage, and it was with no little pride that the Association had sat under Dr. Copeman's presidency. Dr. Copeman stood among the most distinguished physicians of England, and was an honour to the profession and to the Association of which he had been President. [*Cheers.*]

Dr. FALCONER (Bath) said, he had equal pleasure to that expressed by Dr. Sibson in seconding the motion.

The motion was then carried by acclamation, and Dr. Copeman briefly returned thanks.

Address of Welcome from the Edinburgh Municipal Council.—The new PRESIDENT, amid loud applause, called upon the first magistrate, in the absence of the Lord Provost, to bid the Association welcome.

Baillie TAWSE said that, in the absence of the Lord Provost, it became at once his privilege and pleasure to welcome the British Medical Association to Edinburgh on this, the forty-third annual meeting. It was with much pleasure that Edinburgh saw again the profession of medical science gathered together in her walls to hold the annual session in which to see what discoveries and advancement had been made for the prevention and cure of disease. This was a subject which was not uninteresting to any citizens, and it was especially interesting to those who were in the position of Town Councillors, for they were charged with the sanitary as well as the social improvement of the people; and, for a large city like Edinburgh, sanitary questions did possess a peculiar interest, and the Town Council and magistrates of the city were glad to be able to express by their presence on the occasion their great interest in the proceedings of the Association, and in the discussions which were to occupy the members for the next three days. Seventeen years had passed since the Association did the City of Edinburgh the honour of meeting within its walls. Then the Association had a distinguished man for its president in the universally beloved Professor Alison. [*Cheers.*] Now, it had another of the esteemed citizens of Edinburgh added to the list of eminent men who had been presidents, in Sir Robert Christison—

[cheers]—and there could be no doubt that, acting in the strict paths of science, the meeting would tend to the advancement of the objects which the members had at heart—the interchange of knowledge, the elevation of the profession in character, and the fostering of brotherly love and mutual help—objects which would commend themselves to universal sympathy and respect. [Cheers.] Many present were revisiting the scenes of their former studies, where, he trusted they passed time which was neither unprofitable nor unpleasant, and the memories of those times would come back to them again as they stood within the venerable walls of the University, recalling to their minds the instruction they received in the preparation for their future career. They would think again of the voices of their instructors, some of whom had passed hence; but this would not diminish the interest of the old students, and they would be rejoiced to find one still among them in the person of their present President. [Loud cheers.] To those who were thus revisiting the old scenes he would say nothing more; but to those who were visiting this city for the first time, he would say that he hoped they would find that it did possess charms worth their notice, and, though they arrived at a time when Edinburgh would be shown at its best, yet it was not with less cordiality that he tendered them a warm and earnest welcome. [Cheers.] He added, that if the magistrates and Town Council could do aught to increase the pleasure or comfort of the visitors, or add to the interest of the meeting, they should be most happy to do so. [Loud cheers.]

President's Address.—The PRESIDENT added, in his own name and that of the University, to the welcome already expressed on the part of the Town Council and magistrates. After a few introductory remarks he delivered his inaugural address (printed at p. 155). At its conclusion he was also warmly cheered.

Sir WILLIAM FERGUSSON then proposed "That the best thanks of the Association be given to Sir Robert Christison for his able address". He said that he had no doubt the motion would be responded to unanimously. All had doubtless come into this room anxious to hear what a gentleman of Sir Robert Christison's great experience as a teacher, practitioner, examiner, and philosopher would say to an assemblage such as this. The subject he had chosen for his address was one of great importance and interest to all, whether old or young, and he had handled it in such an able manner, that it would be studied by many, very many, more than had heard it this day. [Cheers.] The subject was one which had met with the attention of the Association, and no doubt many of those who had thought upon the subject would take into consideration the maxims of wisdom which had fallen from Sir Robert's lips. The Association had just heard an address from one who had passed more than the ordinary term of life of man in one of the greatest institutions in the kingdom—indeed, if it was not the greatest institution—for its numbers, quoted by Sir Robert, showed that it had had a higher educational power than any other. [Cheers.] The early part of the address was particularly and peculiarly interesting in the information it conveyed, and one part was striking, that in which the orator pointed out that Edinburgh, at one time, seemed to have ruined itself as a teaching power, there being a great falling off at the time when the success had been greatest. It certainly was a curious fact, that when the success had been greater than ever, the decline should have been sudden and marked. He had himself often thought of that fact, and he had arrived at an explanation of the phenomena, and it was that Edinburgh was so successful a teacher, that it taught its pupils to teach elsewhere, and so there being Edinburgh teachers over the face of the country, there was no such necessity as before for men to come to the City University. [Hear, hear.] That could be illustrated further if there were time; but, at all events, it was known that medical schools had arisen in the various parts of the country, and for the teaching power in those schools, he believed that there had to be great dependence upon the men from Edinburgh. In regard to the other part of the address—that of the examining bodies—Sir Robert had to handle a very difficult subject, and he had given his views on a matter with which he was intimately acquainted; for he had had a lifetime's experience to make up his opinions about it. Sir Robert had put before them, in the address they had heard, the result of years of thought—not only of himself, but of others; and though the paper may have seemed long, those thoughts had been given in a briefer form than might have been expected under the circumstances. Looking at the fact, that much more would be heard about it when once it had gone to the public eye and public ear through print, he thought the members would gladly express their thanks to Sir Robert for the address. [Cheers.]

Dr. RADCLYFFE HALL (Torquay) seconded the motion in a few words, in which he bore witness to the originality of Sir Robert's genius.

The motion having been put and carried by acclamation, the PRESIDENT returned thanks, saying that he was very deeply indebted to the Association for the patience with which they had listened to him.

REPORT OF COUNCIL.

Mr. FOWKE, General Secretary, presented the following Report.

"Your Council have much pleasure in meeting you, for the second time in the history of the Association, in the city of Edinburgh, which has been for ages so important a centre of medical learning and literary culture.

"Your Council feel assured that the present meeting will largely contribute to strengthen the Association, and enable it with renewed vigour to carry out its important work in promoting professional unity and bringing the English members into closer intimacy with their brethren across the Tweed.

"Your Council have much pleasure in stating that the hope expressed in their last Report, that not only would the debt of the Association be paid off, but that a surplus would be in the hands of the Treasurer to the credit of the Association at the close of 1874, has been fully realised. After paying £200 for scientific grants, £150 for legal expenses incurred in the incorporation of the Association, and £212 balance of debt due in January 1874, there remained a cash surplus of £500. This has been invested, and will form the nucleus of a reserve fund, and your Council have every reason to believe that at the close of the present year a larger amount will be available for this purpose. The thanks of the Association are again due to the Journal and Finance Committee, and to the Treasurer, who have given up so much time and attention to the financial affairs of the Association.

"The total expenditure of the past year shows an increase of £1,404: £603 of this is due to the increased amount paid for the printing and paper of the JOURNAL, which has been increased in size and in the number issued; £390 has been written off of old accounts and bad debts of former years; £113 for increase of salary to the Editor; £98 for an additional clerk in the office, rendered necessary by the increased work of the Association.

"The income of the year is £9,539, against £8,773 in 1873—an increase of £766—principally due to the subscriptions, this item being £6,190 against £5,448 last year. There also appears this year, for the first time in the balance-sheets, £134 discount obtained by payments of cash for the printer's accounts. The amount for advertisements is rather less, being £2,910 against £3,060 of last year, being a decrease of £150.*

"Your Council have the painful duty to report, that during the last year seventy-three deaths have occurred amongst your members: this, however, is seventeen less than the number in 1873. The resignations were, for the past year, 117, and there have been 859 new members elected. The number of members now on the list is 6,112.

"The satisfactory progress of the Association has during the past, as in former years, been largely stimulated and aided by the vigour, ability, and success with which the BRITISH MEDICAL JOURNAL has been conducted, and the efficiency with which it has reflected the progress of medical science, and advocated the best interests of the profession. To enable it to meet the increasing demands of a growing Association, which now embraces a large proportion of the profession in the British isles, the number of its pages has been increased, and reports of the proceedings of the principal medical societies of the three kingdoms are given. The BRITISH MEDICAL JOURNAL may now fairly aspire to be considered the representative organ of the profession. The thanks of the Association are largely due to the Editor, Mr. Ernest Hart, for the ability and devotion with which he has for many years directed and developed the JOURNAL. Your Council are glad that the increasing prosperity of the Association, to which his labours have confessedly largely contributed, has enabled them to make a suitable recognition of the value of the Editor's services to the Association by an increase of salary.

"At a special general meeting of members held during the past annual meeting at Norwich, August 13th, 1874, it was decided by a unanimous vote of members present, to incorporate the Association under the Companies' Acts of 1862 and 1867. This has been since carried out by your solicitor, Mr. Upton; and the first general meeting was held in Birmingham, on November 4th last, in accordance with the law and the articles of the Association, which requires a general meeting to be held within four months after registration. The Association was registered on October 21st, 1874. Many members have already signed the Articles of Association; and the Council hope that at the present annual meeting all those present who have not previously done so will sign the necessary forms. The Council trust that by the next annual meeting every member of the Association will have become a member of the corporate body. Such a result will greatly strengthen the position of the Association, and the individual members will incur no liability beyond the nominal one of one guinea.

* The financial statement of the Association, to which reference is made in the preceding report, was published at page 562 of the BRITISH MEDICAL JOURNAL for April 24th, 1875.

"In accordance with a resolution passed at the last annual meeting, a Scientific Grants Committee has been appointed, consisting of Dr. Sibson, F.R.S., Chairman; Mr. Alfred Baker; Dr. Bastian, F.R.S.; Mr. Callendar, F.R.S.; Dr. Michael Foster, F.R.S.; Dr. Sharpey, F.R.S.; Dr. Wade; Mr. Wheelhouse; Dr. Wilks, F.R.S.; Mr. Ernest Hart, Honorary Secretary; and the President of the Council and Treasurer, *ex officio*. Grants to the amount of £165 have been made, and reports of the results will be laid before you.

"Dr. Stewart, who was presented, upon his resignation of the office of Honorary Secretary to the Metropolitan Counties Branch, with a testimonial by his friends and colleagues, has generously devoted £400 of the £500 subscribed to the purposes of a grant fund, to be called the Stewart Fund, for the recognition and encouragement of important researches on the origin, spread, and prevention of epidemic disease. Dr. Stewart's name will always be honourably connected with the Association for his many and long-continued services, and the Association will be asked to pass a special vote of thanks to him for this generous, disinterested, and graceful act on the part of Dr. Stewart.

"Mr. Samuel Wood, of Shrewsbury, the Honorary Secretary of the Shropshire Scientific Branch of the Association, has liberally presented a sum of £25 for competition, for the best essay on Pyæmia. The best thanks of the Association are due to Mr. Wood for his generous gift.

"The Report of the State Medicine Qualification Committee, referred to the Committee of Council by the annual meeting at Norwich last year, has been considered, and will be presented to you in a modified form; and your Council recommend that it be passed and forwarded to the General Medical Council for their consideration. The thanks of the Association are due to Dr. Rumsey, F.R.S., Dr. Tripe, Mr. G. W. Hastings, Dr. Parkes, F.R.S., Dr. Heslop, Dr. Ransome, the late Dr. Anstie, Mr. Ernest Hart, Dr. Stewart, Mr. Michael, Dr. Arlidge, Mr. Ceely, Dr. R. Macdonnell, and the late Dr. Donald Dalrymple, M.P., who have bestowed much time and thought on the subject, for their careful and admirable Report.

"The Medical Reform Committee have to report that the English corporations have been active, during the past session of Parliament, in their efforts to form a conjoint scheme of examination, the Royal College of Surgeons having carried an enabling bill through Parliament with that object. In accordance with the policy exercised by your Medical Reform Committee during past years, which has been always sanctioned and approved by the general body of the Association, they have refrained from urging the Bill of the Association on the legislature during the past session, in order not to trammel the laudable efforts of the English corporations towards the formation of a conjoint board. Your Committee feel that the establishment of the conjoint scheme in England will materially strengthen the position taken up by the Association. Your Committee have been in communication with several leading members of Parliament, and have had the benefit of their counsel and advice, as well as the promise of their support; and the Right Honourable Mr. Childers has been conspicuous by his public approval of the principles on which the Bill advocated by the Association has been based. Your Committee regard the question of medical reform as one of the most important of the day—one which must continue to occupy the attention of the Corporations, the General Medical Council, and the Legislature; and they have to recommend the reappointment of the Committee, with power to add to their number.

"A short Report of the Joint Committee on State Medicine will be presented by Dr. Stewart.

"The Parliamentary Bills Committee of the Association, which includes a representative of every Branch, has continued its labours of former years. Its representations to the First Lord of the Admiralty have been rewarded by a large amount of success. The numerous and influential letters of thanks which have been received from distinguished members of the Naval Medical Service, ascribe great influence to the detailed statement of grievances, and suggestions of redress laid before Mr. Ward Hunt by the Committee. The majority of these suggestions were adopted in the warrant subsequently issued, and under the direction of Sir A. Armstrong it is hoped that a period of increasing contentment and efficiency is now in store for the Naval Medical Service.

"The carefully compiled statement of grievances and suggestions for their remedy, laid before Mr. Gathorne Hardy, the Secretary of State for War, by Mr. Ernest Hart, Chairman of the Committee, on behalf of the medical officers of the army, has not yet produced any overt result; but the minister has more than once stated in Parliament and elsewhere, that he has given to the subject-matter of the statement repeated and studious attention, and that he is now elaborating a scheme by which he hopes to cure many of the evils alleged; meantime the service remains unpopular and dissatisfied, nor is it likely that contentment and efficiency will be restored except by concessions of a distinctly liberal character.

"The influence of the Association has been successfully exerted through the Parliamentary Committee, in amending some important measures of social legislation. The whole of the amendments proposed by the Committee were adopted during the passage of the Artisans' Dwellings Bill through the House of Commons, and the sanitary usefulness of the Bill has been thereby enlarged, while the medical officer of health has been strengthened and protected in the performance of his duties. Material amendments, in accordance with the representations of the Committee, have been made in the Adulteration Acts Amendment Bill, which in its original form threatened to deprive the guardians of the public health of the power of preventing and punishing the falsification of food by the retailer.

"The advisability of legislative restriction for Habitual Drunkards, which engaged the attention of your late lamented Associate, Dr. Dalrymple, has been considered by your Branches, more especially by the Birmingham and Midland Counties Branch of your Association; and at the Committee of Council held on July 13th, upon a resolution presented by the Metropolitan Counties Branch, calling the attention of the Committee of Council to this subject, a Committee was appointed, and your Council trusts that at the next annual meeting they will be enabled to place before you a full report upon this important question, and the steps that it may be considered advisable to take.

"The attention of your Council has also been drawn by a numerous and influentially signed requisition, prepared by Dr. Alfred Meadows and Mr. W. Fairlie Clarke, to the abuse of Medical Charities—a matter of so much importance that your Council desire to treat it with great deliberation, and after taking counsel with the Association at large. You will, therefore, be requested to appoint a Committee to consider and report on the subject.

"The attention of your Council has been drawn during the past year by the Aberdeen Branch of the Association to the inadequate remuneration of civil practitioners acting temporarily in a military capacity as army surgeons; and you will be requested to pass a vote authorising your President to sign a memorial respectfully drawing the attention of the Secretary of State for War to the injustice.

"Your Council, with deep regret, have to report the unavoidable absence, through severe illness, of the President of the Council, Mr. George Southam, and feel sure that you will pass an unanimous vote of sympathy with him, and a hope that he may again be enabled to lend his valuable services to the Association. Dr. Rumsey, who has long been connected with the Association, and has rendered so many and valuable services to the cause of public health during a period of thirty years, is, your Council regret to report, unable, through serious illness, to be present on this occasion, and the Association has through its Branches endeavoured to obtain a public recognition of his great services. A Subcommittee, consisting of the President of the Council, the Treasurer, and Dr. Carpenter, was appointed to draw up a memorial on behalf of the Association to the Prime Minister, urging Dr. Rumsey's claims to a government pension, in consideration of his important services.

"Your Council have again the pleasure to report the formation of new Branches—viz., the Thames Valley Branch and the Southern Branch—by which important districts have been opened to the Association. Seldom has a new Branch increased so rapidly in numbers as the Southern Branch, which has already gained importance by bringing into closer connection with the Association the medical officers of the army and navy. The thanks of the Association are due to Inspector-General Smart, Dr. Ward Cousins, Dr. Langdon Down, and others, for their efforts in promoting the new Branches.

"Two Essays have been received in competition for the Hastings Prize Medal, and your Council regret to report that the medal has not been awarded, as the essays have not, in the opinion of the adjudicators, shown sufficient merit.

"There is much important work in hand for the Association and its Committees. The Council hope that each year will witness the formation of new Branches in districts not yet intimately connected with the Association. By these local organisations, the influence of the Association and its power for the good of the profession is greatly strengthened, and the direct co-operation of the Branches in the work of the parent body is extremely beneficial to both. The Council feel that a noble work is before the Association, in thus developing throughout the United Kingdom numerous Branches, all united in promoting the intellectual and ethical advancement of the profession, in aiding the progress of the healing art, in furthering the prevention of disease, and in amending the social and sanitary condition of the people.

Dr. SIBSON moved that, in consequence of the late hour, the report be taken as read.—This was assented to.

Dr. MACLEOD (Glasgow) moved: "That the report of the Council,

together with the financial statement for the year ending December 31st, 1874, be received, adopted, and entered on the minutes."

Sir J. ROSE CORMACK (Paris) seconded the motion.

Mr. OLIVER PEMBERTON (Birmingham) said that, before the report was adopted, he had a subject of interest to many members to bring before the meeting. He saw the names of two ladies who were to read papers. He presumed that those ladies were members of the Association?

Dr. SIBSON said the question asked was one about which the report had nothing to do, and could be asked at any time.

Mr. PEMBERTON replied that he wished to move a resolution that the Secretary be instructed to issue a circular to every member of the Association, asking his opinion as to female practitioners being members of the Association.

Mr. HUSBAND urged that this was a resolution which could not be brought up at that juncture.

The PRESIDENT said he should not allow the subject to be moved. The question was whether the report should be adopted.

Mr. HUSBAND urged that, as there was not a word about the election of ladies in the report, and as, moreover, the subject could be brought up at any time, the report should be allowed to pass.

A vote was then taken on a proposal that the report should be printed and circulated, and considered on Wednesday. This proposal was negatived.

Mr. LAWSON TAIT (Birmingham) moved that a show of hands be taken on the question, whether or not the report should be read.

This was seconded, and the vote was taken. The number in favour of reading the report was very small; and it was then formally taken as read. The motion that the report be adopted was carried.

Vote of Thanks to Mr. Samuel Wood.—Mr. LUND (Manchester) moved: "That the best thanks of the Association are due, and are hereby given, to Mr. Samuel Wood of Shrewsbury for his liberality in presenting the sum of £25 to be given for the best essay on Pyæmia."

Dr. STEELE (Liverpool) seconded the motion; and said that Mr. Wood was the pioneer in this direction, for it was the first grant the Association had received for prosecuting original research into medical science. He hoped that a resolution of this sort would become a permanent item in the business of the Association, and be seen on the agenda of every annual meeting.

The motion was carried unanimously.

Dr. EDWARD WATERS (Chester) remarked that it would be as well to mention, in reference to the statement of Dr. Steele in regard to this being the first donation for prosecuting original research, that Dr. Thackeray, of the same ancient and loyal city, gave £50 as a prize to be worked for similarly.

Vote of Thanks to Dr. Stewart.—Mr. MCCHEANE moved: "That the best thanks of the Association are due, and are hereby given, to Dr. Stewart for his generous and disinterested grant of £400; and the Association trusts that Dr. Stewart may long be spared to assist in the consideration of its disposal." The mover said the resolution so well expressed the sense of the Association that he should only spoil it if he attempted to dilate upon it; and he should, therefore, content himself with moving it.

Dr. COPEMAN seconded the motion, which was carried with acclamation.

The Army Medical Department and Civil Surgeons.—Mr. MASON (Bath) moved: "That the President be empowered and requested to sign a petition to the Secretary of State for War in accordance with the recommendation of the Council, drawing attention to the injustice of the present rate of payment of civil practitioners acting as substitutes for military surgeons."

Dr. FLETCHER (Birmingham) said that, although he knew very little about questions affecting the army, and was not concerned personally in this matter, yet he knew sufficient to say that it was a matter to which the Government should have their attention drawn. The rate of pay offered to these gentlemen was simply degrading.

The motion was carried unanimously.

By-Laws of the Association.—Dr. SIBSON moved, "That the By-laws, as amended, be received and adopted". He said the Association had now been changed from an ordinary body to an incorporated body, and, under these circumstances, it was necessary that the Articles of Association should be supplemented by By-laws; so necessary, indeed, that the very existence of the Association hinged upon the point. The By-laws in print and before the meeting had been prepared by the solicitor, and presented to the Committee of Council, who had submitted them to the Council. These new By-laws were, in fact, the old laws of the Association put into a new shape, with some two or three changes—changes upon which there would be differences of opinion. There was, however, the fact that, whatever might be the

differences, by notice given, these differences could be removed, if the members thought fit in the future to move, second, and carry such alteration. If the meeting adopted the By-laws as they stood, there would be the year's experience to go on and see how they worked, and, at the end of that time—in fact, at the end of ten months—notice of a proposal to alter them would be given, and an amendment upon them would be taken. It was, as he had said, necessary for the very existence of the Association, that the By-laws should now be carried as they stood. They had been submitted in their amended form to the Association's solicitor, and it was to be hoped that the meeting would waive all opinions upon them, and pass them *en bloc*. If the Association did this, he fully believed that, with the experience of a year, some of the By-laws would have to be altered, and it would be found necessary to fall back upon the old; but, as matters stood, he reiterated, the Association did not legally exist until the By-laws were passed; in fact, the next day's meeting could not be held unless this business was done.

Mr. HUSBAND (York) seconded the motion for the adoption of the By-laws, and stated, as Chairman of the Committee who had had the arrangement of these laws, that the gravest consideration had been given to every point and every detail. Then the Committee of Council had considered them, and they had been before the Council. The conclusion had been come to by all, that these should be the By-laws of the Association, and he strongly supported the arguments of Dr. Sibson, and pressed his suggestion that if these By-laws were passed this year, they would be tried by experience in working, and if found faulty in any respect, they could be amended by the proposed amendments being submitted to the Committee of Council, and by them put before the legal adviser of the Association. It was necessary that the laws should be tried in actual work, and actual work would enable the Association to perfect its laws by showing where they were faulty, and what was necessary to be changed. At this late period of the evening there was no time to discuss words or principles, and he trusted the meeting would have confidence in the Council, and show it by passing the By-laws.

Dr. CHADWICK (Leeds) said, there were very important questions in the By-laws, and it was very unfortunate that the meeting should, upon this matter, be driven into a corner. There were in the By-laws most important points—most important elements, too, of discussion, and the laws, if passed, could not be altered.

Mr. HUSBAND: They can be altered by notice being given.

Dr. CHADWICK said, it was all very well for Mr. Husband to say that they could be altered; but, when once the laws were passed, there would be the greatest difficulty in making any alteration in them. As a species of protest against the By-laws being thus put he now spoke; but he should propose no motion against their adoption, but simply announce his dissatisfaction.

Dr. SIBSON reminded the members that if they did forego their privilege of discussing the laws, they could do it next year. It was not the fault of any member or members of the Association that the meeting was in the position of having to accept these by-laws in this manner, but the position was caused by the Articles of Association. He might say that there were several points in the by-laws to which he was desirous of proposing amendments; but he withheld his hands for ten months, and by that time, after careful consideration, and with full knowledge of the working of the laws, changes, if found necessary, could be made; but, if they were not now adopted, it would be impossible for the Association to be worked. The by-laws, he begged to remind them, were not the preparation of the Committee of Council, or of the Council, but of the legal adviser, working upon the old laws. While they were being formed, a subcommittee was appointed, with whom were associated some eminent members of the Association, and their purpose was to bring before the meeting, in a legal form, the old laws which had ruled the Association heretofore, transformed in nomenclature, but still in substance the old laws. He trusted that, with this explanation, the members would waive all objections to the by-laws, which, it might be mentioned, were published in the JOURNAL two months ago, and accept them.

Dr. CARPENTER (Croydon) said the by laws must be accepted, though it was objectionable to accept them in this way; but it was necessary to accept them in consequence of accepting the Articles of Association last year. These by-laws, if accepted, would be the skeleton upon which to hang some flesh, and in the future some sinews could be removed. Every member of the Association should look carefully through the by-laws, for they quite changed the constitution of the Association. He supported the proposition that they should at once be adopted.

After some further discussion, the motion for the adoption of the report was then carried *nem. con.*

Re-election of Vice-Presidents.—Dr. FALCONER stated that it was

necessary the vice-presidents should be re-elected, as the Association had now become fully incorporated, and the vice-presidents were only the officers of the old Association. He proposed that the vice-presidents, Mr. A. Baker (Birmingham), Sir George Burrows (London), Dr. Chadwick (Leeds), Dr. C. R. Hall (Torquay), Mr. W. D. Husband (York), Dr. G. J. Jenks (Bath), Dr. A. Lochee (Canterbury), Dr. G. E. Paget, F.R.S. (Cambridge), Dr. F. Sibson, F.R.S. (London), Dr. J. R. W. Vose (Liverpool), Dr. E. Waters (Chester), Mr. J. Whipple (Plymouth), Sir Wm. Fergusson, F.R.S. (London), being vice-presidents of the unincorporated Association, be, and they are hereby, elected vice-presidents of the incorporated British Medical Association."

Dr. PARSONS seconded the motion, which was carried unanimously. *Re-election of Treasurer.*—Dr. CHADWICK proposed, "That Dr. Falconer, being the treasurer of the unincorporated Association, be, and he is hereby, elected treasurer of the incorporated British Medical Association."

Mr. LAWSON TAIT seconded this, and it was carried amid applause. *Election of General Secretary.*—Dr. WADE moved, "That Mr. Francis Fowke be, and he is hereby, elected general secretary of the British Medical Association, for the ensuing twelve months."

Mr. NICHOLSON (York) seconded the motion, which was carried. The meeting then adjourned.

In the evening, the President held a reception in the Music Hall, which was attended by a large number of members and visitors, including many ladies.

On Wednesday, the Association met at 11 A.M., Sir ROBERT CHRISTISON, Bart., in the chair.

Brighton was chosen, on the recommendation of the Council, as the place of meeting in 1876; and Sir J. Cordy Burrows was appointed President-elect.

Dr. SIBSON, who had acted as President of Council, in the absence from illness of Mr. Southam, announced that Dr. Falconer had been elected President of Council for the next three years.

The following resolutions were proposed and passed:

"That the best thanks of the Association are due, and are hereby given, to Mr. George Southam, F.R.C.S., for the able and courteous way in which he has discharged the onerous duties of President of Council for the past three years; and that he be and he is elected a Vice-President of the Association.

"That the best thanks of the Association are due, and are hereby given, to Dr. Falconer for the way in which he has discharged the duties of Treasurer to the Association for the past nine years; and that he be and he is hereby elected a Vice-President of the Association."

Mr. W. D. Husband was elected treasurer in the room of Dr. Falconer.

The following resolution was passed:

"That the best thanks of the Association are due, and are hereby given, to Dr. Sibson, F.R.S., for the able and courteous way in which he has acted as President of the Council for Mr. Southam."

The following gentlemen were reported to have been elected members of the Committee of Council for the ensuing year: T. Clifford Allbutt, M.D.; J. W. Baker, Esq.; G. W. Callender, Esq., F.R.S.; A. Carpenter, M.D.; J. Matthews Duncan, M.D., Edinburgh; B. Foster, M.D.; E. L. Fox, M.D.; R. Harrison, Esq.; C. F. Hodgson, Esq.; T. Holmes, Esq.; J. R. Humphreys, Esq.; F. E. Manby, Esq.; E. Morris, M.D.; R. Quain, M.D., F.R.S.; T. H. Smith, Esq.; T. Underhill, M.D.; W. F. Wade, M.B.; A. T. H. Waters, M.D.; C. G. Wheelhouse, Esq.; Eason Wilkinson, M.D.

Dr. WARBURTON BEGGIE delivered the Address in Medicine, which is published at page 164. At the conclusion a vote of thanks was unanimously given to him.

In the afternoon, the business of the meeting was proceeded with.

MEDICO-PARLIAMENTARY.

HOUSE OF LORDS.—Thursday, July 29th.

Lunatic Asylums (Ireland) Bill.—On the motion for the second reading of this Bill, Earl SPENCER said that it was necessary to strictly guard the powers to be given under this Bill of removing lunatics from lunatic asylums to poor-houses in Ireland. They could be much better looked after in asylums than in workhouses.—Lord LISGAR said he was of a similar opinion, but the power of removing lunatics from asylums in Ireland to poor-houses was rendered necessary from the asylums being overcrowded with cases of chronic lunacy, which could be as well treated in the poor-houses as in asylums.—The Earl of SHAFTESBURY thought

that the great difficulty would be in dealing with chronic cases in asylums. In many such cases, it would be better for the parties that they should be left in the workhouses, where the companions they met with, and the small share they might take in the affairs of the establishment, would tend to their benefit, though not to their cure. If the illness was treated within the first twelve months, there was good hope of cure, though there was but very little afterwards; so that chronic affections were not likely to be cured in the asylums, and the places of such persons had better be occupied by others whom there was a chance of curing.—The LORD CHANCELLOR observed that the clause upon this subject followed as nearly as possible what was the law of England upon the subject. As to the suggestion that there should be some check upon the removal, he could only say that there were already so many checks in the Bill that it was rather difficult to see how anybody could be removed under it.—The Bill was read a second time.

Tuesday, August 3rd.

Vivisection Regulation Bill.—Lord HENNIKER said he would, with their lordship's permission, withdraw this Bill. He had put it off from time to time in the hope that something might have been known of the probable action of the Royal Commission, and so have given an opportunity for a discussion or advance in some degree towards a satisfactory settlement of the question. That was, however, hardly possible then; and, at that late period of the Session, he thought he should best consider the convenience of their lordships by withdrawing the Bill. He hoped the Commission might be able to report in time to legislate on the subject early next year. If not, and it was proper for him to do so when the time arrived, he would reintroduce the Bill, or call their lordships' attention to the question as early as possible next Session. Meanwhile, he hoped some little good might have been done by calling public attention to the practice of vivisection, which he was sorry to believe largely prevailed. The noble lord concluded by moving the discharge of the order.—The motion was agreed to, and the order for the second reading was discharged.

Sale of Food and Drugs Bill.—On the order for considering the Commons' consequential amendments in the Bill, the Duke of RICHMOND moved that their lordships should not agree to the consequential amendment.—The motion was agreed to, and their lordships did not concur in the consequential amendment.

Lunatic Asylums (Ireland) Bill.—This Bill passed through committee.

MEDICAL NEWS.

UNIVERSITY OF LONDON.—The following candidates have passed the recent Preliminary Scientific (M.B.) Examination.

First Division.

Barker, Frederick Rowland, St. Thomas's Hospital
 Baylis, Frederick, Epsom College
 Best, John Henry, University College
 Bredin, Richard, Royal Infirmary School, Liverpool, and private study
 Brooke, Henry Ambrose Grundy, B.A., Owens College
 Brown, George, Owens College
 Cantin, Louis Alfred, St. Bartholomew's Hospital
 Chuckerbutty, William Goodeve, University College
 Clark, Charles Alfred Dagnall, St. Bartholomew's Hospital
 Clarke, Thomas Furze, King's College
 Colborne, William Wriothlesley, University College
 Collier, Mark Percell Mayo, St. Thomas's Hospital
 Crisp, Thomas, St. Thomas's Hospital
 Cuffe, Edward Meade, Epsom College
 Cunnington, Cecil William, private study
 Davies, David Samuel, St. Thomas's Hospital
 Dismorr, Alfred, St. Bartholomew's Hospital
 Dixon, Alexander Campbell, private study
 Edwardes, William Whitfield, St. Mary's Hospital
 Elsdon, James Vincent, private study
 Faulkner, John Thomas, Manchester Medical School
 Fenton, Herbert Alfred Hill, University College
 Fuller, Thomas Warburton, Guy's Hospital
 Graham, Albert William, St. Bartholomew's Hospital
 Greenwood, Major, London Hospital
 Harnes, Arthur John, University College
 Harrison, Cecil Reeves, University College
 Harvey, Alfred, Queen's College, Birmingham
 Hayle, Thomas Hahnemann, Owens College
 Herschell, George Arich, St. Thomas's Hospital
 Hewitt, William, Royal School of Mines
 Hine, John Edward, University College
 Hinton, William Bartlett, Guy's Hospital
 Hodgson, John, Owens College Medical School
 Horsley, Victor Alexander Haden, University College
 Hoskin, Theophilus, University College
 Hughes, Richard, private study
 Humpidge, Thomas Samuel, Royal School of Mines
 Jones, William Wansbrough, Magdalen College, Oxford

Ledward, Archibald Prentice, Owens College
 Lichenstein, Maurice, private study
 Lory, William Manley, University College
 McAlpine, Archibald, Royal College of Science, Dublin
 McDonald, Greville Matheson, King's College
 Meeson, Alfred, Royal Infirmary, Liverpool
 Michael, Henry James, St. Thomas's Hospital
 Mott, Frederick Walker, University College
 Murray, Hubert Montague, Camden Schools, Brighton and Sussex County
 Hospital
 Nankivell, John Howard, King's College
 Neale, William Henry, private study
 Noble, William James, Keble College, Oxford
 Nourse, William John Chichey, St. Mary's Hospital
 Palmer, Arthur Maurice, University College
 Pasteur, William, University College
 Pearce, Walter, St. Mary's Hospital
 Penny, Edward, Guy's Hospital
 Ponsford, Leicester Cuthbertson, University College
 Puge, Thaelis Wilim Owen, Royal Infirmary, Liverpool
 Quelch, John Joseph, New College, Ex-thourne
 Ráy, Nanda Kumar, University of Edinburgh
 Robinson, Frederick, Leeds School of Medicine
 Ross, David, B.A., private study
 Rushworth, Frank, St. Bartholomew's Hospital
 Russell, George Hannah, Guy's Hospital
 Savill, Thomas Dixon, St. Thomas's Hospital
 Shearman, Percy Edward, University College
 Sheldon, Thomas Steele, Guy's Hospital
 Silk, John Frederick William, King's College
 Smith, Ernest Sutton, University College
 Smith, Robert Percy, St. Thomas's Hospital
 Squire, John Edward, University College
 Suckling, Cornelius William, private study
 Turner, Alfred Moxon, Guy's Hospital
 Wainwright, Edward Harley, University College
 White, William Hale, Guy's Hospital
 Willis, Ambrose Robinson, Royal School of Mines
 Wooldridge, Leonard Charles, Guy's Hospital

Second Division.

Allen, Dennett George, St. George's Hospital
 Barton, William Edwin, University College
 Bassett, Henry Thurstan, Queen's College, Birmingham
 Chillingworth, Andrew, St. Bartholomew's Hospital
 Cranstone, William Lefevre, University College
 Deane, Arthur Dorman, Guy's Hospital
 Eady, George John, private study
 Enright, James, private study
 Finlay, Thomas, University College
 Hagyard, Robert, Leeds School of Medicine
 Hayward, John Davey, University of Bonn and private study
 Hine, Harry, Guy's Hospital
 Hooker, Charles Paget, St. Bartholomew's Hospital
 Hurst, George, B.A. Sydney, University of Edinburgh
 Jones, Charles Montague Handfield, St. Mary's Hospital
 Kendall, Peter Slade, University College
 Money, Angel, University College
 Nettlefold, Edward, University College
 Outhwaite, William, private study
 Price, Edward Morris, University College
 Rich, Arthur Criswell, Royal Infirmary, Liverpool
 Routh, Amand Jules McConnell, University College
 Smith, Ernest Frederic, St. George's Hospital
 Swale, Harold, University College
 Sweeting, Richard Deane Roker, London Hospital
 Symons, George Francis, Guy's Hospital
 Tait, Edward Sabine, St. Bartholomew's Hospital
 Thomas, Walter Duncan, Epsom College
 Williams, William Potts Rees, St. George's Hospital
 Yate, Henry Wright, Epsom College

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners, on July 26th.

Messrs. T. C. Muzliston, Plymouth; J. A. Phillips, Guildford; A. de W. Baker, Dawlish; W. G. Dickinson, Hampstead; W. J. Brookes, Westminster Bridge Road; H. Sworder, L.S.A., Luton, Beds; G. H. B. Fisk, Camden Square; H. F. Lancaster, Amersham Park Villas, S.E.; J. R. Leeson, Teddington; J. W. B. Mason, Osnaburgh Terrace; H. L. Crocker, Plymouth; A. D. Brencley, L.S.A., Denmark Hill; A. T. Scott, L.S.A., Camden Road, N.W.; C. F. Newland, Bradleigh Down, Tiverton; L. Druitt, Strathmore Gardens, W.; D. C. Morgan, Llandriaf Brefi, Cardigan; A. Lucas, L.S.A., Burwell, Cambridgeshire.—J. B. Richardson, L.S.A., Castle Bytham, near Stamford, who passed in Surgery at a previous meeting of the Court, having since obtained a medical qualification, was also admitted a Member.

Two candidates passed in Surgery; and, when qualified in Medicine, will be admitted Members of the College. Five were referred for six months.

Candidates who passed on July 27th.

Messrs. A. G. Ward, Carlton Hill, N.W.; R. W. Greenish, New Street, Dorset Square, N.W.; E. Harrison, Wrexham; H. C. Taylor, L.S.A., Trinity Square, Borough; C. F. Willis, Penton Hook; J. Needham, Victoria Park; T. L. Brown, Camberwell; E. Symonds, Thaxtid, Essex; H. C. Burton, Lee, Kent; M. W. Traill, Kinross, New South Wales; H. J. Hind, L.S.A., Twickenham; T. Davies, Barmouth; T. Wakefield, B.A. Cantab., Notting-ham Place; C. J. Wolllett, Monmouth; L. J. Wilding, L.S.A., Worcester; A. Sangster, M.B. Cantab., Streatham Hill, S.E.; A. C. Routh, Meyrick Square, Borough.

Two candidates passed in Surgery; and, when qualified in Medicine, will be admitted Members of the College. Six were referred for six months.

Candidates who passed on July 28th.

Messrs. B. Jones, Chorley; E. W. Henley, Derby; R. S. P. Collyns, Gower Street; R. Coom, Bodmin; F. W. Cory, L.S.A., Buckhurst Hill; F. G. Harvey, Spalding, Lincolnshire; G. Sibbering, Merthyr Tydfil; C. H. Tamplin, Old Burlington Street; J. V. Farfan, Claverton Street; W. H. Barker, Brighton; F. Le M. Grasset, M.B. Edin., Toronto; H. C. Noott, Dudley, Worcestershire; C. Curwen, Worthington, Cumberland; J. Coudrey, L.S.A., Abingdon, Berks.—Three candidates who had previously qualified in Surgery, having passed in Medicine, were admitted Members: Messrs. W. C. Cooke, Brompton, Kent; J. Hopkins, Northwich; H. Colborn, Wimbeldon.—A. G. Hattie, M.D. Pennsylvania, Antigua, passed his examination under the old regulations, and was also admitted a Member.

Three candidates passed in Surgery; and, when qualified in Medicine, will be admitted Members of the College. Six were referred for six months.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, July 29th, 1875.

Bernays, Sydney Adolphus, Acre House, Brixton
 Leigh, Reginald Heber, Aberdare, South Wales

The following gentlemen also on the same day passed their primary professional examination.

Atkinson, Henry Seymour, King's College
 Bouton, George Charles, St. Mary's Hospital
 Chant, Thomas, London Hospital
 Feltham, William Parsons, St. Bartholomew's Hospital
 Gage, William Henry, St. Bartholomew's Hospital
 Messum, John Alexander G. R., St. Bartholomew's Hospital
 Smith, Thomas Frederick Hugh, King's College
 Stelfax, John Bridwall, Owens College, Manchester

MEDICAL VACANCIES.

The following vacancies are announced:—

ARMY MEDICAL DEPARTMENT—Surgeons. Examination on August 9th and following days.

ATCHAM UNION—Medical Officer for St. Chads. Salary, £122 per annum, and fees. Applications on or before the 12th instant.

BOROUGH OF ROCHDALE—Medical Officer of Health. Salary, £300 per annum. Applications on or before August 7th.

BOURNEMOUTH GENERAL DISPENSARY—Resident Medical Officer and Secretary. Salary, £120 per annum, with furnished apartments, coals, gas, and attendance.

BURY UNION—Medical Officer for the Radcliffe District.

CHRISTCHURCH UNION—Medical Officer for the Eastern District. Salary, £90 per annum, and fees. Applications on or before August 16th.

DAVENTRY UNION—Medical Officer for the Workhouse and the First District.

DUDLEY DISPENSARY—Resident Medical Officer at Michaelmas.

GREAT NORTHERN HOSPITAL—House Surgeon. Ophthalmic Surgeon. Applications on or before August 6th.

HAY UNION—Medical Officer for the Herefordshire District.

INDIAN MEDICAL SERVICE—Two Surgeons. Examination on August 9th and following days.

KEYNSHAM UNION—Medical Officer for the Keynsham District.

LEEK UNION—Medical Officer for the Norton District.

LYMINGTON UNION—Medical Officer for the Hordle, Lymington, and Milford Parishes.

MACCLESFIELD GENERAL INFIRMARY—House Surgeon. Salary, £90 per annum, with board and residence. Applications on or before August 6th.

MALDON UNION—Medical Officer for the Southminster District.

NORWICH DISPENSARY—Salary, £120 per annum, with unfurnished residence and apartments.

ORMSKIRK UNION—Medical Officer for the Second District.

PIOMESGATE UNION—Medical Officer for the Aldeburgh District.

ROYSTON UNION—Medical Officer for No. 5 District. Applications on or before September 6th.

ST. IVES UNION—Medical Officer for the Warboys District.

STAINES UNION—Medical Officer for the Shepperton District.

TIVERTON UNION—Medical Officer and Public Vaccinator for the Western District. Salary, £70 per annum. Applications on or before August 9th.

TOWNSHIP OF MANCHESTER—Assistant Medical Officer at the Workhouse Hospital. Salary, £120 per annum, with furnished apartments, fire, light, washing, and attendance. Applications on or before August 12th.

UCKFIELD UNION—Medical Officer for the Maresfield District.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTH.

FERRIER.—On August 3rd, at 16, Upper Berkeley Street, Portman Square, the wife of David Ferrier, M.D., of a daughter.

MARRIAGES.

STOCKER—GOODMAN.—On August 4th, at St. Paul's, Camden Square, N.W., by the Rev. R. Gordon Cumming, A.M., Alonzo Henry Stocker, M.D., of Peckham House, Peckham, S.E., to Ada Mary Goodman, of The Terrace, Camden Square, N.W., elder daughter of the late Thomas Goodman, Esq.

BURDETT—SHUTE.—On August 1st, at the Parish Church, Greenwich, by the Rev. F. P. Lawson, M.A., brother-in-law of the bridegroom, assisted by the Rev. H. L. Elliott, M.A., Rector of Gosfield, Essex, Henry Charles, eldest surviving son of the late Rev. Halford R. Burdett, M.A., of Gilmorton, Leicestershire, to Helen, second daughter of Gay Shute, Esq., F.R.C.S., of Greenwich.

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAYGuy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAY ..St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAY ...St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.

FRIDAY.....Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.

SATURDAY ...St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

AUTHORS desiring reprints of their articles published in the *JOURNAL*, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the *JOURNAL*, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

CORONERS' INQUESTS.

SIR,—Nothing is more distressing to a bereaved family than the holding of a coroner's inquest, especially when, as in the case of Sir C. Lyell, a preliminary inquiry might have shown its non-necessity. The Lord Chancellor, in reply to Dr. Hardwicke, says: "I cannot but think that if an official application had been made to Dr. Clark (whose certificate was, 'Meningitis, ten weeks; effusion, six days'), he would have given such an explanation as would have rendered a coroner's inquiry unnecessary." These remarks of the Lord Chancellor recall certain suggestions to which you were good enough to give publicity in the *JOURNAL* some years ago, but which, I believe, attracted no attention. When a coroner is paid by salary, it is rare for an inquest to be held unnecessarily—the reverse is more likely to be the case; but when this officer is paid by fees, he is generally ready to act on the slightest intimation, and "death from natural causes" is a common finding of the jury. If the coroner, in all cases of doubt and uncertainty, were empowered first to take counsel with the medical man in attendance, and decide with him upon the propriety or otherwise of a public inquiry, I venture to affirm that many of the inquests now held would be unnecessary. In my own locality this is not unfrequently done, but it places both medical man and coroner in a false position, a conscientious adverse decision involving the sacrifice of fees.

The suggestion thrown out in a former communication was that, where the cause of death did not at first sight satisfactorily appear, a consultation should take place between the coroner and the medical attendant; and, if they were perfectly satisfied, a certificate should be given accordingly, each party charging half his usual fee. Great saving to the public would ensue, and much distress to families be averted.

The present modes of payment by salary and payment by fees are equally unsatisfactory: in the one instance, inquests are too readily avoided, and, when held, medical evidence is too often dispensed with; in the other, inquiries are held which are afterwards proved to have been needless.—I am, etc.,

July 11th, 1875. E. GARRAWAY, Faversham.

We have received £100s. from Messrs. Felton and Sons for the British Medical Benevolent Fund.

THE TITLE OF "DR."

SIR,—Will you allow me to inform your correspondent L.R.C.P. Lond., that the legal decisions quoted by him in the *JOURNAL* of July 24th have no bearing whatever upon the question of who has a right to the title of Doctor? The object of the Medical Act, under which those decisions were given, is to prevent unqualified persons assuming such a title as would lead the public to suppose that they were legally qualified—*i.e.*, registered. A registered M.R.C.S. or L.S.A. would, therefore, not violate that Act of Parliament by calling himself "Doctor" any more than a man would infringe any other Act of Parliament by calling himself "Earl Jones" or "Baron Brown"; but the former would on that account have no more right to the academic title than the latter to the title of nobility.—I am, sir, yours faithfully,

Hackney, August 2nd, 1875. M.D.

ERRATUM.—In Dr. Ambrose's paper on Concealment of Venereal Disease in the Army, which appeared in the *JOURNAL* for July 24th, at page 99, column 1, line 12, the words "Those of the chancres were cicatrising", should read "Three of the chancres were cicatrising".

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

AN APPEAL.

SIR,—I respectfully invite the attention of the medical officers of the public services to the following particulars of a sad case.

An assistant surgeon, whose name it is not perhaps necessary to give, but which can be given to any subscriber who desires to know it, lost his health in the Crimea, and, after a lingering illness, died from softening of the brain, leaving a widow and five children in circumstances of extreme destitution. This officer's ill health was not brought on by imprudence or bad habits: those who have interested themselves in this case, and whose names are given below, know that his habits and conduct always were such as to command the respect of his friends. It must also be added, that he made such provision for his family as he could, by insuring his life in the Army and Navy Insurance Office, afterwards amalgamated with the European. It is useless to add, that no benefit was derived from this insurance, as this office disastrously failed. When this occurred, the state of the assistant-surgeon's health was such that a second insurance on his life was impossible. For several years before his death he supported his wife and family, and met all the expenses of his long illness, on his half-pay of eight shillings per day. Not having served for ten years, his widow is not entitled to a pension. It is proposed to raise a sum of money for the purchase of an annuity for the benefit of the widow, who at this time depends on the charity of her neighbours for daily bread for herself and children.

The following gentlemen will be happy to receive subscriptions in aid of this fund:—Major-General Lewis, Shirley, Southampton; Lieutenant-Colonel Begbie, Shirley, Southampton; Dr. Parkes, F.R.S.; Surgeon-General Longmore, C.B.; Surgeon-General W. C. Maclean, C.B., Royal Victoria Hospital, Netley.—I am, sir, your most obedient servant,

W. C. MACLEAN, M.D.

Netley, July 30th, 1875.

MEDICO.—Taylor's *Manual of Medical Jurisprudence* (Churchill); Scoresby-Jackson's *Materia Medica* (Macdonald's edition); or Neligan *On Medicines*.

THE GOOD-SERVICE PENSIONERS OF THE ARMY MEDICAL DEPARTMENT.

SIR,—Dr. Lush, in his recent speech, might well have called attention to this branch of military medical grievances. There are some twelve hundred or more medical officers, among whom eight good-service pensions are allotted—precisely the same number as given among three hundred officers of the Royal Marines, a corps certainly not over favoured in the distribution of good things generally, yet on whose scale of such positions the doctors should have at least thirty instead of eight to look to. Let us hope that Mr. Hardy's attention may be turned to this practical grievance. These pensions, be it remembered, are professedly given for "meritorious" as well as for "distinguished" services, and as such are peculiarly appropriate rewards for the skilful, hardworking regimental surgeon, toiling year after year, day after day, in the trying duties of a tropical climate; never off duty; ever in the field against the great enemy, death, and his divisional generals, fever, cholera, liver-disease, and dysentery. Many such officers—men well known for skill and hard work—had their whole prospects ruined by the grievous supercessions of 1858 (from which era we may date all the troubles of the department), and are now pining in the obscurity and semi-penury of half-pay on 18s. 6d. a day—first denied their just promotion, and then shelved for the crime of having attained 55 years of age, without obtaining it. In such cases, a pension for "meritorious service" would be some slender consolation. But while the Horse Guards have shown much feeling in that way for deserving but unfortunate officers, and do not allow any general holding a regiment to retain his good-service pension, the medical authorities seem to act on the Scriptural principle, and to bestow their pensions on their surgeons-general—a rank of officers already highly salaried, and who should not be allowed to retain a good-service pension.—Your obedient servant,

H. P.

DR. SAMELSON will find the literature subject of the Conjugate Deviation of the Eyes fully discussed in the last number of the *Archives de Physiologie*.

PRACTICE IN AMERICA.

SIR,—In reply to your correspondent H. G. D., I write to say that I spent several years in practice in New York, and had some opportunity of making observations on the subject referred to in his letter in your last issue. There was no restriction affecting English qualifications, and the principal safeguard by which I observed the dignity of the profession to be protected was the *esprit de corps* subsisting among its worthy members. I believe British degrees and diplomas are in very high repute; and I experienced the greatest courtesy and kindness, as an Englishman, from my professional brethren and from all classes of American society. I should think a properly qualified practitioner emigrating from this country to the States would be sure of a fair amount of professional success, if he had a good address, common sense, confidence in his own judgment, and the necessary patience and funds to await with dignified composure the development of a judicious plan of action. With regard to the profession being overstocked, I fancy it is so everywhere with a certain class of members, honourable and otherwise; but the field is as fair in America as elsewhere, while the balance of *prestige* is in favour of a foreigner among people who are apt to value their treasures according to the distance from which they have been obtained.—I am, sir, yours truly,

July 24th, 1875. M.A., M.D., etc.

P.S.—I enclose my card, and shall be happy to answer any private inquiries to the extent of my information.

SIR,—In reply to your correspondent H. G. D. on the above subject, I will answer his questions as briefly as possible, and give him the benefit of more than two years' experience in the Western States. English diplomas are recognised in all the States, but in the West a man can practise without any diploma; and, if possessed of sufficient assurance, is often more successful than his qualified neighbour. The social status of the profession is, I am sorry to say, not recognised. A medical man is regarded as a tradesman, and enjoys a position in society equal to his tailor or bootmaker. In all Western towns there are plenty of *soi-disant* "doctors"; but a man who could afford to live for the first two or three years partly independent of his profession, and to whom the customs of the country would not be disagreeable, would in the end realise a fair income.—I remain, sir, truly yours,

JAMES P. KEARNEY, L.R.C.S.I., etc.

Much Wenlock, Salop, July 26th, 1875.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, twelve o'clock.

COTTAGE HOSPITALS.

SIR,—M.D. cannot do better than procure a small work entitled *Handy Book of Cottage Hospital Management*, by H. Swete, M.D., and published by Hamilton Adam, and Co., of Paternoster Row; he will therein find every particular he may require as to the expense and practical working of cottage hospitals.—Yours, etc.,
R. S. P. T.

WASHING OUT THE UTERUS.

SIR,—In the JOURNAL of July 17 I notice a letter from A Learner, wherein my name is mentioned in conjunction with that of our late worthy President, Dr. Tilt, asking for information on the subject of washing out the uterus and vagina when any septic matter is contained therein. I shall not allude to the late discussion on puerperal fever at the Obstetrical Society, except to state that not one of the speakers denied, or appeared to doubt, that the contact and absorption of septic poison would cause so-called "puerperal fever." Thus far we are all agreed. The rules I should like to see carried out to prevent the conveyance of septic poison to the puerperal female are these.

1. All maternity hospitals should be isolated, and the strictest attention paid to cleanliness and the immediate removal of all matters likely to become offensive. These should not be hidden under the bedding when the medical officer, etc., goes round the wards; here they are often forgotten, and thus become the hidden source of infection.

2. No one whilst engaged in dissection, or a frequenter of the dissecting-room, should on any account be allowed to attend a woman in her confinement.

3. No medical man engaged in midwifery practice should himself, when it can be possibly avoided, make a *post mortem* examination; and, should circumstances compel him to do so, he should immediately change his clothes, and wash his hands in some disinfecting fluid.

4. No medical man or nurse should, after being in attendance on any case of scarlet fever, diphtheria, small-pox, erysipelas, or any other disease, in the course of which putrid or septic emanations may be present, attend a woman in her confinement without washing the hands in a disinfecting fluid; and in the case of the nurse, in addition, her clothes should be thoroughly disinfected.

5. No accoucheur or nurse should on any account, after being in attendance on a case of puerperal fever, attend a woman in her confinement without taking every precaution to free himself or herself from any septic poison which may have attached itself either to the dress or to the surface of the body. To accomplish this, the accoucheur should wash his hands in a disinfecting fluid, and should, in addition (as I explained at the Obstetrical Society), place a few grains of pure iodine on a plate, and hold under it a spirit-lamp. This of course must be done in a confined space, such as the water-closet, in order that the fumes of iodine should fall over the clothes, etc., of the person to be disinfected, which it will do in small scales, without any injurious effects to the person or clothing, provided the eyes are protected. The monthly nurse should, in addition, change her whole bodily clothing.

That iodine does destroy the poisonous properties of septic matter, I can assert most positively; and, in spite of the antivivisectionists, I will relate how I satisfied myself of the fact. I injected various solutions of putrid matter under the skin of guinea-pigs, and to other portions of the same solutions I added a few drops of tincture of iodine before injecting the solution. In the latter case no injurious results followed, but in the former death always occurred within a few days, with all the symptoms of septic poisoning, afterwards verified by *post mortem* examinations. The stronger the solution, the more intensified the symptoms.

It is scarcely necessary to state that the tincture of iodine is the antiseptic I invariably use if at hand; if not, the permanganate of potassa—Condy's fluid. I prefer the iodine solution for one reason, because iodine is volatilised by the heat of the body, and its vapour inserts itself into every fold of mucous membrane or other tissues penetrating below the mere surface, thus as it were ferreting out the septic poison, and forming with it perfectly harmless compounds (*vide* article Septicæmia, St. Andrew's Graduates *Transactions*, vol. i). There is, then, far less danger of the formation of secondary deposits in distant parts which I have seen follow the use of Condy's fluid. I cannot help mentioning a fact, which will be found very useful knowledge at this season of the year—namely, that tainted or partially putrid meat or game may be rendered perfectly wholesome by washing it in a solution of tincture of iodine, and may be eaten not only with impunity, but with a relish, as all flavour of iodine is removed by the heat of the fire whilst cooking.

We now come to the treatment of the patient suffering from the presence of septic poison in her body. It does not matter whether the septic poison has been conveyed to the patient, and putrefactive fermentation set up thereby in the lochia, or whether some portion of placenta, or blood-clot, or slough, has been retained long enough to become putrid; all that we practically want to be satisfied of is, whether any offensive smell proceeds from the generative organs of the patient. If there do, after removing, as far as practicable, all extraneous matter, wash out the vagina with a solution of tincture of iodine. Three drachms to the half pint of tepid water is the strength of the solution I have been in the habit of using. Keep pumping this up into the vagina with an India-rubber enema until the liquid returns of the same bright colour it had before being pumped up, or, in fact, until there is no further offensive smell. Should the patient not be relieved, and the offensive smell continue, do not hesitate to wash out the uterus, as well as the vagina, with the same solution of iodine. The simplest and most ready way to do this is to attach a good-sized male catheter, by means of a couple of inches of India-rubber tubing, to the pipe of the enema. Introduce the finger up to the os uteri—the attendant, if necessary, pressing down the uterus; guide the point of the catheter into the uterus with the slip of India-rubber tubing attached. Having first charged the enema apparatus with the solution, insert the nozzle of the pipe into the India-rubber tubing, then force the solution steadily up the catheter into the uterus. This must be done gently and regularly, not by jerks, until the solution returns clear, as mentioned before. This process should be repeated twice a day, as long as there is any offensive odour, by the accoucheur, whilst the nurse may wash out the vagina every three or four hours with the solution.

I have only one word of caution as regards the medical treatment: do not be in too great a hurry to check the alvine evacuations, as nature in this way endeavours to get rid of the peccant matter.—Yours, etc.,
A. WYNN WILLIAMS.

June 20th, 1875.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

DISEASE OF THE NAILS.

SIR,—I would strongly advise your correspondent of the 17th July (Dr. Morris) to employ arsenic internally in the case he describes; the indications being, the seat of the affection upon the skin, periodicity and intermission of symptoms, the case being an evident neurosis. Indeed, skin-affections generally, as their true pathology comes to light, are coming to be classed more and more among the neuralgias and other nerve-affections.—Yours, etc.,
ROBT. T. COOPER, M.D.
6, Ladbroke Road, W., August 1875.

SOCIUS SENEX.—1. Yes. 2. No. It is much to be regretted that Socius Senex did not notice the repeated advertisements issued constantly from the office of the Registrar. In accordance with the Act of Parliament, a registered letter sent to the late address must have been returned marked "Address unknown", before the name was taken off the Register. The Medical Council expends about £50 yearly in sending these registered letters to practitioners who have changed their addresses.

MR. G. CHATER (Tenby).—*Skin-grafting*, by John Woodman, F.R.C.S. A second edition of this pamphlet was published in 1873 by J. and A. Churchill. Or, Cases of Skin-grafting and Skin transplantation, a paper by Mr. G. D. Pollock, published in vol. iv (1871) of the Clinical Society's *Transactions*.

ADDRESS IN SURGERY,

DELIVERED AT

THE FORTY-THIRD ANNUAL MEETING OF THE
BRITISH MEDICAL ASSOCIATION,*Held in EDINBURGH, August 3rd, 4th, 5th, and 6th, 1875.*

BY

JAMES SPENCE, F.R.C.S. Ed., F.R.S.E.,

Surgeon in Ordinary to the Queen in Scotland; Professor
of Surgery in the University of Edinburgh.

MR. PRESIDENT AND GENTLEMEN,—When I was honoured by the request of your Council to give the Address in Surgery, I asked to be allowed a short time to consider how far I would have leisure to prepare an address worthy of the occasion; for, in addition to my winter's avocations, I was engaged in a work which it was necessary to finish before the commencement of another session. I knew, moreover, that addresses were not my *forte*, and that any attempt of mine must fall far short of the elegance in composition or the eloquence which had characterised the addresses to which you were accustomed. But, on consideration, I felt that my position as Professor of Surgery in this University, the long experience I had enjoyed as Surgeon to the Royal Infirmary, and the length of time I had been connected with the Edinburgh Medical School, demanded that I should not shrink from the duty of doing my utmost in response to the invitation with which I was honoured: I consented the more readily, that I felt sure that the members of the Association would; as practical men, look rather to the matter than to the manner of my address.

Having accepted the situation, I had not much difficulty in choosing my subject. My avocations as a hospital surgeon and teacher of surgery necessarily forced on my attention the changes taking place in our views of disease and in the practice of surgery. I decided to review the progress of surgery in relation to its past, limiting myself necessarily to a few departments, from the impossibility of overtaking the whole range of the subject.

I believe it is only by reviewing the advance in relation to the past, that we will be able to estimate what real progress our science has made, and in what that progress consists, whether in the discovery of something absolutely new, or in modifying and improving methods of treatment, the intrinsic value of which had not been fully appreciated, or which had fallen into disuse owing to the imperfect method in which the principle had been carried out. In regard to things absolutely new, we might almost echo the saying of Solomon: "Is there anything whereof it may be said, See, this is new? It hath been already of old time, which was before us."

Looking at some of the more prominent recent changes in surgical practice, a superficial observer might almost imagine that instead of progressing, our science moved in a cycle; and were he inclined to be cynical, he might suggest that we had revolved back to the period of sheer mechanical forces, complicated dressings, and red-hot knives. A nearer and more appreciative examination will show us, however, that even in cases where the principle is not new, the method of applying it has been so modified and improved as to constitute a real advance and addition to our resources. Let me take as an example of this, a method of treating fractures of the lower extremity now much used—*extension by weight and pulley*.

The great tendency to shortening and deformity in cases of fracture of the thigh-bone, owing to the contraction of the powerful muscles which surround it, could not but attract the attention of those called upon to treat such injuries; and hence, from the earliest times, surgeons were naturally led to try to overcome the displacing causes by opposing force to force by means of *extension* and *counterextension*. The principle of extension is now almost universally admitted to be best in these fractures; but the method by which it is applied makes all the difference. Those who first applied the principle seem to have had in view rather what mechanical forces could effect, than what the living body could bear. You have only to look at the formidable machinery they employed for the purpose, such as the bed of Hippocrates, the "organon", and the various forms of glossocoma, different kinds of racks and windlasses, in fact, to understand how a revulsion of feeling in the profession should have at one time led to the abandonment of the extension treatment in fractures of the thigh-bone, and to the adop-

tion of the method of laying the limb on its outside, with the leg bent on the thigh, and the thigh bent on the pelvis—a principle of relaxing powerful muscles which had proved most useful in fractures of the leg, but which, for obvious causes, proved most disastrous in those of the thigh. The abuse of a power is not a reason for abandoning its use: we would do better to examine into it, and try whether it be not capable of improvement. I fear, however, human nature has a bias to extremes; and so we often miss making improvements on methods of treatment until they suddenly reappear as novelties, and are accounted, and properly so, as marks of progress. Mr. John Bell, in his great work on *Surgery*, speaking of the machines used in treating fractures, says: "I may, perhaps, do you some service by explaining the simple principles of this department of surgery; and then you will be able to enter the magazines of Scultetus, Hildanus, and Pareus, filled with engines not unworthy of the chambers of the Inquisition, without being tempted to bring out along with you any of their lumber." Accordingly, he does enter the magazines of apparatus, and criticises them with his usual scathing sarcasm. Amongst other "lumber," he unhangs from the walls of the magazine of Hildanus a weight with circle and strap for hanging from the ankle, and drags to light a bed with a surcingle or perineal band of horse-girth for fixing the body to the upper part of the bed; and on this rude apparatus for permanent extension he makes ironically laudatory remarks. Mr. Bell would have been better employed if, when he exhibited the rude apparatus of Hildanus, and admitted its power of maintaining permanent extension, he had thoughtfully considered how its defects might be removed, and it might be converted into a simple and effective means of treating fractures of the lower extremity. Let me again take the dust off this bed and weight of Hildanus, and place them alongside some modern surgical upholstery, and see how like they are. Here is the weight and pulley method copied from a recent work on surgery. How very like! The perineal band or surcingle fixing the patient; the weight hanging from the foot through the pulley fixed at the foot of the bed. But how is the weight hung from the limb? No longer by a circular strap round the ankle, acting on one part only, and so unendurable, but to long plasters fixed to and embracing a great breadth of the limb from immediately below the fracture, and so diffusing pressure that the patient feels no inconvenience, and is scarcely sensible of the extending force. That makes the difference. But something is still wanting to its perfection. Can we get rid of that perineal band, which proves so troublesome to patient, and surgeon, and nurse? How can we dispense with it, and maintain a counteracting force to the extension from the foot? Tilt up the lower end of the bed; place blocks of wood below the feet of the bed; take off the perineal band, and let the body be the counterextending force; and there you have the simplest, least irksome, and most perfect method I know of treating fractures of the thigh, and, if possible, still more useful in treating oblique fractures of the tibia. Until a comparatively recent date, I seldom used anything but the long splint for the purpose of extension and counterextension; and several years ago I drew special attention to what I considered essential to its proper use, *viz.*, maintaining a moderate amount of extension during treatment, more especially when the fracture was oblique; and, so far as the results of my practice were concerned, I had little reason to abandon the long splint for any other method. But it is impossible for any one who has had much experience in its use not to feel that it had defects, and that much care is required to prevent troublesome results, and to overcome some difficulties. I may mention, for example, the tendency to fretting and excoriation of the soft parts, caused by the perineal band or extensor, and by the handkerchief which was generally used for fixing the foot to the splint. Nay, unless great attention was given, the pressure of the handkerchief sometimes gave rise to sloughing, especially in old or very young patients. Indeed, for some years before I began to use the pulley-extension, I had used plasters as the means by which I fixed the foot to the lower part of the splint, so as to obviate the bad effects of the handkerchief round the ankle and instep, and also as maintaining extension in a more direct line, and preventing any eversion of the foot; and I would strongly urge this modification whenever the long splint is used. But there still remained the inconvenience and irritation caused by the perineal band, and the frequent necessity of changing it for cleanliness; and when this band is removed, of course all extension and counterextension cease for the time, unless kept up by assistants; and there is risk of displacement occurring. Another troublesome though less serious effect was the stiffness of knee when the splint was removed at the end of six or seven weeks; and, in some patients of rheumatic diathesis, or those who would not tolerate early passive motion being used, I have known a considerable amount of stiffness remain for years. My predilection for, and my favourable experience in the use of, the long splint, made me very un-

willing to abandon it; but, having to treat a compound fracture of the thigh where the wound was so placed that even the bracketed long splint could not be used, I tried the extension-pulleys, and found that method so effective, that I tried it in ordinary cases, and have found it so simple and effective, so much more comfortable for both patient and surgeon, that I now rarely use the long splint—almost never, except for clinical instruction, that students may see more than one method of treatment. Now, after some years' experience in the use of the extension-pulleys in fractures of the thigh in very young children and in adults, in fracture of the neck of the femur in old persons, and in long oblique fractures of the tibia, I unhesitatingly commend the method to all who may not have tried it. Of course, in fractures of the shaft of the femur, lateral splints are required, just as when we use the long splint, and also for lateral support in fractures of the leg. When there is much bruising, however, I merely use sand-bags to prevent lateral displacement; and I also prefer deep sand-bags to prevent rolling of the limb outwards in fractures of the thigh, to a long lateral splint, as used in America. In fact, the full advantages of the extension-pulley method are only secured when we abandon the perineal *lacque* and long lateral splint, and make the body the counterextending force.

Looking at the extension method, as thus improved and simplified, I think we may fairly reckon it as progress in a most important department of surgery; but, whilst we congratulate ourselves on our advance, and replace the bed and weight of Hildanus in the *armamentarium antiquorum*, let us regard it not as "lumber", but reverently with the homage due to the perception of a true principle, however rude in design and execution the apparatus may be.

The use of plasters, as enabling us to fix apparatus, is capable of numerous applications; and in transverse fractures of the patella, I have used it with advantage to enable me to approximate and retain the fragments, by means of Malgaigne's hooks, without penetrating the skin.

The Process of Union in Fracture has been long a subject of discussion. The old Arabian physicians wrote of the ossifying juices poured out from the broken bone—the *callus*; and surgeons long exercised themselves how to restrain within due bounds the exuberant supply by bandaging-friction, and even by scraping, as recommended by Abulcasis. Speaking of the ideas regarding the exudation of new material for repair of fracture in his day, Mr. John Bell says that many certainly regarded it as "something poured out like lead from a plumber's ladle"; and really if we look to some expressions used, and views held, in our own highly scientific age, I hope I will not be considered uncharitable if I cannot help thinking some such views still exist. What, for example, about that beautiful provision of Nature, provisional callus, figured and described in not a few modern works? Does it exist as a necessary part of union if the broken bone be properly adjusted and carefully retained in position? Is it true that the fibrine of the blood, extravasated from the vessels of the broken bone and the torn tissues, is valuable as a concrete, which is to become organised and ossified, and make the broken part, to use a common expression, stronger than before? I would not venture utterly to deny the correctness of such views and such beautiful provisions of Nature; but this I know, that I have had a few opportunities of examining very recently united fractures in persons who died suddenly from other causes, and in such cases I have never seen trace of the changes described. A little thickening and vascularity of the periosteum, a narrow line of new ossified material, barely perceptible between the broken surfaces, were all the changes visible in the injured bone; but in these cases the fractures had been properly adjusted and retained in position from the first. Might I hint that, to some extent at least, the views to which I have alluded are the result of misinterpreted facts, observations of experiments on animals, or of what is seen in badly or irregularly united fractures?

When the femora of rabbits or dogs are fractured, and the animals killed to ascertain the changes which occur at different periods after the injury, great extravasation of blood into the tissues, and around and between the broken ends of the bone, is a very marked condition in that early stage; and, somewhat later, inflammatory infiltration of the intermuscular connective tissue, and amongst the fibres of the muscles, is superadded, giving rise to consolidation of the parts around the broken bone and for some distance beyond. These phenomena are the result of the laceration of texture and irritation produced by unrestrained movements of the broken fragments. Every movement excites spasmodic muscular action, and, consequently, more laceration and irritation, until the extravasation of blood and until inflammatory infiltration interfere and prevent the muscles from acting, and, at the same time, serve as a sort of retentive apparatus to the fractured bone. In badly adjusted fractures, when there is overlapping, or in comminuted fractures, when the fragments render the fractured surfaces irregular, the new material is furnished in larger amount to fill up the inequalities; but even in such cases, not to the extent that the feeling of

the mass in the limb would lead us to suppose, for the bulk of that is chiefly due to overlapping; and it not unfrequently happens that, in comminuted fractures, partly detached fragments become imbedded in the muscular or connective tissues of the limb, and the new ossific matter so deposited has led some authorities to assume that the extravasated blood has become organised and ossified. Now, whilst the conditions seen in the experiments on animals or in irregularly adjusted fractures may, if you like, be termed provisional, inasmuch as they help Nature's unassisted efforts towards repair under disadvantageous circumstances, I do not believe in such provisional callus being formed when the fracture is well adjusted and retained in position, and muscular action prevented. Nature is not capricious: the healing process is the same in bone as in other textures; the smallest amount of new material is used for reunion. Just as a wound of the soft parts heals with a fine linear cicatrix, if its surfaces be carefully adjusted and retained and undue excitement prevented; whilst a similar wound, left to itself and subjected to irritation from movement or other causes, inflames, suppurates, and heals by broad irregular scar; so in fracture, if properly set and treated, there will be no ferule or mass of provisional callus at the fractured point.

Refraction in Badly Set Fractures.—Refraction and readjustment of a badly united fracture, when the bone has thoroughly consolidated, is a proceeding which, although popularly believed to be frequently resorted to by surgeons, is one which has been rarely practised since the beginning of the present century. Readjustment, however, by bending over the knee, or by pressure and counter-pressure in the case of deformed and recently united fractures, has often been effected; but interference with a badly united fracture, after months have elapsed, has generally been regarded as improper, and likely, from the force required, to lead to serious risk, with little chance of restoring the limb to better form or usefulness. Yet in early surgery, refraction seems to have been a common proceeding amongst Arabian surgeons. Abulcasis, who objected to the practice, reprobates it in strong terms: but if his remedies for softening and diminishing exuberant callus failed, this same Abulcasis had no hesitation in recommending resection of old fractures. "If the distortion be old and firm", says he, "cut across the bone and saw off all that is superabundant, whether of the bone or callus." And he further remarks to his pupils, "that study and practice will make them very expert in the operation". Here, again, we find ourselves coming back to old methods, for amongst our most recent advances, more especially since subcutaneous and subperiosteal operations have been introduced, resections to remove deformity resulting from ankylosis or badly set fractures have been practised with much advantage. The operative proceedings have been varied—sometimes weakening the point wished to be broken—by drills or narrow saws or osteotomes, sometimes by direct section by saws or chisels. Even yet, however, the cases are rare in which surgeons have ventured to break thoroughly consolidated fractures by direct force to remove deformity. No doubt, when we think of the degree of force to be applied, and look at the apparatus necessary for the purpose, a feeling of repugnance arises in the mind; but some things look worse than they really are. I make these remarks in reference to a method of refraction and readjustment of old badly set fractures of the femur, introduced to the notice of the profession by Mr. Butcher of Dublin. Mr. Butcher's case was a fracture of the thigh, attended with great deformity and shortening, in a young man who had met with the injury upwards of six months before he consulted Mr. Butcher. Any one who looks at the photographs of the limbs in that case before and after the operation of refraction, will, I think, agree with me, that it is a triumph of surgery. But when you look on the actual apparatus by which this triumph was obtained, you might be inclined to use the language of John Bell in reference to some ancient apparatus, that it was "an engine of torture fit only for the Inquisition". I have, however, had an opportunity of testing this apparatus, and can state to you that it produced none of the torture or bad effects its appearance might suggest. It happened that at the time I received Mr. Butcher's account of his case of refraction, I was considering that of a patient who had come from the backwoods of Canada to consult me, and ascertain if I could do anything for deformity and great shortening of the limb, resulting from a fracture of the femur he had sustained about two years before. The limb was four inches shorter than the sound one, and a large knee of bone projected, giving rise to great deformity; and, what was worse, the peroneal division of the popliteal nerve had suffered, and the extensor and peroneal muscles were paralysed. The case was most unfavourable, both as regarded the form of the fracture and the length of time it had been consolidated, whilst the paralysis of the foot made me doubtful of any interference; but, seeing that he had come a long distance as a last hope, I determined to try what could be done.

By using galvanism after dividing the tendo Achillis, some increase

of muscular power and development was obtained, and I had made up my mind to partially resect the fracture with a narrow saw, and then break it through, when the report of Mr. Butcher's case was opportunely sent me. On carefully and anxiously studying it, and communicating with Mr. Butcher, I had his apparatus made and refractured the bone; and though, owing to the unfavourable nature of the case, the result will not compare with Mr. Butcher's, yet the operation has greatly improved the length and form of the limb, whilst the patient has suffered no constitutional disturbance, and scarcely any local irritation from what seemed an application of great and direct force. That the apparatus admits of much modification and improvement to adapt it for acting on different forms of fracture, I doubt not; but its efficiency and safety even in its present form has, I think, been proved, and, although the necessity for such operations is daily diminishing, owing to the advance of surgical skill, yet, in cases such as those fractures which occur when the patients are at a distance from medical aid, it is well to have it in our power by simple and safe means to remedy these terrible deformities even after some time has elapsed.

Operations for the Cure of Ununited Fractures cannot be mentioned either amongst recent acquisitions or revivals of surgical resources, for such operations have long been practised. Many improved methods, however, have been introduced in comparatively recent times, such as Dieffenbach's method of resecting and pegging the resected ends of the bone, a method which has been specially successful in oblique fractures of the tibia. In a case recently reported from the practice of Professor Volkmann of Halle, a very neat and ingenious adaptation of this method has proved successful in an ununited fracture of the femur, in which the ends of the bones after resection were chiselled into a step-like form on their opposed surfaces, and so were accurately fitted to each other and pegged. Success in resection of the femur or humerus in such circumstances has not, however, been eminently successful. Even in cases where constitutional dangers were avoided, the reunion has not often taken place. In 1854, I proposed and carried out successfully a modification of resection in an ununited fracture of the humerus, by cutting down upon and merely separating the fibrous texture between and around the broken ends of bone, and snipping them off only to a small extent with strong bone pliers, carefully avoiding the use of the saw, or complete protrusion of the bone during section, so as to have as little disturbance of parts as possible, that the action on the ends of the bone should resemble the nature of fracture, and that the amount of bone removed should be merely enough to open up its texture. Since then I have, on several occasions, used this form of resection successfully. There is, however, a method of treating ununited fractures, especially at an early period, which I do not think has had sufficient notice taken of it, nor been sufficiently or fairly tried; I mean the plan proposed and practised by my predecessor in this University, the late Professor Miller. The method consists in entering subcutaneously a long narrow but strong knife; passing it on to and between the ends of the ununited bone, dividing freely the fibrous union, scraping the ends of bone, and slightly separating the periosteum; then the limb is carefully firmly bandaged and placed in appropriate splints. I know that this plan has never had much favour; perhaps it seemed too simple to effect the purpose, and it was derided and declared to be inefficacious by some who professed to have tried it. But I also know that I have frequently used it and have generally found it successful when the knife has been effectively used, and the after treatment carefully carried out. I have, indeed, so strong an opinion of the efficacy of this method in comparatively recent cases, that I do not think it warrantable to proceed to severer measures until this simple one has been fairly tried, and I purposely mention it here to press it on the attention of the profession.

The Subperiosteal Method.—From the progress in the surgery of fractures, I am almost inevitably reminded of some of the most brilliant improvements in surgery arising from our advance in the knowledge of the anatomy and physiology of the periosteum and the nutrition of bone. With the progress of this department of surgery the name of Ollier of Lyons must always be connected, as the man who has given it the greatest practical impetus; but those who recollect the experiments of the late Professor Syme, and the memoirs of the late Professor Goodsir on the structural anatomy and nutrition of bone, must credit these eminent men with no small share of our advance. The practical application of the subperiosteal method of operating is perhaps seen to the greatest advantage in such operations as that for closing the cleft in the hard palate, and in partial removal of bone in some conservative operations.

In excisions of joints, I think the subperiosteal method must be used with discrimination. In cases where, as in the lower extremity, a firm solid support, and not a movable joint, is desired, its value is at once evident; and perhaps in some excisions of the upper extremity, in which we require to remove a very large amount of bone. In ordi-

nary excisions of the upper extremity, we are more troubled with redundancy than with deficiency, and generally require to remove a considerable amount of bone to prevent ankylosis from occurring; but in truth, in a great many cases, the question is settled for us by the disorganised state of parts on which we operate.

There is one class of cases in which subperiosteal surgery seems likely to achieve some brilliant successes: I mean cases of acute necrosis, as they are called; in other words, cases in which inflammation of the dense shaft of a long bone has been so rapid, general, and violent, that nutritive changes seem arrested; and the bone separated, or nearly separated, from the investing periosteum, is exposed, with its surface bare, smooth, and white, as if dead. Although in such cases the constitutional disturbance, at first from irritative fever, and subsequently from hectic, always places the patient's life in great jeopardy, and though the tendency of the local action to spread to the epiphyses and involve neighbouring joints is very great, we have hitherto been content to wait patiently, often most anxiously, for nature to separate between the dead and living bone, before interfering. In cases where the state of the patient seemed to point to amputation as the only chance for life, the results have been so unsuccessful, that I think it scarcely warrantable. Now, however, by separating any remaining connection of the periosteum, and resecting and removing the diseased portion of the shaft, the long process of separation is avoided; the constitution is saved the tax on its powers from discharge, irritation, and hectic; the periosteum which is left furnishes new bone to take the place of that removed by the surgeon; and the limb gradually assumes its normal form and usefulness. Here, it would seem, we have clear advance in the treatment of disease; and I believe it is a real and great progress. Still we must look at it carefully from different points of view, so as to make sure of this, and avoid injury to the method from its being practised indiscriminately, or in improper cases, or during unfavourable conditions. We must remember that, in what we call acute necrosis, the loss of vitality seldom extends to the whole thickness of any great length of the bone; that, whilst the periosteal sources of nutrition may be largely or entirely cut off, the vascular supply and nutrition of the medullary canal and the ossific centres may not, and rarely are so to the same extent; and hence we can never be sure for some time how much of the affected bone may really perish, whether there may be a large portion to separate ultimately, or merely superficial exfoliations; or, as I have known, the whole surface of a long bone like the tibia may be exposed bare and white, and yet granulate and heal without a vestige of exfoliation occurring.

But, whilst I think it right that these things should be kept in mind, lest we interfere ultroneously and remove texture which natural processes would have saved, on the other hand, looking at the matter practically, when we see a patient suffering from hectic or occasional hemorrhage from ulceration of vessels near the diseased bone, and when we consider how long he must be exposed to such sources of debility before the dead bone separates, and the risk of the implication of neighbouring joints occurring and necessitating amputation, I am shut up to the conclusion that resection and removal of the affected bone must be often indicated; and that, if the cases for its performance be judiciously selected, and the operation be properly effected, this method will be found to be a most valuable addition to our resources.

The important question, no doubt, arises, How far can we trust to the reproduction of new or substitute bone from the periosteum, when the whole thickness and nearly the whole length of a long bone like the tibia has been removed by operation? And this question not unnaturally suggests itself, because we know from experience that under the expectant plan, when large and long sequestra were removed, the thickness of the shaft was never renewed to its full extent, although under that method we had both bone and periosteum to furnish new material. Here, for example, is a specimen, showing a large sequestrum removed when loosened by Nature, and a cast of the leg showing the appearance of the limb after the cure was completed. During last winter, Dr. MacDougall of Galashiels, now of Carlisle, exhibited a child to the Medico-Chirurgical Society of Edinburgh, in whom he had resected the tibia in a case of acute necrosis, and the thorough reproduction was well seen, and the use of the limb was perfect. In April last I operated on a similar case, and resected the shaft of the tibia close to the epiphysis at each end, after separating the periosteum. Here is the portion removed; and as the case is still in hospital, the members of the Association can judge of the probable result, so that I think we may trust to the periosteum for entire reproduction of the part removed.

To these and similar successful cases it may be objected that in cases of compound fractures, when the broken bone protruded, divested of periosteum, resection of the denuded bone was and is frequently practised; but experience has shown in such cases that, when the portion of bone so removed is large, reunion is almost never perfect; the ends of

bone are atrophied and joined together by a tough fibrous material; or, in the case where there are two bones, as in the leg and forearm, the ends of the resected bone approximate and unite with the other bone. A little consideration, however, will show that there is really no parity between such cases and resection for acute necrosis, because in the case of compound fracture the periosteum is not merely separated, but is generally so torn and bruised that its vitality is destroyed, or so impaired that its reproductive powers are rendered very imperfect: whereas in necrosis its vascularity is increased, the membrane thick and flesh-like, and it almost invariably carries with it small nuclear portions of bone-tissue.

Passing to the consideration of the *Surgery of the Articulations*, a wide field opens before me, but I must limit myself to one or two points. In regard to excision of joints, now so firmly established as a conservative measure, and so obviously an advance in the right direction, I shall not enter on it here; but I cannot leave this department of operative surgery without directing attention to a method of excision of the condyloid end of the humerus in cases of ankylosis of the elbow resulting from injury, proposed by my distinguished hospital colleague Dr. Watson. It consists essentially in resecting and removing the condyloid end of the humerus without cutting the attachment of the triceps to the olecranon, or that of the brachialis anticus to the coronoid process—in fact, without removing any part of the articular surfaces of the ulna or radius. By this method the natural movements of the elbow are preserved, and the tendency to recurrence of the ankylosis is prevented. (Paper in *Edinburgh Medical Journal*, 1873.)

Dislocations.—The manual method of reducing dislocations of the hip has been revived and used with great success; so much so, that the reduction of these luxations, which formerly entailed much trouble and the expenditure of great force, can now be effected in recent cases as if by magic. I have said that the use of the rotatory or circumduction method has been revived: perhaps I should rather have said revived as a general practice, for, in truth, it has never really been altogether abandoned. We generally hear it spoken of as the American method, and undoubtedly it is to the writings of Drs. Reid and Bigelow of the United States that we owe the more general use of the practice in this country; but it is not a little curious that it has been so little known or used, seeing that it is mentioned and described in some of the principal French works on surgery—not old black letter, but modern books, in the possession of most of us. Thus in Nélaton's *Pathologie Chirurgicale*, published in 1847-48, there is the following statement in reference to dislocations of the hip. "In 1835, M. Deprés made known a method which cannot be too highly recommended on account of its simplicity and the real services which it has rendered in certain difficult cases. . . . This method consists in flexing the leg on the thigh, the thigh on the pelvis, to exaggerate even the movement of flexion and adduction of the limb, then to exercise with it a gentle movement of rotation outwards, whilst at the same time it is abducted." This method, says Nélaton, is described by Pouteau in his *Mélanges de Chirurgie*. M. Chassaignac, in the second volume of his *Opérations Chirurgicales*, 1862, speaks of this method of reducing dislocations of the hip, and quotes the text of Pouteau as follows. "Surgeon-Major Maison Neuve, of the Regiment of Maugiron, a man of great merit, and trustworthy, assures me that he has reduced such luxations without the assistance of any extension. He first flexes the thigh at a right angle with the body; he then executes with the thigh a movement of rotation, which makes it approach the belly as nearly as possible, then carries it out towards the haunch, and returns it immediately by drawing it down towards the sound thigh." Pouteau adds that this method was known to the ancients, and that it is mentioned by Hippocrates and Paulus Egineta. The diagram to which I point is an enlarged copy of an illustration from a French work on Bandaging and Surgical Appliances, by Dr. Goffrés, published at Paris in 1859, and shows the surgeon in the act of using the manual method of Deprés. For this I am indebted to my friend Dr. Paterson, formerly of Bahia. M. Chassaignac enters very fully on the principle of the method; and there is a curious sort of coincidence in terms between his use of the letter Y, to assist his description, and the use made of the same letter by Dr. Bigelow, to mean a totally different thing. Dr. Bigelow speaks of the Y ligament as playing an important part in the rotatory method, describing the ilio-femoral ligament under that name, on account of the divergence of its fibres at their attachment to the femur. Chassaignac describes the leg and thigh, when bent, as representing a pair of compasses opened at a right angle, the lower or horizontal branch represented by the leg, the upper or perpendicular branch by the thigh—this latter divided at its upper extremity into two parts, like the letter Y, one part being fixed, represented by the ilio-femoral ligament, the other movable, represented by the head and neck of the femur; and then he proceeds to demonstrate how, by using the leg as the arm of a bent lever, whilst the ligament,

being fixed, forms a pivot, the movable part—the head of the femur—is forced or directed to the acetabulum. Here we have an example of advance by the attention of the profession being directed to a method which had been practised from an early period, and which has never been altogether obsolete.

Bloodless Surgery.—It is in connection with operations for necrosis and the excisions of bones and joints that what is termed "Esmarch's bloodless method" of operating is seen to the greatest advantage, and these subjects suggest to me the consideration of that and other methods of "bloodless surgery". The bloodless methods may be divided into two kinds; first, those that have for their object the prevention of loss of blood during the progress of operation; and, second, those by which the surgeon is enabled to divide textures by means of apparatus which, by the very mode of division, prevent the escape of blood at the time, and also act as permanent hæmostatics.

The method of Esmarch, though another example of a great improvement in carrying out a principle, can only be looked upon as a revival, not as new. The principle was clearly enunciated by the late Sir Charles Bell; and the mode of carrying it out by bandaging the limb from below, and then rapidly screwing tight the tourniquet, is described when discussing the value of the tourniquet in amputations, in his *Great Operations of Surgery*. But it is not in amputation that the method is most useful or seen to most advantage; and hence it had generally fallen into disuse. The method of Esmarch, by using the India-rubber roller to expel the blood from the part of the limb to be operated on, and the strong India-rubber tubing to constrict the limb and act as compressor, effects the object in view perfectly, and hence enables us to see the parts on which we operate as in a dissection, and prevents all loss of blood during the operation. It is a most valuable assistance to us in such operations as those for necrosis and resections of bones and excisions of joints. In many cases of removal of large sequestra, or resections of the shaft of a bone especially, we can, by stuffing the wound with oiled lint, and applying a compress and bandaging the limb before removing the circular compressor, render the operation absolutely bloodless. In excision of joints where we require to tie arteries after the operation, I prefer the tourniquet to the India-rubber as a circular compressor. It is equally effective in restraining bleeding; and, by loosening or tightening the screw, the vessels can be secured with less loss of blood than when the India-rubber is employed. Indeed, in many amputations, whilst the incisions are completed bloodlessly by Esmarch's method, the sudden and general oozing from the cut surfaces which follows relaxation of the India-rubber entails more loss of blood eventually than when the tourniquet alone is used. I have repeatedly amputated at the thigh and at the hip-joint, using only the tourniquet or manual compression, with the loss of not more than three or four ounces of blood; and in one case of primary amputation of the hip in the country by candlelight, in which I had the blood carefully collected from the tiled floor, as there seemed to be a large clot, I found, to my astonishment, that it barely amounted to half a teacupful. In many cases of amputation, owing to the septic state of the tissues, or the malignant nature of the disease for which we are operating, I consider it inadvisable to repress the blood and other fluids, such as unhealthy pus or cancer-juices, into the parts above. In such cases, I draw a band of India-rubber tubing, pressing on the limb from above downwards, and tighten it immediately above the part to be removed. This, of course, saves no blood to the patient; but it renders the operation bloodless in another sense, and is especially useful in private practice, as avoiding soiling of the floor or furniture. In cases of excisions of joints, where the parts are loaded with pus, I constrict above and below the point to be operated on, and thus secure a nearly bloodless operation without risk of repressing the unhealthy fluids into the textures higher up. I cannot see the advantage of the Esmarch method in such operations as ligation of the femoral artery. I have had frequent occasion to perform operations of that kind, and also of seeing them performed by others; but it is rare to see any bleeding; and I think it better that the artery and vein should be left in their natural condition, that the operator may see and deal with them. An empty and collapsed vein would, I think, run greater risk of being injured than when seen full, its natural relation to the artery. I make these exceptions because I think that this form of bloodless surgery is liable to suffer from its indiscriminate use, and from over-laudation; but I have already said that I consider it a most valuable aid in proper cases, and it seems as if it were revived now with special relation to the progress of conservative surgery.

The bloodless surgery comprised under the second head consists, as I indicated, in division of parts by means of the various apparatus which prevent bleeding during the process, and permanently. It includes cauterising agents, whether red-hot knives or galvano-cauterics, and crushing divisors, such as the different kinds of *Aratars*. In regard to

the use of the cautery to stop hæmorrhage, I need hardly say we cannot claim that as new, or as a discovery of the present time. Indeed, I referred to this as one cause that might lead an observer to suppose that we were revolving back to primitive surgery. Before the general use of the ligature, no small ingenuity was used to invent instruments which would sear and arrest bleeding as they cut the textures; and some surgeons, when they ventured to cut through living textures, used the summary method of applying hot pitch or tar over the face of the stump to arrest the bleeding. I am old enough to recollect seeing the result of an amputation of the thigh which had been thus treated. The man had been injured on board a whaling vessel; and, for lack of other aid, the ship's carpenter amputated. Whether from his acquaintance with ancient surgical authorities, or simply acting on the rules of his craft, he "paid" the stump with hot pitch. The man recovered well, possibly owing to the antiseptic action of the pitch, and subsequently eked out his means of living by exhibiting himself at the surgical classes as an ancient mariner and a connecting link with antique surgery. Although heated knives are again being used, I cannot and I do not think the profession will hail their revival as a mark of progress in surgery. But, in regard to the use of the galvano-cautery for the purpose of dividing very vascular textures, or for removing tumours in situations where we cannot reach and tie divided vessels, or where there is danger from the blood entering the air-passages during an operation, as in some operations on the month, I think there can be but one opinion of the value of such means, and also that modern surgery has made advances, and I trust is destined to make farther advances in this direction. The chief difficulties to be overcome are in the cumbrous nature of the apparatus and the difficulty of getting a galvanic power in moderate compass to heat a platinum wire of sufficient thickness. In the surgical manipulations, habit of using the wire requires to be attained to keep it in constant and close contact with the tissue to be divided, because, at any point where the wire does not touch and give off its heat to the tissue, it fuses and gives way under the action of the electric current. Those of us who have been accustomed to use the knife will find it advantageous to acquire the mode of manipulation necessary for proper use of the wire. From the very few opportunities I have had of seeing or using the galvano-cautery, I am hardly warranted in expressing an opinion; but I think we require to modify the heat so as to divide the parts more slowly, because a large vessel cut across rapidly by a wire at a white heat will bleed at once as if cut by a knife. The *érasneur* is another means by which bloodless severance of textures can be effected, and it has even been employed for the amputation of limbs. Its real value, like that of the galvano-cautery, lies in its application to operations where the parts to be divided are so situated that we cannot tie the vessels or command bleeding during section of the parts. Its utility in such cases, more especially in operations on the uterus and tongue, has been longer and more largely tested than galvanic cauterisation, and, as compared with our present means of applying the last-named method, it is more simple and more easily managed; but it seems to me that, from the nature of the wound left after the use of the *érasneur*, it is more liable to unhealthy action than that resulting from the cautery; and, if that method could be rendered more manageable, I believe it would gradually supersede the *érasneur*. Meanwhile, however, the *érasneur* is an instrument of great value for the class of cases to which I have alluded, and forms another addition to the resources of our art.

Closely allied to the galvano-cautery—a modification of it, in fact—is galvano-puncture or electrolysis. This agency has been used in the treatment of aneurisms beyond the reach of ordinary surgical operations; and, although from the nature of these cases it has not effected any positive cures, it has, in the hands of my hospital colleague Dr. John Duncan, and others, delayed a fatal issue in cases where external hæmorrhage was threatened, and shown its power as producing coagulation of the blood in the sac.*

It is, however, to the uses of galvano-puncture or electrolysis in certain forms of vascular erectile tumours that I wish more especially to direct your attention, as a most valuable addition to our means of treating these often formidable growths. I do not speak of it as a general method, you will observe; for there are many forms of nævi and erectile tumours, in truth a majority of that class of diseases, in which other methods are more rapidly effective.

Galvano-puncture is specially indicated in those cases in which the erectile tumour is deep-seated and covered by healthy undiscoloured skin. Until a few years ago, our interference in such cases was limited to dissecting off and reflecting the superimposed textures, so as to expose the tumour without touching it with the knife, and then strangulating it by strong ligatures, and, when the growth had sloughed and

separated, replacing the flaps of skin; or by ligature of large arterial trunks indirectly connected with the growth, as, for example, ligature of the carotid artery for orbital erectile growths. The former method was attended with grave inconveniences and dangers, and the latter, besides entailing risk, was most uncertain in its effects, as you can readily understand from the nature of the disease. More recently, injections with the perchloride of iron took the place of these methods, and, in a great number of cases, answered very well, but in others a very considerable amount of sloughing took place before the rest of the tumour had been consolidated, and in such cases severe hæmorrhage occurred, and the life of the patient was endangered. In some cases also the injections of perchloride were attended with a rapidly fatal issue, apparently from thrombosis. I must, however, say that I never saw such a result, though I have long used and continue to use the perchloride of iron injections, and I can only attribute such accidents to the neglect of tearing up the texture of the tumour before injecting the perchloride.

Contrast of the results of different methods is perhaps the most effectual way of impressing their comparative advantages, and shows what advance our science in making; let me, therefore, bring under your notice the following cases from my own practice. An infant, six weeks old, was sent to my care on account of a deep-seated pulsating erectile tumour, occupying the palm of the hand, and extending up the wrist. The tumour had been growing rapidly, and at one point the skin was thin and discoloured. I used injection of perchloride of iron, and part consolidated. Again, it was used, and the consolidation was followed by inflammation and the separation of a small central slough. From the ulcerated surface bleeding took place, and, though arrested by local application of the perchloride, it returned from time to time; and as the child's life was thus endangered, and the growth seemed rather to increase than diminish, I was forced to amputate in the forearm, when the infant was eight weeks old. She made a very rapid recovery, but with the loss of a hand. I show you here the cast of the hand of an infant affected with deep-seated pulsating erectile tumour very similar to the former. In this case I applied electrolysis during three months, while the child was under my care in hospital, and by several applications of the battery the growth began to consolidate and contract, whilst, except at the time of an application, the child suffered no irritation. As it was inconvenient for the mother to remain in hospital, I asked Dr. Connel, of Peebles, who had sent the case to me, to conduct the remainder of the treatment. As the child's parents lived at some distance from Peebles, the applications of electrolysis could only be made at long and irregular intervals. Here is a cast of the hand when the cure was completed; and, when you contrast it with this preparation of the amputated hand of my former case, you will, I think, agree with me that the result is a triumphant vindication of the value of electrolysis in such cases. I have used it also in other cases with advantage, especially in an enormous erectile nævus of the face of a girl. It is of importance that it should not be applied indiscriminately to all cases of nævus or erectile tumours. I think its use should be restricted to cases where the erectile growth is covered to some depth by healthy skin. The needles are coated to a certain length with a nonconducting material, which protects the healthy superimposed texture, whilst the uncovered points passed into the growth act on it at different parts. If needles be applied to a superficial erectile spot, they cauterise and leave more mark than other methods, such as application of nitric acid, perchloride of iron, or iodine. Thus, in treating the large erectile nævus of the face, the electrolysis was only used to the deep-seated portions, while the superficial discoloured marks were treated by applications of perchloride, iodine, etc.

These references to bloodless methods of treating surgical cases remind me that for some time back the medical profession has been trying like Lady Macbeth to wash its hand from all stain of blood. "Ecclesia abhorret e sanguine" was the decree of the Council of Tours, with how much truth let history say. "Medicina abhorret e sanguine" is apparently the watchword of expectant medicine; and so, except in the hands of a few hardened heterodox individuals, venesection has become almost obsolete. What has led to this great change? May I put the question to the seniors present, What led you to abandon general depletion? Was it from the dire effects you had seen of its use? Was it change of type in disease? Or could it be change of fashion?

It has, I know, been fashionable for some time to decry the practice of general blood-letting, and hence any views to the contrary will probably be considered very heterodox. I do not feel inclined, however, to withhold an opinion which my own experience in the past satisfies me is practically correct. The opponents to general depletion denounce the practice as being unscientific, and urge that it is so (1), because it is not in accordance with pathology, and (2) because it diminishes the vital powers of the patient, and thus interferes with Nature's efforts

* I find that Dr. Duncan has had successful results in large cirroid aneurisms.

to overcome disease and restore healthy action. They ask us: "Can depletion remove the inflammatory infiltration which has taken place, and which constitutes the most formidable part of the diseased action?" Most decidedly not—and no one would suppose for a moment that it could do so directly; but, by relieving the preceding phenomena of exciting action and congestion, it will tend to prevent further infiltration, organic change, and functional disorder, and thus leave less mischief to repair. I hold that general depletion is quite in accordance with the pathology of inflammation, so long as we view that action in its progress as a whole, and do not limit our ideas to one part or one result of the action. The second objection is in great part pure assertion, and what grain of truth there is in it is drawn from an experience in treating a class of patients whose previous health or habits, or both, render them unfit to bear even moderate depletion, or patients who have been admitted into the hospital when the inflammation (say pneumonia) was far advanced and extensive. Surely, the employment of venesection in improper cases is no good argument against its judicious use. As to the exaggerated pictures sometimes drawn of the slow and imperfect recoveries, the permanent debility, and the wasted and anæmic forms of the victims of blood-letting, I can only in charity suppose that they are sketched by those who have had no opportunity of seeing the practice they condemn, and who, therefore, draw largely on their imaginations to describe what they suppose should be the results. Although I have seen a good deal of the use, and also, I have no hesitation in saying, the abuse of the lancet, when venesection was practised indiscriminately, and when it was customary for people to be bled periodically as a preventive to disease, I cannot recall any of these fearful results; but I can remember many a case where relief from suffering was afforded and cure of acute disease effected by the prompt and judicious use of blood-letting. It should not be forgotten that the continuance of the intensely febrile state, which is symptomatic of the local inflammation, is a far greater source of exhaustion of the vital powers than the timely abstraction of a few ounces of blood.

From the subject of bloodless surgery, I might very naturally pass to the subject of arterial lesions and aneurisms, and their treatment in the present day as compared with the past. The subject is undoubtedly inviting, and one of the most important in surgery; but there are two reasons why I think it advisable merely to touch on it: first, because there has been so much attention directed to it of late by special series of lectures; and secondly, it is one of my "hobbies", and that kind of equitation does not answer when time is limited. I may, however, briefly state that, though I have successfully employed both flexion and compression in the treatment of true aneurism, and although, as I have pointed out elsewhere, I hold these methods generally advisable in the early stage of aneurism, considered even as a preparation for ligature, and as in many cases effecting a cure. I do not believe either of them will take the place of ligature. The vessels in which it would be most desirable to avoid deligation, viz., the great arteries at the root of the neck, are just those in which efficient compression is not easily secured, and flexion is out of the question; whilst in the arteries of the extremities, my own experience has not impressed me with any great risk if the operation for ligature be carefully performed.

There is one form of aneurism, to the treatment of which I drew attention some years ago.

Traumatic Varicose Aneurism of the Femoral Artery.—In all the cases which I could collate, and they were few, I found the results had been anything but satisfactory. In cases where the direct method had been adopted of opening the sac and tying the artery above and below the wounded point, the inevitable interference with the wounded femoral vein led to its obstruction, and gangrene followed; whilst in cases where the femoral had been tied on the Hunterian method, the operation failed to effect a cure. In the case which led me to consider the subject, I first tried compression and flexion for some time, but without the slightest advantage, and then I decided to tie the femoral above and below the false sac without interfering with or opening the sac, thus avoiding all interference with the wounded vein, and at the same time preventing retrograde circulation into the sac; and I carried my plan into execution successfully. I see that Mr. Holmes, in his lectures before the College of Surgeons of England, whilst he considers my method the best if operation is to be performed, speaks hopefully of compression as likely to obviate the necessity for operation. But, in the case which I published, compression and flexion combined were carefully and persistently carried out for some time without the slightest effect; and when we consider the communication between the false sac and the artery and vein, and consequently the want of limitation to favour coagulation, I cannot speak so hopefully of compression proving successful. If Mr. Holmes considers the operation I adopted somewhat difficult in execution, what would he say to the latest method of treatment published, where the

surgeon, after tying the femoral in Scarpa's triangle without effect, cut out bodily the false sac and the vessels communicating with it as a last resource?

Tumours.—The subject of tumours in the present day has two aspects—a pathological one, purely scientific; the other a clinical or practical one. Doubtless a time will come when the labours of pure pathologists in investigating the anatomical structure of tumours will have more evident relation to practice than now; for as yet the bearings of pathological research, and the various classification of tumours founded on it in regard to practice, are not marked. It is evident, I think, that, for the practical surgeon, any classification which does not proceed upon a study of the clinical or vital manifestations of the growth in its origin or during its progress can be of little service. However valuable a knowledge of the situation and the growth may be, that can only be ascertained after its removal; whereas the surgeon is naturally desirous of facts and observations which will guide him in the diagnosis and treatment of the tumour whilst it still forms a part of the organism. The attempts which have been made to apply the knowledge of the structure of tumours to diagnosis, by examination of small portions of their solid or fluid constituents removed prior to operation, are very imperfect, and might often mislead. It has happened to me in several instances that nothing has been found but blood-discs entire or broken down, or a little granular or amorphous matter, when the structure of the tumour after removal exhibited most marked characters of malignancy; so that practically I have little faith in such explorations as an aid to diagnosis. On the other hand, experience derived from the study of the vital manifestations and tendencies which characterise growths as divided into the "simple and malignant", enables the surgeon from experience to judge of the propriety of interfering or abstaining from operation in certain cases. Thus, if, from the history and examination of the case, he satisfies himself that the growth belongs to the simple class, he knows that, from the limitation of such tumours, he can be sure of effecting its complete removal, although its anatomical relations may be intricate and important; whilst, from the absence of constitutional cachexia, the prognosis of the result is favourable. Until a comparatively recent period, it used to be laid down as an axiom, that removal of tumours of the neck situated under the sterno-mastoid muscle should not be attempted; and we were directed to the failure in result when such attempts had been made; complete removal of the growths having been found impossible, and their rapid reproduction being the consequence. In a case of an enormous deep-seated tumour of the neck which was sent to my care from Lancashire twelve years ago, the objections to which I have alluded were pressed against interference by the late Professor Syme, and I was referred to cases in which John Bell and Mr. Liston had been forced to leave portions of the tumours owing to their connections; but I had examined into these cases, and felt no doubt, from their history, that they were both of malignant character, and, in fact, that even in these cases the tumours were all but removed. I pointed this out as an encouragement for operation where the tumour was of simple character, and therefore limited in its deep relations; and, relying on the character of the tumour, I decided to remove it, and did so successfully. I suppose no surgeon would now hesitate to operate in such cases; but interference with deep-seated malignant tumours is a very different matter, and, I think, should be avoided. There is another feature in the characteristics of tumours in which I have great faith; viz., that a growth originally of simple character, as evidenced by its originally slow development, consistence, etc., however much it may at a later stage degenerate locally and manifest many of the symptoms of malignancy, never does become truly malignant, constituting a diathesis, so to speak, as in cancer or encephaloid growths; and that, therefore, we may remove such tumours with every prospect of success under circumstances where it would be unwarrantable to interfere were the growth truly malignant. In the huge osteo-fibroma of the bones of the forearm which I removed nearly thirty years ago, you have an instance of what I state. It had at first grown slowly, and without bad effect on the health; but latterly, from the pressure caused by its bulk and consistence, the soft parts had ulcerated; local applications had increased irritation, until at last it assumed a fungating surface, wasting the patient by the pain and discharge. When I saw her, she was considered a hopeless case. She was pale; the skin was of a yellowish tinge; and she was so anæmic, that she appeared cachectic; and there were enlarged glands in the axilla and above the clavicle. But, trusting to the original character of the growth, I amputated the arm at once, and in less than three weeks she was able to be out; all bad symptoms disappeared, and for many years she continued to enjoy the most perfect health, and, so far as I know, is still alive and well. I point to these cases as examples of the value to the surgeon of the classification of tumours founded on the study of their clinical history and vital manifesta-

tions; but at the same time I am far from undervaluing the study of the structural anatomy and development of tumours in its proper place.

It must be allowed that the introduction of anæsthetics has given facilities for surgeons performing operations for the removal of tumours which could hardly have been attempted formerly without great risk, owing to the movements of the patient. My colleague Dr. Watson has now on several occasions excised the entire thyroid body successfully, an operation the feasibility of which had often been discussed formerly, but never accomplished until the present time, so far as I am aware. The success which now attends the performance of ovariectomy is, I believe, also greatly due to the leisurely and careful manner in which the steps of the operation can be accomplished, together with the advances which have been made in the accuracy of ovarian diagnosis. The success which has attended the operations of modern ovariologists must excite admiration and congratulation on the relief afforded to suffering; but, when we contrast the advantages under which the operation is now performed with the conditions under which it was first performed in this city by John Lizars, we must be struck with the self-reliance and undaunted courage with which that bold surgeon carried out what was then a very formidable operation, in the face of opposition from the principal medical authorities of the time; and I think too little credit has been given him in regard to the work he did and the success he obtained under great disadvantages.

Air-Passages.—In the important department of the injuries and diseases of the air-passages, great advances have been made both in regard to diagnosis and to treatment. The use of the laryngoscope in cases of chronic or subacute disease of the larynx, and for enabling us to ascertain how far the symptoms depend on organic changes, or merely on paralysis or spasm affecting the vocal cords from diseased innervation, or for discovering the position of small foreign bodies entangled in the larynx, or of intralaryngeal growths, is an invaluable accession to diagnosis, and in determining the question of operation and plan of procedure in different circumstances.

The operation of tracheotomy has also been extended to a class of cases in which it was formerly considered unsuitable; and new operations, such as the partial or even complete excision of the larynx, have been successfully performed; and in one case by Professor Billroth, an artificial substitute was adopted, which enabled the patient to speak and read intelligibly.

Having had a very considerable experience in operations on the air-passages for injury or disease, I desire briefly to draw attention to some practical points. First, as regards injuries. There are some conditions not sufficiently insisted on in surgical works as to their dangers, or the practice to be adopted, where action requires to be prompt. Thus the danger from emphysema of the loose connective tissue of the neck is seldom adverted to; and yet I have seen a patient all but suffocated from this cause from a small oblique wound of the larynx inflicted with a penknife. In that case, I had to perform laryngotomy, and was obliged to make numerous incisions to afford relief; when a simple enlargement of the wound, in the first instance, would have allowed the air to escape externally. Again, in tracheotomy for removal of foreign bodies, it is generally considered unnecessary to use a tube after the foreign body has been expelled, but merely to allow the incision to close at once. The consequence is that a good deal of trouble often results, for the wounds in the trachea and the superimposed parts do not correspond, and air and mucus escape into the cellular tissue, sometimes giving rise to considerable emphysematous swelling of the neck, and often leading to deep-seated irritation of the wound. In my own operations after removal of foreign bodies, I insert a tracheotomy tube, and retain it until the surface of the wound is glazed by the effusion of lymph; and then approximate the margins of the wound by strips of plaster, so as to avoid all risk of confinement of air or mucus in the tissues in the vicinity of the trachea. Another point of importance is the question of exhibiting anæsthetics in operations for removal of foreign bodies. Many years ago, I drew attention to this, and pointed out that when the foreign body was loose in the trachea or bronchus, the exhibition of anæsthetics interfered with the force of the expulsive powers which usually eject the foreign substance; and, as happened in one of my own cases, the foreign body may be carried back by the incoming current of air, occlude the bronchus, and cause collapse of the corresponding lung. In other cases, as when the body is impacted in the bronchus or larynx, anæsthetics are most useful in enabling us to search for and remove the foreign substance. In doubtful cases, the rule should be to open the trachea without using anæsthetics; and, if the foreign body be not expelled by the natural forces, then to administer chloroform to enable us to deal with it effectually. When, as in the case I have alluded to, a foreign body, such as a plum-stone, is impacted, and fairly occludes the bronchus, being carried before the inspired air, it follows that, the lung beyond being col-

lapsed, there is no force behind to eject the substance. In such circumstances, it is well to avoid trying too much to displace it by means of bent probes or other instruments, unless the end of the instrument can be passed over and beyond the body, so as to tilt it out or allow air to pass to the lung beyond. Our continued efforts, besides exciting local irritability, are very likely to impact it more thoroughly; and I would therefore counsel the surgeon to abstain from useless efforts, and allow the patient to breathe by the sound lung, and wait the loosening of the foreign body by vital dilatation caused by its presence, when air will gradually pass beyond and expel it.

In hollow or tubular foreign bodies, the case is different; they can be easily removed if we take the proper method—one which I practised some thirteen years ago, in a case where this trachea-tube had slipped down and became impacted in the left bronchus. Instead of trying to open the forceps and seize the edges of the tube, I passed the forceps closed into the tube, and then, on expanding the blades and maintaining them expanded, the foreign body was withdrawn with the utmost facility.

The propriety of tracheotomy in cases of threatened asphyxia from œdema glottidis, arising from swallowing boiling fluid or inhaling the steam of boiling water, would seem so evident as affording the only chance for life, that we would scarcely expect any difference of opinion; and yet I find it is by some considered unwarrantable, because the average results of such cases show few recoveries. Now, in the first place, I doubt if we have statistics so extensive or accurate as to warrant such a conclusion; but allowing that the recoveries are few, we see that the want of success is mainly due to the fact that these injuries implicate other structures, such as the pharynx or œsophagus, or are complicated with the shock and other conditions of general scald. If, however, in such injuries, œdema of the parts about the glottis threaten asphyxia, it is evident that the patient has no chance of life, except by the operation; whilst no one will venture to deny that tracheotomy has, in many such cases, rescued the patient from impending death.

The value of tracheotomy in the acute and chronic affections of the larynx in adults, whether to afford relief from suffocative paroxysms or as a precautionary measure, is now so generally admitted that I need not occupy your time with that; but I desire to draw attention to two classes of cases in which this operation is sometimes performed, as affording temporary relief from suffocative paroxysms or impeded respiration. I mean (1) cases of aneurism or tumours pressing upon the laryngeal nerves, and causing spasm of the glottis; and (2) aneurismal tumours of the aorta or innominate impeding respiration by direct pressure on the trachea at the root of the neck. In the former class of cases, I consider that the operation is not only warrantable, but advisable, or even imperative, because it gives relief from impending suffocation, and also alleviates conditions which tend to increase the aneurism, or even to hasten its rupture; so that tracheotomy prolongs life with comfort to the patient. In the second class of cases (aneurismal tumours at the root of the neck, pressing directly on the trachea), I cannot see the principle on which the operation is recommended. In such cases, the tumour is lower down than where we can open the trachea; and if we use a tube long enough to pass beyond the aneurism, we are in great risk of rupturing the sac, which generally, in such cases, presses upon, and causes absorption of, the tracheal fibro-cartilages, and projects the mucous membrane. Indeed, as pathological specimens shew, the tracheal textures become incorporated, as it were, with the sac, and the aneurism generally thins and tends to ulcerate towards the trachea. Hence I cannot see how an opening in the trachea on the distal side of the impediment can relieve the breathing, whilst there is very evident risk of killing the patient by wounding the projecting and attenuated sac in opening the trachea, or rupturing it in trying to pass the trachea-tube beyond it. Here is a preparation from a case in which I made a very narrow escape from being involved in a most unpleasant predicament. I was asked to see a lady who had long suffered from bronchitis and asthmatic attacks, and in whom laryngeal symptoms seemed to indicate commencing œdema glottidis. As the medical gentleman informed me that the late Dr. Begbie had been seeing the patient, and as I understood that the laryngeal symptoms were not very urgent, I suggested that Dr. Begbie should be first asked to see the patient; and if he considered tracheotomy advisable, I would come and operate. I heard nothing farther until, meeting the medical attendant a day or two afterwards, I inquired about the case, and was informed that, after Dr. Begbie had examined the patient generally, he proceeded to examine the throat and mouth by gently depressing the tongue; this caused retching, followed by a fearful gush of arterial blood, which proved instantaneously fatal. If I had operated, the insertion of the tube could scarcely have failed to have ruptured the sac, and I leave you to conceive the situation. I think I have said enough to show that I am decidedly opposed to operation in cases of this latter class. But

should anyone be inclined to operate, I would advise the use of a large-sized, bulbous-pointed, soft gum catheter, with an enlarged opening, to pass beyond the tumour, instead of the metallic tube.

Although from an early period tracheotomy was occasionally resorted to in croup in children, it is only of comparatively recent date that it has been recognised as a warrantable operation in such cases. In this city and in Leith croupous affections used to be very common, and yet the operation of tracheotomy was so rare that I never saw it performed for croup when I was a student; indeed, so great was the prejudice against it, that I have been informed that in 1820 a medical gentleman of high standing in this city, who was anxious to afford a chance of relief to two of his children affected by croup, could not prevail on any of the principal surgeons to perform tracheotomy. At his urgent request, Dr. Brice, a gentleman in general practice, operated on one of the children, without ultimate success, as both the children died. This strong prejudice against operations in croup arose, I think, from somewhat erroneous views regarding its pathology. In *post mortem* examinations, the false membranes extending from the larynx into the trachea and bronchi, and often found in the form of complete tubular casts—a condition so different from the laryngitis of adults—led to the idea that the trachea was affected in the first instance, or at least simultaneously with the larynx, and the disease was named "cynanche trachealis", in contradistinction to laryngitis. Hence most physicians and surgeons considered it improper to operate when the disease, as they thought, was situated at and beyond the part where the aperture in the trachea could be effected. From what I have noticed of the progressive symptoms of croup, and seen of the state of the diseased parts in cases when children died in the early stage, and especially from the immediate relief from impending suffocation afforded by tracheotomy even in cases which subsequently proved fatal by extension of the false membrane, I feel satisfied that the disease always commences in the larynx, and only extends downwards as it progresses; and hence I dismiss the objection that the disease is from the first situated too low down for tracheotomy to afford relief. The principal objection to operating in croup is undoubtedly the tendency of the disease to spread downwards after the operation. We owe it to our continental brethren, especially to Trousseau, that tracheotomy in croup has now become an established operation. I must confess that from early teaching I was strongly prejudiced against the practice; but, fortunately for me, it happened that a child was brought to me in the agonies of suffocation, so that I could not but try to relieve it. The relief was immediate and the result successful, and thus I could not deny the like chance to others. I have now performed tracheotomy for simple croup and diphtheritic croup one hundred and three times, and saved thirty-four out of that number, or an average of about one life saved in three cases; and it must be remembered that at first I only operated as a last resort, and even yet I do not see my way to operate quite so early as some French surgeons seem to do. I think, however, that there should be no delay when the character of the breathing and the contracted state of the thoracic parietes show that the lungs are not being distended with air. By operating early, we avoid the risk of œdema or congestion of the lungs, and of the effects of non-oxygenised blood circulating in the brain.

I think it right, however, to warn my younger brethren that it will require some effort to bear up against discouraging results. I know of no class of cases in which the experience is so painful: an average gives little idea of it. You may have five or six cases in succession, all proving fatal, before you meet with one redeeming success; but then you have the temporary relief almost invariably afforded to the little sufferer; the resuscitations in some cases apparently dead; and, if you persevere, the average of success will come. Above all, we must recollect that, however disagreeable or unpleasant the operation may be to ourselves, we are bound to lose sight of that, and give the patient the only chance for life.

In speaking of operations in croup, I have used the terms simple and diphtheritic croup; and I have done so advisedly, because, whilst the average results of my operations have been as good in the one disease as in the other, I consider them as essentially different diseases, and I do not believe that an extended experience would give the same amount of success in diphtheritic as in simple croup. It has been with no small amazement I have read some of the views recently propagated, that croup and diphtheritic croup are identical. I can hardly conceive two diseases more different, whether we consider them in their causation, symptoms, or sequelæ. In one feature, doubtless, there is similarity, because when in diphtheria the air-passages become affected, the presence of the membrane exuded necessarily gives rise to the same physical symptoms as to sound of voice, breathing, and asphyxiating paroxysms, as the false membrane in simple croup does. But in diphtheria, the exudations in the larynx or elsewhere are the local expres-

sion of a special blood-disease, which may and often does destroy life without affecting the air-passages at all, whereas in simple croup the false membrane is the result of a local inflammation. The causes or circumstances in which the two diseases originate are, according to my experience, very different. Ordinary croup almost invariably arises from exposure to cold, or occasionally from some source of local irritation, leading directly to inflammation of the mouth, as dentition. It is most frequent during cold moist weather, and specially during the prevalence of easterly or north-easterly winds. The late Professor Alison used to say that, according to his observation amongst the poorer classes, the affection most frequently occurred between Saturday night and Monday morning; and he attributed this to the custom of washing the floors of the rooms on the Saturday night after the children were in bed. Diphtheria, on the other hand, prevails at all seasons and during all kinds of weather—sometimes as an epidemic, and then generally coincident with scarlet fever, but always more or less connected with, or influenced by, the effects of sewage-emanations or imperfect drainage. Hence we meet with it more frequently amongst the better classes and in houses with modern accommodations, such as fixed wash-basins and water-closet accommodation in immediate connection with nurseries or bedrooms.

Diphtheria is undoubtedly infectious both by direct contact of the sputa with a healthy mucous surface, as has been too often proved by members of our profession and by mothers, or by emanations from the affected person, as evidenced by the manner in which it spreads in a family. Simple croup, as I have been accustomed to see it, has no such contagious or infectious character. In dispensary practice, I have frequently seen a child affected with croup lying in a confined room amongst other children; but I never knew the disease to spread as diphtheria does. The peculiar nervous affection, the paralysis which follows diphtheria, has no counterpart in ordinary croup; nor, in cases of simple croup, were we accustomed to see the white leathery pellicle on the tonsils or fauces, though it was a very common disease in Edinburgh and its vicinity. I know that in France the fauces were always examined, and that false membranes or pellicles were considered symptomatic of croup; but that only leads me to believe that the disease in France was always of a different type—diphtheritic, in fact.

Certainly, in this country, croup, as we used to meet with it, is rarer, whilst diphtheritic croup is more frequent, and met with under different circumstances. From 1828 until about twenty-five years later, diphtheria seemed to have ceased, though simple croup was common; but, when nearly a generation had passed away, the disease was unhesitatingly recognised by some who had seen the previous epidemic; and I would refer you to the interesting paper on Diphtheria and its sequelæ by the late Dr. Begbie, in his work entitled *Contributions to Practical Medicine*, in corroboration of what I say. Considering the two diseases from a surgical point of view, even in successful cases, the constitutional conditions are marked in diphtheria by paralytic complications affecting the pharynx and larynx, by albuminuria and the asthenic state of the patient, and by the tendency of the wound to take on the diphtheritic action. But it is in the fatal cases that I think the distinction between the two forms of disease is most marked by the mode of death. In a case of simple croup, the result is decided within two or three days; indeed, generally in a shorter period, by the false membrane extending beyond the opening and tube. In diphtheria, I have on many occasions lost patients eighteen days or three weeks after the operation, and when the tube had been removed for some time, from asthenia and gradual failure of vital powers, or from paralysis of the pharynx, preventing swallowing, and so leading to imperfect nutrition; and, in other cases, I have known it prove fatal from sudden failure of the heart's action and syncope.

I drew attention to these differences many years ago in a paper read before the Edinburgh Medico-Chirurgical Society, and subsequently published; and, looking back on large experience in croup and diphtheritic croup, I think the distinctive characters are too marked to allow me to consider the diseases as identical, merely because they possess one feature in common.

The bold operation for complete removal of the larynx for malignant disease, successfully carried out by Professor Billroth, and the adaptation of an artificial substitute, so ingeniously constructed as to enable the patient to read and speak, has not, so far as I am aware, been yet practised in this country, though I understand other successful results have been obtained on the Continent. Looking at what has been done, may we not anticipate a time when operative skill and mechanical ingenuity proceeding *pari passu* may reduce the dangers of the operation to a minimum, and advance the powers of the artificial substitute to the maximum; and so enable an unfortunate ungifted with the power of song to get rid of his unmusical larynx, and suit himself with one, à la Mario or Lablache, according to his taste?

Treatment of Wounds and Surgical Dressings.—I could not properly conclude an address on Surgery in the present day, without some remarks on a subject which is attracting so much attention as the treatment of wounds and surgical dressings. The history of surgery contains no stranger chapter than the singular changes which from time to time have taken place in regard to the treatment of wounds. If we go back to the quasi-scientific age, when learned physicians laid down rules for dressing wounds *more canonico*, we find it was considered essential that every wound should undergo certain regular stages, "digestion, mundification, and incarnation", and no wound was allowed to heal by first intention. After amputation by the circular method, the cavity of the stump was stuffed with charpie soaked in aromatic spirits, or balsamic lotions, to prevent putrescence; and, in flap amputations, the section of the limb and the flap were dressed separately until granulation took place. Into every deep wound tents or leaden tubes were thrust, to keep open a track for discharge to escape. We are at first apt to wonder how or on what principle such treatment could have been adopted, and how, in only a somewhat modified form, it continued to hold its place until the time of Hunter, and, in some places, until a much more recent period. Yet its first beginnings were probably the result of observation of certain cases or forms of wound, and used exceptionally until, in course of time, from mere routine practice it became exaggerated and used in all cases.

Most practical surgeons will admit that, in wounds implicating textures possessing different degrees of vitality and physical conformation, as in amputations, it can hardly be expected that all the divided structures should heal with equal rapidity, or in the same way. Whilst the skin and softer textures generally do so speedily, the denser and less vitalised textures, such as bone and tendon, must undergo changes of slower character; and, situated as these are deeply in the wound, serous and bloody discharges are liable to collect around them, and, when the soft textures have united throughout by first intention, these bloody or serous discharges, being prevented from escaping, may, and often do, lead to deep-seated irritation and suppuration, and hence the revived use of drainage-tubing in many cases in the present day. Such considerations probably at first led to the use of tents and the other parts of the system; and the amount of discharge arising from the method of dressing seems only to have served as an argument for the necessity of keeping the wounds open to allow its escape. Then we must recollect that at that time surgeons acted merely as hands to the learned doctors, and to have ventured to have gone against the canonical authority was to be branded as a quack; and so the men who saw most of the dressing of wounds either kept silent, or became the itinerant operators to whom we owe no small debt for the simplification of dressing wounds and of operations.

Even when the simple method of healing wounds was introduced, it was seldom professed openly. It was always ornamented with a judicious touch of the mysterious or philosophical as it was called. Perhaps no truer enunciation of the principles of the treatment of wounds has ever been made than that of Paracelsus, who was one of those who ventured to oppose the orthodox physicians. "It is the nature of flesh," says he, "to possess in itself an innate balsam which heals the wounds. . . . Nature hath her own doctor in every limb; and wherefore every chirurgeon should know that it is not he, but nature who heals. What do wounds need? Nothing. . . . So the surgery of wounds is a mere defensive to prevent nature suffering from any accident from without, in order that she may proceed unchecked in her operations." Yet Paracelsus thought it necessary to invent a sympathetic powder to recommend this method to the public. Mr. John Bell, in his remarks on wounds, says, "We find no one surgeon in Europe who ventured to unite wounds directly by adhesion, without pretending to have learned from some eastern sage, or to have found out by deep studies in philosophy and alchemy, a sympathetic, or as they often called, a philosophical cure of wounds," and he is very severe on what he denounces as pretences of philosophy or science "To make sure of rousing at least one-half of the learned world to combat in their behalf." Perhaps he is too severe in denying them the title of philosophical. If "The proper study of mankind is man," then assuredly on that important study these men had founded their philosophy. They had noticed that patients in general feel rather flattered by something special being done, some little halo of mystery to brighten their sufferings, and give importance. They saw that for one "Good Hezekiah" who meekly submits to so simple an application as a "poultice of figs," they would meet with a dozen Naamans "ready to turn away in rage" if there were not "some great thing" done, or some fuss made about their cases; and so, whilst they treated the wounds simply or left them to nature, they amused and distracted the attention of their patient by enacting various little incantation scenes or mysteries. Some, like Paracelsus and Coldbatch, applied their sympathies locally to

the wound in the forms of vapour, powder, or constrictive plasters. Others still of higher philosophical type, like Sir Kenelm Digby, did not trouble themselves to see the patient, but merely some blood-stained rag from the wound, or the weapon that inflicted it. On these they bestowed all their care and attention, merely requiring that the patient should keep his wound "clean and cool". They had their failures like others, but their philosophical theory enabled them to account for them. Something had been overlooked in bringing them the bloody rag or weapon, and so "the finer spirits had escaped", and, of course, the failure was an accident, and no fault of the system. Were I the patient, I would decidedly prefer that the surgeon should bestow his attention on the blood-stained rag, leaving the wound "clean and cool", or swathe the knife which had inflicted the wound in any amount of cabalistically prepared bandages, rather than he should wrap up and overheat the wound with fold after fold of dressing and greasy cerecloth bandages, compressing the parts and confining the bloody and serous discharges. In a word, I would rather that his incantations were performed on something else than my wound. The truly philosophical views of the adhesive process, taught by John Hunter, gradually led to clearer notions as to the requirement of wounds and the principles on which their treatment should be conducted; and nowhere were these views more fully and intelligently carried out into practice than in this city, mainly through the influence of the writings of John Bell, and subsequently by the treatises of Liston and Syme on the treatment of incised wounds. The principles laid down were simple: thorough cleansing of the cut surfaces, waiting until all oozing had ceased and the surfaces glazed with lymph, before uniting them finally by sutures: cold applied for some hours to moderate excited action, then light dry dressing, and no interference with the wound except what was required to keep it clean. But, at the same time, great attention was paid to the general state of the patient. The results obtained were excellent, and, until recently, this has been the system in use here. But simplicity has sources of failure, for it is apt to lead to carelessness in dressing. We are again in a transition state in regard to the treatment of wounds. The antiseptic method (as it is termed) of my esteemed colleague, Professor Lister, is being pressed in some quarters to the exclusion of conditions which I think, at least equally, if not more, important in the treatment of wounds and operations. This is not the place, nor is there time, to discuss the theory as to production of putrescence by germs from without, or whether that condition may not also arise from within owing to certain states of the blood and general system; nor yet as to the comparative value of the different antiseptics at present contending for pre-eminence. But some of the statements advanced in favour of the antiseptic system so ignore the success obtained by simple dressing and treatment of wounds, or assert such an amount of infallibility as to the curative powers of the special method, as to require notice. When I read statements to the effect, "that the antiseptic method is to be regarded as one of the most important contributions to modern practice, inasmuch as it makes wounds heal by first intention, instead of going through the painful process of granulation and suppuration", I can only regard such statements as arising from want of experience in, or misrepresentation of, the simple method of treating wounds; for, assuredly healing by granulation is neither the object nor yet the general result of that treatment. Suppuration, I believe, is not unknown under the antiseptic method, whilst the average duration of treatment is certainly not lessened. But when I find a German professor and hospital surgeon stating that, after a year and a half's experience of the antiseptic treatment, he is able to guarantee with certainty a perfectly successful result to his operations, such assertion challenges closer examination, demands proof, and forces me to ask the question, How far, apart from other conditions, do different modes of dressing stand in the relation of cause to successful results? The answer to this important question must rest on sufficient data and carefully weighed statistics. It will not suffice to point to some brilliant results in individual cases, because all methods of treatment can produce that kind of proof; nor will it do to state that no deaths from pyæmia have occurred under the system. At one time, that term was never met with in the bills of mortality, and it is rapidly disappearing now. The statistics for proof must indicate the nature of the disease or injury for which the operation was performed, and the cause of death in fatal cases (for deaths still occur), not by a conventional term, but by giving the symptoms during life, and the organic lesions found after death.

With extensive statistics of this kind, we would be better able to judge of the comparative advantages of different systems of treatment. At present all is assertion or reference to special cases, or to the not very definite statistics of foreign hospitals, and it is not a little curious that we hear most of the success from abroad. I think sufficient time and scope have been given to the antiseptic system in this country to

enable those who use it to furnish statistics such as I have indicated, and thus to enable us to judge more dispassionately of its real merits. In comparing of late the results of my own hospital practice, I have been struck with the success which attended very simple treatment, and this leads me to question our progress in departing from such treatment for more complicated methods. Thus I find that, during a period of three years, out of sixty-three major amputations for disease, there were only three deaths; and of twenty-three cases of excision of joints, only two deaths, at a time when the treatment consisted in thoroughly cleansing the cut surface by pouring tepid water over it, and occasionally applying tincture of iodine alone, or diluted, on the flaps; whilst the dressing consisted merely in laying a veil of lint or thin muslin over the stump. Again, when preparing statistics of my amputations for my published lectures, I found evidence that certain conditions, such as the nature of the disease or injury necessitating the operation, had most important influence on the result; such influence, indeed, as I could not have supposed until the statistics brought it distinctly before me, and my later statistics corroborate my former; so that I cannot accept the statement that any method of dressing, however good, will ever enable us to guarantee success. Whilst I speak of the antiseptic system, meaning the special method, I need hardly say that all surgeons have for their object the avoidance of putrescence, though their views may differ as to the best way of attaining their object.

I cannot close without recommending to notice the advantages obtained in treating lacerated wounds and burns of the extremities by continuous immersion in the tepid bath. The avoidance of all meddling with the injured part, and of the agony of the patient caused by changing dressings, is thereby so completely obtained, that the method requires only to be fairly tried to shew its advantages. In the case of burns these advantages are most conspicuous, for the constant moisture keeps the cicatricial tissue pliable, and motion of the parts can be effected gradually, whilst the limb is immersed in the bath. The water may be rendered antiseptic by carbolic or boracic acid should that be considered desirable.

In conclusion, I think the retrospect I have taken shows that when true principles have been disregarded or lost sight of, they have ultimately had their value recognised, and, modified and improved, have become the advances of the present day; and so for the future I feel confident, that all that is true and good in any system will emerge with greater beauty and usefulness for having been purged of its dross by the tests of observation and candid criticism.

NORTHAMPTON.—In Mr. Haviland's report on the sanitary condition of the borough of Northampton, it is stated that during 1873 the death-rate was 20.3 per 1,000 living, whereas in 1872 it was 29.7, one of the highest death-rates in any of the large towns and cities of England and Wales. Last year, the death-rate was 21.5 per 1,000. The reduction in the mortality for this town from 25.1 during the decennial period 1861-70, to an average of 20.9 during the past two years, is a matter of considerable satisfaction, for it indicates a saving of as many as 172 lives *per annum* out of the total population; and it is to be hoped that the town council will do all in their power, by carrying on their sanitary work, to facilitate and render permanent this downward movement of the death-rate. In this direction, there is undoubtedly yet much to be done. Thus, whereas throughout England and Wales the infantile death-rate is 184 per 1,000 infants living, it is 223 in Northampton; and this mortality has, to a large extent, been brought about by diarrhoea and other diseases which are so far preventable that their prevalence may, to a considerable extent, be controlled by efficient sanitary administration. Although there is also room for improvement as regards the "fever" death-rate, it is satisfactory to note that, whereas it was formerly unduly high, it is now less than the average for the country generally; and this result Mr. Haviland in a large measure attributes to the general use of the Northampton Waterworks Company's water, which has taken the place of the contents of shallow wells, which for ages had become polluted by their close proximity, in a porous ironstone, to filthy receptacles of sewage of every description. The epidemic of scarlet fever which occurred in so many parts of our country last year caused a considerable mortality in Northampton; and, in urging upon the town council the provision of proper hospital accommodation for the isolation of those sick of this and other allied diseases, Mr. Haviland calls attention to the beneficial results which attended the construction of the small-pox hospital a few years ago. The lessons to be learnt from the death-rates prevailing in this town were rendered the more plain to the sanitary authority to whom this report was addressed by the use of Mr. Haviland's now well-known maps, in which the geographical distribution of the various diseases referred to was rendered easy of comprehension.

ADDRESS IN PHYSIOLOGY,

BY

WILLIAM RUTHERFORD, M.D., F.R.S.E.,

Professor of the Institutes of Medicine in the University of Edinburgh.

MR. PRESIDENT AND GENTLEMEN.—In the medical schools of Scotland physiology is still designated the Institutes of Medicine. This somewhat ancient title has the advantage of continually keeping before the minds of our students the fact, that physiology lies at the very foundation of scientific medicine. Much, indeed, has been done in Germany and elsewhere to detach physiology from medicine, and to develop it as a branch of purely natural science. Such a development, however, gives to physiology an aspect somewhat different from that which it wears when we regard it as the Institutes of Medicine; and, therefore, this title is useful to the teacher, inasmuch as it constantly reminds him that he is more especially to dwell on those facts of physiology which are of value to the practitioner of medicine.

Physiology is—I need scarcely remind you—an experimental science. Apart from those which are the result of artifice, experiments of great physiological significance are being continually wrought for us by accident and by disease. Physiology owes much in the past to those who, like you, are engaged in the daily study of these pathological experiments; for, was not the function of the spleen an enigma until the effect of one of its diseased conditions was observed? Has not psychology been revolutionised by a study of brain-disease? Did not Hughlings Jackson, with singular sagacity, apprehend from a study of disease, that convulsive movements may spring from the cortex of the brain; a fact which, as you know, has since been demonstrated by laboratory experiment? Was not the crossed action of the cerebrospinal axis revealed by the study of disease? and, indeed, was not the very foundation of nerve-physiology to a large extent based upon a study of nervous disease by Charles Bell? Assuredly we cannot afford to detach physiology from medicine; for, without a doubt, in the future as in the past, the study of those bodily conditions that are abnormal will throw much light on those that are normal.

But, on the other hand, need I remind you of the difficulties you encounter in the analysis of these experiments of disease, as you endeavour, for example, to determine the nature and the seat of some malady—say of the brain; the cause of a dropsy; the indication of some change in temperature, in the state of the pulse, the respiration, or some secretion; and, need I aver that, in this difficult task of pathological analysis, your labours grow less as physiology advances; and, if you look around you, is it not evident that those whose knowledge of physiology is the most profound, are precisely those who are most able to conduct this analysis with skill and with success.

At the present time, there is reason for some feeling of anxiety with regard to the manner in which this much-needed knowledge of the Institutes of Medicine is to be attained by our students. In recent years, the teaching of physiology has made a great stride in this country. Laboratories duly appointed have been, and are being, organised. The method of physiological instruction has, in most instances, passed from the mere prelection, illustrated by diagrams, to an experimental exposition of the subject. Very many of those whom I now address, had doubtless an experience of physiological tuition similar to my own. I remember well how much we were told about the action of the bodily organs, but how little we were shown of such actions. We were lectured about the action of the heart and its valves, but the motions of the heart we never saw, the operation of its valves was never shown to us. We heard about the manner in which the blood-pressure might be measured, and we were duly apprised of the number of pounds and ounces of pressure on the square inch, but this fundamental experiment we never saw, nor did we even see the instrument that was used for the purpose. We heard about the chemical transformations which the food undergoes when affected by the saliva and the gastric juice; but of the manner in which it might be demonstrated that these changes really do occur we knew nothing. The bile was said to contain certain acids and pigments; the urine had urea, uric acid, etc., but all demonstration of these great facts was neglected. In alluding to these defects in the tuition of physiology from which some of us have suffered, I would not have it supposed that I desire to cast reflections upon the teachers; such is far from my intention, for I know the difficulties against which they had to contend, and I know the success with which they finally overcame them; but I merely desire to remind some of you how much

you, like myself, were crippled in the study of practical medicine, by the sadly imperfect manner in which we learned the cardinal facts of physiology.

At this moment there is a distinct danger of a return to something like this miserable mode of instruction, in consequence of the fanatical clamour of a number of persons excited, it must be admitted, by one or two members of our own profession.

I cannot suppose that any member of this Association entertains the idea that experiments on the lower animals are not justifiable for the discovery of new truth; but I am aware that there are some who entertain the idea that vivisection is not necessary when it has for its object the mere demonstration, for educational purposes, of facts already known. Those who hold this doctrine, appear to me to forget that physiology is an experimental science, and that no right conception of the subject can be obtained unless the student be shown the experiments that are necessary for the demonstration of certain facts. No language, however clear, can depict the movements of the heart or the circulation of the blood, so as to call forth a picture so vivid and true, as that which without an effort springs forth the moment these things produce an impression through the organ of sight. The manner in which the blood-pressure is affected by retarding the heart's action, by dilating the arterioles, or by muscular contraction; the changes which follow division of the sympathetic nerve in the neck; the action of the chorda tympani on the submaxillary gland; the result of stimulating the cortex of the cerebrum; the reflex power of the spinal cord; the tetanus from strychnia; the paralysis from curara; these and other equally great fundamental facts in physiology give rise to nothing more than vague and feeble conceptions unless they are witnessed. Has not every teacher repeatedly observed the altogether different mental attitude which the student assumes the moment you pass from a mere description to a demonstration of phenomena? You far more forcibly arrest his attention, and far more deeply imprint upon his mind the facts which you would bring home to him. He is apt to forget that which he has merely been told, but the impression of that which he has seen is with difficulty effaced.

There is, however, a great deal more than this. It is not enough that the student of medicine should be crammed with so many facts about the bodily machinery—it is of infinitely greater importance that he should be really *educated* in a knowledge thereof. He cannot be educated unless you assume that he has a right to question your statements, and to demand from you a demonstration of the truth of what you say. It is not enough that you merely state to him, in an *ex cathedra* manner, that this or that is so; you ought on all possible occasions to *prove* to him that it is so. You ought to appeal to him as an individual, who can and who ought to think for himself, and, therefore, as an individual who is not merely to be crammed, but to be convinced.

Every examiner in physiology must have repeatedly observed how glibly the student may repeat to you a statement of fact, but how sorely puzzled he often appears when you ask him for the evidence upon which his statements are founded. Moreover, every one must have noticed how often the student lacks knowledge that is definite: he mingles together things that are certain and things that are uncertain, because he has not been sufficiently trained to examine experimental evidence. Of how little avail is this unreasoning and indefinite knowledge when the student comes to thread his way through the difficult analysis of disease! He either believes or he doubts too much. He oscillates from one extreme to the other, because he is wanting in definite knowledge, and because his critical power has not been sufficiently developed.

Now, I maintain that this definite and critical knowledge regarding the bodily mechanism cannot be attained unless our students be shown experiments on living animals; and I hold that those authorities who seem to be of opinion that this method of tuition may be dispensed with, are entirely overlooking the vast importance—not only to the student himself, but to our whole race—of an experimental manner of laying the foundation of a knowledge of the institutes of medicine.

It is, I believe, too much to assume that those who advocate a flimsy and superficial method of teaching physiology, are altogether actuated by feelings that are termed humane. I fear that there is lurking behind this disposition a feeling of indifference to what are the true principles of medical education, or, what is more likely, there is an incorrect appreciation of these principles. It must, however, be admitted that, notwithstanding the vast importance of physiological experimentation in the teaching of medicine, the circumstances under which it is possible demand serious consideration.

No one can deny that animals daily suffer pain in order that they may be eaten by man, and also in order that man may not be eaten by them. If it be thought necessary to put countless animals to a painful death for the purpose of keeping the human race alive, may not the

physiologist inflict pain, not only for the discovery of new truth, but also for the right education of those who have to spend their lives in preventing and in healing disease? Is the one object less important than the other? Indeed, is not the object in both cases precisely the same? Why, then, this clamour against physiologists? The pain produced in all the physiological experiments performed in this country in the course of a year is, I believe, as nothing when compared with that inflicted upon animals by the members of her Majesty's Lords and Commons on an autumn holiday.

I would not, however, for a single moment speak lightly of the production of pain, for it is the function of those who pursue medicine to alleviate pain and suffering. Our students would, indeed, be badly trained for the pursuit of a calling so humane as that of medicine, if they did not find us on all occasions carefully avoiding the giving of pain that is not absolutely necessary. Therefore it is our duty, for this as well as for other and obvious reasons, to use narcotics in our experiments upon animals whenever it is possible. It is not necessary for a sound physiological education that our students be shown *all* the experiments that are needed to demonstrate physiological truths. We probably do enough if we show them experiments on the cardinal points of physiology; and I aver that all the experiments on the higher animals that are really required for the purpose of education can be performed with the aid of narcotics.

Seeing that this is so, why should it be that some have become convinced that, in consequence of the present inflamed state of the popular mind on the subject of vivisection, the right education of medical students must be abandoned? The popular mind has been abused by inaccurate and misleading statements regarding both our motives and our actions. I maintain that a great and deplorable error was committed when the unreasonable clamour of the antivivisectionists was met in the spirit of compromise, instead of the spirit of stern resistance. I believe that the unfortunate vivisection Bill that was laid on the table of the House of Commons conferred a dignity upon the policy of the antivivisectionists which, but for that Bill, it would probably never have possessed. It is true that there has been a withdrawal of that singular Bill, according to which we were to have been fined fifty pounds, or to have been sent to prison for two months, if we had dared to show our students any experiment even upon a narcotised animal; but the effect of the Bill is not effaced. The increased boldness which it has given to the pretensions of the antivivisectionists is only too evident. All that we can now hope for is, that the good sense of our legislators will in the end prevail, and that they will do nothing to hamper the education of our medical men.

I have felt, sir, that in an address on Physiology I could not pass over in silence this, the leading topic of the day. I have alluded to it but briefly; for, although it is of the deepest importance, there is another subject to which I would ask your attention.

Nine months ago, in an introductory address given in this University, I had occasion to review the present aspects of physiology (*Lancet*, Nov. 1874). Having nothing further of a general character to say thereon, I have selected a special subject in physiological pharmacology which will, I trust, prove interesting to the practitioner of medicine.

The remainder of the address was devoted to a report of a large number of experiments on the biliary secretion of the dog, by Professor Rutherford and Monsieur Vignal. As this part of the address was illustrated by a large number of graphic representations of the results of the experiments, and as the expenses of the research have been defrayed by the Scientific Grants Committee of the Association, a full account of the experiments, with woodcuts of the curves shown in the lecture, will be published in the *JOURNAL*. The following is a brief *résumé* of this part of the address.

It has been shown by Professor Hughes Bennett's Committee appointed by the British Medical Association, that in dogs with permanent biliary fistule, and living upon a fixed diet, that "spontaneous diarrhoea, dysentery, and purgation produced by blue pill, calomel, corrosive sublimate, and podophylline, always diminished the solid constituents of the bile, and, with one exception, the fluid portion of the bile also".

More recently, Röhrig performed experiments on the action of cholagogues in fasting curarised animals with temporary fistule, and found that large doses of croton-oil greatly increased the secretion of bile, and that a similar effect, though to a less extent, was produced by colocynth, jalap, aloes, rhubarb, senna, and sulphate of magnesia, the potency of these agents as hepatic stimulants being in the order mentioned. He found also that castor-oil had little effect, and that calomel, while it seldom recalled the biliary secretion, nevertheless somewhat augmented it when it was taking place slowly.

In Dr. Rutherford's and M. Vignal's experiments a modification of Röhrig's method was adopted. Dogs which had fasted for eighteen hours were curarised, and artificial respiration maintained. A cannula was tied in the common bile-duct; the cystic duct was clamped. The bile flowed from the cannula into a finely graduated cubic centimeter measure, and the quantity secreted was recorded every fifteen minutes. It was shown that this method of continuous observation yielded results far more reliable and instructive than that adopted by Röhrig.

Two experiments on the secretion of bile in dogs that had fasted for eighteen hours, and which received nothing more than the doses of curara used in all the experiments for the purpose of keeping the animals at rest, showed that the biliary secretion was not affected by the doses of curara given; that the biliary secretion, on the whole, somewhat diminishes in the course of an experiment lasting from six to eight hours, but that the chemical composition of the bile remains almost exactly the same.

The curara was always injected into a vein; the various substances hereafter mentioned were injected directly into the duodenum; for this purpose, the wound in the abdominal wall was opened, and the substances injected through the wall of the viscus.

Three experiments with croton-oil showed that, although it produced violent irritation in the alimentary mucous membrane in all cases, it increased the biliary secretion in only one instance. A high place is, therefore, not assigned to this substance as a stimulant of the liver.

Six experiments with podophylline proved that this substance greatly increases biliary secretion. A definite statement regarding the composition of the bile before and after podophylline will be given in the report.

Röhrig's statement that aloes deserve a high place as a hepatic stimulant was confirmed by three experiments, in which the extract of Socratic aloes was employed. The analysis of the bile (not hitherto given), however, showed that after aloes the bile is more watery; nevertheless, the velocity of secretion is so much increased, that it certainly causes the liver to excrete more biliary matter.

Three experiments with rhubarb proved that it is a far more important hepatic stimulant than Röhrig has stated it to be. Doses of rhubarb were given nine times in the course of the experiments, and they never failed to excite the liver within half an hour after they were given. Analysis of the bile before and after rhubarb in all the three experiments proved the remarkable fact that, notwithstanding the greatly increased velocity of secretion after rhubarb, the bile-solids secreted by the hepatic cells are not diminished. The rhubarb apparently calls forth an increased secretion of normal bile.

Three experiments with senna proved that its power as a cholagogue is far below that of rhubarb. The bile is rendered more watery.

Four experiments with the aqueous extract of colchicum proved that it is a very decided cholagogue. The bile was rendered more watery, but the increase in the velocity of secretion was such that the amount of biliary matter excreted by the liver was certainly increased.

Two experiments with the solid extract of taraxacum proved it to be a cholagogue, though not a powerful one.

Two experiments with scammony proved that it has a slight cholagogue action.

Of four experiments with calomel, the secretion of bile was slightly increased in one, but there was nothing but diminution of the secretion in the other three. Purgative action was produced in all. The bile was rendered more watery.

Two experiments with gamboge gave no evidence that this substance is a cholagogue.

One experiment with castor-oil confirmed Röhrig's statement that this substance has scarcely any cholagogue power.

Two experiments with dilute alcohol injected into the stomach showed that, after the alcohol was given, the secretion of bile slightly diminished.

In the report, a full account will be given of the *post mortem* examination of the state of the alimentary canal (hitherto entirely omitted in such experiments), so that the effect upon the biliary secretion and that upon the intestinal mucous membrane can be compared.

It was shown that the increased biliary flow from podophylline, rhubarb, etc., in these experiments could not be ascribed to reflex contraction of the gall-bladder; for this had been previously well nigh emptied by digital compression, and the cystic duct had been clamped; nor could it be ascribed to reflex spasm of the larger bile-ducts, for the exaggeration of the biliary flow was far too great and far too prolonged to be explained in this way. Reasons were adduced for regarding it as probable that the agents are absorbed, and act on the liver directly. It was not professed, however, that their *mode of action* was definitely settled, the experiments having had for their primary object a determination of the facts of the case.

The opinion was expressed that powerful purgative action tends to diminish the biliary secretion.

The diminished secretion of bile in *non-fasting* animals after podophylline, observed in the experiments of Dr. Bennett's Committee, probably resulted from a diminished absorption of food from the alimentary canal, in consequence of the purgative action.

When a hepatic and intestinal stimulant, such as podophylline, is administered to an animal that is not fasting, it is probable that (1) the liver is excited to secrete more bile; (2) the absorption of bile and food from the small intestine is diminished on account of the purgative effect.

In conclusion, it was pointed out that this research proposed to be simply a contribution to comparative physiological pharmacology; and that it was left to the clinical investigator to compare these results with those observed in human pathological conditions.

AN ADDRESS

DELIVERED AT THE OPENING OF

THE SECTION OF MEDICINE,

At the Annual Meeting of the British Medical Association,
in Edinburgh, August 1875.

By W. T. GAIRDNER, M.D., F.R.C.P.Ed.,
Professor of Medicine in the University of Glasgow; Vice-President of the
Section.

IN taking the chair of the Section of Medicine, I have, in the first place, to submit to the Section the letter I have received from Dr. Quain, expressing his extreme regret at being unable to be present at this meeting, owing to unavoidable circumstances which have led to his devolving his duties on the Vice-Presidents. (After reading the letter, Dr. Gairdner continued.) You will not, under these circumstances, expect me to give you a very elaborate or systematic address, the more so as, in occupying the same position at Leeds some years ago, I to some extent anticipated what I might have said on the present occasion. I will rather ask you to receive a few thoughts that have occurred to me almost on the way to this meeting, and in listening to the admirable address which we have just heard from Dr. Begbie; I refer especially to that part of the address in which he spoke of Cullen. It is impossible for anyone, being in Edinburgh, and inheriting the traditions of the Edinburgh Medical School, not to associate Cullen with the *genius loci*, of which, indeed, he was eminently a representative man. The fame of Cullen was, moreover, world-wide, and extended beyond medical circles; he was a distinct and noteworthy personage in that literary and scientific society which included Adam Smith, David Hume, Robertson the historian, and Black the distinguished chemist. Cullen had, by reason of his accomplishments, something in common with all of these and all the other eminent men of that time, and was highly esteemed by them all. In point of medical experience, he was at the very head of his profession; a most distinguished clinical teacher, constantly associated with his students in the observation of hospital cases, and, besides this, engaged in private consultations which brought him into extensive correspondence (as his manuscripts in the College of Physicians show) with all parts of the country. Now, one of the most remarkable facts in the history of the epoch of Cullen is one which was not alluded to by Dr. Begbie, but which, nevertheless, might be made available in discussing, or in reflecting over, the signs of progress in the medical art to which he alluded. About a hundred years ago, when Cullen was at the height of his fame, the Chair of the Royal Medical Society was filled by a man who had been the pupil, the friend, almost the dependent, of Cullen, and who then and afterwards became his most bitter antagonist. He was not a man of large personal experience in the art of medicine; his learning and accomplishments were of a very limited kind; his private life and character were the reverse of laudable; his personal and social standing was in every point so much inferior to that of Cullen as to admit of no comparison. Yet this man, first in the Royal Medical Society among the younger students, and afterwards by a literary and doctrinal influence which extended in a wave of controversy to the very extremities of European civilisation, became the recognised author of a system which all but subverted that of Cullen for a time in Edinburgh, and, up to the end of the century, occupied the minds of men in Italy and Germany to an extent that we can hardly even comprehend now-a-days from anything we know of the system itself. I will almost take it upon me to affirm that there are not two men in this room—if, indeed, there are so many in the whole British Medical

Association (and I do not pretend to be one of the two)—who could at this moment give off-hand a reasonably clear account of the doctrine which was called Brunonianism, and of its application to the leading varieties of disease and their treatment. Yet it would be an inquiry fraught with the deepest interest to us, and I know none which would more effectually gauge for us the progress of the art of medicine during these last hundred years, and thereby show us if we are in reality getting upon solid and surer foundations, than to ask ourselves whether, if some such man as this John Brown were to arise now and to broach such a system as he advocated in 1775, it would have a shorter life, and be less revolutionary in its effects. I cannot enter upon that question to-day; I cannot even talk to you, however briefly, of the respective merits of Cullen's and of Brown's teaching; but I happened, in looking over a few books on the subject yesterday, to light upon an actual and apparently authentic prescription of John Brown's, preserved for us by one of his pupils; or rather, perhaps, let us call it the net result of his system conveyed in written advice to a hypochondriac patient as follows. I think you will recognise in it something not unlike what we have seen and known in our own time.

"For breakfast, toast and rich soup made on a slow fire; a walk before breakfast and a good deal after it. A glass of wine in the forenoon from time to time. Good broth or soup to dinner, with meat of any kind he likes, but always the most nourishing. Several glasses of port or punch to be taken after dinner, till some enlivening effect is produced from them; and a dram (of whisky?) after everything heavy. One hour and a half after dinner, another walk. Between tea-time and supper, a game with cheerful company at cards or any other play, never too prolonged; a little light reading; jocose humorous company, avoiding that of popular Presbyterian ministers and their admirers, and all hypocrites and thieves of every description. Lastly, the company of amiable, handsome, and delightful young women, and an enlivening glass."

I think that from this prescription we can obtain a pretty good idea what was the nature, or at least the upshot, of the famous Brunonian system, the end and issue of all those lectures and expositions upon direct and indirect debility, and upon excitability, which formed the key-stone at once of Brown's doctrine and of his practice. It is a very curious proof how things go to sleep and are revived again, that we should have seen a practice, not, indeed, based upon the same theory, but very like this in its processes within our own time, even within these few years, to such an extent as to have led to a formal declaration against it by many of our most distinguished physicians. I can testify for one that people have come to me repeatedly who had been formally advised, very much after the manner of John Brown, to take, say, four or five, or more, glasses of port wine after dinner and after that as much toddy as their heads could carry, and this as part of a regular prescription going on for weeks together. But, if anyone should ask, Could such a practice, however indulgent to the weaknesses and follies of self-indulgent people, be successful in our day in floating such a general theory of disease and cure as the Brunonian system? I should incline to reply in the negative; and I should rely on giving that answer not only upon the great advances that have been made in physiology and pathology, the sciences upon which all genuine improvement in the medical art is founded, but also upon the much more exact and complete methods of clinical observation pursued in the present day, even as compared with the time of Cullen. I refer especially, of course, to the methods taught to the average general practitioner in our schools; for no one would wish to deny that we have had great and true, nay, eminently exact, clinical observers in the past, even in the remotest ages.

No doubt, too, there are still many imperfections; but, on the whole, we are pretty safe in saying that now-a-days, in every well appointed school, the clinical study of medicine is far more carefully attended to in detail than in any previous age; and the introduction of those practical methods of teaching and examination to which Sir Robert Christison has referred has in no department been more successful than in medicine proper. There seems reason, therefore, to believe that we have been gradually gaining for the art of medicine a more secure position in connection with demonstrable or demonstrated facts, and that we have gone some way towards making it impossible for any man, coming forward with a new theory not based upon the careful study of facts, to make such a revolution in opinion as was the case in Brown's time, and such as has over and over again been witnessed in the history of medicine almost from the days of Hippocrates. In regard to the methods of medical teaching in general, I sympathise very much with Sir Robert Christison's remarks. The true way is not to depreciate lectures as opposed to practical teaching, but to maintain both in a high state of efficiency, so that the excesses of doctrinal development may be corrected by the constant appeal to facts, while, on the other hand,

the facts may be more carefully correlated, and their real significance brought out by carefully regulated systematic instruction. And for this purpose the true ideal is to have as much as possible the systematic and the practical teaching in one hand, so that no one is led by the nature of his office to become a mere lecturer or a theorist only, and no one, on the other hand, a mere demonstrator of facts and experiments. If you will allow me to use a comparison that is with me a familiar one, I would say that the art of medicine is like a tree; it must have its roots in the soil of facts, and its branches and leaves in the upper air, amid the currents of human thought. Unless its roots are well fastened down into the ground, it will be blown over; but, unless its leaves are freely inhaling every breath of opinion, it will wither and die, as surely as if it were torn up by the roots. And this should be the character of our work in this Section: careful and exact observation, followed by discussion, in the most absolutely free spirit, of all points involving differences of opinion.

REPORT OF PARLIAMENTARY BILLS COMMITTEE, 1875.

THE Parliamentary Bills Committee beg to report that they have held numerous meetings during the year, and have taken steps to bring under the notice of Parliament, and of the Government, amendments in the Artisans' Dwellings Bill, in the Adulteration Acts Amendment Bill, and in the Public Health Acts Amendment Bill.

The amendments proposed in the Artisans' Dwellings Bill were chiefly directed to the amendment of the clauses relating to areas of improvement; to the protection of medical officers of health in performing the very onerous duties cast upon them under this Act; and to diminishing the expense attendant upon the preparation and approval of improvement schemes. Your Committee had the advantage of the active co-operation of Mr. Kay-Shuttleworth, M.P., the Right Hon. Lyon Playfair, M.P., and of Dr. Tripe, Dr. Meymott Tidy, and other experienced advisers; and they had the satisfaction of finding that the clauses drawn in accordance with their recommendations were framed, approved, and passed by the House of Commons in committee on the Bill, and have now become law.

Your Committee were unable to approve of many of the clauses of the Adulteration Acts Amendment Bill as originally introduced into the House of Commons, especially those which required the proof of distinct knowledge on the part of the retailer of the nature and effects of the adulteration of articles sold. They were unsuccessful in obtaining the removal of the objectionable words in these clauses when the Bill was under discussion in the House of Commons; but, by further representations to influential members of the House of Lords, they succeeded, in combination with other bodies entertaining the same regard for the public welfare in this respect, in obtaining the assent of the Government to considerable amendments, which will tend to ensure a large amount of protection to the public from fraudulent and deleterious adulteration of articles of food, while they lessen the probability of any undue pressure upon innocent vendors. The Public Health Acts Amendment Bill was, in the first instance, presented to the House of Commons by the President of the Local Government Board, as an amending Bill as well as a consolidating Bill. Your Committee felt that as an amending Bill it was wholly insufficient, and indeed quite illusory. They felt it their duty to co-operate with the standing committee of the medical officers of conjoint districts in distributing to members of the legislature an elaborate series of amendments, designed to meet proved defects discovered in the working of the existing health-laws. These were also brought under the notice of Mr. Sclater-Booth, the President of the Local Government Board, by Mr. Ernest Hart, Chairman of the Committee, and Dr. Bond of Gloucester, Secretary of the Standing Committee of medical officers for conjoint districts. Mr. Sclater-Booth, however, strongly urged the necessity of passing the Bill of this year as a consolidating measure, and, as the advantages of consolidation are obvious, and as Mr. Booth assured Dr. Lyon Playfair in the House of Commons that he would treat this purely as a measure for consolidation, leaving the ground open for early amendment of the law, your Committee did not think it advisable to use the parliamentary influence of the Association and its Branches to oppose the Bill. The thanks of the Association, and indeed of the public, are certainly due to the honorary local secretaries of Branches for the trouble which they took in bringing the matter under the notice of their local representatives in Parliament. Letters were received from upwards of sixty members of Parliament undertaking to assist in setting the views of the Association on this subject before the legislature, and no doubt the same assistance will be forthcoming, and may be effectually used, on a future occasion.

It is probable that the Committee will draft the amending clauses which were then circulated in the form of a separate Public Healths Acts Amendment Bill, which will be introduced into Parliament early next year by an influential member of the House.

Your Committee have the satisfaction to report that a Royal Warrant has been issued, granting to the medical officers of the Navy a considerable number of those concessions, as to rank, pay, and retirement, which were laid before the First Lord of the Admiralty by a deputation of the Committee. The Committee have had the pleasure of receiving the warm and grateful thanks of many eminent members of the naval medical service for the successful results of that representation, which is believed to have had a very valuable effect. Your Committee have renewed representations to the Secretary of State for War as to the redress needed for many grievances of the army medical officers. Great pains were taken to ascertain the facts, and to submit to Mr. Gathorne Hardy suggestions which would meet the views of the service at large, and were such as might be reasonably entertained. Mr. Hardy has since several times stated that he has tested these suggestions very minutely, and that he is still giving them his careful consideration. Your Committee trust that before long a Royal Warrant will be issued making such amendments as to pay, retirement, relative rank, and allowances of army medical officers, as will restore contentment and popularity to that important service.

Your Committee beg to remind the Branches of the Association that each Branch is entitled to elect a representative annually on this Committee. One or two Branches during the last year omitted to do so. It is desirable that every Branch should have its representative member on this Committee, in addition to those who are elected by the Association at large. The labours of this Committee are considerable and continuous throughout the year. They involve a modest expenditure, and the Committee recommend that the Association grant £15 during the ensuing year towards these expenses.

ERNEST HART, *Chairman.*

REPORT OF THE SCIENTIFIC GRANTS COMMITTEE.

YOUR Committee beg to report that they have held five meetings with the object of arranging the principles of distribution of the fund entrusted to them, and the determination of particular grants for the present year, in response to applications for such grants from gentlemen proposing to pursue definite scientific investigations in furtherance of the medical art.

Your Committee have thought it desirable to adopt for the present year the "conditions" for grants which have been and are in use by the British Association for the Advancement of Science.

The following are the grants which were recommended by the Committee at their meeting in London in January 1875, and approved by the Committee of Council:

Mr. Hicks, Researches on Alcohol	£50
Dr. P. M. Braidwood and Mr. Francis Vacher, Birkenhead. The Life History of Contagion	15
Dr. R. Caton, Liverpool Royal Infirmary. The Electric Currents of the Brain	20
Dr. J. M. Fothergill, London. The Effect of certain Agents upon the Circulation	10
Dr. M'Kendrick and Mr. James Dewar, Edinburgh. Physiological Action of Chinoline and Pyridine Compounds	25
Dr. Mahomed, London. The Pathology of Albuminuria	20
Dr. Munro, Cupar. An Antidote for Chloroform	5
Dr. W. H. Spencer, Clifton, Bristol. The Action of Uranium Salts in Diabetes	20

£165

Of these grants the following amounts have been expended:

Dr. P. M. Braidwood	£12 12 4
„ R. Caton, Liverpool	8 16 9
„ Fothergill, London	3 18 10
„ M'Kendrick	5 0 0
„ Mahomed	5 12 8
„ Munro	2 15 11
„ W. H. Spencer	13 15 11

Interim reports have been presented by Dr. Fothergill on the action of Aconite and Digitalis; by Drs. Braidwood and Vacher, on the Life History of Contagion; by Dr. Spencer, on Uranium in Diabetes, and on Trimethylamine in Rheumatism; by Dr. Mahomed on Albuminuria; by Dr. Caton on the Electric Currents of the Brain. Mr. Hicks has been

unable to carry out the proposed research on Alcohol during the year, and has not drawn the sum allotted.

The Committee beg also to recommend the Committee to make a grant of £30 in aid of researches carried out during the past year on the Biliary Secretion, by Professor Rutherford of the University of Edinburgh, and M. Vignal; the results of this investigation will be laid before the Association at the present meeting by Professor Rutherford in his Address on Physiology. The balance in hand will then be £101:6:5, which will be returned to the treasurer.

Your Committee recommend that a further grant of a total sum not exceeding £300 be made for the purposes of scientific grants during the year ending July 30th, 1876. They will be happy to receive at once applications for grants from physiologists and members of the profession generally, in aid of scientific researches; they are desirous that such researches should in all cases have relation to the advance of medicine and its auxiliary branches, and will be especially glad to further scientific research in the departments of therapeutics, and clinical medical and surgical research.

FRANCIS SIBSON, *Chairman.*

REPORT OF JOINT COMMITTEE ON STATE MEDICINE, 1875.

YOUR Committee, in presenting their report for the past year, desire to return their best thanks to the 135 medical officers of health who sent replies—many of them very full and of great practical value—to the schedules issued by them last year. If they have not yet communicated to their correspondents the results of that inquiry, it is because the time for making a profitable use of the information has not yet come.

Your Committee at one time thought that last spring would have been the time for energetic action on their part; and, judging merely by the bulk of the Public Health Bill of this session, some may be of opinion that they have acted wrongly in remaining quiescent. But, as the Bill was almost entirely one of consolidation of previous statutes, and so directed to the accomplishment of one of the objects earnestly sought for in their original memorial to the Government, your Committee did not consider it advisable needlessly to interfere with the progress of a measure which, though still incomplete and in various respects inefficient, is a step in the right direction, and will enable many to study this important subject in a single Act, instead of having to unravel the perplexing and often inconsistent provisions of twenty or thirty. They will thus be enabled with comparative ease to qualify themselves for the intelligent consideration of the amendments which, according to the express statements of Her Majesty's ministers, will be submitted to the next session of Parliament. It was this assurance which chiefly weighed with your Committee in deciding to reserve any communication to the Government until the nature of the amendments shall appear.

Your Committee have observed with satisfaction that, during the recent discussions on the Public Health Bill, there has been a steady approximation to the views constantly maintained, and the proposals persistently brought forward, by the Committee; and that, in particular, it is now plain that several important principles urged by them from the beginning, such as the adoption of larger areas and the readjustment of boundaries, will be adopted. In proof of this, your Committee refer with much pleasure to Section 284 of the Public Health Bill, 1875, which empowers the Local Government Board, "on any representation made to it that the appointment of a medical officer of health for two or more districts, situated wholly or partially in the same county, would diminish expense, and otherwise be for the advantage of such districts, by order to unite such districts for the purpose of appointing a medical officer of health." They are happy to observe, from this provision, that the Imperial Legislature is at length beginning to perceive that it may be possible to promote both economy and efficiency by the appointment of skilled officers: an idea which was thus formally propounded in the original memorial of the Joint Committee, dated May 1868; "yet it is believed by those who have directed their attention to the subject that the amount actually disbursed under the present disjointed and very inefficient system would, if otherwise distributed—the districts and many of the duties being consolidated—go far to maintain a sufficient staff of specially trained and highly qualified district scientific officers with inspectorial functions. Without such officers, it is vain to expect any material improvements in this important department of the public service."

Your Committee are also happy to observe that the same section permits the appointment of assistants to the officer appointed for the united districts. The mode of dealing with nuisances, where the cause

of the nuisance arises without a district, prescribed by Section 106, is also a very marked improvement on the existing law.

Your Committee cannot help referring to a speech of Mr. Stansfeld, delivered at Halifax on January 11th, 1875, in which it was made to appear that the British Medical Association had been adverse to "a system of local self-government" in sanitary matters, and that Mr. Stansfeld, in reply to a deputation in 1872, had combatted these views in the following terms:—"He could understand the position, the point of view, of professed and scientific sanitarians. Their first idea was health, their second local government; but not in the sense of trusting it; on the contrary, they led to a hopelessness about it, and sometimes to an unmerited contempt. . . . Local administrators would not display intelligent interest in their new functions, unless they were shown respect and trust. Respect for the principle of local self-government, and a keen sense of the importance in these days of inspiring local administrators themselves with the feeling that they were treated by the Government with respect, were his guides in the administration of the Poor-law and of the Local Government Boards." Your Committee read the report of this address in the *Times* of January 12th with the most profound astonishment, and think it sufficient comment on the statements contained therein to refer to the following extracts from the Committee's report of 1871, and from the memorial presented in 1872 by the very deputation mentioned by Mr. Stansfeld. At page 8 of the report are these words:—"We cannot too strongly urge on the Legislature the necessity of limiting the powers and functions of the central authority within the narrowest bounds consistent with effective action." And at page 15:—"This mode of administration" (by the frequent intervention of the central authority and its officials) "has the threefold disadvantage of being costly, of being inefficient, and of keeping the country in a state of perpetual tutelage. If, on the other hand, the inspectors, or rather, chief officers of health, highly trained in all the departments of public medicine, were resident in their districts, each one of them would be a centre of instruction whence sound and enlightened views on all sanitary matters would emanate, so as gradually to enlighten the public mind, stimulate local action, and reduce to a minimum the need of interference by the central authority." And the seventh paragraph of the above mentioned memorial, which was read *in extenso* at Mr. Stansfeld's own request, is as follows:—

"That, though they have always insisted on the necessity of a central check on local inefficiency and caprice, your memorialists did not contemplate, and cannot regard with approval, the investiture of any department of the executive with powers so large as those which the Public Health Bill" (the first draft of Mr. Stansfeld's own Bill) "proposes to confide in the Local Government Board; and that the costly alternative adopted in the Bill of providing a system of central inspectorial supervision of undefined proportions and cost, rather than efficient local government, cannot be considered either wise, expedient, or effective."

Throughout the same address, your Committee observe with surprise the adoption by Mr. Stansfeld of all or nearly all the principles and amendments on the Sanitary Act, urged on his attention from time to time by the Committee collectively and by some of its active members in their individual capacity, as though these had originated with himself, and were in opposition to the views of the Committee.

Your Committee cannot conclude this brief report without expressing their deep regret, shared, they are persuaded, by the whole of both Associations, that so eminent a member of the Committee as Dr. Rumsey, who had so much to do with its formation, and whose name has been identified with every stage of our sanitary progress during the last forty years, has been disabled by paralysis from the exercise of his profession, and from those invaluable public labours which have contributed much more to the good of the commonwealth than to his personal advantage. Your Committee rejoice that many members of the Associations have already manifested, and they trust that many more will yet manifest, in a tangible form, their sense of his private worth and great public services.

WILLIAM CLODE }
W. H. MICHAEL } *Honorary Secretaries.*
A. P. STEWART }

FOREIGN NEWS.—Professor von Langenbeck has been chosen Dean of the Faculty of Medicine in the University of Berlin.—A festival of German military surgeons was held in their new hall in Berlin on August 2nd. Herr Stenzel, a student, read a discourse on the Action of Modern Projectiles on the Human Body; and Professor Gurlt gave an address on the History of Military Surgery in Prussia during the last 150 years.

BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st, Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, AUGUST 14TH, 1875.

A REVIEW OF THE EDINBURGH MEETING.

THE fair fortune with which the Edinburgh meeting commenced lasted till the end, and the good work which deserved success attained it. The President, Sir Robert Christison, and all the local officers must be congratulated on the completeness with which in nearly every case their intentions were fulfilled; while the Association at large, and especially of course the members who attended the meeting, owe a large debt of gratitude for the unsparing labour, the thoughtful preparation, the unstinting liberality, and the cordial good-will which the profession in Edinburgh lavished on them at this meeting. We have the satisfaction of knowing that the entertainers at the close of their labours are justly gratified by the signal success of the great professional meeting which they organised, and feel that their work has not been in vain. The recollections which all will long retain of the Edinburgh meeting are of the most agreeable kind. The first and most striking impression which has been produced is, we believe, that which every such great gathering is likely at once to make. The social influence of an assemblage of over a thousand members of one profession is in itself the creation of a power: the contagion of vast assemblies is potent: the atmosphere of good fellowship, of academic impulse, of learned emulation, of professional self-respect, which pervades such a gathering in so great an university, under so cultivated and eminent a President, and addressed by orators so skilled and highly cultured—such an atmosphere widely diffuses itself; it cannot be breathed for a week together without influencing the individual mind. The meeting presented at every side aspects worthy of respect, and which could not but give birth to impressions at once useful and agreeable to all who took part in it, or who attentively considered it. Many hundreds of old graduates returned to find their Alma Mater more flourishing than ever, extending widely her habitation, varying her methods of examination, enlarging her power of teaching, and showing that with the experience of age may be combined the elasticity and vigour of youth. Those to whom the Edinburgh medical schools have hitherto been only a name, have learned to connect with well known names the precise ideas and associations which belong to the concrete facts. The systems both of teaching and of examination in Edinburgh are well worthy of attentive study, and the men who administer both were there to explain and to describe them. Sir Robert Christison, wisely, as we think, chose this opportunity to discuss historically and critically the rise and progress of the Edinburgh University system. We totally differ from a writer who thinks the occasion ill chosen, and we feel sure that the President's address will be consulted with advantage and with interest for years to come, by all who are interested in the development of medical education. Such an interest every member of the profession must fairly be held to have; nor could any more suitable topic be found on which to address such an assemblage of medical men as met in Edinburgh, than to trace the history of its great Medical Faculty, to describe its methods of instruction and examination, and to endeavour to ascertain how it has become great, whether its methods are suitable for general adoption, and what are the principles which may be discovered by examining its past and present circumstances. Sir Robert Christison is peculiarly well qualified by his calm and judicial quality of

mind, not less than by the rare experience of half a century, to fulfil this high task. Only a very superficial mind could, we imagine, find his discourse dull, and to no person of ordinary intelligence could it possibly be uninteresting.

The address was unquestionably of greater length than was convenient for the disposal of other business, and hence there was disclosed more clearly than on any former occasion a difficulty in the arrangement of the business of the first day's meeting. This has before been occasionally apparent in a lesser degree, and the managers of the business of the annual meetings will now, no doubt, feel called upon carefully to consider the matter. The things to be done on the first day of meeting, besides the delivery of the President's address, have a considerable, and not always a merely formal, importance. The Report of the Council has always to be submitted, and with this the old Council expires; and certain official appointments are made. This year the business was more heavy than usual, since the By-laws, which have been recently remodelled to suit the position of the Association as an incorporated body, had to be brought up and passed. The Report of the Council is always an important, although usually by no means an exciting, document. It contains few things which are not already known to the members. It is a summarised account of the official doings of the Association. It contains a note on the balance-sheet, which has been printed previously for all the members; a condensed note of the work of the various committees, which has also for the most part been made known from time to time during the year, and each of which committees on a subsequent day presents its own detailed report; and it refers briefly to any important incidents of the year. It has already passed through the hands of the General Council of the Association, a body of several hundreds of representatives of the Branches, and has there been thoroughly examined. Like all such documents, therefore, it is usually entirely divested of any sensational element, and it has little of novelty. It is, however, a paper of considerable interest, and affords a legitimate opportunity for any member to raise a discussion on the wide range of subjects thus analysed, to express his views on any of the various points connected with the subjects mentioned, and with the general management of the Association. Such opportunities are numerous throughout the year at the various Branch meetings or in these columns; and the representation of the Association is so extensive in the Committee of Council, which consists of representatives of all the Branches to the number of over a hundred, and in the General Council to the number of several hundreds, that it is rare to find that any novelty is discussed. Moreover, the difficulties of discursive debate in an assembly of near a thousand persons are so great, that men instinctively choose the minor meetings of Branches and Councils, which are frequently taking place all over the United Kingdom, to thresh out subjects of debate and put them in a state in which general agreement is previously attained before bringing them to a great meeting. Sir Robert Christison justly observed, that very large general meetings become, by their bulk, so unwieldy that they almost invariably confide to their representative Councils the preliminary discussion of subjects likely to raise much difference of opinion. This is of course particularly the case where, as in the British Medical Association, the whole body is formed of an union of separate bodies, with large powers of self-government and free debate, and having a widely spread and democratic representation in a Council wholly composed of their freely elected delegates. Nevertheless, the opportunity of free debate on all lawful occasions is a privilege which Britons wisely hold dear; and experience has taught us all that the essence of liberty is best preserved by an undeviating maintenance of all the forms by which it is guarded. In the bare half-hour which remained on the first day of the late meeting for the transaction of much business, and with the urgent necessity then existing for receiving the report of the Council before it became officially defunct, there was no time for reading the printed Report or debating it, if any one desired it, unless members remaining in the meeting were willing to forego their dinners. The struggle

then arose between two sacred principles: should the Report be read out and dinner be sacrificed, or should it be accepted on the faith of the General Council and of those who had read it, and should the members dine? The gastric principle prevailed, and so Report and By-laws were voted in succession and in mass. To none could this be a matter of greater regret than to those who were compelled to recommend it. Dr. Sibson, Dr. Falconer, Mr. Husband, Dr. Carpenter, and many others who had devoted great time and trouble to the preparation of these documents, and the Council who had discussed them, could but desire that the full honours of debate should be accorded to them. But the conflict between the forms of debate and the pangs of hunger was an unequal one, and the prospect of dining was to the majority more delightful than that of a conversation on the By-laws. Next year, however, it will be well to provide against the recurrence of what was an unprecedented waiver of privilege. There are more ways than one by which this can be arranged, and we need not now discuss the slight changes in the programme by which it can be effected.

The succeeding days of the meeting passed off without any check or hindrance to their course of uninterrupted success. Of Dr. Begbie's address in Medicine, we have already spoken. Mr. Spence's careful, thoughtful, and interesting address in Surgery, maintained his reputation as a surgeon of vast experience, and one who uses his material cautiously and securely to advance the art of which he is a distinguished professor. Perhaps that part of his address which will be most critically read is the conclusion, in which he displays the good results attending the careful application of the rules of cleanliness, neatness, and approved open dressings in the major surgical operations in his own practice. He spoke of a series of sixty-three major operations in his own practice during three years, of which sixty had been successful. It is understood that he did not refer to the last three years, but to a particular series of years, in which the atmospheric and other epidemic conditions being favourable, this result had been attained. This reservation being made—and it accords with Mr. Spence's views, we imagine, that stress should be laid upon it—it must still be admitted that such a statistic is striking and instructive. It may of course, be said, that it is the boast of the antiseptic system that it renders patients secure from such atmospheric conditions of danger, and rescues them from the perils of the epidemic hospital diseases which are the terror of the surgeon. But those who are favourable to the views which Mr. Spence maintains, state that the great originator of the antiseptic system of surgery and his disciples have not made public any such consecutive tabular statement of results achieved during a series of years, as would indicate that those results are independent of the epidemic conditions of recurrent cycles of years. This argument we state, without assigning to it so much importance as it appears to have in the minds of those who urge it. Test-cases frequently repeated are almost as convincing as accumulated figures; and we believe that the brilliant chemical demonstrations of Mr. Lister, and the most interesting report which he gave of the results achieved in re-establishing "salubrity" in foreign surgical wards as well as in his own, have convinced hundreds that "epidemic constitution" is often only a vague phrase which covers without expressing "atmospheric impurity"; and that the antiseptic method of protecting open wounds from zymö-poisoning is capable of reversing the conditions which sometimes neutralise surgical skill, and commonly hang around the bed of the subjects of surgical injury. Of course it may be urged, that the antiseptic method is, above all things, a means of absolute cleanliness, and that, by the introduction of surgical cleanliness under the solemn guise of advanced science, the lives of innumerable patients would be saved in the wards of most great continental hospitals; but, after all deductions have been made, which, as the results of Mr. Spence and Mr. Callender show, ought to be made, there remain achievements to the credit of Mr. Lister's method which every one must admire, and at which most men are still fain to wonder. The two sides of this great question in surgery have been very clearly and very picturesquely contrasted at this meeting. After

listening to Mr. Spence's address, the members passed to Mr. Lister's demonstrations; and to both they must feel indebted for the labour and the time which they bestowed in elaborating the facts submitted for consideration. Mr. Lister's fine genius for patient and accurate scientific research was fully appreciated; his dressings and his general precautions are themselves the work of an experimental genius, and his splendid demonstrations on the processes of infection in the physiological section, held a great audience spell-bound for two hours, and have left a great impression on the minds of all who were present. Undoubtedly, Mr. Lister's efforts contributed in a high degree to the scientific success of the meeting.

Dr. Rutherford, in succeeding to the chair of Hughes Bennett, for many years a scientific leader in this Association, and the author of its "Scientific Grants", inherits a relationship of which he has at once brilliantly fulfilled the functions. No small part of the work of the Edinburgh Committee on the action of mercury was done by Drs. Rutherford and M'Kendrick; and the Address in Physiology, which Dr. Rutherford gave this year, includes and mainly consists of an abstract of a report of a most valuable investigation of the action of other drugs on the liver, of which the full details will soon appear in the JOURNAL, as a report to the Scientific Grants' Committee of the British Medical Association. The spirited and outspoken defence of the experiments on animals by which such investigations are carried on, elicited important remarks from Dr. Burdon Sanderson and Sir Robert Christison. Here especially, as at many other periods of the meeting, it was impossible not to regret deeply the absence of Dr. Hughes Bennett. He, almost more than any other man, was entitled to claim that in his hands, and, under his influence, experimentation had been so carried on as to advance knowledge, to increase precision, and ensure soundness in medical science and practice. He had desired, particularly in his own University, before his own townsmen, and the pupils, colleagues, and medical brethren who appreciate his character and labours, to repel the poor aspersions which unscrupulous and ignorant *doctrinaires* have thrown upon the practice to which suffering humanity owes priceless boons. Unfortunately, his weak state of health forbade his taking part in the meeting, although it had been hoped till the last moment that he would have shared in the welcome which his University gave to an Association which owes him much, and gratefully acknowledges its debt.

The Sectional meetings were more frequented than they had ever been before. Audiences of between two and three hundred thronged the rooms in which any particularly interesting paper was read, or any important demonstration was given. Among the most crowded meetings were those in which the papers of Mr. Lister, Dr. M'Kendrick, and Mrs. Garrett-Anderson were read. In the latter case, no doubt, curiosity had much to do with the attendance; but we understand that this lady produced a very favourable impression, and that, at the close of her paper, the unusual compliment of a special vote of approbation was paid amid loud and general acclamation. This was done at the instance of the most competent members of the section. In another section, Mrs. Hoggan described and demonstrated an important method of histological preparation, of which something has been before heard elsewhere. In the course of the general meeting, a question was put by Mr. Oliver Pemberton, the well-known surgeon of Birmingham, and the reader of the Address in Surgery at the Birmingham meeting, as to the portals by which these two ladies had been admitted to the Association. Dr. A. P. Stewart mentioned that Mrs. Anderson was elected two years ago by the Metropolitan Counties Branch, of which she has, we believe, attended more than one meeting. Mrs. Hoggan was elected by the Committee of Council, and is not a member of any Branch. Mr. Pemberton moved, and Dr. Marshall of Clifton seconded, a resolution, which was carried almost without a dissentient, instructing the General Secretary to issue, before the next annual meeting, a form of question to every member of the Association, inviting their opinion as to the advisability of admitting ladies practising medicine as members of the Association. The subject will, there-

fore, probably receive the full and no doubt temperate discussion, for which there was no opportunity in the few minutes which succeeded Sir Robert Christison's address, or preceded that of Dr. Begbie. It is very convenient for all, that printed notice be given in the printed agenda prepared before each meeting, of any important resolution of a novel or independent character, or raising any important point of procedure or principle. Both were involved in this resolution; and it would have been more satisfactory if the precedent of a *plebiscite* on a question not yet discussed had been established after a thoughtful debate. A verdict of any sort commands more ready acquiescence when arguments on both sides have preceded it; a *plebiscite* is an unusual and important incident in the history of the Association, and so potent a judgment would have been more effectually invoked after pleadings on both sides had been heard. By a little deliberate arrangement this might have been provided for on the last day of the meeting. The Brighton meeting may, however, possibly be enlivened by arguments *post factum*.

The work done in the Sections will be reported in this and subsequent issues. The Presidents' addresses will have been read with great interest. Mr. Playfair showed once more the acuteness of his political insight and the grasp of the principles of sanitary legislation which have signalled his parliamentary utterances throughout. The member for the University of Edinburgh has by his career already done high honour to his University, and has rendered great services to the nation. The independence with which he has throughout maintained sound principles of health-legislation, and assailed the mischievous proceedings of his colleague Mr. Stansfeld, deserves hearty recognition. It is to Mr. Lyon Playfair chiefly, that we must look in the House of Commons for the inauguration of a legislative system which shall provide adequate areas of administration and a good local system of sanitation. The demand for an inquiry into results is probably the first step towards such an amendment, and we are glad to learn that he intends urgently to press it.

Dr. Matthews Duncan's address is characteristically outspoken, learned, and incisive in tone. His remarks on the younger surgeons of Great Britain are calculated to arrest attention. We have had more than once to suggest reflections during the last decade, which are not altogether out of harmony with his plea for the more earnest cultivation of the higher elements of surgical greatness in our hospitals and schools. Dr. Quain was missed from his post of honour in the Medical Section. His place was filled by the able Professor of Medicine in Glasgow, Dr. Gairdner, a conspicuous ornament of the meeting. The Section of Psychology had as its Chairman the President of the College of Physicians of Edinburgh, to whom the Association is indebted not only for his services in this capacity, but as the head of a corporation which welcomed the Association with splendid and cordial hospitality.

Two of the Sections passed important resolutions, which were subsequently approved by the general meeting, appointing influential Committees to prepare reports for the next year's meeting. The Committee on Poor-law Medical Relief in Scotland, appointed as the result of the reading of a paper by Dr. Joseph Rogers, late President of the Poor-law Medical Officers' Association of England, has before it an important work. Dr. Rogers pointed out that the medical officers of Scotland suffer under disadvantages from which, partly through the influence of the British Medical Association, and partly by their own efforts, the Poor-law medical officers in other parts of the kingdom have been relieved. These are, the necessity of providing medicines out of their salaries; the tenure of office for an annual term only, renewable only at the good pleasure of the parochial boards; and the want of the large aid from the Consolidated Fund which helps to secure for them and for the sick poor central protection and most liberal treatment. The Committee has power to add to its numbers, and we call the attention of the Poor-law medical officers of Scotland to its formation. They should supply materials by forwarding to the chairman information showing how the present system acts in imposing on them ill-remunerated labour, in placing them at the mercy of local

boards, with whom rigid and immediate economy of money is often a ruling consideration, and in restricting their usefulness to the sick poor.

The Committee on Anæsthetics is, we think, a timely one, and has before it an important field of statistical and clinical inquiry and scientific investigation. It will probably work by subcommittees, confiding divisions of the work to specially skilled hands among its members.

To bring this review to an end without further prolongation, we must pass over many other important incidents of this fruitful meeting. The Museum, the organisation of which heavily taxed the energies of Dr. Underhill, was ably conducted by him, and by the Museum Committee, of which he was Secretary, and Professor Turner President. An excellent printed catalogue was prepared by Dr. Underhill, and we shall separately notice its more important contents. The various entertainments provided by the liberality of the subscribers to the Reception Fund, the University, and the College of Physicians, we must pass with a bare reference; and equally so the Dinner, although not without a hearty word of thanks to the Entertainment Committee and their most active Chairman, Dr. Gillespie, whose exertions for the comfort of the members were untiring, and were most successful. The private hospitalities of the leading members of the profession in Edinburgh were both wide-spread and catholic. The *fête* at the Botanical Gardens was rendered especially interesting by the thoughtful labour which Professor Balfour had expended in displaying connected series of its treasures. The excursions were favoured throughout with fine weather, as the whole meeting had been; and the final impression on the minds of all is, that the meeting in Edinburgh in 1875 has been the most successful professional congress ever held in that city, and one which will be memorable in the history of the Association, as having done much to promote a cordial feeling of affectionate unity between the profession in the northern and southern divisions of the United Kingdom. To promote such unity is one of the great purposes of the British Medical Association.

THE ROYAL HOSPITAL, PLYMOUTH.

THE Royal Hospital at Plymouth has been recently severely criticised on some points in its construction and management. Amongst other statements, it is averred that the hospital is built at the head of a tidal creek, into which a certain amount of drainage is received which renders the mud at low tide very offensive; that the windows in the wards are five feet high above the level of the flooring, so that a patient must stand on a chair to look out; that the view obtained from these windows is obstructed by a dead stone wall, instead of comprising the square with its grass and flowers, and the beautiful scenery for which the neighbourhood of the hospital is famous; that a large set of rules, prominent amongst which are instructions to be followed in the event of a patient dying, are hung up in the wards; that when a patient becomes convalescent, he is compelled to take the air in a stone colonnade, running from east to west, and exposed to a sharp easterly breeze; and that the wards present a cold and dreary appearance, more likely to retard than expedite the recovery of a patient who, from the circumstances of the case, is more likely to suffer a relapse than to attain a speedy recovery. We considered these charges of so grave a nature that we have taken some trouble to ascertain the real facts of the case, which we now reproduce.

The hospital at Stonehouse was built in 1760, at which time the tidal creek was not a receptacle for the drainage of the large suburbs which have grown up especially during the last twenty years, and the mud which is now at times offensive has only recently become so from the sewage being allowed to run into it. Besides, the Admiralty and War Department, the Lord of the Manor, and the freeholders of Stoke, Stonehouse, and Plymouth, have interest in this property. The Sanitary Boards have not been idle, and the question of sewage is now under consideration at the hands of an eminent engineer on the part of the Government, who, with the local authorities, is preparing a report on the best means to remedy what is evidently a growing evil.

The height of the windows from the floor is not more than four feet ten inches out of a total of thirty-four feet, being only three feet nine inches above the level of the ward-floors. All the windows were formerly barricaded with iron bars to prevent the escape of the patients, but these bars have all been removed for some years, as, owing to better discipline, the few patients who may be inclined to be unruly are kept under proper restraint without difficulty. The view from the windows extends over the green slope of the glaciis towards Devonport. Again, the ward referred to is only twelve feet high at the highest part, and is—with the exception of one side of the hospital, where the top of the ward is on a level with the middle floor of the building—considerably (six feet) below the window-sills of the lowest parts, its average distance from the main building being eighty yards. None of the regulations referred to are hung up in the wards, although some of them, now obsolete, are placed in the corridors out of view of the patients in the wards. The wards are brighter and more cheerful, with pictures; and a bountiful supply of flowers is to be found in all of them. When a man is convalescent, he is allowed to take his airing in the recreation grounds, where quoits, croquet, and other games are provided; and the stone colonnade is on three sides of the inner quadrangle, where protection can always be found, however great the heat or bleak the wind, and not one of the sides of the colonnade faces due east. In cold weather, the patients prefer to remain in the spacious smoking saloons, where fires are always kept in the winter months.

Such are the exact facts in relation to this hospital at Stonehouse; and it appears evident that the information supplied must have been sent under a misapprehension of the points raised, and without knowledge of the subject treated. We should be sorry to discourage free and impartial criticism; but, if our hospital authorities are to be condemned without good reason, we should do all in our power to discourage and expose such treatment.

Inspector-General Domville has recently been appointed to the Plymouth Hospital, and we have no doubt that any modifications in the system of management which may be considered necessary will, under his able and experienced management, be speedily made, so that little will be left to be desired in this respect even by experienced hospital reformers. We may add, that we have reason to know that the steps already taken to remove the nuisance caused by the drainage into the creek will speedily obviate all cause for complaint in this respect.

THE PORTSMOUTH BOARD OF GUARDIANS.

THE medical officers who serve under the Local Government Board have at all times an arduous and responsible post to fill, and in no town can this be the more the case than at Portsmouth, where the infirmary accommodates 250 patients, and where the medical officer has usually the health of about 1,100 inmates in his keeping. With such demands upon his time and energies, he ought at least to be treated in a considerate manner by the guardians. Generally speaking, this is now the case; but we hear occasionally of unhappy exceptions. Such an one has recently occurred at Portsmouth, where Dr. Diver, who for three years has had charge of the workhouse, and who was "proclaimed one of the most skilful and humane officers in the kingdom", has been subjected to a petty persecution, which has resulted in the loss of his services. We quite agree with a local newspaper in saying, that we do not wish to excuse even the most trivial departures from the consolidated orders; but there cannot be a doubt that most of the allegations so common a few months ago were the grossest exaggerations, and that a highly efficient and attentive officer has at length been driven from his post. Perhaps the best testimony Dr. Diver can receive is that which has already been borne by his workhouse patients, who have manifested their regret at his retirement in the most unaffected and unmistakable manner. We hope this expression of opinion on the part of those who have been so intimately connected with him, will open the eyes of the guardians to the harshness of their

conduct towards their medical officers, and, at the same time, that it will go far to counteract any professional injury which it might otherwise have inflicted upon him.

UNIVERSITY COLLEGE HOSPITAL.

THE vacancies recently caused by the promotion of Dr. Ringer and Mr. Christopher Heath have been filled up by the appointment of Dr. G. Vivian Poore, of Charing Cross Hospital, to be assistant-physician, and of Mr. Arthur E. J. Barker, surgeon to the City of Dublin Hospital, to be assistant-surgeon.

INSTRUCTION IN PSYCHOLOGICAL MEDICINE.

THE following important resolution was adopted by the Royal College of Physicians of London, on July 19th: "That the registrar prepare and submit a regulation to the College, 'That students who wish to qualify for the examination for the membership or license of the College may substitute, if they so desire, a three months' course of clinical instruction in the wards of a lunatic asylum for the same period of attendance in the medical wards of a general hospital.'"

TRIPLET BIRTHS.

M. DEPAUL lately submitted to the Academy the placenta of a triplet born at Bordeaux. The three children were females and were, when the case was reported, still alive and in good health. The placenta formed one entire mass; the three cords were perfectly distinct, one was inserted in the centre of the placenta, another on the edges of this organ, and the third on the membranes. There were three amniotic pouches which were rather difficult to trace on the specimen; but, according to the report of the medical gentleman who forwarded it, there were during parturition three distinct ruptures of the membranes, which took place before the birth of the children. By a remarkable coincidence, the Paris papers have reported that a *concierge* in the fourteenth arrondissement in Paris, has given births to triplets, two boys and a girl. The mother is aged 35, and has been confined for the third time. The boys, who were in the same amniotic sac, were born first, at an interval of an hour between each; the girl, who was in a separate sac, was born half an hour after the last boy. The whole three are alive, well-formed, and sufficiently strong, particularly the first boy and the girl.

RETIREMENT OF ROKITANSKY.

ON Friday, July 16th, Professor Rokitansky delivered his last lecture in the pathologico-anatomical class-room of the University of Vienna, in the presence of a large audience, including many professors and doctors of medicine. Among the guests was, Dr. Ziguin, physician to the Czar of Russia, and chief of the sanitary department in St. Petersburg. Professor Rokitansky, who was received with loud applause on taking his place for the last time, spoke a few words in resigning his post, and said that he should not become entirely inactive. He then delivered his farewell address to his pupils. He explained the essential character of pathology, and commented on the modern direction of science and of the impossibility of resisting progress. Finally, he exhorted his hearers to diligent and conscientious work. He admonished practising physicians to give an academical impress to all their work, and to always remain true to academical principles.

ACTION OF COMPRESSED AIR.

M. BERT has shown, by a long series of experiments, that air compressed to a certain degree kills living beings in a very short space of time. This result, according to M. Bert, is due, not to the pressure of the air considered as a physico-mechanical agent, but to the tension of the compressed oxygen. These researches have led M. Bert to study the effects of compressed air on the different fermentations, and with this view he submitted fresh meat, beaten eggs, urine, wine, and milk, to a strong tension of oxygen, and the result has been that these substances have been kept in a perfect state of preservation. From these facts, M. Bert has deduced the following conclusions, which he sub-

mitted to the Academy of Sciences. 1. Oxygen of high tension effectually stops the fermentation properly so-called, so much so that the process is not resumed on the restoration of the normal pressure; it kills all fermenting agents. 2. Its action on diastasic ferments is unappreciable: notwithstanding the presence of oxygen, they continue to be active for an unlimited period. It will be seen that this new method of analysis may be usefully applied to the study of the blood in malignant pustule or charbon, and the different viruses and venoms of infectious diseases.

TEMPERANCE DRINKS.

WE learn with great pleasure, from a paragraph in the *Times*, that the Committee of the Church of England Temperance Society propose to establish in the crowded and poorer districts of London, wherever suitable accommodation can be obtained, street-stalls for the supply, at a low rate, of light but substantial refreshments, together with tea, coffee, cocoa, and other drinks suited to the varying seasons. Visitors to Munich will remember the temperance stalls in that city. It is intended to establish the stalls in London through the agency of the parochial branch societies, and the object of the movement is to provide for the working classes counterattractions to the publichouses. An experimental stall was submitted to inspection recently at Lambeth Palace. The structure is neat in appearance, compact in its details, and can be easily wheeled from place to place, as the exigencies of trade or the state of the weather may require. The principal objection that can be urged against the stall—regarding it as a competitor of the publichouse—is that persons using it will have no protection either from sun or rain. This might, however, be remedied, by extending the eaves of the permanent wooden roof, or by affixing to it for use, as occasion may require, a projecting screen of canvas or similar material. It was stated that the cost of each stall, together with the necessary fittings, will not exceed £20.

SCOTLAND.

MR. HAWKSHAW, brother of Sir John Hawkshaw, has been making examinations in Port Glasgow and Greenock with the view of ascertaining the causes of the pollution of the tributaries of the Clyde.

THE weather during July was, in Shetland, remarkably fine and dry; with the exception of one or two days, the whole month was unprecedentedly dry and warm. For ten successive days, the sky was cloudless, and the thermometer from 100 to 120 degrees Fahr. in the sun at noon.

THE Summer Session at the University of Aberdeen was brought to a close last week, when the degrees of M.D. and M.B. were conferred on thirty-three and fifty-nine gentlemen respectively. The John Murray Medal and Scholarship were awarded to Mr. Albert Westland, as the most distinguished graduate of his year.

A MEDICAL MAN DROWNED AT MILLPORT.

THE attention of some men who were standing on the new pier at Millport on the morning of August 5th was attracted by a black object in the water. This was found to be the body of Dr. A. D. Kerr, who had recently commenced to practise in the town. When the discovery was made, the tide had ebbed, and the body lay in a shallow close to the pier. It is conjectured that the deceased gentleman, who was for some years a practitioner in Greenock, had accidentally fallen into the harbour.

POLLUTED STATE OF LINLITHGOW LOCH.

AT a meeting of the Local Authority of Linlithgow held last week, the Sanitary Inspector laid before the meeting a communication from the Board of Supervision regarding the present polluted state of the loch, accompanied by a report by Professor Douglas Maclagan, obtained at the instance of Her Majesty's Commissioners of Works. The report bore that Dr. Maclagan, along with Dr. Affleck, had examined the loch on the

27th July, and had since analysed a sample of the water. He had come to the conclusion that the proximity of a town to a still water so largely impregnated with decomposing organic matter must be detrimental to the health of the inhabitants, and especially so in dry and hot weather. The meeting remitted consideration of the matter to a committee, and also instructed the medical officer to draw up a report on the subject.

HEALTH OF LEITH.

THE public health returns of the borough of Leith for the past month show a death-rate of 99, equivalent to an annual mortality of 24 per 1,000. Of these deaths, 10 were due to zymotic diseases; the total number of births in the same period was 186, including 8 illegitimates.

REMARKABLE LONGEVITY.

It has been ascertained that there are living within the bounds of the borough of Crieff, the population of which is about 4,000, no fewer than forty persons whose ages range from 80 to 96 years. Ten of that number are 90 years and upwards, their united ages amounting to 925 years; the ages of the remaining thirty persons vary from 80 to 88 years. The majority of these aged persons enjoy fair health, and are able to walk about.

THE CHAIR OF MEDICINE AT ST. ANDREW'S.

AT the last meeting of the St. Andrew's University Court, a communication was submitted from the Senatus Academicus intimating that the Chair of Medicine in the University had become vacant by the death of Dr. Oswald Home Bell. The Court proceeded to take into consideration the terms on which the Chair had been reconstituted and held since Dr. Reid's appointment in 1841, especially embodied in a minute of the University of that date. The Court unanimously resolved that these terms should be considered to be still in force to the following effect:—That "the Professor shall be a teaching Professor, who shall open classes to be regularly taught during the session of the United College for the instruction of those students who may apply to him in the principles of medicine and anatomy, with a view to make an *Annus Medicus*." The Court further found that the whole correspondence and supervision connected with the system of medical graduation in the University should be considered to be a part of the ordinary work of the Professor. And looking to these duties and the circumstances of the University, the Court were of opinion that the person to be appointed should not engage in the work of a general medical practitioner in the town or neighbourhood, but saw no objection to his engaging in a special or consulting practice.

GIFT TO THE UNIVERSITY OF ABERDEEN.

IT is reported that Dr. James Taylor of Greenskares, Banffshire, retired Deputy-Inspector of Hospitals and Fleets, has conveyed in trust to the University of Aberdeen his estate of Greenskares, for the purpose of founding bursaries in connection with the University for young men born in any of the parishes or educated in any of the schools of Banffshire. The bursaries are to be tenable for four years, of the annual value of £30, and to be determined by competition. The estate is rated in the county books at nearly £400 a year. All steps connected with the conveyance of the trust have been completed.

THE MEDICAL RELIEF GRANT FOR SCOTLAND.

SOME time ago, a memorial was forwarded by the Barony Parish Parochial Board of Glasgow to the Secretary of State for the Home Department, complaining of the small amount of the medical grant for the relief of the poor in Scotland, and of the mode in which it was apportioned. According to the present system, the sum of £10,000 is annually distributed for the medical relief of the poor in Scotland, while for England and Wales no less a sum than £127,000 is annually paid. The other point of complaint was, that the amount payable to Scotland was distributed among the Parochial Boards under the census of 1841, instead of under that of 1871. In consequence of this, from the increase of the population, the Barony and Govan parishes have been for

several years underpaid to the extent of £630 a year. These grievances, however, as will be seen from the following communication, are now likely to be remedied.

Whitehall, July 30th, 1875.

Sir,—Referring to the memorial by the Parochial Board of the Barony Parish of Glasgow, in regard to the amount and the mode of apportionment of the medical grant for the relief of the poor in Scotland, I am directed by the Secretary of State to inform you that the Lord Advocate has advised that next year the amount of the grant should be increased, so that it may bear a more accurate proportion to the English grant for the same object, and that the opinion of the Board of Supervision should be ascertained as to whether it would be proper that the apportionment should take place upon the footing of the census of 1871.—I am, sir, your obedient servant,

(Signed) HENRY SELWYN IBBETSON.

J. Maxton, Esq., 175, St. Vincent Street, Glasgow.

CLOSURE OF GOURROCK GRAVEYARD.

AFTER a prolonged investigation, the Sheriff has found that the Gourrock graveyard is so crowded with bodies, or "otherwise so conducted as to be offensive or injurious to health", and, therefore, a nuisance under the Public Health (Scotland) Act of 1873. He has accordingly decreed that it shall be prohibited as a place of sepulture. The reasons given for this judgment were that the ground was too small for the size of the town, that the graves were not far enough apart from each other, that their depths were insufficient to prevent noxious gases from flowing into the air on the occasion of interments; and that the graveyard could not be conducted, under the circumstances, so as not to be a nuisance to the public health.

THE CHAIR OF MIDWIFERY IN ABERDEEN.

WE learn that the Chair of Midwifery and Diseases of Women and Children in Aberdeen University, vacant by the death of Dr. Inglis, has been filled by the appointment of Dr. Stevenson of Edinburgh. Dr. Stevenson has made so good a name for himself in Edinburgh by solid work done in the department of the Chair, that his appointment cannot fail to be beneficial to the Aberdeen School and satisfactory to the profession in the north of Scotland.

IRELAND.

THE IRISH PHARMACY ACT.

THE King and Queen's College of Physicians have granted the use of apartments in the College for the meetings of the Council of the Pharmaceutical Society, established under the new Pharmacy Act.

STEWART INSTITUTION FOR IMBECILE CHILDREN.

THE half-yearly meeting of the Council of this charitable institute was held last week in Dublin, the chair being occupied by Lord James Butler. From the report of the Managing Committee, it is satisfactory to find that the establishment continues to progress satisfactorily, a large increase over that of the preceding six months having taken place, under the head of pupils' maintenance. The expenses of an institution of this kind are exceedingly heavy, and the last half-year's expenditure was in excess of the income; but a sum has been received on account of the lunatic asylum which covers any deficiency, and leaves a small balance to the credit of the charity. Since last report, six children have been admitted, and the Committee hope to hold another election shortly, as the number of applications for admission is daily increasing. Among those who have helped the institution within the past few months, the name of Mr. P. P. Law may be mentioned, having given a donation of £500 to the general fund; legacies have also been received of £100 to the general fund and £100 to the building fund from the late Miss S. D. Pilkington. The Committee have completed a contract for the erection of the new building at Palmerston, and the work is now proceeding satisfactorily, and it is expected that it will be ready for occupation in the course of next year.

DUBLIN DAIRY-YARDS.

SOME of our readers may recollect that in September 1871, Mr. Benson Baker published in our columns an account of a sanitary tour in Dublin. In that article, Mr. Baker specially referred to the nuisances arising from the Dublin dairy-yards. It appears that nothing has since been done to abate these nuisances, and that, in spite of the law, a large number, probably 5,000 dairy cattle, are kept "so as to be a nuisance and dangerous to health" within the city of Dublin. It appears that the sanitary authority of Dublin is as unwilling as ever to interfere with the liberty of the dairymen to injure their neighbours and poison Dublin babies with diseased milk, but that the authorities of Mercer's Hospital are determined not to have their patients injured, so have complained to the Local Government Board about a large and filthy dairy-yard next to the hospital. The Public Health Committee, as usual, say *non possumus*, but the matter having been brought under the notice of the Committee of the Dublin Sanitary Association, the following proceedings took place. A report recently issued by the Public Health Committee of the Corporation of Dublin relative to an alleged nuisance existing in immediate proximity to Mercer's Hospital, and arising from an overcrowded and filthy dairy-yard, having been brought under the notice of the committee, it was resolved:

"That this committee is of opinion that the keeping of cattle in such a locality is in itself a nuisance and injurious to health within the meaning of section 8 of 18 and 19 Vic., cap. 121 (Public Health Act, 1866).

"That it is desirable that the keeping of cattle in the proximity of a hospital or other inhabited building should at once be prohibited.

"That this prohibition is especially called for in the case of a hospital, the inmates of which are necessarily in a low state of health, and therefore unable to resist the inroads of preventable disease."

We have not space further to refer to this matter, but the authorities seem to be shielding the dairymen.

THE GOVERNORS OF THE DUBLIN HOSPITAL FOR INCURABLES AND POST MORTEM EXAMINATIONS.

At a meeting of the Governors of the Dublin Hospital for Incurables, held on July 28th, to consider a motion to rescind a resolution passed at last meeting against having *post mortem* examinations in the institution, there was a large attendance of governors, Frederick Stokes, Esq., in the chair. Dr. Baxter, in an able and elaborate speech, showed the advisability of, on certain occasions, having such *post mortem* examinations, and moved a resolution to that effect. He was seconded by Adam Findlater, Esq., J.P., and by Drs. Stewart, Mulock, and Granby Burke. On the other side, Mr. Thomas Dockrell gave a very striking illustration of bad effects in a case of which he had knowledge. Mr. Kelly and Dean O'Connell, and Mr. John Wardell, were also against the practice of dissections. Mr. Richard Allen was against the system generally, considering that the feelings of entering patients should be respected, but there were cases, he said, in which it might be necessary for the benefit of science and suffering humanity. The chairman particularly called the attention of those present to the fact that the institution was not an hospital in the hospital sense of the word. The doctors had in most cases exhausted all their skill and ingenuity on the cases before admission, and, in fact, they should be incurable before being entitled to a home in the institution. The chairman then moved an amendment to the effect that in no case, either by medical officers in the institution or by any other, should dissections be allowed, on pain of dismissal of any officer assisting. The resolution was put to the meeting and declared to be carried.

REPORT OF THE LOCAL GOVERNMENT BOARD FOR IRELAND.

FROM the annual report, 1874-75, lately issued, we learn some matters which may be of interest to our readers. During the year, the total number of deaths in the various workhouses amounted to 11,119; the number from fever being 762, whilst the mortality from small-pox caused 142 deaths. The deaths from this latter disease in all Ireland were 540, and the importance of early vaccination cannot be too

strongly impressed upon the sanitary authorities and the poor, because of the very large proportion of the entire mortality from small-pox that falls on the first five years of life; viz., four-fifths. It is, therefore, unsatisfactory to find a continuous decline in the number of infants vaccinated each year from 109,222 in 1872 to 100,061 in 1873 and to 96,850 in last year. The cases of medical relief afforded under the Medical Charities Act for the year amounted to 687,165, of whom 186,138 patients were attended to at their own homes, and the remaining 501,027 at the dispensaries of the various unions. As regards visiting-tickets, the Board has called attention to the matter on former occasions, in the hope of thereby procuring the abatement of an abuse in the issue of tickets for dispensary relief; and they consider that there must be far too great laxity in Leinster, Munster, and Connaught in issuing tickets and in cancelling those bestowed upon improper objects. The only check provided by the Medical Charities Act against the abuse, consists in the power given to dispensary committees to cancel such as they consider to have been bestowed on persons whose circumstances might enable them to procure the services of private practitioners. The abuse in question injures the private practitioners, the ratepayers, at whose expense the medicines and medical appliances are provided, and the recipient, who is demoralised by accepting gratuitous relief to which poverty gives him no just claim. During the year, midwives were appointed in four dispensary districts, and regret is expressed that the appointment of these most useful officers has not more frequently been applied for. The number of persons vaccinated amounted to 139,587, of whom 20,250 were over ten years of age: a proof that the wisdom of re-vaccination about the time of puberty is beginning to be understood by the lower classes. The expenditure for medical purposes came to £140,992, being an increase of £1,752 over that of the preceding year, and equal to 2.51d. in the pound on the Poor-law valuation of £13,449,553. In reference to the Public Health (Ireland) Act, 1874, the Board regret that much disinclination has been evinced to compensate the medical officers of dispensary districts for the additional obligations cast upon them by this Act, and state that considerable delay took place after the operation of the law in October last, before sanitary authorities, both urban and rural, could be induced to comply with their views in regard to the salaries. The Act has, however, notwithstanding the question of remuneration, been for some time past almost universally in operation; and the records of proceedings show great activity in the removal of nuisances and in other sanitary operations, especially in the supply of pure water to towns and villages, and the improvement of the sewerage.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

THE KENSINGTON MEDICAL OFFICER OF HEALTH.—At the last meeting of the Kensington Vestry, the salary of Dr. Dudfield, the medical officer of health, was by an unanimous vote, and in terms indicating a hearty appreciation of his services, raised from £300 to £400 *per annum*.

VACCINATION.—Mr. J. Acworth Angus, Public Vaccinator, Western District of the Newcastle-upon-Tyne Union, has been awarded for efficient vaccination the sum of £54 3s. from the Local Government Board. Mr. Jonathan Dalgliesh, of the same district, has received £43 16s. This is the third time of receiving the grant.—Mr. W. A. Sumner, Public Vaccinator for St. Marylebone, has been awarded £149 18s. (second time) by the Local Government Board for the efficient manner in which vaccination has been carried on at his stations.—The Local Government Board have awarded to Mr. John Berry the sum of £19 1s. for efficient services rendered as Public Vaccinator for the Leyland District, Chorley Union.—Mr. T. Wells Hubbard, of Lenham, Kent, has been awarded a grant of £8 14s. by the Local Government Board, for efficient vaccination. This is the second time Mr Hubbard has received the extra grant.

FORTY-THIRD ANNUAL MEETING
OF THE
BRITISH MEDICAL ASSOCIATION.

Held in EDINBURGH, August 3rd, 4th, 5th, and 6th, 1875.

SECOND GENERAL MEETING, WEDNESDAY, AUGUST 4TH.

THE second general meeting of members was held in the Chemistry class-room of the University. Dr. FALCONER, the President of Council, took the chair at the opening of the meeting, in the temporary absence of the President.

Place of Meeting for 1876.—Dr. FALCONER reported that, at the meeting of Council held in the morning, two places had been proposed for holding the next meeting of the Association. A large majority were in favour of the next meeting being held at Brighton in 1876, and that the President-elect should be Sir John Cordy Burrows. He moved a resolution accordingly.

Mr. HUSBAND (York) seconded the motion, and said he was sure it would be adopted.

Dr. MARSHALL (Clifton) said that, before this motion was carried, it would be right that the Association should be put in full knowledge of all the circumstances connected with that recommendation, and it ought to be mentioned also that the invitation from Brighton was by no means unanimous. Indeed, he was led to understand that a special request had been made that the meeting should not take place at Brighton next year. Considering the statement made by a considerable minority that there were local reasons which rendered it undesirable that the meeting of the Association take place at Brighton before 1877, and also taking into account the very cordial and warm invitation which they had had from the whole profession in Liverpool, the invitation being signed by between ninety and one hundred medical men without a dissentient voice, he felt warranted in proposing that the invitation from Liverpool be accepted for 1876 in preference to that from Brighton.

Dr. A. P. STEWART seconded the amendment. He thought it had been a wholesome and a very proper rule that, where there was any division of opinion in a proposed place of inviting the Association, the visit should not be to that town. [*Hear, hear, and applause.*] The reason why they had not met at Brighton some time ago was the same as that now urged—namely, that there had been a division of opinion as to the propriety of the Association being invited there. He did not think it would be becoming in the Association to accept an invitation where there was even the slightest diversity of sentiment among the members of the profession; and when they had an unanimous invitation from Liverpool, it was their duty to accept it.

Dr. A. B. STEELE (Liverpool), as representing the Lancashire and Cheshire Branch of the Association, which Branch comprised the town of Liverpool, appealed to Dr. Marshall and Dr. Stewart to withdraw their resolution. Liverpool had, he said, sent a cordial and unanimous invitation for next year, and they should be quite prepared to do the same thing another year when there was a vacancy; but they had no particular predilection in favour of 1876. [*Applause.*] A long time had elapsed since the Association met in Liverpool, and the profession there were beginning to think that their claim ought to be considered, but they did not desire to press it on the present occasion, and under existing circumstances. Whatever difference of opinion existed in Brighton now, might possibly, on a future occasion, exist in Liverpool; but, even should that occur, he thought they should always be able to bring from Liverpool a largely supported invitation. He was sure he was expressing the feelings of the Liverpool deputation when he asked that the amendment should be withdrawn, as Liverpool would be extremely sorry to be the means of introducing anything like dissension upon a point on which there ought to be unity. [*Applause.*]

Dr. MARSHALL, thus appealed to, said he was in the hands of the meeting, though of opinion that it would be very undesirable to go to a place where they were told they were not wanted.

The PRESIDENT said that, listening to the sounds that were emanating from the meeting, he thought a very large majority were inclined to go to Brighton. A little difference of opinion in the medical profession was a thing they need not at all wonder at. [*Laughter and applause.*] There might be reasons for the difference of opinion in Brighton which would disappear in a short time. There had been a difference of opinion in regard to the meeting of the Association in

Edinburgh at this time. He was one of those who had thought that the meeting there should be delayed for three years, that they might be able to present to the Association the new Infirmary in full working order, and the new medical College, where they would have had ample accommodation for their meetings, though they might even appear in the proportion of 2,500 members. But he had yielded to the wish that the Association should at once come to Edinburgh.

A show of hands was then taken, when a very large majority declared in favour of Brighton.

President of Council.—Dr. SIMSON (London) reported that the Council, at its meeting that morning, had resolved that Dr. Falconer, who had been for many years Treasurer of the Association, should be elected President of the Council, in room of Mr. Southam, whose term of office had expired.

The PRESIDENT said he had received a letter that morning from Mr. George Southam, which he thought was intended to be communicated to the meeting. In this letter, Mr. Southam expressed his regret that his continued illness, although somewhat alleviated, would prevent his being present at the meeting of the Association, and handing over personally his office to his successor. He had accepted the appointment with much diffidence, knowing the responsibilities attached to the office and the difficulties surrounding it; but he rejoiced at being able to congratulate the Association on its present prosperous condition. He reflected with pleasure on the facts that the membership had been increased from 4,200 to 6,100 during his tenure of office, and that the finances had been considerably augmented, and placed on a new and satisfactory basis. He spoke of the grants made for the encouragement of science and the incorporation of the Association. He referred to the large and important gatherings at London and Norwich, and to the arrangements made for holding an equally successful one at Edinburgh. He acknowledged the valuable assistance given by his colleagues in the Council, and concluded by expressing a hope that, if spared, he would be able to take the same active interest in the affairs of the Association he had hitherto done.

Vote of Thanks to Mr. Southam.—Dr. FALCONER moved: "That the best thanks of the Association are due, and are hereby given, to Mr. George Southam, F.R.C.S., for the able and courteous way in which he has discharged the onerous duties of President of Council for the past three years, and that he be and is elected a Vice-President of the Association." Only those who had been associated with Mr. Southam could form a true estimate of his attachment to his work, and of the thoroughness with which he performed it. They regretted extremely that circumstances had prevented him from completing his three years' term of office.

Dr. CHADWICK (Leeds) having seconded the motion, it was agreed to unanimously.

Vote of Thanks to Dr. Falconer.—Mr. ALFRED BAKER moved: "That the best thanks of the Association are due, and are hereby given, to Dr. Falconer for the way in which he has discharged the duties of Treasurer to the Association for the past nine years, and that he be and is hereby elected a Vice-President of the Association." When Dr. Falconer took the office of Treasurer, the condition of the Association was very different from what it was now, and the position of Treasurer was one which must have caused a constant call upon his time, and given him, indeed, much anxiety. Dr. Falconer had, besides, shown the greatest interest in the annual meetings of the Association, and in the conduct of its general business, and the honour of being a Vice-President had not been more thoroughly earned by any one. [*Loud cheers.*]

Sir J. C. BURROWS (Brighton) seconded the motion; and said that, when Dr. Falconer undertook the position of Treasurer, the Association was in debt, and he had the satisfaction of leaving it in a most satisfactory financial condition. The contrast was, indeed, great between the time when Dr. Falconer took, and when he resigned, the Treasurer-ship: then the Association was in a condition which caused alarm to its friends, now it had a balance at its banker's.

The PRESIDENT said he should take it that the motion was carried by acclamation. [*Loud cheers.*] He had a strong fellow-feeling with Dr. Falconer in this matter, as he (Sir Robert Christison) had held the same office in the Edinburgh University. He knew the great trouble it cost to keep out of debt, in particular in consequence of the many demands made upon the funds. He had hitherto been successful, like Dr. Falconer, in keeping the University out of debt, and of seeing its funds largely increasing year after year; and he hoped the same would be the case with the successor of Dr. Falconer.

Dr. FALCONER could not allow the motion to be carried without expressing his thanks to the Association for the appointment they conferred on him nine years ago. It was perfectly true that the finances at that time were very narrow, but they must not attribute to him the present

prosperous condition of the funds. They had had a good Finance Committee and a good Committee of Council; and he must not omit to mention the name of the General Secretary—[*applause*]—who had ably assisted him in every possible way. It was now his (Dr. Falconer's) duty to resign the office of Treasurer into the hands of the Association; and though he retired from the office with some regret, he found himself in a position in which he hoped his labours would still be useful to the Association. [*Applause.*]

Election of Treasurer.—Dr. SIBSON proposed that Mr. Husband of York be elected Treasurer of the Association for the next three years. [*Cheers.*] Mr. Husband had taken a very active and intelligent part in the affairs of the Association for many years past; and in Mr. Husband the Association would have a Treasurer who would be most careful of the funds—who would take care that every shilling due to the Association was collected and passed to the bankers, and every shilling in the bank was only expended in a proper direction. [*Cheers.*]

Dr. FALCONER seconded the motion, and said the appointment of Mr. Husband to this position would be most gratifying to him. [*Cheers.*] The motion was unanimously carried.

Mr. HUSBAND thanked the Association for the vote; and said that he feared that, now the Association was in a prosperous condition, demands of a heavy character for grants would be made; but he trusted that moderation would guide them in all things. He had now to propose a vote of thanks to Dr. Sibson for having taken up the duties of the office of Mr. Southam in his absence through illness, and for the able manner in which the work had been carried on. The motion was certainly only one of form; for everyone who came into contact with Dr. Sibson had for him the highest respect, and all knew the active part he had taken in the executive duties of the Association. [*Loud cheers.*]

Dr. CHADWICK (Leeds) seconded the motion; and said that, having known Dr. Sibson for many years, and having watched his untiring energy in all the affairs of the Association, it gave him great pleasure, and, indeed, he felt it an honour, to second the motion for a vote of thanks to this gentleman for these specially arduous services. [*Cheers.*]

The PRESIDENT asked that the vote should be carried by acclamation; and the meeting, with loud cheers, assented.

Dr. SIBSON acknowledged the vote.

Members of Committee of Council.—Dr. FALCONER reported the election of the following twelve members in the Committee of Council for 1876:—T. Clifford Allbutt, M.D.; J. W. Baker, Esq.; G. W. Callender, Esq., F.R.S.; A. Carpenter, M.D.; J. Matthews Duncan, M.D.; B. Foster, M.D.; E. L. Fox, M.D.; R. Harrison, Esq.; G. F. Hodgson, Esq.; T. Holmes, Esq.; J. R. Humphreys, Esq.; F. E. Manby, Esq.; E. Morris, M.D.; R. Quain, M.D., F.R.S.; T. H. Smith, Esq.; T. Underhill, M.D.; W. F. Wade, M.B.; A. T. H. Waters, M.D.; C. G. Wheelhouse, Esq.; and Eason Wilkinson, M.D.

Election of Honorary Members.—Dr. FALCONER moved that the Right Hon. John Inglis, President of the Court of Session, and Chancellor of the University; the Right Hon. Edward Strathearn Gordon, M.P., Q.C., Lord Advocate for Scotland; and the Right Hon. Lyon Playfair, M.P., be elected honorary members of the Association. [*Applause.*]

Sir JOHN CORDY BURROWS seconded the motion, which was unanimously agreed to.

The Admission of Lady Members.—Mr. PEMBERTON (Birmingham) said he wished to bring under notice the subject which he brought before the meeting on the previous day. It would be in the recollection of those present on the previous day that he referred to the names of two ladies who had their names down for papers to be read, and he presumed they were members of the Association. How they became so—whether by a vote of the Committee of Council, or by the vote of any Branch—he did not know; but he thought that on a question of this kind the voice of the Association should have been taken previously. [*Hear.*] He was not here to-day to say whether the matter commended itself to his judgment or whether it did not; whenever that became a matter of discussion, he should be prepared to express his own sentiments. As far as he read the rules of the Association, the members were only described as “he” or “him”, and not as “she” or “her”—[*laughter*]—and he therefore moved: “That it be an instruction to the Secretary, between now and the next annual meeting, to issue a circular addressed to every member of the Association, requesting an opinion, ‘yes’ or ‘no’, as to the admission of female practitioners to membership.” [*Applause.*]

Dr. MARSHALL (Clifton), in seconding the motion, took occasion to say that the members of the Association must be content at their annual meetings to spend some little time in business as well as in mere complimentary speeches. The previous day they performed the astounding feat of passing their Report, which few knew and but few had read.

They left it to the Committee of Council to do their duty for them, and thanks were due to the Committee for doing it so well. Still, at these annual gatherings, the members ought as a whole to express their opinion and take account of what had been done. [*Hear, hear.*] During the past year, two ladies had been admitted members of the Association—whether by the Committee of Council or by a local Branch he did not know—but, in either case, he thought a great liberty had been taken with the rules of the Association. [*Hear, hear.*] This was a matter of which those residing in a place like Edinburgh could hardly estimate the importance to the members of the Association generally. In Edinburgh, they had their medical societies to discuss medical topics; but those living in large English towns had no other medical society but this, the British Medical Association, and the election of lady members changed the whole position. Now, without entering into the merits of the case, he thought so important a change should not have been taken without thoroughly ascertaining the feeling of the entire Association. [*Hear, hear.*] He knew he might be told that it was open to any individual Branch to say whether or not any member of the profession should be a member of that Branch; but, if it was the opinion of the Association that there should be female members of the profession, let that be ascertained, and then there would be an end of the question. [*Hear, hear.*] In his own neighbourhood, there was a lady practising medicine, whose professional acquirements commanded the greatest respect, and he was glad to say that she was meeting with much success. [*Hear, hear.*] But he should think that, if she became a member of the Bristol branch, their discussions would be hampered, and their social gatherings would become much more formal. If the general principle were carried, and women were to be eligible, this lady would be a most proper person, and he should be happy to propose her name. He hoped the general feeling of the Association would be taken on the subject, and he cordially seconded the motion.

Dr. A. P. STEWART stated that Mrs. Garrett Anderson, one of the ladies referred to, was admitted in due form by the Metropolitan Counties Branch, and he had great pleasure in proposing her name—[*hear*]—not that he approved of the general principle of lady doctors, but because the rules admitted any legally qualified member of the profession, and as she was a legally qualified member he did not see how she could be kept out from membership.

Dr. CARPENTER (Croydon) submitted that in point of order such a resolution could not be put. This meeting was held under the by-laws which required seven days' notice of a motion, and the agenda paper was to be the guide of the business to be transacted. It was therefore necessary to have notice given of this matter for discussion. They had on the previous day passed by-laws giving the Association a proper legal standing. They were now binding upon the Association, and one of these stated distinctly that seven days' notice must be given of any matter on the agenda paper. It was, therefore, not competent to pass that resolution at all. It could not be put from the chair legally, but must be retained to be discussed at the next meeting of the Association on notice given. Whatever resolution on this question was passed would not be binding upon the Association. He moved that Mr. Pemberton be requested to give notice of his motion.

Mr. ERNEST HART reminded the Association that the by-laws had been approved of by the Board of Trade for the purpose of the Association's incorporation. If it were competent for them to pass a resolution against lady members, it would be necessary to submit it to the Board of Trade for approval. This would be asking that a disability should be imposed upon the members, for they could now admit or refuse a legally qualified member of the profession, but the resolution against lady members would have them say that they should not have this power; that the power should be taken away. If at any future time a considerable number of ladies were practising they might wish to admit them to the Association, and they would then require to go and get the disability removed which some wished to impose.

The CHAIRMAN said he had taken the advice of those better able to judge than himself, and had ascertained that the motion was in order.

Dr. STEELE asked that the resolution should be again read. This was done; and Dr. Steele said the resolution involved no point whatever regarding the constitution of the Association. Surely the Association could give instructions to its Secretary without seven days' notice of the motion. He supported the motion; and when the Association obtained the information—the “yes” or “no” asked—it would be quite time to consider whether any alteration should be made in the constitution of the Association.

Dr. YELD (Sunderland) said the resolution ought to be put.

Dr. SIBSON said he did not see why such a motion should be objected to.

Dr. CARPENTER said he would withdraw his amendment; and the motion by Mr. Pemherton was then carried.

The Address in Medicine was delivered by Dr. WARBURTON BEGBIE. It was published at page 164 of last week's JOURNAL.

Dr. GAIRDNER (Glasgow) moved—

"That the best thanks of this meeting are due, and are hereby given, to Dr. Begbie for his able and interesting Address in Medicine." He commenced by addressing the assemblage as "ladies and gentlemen", saying that he was sure the good sense of the meeting would permit him to acknowledge the presence of lady members. [*Cheers.*] To him had been entrusted the duty of moving a formal vote of thanks to Dr. Begbie for his address [*cheers*]; and, though this motion was formal, it must be accompanied by some remarks. As to the address itself, the attentive faces around the theatre during its delivery were the criticism and the proof of its great excellence. [*Cheers.*] He did not venture to criticise further that address; but there happened to be one or two things to be said of Dr. Begbie, and no one could say them better than one who, like himself, had known Dr. Begbie under many circumstances. It so happened that they rose within a few years of each other—pursuing studies at the same time, lecturing together in the same place to students who very often passed over from one to the other, and this for fourteen or fifteen years; and it was simply a matter of fact that, in an atmosphere charged with medical storms, and under circumstances in which they differed in opinions, no shade or shadow had ever passed between them as regarded each other; and that was a circumstance upon which they could congratulate each other. [*Cheers.*] The speaker then dwelt upon the modesty of Dr. Begbie, as shown by the impersonal character of his address, when it might have been more personal. Dr. Begbie had shown that the ancients had not done all, but that they had left something for the moderns to do; and much of what they had not done had been accomplished by Dr. Begbie.

Dr. RUSSELL REYNOLDS seconded the motion, and said the address had been of a most interesting and instructive character. [*Cheers.*]

The motion was carried by acclamation, and the meeting closed.

THIRD GENERAL MEETING, THURSDAY, AUGUST 5TH.

THE third general meeting was held in the Chemistry Class-room of the University at 10 A.M.

Report of the Committee on Qualifications in State Medicine.—Dr. FALCONER presented the report.

Dr. A. P. STEWART (London) moved "That the report be received and adopted, and that copies be forwarded to the General Medical Council." He reminded the meeting that the subject came before the Association in consequence of a committee named on the motion of their much esteemed friend Dr. Rumsey, who was indefatigable in this work, but was now laid aside by illness. All knew how great had been that gentleman's services to public medicine; but in this last work before his illness he had done the profession the greatest possible service. [*Hear.*] The members of the Association were all as one upon the necessity of having specially trained men as medical officers of health. There were not at present a large supply of gentlemen specially qualified for this work, and they thought it right to look forward to the time when, by the five years' clause in the Public Health Act of 1872, it would fall to local authorities to make their appointments anew, with the view of providing for having a number of men thoroughly trained for the special purpose of attending to the public health. He thought this object would be well met by the articles which had just been read.

Dr. CARPENTER (Croydon) seconded the motion. The subject, he said, was one which must be acknowledged on all hands to be of great importance. It would be seen from the report that it was recommended that all medical men in attendance on the poor of this land should have a certain fair knowledge of the principles of public hygiene. Now, it seemed to him to be absolutely necessary that those who were most likely to come into contact with that class of disease which was styled the filth disease should have a fair knowledge of its causes, and that they, of all people, should have some knowledge of public hygiene. It was also considered necessary that every man who entered the portals of their profession should be capable of attending to the poor, and therefore it followed that every man should have a knowledge of the means for the prevention of disease. But it followed from this that it was not absolutely necessary that every medical man should make the subject of State Medicine a special study, because it was one, like every other branch of the profession, of which a life devoted to it would not give a man time to get a perfect knowledge; and it followed, therefore, that there was a necessity for officers who should devote special attention to the prevention of disease. It followed as a natural sequence from this, that those who took up the subject of State

Medicine for the prevention of disease should have an opportunity of obtaining a proper recognition of their knowledge after an examination held for the purpose. Having obtained such a certificate or diploma, the holder of it should be entitled to have an opportunity of registering it, and provision for all these points was included in the report. The report went to the root of the matter, and those who took up this subject would be likely to have their claims to recognition observed. The object of the Association now was to bring the subject under the attention of the Medical Council, who, he hoped, would consider it and carry the recommendations.

The motion was unanimously adopted.

Report of the Joint Committee of the British Medical and Social Science Associations.—Dr. A. P. STEWART presented this report, which is published at p. 202.

Dr. CHADWICK (Leeds) moved "That the report be received and adopted, and the committee reappointed, with power to add to their number". He said that those who had attentively listened to the report would find sufficient evidence in it that it vindicated itself, and that those who composed the committee had been diligently and assiduously discharging the functions committed to their charge. The report also justified the proceedings which the resolution of the Association contemplated, and showed that those gentlemen were ready and willing, when defence was required, to uphold the position they had previously occupied, and to allow no upstart statesman or other person, anxious to decorate himself in other than his own feathers—[laughter]—to usurp the position of critic with the words they have provided for him. [*Hear.*] The report concluded with a delicate and very proper reference to the loss of service the committee had sustained by the illness of Dr. Rumsey, one of its most active members, and a gentleman who had given a lifetime to the service of the public to the neglect of his own proper needs, illustrating the present position of affairs, and pointing the moral that it would be far better for such statesmen as those to whom he had referred to exercise their powers in providing something like an adequate remuneration to those who worked for the State, rather than taking the bread out of their mouths, and casting it to the dogs. [*Hear.*] Knowing Dr. Rumsey's private worth and the self-sacrifice with which he had so long devoted himself to the public service, he hailed with pleasure the reference made to him, which, while it in no way touched the high position he had attained, showed that they were not insensible to his merits.

Dr. T. CLIFFORD ALLBUTT (Leeds) seconded the motion, and said that, while the committee had avoided anything like a vexatious interference with the State affairs, it was apparent they were ready to take action when the opportunity offered. It was apparent now that, after all these years' fighting, the country was ready to accept the views of the Association as to the necessary qualification of the health-officers.

The motion was carried unanimously.

Scientific Grants.—Dr. FALCONER read the report of the Scientific Grants Committee (see page 202).

Dr. HEATON (Leeds) moved "That the report be received and adopted, and that a grant of £300 be made for the year 1876, in accordance with the recommendation of the report." He said the members of the Association knew so well what good work had been done as the result of the money grants made by the Association in former years, and they also knew so well the interesting and important matters which had been and were still under investigation, and the distinguished ability of the men to whom the various investigations were entrusted, that he was sure they all felt satisfaction in adopting this resolution. [*Hear.*]

Dr. MORTON (Glasgow) seconded the motion, and added that his only regret was the sum was not larger.

Mr. HUSBAND (York) said, in reference to the remark of the last speaker, that he believed the Association was willing to make as large grants as might be necessary for the investigations of science, and would do so when scientific men were unwilling to make those investigations themselves; but hitherto the grants made—and the facts reflected the highest credit upon scientific men—had been more than sufficient. [*Cheers.*]

The motion was carried.

The Address in Surgery was delivered by JAMES SPENCE, F.R.S.E., Professor of Surgery in the University of Edinburgh. It is published at page 189.

Dr. G. H. B. MACLEOD (Glasgow) moved "That the best thanks of the Association be given to Professor Spence for his able and interesting Address in Surgery."

Mr. SPENCER WELLS seconded the motion. Referring to the criticism which had been passed upon the antiseptic system, he said that the criticism must, from the spirit in which it had been given, result in the greatest good to science. [*Cheers.*]

After some remarks from the PRESIDENT, the motion was unanimously carried.

The Sections met in the afternoon.

FOURTH GENERAL MEETING, FRIDAY, AUGUST 6TH.

The Address in Physiology was delivered by WILLIAM RUTHERFORD, M.D., F.R.S.E., Professor of the Institutes of Medicine in the University of Edinburgh. An abstract of it is published at p. 198.

DR. BURDON SANDERSON moved

"That the best thanks of the Association be given to Professor Rutherford for his able and interesting Address in Physiology."

He said that the subject of vivisection, to which Dr. Rutherford had referred, was one which could not have been avoided, for it was a subject which at present moved the heart of certain classes in this country, more particularly in England, to an extent of which, he dared say, the Scotch people, less moved by emotional considerations, could hardly form a just conception. If there were any present who felt with those now engaged in agitating this question—and he had no doubt there were some present who felt a great deal for the poor animals, the last days of whose biographies were written in the tables before them—he would draw attention particularly to the statement made by Dr. Rutherford—namely, that in the experiments used in illustrating the processes of physiology for purposes of teaching, it was possible to demonstrate all the great facts—particularly that all those very great fundamental facts which had made the last twenty years more notable in the history of science, excepting those of Galen, Harvey, and Haller, might certainly be exhibited to students in animals altogether free from suffering. [*Applause.*] He was not quite sure, however, but that if Dr. Rutherford had omitted this his first argument, they should all have felt that the evidence he had given in the results of his researches would have carried conviction to all. If there were any objector present he should say, *Si monumentum queris, circumspice.* They had the results of his researches relating to questions in which they were all personally interested. The merit of such investigations no one was disposed at all to doubt, for it was by means of such investigations alone that they could attain an answer to that question which of all others interested them most in physiology, or in fact in any of the applications of science to medicine—the question, How did those agents, of which they had a vague knowledge by means of their experience in medicine, affect the great functions of the body? If there were any one present who thought this a question of very little importance, he could only say he was very sorry for such a person: but he was sure there was no one who would so regard the question. [*Cheers.*] They all must feel that it was of immense importance to them that those truths which they were using daily in practice should be known to them, not merely by the knowledge they gained from experience, but also by that kind of knowledge which could only be obtained by the application of scientific methods of investigation; so that, as regarded the experiments of which they had been hearing an account, the only question was whether they had been performed with all that skill and judgment which were necessary in order that the best results might be obtained, in order to insure that for every grain of suffering which was inflicted on the animals which were the subjects of investigation, there might be got an equivalent of valuable knowledge. In the present instance, there could not be the slightest doubt that the knowledge gained was of the most important and most valuable kind: let them, therefore, put it down as their principle, that not only in this Edinburgh school—for it was already there—but in every other school of medicine also, the best methods of instruction should be used, the best apparatus and best experimenters employed, and the best teaching in physiology given. And then, if that was so, if they showed that they were doing their work in the most efficient manner, that they had before them an earnest purpose, that they had the highest possible motive—and there was no motive so high as the desire to increase knowledge for the benefit of the race—they might feel perfectly certain that those wise persons who were engaged at present in considering the subject would not only be guided by motives of humanity, but would also afford evidence of a sagacious consideration of the necessities and requirements of the case. He had himself the most profound confidence in the sagacity of the Legislature: not that that body never made mistakes, but generally, when it was well informed, it acted with judgment. All they had to do was, he believed, to secure that perfect information might be given to Parliament, and then they might be quite sure that, if there were legislation, the results would be such as would further and protect science, not tend to its destruction. [*Applause.*]

DR. STRUTHERS (Aberdeen), in seconding the motion, said it was evident that results of the greatest importance to practical medicine were flowing from physiology; and it was equally evident that the great

science of physiology, in the hands of Dr. Rutherford, was most ably represented in this University. [*Applause.*]

SIR ROBERT CHRISTISON—I am sure you will authorise me to thank Dr. Rutherford for his most admirable paper, in which he has shown the cause of error in previous investigations. This is one of the fruits of vivisection. [*Applause.*] I understand there was a great shyness to broach this question of vivisection at the present meeting. I think that was a great mistake. It ought to have been made, in my opinion, a prominent question. It has been made a very prominent one with the public, who are completely in error in every respect regarding it—[*applause*—and therefore we should have taken advantage of this great meeting to show where the truth lies, because the truth can be shown by a few of those who have been engaged in vivisection all their life, in a few words. And, late as it is, I will show you how I think I can put down the matter at once. I put it down by the system of cross-questioning, by which I have been a good deal tormented in the course of my life as a witness, and I shall give all those who are so desirous to put down vivisection, in brief words, a history of vivisection. When I went to Paris after graduating, and staying in London, I found all scientific Paris resounding with the recent experiments of Orfila on toxicology, by which he at once erected toxicology into the dignity of a science; and not only so, but, as is the invariable result of scientific investigation, he indicated most important practical results of his extensive experiments. I venture to say that there is not in the whole history of experimental medicine or vivisectionism so long, so numerous, and protracted a series of medical experiments as those performed by Orfila. But we know the result. Would any one wish that these experiments had not been made? I should think there can be but one answer to that question. [*Applause.*] A very short time before I went to Paris, in the same way, a great noise was made in the scientific world by experiments upon animals as to nutrition by substances which did not contain azote, upon which has been founded the accurate dietic treatment of gout and gravel. I would like to know if the gravelly people who are antivivisectionists would desire these experiments undone, and that we should still be in ignorance of the proper dietary for gravel. [*Applause.*] Coming to myself, I conducted a series of experiments at one time as to oxalic acid, in the course of which we found the cause of the difficulty that had been found in treatment with oxalic acid. We found that it produced two sets of consequences, one corrosion and irritation, and the other a most powerful action on the brain and spinal cord; and it was found that, while certain antidotes destroyed the corrosive action, they made no impression upon the action on the nervous system, which was the source of danger. When the acid was neutralised by an alkali, the irritation and corrosion were put an end to, but without altering in the least the effect on the nervous system or the tendency to death. Here, then, was pointed out the practical conclusion that, in the treatment of poisoning with oxalic acid, we must not use alkalies, but must take the chemical counter poisons which produced an insoluble substance. Would any one desire that these experiments should not have been conducted? [*Applause.*] Not long afterwards, in criminal trials, it came to my lot to inquire what was the duration of time between the administration of hydrocyanic acid and death. I made experiments upon animals, and found that when a large dose was given death ensued in four seconds. I do not suppose that these experiments would be much regretted, because they inflicted a very short torture upon the animals. Then, in the next place, there was a remarkable criminal action from an offence committed in the north of Scotland. The charge was that of poisoning with the laburnum bark, and I was consulted by the Crown in the matter. Curiously enough, nothing was known about the action of the laburnum bark. It was known that the seed, the flowers, and the leaves were poisonous; but no experiments had been made as to the bark. You might form a probable conclusion on the matter; but in a criminal prosecution a probability will not do. I therefore found it necessary to make experiments, and I found that when the bark was used it was a most powerful and most remarkable poison indeed. I do not suppose that any one would desire that these experiments had not been performed, when in this way you can either establish the guilt of a criminal or save a man's life. [*Applause.*] Then the Calabar bean was brought under my notice by some curious observations made by our missionaries in Old Calabar. I saw that it was a most dangerous poison to arrive here when people were in ignorance of its action. I resolved to make experiments, and I made, in the first instance, a very cruel experiment—as I suppose the antivivisectionists would believe—I made an experiment upon myself, and some of my friends thought that I had made a narrow escape. I did not think that my escape was very narrow, because I apportioned my dose with some care; but the effects were most violent. I then made a few experiments upon animals, and found that the effects upon them were identical. I therefore gave a short account of the matter, and

afterwards remitted the further investigation to my assistant, Dr. Fraser, who was led to discover, in the course of his inquiry, the very remarkable action of the Calabar bean upon the pupil. I do not suppose that any one would say that these experiments should not have been performed. [*Applause.*] But this is not all. A considerable time ago I thought I had invented a way by which I could settle what was at that time a very important and difficult question, whether certain medicines or poisons acted through the medium of the blood or through the nervous system. I made one experiment with a view to settle this question; but it was so cruel an experiment that I could not repeat it, and I abandoned the inquiry on account of the cruelty of the experiment. What are we to infer from this? That in a great school such as that of Edinburgh, where men of science know what they ought and what they ought not to undertake, nothing will be done that will be in the least degree offensive to public decency or public opinion; and further, that cruelty is just as disagreeable to vivisectionists as it is to all those super-delicate people who are offering twenty guineas reward for the discovery of a vivisectionist. [*Applause.*] You see that if the cruelty is greater than the object in view, the cruelty will prevail, and the investigation will be abandoned. [*Applause.*] I refer, lastly, to the investigation of Dr. Rutherford. We see what have been the results of that investigation. I do not say that Dr. Rutherford will say that these experiments were not cruel; but I will put against the cruelty the nauseousness of them to the investigator. Dr. Rutherford's experiments are fully justified by the importance of the conclusions to be drawn from them. The physiological results of these experiments are extremely interesting, but the practical results are of very great importance. [*Applause.*] I do not know how the antivivisectionists are to answer these statements; but I shall be very glad to see the answer as soon as they are prepared to give it. [*Loud applause.*]

CONCLUDING GENERAL MEETING.

The concluding general meeting was held in the Chemistry Classroom, at 1.30 P.M.; Sir ROBERT CHRISTISON, Bart., in the chair.

Report of the Parliamentary Bills Committee.—Dr. FALCONER presented the report of the Parliamentary Bills Committee, published at page 201, and moved its adoption.

Inspector-General SMART (Haslar) seconded the motion, and bore testimony to the efficiency with which reforms of the medical affairs of the Navy had been advocated by the Parliamentary Bills Committee, although some things yet required reform. He hoped that the Army would benefit equally by the same kindly efforts of this great professional Association.

Habitual Drunkards.—Sir ROBERT CHRISTISON brought under the notice of the meeting the following resolution, which had been passed by the Section of Public Medicine:

"That excessive intemperance is in many cases a symptom of a special form of insanity, which requires special treatment, with a view, first, to the recovery of those affected; and, secondly, to the protection and advantage of them and of society; that, in the present state of the law, such treatment is quite unattainable; and that it is desirable that legal provision be made to render it attainable." [*Applause.*]

Dr. A. P. STEWART (London) moved:

"That the Association desires to afford assistance in aid of the views expressed in the foregoing resolution, and that the resolution be referred to the Committee on Habitual Drunkards recently appointed by the Committee of Council."

Dr. CARPENTER seconded the motion; and said, if it were carried, it would help to strengthen the hands of those who were striving to carry on this movement.

Dr. PEELE RITCHIE (Edinburgh) said the resolution, and some of the remarks made in support of it at the meeting of the section on the previous day, would but lead the general public to believe that the Association considered that only a portion of the cases of habitual drunkards suffered from a species of insanity, and that such cases alone should be legislated for. He moved as an amendment:

"That drink-craving—whether the result of vice or the manifestation of a special form of insanity—frequently renders the subject of it unable to manage his own affairs, and therefore a nuisance to society; that such cases require special treatment; that the existing law, although it recognises the necessity for dealing with such cases by providing for the confinement of incapables, is insufficient; and that it is desirable that legal provision be made to render such treatment attainable."

The amendment was not seconded, and the motion was carried.

Medical Relief of the Poor in Scotland.—The following resolution of the Public Medicine Section was brought before the meeting:

"That, in the opinion of this section, the interests of the sick poor in Scotland would be furthered, and the system of parochial relief would be placed on a more satisfactory footing, if the following measures

of reform were adopted universally throughout Scotland—namely, that the cost of medicines be supplied by every Parochial Board, exclusive of the salary of the medical officer; that medical officers be removable from office by the Board of Supervision only; that the Parochial Board be required to superannuate such officers; and that the Parliamentary grant in aid of medical relief be placed on the same footing as in England and Wales."

Mr. HUSBAND moved:

"That Sir Robert Christison, Dr. W. T. Gairdner (Glasgow), Dr. Matthews Duncan (Edinburgh), Mr. Ernest Hart, Dr. Strachan (Dollar), Dr. Joseph Rogers (London), Dr. Littlejohn (Edinburgh), Dr. Mackay (Elgin), and Dr. Alex. Ogston (Aberdeen), be a Committee to carry out the resolution of the Public Medicine Section relating to the system of poor relief in Scotland, with power to add to their number, and that Dr. Matthews Duncan be appointed chairman."

He said he was sure that all who had listened to the interesting paper by Dr. Rogers would at once see the necessity of carrying out a change of the Poor-law system in Scotland.

Mr. ERNEST HART seconded the motion, which, he said, was one which would recommend itself with peculiar force to this meeting. He drafted the resolution in the Public Medicine Section as the result of the very able paper by Dr. Rogers of London, who was well known as an Irish and English Poor-law reformer of many years' standing—[*cheers*—] and as having devoted many years of his life to attain the ends necessary for a better Poor-law system. Some of these ends—as a higher rate of pay, freedom from removability, except with the sanction of the higher authority, and the system which should ensure for the sick poor a greater liberality of treatment—had been attained to a great extent in England and Ireland, largely through the efforts of Dr. Rogers; and the Association was anxious to introduce these improvements to Scotch soil. [*Cheers.*]

The PRESIDENT said that no one could refuse to admit this reasonable resolution, unless it were some bigoted members of local boards.

The resolution was unanimously passed.

Anæsthetic Agents.—The following resolution, passed by the Surgery Section, was brought before the meeting:

"That this section is of opinion that it is desirable that a committee be appointed to inquire into and report upon the use in surgery of various anæsthetic agents and mixtures of such agents; that it be part of the object of such committee to collect and summarise the experience of British practitioners of surgery and medicine as to the relative advantages of chloroform, ether, nitrous oxide gas, and other agents, and to carry out suitable experimental investigations; that Professor Lister of Edinburgh, Professor Pirrie of Aberdeen, Mr. Annandale, Dr. Thomas Keith, Dr. J. Duncan, Dr. M'Kendrick, and Dr. Crum-Brown of Edinburgh; Dr. Burdon Sanderson, Mr. Spencer Wells, Mr. Ernest Hart, and Mr. Clover, of London; Dr. Macdonnell and Mr. J. Morgan, of Dublin, be requested to act as a committee for this purpose, with power to add to their number."

Dr. CHADWICK (Leeds) moved:

"That, in accordance with the resolution now read, a committee on anæsthetics, consisting of the gentlemen whose names are given above, with power to add to their number, should be appointed, and that application for a grant be referred to the Scientific Grants Committee."

He said that, notwithstanding the benefit to the community that had resulted from the introduction of anæsthetics, much remained to be done in the investigation of this subject. They would, he was sure, have full confidence in a committee such as had been named.

Dr. RADCLIFFE HALL (Torquay) seconded the motion. It seemed proper, he remarked, that in this, the classic land of the origination of anæsthetics, to a great extent, any new discovery in that direction should have its origin at this meeting in Edinburgh.

The PRESIDENT said they must all wish that the efforts of this committee should be attended with success. They knew the great division of opinion that still subsisted on this question. They knew that a great revulsion had taken place in America, and that a change of opinion was occurring here amongst surgeons in favour of going back to the old anæsthetic in place of adopting the new one—chloroform. With regard to the others, they were only in probation. He thought they might look to the inquiries of this committee with confidence.

The resolution was carried.

Vote of Thanks.—Sir J. CORDY BURROWS (Brighton) moved—

"That the best thanks of the Association be given to the Right Hon. the Lord Provost, the Magistrates, and the Town Council of the City of Edinburgh, for their warm reception, and their liberal donation to the Reception Fund."

He took occasion to say that, by the vote of his Town Council, everything would be done to make the visit to Brighton a pleasant one.

Dr. GAIRDNER (Glasgow), seconded the motion, which was unanimously carried.

Mr. HUSBAND (York) moved :

"That the best thanks of the Association be given to the Senatus Academicus, to Principal Sir Alexander Grant, and to the Secretary, Professor Wilson, for granting the use of the University building for the meeting of 1875."

He would have added for giving the garden party, to which they were just about to proceed, but that had yet to come; and altogether, he said, the meeting had been a most successful one.

Dr. BEGLEY (London) seconded the motion, which was at once agreed to.

Honorary Members.—On the motion of Dr. FALCONER (Bath), seconded by Sir J. CORDY BURROWS, the name of Principal Sir Alexander Grant was included in the list of honorary members, from which it had been accidentally omitted.

Votes of Thanks.—Dr. MARSHALL (Clifton) moved :

"That the cordial thanks of the Association be given to the President and Council of the Royal College of Physicians of Edinburgh, for their hospitality in receiving the members of the Association in the Industrial Museum."

Of all their meetings, he believed this had been the most successful, and one of the most charming features of it was the brilliant reception given to them by the College of Physicians.

The Rev. Dr. BELL (Goole) seconded the resolution, which was cordially agreed to.

Mr. DOLMAN (Derby) proposed the following resolution.

"That the best thanks of the Association be given to the profession and citizens of Edinburgh for their cordial and hospitable reception." The members had had the greatest kindness and cordiality shown to them since they entered the beautiful city.

Dr. BROADBENT (London) seconded the resolution, and it was then passed.

Dr. LYON PLAYFAIR moved :

"That the warmest thanks of the Association be given to Sir Robert Christison—[*applause*].—Dr. Matthews Duncan, Vice-Chairman of the Reception Committee, Professor Douglas Maclagan, Professor Turner, Chairman, and Dr. Underhill, Secretary of the Museum Committee, and to Dr. Gillespie, Chairman of the Entertainment Committee, for their indefatigable exertions to promote the success of the present meeting."

The mover said they had all conjoined to give the Association a warm welcome.

This was passed with acclamation.

Dr. HEATON (Leeds) proposed :

"That the warmest thanks of the Association be given to the Local Treasurers, Mr. Joseph Bell, Dr. R. Blair Cunynghame, and Dr. T. S. Clouston; and to the Local Secretaries, Dr. J. Batty Tuke, Mr. Chiene, Dr. McKendrick, and Dr. John Bishop, for their arduous labours in connection with this Association."

Dr. HENRY (London) having seconded this resolution, it was cordially agreed to.

Dr. KEALY (Gosport) moved :

"That the best thanks of the Association be given to the Directors of the Royal Asylum, the Directors of the Hydropathic Establishment, Melrose, and the Fife and Kinross Board of Lunacy, for hospitably entertaining the members of the Association."

Dr. NICHOLSON seconded the vote, and it was agreed to.

Dr. FALCONER then took the chair, and said he had a resolution to propose, the mere mention of which would ensure its acceptance. It was a vote of thanks to the President. [*Loud cheers.*] The motion was :

"The cordial thanks of the Association are due and are hereby given to Sir Robert Christison, Bart., for the able way in which he has presided over the forty-third annual meeting of the Association." [*Cheers.*] Dr. Falconer said Sir Robert had assisted the Association very greatly, and had settled his memory in all their hearts. He was sure they wished him all happiness and prosperity.

The meeting rose *en masse*, and carried the motion with rounds of cheers.

The PRESIDENT, in replying, said that some of his friends had been rather afraid of his undertaking the fatigues of the office; but he had done so with perfect confidence in his ability to go through the work of the week, and knowing that younger and more active friends in town would lighten the preliminary business for him as much as possible. [*Applause.*] And now he wished to say that he felt he had even profited by the work. [*Renewed applause.*] The only great labour he had had was that of answering the innumerable letters sent to him as President, many of which were very amusing. For example, a gen-

tleman had written to say that he expected members of the Association would be furnished with specimens of Scotch music, Scotch dancing, and Scotch dress. [*Laughter.*] Not knowing that the 79th Highlanders were in Edinburgh, he had answered this gentleman's note, telling him, with reference to his anxiety about Scotch dress, that, if he went into Princes' Street any afternoon, he was sure to meet half-a-dozen gentlemen wearing the kilt, all of them countrymen of his own from the south of England, on their way to the Highlands, believing they were wearing the national costume. [*Loud laughter and applause.*] As for the national music, he need not perhaps remind them that they had heard on the previous evening four pipers of the Queen's Edinburgh Volunteer Brigade; and, if that were not enough, they would have a chance of hearing twice that number of pipes in the course of that afternoon. [*Renewed laughter.*] In conclusion, he begged to return the members of the Association thanks for their kindness in appointing him their President, and for the attention with which they had received anything he had put before them in the course of their meetings. He should long remember this occasion; and, if any person of his age were afraid at any future time to undertake the duties he had undertaken, they might tell him that he should find the work act upon him as a powerful tonic, equal to any chalybeate—[*laughter and applause*].—and that he should, after the session, be equally prepared for the next operation, which was that of climbing the Highland mountains and rowing upon the Highland lakes. [*Loud and continued applause.*]

This concluded the business.

CORRESPONDENCE.

DEGREES AT THE UNIVERSITY OF CAMBRIDGE.

SIR,—In your report of the proceedings of the session of the General Medical Council for Friday, June 18th, there is a sentence which is calculated to mislead. I refer to the remark of Dr. Quain, "that he thought the visitors should have called attention to the fact that there was no examination in surgery at Cambridge". This, of course, must refer to the examination in medicine for the degree of M.B.

There is a very searching examination in surgery and midwifery for the degree in surgery, which can be taken only after passing the examinations for the M.B. degree. Now, I think that there are some very good reasons why there should be no examination in surgery for the degree of M.B. If surgery is to be required, why not also midwifery? Thus two additional subjects would be introduced into this examination.

We may regard the standard of any pass examination as representing the utmost amount of knowledge which can be got from the lowest of those who pass; and, although it is a good thing to raise this standard and to keep it as high as possible, yet we know very well that it cannot be forced up beyond a certain point. Supposing, then, that this limit is attained in the case of the M.B. degree at Cambridge, and that another subject is introduced into the examination, I maintain that the standard in medicine will necessarily be lowered, and this degree, instead of showing that the man has possessed the utmost amount of knowledge of medicine which can be obtained by the highest class of men who enter the profession, will show perhaps that he knows many things, but has not specially excelled in medicine, as the title of his degree might imply.

If the standard for this degree can be raised at all (which I very much doubt), let it be in medicine. It has ever been one of the principles of the University of Cambridge that clear and accurate knowledge of one subject should be preferred to a little knowledge of many; and I sincerely hope that this principle will be maintained in our medical and surgical examinations, as I believe it has been hitherto.

I am, sir, yours truly, A. WANKLYN, M.B., M.C.

Leek, June 28th, 1875.

ETHER AS AN ANÆSTHETIC.

SIR,—For the safe and efficient administration of ether-vapour for producing anæsthesia, several things are needful to be known and remembered, which are chiefly these.

1. That kind of ether should be used which is fittest for the purpose of inhalation, and this is the pure anhydrous washed ether, of specific gravity .720, free from alcohol and water. Robbins' "ether for local anæsthesia" is a dangerous compound for inhalation. It was this last which was used in a case recently fatal at Manchester.

2. The ether should be given in such a way that the inhalation may

be commenced with a very weak vapour, which, after a few inspirations, can be rapidly increased in strength. If we begin with too powerful a vapour, the air-passages are intolerant of it, and the patient resists the inhalation; but, after a few moments' inhalation of a weak vapour, its strength can be increased without inconvenience and the patient rapidly brought under its influence. I think a cone of felt, covered with thin mackintosh, is the simplest and best apparatus for this purpose.

3. Stimulants should not be administered before the inhalation. Ether is itself a stimulant, and can be safely given in cases where there is great depression; but, as Mr. Clover has pointed out, it is very undesirable to have alcohol in the stomach when ether is being inhaled.

4. Whatever danger may belong to ether, has relation to the respiratory function; the breathing should, therefore, be watched. And I may add, it is desirable so to place the head of the patient that the saliva (the secretion of which is increased by the ether) may run out at the corner of the mouth rather than into the trachea.

The superior safety of ether over chloroform is not, I think, doubted by any one; and in my paper, read at the Royal Medical and Chirurgical Society in 1871, I pointed out other advantages which it possesses. A greatly extended experience has confirmed the opinions I then expressed; and, with your permission, I would repeat the words with which I concluded that paper.

"It has been said that one great advantage of anaesthetics is the mental tranquility with which a person is enabled to regard the prospect of an operation which is to be robbed of its pain; but I am not sure that this is not often counterbalanced by the dread of an anaesthetic which it is known may of itself prove fatal. It seems to me, therefore, that for this, as for the other reasons herein advanced, we should avail ourselves of an anaesthetic so safe as ether appears to be, rather than of one, however much it has to recommend it, to which is attached the danger which unquestionably pertains to chloroform."

I am, sir, your obedient servant,

J. WARRINGTON HAWARD.

Montagu Street, Portman Square, July 28th, 1875.

MEDICO-PARLIAMENTARY.

HOUSE OF LORDS.—Saturday, August 7th.

Sanitary Law (Dublin) Amendment Bill.—This Bill was read a second time.

Public Health (Scotland) Act (1867) Amendment Bill.—This Bill passed through committee.

Wednesday, August 11th.

The Royal assent was given by Commission to the following Bills: Pharmacy, Public Health, Sale of Food and Drugs, Metropolitan Board of Works (Loans), Department of Science and Art, Public Health (Scotland) Act, 1867, Lunatic Asylums (Ireland), Amendment Local Government Provisional Orders Confirmation.

HOUSE OF COMMONS.—Thursday, July 29th.

Public Health Bill.—The Lords' amendments to the Public Health Bill were agreed to.

The Sanitary Law (Dublin) Amendment Bill passed through committee.

Female Medical Practitioners.—Mr. COWPER-TEMPLE called attention to the exclusion of women from registration as practitioners of medicine, and asked whether the Government meant to introduce any measure on the subject in the next session of Parliament.—Lord SANDON replied that the matter was first brought under the notice of the Government at the beginning of the session; but, before forming an opinion respecting it, they decided on referring it to the General Medical Council. That body met in June; and, after carefully considering it, addressed a letter to the Lord President of the Council for Education. During the recess, the Government would give the question their best consideration, and state next session whether they thought legislation desirable or not; and, if desirable, they would explain their views and say whether they would move in it themselves or support the right honourable gentleman in doing so.—Mr. RUSSELL GURNEY approved of the course taken by the Government in consulting the General Medical Council, and was glad to find that the Council had expressed a decided opinion that women ought no longer to be excluded from the profession. After such an opinion, he could hardly imagine that they could remain without some legislation.

Tuesday, August 3rd.

Medical Department of the Navy.—In answer to Mr. Forsyth, Mr.

HUNT said the Director-General of the Medical Department of the Navy was appointed for a fixed term, which would expire on the 5th of April, 1879.

MILITARY AND NAVAL MEDICAL SERVICES.

ARMY MEDICAL DEPARTMENT.—The following is a list of army medical candidates, who were successful at both the London and Netley examinations, having passed through a course of instruction at the Army Medical School, Netley.

	Marks.		Marks.
1. Charlesworth, H.	4261	5. Mapleton, E. A.	3976
2. Dorman, J. C.	4100	6. Kelsall, E. W.	3560
3. Le Motté, G. H.	4014	7. O'Sullivan, D.	3435
4. Chester, W. L.	4006	8. Sharpe, C. E.	2933

NAVAL MEDICAL SERVICE.—List of naval medical candidates, who were successful at both the London and Netley examinations, having passed through a course of instruction at the Army Medical School, Netley.

	Marks.		Marks.
1. Marsh, H. E.	4077	6. Lynch, A. R.	3148
2. Strickland, H. G. T.	3799	7. Dudley, J.	2843
3. Patterson, A.	3668	8. Sherlock, J. J.	2420
4. Roman, M.	3393	9. Bookey, D. B.	2381
5. McAdam, J. A.	3285		

REGIMENTAL SYSTEM VERSUS UNIFICATION.

SIR,—The pains you have taken to advocate the cause of the Army Medical Department claim the warmest acknowledgment from its members; and, as you have evinced every disposition to hear patiently the views which have been propounded in favour of either form of organisation, I venture to put forward my plea for the system in which I have grown grey.

At the outset, comes the objection that regimental medical officers were filling the papers with their complaints, whilst unification merely loomed as a shadowy form in the future; but, in fact, setting aside the minor remonstrances about cocked hats and gold belts, which were the mere rose-leaves beneath our beds, nearly all these complaints were founded on the grievances resulting from the systematic and deliberate infringements of the spirit of the Royal Warrant, which, giving us relative rank, declared that it should carry with it all precedence and advantages pertaining to the substantive rank, excepting, of course, actual command. Had that warrant been honestly carried out, and had some provision been made for the flow of promotion in the junior rank, the block in which had probably scarcely been foreseen when that warrant was promulgated, there would have been to this day comparatively few contributions to your correspondence columns on the grievances of the department. From the first, however, covertly or openly, many of the advantages nominally conferred by that warrant were really either withheld or covertly or openly rescinded or evaded. Position at mess was never entirely accorded in correspondence with relative rank, but in some regiments commanding officers did allow medical officers, when senior, precedence next to themselves. Then the Commander-in-Chief decided that no second place was to be recognised, and finally deprives us of any place at all; so that I have had the satisfaction in my own regiment of seeing the mess-sergeant come into the ante-room, and, entirely ignoring me, who paid more in mess subscriptions than any other officer, announce to a subaltern that dinner was upon the table: not a very important thing, you will probably think, to complain about, but a blister on one's foot, or a toothache, though they do not procure much sympathy for the sufferer, may cause him quite as much annoyance as graver maladies. A similar system was pursued with reference to mixed boards. The Royal Warrant entitled the medical officer to sit as president of any board or committee (courts-martial, etc., specially excepted) when he was senior to the other members. This was met by a circular, directing that committees were to be so constituted that the non-combatant never should be senior, and finally he was ejected from such committees altogether, and is now called upon to sign his name to the proceedings as "attending" without having a vote in the matter.

Similar tactics have been adopted with regard to quarters, allowances, and, finally, forage; so that the relative rank is now little more than a mockery. Complaints on subjects like these cannot justly be laid to the score of the regimental system; and one of the greatest causes for the extreme disgust and discontent with which the late warrant has been received, is the perception that it is really a settlement of all the points on which complaints were previously made in a sense unfavourable to the interests of medical officers.

Now, under the guise of unification, we find ourselves compelled to contribute to messes and bands with which we have no further connection than that of paying for them. What, then, are the advantages of unification? A pamphlet just circulated in India, and which will probably be in your hands ere this, written by a gentleman whose English proves him to be an Irishman, and whose startling suggestion, that all surgeons in future admitted to the service should be compelled, during their first five years, to contribute to a widows' fund, irresistibly leads to the conclusion that he is a Benedict, gives a glowing programme of the future of the *Royal Army Medical Department*.

Station messes of medical officers are to be forthwith established in all large stations, and a series of hospitalities (dinner-parties and occasional balls, I presume) inaugurated and carried on in the name of the senior medical officer and his subordinates; and thus we rise at a bound from the hangers-on of regiments to be the entertainers on our own account of the corps which formerly slighted our pretensions, but which for the future will look upon the Royal surgeons as they regard the Royal Engineers. Mess-houses will, of course, be erected, and the Government contribution of £10 for each member as a contribution towards mess expenses, he is quite confident, only has to be asked for to be given in India, in lieu of that Regent's allowance, which we should, of course, draw at home. What touching confidence in the liberality of that Government which has always shown itself so ready to loosen its purse-strings on our behalf! I believe that some such dream as this is really at the bottom of the confidence which the very few members of the department who believe in unification feel in our future prospects: the "cream of the medical officers of the army", "the most thoughtful men of the department", as they delight to call each other. Verily, the departmental milk must be poor in cream; for I have not met more than two or three men who did not look upon unification as a delusion, and they so far resembled cream, that they had risen into snug births, where unification could do them no harm. A simple reference to the Army List, and a calculation of the number of stations in which a mess of half a dozen medical officers could by any possibility be maintained, ought to be sufficient to dissipate such a dream for ever. Remember that the one medical officer attached to each regiment would, of course, be lost to the medical mess; and that, of the senior officers, a large proportion are married, and have little messes of their own to look after. The one military medical mess in existence at present, though magnificently housed, and, I doubt not, well managed, is not, I believe, of that cheery pleasant character to render its members particularly anxious to see similar institutions multiplied elsewhere. I dwell thus upon this question of messes, because it is really of the very greatest importance as regards not only the comfort, but the *morale* of the surgeons of the future. In the great majority of cases, a military medical mess, even on the most modest scale, is an impossibility. When surgeons-major have lost their regimental positions, and young surgeons are attached as excrescences to messes to which they will not really belong, there will be no one to press upon mess-presidents the propriety of making solitary medical officers honorary members of their messes, and regimental medical officers well know how often such reminders were useful.

What, then, will be the position of the young surgeon under this new system of an unified department? He will be sent to an average station, where there are perhaps three or four other medical officers, of whom one or two will be married and another probably dining at a regimental mess. His days, of course, he will spend in laboriously improving his professional knowledge, and perfecting himself in the employment of the microscopes and other scientific instruments of research with which a liberal government will doubtless stock all station-hospitals. His meals, prepared by a hard-fisted soldier, he will eat in solitary splendour on a barrack-table, in the one squalid room which is to serve him as study, dining, and breakfast room and bed-chamber; or he may prefer to eat cheap dinners at second-class inns, for the purpose of enjoying the pleasant society which he is there likely to meet. Is such a course of life likely to train men to add dignity to the reorganised department? What other prospect, I ask, is before them?

Economy is supposed to be one of the recommendations of the new scheme. Two medical officers will henceforth do the work of three, and I admit that this may really be carried out in time of peace; but the whole object of maintaining an army at all is to be ready for war. Where, then, will you get your medical officers? Remember that, whilst a soldier may be made tolerably useful in from six to twelve months, a course of study extending over four or five years is absolutely necessary to produce a medical officer. If the demand in time of peace fall off, the supply correspondingly diminishes; and, on an emergency, no sudden increase would be possible without offering

terms large enough to attract men from civil practice, and, as was done before, taking no note of quality in the demand for quantity.

Then the foreign service is to be equalised. Had any endeavour been made to equalise foreign service under the old system, in so far as circumstances allowed, we might have some confidence in the result of a new system putting more power into the hands of the head of the department; but it is well known amongst ourselves that a long spell of service at home was treated as a valid reason why a man should not be sent abroad, and that one whose previous service had been all out of England was not considered to be entitled to remain at home a day longer on that account.

As regards the regimental system, in spite of the assertions and misrepresentations of the author of the pamphlet to which I have referred, there were few posts where a man was more thoroughly master of his position than was a regimental surgeon in his own hospital. The colonel was theoretically responsible for the hospital as for everything else to the regiment, but he held the surgeon responsible, and, as a general rule, never thought of interfering, excepting where there was gross or palpable mismanagement. Nominally, he appointed the sergeant and orderlies; but it was usually done on the surgeon's nomination, and he would never think of removing either one or the other without the surgeon's concurrence.

Another merit of the new scheme is, that all men are to be either in hospital or at duty: light duty, or being excused particular duties, is henceforth to be unknown. This, so far from being an improvement, I look upon as a senseless retrogression. A man must encumber the hospital because he has a whitlow and cannot shoulder his rifle smartly enough, or because he has a boil on his neck and cannot button his collar! In civil life, if a man cannot do all his work, he does what he can. Why should not a soldier do the same? The hospitals will be filled, and no good done either to the service or to the individual.

In conclusion, I will say, Restore us to our regiments, and, instead of abolishing the regimental system, remove those grievances which worried medical officers, and were simply the outcome of the jealousy of the military officers at the sudden change made in the position of men whom they had hitherto looked upon as mere useful appendages to their regiments.—I am, sir, your obedient servant,
India, April 14th, 1875. A SURGEON-MAJOR.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following members were elected Fellows of this College at a meeting held last week.

Adey, Charles Augustus, M.D. Edin., St. Leonards
 Burder, Charles Foster, M.D. Aberd., Clifton, Bristol
 Corfield, William Henry, M.D. Oxon., Bolton Row
 Falls, William Stewart, M.D. St. Andrew's, Bournemouth
 Fearnside, Henry, M.B. Lond., Preston, Lancashire
 Matterson, William, M.D. St. Andrew's, York
 Monckton, Stephen, M.D. Lond., Maidstone
 Montgomery, James Barclay, M.D. Glasgow, Penzance
 Ord, William Miller, M.B. Lond., Brook Street, Grosvenor Square
 Semple, Robert Hunter, M.D. St. Andrew's, Torrington Square
 Shepherd, Augustus, M.B. Oxon., Seymour Street, Portman Square
 Thorae, Richard Thorne, M.B. Lond., Inverness Terrace
 Tuke, Daniel Hack, M.D. Heidelberg, Falmouth

UNIVERSITY OF LONDON.—First M.B. Examination. Pass List. Entire Examination.

First Division.

Benham, Frederick Lucas, University College
 Dunbar, James John Macwhirter, St. George's Hospital
 Gadshy, John Topham, University College
 Goodchild, Francis, St. George's Hospital
 Hayward, Thomas Ernest, St. Bartholomew's Hospital
 Henderson, George Courtenay, University College
 Lyddon, Richard, St. Bartholomew's Hospital
 Miller, Richard Shalders, University College
 Nicholson, John Francis, St. Thomas's Hospital
 Prowse, Arthur Baucks, Liverpool School of Medicine and St. Mary's
 Pyle, Walter, St. Bartholomew's Hospital
 Taylor, Harold Gilbertson, King's College
 Willcocks, Frederick, King's College

Second Division.

Blamey, James, University College
 Bond, James William, University College
 Bott, Henry Septimus, University College
 Bury, Judson Sykes, University College
 Cattle, Charles Henry, Leeds School of Medicine
 Claremont, Claude Clarke, University College
 Collins, William Edward, St. George's Hospital
 Davy, Henry, Guy's Hospital
 Garbutt, John Gilliot, M.A., St. Mary's Hospital
 Gristock, William, University College

Horrocks, Peter, Guy's Hospital
 Hudson, James, University College
 Hunter, Christian Bernard, University College
 James, Alfred, University College
 Joll, Boyd Burnett, University College
 Lloyd, David, University College
 Lubbock, Montague, Guy's Hospital
 Mears, William Pope, London Hospital
 Mortimer, John, University College
 Nicholson, William Rumney, University College
 Paddison, Edmund Howard, Guy's Hospital
 Sedgfield, Arthur Robert Wyatt, King's College
 Shaan, William Frederick, Liverpool School of Medicine
 Silcock, Arthur Quarry, University College
 Stevenson, Leared Henry, Guy's Hospital
 Thomas, John Raegan, St. Bartholomew's Hospital
 Watson, Charles John, University College
 Weiss, Hubert Foveaux, St. Bartholomew's Hospital
 Wiglesworth, Joseph, Liverpool School of Medicine
 Wilkinson, Arthur Thomas, B.A., B.Sc., Owens College School of Medicine

Excluding Physiology.

First Division.
 Lowe, Howard Griffiths, Queen's College, Birmingham
 Plumbe, Samuel Thomson, St. Bartholomew's Hospital

Second Division.
 Beevor, Charles Edward, University College
 Blake, William Henry, University College
 Drysdale, Alfred Edgar, University College and Liverpool Infirmary
 Roedel, Waldemar Joseph, St. Bartholomew's Hospital
 Smith, Herbert Urmsen, St. Thomas's Hospital

Physiology only.

First Division.
 Cross, Francis Richardson, King's College

Second Division.
 Bigger, Samuel Ferguson, Liverpool Royal Infirmary
 Champneys, Henry Laurence, Guy's Hospital
 Finch, Alfred, Guy's Hospital
 Hellier, John Benjamin, Leeds School of Medicine
 Smith, Thomas Bower, University College

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a meeting of the Council held on the 9th instant, the following gentleman was admitted to the Fellowship.

Poppleton, Joe, L.S.A., of Bradford, Yorkshire; diploma of membership bearing date October 5th, 1873

UNIVERSITY OF DUBLIN: Degrees and Licences in Medicine and Surgery, June 30th, 1875.—Master in Surgery (*honoris causa*).

Colles, William

Bachelors in Medicine.

Baker, Arthur W.
 Cochrane, Robert S.
 Clibborn, William
 Fox, Allan Nesbitt
 Fisher, Thomas Carson
 Goodman, Francis G.
 Halpin, Nicholas John

Hart, William Hume
 Hayes, Thomas Crawford
 Montfort, Archibald Henry
 Power, John Joseph
 Smyth, William B.
 Stanley, William H. R.
 Walter, William

Bachelor in Surgery.

Hunter, William L.

Masters in Surgery.

Banks, Alfred
 Bleakley, Alexander S.
 Baker, A. W. W.
 Fisher, Thomas Carson
 Griffith, James de Burgh
 Hart, William Hume

Halpin, Nicholas John
 Moran, James J.
 Nixon, George Michael
 Power, John Joseph
 Stack, Richard T.

Doctors in Medicine.

De Montmorency, Hon. Arthur Hill
 Trevor
 Elliott, Christopher
 Hayes, Thomas Crawford
 Hurford, Cedric Herbert
 M'Nunn, Charles Alexander

Meredith, John Edward
 Newman, Horace Townsend
 Oulton, William H.
 Tredenneck, William M.
 Woods, Oscar Thomas

Licentiates in Medicine.

Byrne, Edward H.
 Lane, John

O'Carroll, Martin

Licentiate in Surgery.

Byrne, Edward H.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, August 5th, 1875.

Dudgeon, John Matthew, Dalbeattie, Kirkcubrightshire
 Edwards, Edward Joshua, Llansanffraid, Montgomeryshire
 Highton, Thomas, St. Thomas's Hospital

The following gentlemen also on the same day passed their primary professional examination.

Allen, M. H. L., St. Mary's Hospital
 Bennett, Arthur, London Hospital
 Bowen, Owen, Guy's Hospital
 Cree, Percy K., Middlesex Hospital

Gillam, Thomas H., St. Bartholomew's Hospital
 Goode, Charles F., St. Mary's Hospital
 Hallsworth, F. A., St. Bartholomew's Hospital
 Harper, Robert R., St. Thomas's Hospital
 Jaquet, J. L., Westminster Hospital
 Johnstone, William, University College Hospital
 Joseph, S. W. L., St. Thomas's Hospital
 Moorehouse, Edward D., Owens College, Manchester
 Stephens, Charles, Liverpool Hospital
 Walker, William, Middlesex Hospital

MEDICAL VACANCIES.

The following vacancies are announced:—

BOURNEMOUTH GENERAL DISPENSARY—Resident Medical Officer and Secretary. Salary, £120 per annum, with furnished apartments, coals, gas, and attendance.
 BURY UNION—Medical Officer for the Radcliffe District.
 CARNARVON UNION—Medical Officer for the Llandwrog District. Salary, £60 per annum.
 CHRISTCHURCH UNION—Medical Officer for the Eastern District. Salary, £90 per annum, and fees. Applications on or before August 16th.
 CROYDON GENERAL HOSPITAL—House-Surgeon. Salary, £80 per annum, with board and lodging. Applications on or before the 18th instant.
 DAVENTRY UNION—Medical Officer for the Workhouse and the First District.
 DORE UNION—Medical Officer for the Koutchur District and the Workhouse.
 DUDLEY DISPENSARY—Resident Medical Officer at Michaelmas.
 HAY UNION—Medical Officer for the Herefordshire District.
 KEYNSHAM UNION—Medical Officer for the Keynsham District.
 LEEK UNION—Medical Officer for the Norton District.
 LYMINGTON UNION—Medical Officer for the Hordle, Lymington, and Milford Parishes.
 MALDON UNION—Medical Officer for the Southminster District.
 NORTH STAFFORDSHIRE INFIRMARY—House-Physician. Salary, £80 per annum, with board, lodging, and washing. Applications on or before the 18th instant.
 NORWICH DISPENSARY—Salary, £120 per annum, with unfurnished residence and apartments.
 ORMSKIRK UNION—Medical Officer for the Second District.
 PEMBROKE UNION—Medical Officer for the First District.
 PLOMESGATE UNION—Medical Officer for the Aldeburgh District.
 ROYAL SOUTH HANTS INFIRMARY—House-Surgeon. Salary, £80 per annum, with board, lodging, and washing. Applications on or before September 6th.
 ROYSTON UNION—Medical Officer for No. 5 District. Applications on or before September 6th.
 ST. IVES UNION—Medical Officer for the Warboys District.
 STAINES UNION—Medical Officer for the Shepperton District.
 UCKFIELD UNION—Medical Officer for the Maresfield District.
 WARWICK COUNTY LUNATIC ASYLUM—Second Assistant Medical Officer. Salary, £100 per annum, with board, lodging, and washing.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

COTTLE, Wyndham, B.A., F.R.C.S. Eng., appointed Assistant-Surgeon to the Hospital for Diseases of the Skin, *vice* Waren Tay, F.R.C.S. Eng.
 CRABB, James, M.B., C.M., appointed Resident Surgeon to the Royal Hospital for Sick Children, Edinburgh.
 *DUDLEY, J. G., M.A., M.D. Cantab., M.R.C.P., appointed Consulting Physician to the North London Hospital for Consumption and Diseases of the Chest.
 LEFTWICH, Ralph W., M.B., C.M., appointed Resident Medical Officer to the East London Children's Hospital.
 TAY, Waren, F.R.C.S. Eng., appointed Surgeon to the Hospital for Diseases of the Skin.
 *THOMPSON, James, A.B., M.B.T.C.D., L.K.Q.C.P.I., M.R.C.S., etc., appointed Police Surgeon for the Borough of Royal Leamington Spa.
 TOMKINS, H., L.S.A., appointed Physician's Assistant to the Manchester Royal Infirmary, *vice* C. E. Smith, L.R.C.P. Ed., appointed House-Surgeon.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTH.

MACCARTHY.—On August 5th, at Thomhall, Polmont, N.B., the wife of D. A. MacCarthy, M.D., Retired Staff-Surgeon, Royal Navy, of a daughter.

MARRIAGES.

ATKINSON—POSGATE.—On Friday, August 6th, at St. Mary's Parish Church, Reading, John Furniss, son of the late William Atkinson, of Broom Grove, Sheffield, to Clara Elizabeth, younger daughter of W. T. Posgate, late of Heathfield, Halifax, and niece of William Exall, of Holy Brook House, Reading.

BARRY—EXALL.—On Friday, August 6th, at St. Mary's Parish Church, Reading, Frederick William Barry, M.B., eldest son of William Barry, of Scarborough, to Ellen Montague, elder daughter of William Exall, of Holy Brook House, Reading.

SIMS—FULLER.—On August 5th, at St. Thomas, Portman Square, by the Rev. Arthur Sinclair Brooke, M.A., Chaplain to the Royal College, Cooper's Hill, Francis Manley Sims, Esq., F.R.C.S., of 25, Half Moon Street, Piccadilly, to Alice Belgrave, second daughter of the late Henry William Fuller, M.D., Senior Physician to St. George's Hospital.

AN infirmary is to be established at Andover, towards which Sir Charles Pressley has subscribed £1,000, Mr. Henry Thompson £500, and the Earl of Portsmouth £10 per annum; and Mr. Gue has given the necessary land.

OPERATION DAYS AT THE HOSPITALS.

MONDAY	Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.
TUESDAY	Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopedic, 2 P.M.
WEDNESDAY ..	St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.
THURSDAY	St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopedic, 2 P.M.—Royal London Ophthalmic, 1.30 P.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.
FRIDAY	Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.
SATURDAY	St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with Duplicate Copies.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

PUERPERAL CONTAGION AND SEWER-GAS.

SIR,—In connection with the discussion of puerperal fever, the following history is of interest. On June 2nd, 1874, a primipara was confined. She was attacked with puerperal fever of a typhoid type. Her illness of a few weeks' duration ended by recovery. The day after the confinement (June 3rd, her sister arrived from a distance to act as nurse. On the 11th, she became suddenly very ill, and was at once removed to another house. On the following day the diagnosis was scarlet fever. She passed through a dangerous illness. A nurse was then engaged on the 11th to attend the puerperal patient, but in two days it was imperative to order her removal, owing to her being attacked with erysipelas of the face. The drainage of the house was at fault, there being a pipe which allowed gas from the main sewer to enter one of the bedrooms.—Yours truly,
T. KAY GRAY, M.B.

C. L.—Mr. Frank Buckland, M.A. Oxon, is a member of the Royal College of Surgeons; he was formerly a surgeon in the Royal Horse Guards. His father, the eminent geologist, was Dean of Westminster.

M.D. ERLANGEN.

SIR,—Owing my degree of M.D. to a letter in the small print of the JOURNAL some seven years ago, and perceiving that the kind of information which was useful to me may be useful to others, I no longer hesitate to supply the following particulars. A medical man desirous of obtaining the M.D. of Erlangen should write to the Dean of the Medical Faculty of the University (in Bavaria), requesting permission to offer himself as a foreign candidate for the honour, and asking that, if his prayer be granted, he (the Dean) will forward the necessary information, and state during what month he should present himself. The letter should mention his English diploma, that he is registered, and that, if permitted, he will forward by post his thesis for the approval of the Faculty. In sending the thesis, it will be well to mention the day (five or six weeks in advance) on which he will present himself, should it be approved. If the thesis be satisfactory, he will hear from the Dean that he can appear at the time named. Testimonials, diplomas, and the certificate of registration must be taken with him. The examination is written and oral on the following six subjects: Anatomy and physiology, morbid anatomy, pathology, medicine, midwifery and diseases of women, and surgery. There is a separate examiner for each subject; but the whole court examine the candidate on his thesis; success depends much on the thesis. The examination is conducted in English, and the thesis may be written in English. The fee is 240.

A convenient way of reaching Erlangen is to go from Frankfurt to Nürnberg in one day, and stay the night at the Hôtel de Bavière in the latter place, where all information concerning Erlangen can be obtained.

At the University town, a little German will be almost indispensable for comfort; but, with a little previous knowledge of the pronunciation and grammar, *Bröderer's Manual of Conversation* will afford every assistance necessary. My experiences relate to the year 1872.

I enclose my card, and remain, sir, your obedient servant,

M. D. ERLANGEN, F.R.C.P. Lond.

BRASS PLATE, L.I.F.—It is quite a matter of taste. The illustrious Hunter, who was noted for his simplicity of character and singleness of mind, had a plain brass plate on his door in Leicester Square, inscribed "John Hunter".

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

ON PAIN—PHYSIOLOGICAL OR PATHOLOGICAL.

SIR,—After informing us that "pain is either physiological or pathological", and that "pain is physiological in the act of parturition; the contraction of uterine muscle would not be to any effective purpose without pain". Dr. Spender, in his treatise *On Pain*, goes on to say: "The administration of opium for pain, as part of the physiology of parturition, involves one of the most delicate problems of therapeutics. It would be a blunder of the first magnitude, and which no scientific practitioner would commit, to try to deaden this pain by any process of so-called narcosis. Up to a certain point, pain is an expression of motor energy and power. The ordinary and rational formula would therefore be, the greater the pain the sooner will the parturient process be over." Now, without attempting the useless labour of threshing over again the old straw of a fallacious theory, without even stopping to inquire how such statements as the above are supposed to accord with the text of Sir William Hamilton, I will only remark that a few pages further on we come to an entire refutation of them in a quotation from some sensible observations by Mr. Lambert, late house surgeon in the Maternity Hospital, Edinburgh.

"Chloral is of great value in the relief of pain during labour; and it may be administered, under favourable circumstances, during and at the close of the second stage, with the result of producing absolute unconsciousness in the same sense in which we understand unconsciousness under chloroform. A labour can be conducted from its beginning to its end without any consciousness on the part of the patient, under the sole influence of chloral. Chloral not only does not suspend, but rather promotes uterine contraction, and labours under the influence of chloral will probably be of shorter duration than ordinary labours without chloral" (*Edin. Med. Journal*, Aug. 1870).

The reader may not unreasonably inquire, "What proof does Dr. Spender bring forward in support of his assertion that 'pain is physiological in the act of parturition', and that 'the contraction of uterine muscle would not be to any effective purpose without pain'?" and he would be surprised to hear that no attempt is made by the author to prove either of these assertions, or, indeed, any other of those which I have quoted from his *Prize Essay on Pain*. Why, it may be asked, does he, by preference, refer the pain of labour to the contraction of uterine muscle, and leave out of account the equally essential, and what might, *prima facie*, be considered the infinitely more painful process—namely, the extreme stretching of the parts? The very fact that the contraction of uterine muscle is a purely physiological process, should at once negative the hypothesis that its normal condition must be painful. Where in Nature do we find any analogy in support of such an idea? Not to the contraction of uterine muscle, but to the inordinate distension of the parts involved, and more especially to the resistance offered at the mouth of the womb and at the external orifice, may chiefly, if not entirely, be ascribed the ordinary pain of labour. And as in every instance the amount of such resistance is variable, being dependent on a variety of conditions antecedent to and concomitant with labour, all of which may be shown to have a special bearing on temperature, we now arrive (*pace* Dr. Leishman) at an intelligible explanation why the pains of labour should be so variable in duration and intensity. And if, as I have shown, this so-called physiological pain is a matter which, by the simple regulation of temperature, may be brought completely under control, and if, when under control, the parturient process, so far from being delayed and rendered nugatory thereby, is, in fact, promoted and rapidly brought to a close, what conclusion can we possibly arrive at than that the whole conception of physiological pain is a false and mischievous phantom, which it is clearly our duty, in the interests of all concerned, to exorcise as speedily as possible. And when the true philosophy of the subject shall be generally understood, it will be impossible any longer for a great professor to talk of painful and tedious labours as being "perfectly normal", and having experienced no such suffering in his own person) complacently to inform his audience that "such occurrences are generally of no great importance". Nor shall we hear any more of such assertions as that "up to a certain point" [what point?] "pain is an expression of motor energy and power"; nor such suggestions as that there is any essential connection (except an inverse one) between the amount of pain and the progress of labour; nor, above all, shall we be withheld by any such fallacious reasoning from administering to our patients, when needful, remedies of a soothing or even of a narcotic character from the moment the pains begin, if, indeed, we cannot effectually anticipate them by simple hygienic means.—Yours, etc.,
M.D.

Harlesden, June 1875.

MATERNAL IMPRESSIONS.

I AM not a believer in maternal impressions, or, perhaps, I should rather say, I am disinclined to believe in their occurrence, as I cannot see the link which connects the impression on the mother with the development of the fetus *in utero*. The following case, which has just occurred in my own practice, is one of those where the *post hoc propter hoc* argument appears unusually strong. I have removed a small supernumerary little finger from the right hand of a child only six weeks old, and the following history was given me by its mother. When a month and a half pregnant, and while she was still unaware of her state, being engaged in suckling her former infant, and not having menstruated since its birth, a *colporteur* entered her cottage to distribute tracts. She noticed with surprise that he had a small supernumerary finger attached to the little finger of his hand, and told her husband and her sister of the occurrence on their return home. Seven and a half months afterwards her present child was born, and she was astonished to find that it, too, had a small supernumerary little finger in the same situation. About three years ago, I published a curious case of monstrosity, also explained by the mother as resulting from a so-called "impression" in the early stage of her pregnancy. And I am aware how frequently cases—apparently authentic—are narrated. But the interest of the present case appears to me to consist in the fact, that Dr. Montgomery's explanation—generally received, I believe—of the occurrence of limbs, or portions of them, in abnormal situations in new-born children; viz., that the parts have undergone spontaneous intrauterine amputation by constriction, either by bands of lymph or by the umbilical cord, and then become attached in their new situation by adhesive inflammation, is here inapplicable; for why should the child have had the other fingers of each hand perfect if this were so? I have never heard any theory advanced which attempted to explain these cases, yet the number already detailed in the pages of your JOURNAL, which might, no doubt, be swelled enormously if the subject merited it, is so considerable that I am tempted to narrate this one.
J. HOLMESJOY.

Tamworth, June 1875.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

PROFESSIONAL ASSOCIATION WITH A BONE-SETTER.

We are very glad to find the following article in a local paper on a subject to which we have already referred, and on which we had expressed an opinion similar to that which our contemporary intelligently endorses.

"It says much for the sense which the medical men of North Wales have of the dignity and rights of their profession, when we find that only one of their number is found applying for the appointment at the Penrhyn Quarry Hospital, which had become vacant through Dr. Hamilton Roberts' honourable retirement from the post. There is much in the appointment which, under other circumstances, would have been sure to invite keen competition for it. The emoluments are not inconsiderable, and the successful candidate would enter upon his work with a fair prospect of having a fortunate career before him. This, and much more to the same effect, might be said if the medical men of North Wales were under the influence of no other than pecuniary considerations; if professional honour were an abstraction to which the mass of them were strangers, and professional privileges were fictions not worth contending for. But, in reality, the case stands quite differently; and it is no small credit to those concerned to find that the action which was determined upon at the recent meeting of the local Branch of the British Medical Association is almost unanimously endorsed by the profession. Five candidates were rightly or wrongly named in connection with the appointment—one being a medical man from Manchester, for whom some one has, with gratuitous ingenuity, discovered a perfectly imaginary relationship with Dr. Richards, the President-elect of the North Wales Branch of the Association. Another name on the list was Dr. O. T. Williams, of Bangor, whose letter is more than sufficient to assure the public that he would be one of the last to aspire to the post on the conditions under which it has become vacant. Dr. Williams was in no sense whatever a candidate; and two other medical men, Dr. William Williams and Dr. Ellis, were only such in a limited degree, as both of them stipulated that they would not accept the appointment unless they were guaranteed against having to co-operate with the unqualified practitioner who is now acting in the two quarries. This practically excluded both from the competition, so that it is strictly true to say that the whole of North Wales only contributed one candidate. The appointment of Dr. Williams, of Pen-y-groes, whose skill is highly spoken of, therefore became a matter of necessity. The lay view of the question, we venture to think, will not widely differ from that which the profession have taken, for the course which the Medical Association have determined upon is, inferentially, a censure upon those of their brethren who see no impropriety in associating with irregular and unauthorised practitioners."

A MEMBER.—The *Calendar* of the College of Surgeons will give you full information. It is published annually, generally in September.

HOSPITAL REFORM.

As a former hospital and dispensary physician, I am much interested in the flagrant question of hospital reform. I trust that this question will at last be satisfactorily solved, not only in the metropolis, but throughout the kingdom. During the last twenty years, hospitals for stone, heart, throat, skin, nervous system, paralysis, women, ears, hip-joint, and other specialities, have luxuriantly flourished, and are now so exuberant that the anomaly threatens of hospitals remaining rather without patients than of patients languishing from deficiency of eleemosynary medical aid. Given an aspiring M.R.C.S. or L.R.C.P., glowing from the schools, and recently commissioned from Lincoln's Inn Fields or Pall Mall, together with a benevolent captain or other maunabiated individual to act as secretary, the unities seem to be complete to float a hospital or dispensary; hence these institutions multiply in almost geometrical progression, and beget, rather than minister to, the cravings of disease. I cite a few of them:—Hospital for Diseases of the Heart, founded in 1857; Hospital for Stone, founded in 1860; Hospital for Diseases of the Throat, founded in 1863, and another last year; Hospitals for Diseases of the Skin, four founded since 1863; Hospital for Disease of the Nervous System, founded in 1866; Hospital for Women, founded in 1871. The last-named charity (?) is reported to have eight beds, thirty-two in-patients and five hundred out-patients, or rather more than one daily, during the year; and, conceding this statement to be unexaggerated, it would be interesting to also learn the expenses of the institution and its concomitant usefulness.

To make specialism more specialistic, it appears possible, with the coming race, that, to accommodate the widening crowd of applicants, the above will so fungate and ramify, that a throat-hospital may have laryngeal, uvular, tonsillar, pharyngeal, and oesophageal departments, with a *clinique* for the cartilages; a stone-dispensary may become separated into urethral, vesical, and renal sections; a skin-hospital into cuticular and dermal branches; a hospital for the nervous system into divisions for the cerebro-spinal centres and for the sympathetic, with sub-departments for hysteria, neuralgia, nightmare, dreams, and disorders of the psychic energy, unless the last affection attain an independent foundation. It may be conceived that hospitals for women will be ultimately limited to maids or matrons, with subdivisions, according to the organ or tissue suspected to be diseased; and, by the force of bathos, it may be opined that dispensaries for polyypus, indigestion, and affections of the suprarenal capsules, will be instituted; and, the solids having become exhausted, for maladies of the blood, lymph, and bile, many of which would be scarcely more absurd than some of the existing charities for the sick.

Whilst such institutions are permitted to increase, and the medical appointments to them eagerly coveted as gratuitous honours, remuneration for duties at the older hospitals will be in vain sought for by future medical and surgical practitioners. The face of the profession should ever be averted from the creation of rural (cottage) hospitals, unless it be arranged that payment is to be offered for the work performed; and it only demands firm co-operation throughout the country to insist upon and obtain redress. The apology of poverty cannot be pleaded as excuse in the acceptance of honorary and unpaid appointments; and without an efficient staff every hospital and dispensary must remain a nonentity, or at once collapse. Heaven forbid that hospitals should be abolished. It is their reform I advocate, with restriction of their benefits, as far as possible, to the deserving poor, and that their mainspring and executive (the medical staff) should obtain due recognition and requital on a par with other professions.

July 12th, 1875.

WM. BOYD MUSHET.

DR. MALCOLM (Edinburgh).—Your son, having passed his preliminary examination in Arts, can commence his professional studies at once.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, no later than *Thursday*, twelve o'clock.

DR. MALCOLM.—A similar provision is made under the will of Mr. Thomas Axe which is dated July 20th, 1691, and directs that of the profits of premises at Bland ford, "three-twelfths be given to some man or woman of exemplary life, and some skill in physic and surgery, who should industriously endeavour to help all the poor of Ottery St Mary, Devon, gratis in cases of sickness and accident, till better advice could be had." Testator's kindred were to be preferred for the office; the clerk's wife next; the vicar's wife before any other, if she should be very fit, or as fit as Mrs. Alford, the late vicar's wife. He also gave another twelfth portion to the person above described wherewith to buy "drugges and plaisters."

COTTAGE HOSPITALS.

SIR,—If your correspondent M.D., in the JOURNAL of the 31st July, will write to me, I shall be happy to give him any information in my power about the practical working of our cottage hospital.—Yours faithfully,
G. W. EVANS.
Bridport, August 3rd, 1875.

A PROVINCIAL FELLOW.—According to collegiate etiquette, only the members of the Council of the College of Surgeons who have passed the chair wear the President's gown on public occasions. Sir James Paget, Bart., has succeeded Mr. Clark as President.

EXAMINATIONS.—The following were the questions on the principles and practice of medicine, submitted to the candidates for the diplomas of membership of the Royal College of Surgeons, at the recent meeting of the Court. 1. A patient is labouring under general dropsy. What are the different conditions on which it may depend? and what will be the probable state of the organs chiefly affected on examination after death? How would you distinguish and treat such cases? 2. What are the diseases characterised by the presence of pustular or vesicular eruptions in the skin? On what do such eruptions generally depend? 3. Mention the chief formulae in the *British Pharmacopœia* into which opium enters; state the proportions of the drug, the doses in which the formulae are to be used, and the purposes for which they are specially adapted. Write a prescription for a draught to procure sleep.

ERRATA.—In Sir Robert Christison's Presidential Address in last week's JOURNAL page 159, column 1, line 6, *for* "vigour" *read* "rigour"; and in page 161, col. 2 line 12 from bottom, *for* "simply" *read* "singly". In the same number, at page 184, column 1, line 25, it should have been stated that Dr. Balthazar Foster (Birmingham) moved, etc.—instead of Mr. Lawson Tait. A similar correction is required at page 185, column 1, line 18.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Bristol Daily Post; The Daily Bristol Times and Mirror; The Derby and Chesterfield Reporter; The Lincolnshire Herald; The Glasgow Herald; The Sunderland Daily Echo; The Carnarvon and Denbigh Herald; The Manchester Guardian; The European Review; The Hackney and Kingsland Gazette; The Worcestershire Chronicle; The Birmingham Daily Post; The Brighton Daily News; The Sussex Daily News; The Glasgow Herald; The Cork Examiner; The Scotsman; The Cork Daily Herald; The Southampton Times and Hampshire Express; The Hampshire Advertiser; The Birmingham Morning News; The Chester Courant; The Metropolitan; The Live-Stock Journal; The Shield; The Grocer; The Shipping and Mercantile Gazette; The Advertiser; The Islington Gazette; The Penrith Observer; The Hastings and St. Leonard's Gazette; The Ickley Free Press; The Leicester Daily Post; etc.

COMMUNICATIONS, LETTERS, &c., have been received from:—

Sir Robert Christison, Edinburgh; Dr. Rutherford, Edinburgh; Mr. Spence, Edinburgh; Mr. F. E. Manby, Wolverhampton; Dr. Peel Ritchie, Edinborough; Dr. Angus MacDonald, Edinburgh; Dr. C. E. Underhill, Edinburgh; Mr. A. Walker, Dudley; Dr. Surthers, Aberdeen; Dr. Sibbald, Edinburgh; Dr. G. E. Shuttleworth, Lancaster; Dr. W. T. Gairdner, Glasgow; Mr. J. A. Goodchild, Ealing; Mr. W. G. Kemp, Bayswater; Dr. R. Caton, Liverpool; Mr. William Bennet, Liverpool; Inspector-General Dartnell, Birmingham; Mr. T. W. Hubbard, Maidstone; D. A. B. Munro, Bradford; Mr. R. W. Leftwich, London; Dr. A. Peddie, Edinburgh; Mr. S. W. Sherlock, London; Mr. J. T. Clover, London; Mr. Hinnell, Bury St. Edmunds; Our Dublin Correspondent; Mr. H. E. Trestrail, Aldershot; Dr. John Roberts, Chester; Dr. Colthe, Homerton; Mr. A. Allen, Halesy Bridge; Dr. J. H. Balfour, Edinburgh; Mr. T. M. Stone, London; The Registrar-General of England; The Registrar-General of Ireland; Dr. B. Foster, Birmingham; Mr. J. Crabb, Edinburgh; Dr. Macaulay, London; The Secretary of the Royal College of Surgeons of Edinburgh; Dr. A. P. Stewart, London; Mr. R. H. B. Wickham, Newcastle-on-Tyne; Dr. Tilt, London; Mr. W. Adams, London; Mrs. Hoggan, London; Dr. C. R. Drysdale, London; Dr. C. Muirhead, Edinburgh; Mr. Cullingworth, Manchester; Dr. Maclean, Netley; Dr. Brotherton, Alloa; Dr. Caton, Liverpool; Mr. Eastes, London; Dr. Haddon, Manchester; Dr. Edis, London; etc.

BOOKS, &c., RECEIVED.

The Philosophy of Laughter and Smiling. By George Vasey. London: J. Burhs, Southampton Row. 1875.
Health in the Nursery, and how to Feed and Clothe a Child; with Observations on Painless Parturition. By E. Holland, M.D. London: H. K. Lewis, Gower Street. 1875.
Vernon Galbray, or the Empiric; the History of a Quack Dentist. London: E. T. Whitefield, Strand. 1875.

REMARKS

ON

CRIMINAL DEATHS IN THE NAVY AND ARMY.

By WM. R. E. SMART, M.D., C.B., Inspector-General R.N.

THE subjoined table has been carefully compiled from the official Health Reports of the Navy and Army through Thirteen Years, 1860-72 inclusive.

Table displaying the Periodical Differences, Grand Totals in Thirteen Years, and the Yearly Averages, with Ratios of Suicides, Homicides, and Judicial Deaths, together with the Primary and Secondary Mortality from Intemperance, per 1,000 of Mean Strength.

NAVY.	Mean Strength.	Suicides.		Homicides.		Judicial Sentences.		Mortality from Intemperance.					
		No.	Ro.	No.	Ro.	No.	Ro.	Primary.		Delirium Tremens.	Totals.		
								No.	Ro.	No.	Ro.	No.	Ro.
1860-1864	292,470	51	.174	14	0.48	27	0.93	49	1.68	76	2.60
1865-1867	151,635	19	.125	2	0.013	12	0.79	20	1.32	32	2.11
1868-1872	241,040	22	.091	2	0.08	15	0.62	25	1.04	40	1.66
Totals of 13 yrs	685,172	92	.134	18	0.26	54	0.79	94	1.37	148	2.16
Yrly averages	52,705	7.07	.134	1.38	0.26	4.15	0.79	7.23	1.37	11.38	2.16
ARMY.													
1860-1864 ...	954,048	245	.256	36	0.38	15	0.16	117	1.23	249	2.60	366	3.83
1865-1867 ...	508,850	74	.322	13	0.26	3	0.06	83	1.63	127	2.49	210	4.12
1868-1872 ...	826,526	324	.392	41	0.49	5	0.06	69	0.84	162	1.97	231	2.80
Totals of 13 yrs	2,289,454	743	.324	90	0.39	23	0.06	269	1.17	538	2.35	807	3.52
Yrly averages	176,112	57.2	.324	6.92	0.39	1.77	0.06	20.69	1.19	41.38	2.35	62.07	3.52

It presents at a glance striking differences in the ratios per 1,000 mean strength in favour of the navy under each of the headings suicides, homicides, judicial deaths, and mortality from intemperance; opening up an interesting inquiry into the probable causes of inequality, which at first sight involves the probability that the mortality from these causes is allied, or that it may be altogether relative to the amount of intemperance that prevails in each of the services; but to solve this interesting question, further investigation is needed.

It is difficult to present strict parallelism, as the returns are based differently, those of the navy including officers with men constituting the crews, while those of the army exclude the commissioned officers, which is disadvantageous to the ratios of the navy, as in it the suicidal deaths, as well as those from intemperance, hold higher proportions among the officers than among the crews; so that, these being deducted, which it would be difficult to effect with certainty, and the naval ratios made parallel with those of the army, they would be still lower than represented in the table.

Owing to the limits of age of seamen and soldiers, from twenty to forty-five, there is no external standard for comparison, as elsewhere all ages from infancy to senility are included in the death-returns. Thus if the returns of the Registrar-General for the metropolis through a similar period of thirteen years—1862 to 1874 inclusive—be examined, it is found that in an average population of 3,030,000, including all ages, there were 3,544 suicides, giving a ratio of .089 per 1,000, against .134 in the navy, and .324 in the army; but with corrections for ages and for sex it cannot be doubted that the ratio for the metropolis would at least equal the ratio in the navy.

The Census of 1871 in the metropolis gives: total population, 3,254,260 persons; of ages between 20 and 45, 1,111,655, of which there were, males, 511,895; females, 598,760. This exceeds a third of the entire population between those ages when suicide is more frequent than at other periods of life; and the male sex, most given to it, bears a remarkably less proportion than the female sex. Thus, probably one-half the suicides are due to the same period of life as in the navy and army, and of this half the male sex will carry a greater proportion than the female; for these reasons it may be assumed that the suicides in the metropolis, among males from 20 to 45, are at least equal to those in the navy, viz., 134 to a million persons.

Before examining the table, it must be observed that the "average annual strengths" given—52,705 for the navy, and 176,111 for the

army—are obtained by dividing the sum of the annual strengths by the number of years involved, and that the same rule has been applied to the mortality. Again, the ratios of suicidal and homicidal deaths in both services would be augmented, if it were usual to return as such all who are "found drowned", which are excluded likewise from the returns of the Registrar-General, where, unless proof be afforded of murder or suicide, they are classed "accidental", as in the services of the state.

The summary of the statistics embracing their essential data lies in the following ratios per 1,000 annually.

	Suicides.		Homicides.		Judicial.		Intemperance.	
	Nos.	Ratios.	Nos.	Ratios.	Nos.	Ratios.	Nos.	Ratios.
Navy	7.07	.134	1.38	.026	—	—	11.38	2.16
Army	57.2	.324	6.92	.039	1.77	.009	62.07	3.52

On these data it may be noted:

1. *Suicidal Deaths* are nearly as two in the navy to five in the army. This large disparity may be, in a great degree, dependent on the difference of modes of life in the sister services. The duties on ships are more continuous and more exciting than those of camps and barracks, where the soldiers have more duty of a solitary character, and longer periods of idleness in which they may withdraw from association with their comrades, and then give way to distressing mental causes; while seamen off duty have no other resort than among their messmates, whose society must tend to banish gloomy thoughts and sentiments, thus counteracting tendencies to suicide.

That a high ratio of suicidal deaths is incidental to military life in general may be inferred from the still higher ratios than those of the English army that prevail among other European nations, of which it has been authoritatively asserted that Austria presents .85; Germany, .54; France, .51; and Belgium, .45 per 1,000; against which ratios that of the English Army, .324, as I find it to be, is rather a flattering result. Probably much of this is attributable to the voluntary service of England and the compulsory service of continental nations, rather than to any superiority of class.

Again, amongst our troops, the tendencies to suicide are developed much more strongly on foreign service than at home, and more in India than elsewhere. Thus of the total 743 suicides in thirteen years, 253 occurred at home, and 324 in India, leaving 166 for all other stations of the British army, affording the following ratios:

Period of Thirteen Years, 1860 to 1872.

Stations.	Total Strength.	Suicides.	Ratios per 1,000
At home	1,026,647	253	.246
India	779,630	325	.415
Other Stations	483,127	166	.344

As the forces at home are made up of recruits in a greater proportion than elsewhere, it becomes clear that suicide is not most frequent among the younger soldiers. With respect to ages, the same law holds good everywhere, that the tendency to suicide gradually increases from manhood up to middle age, at which military and naval service ceases. And it may be assumed that the scale of ratios increases with greatest rapidity on those stations where the total ratio ranges highest.

The men of certain arms of the service are more or less prone than others to the commission of suicide; of which it may be asserted generally that the highest ratios are found amongst ordinary cavalry; probably from increased liability to vexation and punishment, owing to their double responsibility of horse equipments as well as of personal accoutrements. Next comes the artillery, to which in part the same reasons apply, and the depot battalions with a greater proportion of recruits, who often find the glitter of military life dulled by its realities of drill and discipline, amidst which they are apt to repine over the causes that have induced them to enlist; next follow the Foot Guards and infantry regiments of trained soldiers; and then come the Engineers, who are skilled workmen, having their time more fully occupied in their various handicrafts, bringing increased pay; and, lastly, the Household Cavalry, whose colonels have unusual facilities in dismissing objectionable characters.

In the navy, suicides are more frequent among the officers than the men, and among the seamen than the marines, who, when embarked, form in some measure an *imperium in imperio*, supervised and in some degree protected by their own officers, which maintains

* Mr. Millar, of the Army Department, has shown that the Hospital Staff present the highest ratio.

among them an *esprit de corps*, which is everywhere a safeguard from suicide.

The classification of the modes of suicide had recourse to is not without interest in this comparison.

	By Gunshot.	By Cut-throat.	By Drowning.	By Hanging.	By Poisoning.	From Heights.	On Railroads.	Multiple.	Brain-injury.	Harikari.	Unstated.	Total Suicides.
Army ..	305	128	64	61	45	11	10	7	7	0	15	743
Navy ..	10	17	38	14	6	0	0	1	0	1	6	93

Of the first four modes in this category of criminal deaths, it may be credited that they agree in presenting fewer of the characteristics of premeditation, and more of those of hasty resolve; the victims availing themselves of means at hand to perpetrate the act of self-destruction; the soldier availing himself of his rifle or razor, or of his personal habiliments—his braces or leather straps, or of the tank in, or the stream that flows hard by, his camp; the sailor, of the deep water that floats his home, of his razor, of the rope always at hand, and least frequently of his weapons.* The other modes, which signify a determined premeditation, bear, in both services, but a small proportion to those of hasty resolve. For certainty of action is the one thing sought by those who procure poisons, or walk to precipices, or wait for the advancing train, or inflict upon themselves multiple deadly injuries, which, as shown in this table, are rarely availed of by the seaman in comparison with the soldier. In the naval column, the death by hari-kari was that of a Japanese officer while receiving instruction, who destroyed himself premeditatedly in the mode held in honour by his nation. This is not counted among those of our own crews.

Statistics demonstrate clearly that, whilst suicide is decreasing in the navy, it is increasing in the army. The comparison of the first and last quinquennial periods of the whole term affords these results:

	1860-64 inclusive.			1868-1872 inclusive.		
	Strength.	D.D.	Ratios.	Strength.	D.D.	Ratios.
Navy	292,470	51	.174	241,040	22	.091
Army	954,648	245	.259	826,526	324	.392

Or, while it has fallen from .174 to .091 per 1,000 in the navy, it has risen from .256 to .392 per 1,000 in the sister service. The primary indication of this more satisfactory condition of the navy, is probably an improving *morale* of the crews, influenced by a milder discipline, regulated more closely by fixed regulations that call into action the reasoning powers of men who know their responsibilities, and the exact sum of their liabilities to punishment, than that obsolete discipline that left them much more subjected to the somewhat arbitrary wills of their officers. The inference may be drawn also that, occurring as it does collaterally with the vast change in the type of our ships in the substitution of more capacious iron ships for those of timber, our seamen find more that is conducive to their physical wellbeing, as shown in the improved health of the service consequent on that change, a sounder state of mind being a natural result of improving bodily health in the mass of men, as it is well known to be by each of us individually. The difference under this head existing in the army may be tabulated thus:

Terms of Service.	At Home.			In India.			Other Stations.		
	Strength.	D. D.	Ratios.	Strength.	D. D.	Ro	Strength.	D. D.	Ro.
1st 5 years.	397,711	97	.241	317,817	88	.277	238,520	60	.251
2nd ditto.	412,225	100	.242	233,477	157	.554	130,824	67	.51

This proves that, while the suicidal ratios have undergone no marked change on home service, they have risen from .277 to .553 per 1,000 in India, and from .251 to .512 per 1,000 in other military possessions. Such facts are pregnant with interest to all vital statisticians, but, as they appertain to another service than that to which I belong, I shall not presume to offer any views as to the probable causes, leaving these to be dealt with by more competent heads, who may be in a position to trace out whether the increase is attributable to differences in the stamp and character of the men themselves, or to alterations in the conditions

* Since 1863, soldiers have not been permitted to retain ammunition in their pouches.

under which they serve. It appears, however, on the very face of the above table, that suicidal deaths are not increasing in ratio among the home force which consolidates the recruits and younger soldiers while undergoing their hard initiative drills, but among those who, having completed that period, are serving as trained soldiers abroad; and there is strong reason to believe that the ratios show everywhere an increase proportionate to length of service bringing them nearer to the period of discharge.

Murder and Manslaughter.—Under this definition, the Registrar-General's returns for the metropolis in thirteen years give 1,622 deaths, or an annual mean of 125, which gives a ratio of .041 per 1,000 of all ages; and it is found that the returns of the navy and army both present a lower ratio than this—of .026 in the former, and .039 in the latter service, proving that the men are not unduly guilty of this crime, nor exposed to violence from the various peoples amongst whom the service distributes them.

Homicides are more frequent in the army than in the navy by 50 per cent., and in the latter service their occurrence has been reduced to a minimum, while, in the former, they have undergone no decrease, standing in that respect analogous to the ratio of suicides. The navy returns afford some clue to the circumstances, by recording the hands by which murder has been inflicted; thus we learn that, out of eighteen murders, only two were due to shipmates; eleven were perpetrated on the shores of the Pacific Ocean, five by Japanese, four on Vancouver's Island, and two in Central America; two in India, one on the Coast of Africa by a Portuguese soldier, one by a Maltese, and one in England. Loss of life by malice or in quarrels is now happily rare in the navy so long as the men are on board; but it occurs among seamen when on leave ashore, assignable, in all probability, to quarrels in drinking-shops and brothels with men of the place; those, however, in Japan, would appear to have been assassinations during periods of unfriendly national relations, and might be, with strict justice, classed as death by violence on duty, thus diminishing the ratios of homicides in the navy. Doubtless, some of those in the army returns were committed by strangers, but no guide to this is to be found, only the modes of perpetration being shown; but the preponderance of gun-shot would lead to a contrary inference. The modes are thus specified: By gunshot, 39; incisions, 25; fractures, 10; injured brain, 7; injured viscera, 2; hanging, 2; suffocation, 2; unspecified, 3; presenting an assortment resembling in the main the features of the suicidal list; to which another similarity presents itself in the increase from 36 in the first quinquennium to 41 in the last; which, as in the suicides, contrasts with the navy returns, that show in the last nine years only four murders (assassinations unconnected with the service) against 14 in the first four years of the period.

	Total.		1860-64.		1865-67.		1868-72.	
	No.	Ratio.	No.	Ratio.	No.	Ratio.	No.	Ratio.

Army	90	.039	36	.037	13	.025	41	.041

Deaths by Judicial Sentence.—Of these, the navy had no example in thirteen years. To account for this, when two murders by shipmates are detailed, it must be supposed that these occurred where the offenders could be handed over to the civil authorities. The general fact of *no record* indicates sufficiently that the naval service is tolerably free from the crimes which are punishable by death under Admiralty Articles of War and the Mutiny Act.

In the army statistics for the same period, not fewer than twenty-three suffered death for crimes unspecified; and of these fifteen fell in the first, and only five in the last five years of the period, showing that, while the ratios of suicide increased, that of death for crimes sank still more remarkably.

The following deductions are evidenced.

1. In the period 1860 to 1872, criminal deaths, in the forms of suicide, homicide, and judicial deaths, have borne much higher ratios in the army than in the navy.

2. These, excepting by judicial sentence, have increased in ratio very substantially in the former service, while in the latter they have undergone an equally well marked decline.

Since these results are opposed, the causes cannot be uniform; they may be assumed to be multiple. To approach these with due caution, the first step will be to ascertain the ratios of death from intoxication, which experience teaches to be a general cause of criminal deaths in every form.

The Results of Intemperance are more definitely shown in the public

services than they can ever be in private life, so far as relates to death caused by immediate debauch, or consequent—*i. e.*, the form of delirium tremens—on prolonged indulgence. But, beyond these self-evident effects, there are no data to indicate the evil consequences of the immoderate use or abuse of alcoholic stimulants, as the remote but efficient causes of cirrhosis and amyloid diseases of the liver, as well as of acute inflammation of it ending in abscess, of Bright's disease of the kidney, or of degeneration in the coats of the larger arteries, which, although they are indefinite consequences, may be far more widely spread and more largely destructive of life than those results which are self-evident and unmistakable. These I would classify as the primary, the secondary, and the tertiary results of alcoholism, and shall deal with the first two only.

	Total Deaths.		Primary.		Secondary.	
	No.	Ratio.	No.	Ratio.	No.	Ratio.
Navy	148	.20	54	.078	94	.13
Army	807	.35	269	.113	538	.235

All these ratios are favourable to the opinion of a greater degree of sobriety existing in the navy than in the army, which would be more strongly apparent were it easy to eliminate from the navy returns the sickness and mortality among officers, which are not admitted into army medical statistics; for the navy returns include 32 deaths of officers, holding a relatively greater ratio to their strength than the remaining 116 deaths to the mean strength of the crews. Concerning this point, it is worthy of note, that the large number of deaths of officers is, with exception of two only, by the secondary consequences—delirium tremens; while that of the crews stands in proportion of 5 by alcoholism (or primary) to 6 by delirium tremens, etc., secondary results of intoxication, of which the former may arise from casual but excessive, while the latter arises from habitual, indulgence or abuse.

The mortality resulting from the primary conditions of alcoholism has a difference of classification in the two services. In the navy returns, they are separated into alcoholic poisoning, 15, drink-apoplexy, 28, and asphyxia, from solid food finding its way into the larynx during vomiting while intoxicated, 11; making a total of 54. In the army, all cases admitted suffering from the effects of alcoholism not amounting to delirium tremens were classified as "Ebiosias" prior to the introduction of the new nosology in 1868, since which the classification has been similar to that used throughout in the navy in all cases that have perished immediately from drunkenness, while others are returned as dyspepsia, febricula, etc., which are rarely fatal forms of disease; and it is gratifying to notice that there is a rapidly declining ratio of this kind of brutal excess in both services. Comparison of the quinquennial periods shows in the navy a decline from 27 to 15 deaths, and in the army from 117 to 69, the lowest numbers presenting in the last three years of the whole period of thirteen years.

Analogous results are found relating to delirium tremens ending fatally, of which there were in the navy 49 instances in the first quinquennium, against 25 in the last; and in the army there were, similarly, 117 against 69. Thus, judging by these results, the inference follows, that indulgence in alcoholic or intoxicating drinks to an extent causative of disease and death is happily a decreasing vice in both services. But, in estimating these results of intoxication, I would go beyond the official returns in alluding to a wide margin of uncertainty across which the veil of charity is drawn; for it is impossible to deny that many of the casualties in the services are attributable to the wavering nerve-power, conjoined with undue daring, that alcohol engenders amongst men whose very calling renders them familiar with dangers from which untrained men would instinctively shrink. Also, in the numerous instances of "found drowned, without any assignable cause", it needs no argument to convince that some may have been suicidal, and still more of them the consequences of drink. Nor can I in any other way account for the excessive mortality by drowning shown in the army returns, where, through this period, the "drowned" constitute nearly one-half the deaths by violence or negligence in a service free from special dangers by water. Again, from the list of diseases, it may be shown that in deaths by "apoplexy" there is a decrease almost commensurate with that of mortality from primary alcoholism; and that this is more strongly exemplified with reference to "epilepsy", which, as a pathological condition *per se*, is rarely mortal; whereas in the navy returns it is assigned as the cause of 26 deaths in thirteen years, while, as the cause of loss of service by invaliding, it offers the large number of 1,086 disabled men. A striking relationship to the mortality directly assignable to alcoholism is de-

ducible from the parallelism between them, showing from epilepsy 523 invalidings and 15 deaths in the first, reduced to 246 invalidings and 6 deaths in the last quinquennial period: a noteworthy improvement in health-statistics, quite as important and instructive as the simultaneous decline in the mortality from intemperance.

The all important questions now present themselves as to the relations, if any, that exist between this proved decline in habits of intoxication and criminal deaths by suicide and by judicial sentence.

With regard to the first of these, there is found to be in the navy a parallelism that points to a probable relationship; for, side by side with a decline in the stated quinquennial periods, from 76 to 40 deaths by alcoholism and delirium tremens, there is found to be a decline from 51 to 22 suicides, which parallelism does not obtain in the army; where, side by side with a decline of the fatal results from intemperance, from 366 to 231 in the five-yearly periods, there is a positive increase from 245 to 324 in suicides—proving, beyond a doubt, that this deplorable augmentation can have no relationship to habits of indulgence in intoxicating liquors which coexist in a decreasing ratio. This fact alone demands the deepest consideration of military authorities, especially, as in those flagrant crimes towards others which induce death by "judicial sentence", there has been a decline from 15 to 5 in the stated quinquennial periods, proving, that in this important element, there has been an advancing "morale" in the army. Where, then, it may be asked, is search to be made for the great increase of suicide? Does it lie in the nature of the service, or in the characters of the victims?

It having thus been determined by comparison of the medical statistics of the great fighting services of the State, that, coincident with a decline in these services of the fatal results of intoxication, there is a decrease of suicide and of homicide in the navy which is not counterpoised in the army returns, where, indeed, the opposite conditions exist in spite of fresh precautions, it follows that, to explain so marked a contrast, other reasons—adjuvant in the one case, and counteracting in the other—must be sought for; for, if the inference be correct, that the prevention of crime has been chiefly dependent on, and not merely coincident with, a decrease in habits of intemperance, then, to account for the great contrast between the statistics of the sister services, it may be assumed that other causes have co-operated to raise the moral standard of the seamen of the navy; while, as regards the life of the soldier, there are agencies at work that have more than counterbalanced the benefit of comparative sobriety in deterring from criminal acts.

I should fail if I attempted to show further than I have already done, that the difference in the ratios of criminal deaths bears no direct relation to those by intemperance, unless it be that, in the navy, there is co-operation of other ameliorating causes, whilst in the army the decline of intemperate habits is more than counterbalanced by recently developed productive causes of suicide which lie beyond my power of investigation. With regard to the service to which I belong, I will now proceed to point out what appear to me to be the changes in the position of the seamen of the navy on which their improved *morale* is based.

During the latter half of the present generation, the entire system of educating and training the seamen of our navy has undergone a deep searching revolution, the mainspring of which has been the foreseen difficulty of manning the fleet in war time by means of impressment.

Formerly, even the cream of our man-of-war's men were held to the service by the loohest of ties, and served alternately in the navy and in the merchant service, turning away from the former when wearied by its inseparable restraints, or after undergoing punishment for impropriety of conduct; often, too, when paid off from ships, their money being spent, they were compelled to join merchant ships, there being no men-of-war fitting out, in order to avoid destitution. In this respect, the new system of continuous service has benefited the seaman incalculably in his social condition, as, when paid off, he is no longer cast ashore, but is borne on the books of a guard-ship until drafted into a seagoing ship, and is allowed a reasonable period of leave to visit his friends, wherever they may be, instead of wasting his hard-earned wages in the purlieus of seaports; and he is thus taught to be a self-respecting member of society.

Those who recollect the condition of our naval towns in days gone by, when the paying off of a ship of the line caused the streets to be crowded with drunken sailors and their abandoned associates, are now struck with the wonderful contrast in them. Where a reeling sailor, full of practical jokes, was met at every turn—every allowance being made for the freaks of "Jack ashore", now, on the paying off from a ship, those of the crew who belong to other ports are transferred at once by steamers to their homes, and borne on the guard-ship's books. During their leave, they have civilising places of resort, as well by night as by day, in sailors' homes and institutes, where reading-

rooms and amusements, with means of moderate indulgence without intemperance, are provided to suit their wants; and thus the streets are rendered free from disorderly scenes, and in them a drunken sailor has become as much a *rara avis* as a sea-gull would be in an inland town. Formerly, "to hand and reef the sails, to shift the spars, to heave the lead, and to steer the ship and work the guns", were the simple requirements of an able seaman, and the boys for the first time entered were just so many as were wanted to fill the places of officers' servants; now, every seaman must be in every sense a skilled artisan in seamanship and in gunnery, and his improving or deteriorating qualities in each of these, as well as in conduct, are noted every year on his parchment certificate, which forms the criterion for his promotion, as well as the guide to his claims for badges and rewards and for pension on discharge. Encouragement is afforded him by a savings' bank to be prudent in money matters, and, by an easy mode of remittance, to be thoughtful and considerate towards his relatives; thus cultivating good social principles, while, in instruction by a seamen's schoolmaster and the use of a good ship's library, he has the means of improving his mind.

The watchful pains of their superiors in these matters have done much towards changing the characters of our seamen, as is strongly marked in the large proportion of married men having respectable wives, in the voluntary classes they form for religious instruction, also in the benefit societies they maintain in most large ships for the aid of those who are disabled by the accidents incidental to their calling, and in the liberal donations they make to charitable institutions on shore for the benefit of the orphans of their class.

On board his ship, the sailor is surrounded with conditions that enforce regularity of life, and, beyond these, the total abstinence movement is making a most satisfactory progress in the navy, mainly promoted by the philanthropic efforts of a few benevolent ladies, who devote themselves to its diffusion at the seaports. These men are allowed the value of their ration of spirits, while others receive theirs under restrictions that render it difficult to exceed their ration. Twice daily, the whole crew are paraded for inspection, and, during their watches on deck, they are so frequently brought under the notice of their officers, that any approach to intoxication is almost sure of detection during the active exertions they are then frequently called on to make; and, in the routine of ships, the whole crew are often employed in general drills or in exercise aloft; and thus, when at sea, discipline and routine duties combine to render drunkenness an exceptional fault. When in harbour, the discipline is relaxed, and, during the daytime, the whole crew are employed on duty while the ship is refitting; in English harbours or in those of friendly nations, leave on shore, by day or by night, according to the degree of safety, is granted; while, in most ships, in order to moderate the desire for the shore, a greater scope of evening amusements on board is permitted; and I have known, in some ships, considerate officers to allow what is termed "the ship's company's cask of beer" to be introduced and dealt out in safe quantities, with much benefit to the health and morality of the ship, because "Jack", enjoying his pint of beer and pipe, with songs and the dance, is a contented man; and in some ships the canteen system is adopted. Under such kindly treatment, drunkenness is rare, and those terrible evils of direct excess, as poisoning by alcohol, alcoholic apoplexy, and suffocation by food in the act of vomiting, which occur among those who indulge to excess in the inferior kinds of spirits which are freely supplied in seamen's haunts ashore, are avoided, and the evil delirium tremens—to which they are exposed by the sudden withdrawal of stimulants after debauch, is prevented.

Under the obsolete system of entering boys from the shore to each ship, when put in commission, they were exposed to the prolific dangers of example from the worst men of their messes, of which they were the more susceptible from want of primary training; but this is now, in a measure, obviated by the excellent system of educating a superior class of boys for the navy in the schools of Greenwich Hospital, and in the preliminary training so well provided for in our training ships for all boys before drafting them into seagoing ships. In this manner, five thousand boys are brought up for the navy annually, with the good results not only of adapting them to the service, but of eliminating at an early age such as, from defects of constitution, are or will soon be unfitted for the arduous duties of the seaman's calling; thus securing a healthier and more vigorous class of men at the threshold of the service. The age for entry is between 15 and 16½ years, and, after a year's training to qualify for first class, they are drafted into seagoing ships. Each boy, when drafted from a training-ship, takes with him a certificate of his efficiency in the details of "gunnery instruction, seamanship, and school education", in each of which details his proficiency is marked "fair, good, or very good". Boys who pass through the training ships are engaged to complete ten

years in the fleet after their arrival at 18 years of age, with this subsidiary advantage to the mercantile community at large, that, if, after that length of service, they elect to leave the navy, they pour into the merchant navy a large community of well trained seamen, who, for the most part attaching themselves to the Naval Reserve, form a considerable dépôt for the navy in the event of war, to which their primary apprenticeship will be the link of safety. During the period of tutelage in training ships, they are taught, if previously uneducated, to read, write, and cypher, and are trained in habits of sobriety, cleanliness, and obedience to command, and those personal adjuncts of making their own clothes, taking care of their "kits", and otherwise providing for their own wants, in which they prove themselves to excel, whenever the calls of the service detach them from their ships on boat service or in naval brigades, of which there are many praiseworthy examples. Fortunately for the country, this admirable system will admit of indefinite extension proportionate to its wants, and thus the service, training its boys at home in boat service, in duties aloft, in sword exercise and gun drill, before they are sent to sea in ships of war, secures all the preliminary rudiments of the "skilled artisan", which every able seaman must be now, when the means of combat have undergone so vast an extension in the altered class of ships, provided with scientific artillery of refined construction.

The training of boys to the specialties of the navy, and the improved treatment of seamen under the modern system of continuous service, are, I believe, the fundamental causes of that remarkable improvement in the *morale* of the seamen of the Royal Navy, which is irrefutably proved to exist in the medical statistics of decreasing intemperance, as well as of criminal deaths by suicide and homicide, which may reasonably be imputed to that enervating and destructive vice.

In offering these facts as a further exemplification of the pervading force of the maxim, "Obsta principiis", so far as the State service with which I am familiar is concerned, I would here terminate my inquiry into causations, as I feel my own inability to indicate those which lead to contrary results in the sister service, beyond ascertaining that these results of increasing criminal deaths by suicide and homicide coexist in the army on foreign stations with a decreasing ratio of deaths by intemperance, which is an important leading point in arriving at just conclusions as to the truly efficient causes.

ON "MALTA FEVER": WITH A SUGGESTION.

By W. C. MACLEAN, M.D., C.B., Inspector-General;
Professor of Military Medicine in the Army Medical School, Netley.

IN the course of the invaliding season at Netley now drawing to a close, my colleague Surgeon-Major Webb remarked to me "that many of the invalids from Malta arrive in a more shattered condition than those from India". The remark was just, and suggestive of serious reflection as to the sanitary condition of that important military post.

To what is this "shattered" condition due? The answer must be, "Malta fever". What is this fever? Is it malarial, enteric, or relapsing? or is it a hybrid, *i. e.*, typhoid fever complicated by a thread of malaria—a typho-malarial fever, to use a term now creeping into our nomenclature? It is very desirable that a satisfactory answer should be given to this question; and this answer, it is plain, must come from those who have the opportunity of studying the disease where it arises, with the additional advantage derived from careful observation of the sanitary surroundings of the population, civil and military. This much is certain: it is one of the most distressing forms of fever, both in its primary manifestations and in its sequels, which the British soldier has to face, and the medical officer to treat, in their respective careers; and the latter is often called on not only to treat it, but to suffer from it in his own person.

The most notable part of the disease is its extraordinary duration, extending not infrequently over seventy days before anything approaching to convalescence is established. We have at this time a young medical officer under observation here, who landed from Malta on June 22nd. At that date, he had been on the sick-report with "Malta fever" for sixty days. His temperature on arrival at Netley was 104 deg. Fahr.; and even now, under the most favourable hygienic conditions, careful diet, and good nursing, this young officer has little more than entered on the distressing stage of neuralgic and rheumatic pain through which the majority of those affected have to pass before convalescence. It will be seen from this that the term "long fever", by which the disease is known among soldiers, is appropriate.

I do not pretend to be able to give a good clinical description of this fever; for, although familiar with its sequels, I have never had an opportunity of studying it in its "home". As in most fevers, there is a stage of *malaise* of some days' duration, followed by a sharp rigor,

with well marked gastric and hepatic disturbance. Sometimes this stage is as well pronounced as in the severe remittents of a malarial locality in the tropics. With the above symptoms, there is severe headache, generally frontal. The temperature-curve differs widely from that in true malarial fever; it does not rise rapidly; and some days elapse before it attains its maximum, which appears to be 104 to 105 deg.; and this, as I have mentioned, is often maintained for forty, fifty, sixty, and even seventy days, with, as the unavoidable result, wasting and degeneration of muscular tissue and excessive prostration. From all I can gather, the disease is not, as a rule, paroxysmal, although in some cases of officers landed from Malta, seen by me in consultation, I have observed a distinct and well-marked morning remission, as in a malarial remittent. Such cases were benefited by quinine, which is seldom found useful in "Malta fever". Sometimes there is diarrhoea, with or without iliac tenderness; the evacuations being sometimes dark-coloured and offensive; at other times, particularly when there is abdominal tenderness, presenting the appearance commonly seen in enteric fever. In a word, if I may venture to judge from what I have gathered from our Malta invalids at Netley, sometimes the symptoms of typhoid, sometimes those of malarial fever, predominate. In the majority of the cases seen by me, the spleen has been more or less affected. We have in our wards at this time a case in which this gland is as much enlarged as if the patient had come direct from the Peshawur valley.

There is one symptom common to every form; viz., a stage of neuralgic and rheumatic pain, sometimes muscular, sometimes articular, not unfrequently both, through which eight out of ten of those affected have to pass before they can be said to be really convalescent. This stage is often not reached till some weeks after the more urgent febrile symptoms have subsided. A rise in the temperature usually precedes the setting in of this fresh addition to the patient's sufferings. A number of weakly young soldiers do not convalesce at all, or only to a partial extent; developing, instead, either tuberculosis or some other form of destructive lung-disease, the result of the metamorphosis of catarrhal or pneumonic deposits which have taken place in the course of the disease, or which may have existed previously.

My friend Staff-Surgeon Lambert, R.N., who served for some time in the Naval Hospital at Malta, and who suffered severely from the disease himself, informs me that a large number of seamen were in his time invalidated home, after having gone through this fever, on account of deposits of this kind, which, in the vigorous and those presumably not of a phthisical tendency, were absorbed, as many of them returned after some months' absence, in good health.

It would appear that the treatment of this disease is, to say the least, unsatisfactory. It is certain that, save in cases in which malarial symptoms predominate in a very marked manner—in other words, where the fever is more or less paroxysmal—quinine is useless, if not hurtful, exercising no influence either in reducing temperature, shortening the duration of the disease, or even mitigating the pains of the rheumatic stage. This being so, I have a suggestion to offer on this point for the consideration of those who have to contend with this disease. It may appear very unscientific, very empirical, to discuss remedies before we have settled the proper place of this fever in our zological system; but I am afraid this is what physicians have to do every day. There is, however, no reason why the use of this or that provisional remedy should in the least interfere with those careful observations which are so much needed here. Let us hope that more than one of our capable medical officers quartered at Malta will take this fever in hand, and, after the manner of Louis, and Jenner, and Parkes, and Stewart, patiently investigate it. Judging from the careful report of those who have studied the sanitary surroundings of the troops, there is much to rouse the suspicion, at the very outset, that a fecal element plays an important part in the genesis of this disease, for the whole inhabited part of this "military hothouse" seems supersaturated with excrementitious matters; so much so that, on looking over the report of the Committee of which Surgeon-General Ker Innes was President, it has often struck me that if, by any accident, yellow fever were introduced into that closely peopled island, with its stercoraceous accumulations in houses, it would find the conditions most favourable for the development of its destructive power.

Some months ago, Dr. Alfred A. Woodhull, of the United States Army, was good enough to send me a copy of a paper of his, reprinted from the *Atlanta Medical and Surgical Journal*, giving an account of his clinical studies with large non-emetic doses of ipecacuanha in the treatment of dysentery. From this, it clearly appears that this method of treatment, once more happily established in India, is not much known or appreciated in the United States. Dr. Woodhull's cases, which are carefully and conscientiously recorded, show that the *radix antidiysenterica* is as effective against the dysenteries of

America as it is in India. I have since received from the same author a reprint of another paper from the same journal, giving his "clinical studies on the use of non-nauseating doses of ipecacuanha in intermittent fevers". Dr. Woodhull gives a series of twenty-eight cases treated with ipecacuanha in doses varying from one to twenty grains. Emesis followed only once or twice, and nausea very seldom, although the author thinks "a good preliminary emetic would sometimes be useful". Dr. Woodhull gives the cases in some detail, with the thermometrical readings; and he notes that they were kept under observation as long as the thermometer gave any indication of a tendency to relapse, whether the patient was or was not sensible of an aguish disposition. Ipecacuanha was the only remedy used, for the most part in grain-doses every three or four hours. There were nine "recurring cases", but in only one did more than two chills recur after beginning the medicine. Four cases had only one chill after resuming the ipecacuanha. In thirteen cases, no chill was experienced after the exhibition of the remedy. It is particularly noted that, when dysenteric symptoms co-existed with those of intermittent fever, they were promptly suppressed by large doses of ipecacuanha. Dr. Woodhull has a theory as to the action of the drug. He regards it as a nerve-stimulant, especially to the ganglionic system. Into this question I do not mean to enter here. The suggestion I beg respectfully to offer to medical officers who have to treat "Malta fever" in its "home", is to give this drug a fair trial in the manner used by Dr. Woodhull. I have long been anxious to see a fair trial given to ipecacuanha in the treatment of the early stages of typhoid fever pure and simple, not for the sake of its emetic properties, but for its power as a blood-depurant. There is abundant evidence that the functions of the liver are much disordered in the early stages of "Malta fever"; and I have elsewhere shown that ipecacuanha is one of our best and safest remedies in acute hyperemia of this gland. I ask for a fair trial to this method of treatment with confidence, because, if it fail, it is not likely to do harm, or to expose patients to the smallest risk or even inconvenience.

MALIGNANT DISEASE OF BOTH OVARIES.

By M. CHARTERIS, M.D.,

Physician to the Glasgow Royal Infirmary.

A. M., a female aged 21, was admitted into the Glasgow Royal Infirmary on March 27th. She had been sent from a neighbouring mining town to the Maternity Hospital, under the idea that she was pregnant, and was transferred from there to the Royal Infirmary. Her history was as follows.

From the age of fourteen, she had been a prostitute; and she stated, without a blush of shame, that she had often had connection with three or four men in a night. Fifteen months ago, she had a child, which died shortly after birth; and since then she had never been well. As soon as the lochial discharge ceased, having no friends, and no other means of subsistence, she commenced again her calling, and continued at it until two months previously to her coming to Glasgow, when she caught a cold, and noticed her feet and legs swelling; and a pain which had existed in her right side since her confinement became greatly aggravated.

Her symptoms, on admission, were as follows. Her appearance was pale and pasty, with facial palsy of the right side. Her feet and legs were considerably swollen. Her abdomen was distended. On percussing it, dulness was detected over the right iliac region, which became more defined when she lay on the opposite side. What this dulness was due to gave rise to some difference of opinion. By some it was considered to be caused by the ascitic fluid gravitating to the side. Others suggested that it was an enormously enlarged liver: an opinion which her previous dissipated career somewhat favoured. On a subsequent day, however, and on more carefully percussing the region, it was found that the dulness was distinct from the area of hepatic dulness, though this was considerably increased, and was incompatible with the supposition of its being simply ascitic, from the fact that the dulness, though not so well defined in some positions as in others, was never entirely absent from one particular spot in the iliac region. An obscure, ill-defined, dull percussion-sound was also found on the left side of the same region. On examining with the speculum, the introduction of which caused great pain, the os uteri seemed normal. The sound was inserted; and, so far as could be judged, nothing was found wrong with the uterus. There was, however, a purulent discharge from the vagina, which was considered most likely to be of gonorrhœal origin. The urine was albuminous; and, under the microscope, tube-casts were seen in great abundance. The respiratory and cardiac systems were at that time healthy. Her digestion was greatly impaired. She had little

appetite for food, and very frequently, though not constantly, vomited what she was able to take. Her most urgent symptom from her admission to her death was the great pain she had in the right iliac region—a pain increased on the slightest pressure, not confined to the spot touched, but spreading down the thigh on the inner side. Later, the pain became most intense and was aggravated by pleurisy of the right side, with subsequent effusion. She died on April 18th, twenty-three days after her admission.

I am indebted to Dr. Foulis, the Pathologist to the Royal Infirmary, for the following report of the *post mortem* examination; and to Dr. Whitaker for the woodcut, which admirably depicts the position and appearance of the tumours.

The abdomen was distended; the legs cedematous. On opening the abdomen, about two and a half pints of turbid yellow fluid was found in the peritoneal cavity. The stomach was contracted, containing a small quantity of yellow fluid. The liver weighed 4 lbs. 7 oz.; the tissues friable. The kidneys were large, weighing ten ounces each. The capsule was not adherent; the surface was smooth and glistening. The colour was pale yellow, mottled here and there with red streaks. On section, the cortical substance was enormously increased; its prevailing colour yellow, mottled with red. The pyramidal substance was of nearly natural appearance. The ovaries were converted into large oval tumours of nearly equal size, six inches long by three inches broad, of a mixed colour, pale salmon mingled with slate colour. The surface was quite smooth, but overlaid in many parts by a layer of firm organised lymph. On section, the surface was smooth and glistening. It was of a mottled yellow and pale brown colour. The fimbriated extremities of the Fallopian tubes were also affected with the same change of structure, though in a much less degree than the ovaries. The uterus was small, not altered. The heart was not abnormal in size. The ventricles were contracted, and contained only a small quantity of a pale clot. In the pericardium were about two and a half ounces of clear reddish serum. In the right pleura were about two pints and a half of turbid yellow fluid; the right lung was compressed against the upper and back part of the pleural cavity. The lower lobe of the right lung was non-crepitant. The left lung was congested. The brain was natural. The spleen weighed five and a half ounces; its structure was soft, and of a dark plum colour. The microscopic examination of the tumour showed a structure of groups and masses of round cells, with a loose interlacing stroma. The structure was that of the round-celled sarcoma.

It will be seen that the structure of the tumour was that of the round-celled sarcoma, which, doubtless, must have increased with amazing rapidity. As previously mentioned, the woman had a child fifteen months before her death, so that the tumours had been formed subsequently to that period. That the tumour in question is extremely rare will be evident from the fact that Rokitsky does not even allude to a case of the kind. Virchow mentions having seen one, and records it as being of the greatest possible rarity, and that it invaded both ovaries. Kiwisch has seen two cases. Of English authors, we find Mr. Spencer Wells, in his last edition of his work, 1872, stating that, until the present year, he doubted their existence, but since then he had seen two distinctly characterised, and taking their origin in the ovarian tissues. In both cases, the right ovary alone was affected. In one case, the tumour weighed nine ounces; in the other, four pounds and a half.

Dr. Wilks, in the *Transactions of the Pathological Society*, vol. x, gives a detailed account of the case of a girl, aged 19, who died under Dr. Addison's care in Guy's Hospital. In this case, the ovaries seem to have been both affected, and the disease also invaded the pyloric half of the stomach. The tumour seems to have been of a fibroid character.

My colleague Dr. Scott Orr has kindly supplied me with the manuscript of a case which came under his care in 1861. It will be observed that, in many particulars, it bears a very striking resemblance to the one I have narrated.

"A poor girl, aged only 18, was admitted into the Royal Infirmary in the winter of 1861. She had only been a few months ill; and yet, on her admission, her abdomen was greatly distended by a large firm swelling, which gave her the appearance of being about seven or eight months pregnant. She was tolerably plump and healthy-looking when first admitted; but soon her sufferings become so great, and she was so wasted with hectic fever and pain, that she quickly assumed the well known cachectic appearance of confirmed malignant disease. I had little doubt from her history that the disease was ovarian, and of a malignant character. On examining her *per vaginam*, however, I was not a little puzzled to find, filling the whole pelvis, a large irregularly nodulated tumour, having the hard scirrhus feel of a carcinomatous uterus. The os uteri was with difficulty reached. It was tilted forwards towards the symphysis pubis. The question now came to be, was the abdominal tumour connected with the supposed uterine swelling, or were there two distinct tumours; the one uterine, the other ovarian. I lean to this latter opinion, believing that such malignant ovarian growths may be associated with like degenerations of other organs. The patient soon sank, and died worn out with exhaustion; and an opportunity was afforded of ascertaining the true condition of morbid parts. One ovary was found loose and unattached, floating among the bowels, enlarged fully to the size of a child's head. The other was not quite, but very nearly, of equal size. It filled the whole pelvis, into which it was pushed down, and pretty firmly attached; and it was its irregular nodulated surfaces which had been felt during life through the vaginal parietes. The structure of the tumours was truly malignant, presenting the soft hair-like character in many places, while in others suppuration had taken place, and in others the hæmorrhagic character revealed itself, as seen in fungus hæmatodes. The uterus was small and contracted, free from disease, but displaced forwards, its os lying as I had felt it during life. It is worthy of notice, also, that the liver was found to be largely infiltrated with cancerous disease.

"These appearances fully explained all the poor girl's sufferings, for they displayed an activity and acuteness of morbid action which could not have gone on without great pain and distress. The early age at which this malignant form of ovarian disease was developed was surely a very peculiar feature in this instance, and it struck me very forcibly at the time, being the only case of cancerous degeneration of the ovary with which I remember to have met."

REMARKS.—In Dr. Scott Orr's case, it is not particularly noted what occupation the girl had; but with regard to my own case, this was very evident. It is probable that the kidneys were first implicated, as their large size and weight abundantly evidence. Albuminuria and a debilitated constitution resulted. Then the girl's mode of life necessitated great ovarian irritation. What part the ovaries play in sexual intercourse, no one can tell; but that they hold an important one, no one will attempt to deny. With a reduced constitution, the woman plied her unhappy calling, and the constant irritation probably originated the form of cell-growth described. The fact that both ovaries were affected materially assists this hypothesis. The woman, it may also be mentioned, seemed, both in her conduct and conversation, to savour more of the lower animal than of the woman. Her talk was such as to disgust nurses and patients; and, latterly, we were obliged to put her into a side room with a typhoid fever patient, who, on the second day afterwards, begged to be placed in the general ward, and to be freed from her society.

ON THE NATURE AND TREATMENT OF ALPECIA AREATA (AREA CELSI).*

By JAMES H. STOWERS, L.R.C.P.Lond., M.R.C.S.Eng.,
Shrewsbury.

AMONG the many cutaneous affections met with in practice, there are few, I believe, that have received more attention from the profession of late than the above. Numerous writers have done much to enlighten us as to the true nature of this disease, especially Jenner, Hutchinson,

* Celsus, *De Re Medicâ*, lib. vi, cap. iv.

Rindfleisch, Bristowe, Dühring, and others. Again, in the *St. Bartholomew's Hospital Reports for 1872* (vol. 8), Dr. Dyce Duckworth contributed one of the most able papers that have been written within the last few years upon the nature and treatment of alopecia areata. Much evidence has been adduced on both sides as to its parasitic or non-parasitic origin; but, notwithstanding, the majority of those who have studied the microscopical characters of the altered hairs obtainable in this affection do certainly speak most emphatically, and I believe with truth, in favour of its being independent of any fungus-element. That this disease may occur associated with other parasitic affections—tinea tonsurans, for example—there can be no possible doubt; but the fact of a fungus being but seldom found with true alopecia proves that that alone cannot be the real cause. The bulk of evidence tends to show that it is an abnormal condition dependent upon nutritional changes in the scalp, producing a disturbing influence upon the hair's growth, loosening it in its follicle, allowing its closely arranged fibrille to become separated (thus accounting for the swelling in the shaft in the early stage), and rendering the hair so brittle that it either fractures with the slightest touch, or falls away with many others, leaving the characteristic patch. For my own part, I have examined microscopically many specimens of hairs, and have totally failed to find anything suggestive of a parasite. My attention has lately been drawn to two cases of alopecia successfully treated with local stimulants, and published in the *JOURNAL* of November 14th, 1874, by Mr. C. R. Roose. I wish, therefore, more particularly to speak concerning that form of treatment, and to give my experience in its use.

During the period when I was clinical assistant in the dermatological department of St. Bartholomew's Hospital, I had an opportunity of seeing very many instances of alopecia, and in my note-book I have notes of several cases precisely similar to those referred to by Mr. Roose. Without local stimulants, I believe it impossible to produce a cure. Good nourishing diet, and tonic medicines to improve the general health, as cod-liver oil, steel, mineral acids, and nuxvomica, are indispensable; but even these, without a stimulating topical application, are insufficient. At one time, it was my practice to compare the results of certain local remedies, and note the efficacy of each. Among those used were the blistering fluid of the *Pharmacopœia*, tincture of capsicum, spirit of turpentine, and the strong solution of ammonia, alone and combined. It is interesting to note how the scalp, when its nutrition is impaired, the vitality being lowered, will tolerate the use of such powerful applications for a long period, with less irritating effect than in health. The first remedy—the blistering fluid—was used in several cases with a fair result. However, when the disease is extensive, much inconvenience is experienced by the patient from a large vesicated surface; and, moreover, it was found that the result was not better than that of other applications. Tincture of capsicum in the form of a lotion, with glycerine and rose-water, proved useful, but yet inferior to either spirit of turpentine or solution of ammonia.

The relative merits of the two remaining fluids were then noticed. Cases were chosen in which several patches of the disease existed simultaneously upon the scalp of the same patient, that the influence of each remedy could be the more easily compared. A large number of cases were thus treated. The strong solution of ammonia was applied with a small piece of flannel, and carefully rubbed in night and morning until the surface became reddened. At first, the scalp appeared insensible to it, very little smarting occurring. This was repeated daily until the surface became sensitive, and the strength was reduced, or the application used less often. When the scalp became irritable, it was discontinued for a few days. In a few weeks, fine white downy hairs appeared, and gradually the hair normal in character returned. The scalp was ordered to be shaved periodically, to stimulate the hair's growth, and allow the more thorough application of the fluid. The spirit of turpentine was used in the same way.

A careful prognosis as regards time must always be given; for improvement is but slow in many instances, requiring even months before the patient can be convinced that good is being done. If patience and perseverance, however, be exercised, benefit is sure to follow, although it may seldom happen that some of the hair-follicles are so changed and atrophied that their function cannot be restored to normal.

Dr. Duckworth published in the *St. Bartholomew's Hospital Reports for 1873* (vol. ix), the conclusions that we were able to draw as the result of our observations, and I cannot do better than repeat them in his own words. They were as follows.

1. The local treatment by strong solution of ammonia is apparently more satisfactory than that by spirit of turpentine.
2. The renewal of the hair-forming function is probably hastened more by ammonia than by any other local application.

3. Turpentine appears to be only second in importance as a topical agent.

4. The ammonia treatment is, on the whole, less universally applicable in these cases than turpentine.

5. In certain cases—a decided minority—the ammonia treatment cannot be borne because of its severity, e. g., exciting vesication. Turpentine never produces these effects, and is a less formidable agent in all respects.

6. Ammonia may, therefore, be regarded as a valuable local application in these cases.

I will only add that, since the publication of these conclusions, I am able to speak even more highly in favour of ammonia as a curative agent.

A RARE INJURY OF THE SHOULDER-JOINT.

By GUSTAVUS FOOTE, M.R.C.S., Kington, Herefordshire.

ON March 18th, 1871, a man named David Higgins came to my surgery, saying he had fallen down when he was very drunk three days previously, and had hurt his arm. On examination, the arm from the shoulder downwards was found enormously swollen, especially about the elbow, and for the most part hard and brawny; there was flattening of the shoulder. I told him the arm was out of joint, and proceeded to reduce it, which was easily effected, but it fell back immediately into the old place. On a more careful examination, I discovered the upper portion of the shaft of the humerus loose in the axilla, broken off at about the surgical neck; I had merely reduced the broken shaft, leaving the upper end in the axilla. The diagnosis then was, a dislocation into the axilla and a fracture of the bone at the surgical neck occurring at the same moment. Two days later, my friend Mr. Garrard saw him; and, after a long and careful examination, he agreed with me as to the nature of the accident. The treatment I adopted was merely to make sure that the ends of the bone should be kept in apposition, and to place the arm in a sling; the object being to cure the fractured humerus, and promote the formation of a false joint under the coracoid process of the scapula. The swelling gradually subsided, the bone readily united, and a fairly good joint was formed. The patient was able to continue his employment as a mason, having free use of his arm; he could not, however, raise it upwards so as to bring the hand above the head.

I did not see the man again until September 5th, 1874, three years and a half after the accident. He was then suffering from alcoholism; the symptoms being general paralysis and vital prostration. As he had no home, I had him conveyed to the infirmary at the union house, where he slowly sank, dying on the morning of the 10th. A *post mortem* examination was made twelve hours afterwards. The arm presented an appearance of dislocation downward into the axilla. An incision was carried from above the acromion process down the arm, to below the insertion of the deltoid, which appeared wasted, then across the upper part, and the bone was completely exposed by dissection. A singular condition of things was discovered. There had been fracture of the humerus at the anatomical neck and at the surgical neck of the bone; the head of the humerus was still in the glenoid cavity, and its attachments were firm. The lower end of the loose fragment had become united most accurately with the shaft, and the upper extremity had formed for itself a very good false joint, the cavity being formed by the under surface of the coracoid process, and the corresponding portions of the second and third ribs. At the point of union between the two ends of the bone on the outer side, callus had been thrown out, and a bony union had been formed with head of the bone still in the glenoid cavity. There were in fact two joints, the false and the true one. While *in situ* the arm could be moved freely in any direction, except upwards. The diagnosis proved to be nearly accurate, for practical purposes quite so. The only way in which I can account for this singular accident is by supposing, that when the man fell down the shoulder must have struck against a smooth projecting stone in the road.

The only case at all similar that I can find recorded is one mentioned by Sir Astley Cooper in his treatise of *Dislocations and Fractures*. A Mr. Blackburn fell from his horse and was declared to have dislocated his shoulder. It was not until after his death that the real nature of the accident was discovered; it was then found there had been a dislocation of the humerus, with a fracture at the anatomical neck; the detached head of the bone had become fixed by osseous union to the inner edge of the coracoid process, and the upper end of the shaft had formed a good useful joint.

FORTY-THIRD ANNUAL MEETING
OF THE
BRITISH MEDICAL ASSOCIATION.

Held in EDINBURGH August 3rd, 4th, 5th, and 6th, 1875.

PROCEEDINGS OF SECTIONS.

SUBJOINED are abstracts of most of the papers presented to the several Sections of the Association at the Annual Meeting. The papers themselves, as opportunities occur, will be published in full in the JOURNAL.

SECTION A.—MEDICINE.

Wednesday, August 4th.

In the absence of the President, Dr. R. QUAIN, F.R.S., the Chair was taken by Dr. W. T. GAIRDNER, Vice-President, who delivered an introductory address, which was published at page 200 of last week's JOURNAL.

On Types of Continued Fever. By JOHN BEDDOE, M.D., F.R.S., etc., Clifton.—The author touched very briefly on the modern classification of continued fevers; and, having related the history of two cases occurring in his own practice which had lasted over two months, expressed his belief in the existence of a type of fever of protracted duration, specifically different from the enteric, and related to synochus.—Sir ROBERT CHRISTISON said that Dr. Beddoe's paper opened two subjects; first, an instance of a different form of fever from those which were at present generally recognised by physicians and in books; and, secondly, the relation which that form of fever might have to other forms. Sir Robert then directed attention to an instance of a fever such as Dr. Beddoe had described as different from ordinary typhus, and different from that which was improperly called typhoid fever, and which more properly should be called enteric. This form of fever was tedious and slow, and the approaching convalescence was followed by the return of the fever in about two months. He believed this peculiar fever to be due to a life of great excitement, and also to living too well, although not intemperately. County magistrates, he thought, constituted a considerable portion of the number of patients he had seen. He had had a long experience of fevers, and he had never seen such a case in the hospitals. He came to the conclusion that there were more forms of fever than those who had written on the subject were disposed to allow. The observations of Dr. Cullen, who was one of the most accurate physicians that ever lived, had been neglected; and they must treat him with great respect, because he did not found his conclusions upon pathological anatomy, but upon minute and accurate observation of the disease. He had described fevers that were not known in the present day.—Dr. JOHN HADDON (Manchester) hoped that the discussion would direct the attention of general physicians to recording the symptoms of fevers, so that, by a comprehensive grasp, they might be enabled to generalise to some useful purpose.—Dr. DAVID YOUNG (Florence) called attention to the Roman, Venetian, and Naples fevers, which were malarious and intermittent. Apart from the pure malaria and the malarious typhoid, there was a fever very common, and which seemed to resemble that described by Dr. Beddoe. He had noticed forty cases of that fever in the last three years, not one of which bore the least resemblance to typhus or pure typhoid, and not one of which lasted longer than five weeks.—Dr. T. D. GRIFFITHS (Swansea) thought that these low fevers had their origin in a diseased state of some of the organs of the body. Medical men ought to study fevers more than they had hitherto done before increasing the number of types.—Sir JOHN ROSE CORMACK (Paris) said that the conditions under which such a class of fevers occurred should always be carefully studied before deciding that it was different from the usually received types. What was known, for instance, as Roman fever was, so far as he could see, a description of obscure or irregular ague.—Dr. MACLAREN (Glasgow) agreed with Sir John Cormack in his last statement, and, in the absence of *post mortem* proof, would be inclined to put down the cases mentioned by Dr. Beddoe and Sir Robert Christison as cases of enteric fever.—In answer to the Chairman, Sir ROBERT CHRISTISON said the cases to which he had referred were quite unconnected with one another.—The CHAIRMAN said he very much doubted whether a classification of fevers could yet be made upon any basis but the three recognised types and a number of anomalous types.

Treatment of Aneurism of the Arch of the Aorta by Means of Galvano-Puncture. By T. MCCALL ANDERSON, M.D., Glasgow.—After giving a report of two cases in which this treatment was carried out

with success, Dr. Anderson laid down the following rules. 1. The continuous current battery should always be employed, never the induction apparatus. 2. The kind of battery is of less consequence, if it be in good working order; but the cells should be large, so as to increase the chemical effect. 3. The needles should not be very thick, but very sharp, and should be oiled before being introduced, and that portion of them which traverses the skin, walls of the sac, and intervening tissues, should be insulated by means of a coating of vulcanite. 4. The needles should be connected with the positive pole of the battery. 5. A weak current of electricity should be used (from four to eight cells of a large Stöhrer's battery), and the operation may be continued for about an hour. 6. The number of operations, and the length of the intervals between each, must depend upon the effect of those which preceded them. Dr. Anderson concluded by referring to the dangers connected with the electrolytic treatment; viz., inflammation, and the entrance of air and of clots into the circulation; and observed that it was a question to which attention should be specially directed in the future, whether the consolidation of that portion of the aneurism which approaches the surface may not, in some cases at least, favour the extension of the disease in other directions, and lead to internal pressure-symptoms, and to rupture into internal organs.—Dr. CLIFFORD ALLBUTT (Leeds) stated, as the result of his experience, which was drawn from five or six cases, that the mode of treatment described by the author must be considered as successful. The points on which success depended he regarded as the use of a feeble current (five cells), with Ladd's galvanometer, derived from large plates, and the introduction of the positive pole only. It was well also to use several needles, all connected with the same pole. Strong currents were injurious, and small plates did not give so good results. Notwithstanding this, the author said, embolism must be regarded as a risk. It occurred the day following one of his operations, in which he had introduced both poles into the sac.—Dr. ANDERSON, in replying, remarked that it must be remembered that, when embolism occurred after an operation, it did not necessarily follow that it was due to the mode of treatment.

Auscultation of the Œsophagus. By T. CLIFFORD ALLBUTT, M.D., Leeds.—Dr. Clifford Allbutt read a paper on the investigation of the œsophagus by means of the stethoscope, and stated that this method deserved to be better known to physicians than it is at present. He referred to Hamburger (*Österreich. Med. Jahrbücher*, 1867, et seq.) as the only person who to his knowledge had given much attention to the matter. Hamburger's papers contained much information of solid value, mingled probably with some exaggeration and inaccuracy. He (Dr. Clifford Allbutt) had, however, been able to verify the more important part of Hamburger's observations, and had found the stethoscope most valuable in distinguishing spasmodic from organic dysphagia, and in ascertaining the site and the degree of constriction. He gave instructions in the method of using the stethoscope for these conditions, and described in some detail the normal œsophageal sounds. He then proceeded to compare the variations from the normal sounds which are met with in disease, dividing them into variations of—1. Tone; 2. Apparent size of the morsel; 3. Rapidity of its translation; 4. Direction of its passage; 5. Energy of œsophageal contraction.—Dr. GAIRDNER remarked that this was undoubtedly a very valuable paper. The subject was new; it demonstrated the powers of clearly defining and diagnosing between various diseases, and was, therefore, of the highest importance.—Dr. CRICHTON (Perth) confirmed the result of the author's investigation by his experience in one case where, by the stethoscope, he had been able to find the exact seat of a stricture.

The Appearance of the Tongue in Health and Disease. By R. TORRANCE, L.R.C.P. Ed., Matfen.—In this paper the appearance of the tongue was described, in the first place, in a state of perfect health; and, in connection with this state, the author referred to the effect of an exalted nervous system upon it, as illustrated in persons of a highly nervous temperament. Then its appearance in the various inflammatory disorders followed, inflammation being a subject which engaged a large share of the attention of both physician and surgeon, it being continually the object of treatment and watchful care. Next was described the appearance of the tongue in the diseases of the digestive organs; it being a good index to the state in which they offer themselves for treatment. The appearance of the tongue in fevers formed an important addition; and the paper concluded with that in connection with the various diseases of the organs of respiration and circulation.

Notes of Four Cases of Thoracic Aneurism. By E. RICKARDS, M.B., Birmingham.

Erysipelas and Scarlet Fever occurring almost simultaneously in one Family. By J. D. GILLESPIE, M.D., Edinburgh.

The Treatment of Lupous Disease of the Skin by Erosion and Acupuncture. By BALMANSO SQUIRE, M.B., London.

Thursday, August 5th.

The chair was taken by Dr. GRAINGER STEWART, Vice-President.

Treatment of Acute Rheumatism by Tincture of Perchloride of Iron. By J. RUSSELL REYNOLDS, M.D., F.R.S., London.—Dr. Reynolds commenced by referring to the paper on the same subject, which he read at the meeting of the Association in 1869. He now, by the citation of a number of cases, showed how early relief had been afforded, not only from pain, but from the abnormal heat, by the use of the remedy referred to. Of the cases cited, 44 per cent. of first attacks were convalescent within the first week, while of those in their second, third, or fourth attacks, 42 per cent. recovered within the same period.

Rheumatic Fever and its Treatment. By JAS. JOHNSTON, M.B., Birmingham.—The author brought forward for consideration, with regard to the causation of rheumatic fever, the non-conversion of starchy food into glucose, in consequence of irritation from improper food or from exposure to cold and damp, and the conversion in the cæcum of the undigested starch into lactic acid, which, being absorbed, produced the phenomena of the disease. In regard to the treatment to be observed, he advocated the use of bicarbonate of soda given in enema, instead of potash. In twenty cases so treated, the temperature had gone down to below the normal state in the course of seven days.—Dr. LONG FOX (Bristol) said that, in spite of all that had been said by the two authors of the papers, and especially by Dr. Reynolds, he did not think that heart-disease accompanied so often as had been represented cases of rheumatic fever. In fact, he believed that in many of the sixty cases referred to by Dr. Reynolds, the patients had come to him with heart-disease to a great extent already developed before the attack of rheumatic fever. That disease had been treated in a good many different ways by different physicians; and he thought he was quite within the mark in stating that few of them were satisfied that the system advocated by Dr. Reynolds was superior to any other of the modes of treatment. For his own part, he was more content with the practice of frequent blistering of the joints than he was with anything else; especially when that was combined with alkalis, and when the patient was watched with the utmost possible care, and the greatest attention at the same time paid to the bed and blankets.—Dr. CRIGHTON (Tavistock) said he had been in the habit of treating cases of rheumatic fever with large doses of tincture of perchloride of iron, combined with liquor ammoniæ acetatis, and the results had been that the fever, which otherwise would not have been subdued within, say six weeks, had been reduced within ten days or a fortnight. At the same time, under that treatment he found that the amount of heart-disease accompanying rheumatism had been very greatly reduced.—Dr. W. STEPHENSON (Edinburgh) said he thought that, in investigating such subjects, or in drawing conclusions from their treatment, they should keep in view the age of the patients. They all knew that children suffering from rheumatic fever were much more subject to have their hearts affected by it than adults were. In fact, it was now generally understood that, after thirty years of age a man's heart was pretty safe from the effects of rheumatic fever. He concluded by stating that, in his opinion, the results of Dr. Reynolds' method of treatment had been very satisfactory indeed.—Mr. MEACHAM (Manchester) said he was on one occasion laid up for six months with rheumatism in the knee; therefore, he could speak from experience. All sorts of remedies were applied, but he objected altogether to blistering. He believed that carbonate of soda was one of the very best remedies they had in medicine for rheumatic fever or rheumatism. He had not had an attack now for nineteen years. He had taken he could not say how much carbonate of soda, and he should not have any objection to take two drachms at any time when he suspected an attack was approaching.—After some observations by Dr. RICHARDS (Bangor), and by Dr. SHANN (York), Dr. REYNOLDS and Dr. JOHNSTON replied.

The Pneumonias of Childhood, as illustrated by Clinical Charts. By W. STEPHENSON, M.D., Edinburgh.—The author remarked that the views generally entertained on the subject were in many respects erroneous, and that the manner in which it was handled in our books on diseases of children failed in presenting it accurately, and led to confounding the different views one with another. After criticising the ordinary terms applied to the inflammations of the lungs in children, as showing the inaccurate ideas existing regarding the subject, he demonstrated the character of the disease in its two chief forms by means of charts of the temperature, night and morning, taken in the Children's Hospital. He showed that by the chart the character of the disease might be recognised at times when otherwise it might be overlooked, or before evidence of its existence could be found in the lungs. The recognition of distinctive types in thermometric charts gave a truer perception of the constitutional condition than could be gained by other means, and furnished more reliable indications for treatment than physical signs.

Tetany. By JOHN HADDON, M.D., Manchester.—After commenting on the very recent date at which this disorder had been described in the country, he related two cases which he observed in March 1875. Case I had suffered for more than twelve months from menorrhagia and diarrhoea, and, during the attack, which was one of medium severity, there was one-fifth of albumen in the urine. Bromide of potassium was given in half-drachm doses every hour, and the tetany soon disappeared. Case II had a mild attack. She had been troubled for two years with diarrhoea, which was caused by a constriction in the rectum. The same treatment as in Case I was followed by a like satisfactory result. After commenting on the probable cause in each case, he concluded by urging the profession to watch for and record cases of tetany, seeing that we must have a wider experience of this affection before we can hope to ascertain its real cause.—Dr. STEPHENSON gave details of a case which he had met with, in reference to the etiology. Pregnancy aggravated the affection, but the patient had suffered from the disease before marriage.—Dr. GRIFFITHS (Swansea) had met with a case, in which masturbation was believed to be the cause. A brother of the boy, who also masturbated, suffered from intermitting hæmaturia, which occurred after the act, and no other cause could be assigned.

Account of some Experiments relating to the Pathological Anatomy of Myelitis. By D. J. HAMILTON, L.R.C.P. & S., Falkirk.—Experiments were made on small animals. The spinal cord was artificially inflamed by having a thread passed through it. The appearances found were contraction of the axis-cylinders, subsequent fissiparous division of the contracted portions, and the formation of pus from these. The nerve-cells were affected with granular or "œdematous" degeneration. The neuroglia was somewhat increased, but not to a great extent. The perivascular lymphatic spaces of the surrounding pia mater were filled with lymphocorpuscles. One or two cases were quoted in confirmation of the facts.

Some further Remarks on the Use of Spirometry in Medicine, demonstrated by a New Double Spirometer. By V. JAGIELSKI, M.D.

Remarks on Hooping-Cough and its Treatment with Carbolic Acid Vapour, with Description of a Steam-draft Inhaler. By ROBERT J. LEE, M.D., London.—Dr. Lee directed attention to the very slight variation in the annual mortality from hooping-cough, to its widespread geographical distribution, and to the results of various kinds of treatment. The conclusions which he deduced were the results of observation of six hundred cases, and the most important remarks were connected with the rise and fall of the disease at the first or second quarter of the year, and the frequency with which the disease was not diagnosed on account of the absence of the laryngeal spasm or whoop. The use of carbolic acid was recommended as proving more satisfactory than any other kind of remedy; and the method of administering it in the form of vapour by means of the steam-draft inhaler was explained. A solution of one part of carbolic acid in ten of water was kept as a standard for mixture in the proportion of two drachms to four ounces of water. This was introduced into the inhaler, and every four hours its vapour was inspired for ten minutes or a quarter of an hour. Dr. Lee explained the construction of the steam-draft inhaler, and the advantages of its use in other maladies of the respiratory organs, as well as in hooping-cough.

Case of Paralysis of the Serratus Magnus Muscle. By SAMUEL WOODMAN, F.R.C.S., Ramsgate.—The patient was a man, aged 39, who had been appointed lamplighter in a temporary ship, the lamps of which were placed high above the platform on which he stood. Six months after his appointment (about May 1874), he felt a weakness in his right shoulder, which continued to increase until he became unable to use the arm. When he came under Mr. Woodman's care, there were the usual signs of paralysis of the serratus magnus; he had bulging of the ribs and raising of the affected shoulder. There was no paralysis of any other muscle than the serratus magnus. He had been treated by daily faradisation, cold douches, rest of the arm in a sling, and doses of quinine and strychnia. There had been considerable improvement in the course of two months.

Friday, August 6th.

The chair was taken by Dr. LOWE, and afterwards by Dr. GAIRDNER.

Case of Abnormal Disposition to Sleep alternated with Choric Movements. By W. T. GAIRDNER, M.D., Glasgow.—The phenomena of the case were unique, and were observed over three years. The patient, a young girl, was not cataleptic; the muscular movements had no resemblance whatever to the peculiar rigidity of catalepsy, and differed from choreic movements in the fact that they alternated with states of consciousness. When asleep, she was still and tranquil; when awake, almost without intermission, she was a prey to involuntary muscular movement. She was not subject to any condition of hysterical coma, ecstasy, or trance; had been subject to no known cause of hysterical

derangement; and had never sought to attract attention, or been in any way made an exhibition of, publicly or privately. In her waking moments, she was cheerful, and even lively, presenting no trace of exaggerated self-consciousness and no dramatic or inventive faculty. She had no religious or metaphysical prepossessions; in fact, apart from the peculiarities of her case, she was a normal person of her years. She was not somnolent, and there was an entire absence of any form of externally controlled will. There only remained one hypothesis: that this girl was a malingerer; but anything like premeditated deception or scheming would imply powers as well as motives for deception, which seemed to be wholly absent. The involuntary muscular movements were in themselves wholly painless, however disturbing. By far the most persistent involuntary jerking movements were a slight rapid motion of the head, twitching of the left side of the mouth, and jerking of the right arm. There never was any nodding movement. To a certain extent, the movements were increased by mental emotion, but ceased when the girl was asleep. The shakings were entirely beyond the control of her will. The sleep was very deep, sound, and natural, and the girl could not be roused by agitation, concussion, or ordinary noises; but she could be readily awakened by calling her name close to her ear. The most startling feature of the case was the sudden transition between sleep and thorough waking. So great was the tendency to fall asleep, that she had frequently been known to drop asleep when walking about or standing; but, if kept awake, she could read, play the piano, or do ordinary woman's work. If allowed to fall asleep and then suddenly awakened, she showed no want of self-possession, and resumed her occupation or conversation exactly at the point where she had been interrupted. Very rarely a spasmodic movement was observed when passing from sleep to waking. On two occasions, she slept for eight days without waking, and in several instances she slept continuously for two or three days, but, on waking spontaneously, she had no conception of having slept more than one night. There was, finally, a certain amount of dull pain or uneasiness in the left temple.—Dr. CLOUSTON (Edinburgh) said this was a very extraordinary case described in a very interesting manner. He had seen a case with many parallel features occurring in the course of general paralysis, and after an epileptic attack. He had had the case of a lady who suffered from twitchings of the left side of the face and of the right arm and shoulder. She also, for two or three days, had a very extraordinary tendency to somnolence. He had never been in the least degree satisfied with any of the ordinary theories of sleep. It always seemed to him that there must be a sleep-centre, and that this must be in the upper part of the brain, where the conditions of consciousness were determined. The present instance confirmed the theory that the sleep-centre could act instantaneously in certain cases.—Dr. J. MILNER FOTHERGILL (London) and Dr. GRAINGER STEWART (Edinburgh) commended the paper.

Notes of a Series of Cases of Rubecula Notha. By G. E. SHUTTLEWORTH, M.D., Lancaster. The author remarked that, in many of the standard text-books on medicine, considerable obscurity existed with regard to the disease described by Dr. Benjamin Babington in 1864 as *rubeola notha*. He attributed some of this obscurity to the varying names under which the affection had been described by various writers, citing those of *rubella*, *rubeola notha*, *bastard measles*, *anomalous exanthem* or *rosella*, *rosalia*, *rubeola sine catarrho*, and *epidemic roseola*. Noticing that the London College of Physicians gives no place in its nomenclature to the term *rubeola notha*, but no longer applies to measles the old name *rubeola*, he suggested that the latter term might with advantage be officially defined as the pathological equivalent in this country of the *roscole* of Trousseau, the *rötheln* of Vogel, and the *rosalia* of Italian authors. He mentioned, however, that the name epidemic *roseola* has been adopted by Dr. William Squire, who gave an excellent account of the affection in the BRITISH MEDICAL JOURNAL for January 29th, 1870. Having quoted from Dr. Tilbury Fox (*Skin-Diseases*, 3rd edition, page 93) a graphic description of the disease under discussion, the author went on to give an account of the series of twenty-seven cases which fell under his notice at the Royal Albert Asylum, Lancaster, in July, August, and September, 1874. He exhibited, in a tabular form, an account of the leading symptoms in each case, such as the character and duration of the rash, the state of throat and tongue, the range of temperature and pulse, the condition as to sequelæ, desquamation, etc., with a statement of the exanthems previously undergone. From this it appeared that, while some of the early cases resembled mild cases of scarlatina, others were rather of the type of measles; but that the majority presented merely a brownish-red elevated discrete papular rash, lasting two or three days, with slight elevation of pulse and temperature on the first and second days. There were no serious sequelæ, and only in two cases desquamation was discovered, and that of the finest furfuraceous character. The question was, What was the exact pathology of the affec-

tion? There was no doubt that the 27 cases bore a homogeneous relation to each other; they were not mere summer *roscola*, for the weather was even cold at one period of the epidemic; they were not cases of scarlatina, for in no case were there the full characteristic signs or sequelæ of this disease; they were not measles simply, for there was an almost universal absence of catarrhal symptoms, and more than half the patients had previously had measles; and there was no reason to suspect that the rash was dependent upon any error of diet or hygiene. It was argued, therefore, that the author was justified in describing these cases under the designation of *rubeola notha*; and it was urged that the diagnosis of this affection as entirely distinct, on the one hand, from scarlatina, and, on the other, from measles, might often be a matter of great moment to the practitioner.—Dr. FARQUHARSON (London) made a few remarks on the paper.

Case of Pulmonary and Tricuspid Valvular Disease. By ALEXANDER MORISON, M.B., C.M., London.—E. W. G. M., aged 20, fair, well grown, but with an anxious expression and cardiac symptoms, had scarlatina at 5 or 6 years old, and was known to have heart-disease at the age of 8. His paternal and maternal family history was rheumatic, cardiac, and phthisical. Till 18 years of age, he performed his duties as bank clerk satisfactorily, when the unwonted exercise of cricket seems to have upset the compensatory balance, effected probably by hypertrophy in his diseased heart, and cardiac symptoms became urgent. The pulse was 78 to 84, regular, small, but distinct. There were undulatory pulsations in the suprasternal fossa, and regurgitation into the external jugulars. The carotids were normal. The præcordial region bulged forward. There were flattening under the left clavicle, visible systolic pulsation from the second left intercostal space to below the nipple, well marked epigastric pulsation, increase of the transverse heart-dulness, and coarse *frémissement catinaire*. A systolic bruit was heard close to the left edge of the sternum, below and to the inner side of the nipple, not traceable round the left chest. There was a double murmur, best heard over the third left cartilage, harsh and grating, not propagated into the large arteries, but towards the left shoulder. He had angina passing to the right shoulder and down the right arm. The breathing was harsh. There was no marked dulness, no crepitation. The liver was enlarged. He had albuminuria. The bowels were regular; but latterly he had had some diarrhœa. There was purpura, chiefly on the legs and fore-arms, most abundant round the joints; some on the right half of the trunk. Shortly before death, he had œdema of the right eye and the right half of the scalp, less so of the left eye. This passed off; the urine, which had been nearly suppressed, having apparently, by means of a diuretic, become more abundant. He died without convulsion, and was only unconscious during the last half hour of life. At the necropsy, there was found valvular obstruction at, and regurgitation through, the pulmonary and tricuspid valves, which were much altered by warty vegetations. The tricuspid obstruction was not so pronounced as the other conditions. The right ventricle and auricle were dilated, the latter somewhat hypertrophied. There was a partially defibrinated clot in the auriculo-ventricular orifice, and another passing through the pulmonary opening and stretching into the two chief bifurcations of the pulmonary artery. The mitral and aortic valves were healthy, though there was some deposit on the mitral segments. The left ventricle was not hypertrophied. The muscular fibres were healthy. The lungs were small, crepitating, but with scattered patches of induration. Both extreme bases were solid. All the organs behind the seat of obstruction were enlarged and engorged. The kidneys were much engorged. There was slight effusion into the pericardium, and on the surface of some other serous membranes were scattered ecchymoses. Mr. Morison, after pointing out the extreme rarity of such cases, and the difficulty of diagnosing acquired from congenital disease, ascribed the valve-lesions to scarlatinal endocarditis; and considered the kidney-affection as more recent than the heart-disease, indicating as points of interest in the case the great dyspnoea simulating pulmonary thrombosis, and un-influenced by position, the remarkable absence of dropsy and the right-sided angina, œdema, and purpura, the last of which might be attributable to the patient's habitually lying on his right side, and perhaps also in some measure to the quality of the blood and the nature of the obstruction.

The Syphon Stomach-tube, a Substitute for the ordinary Stomach-pump. By A. HARVEY, M.D., Aberdeen.—Dr. Harvey exhibited and described a new syphon stomach-tube, a substitute for the ordinary stomach-pump. The instrument was a flexible India-rubber tube, which, when inserted into the stomach by the mouth, was filled with fluid. This being done, the ordinary conditions of a syphon were fulfilled, and the stomach emptied. In a similar manner, the tube could be employed in filling the stomach.—Dr. GAIRDNER and Dr. MOIR (Edinburgh) commended the value and simplicity of the instrument.

SECTION C.—OBSTETRIC MEDICINE.

Wednesday, August 4th.

THE President, Dr. MATTHEWS DUNCAN, delivered an address, which was published at page 171 of the JOURNAL for August 7th.

Embryotomy, its Various Modes of Procedure: with Illustrative Cases. By A. KEILLER, M.D., Edinburgh.—Dr. Keiller exhibited a considerable number of instruments, old and new, and drew particular attention to a modification of Ziegler's forceps which he had devised, so as to constitute a small cephalotribe.—Dr. MOIR (Edinburgh), while acknowledging great advantage from the introduction of the cephalotribe, thought it right to remark that he had operated with the perforator, small forceps, and blunt hook, without any very great difficulty, many times before the introduction of the newer instrument.—Dr. STEELE (Liverpool) said that, in his own practice, the cephalotribe had been but seldom necessary. It was, however, very desirable to have the most perfect possible instrument for the rarer and more extreme cases.—Dr. BASSETT (Birmingham) said that Dr. Braxton Hicks's cephalotribe had answered every requirement in his (Dr. Bassett's) hands.—Dr. ATHILL (Dublin) was not enamoured of the new instrument introduced to the notice of the Section. He thought it too small to exert the necessary force.—Dr. GIBSON (Newcastle-on-Tyne) thought the cephalotribe ought to be much more generally used.—Dr. KEILLER briefly replied to the several speakers.

Turning versus the Forceps in Cases of Difficult Labour. By T. MORE MADDEN, M.D., Dublin.

On a Form of Accidental Hemorrhage alternating with Watery Discharge. By I. HARRINSON, F.R.C.S., Reading.—Mr. Harrinson described two cases that had lately come under his notice, in which, after a fall in one case and a shock in the other, hæmorrhage occurred at monthly intervals, there being also a continuous watery discharge. In both cases, the placenta were pale and soft, and there was partial separation of the membranes.

A New Kind of Midwifery Forceps: and an Obstetric Thimble for Rupturing the Membranes. By DAVID GORDON, M.D., Edinburgh.—The forceps was described as possessing the following characteristics. 1. The blades are separable from the handles, and much curved where they join the shanks. 2. The shanks or stems are very close to each other, and have sockets to receive the ends of the handles. 3. The handles are curved, and imitable by a movable screw. They have nipples to glide into the sockets of the stems, with strong catch-springs to fix them there. 4. The handles, united by the screw, are easily attached to the blades, and no locking is needed.—Dr. Gordon also showed a thimble which fits the index finger, exposes the point of the finger opposite to the nail, and has a sharp point which curves over the free edge of the nail.—Dr. SWAYNE (Clifton) doubted whether the forceps would prove generally applicable.—Dr. STEELE (Liverpool) thought that the so-called improvement was really a retrograde step.—Dr. BASSETT (Birmingham) thought that the best kind of midwifery forceps was the long one with double curve.

Ovarian Dropsy: Some Points in its Pathology and Treatment. By PROTHEROE SMITH, M.D., London.—Dr. Smith called attention to the greater frequency of ovarian dropsy now, as compared with what was known of its occurrence forty years ago. He invited discussion as to its predisposing cause, and the means best calculated to arrest it. He stated his grounds for believing that, to a certain extent, the increase in the disease may find some explanation in the general abandonment of venesection in practice in this country. He advocated the adoption of blood-letting, under certain restrictions, as a prophylactic measure, when indicated by symptoms diagnostic of uterine and ovarian engorgement. He divided his paper into three parts by asking: 1. Can any reliable prophylactic means be devised to lessen the frequency of ovarian disease, by obviating *in limine* its cause? 2. What is the best manner of preparing patients for ovariectomy, and of performing the operation, with a view to success? 3. What treatment, after the operation, is best calculated to ensure the recovery of the patient? Dr. Protheroe Smith hoped the answers to these questions elicited in the course of discussion would greatly enrich, if not exhaust, a theme of such grave importance. Whilst calling upon those whose more extensive experience specially qualified them to speak on the subject, he gave the result of his own observations as to several important points regarding the preparation of the patient for ovariectomy, the mode of performing the operation, and the after-treatment.—Dr. GRIFFITHS (Swansea) thought that it was very doubtful whether Dr. Smith was right in stating that ovarian dropsy was more frequent now than formerly. He also thought it was an unsupported statement that this condition was due to congestion; and as for prophylactic measures, who was to say when ovarian dropsy was impending?

On the Prevention and Management of Miscarriages. By ARTHUR W. EDIS, M.D., London.—A brief allusion was made to the mortality occasioned by miscarriages, the life of the foetus being invariably sacrificed and the mother's life often jeopardised: and not only this, but the fecundity of the female was often destroyed from the effects of uterine disorder following a miscarriage, to say nothing of the distress and suffering often occasioned. In a series of 2,000 cases observed by the author, there were no fewer than 1,147 miscarriages compared with 4,588 children born at full time. Miscarriages were far too lightly esteemed, both by the public at large as well as by practitioners. Patients with well marked flexion of the uterus, constitutional syphilis, chronic metritis, and numberless other affections, were allowed to go on aborting without sufficient pains being taken to prevent a recurrence. The prevention of miscarriages depended entirely upon proper measures being employed to avoid the contingency of a recurrence of the cause or combination of causes that induced the expulsion of the ovum in the first instance. To say that a patient had acquired the "habit of aborting" was merely asserting our ignorance of the cause, and expressing in other terms the fact that the woman aborted because she aborted. As regards the management of miscarriages, the necessity of a vaginal examination was strongly insisted on. The influence of ergot in the early stage, in arresting threatened miscarriages, was favourably alluded to, and the employment of carbolic acid injections where any portion of the products of conception were retained was urgently recommended. The author concluded by urging a more careful study of the subject; miscarriages being frequently the starting-point of a long course of uterine distress: dysmenorrhœa, sterility, etc.—An interesting discussion followed, in which Dr. BASSETT, Dr. JOHN HADDON, and Dr. SIMPSON, joined.

Placenta Prævia. By W. DONOVAN, L.R.C.P.Ed., Carrignavar.—Dr. Donovan said that he believed the cause of hæmorrhage in placenta prævia to be that the part of the placenta lying directly over the os internum uteri, is unattached by blood-vessels or otherwise, and, therefore, does not expand uniformly with that part attached to the uterine walls. Consequently, during the latter month of pregnancy, the rapid enlargement of the uterus causes an amount of strain on the zonal vessels of the placenta sufficient to rupture them.

Case of Inversion of the Uterus of three months' standing. By J. H. EWART, Esq., Manchester.—The patient was a young married woman, who had been attended in her first confinement by a midwife. She was at full term, and the labour went on well to the end of the second stage: there was then, according to her account, some difficulty with the after-birth, which the midwife endeavoured to overcome by pulling at the cord. Eventually, a surgeon was called in, and he and his assistant attended the patient up to the time of her admission into hospital three months afterwards, during the whole of which time she suffered more or less from hæmorrhage, sometimes quite alarming in its character. No vaginal examination was made before her admission. When she was examined at the hospital, there was found to be an inversion of the uterus. The author used as much manual force as he deemed advisable; and then one of his colleagues, thinking further efforts at reduction were necessary, proceeded to use great force. He ultimately succeeded in reducing the inversion, but at the expense of some laceration of the vaginal wall and of the perinæum. The patient, however, had no bad symptom. Attention was called to the valuable papers of Drs. Barnes and Braxton Hicks: and the author said that in any future case he would firmly discountenance the treatment adopted in the case here recorded.

Thursday, August 5th.

Memoir of the Life of William Smellie, M.D. By ALFRED H. MCCLINTOCK, M.D. Dublin.—Owing to the limitation of time, he had to confine his paper to the personal history of Smellie, about whom he had been able to collect some new and interesting particulars. He was a native of Lanarkshire, and was born some time in the year 1697. He studied midwifery in Paris under the celebrated Gregoire. About the year 1722, he settled down to general medical practice, in the neighbourhood of Lanark, where he remained till the year 1739, when he changed his residence to London. Soon after this, he had the celebrated William Hunter residing in the house with him. Smellie began to give lectures on midwifery, and to attend labour cases at their own homes, along with his class, about a year or two subsequently to his settling in London. These lectures attracted large numbers of pupils; for, in the course of ten years, he says he had nine hundred pupils, exclusive of females. The first volume of his *Midwifery* appeared in 1752, and was the result of thirty years' experience, and of six years' careful preparation. It was followed at different times by two other volumes, chiefly taken up with the narration of cases, there being about 540 of these recorded in the two volumes. This work at once attracted

great attention, and was translated into French, German, and Dutch; so that it soon came to be regarded as the highest obstetrical authority. It will ever hold the place of a most valuable standard work upon midwifery, and be carefully read by all earnest students of this branch of medicine. This treatise of Smellie's did more to improve the practice and raise the character of the British school of midwifery than any other work that ever appeared before or since, and has most justly immortalised the name of its author. Towards the end of the year 1759, Smellie resolved to leave London. Accordingly, having made over his class, museum, and teaching appliances, to Dr. Harvie, he left London, and returned to his native county of Lanark. This Dr. Harvie is supposed to be the same who married a niece of Smellie's, and to whom he bequeathed his property, etc., Smellie himself not having had any issue by his marriage with Eupham Borland. Having established himself near to the town of Lanark, in a place called after him, "Smyllum" or "Smylane", he spent his leisure hours in preparing the third volume of his *Midwifery*. He only just lived to complete this great work. Mr. Onslow, writing of Smellie in 1821, said he did not know where Smellie died and was buried. However, Dr. Maxwell Adams, of Lanark, cleared up this matter by the discovery of Smellie's tomb in the old churchyard of Lanark, on which it is stated that "he died March 5th, 1763, aged 66". He bequeathed a sum of £200, all his books, and some other matters, to the Grammar School of the town of Lanark. There is a portrait in oils of Smellie in the Royal College of Surgeons, Edinburgh. This is supposed to be the one mentioned in his will as having been painted by himself. Where Smellie received his medical education or obtained his degree, are questions that yet remain to be answered. He was a man of close and accurate observation, of great diligence, very methodical, and withal of a very philosophic turn of mind, which made him candid in confessing his faults, and ready to admit the merits of others. He inaugurated a new era in English midwifery, and contributed very materially in overcoming the strong prejudices then existing against the use of the forceps, and against male obstetric practitioners. His writings contained many and original observations, especially upon the mechanism of parturition, the thickness of the gravid uterus, the process of labour; the shape, application, and use of the forceps; the management of the placenta, etc. The cases recorded in his second and third volumes, not only were a mine of clinical experience that would amply repay the reader, but they abounded in observations rich in practical wisdom. So remarkable a man as Smellie could not possibly avoid having detractors and opponents, and foremost among these was Dr. John Burton of York—the original of Sterne's Dr. Slop. But Smellie treated all their attacks with great indifference, and only once condescended to reply to them.—Dr. PRIESTLEY (London) had listened with the greatest possible pleasure to the memoir, and was glad to be able to announce to the Section that Dr. McClintock had undertaken the editorship of Smellie's works on behalf of the New Sydenham Society.

The Examination of the Female Bladder. By J. MATTHEWS DUNCAN, M.D., Edinburgh.—Dr. Duncan proposed that, after dilatation with the dilator of the shops—an instrument much in need of improvement—a speculum be introduced similar to the rectum-speculum.—Dr. PRIESTLEY (London) asked what were the results as to frequency of urination and power of retaining the urine.—Dr. LEGAT (South Shields) asked if Dr. Duncan had found female urethrae to vary considerably in size.—Dr. STEELE (Liverpool) asked if the mode recommended revealed a large surface of the mucous membrane.—Dr. Moore, Dr. Lombe Atthill, Dr. McClintock, Dr. Copeman, Dr. Protheroe Smith, Dr. Young, Dr. Wallace, and Dr. Chambers, took part in the discussion.—Dr. MATTHEWS DUNCAN said that, so far from having met with any ill effects, the dilatation had, in his hands, given so much relief to the symptoms, that a repetition of the proceedings was desired on the part of the patients. He had found that female urethrae differed extremely in calibre. In reply to Dr. Steele, he said his impression was, that the whole surface of the bladder could be brought into view by the specula now shown and recommended.

Intemperance in Women, with Special Reference to its Effects on the Reproductive System. By JOHN HADDON, M.D., Manchester.—Dr. Haddon first considered the existence of intemperance amongst women. Secondly, he pointed out its causes, the principle of which he believed to be; 1, the common practice of using stimulants in some form as a beverage in the family, and as a mark of hospitality to strangers; 2, the frequent prescription of stimulants by the profession, and; 3, domestic or other cares which make many drunkards. He then considered its effects on the woman's constitution, and pointed out some symptoms likely to be met with, among which he specially referred to its tendency to cause irregularity of the menses, menorrhagia, and abortion. He next endeavoured to show that no child-bearing woman should use any alcoholic stimulant; and concluded with some

remarks on the remedy for female intemperance.—Dr. E. LONG FOX (Clifton) strongly objected to the view that the habit of drinking was in any measure due to the dangerous prescribing of medical men.—Mrs. GARRETT ANDERSON (London) thought the prevalence of intemperance in women had been greatly exaggerated; but she was ready to acknowledge that it was much too common, and she could not wholly free medical men from blame in the matter.—Mr. Morgan (Lichfield), Dr. Priestley, Mr. Meacham (Manchester), and Dr. Moir, also took part in the discussion.

Obstetrical Statistics. By J. G. SWAYNE, M.D., Clifton.—Correct obstetrical statistics, especially of cases attended in private practice, are of great importance just at the present time, when the principles and practice of midwifery are undergoing radical changes. The records of private practice will supply what we cannot obtain from lying-in hospitals, viz., correct statistics of midwifery practice amongst the richer classes of society. Dr. Swayne then referred to statistics derived from his own practice, in order to show that the process of labour, especially in the third stage, is attended with greater danger amongst these than amongst the poor, in consequence of the greater liability to hæmorrhage and adhesion of the placenta. He also referred to his own statistics of the varieties of cranial presentation, and pointed out that they differed from those usually given, in assigning a greater frequency to the fourth than to the third position of the head. With respect to forceps operations, his own figures show that the modern practice of employing that instrument with much greater freedom, is attended with very good results, but that further researches are needed to determine the relative advantages of the long forceps and turning, in deformity of the pelvis. With regard to puerperal convulsions, they show that there is no good reason for abandoning the old practice of bleeding, whilst fully bearing out the utility of anaesthetics. Lastly, good statistics of private practice are more than ever needed in order to throw light upon the etiology of puerperal fever, a disease which has been lately very prevalent, and of which the prevention is a far more promising subject for consideration than the cure.—Remarks were made on the paper by Dr. Bassett, Dr. Nesfield, Dr. Steele, Dr. W. Macdonald, Dr. Moir, and Dr. Keeling.

On Uterine Flexions and Displacements; and their Mechanical Treatment. By J. G. S. COGHILL, M.D., Edinburgh.—Dr. Sinclair Coghill confined his remarks mainly to the mechanical treatment of uterine flexions and displacements, only referring incidentally to their pathology. He alluded to the association of the Edinburgh Medical School with this department of medicine; and, in this connection, paid a warm tribute to the practice and inventive skill of the late occupant of the midwifery chair, Sir James Y. Simpson. He referred to the reaction which set in against his teaching and example, explained its causes, and suggested that probably the rule *in medio tutissimus ibis* in this as in other debated questions would be the safest guide. The author next pointed out the leading principles on which this treatment should be based, in the various forms of uterine distortion and dislocation. He concluded by deprecating strongly the *nimia diligentia* in this as in other departments of practice. Several interesting cases were described in illustration of the views submitted; and a variety of instruments, several of original design, were exhibited, and their use demonstrated.

Nitric Acid as a Caustic in Uterine Practice, and its Superiority as such to Nitrate of Silver. By JAMES BRAITHWAITE, M.D., Leeds.—Nitric acid is the caustic which, of all others, is the best adapted for use in cases of chronic inflammatory disease of the os and cervix uteri, resulting in erosion or ulceration. Nitrate of silver is inefficient, and requires frequent reapplication, to atone for its defects both in degree and in the nature of its action. Nitric acid, on the other hand, acts as a caustic in these cases with certainty, and neither does too much nor too little. Its application is productive of little or no pain; and, when it has once been properly applied in some cases, no further speculum-examination is required, such reliance may be placed upon its effects. If an examination be made, which is always better, it need only be after an interval of a month, and then the acid may be applied again to any spot which appears to require it. The resulting sore has a very strong tendency to heal, and does so partly by contraction and partly by fresh formation of mucous membrane, which is not cicatricial in appearance. The contraction is greater than follows the application of any other caustic, and is the very thing required to ensure the permanence of the cure. The contraction in cases of cervical catarrh is only contraction to a healthy size of the canal, provided the acid is used with proper care. The peculiarly lasting and permanent action of nitric acid enables us to do away with the repeated speculum-examinations, so distasteful to both patient and surgeon; and gives the latter a feeling of confidence of success which he cannot have with any other caustic. The use of nitric acid, common as it is in

other diseases, is referred to by very few writers, and is entirely omitted by most of our standard authors upon diseases of women, all of whom recommend nitrate of silver, or mention its use as the usual practice.

On the Management of the Lying-in Woman. By THOMAS WHITE-SIDE HIME, B.A., M.B., Sheffield.—Dr. Hime began his paper by stating that the old and still established theory which represents the lying-in woman as being in a state similar to that of a person after a serious amputation, the uterus being compared to the part operated on, is unscientific and untenable. Parturition is a physiological process, the fulfilment of a natural function, and has no analogy with an operation which is an interference with function. Amputation, whether the result of disease or accident, involves consequences which have no analogue in the process of parturition. The uterus after labour is no more comparable to a stump after amputation than the uterus after or during menstruation. After natural labour (to which Dr. Hime's paper chiefly referred) there is nothing comparable to the collapse succeeding a major amputation; there is no fever, no suppression of secretions, no suppuration, or, if pus be present, it is not derived from the uterus at all, but from the vagina or external genitals, in the great majority of cases. The insignificant rise in temperature, from 0.5 deg. C. in multiparæ, to 0.8 deg. C. in primiparæ, is due to normal physiological and not to morbid action, being the effect of muscular exertion, increased activity of the lungs, liver, and other organs, when relieved from the pressure of the gravid uterus, and is only fleeting. Milk fever is far more talked of and written about than seen, and is of rare occurrence. The rise in temperature which accompanies the commencement of mammary activity is slight, temporary, and unaccompanied by mental depression or constitutional disturbance of any kind. Operations performed immediately after labour will yield kindly, of which Dr. Hime related several instances in his own practice. Regarding parturition as a normal physiological process, Dr. Hime urged the importance of a decided alteration in the common mode of treating lying-in women as *patients*, and confining them to bed for ten or twelve days on low diet; the ordinary puerperal dietary being such as would certainly not be given to any patient after amputation. He urged that water-gruel, barley-water, tea, and dry toast, should be abandoned for milk, eggs, good soup, chickens, and other digestible meat, to be given from the first, and of course in quantities suitable to the conditions of individuality, want of exercise, etc. Stimulants are decidedly injurious, except in special cases. It is often urged that, as a large amount of waste uterine tissue, etc., has to be got rid of, low diet should be adhered to; but milk has also to be secreted, and any how health and vigour will promote excretion, and the performance of all vital functions better than a state of debility. Opiates, ergot, and other drugs should only be given under necessity. The child should be applied as soon as the mother's state permits; if there be no milk at first, only for a minute or so to encourage its secretion, and the involution of the uterus. The binder is more of an euthanæsia than a benefit after the first twelve hours, but not so the early removal into a fresh bed, and room, if possible, and this may be done within forty-eight hours. The woman may sit up in bed for a short time from the first, a continual maintenance of the recumbent posture for ten or twelve days being as injurious as it is unnecessary, and most patients may be on the sofa on the fourth or fifth days. Above all things, the medical attendant should see that his directions are carried out, and not trust they will be so, especially as to the speedy removal of soiled linen, etc.; not that its presence, any more than the neighbourhood of privies, want of ventilation, etc., will *per se* develop metria any more than typhoid; otherwise, eight or nine tenths of lying-in women must inevitably suffer from it, a result equally certain if medical men could convey the germs of disease with them as readily as is assumed. Cleanliness and ventilation always tend to preserve health and check disease, but they are no more needful for the lying-in woman than good nourishing food. After natural labour a woman is not in a diseased state, and the maintenance of health and vigour will be the most successful means of averting all risks.

Notes of a Case of Transfusion by Aveling's Apparatus. By GEORGE HOGGAN, M.D. Lond.—The case was one of secondary hæmorrhage after removal of a diseased cervix uteri. The patient sank.

Friday, August 6th.

Notes on a Case of Triplets complicated by Double Uterus. By A. G. DUNCAN, M.B., Crimond.—This was a very rare and interesting case, in which there was a depression in the abdomen indicating a division between two tumours formed of the two halves of the uterus, one containing two children, and the other one. The children, all females, were born alive; their united weight was 20 lbs. On subsequent examination, the uterus was felt to be divided by a septum.

On Dysmenorrhœa. By E. GARRETT ANDERSON, M.D.—In this paper, Mrs. Garrett Anderson discussed the following questions. 1.

How far is the mechanical theory of dysmenorrhœa supported by facts? 2. What is the relation between mechanical or obstructive dysmenorrhœa and the so-called neuralgic, congestive, and rheumatic forms of the complaint? 3. To what extent ought the mechanical theory, if we accept it, to guide our treatment? With regard to the first question, Mrs. Garrett Anderson agreed with Dr. Marion Sims and Dr. Barnes, that the essential cause of dysmenorrhœa was retention of the uterine secretion. This view was supported by the curative influence of parturition. The author differed, however, from Dr. Sims when he denied the existence of constitutional dysmenorrhœa; for in a large number of cases the retention might depend on a constitutional condition. The anæmic, congestive, and rheumatic forms of dysmenorrhœa were commented on; also that dependent on uterine flexion. Mrs. Garrett Anderson did not believe in neuralgic dysmenorrhœa, as the term was commonly understood. The form thus described might depend on obstruction, or on abrasion of the os, with endometritis of the cervix or fundus. Cases of ovarian origin were believed not to be common in early woman, nor to be often primary. "Intermenstrual" dysmenorrhœa was not dysmenorrhœa at all, and was probably due to ovarian congestion. In regard to the treatment, Mrs. Garrett Anderson pointed out that there were facts which seem to indicate that, in accepting the mechanical theory of dysmenorrhœa, it is not necessary to adopt in the first instance and in most cases a mechanical line of treatment. Various constitutional conditions frequently gave rise to obstructive dysmenorrhœa, which could often be removed by constitutional measures.—Dr. ATTILL (Dublin) thought that, in girls menstruating recently, dysmenorrhœa might be due to anæmia; but in others to some form of inflammation. He did not agree with the view of child-bearing curing obstruction. He did not think flexion *per se* the cause of dysmenorrhœa. A perfectly healthy uterus could not flex itself. After marriage, dysmenorrhœa occurred from endometritis. In the cases where dysmenorrhœa began after marriage, there was nearly always a painful point at the os internum; and the pain could be produced by touching this point. He thought mechanical treatment was carried to too great a length. He did not agree with Mrs. Garrett Anderson that no mechanical treatment should be adopted before the age of thirty, as it sometimes was useful at a much earlier age.—Mr. SPENCER WELLS (London) thought the few words in which Mrs. Garrett Anderson alluded to ovarian dysmenorrhœa scarcely did the subject justice. It might be observed that, two days before menstruation, pain was often present, alternating at different periods in one side and the other. No doubt it was due to constitutional causes, but also to inflammations; and the pain arose before the excretion found its way into the uterus and vagina. He thought that the introduction of a sponge-tent before the menstrual period often was of great use.—Dr. A. SIMPSON (Edinburgh) remarked that it was overlooked in the paper that, after dysmenorrhœa was established, it was rare to find that there was not some organic affection of the uterus; but it was not easy always to say the exact cause of the pain, as that might be various. He did not think there was any medical practitioner in Great Britain who would not at once, in a young girl even, make a vaginal examination, and would not at once have recourse to surgical treatment. He alluded to cases in the unmarried, and also to the state of the uterus during the menstrual period. In his experience, the uterus became erect during menstruation; and this was a fortunate thing; for antelexions were so common that, without this erection, dysmenorrhœa would be much more common. He alluded to the effects of marriage in relieving pain, but without pregnancy; and this led to the mechanical treatment being introduced. The treatment was often used by men who did not know the value of it.—Dr. STEELE (Liverpool) thought the many differences of opinion could be removed if dysmenorrhœa were regarded as a symptom, and not as a disease. He agreed with Mr. Spencer Wells, that many cases were of ovarian origin. Sufficient attention was not given by the author of the paper to the state of the excretions of the bowels. The treatment must be purely eclectic.—Mr. HARRINSON (Reading) asked Mr. Spencer Wells whether the use of tents was free from danger.—Mr. SPENCER WELLS thought the danger arose from the way in which the tent was used. If it were carefully introduced, and not left too long, he did not see any danger.—Dr. KEILLER (Edinburgh) expressed his hearty approval and admiration of the paper. It was just what he would have expected from his old pupil. He thought that much danger was done by indiscriminate surgical and mechanical treatment. He did not now use the dilating instruments so frequently as he did when a younger man.—Dr. MCCLINTOCK (Dublin) expressed his approval of the paper, and seconded the observations of Dr. Keiller. He was satisfied that the large majority of cases which came under his own observation could be treated by medical means.—Mr. FREER added his opinion to that of Dr. Steele, that the overloading of the intestines must not be overlooked. It was

due to two causes: sedentary occupation, and the ligature worn for the sake of symmetry, which tended to keep up a state which led to irritation of the uterus.—Dr. LEGAT (Shields) observed that there was one point not alluded to. The pains of dysmenorrhœa resembled after-pains. These varied in different persons; and there was no obstruction and no flexion in these cases.—Dr. G. BUCHANAN (Glasgow), being a pure surgeon, could not express an opinion on the subject; but he moved a vote of thanks to Mrs. Garrett Anderson for her excellent paper. This was seconded by Dr. PRIESTLEY, and carried.—Mrs. GARRETT ANDERSON returned thanks for the compliment paid her. She did not intend to convey the idea that endometritis did not occur before marriage. She did not mean that surgical treatment should not be adopted before the age of thirty; but in London she thought it was too frequently adopted in young girls, such as frequently, coming from the country, became anæmic and subjects of dysmenorrhœa. Nor did she mean to imply that there was not ovarian pain; but she thought it was secondary. She was not competent to give an opinion on Dr. Simpson's question, but was under an impression the reverse of that stated by him. She included Dr. Steele's treatment under the ordinary routine treatment. In reply to Dr. McClintock, she said she believed that obstruction might exist. Although a sound could be passed, the passage would be very different when in a state of congestion. She hesitated about doing good with pessaries, without postural treatment at the same time. She used Chambers's and often Wood's pessaries. The danger of pessaries ought never to be overlooked. As to the question of Dr. Legat, no doubt the pains were much the same, both being due to irregular contraction of the uterus; but she was not prepared, in the present discussion, to go into the subject of after-pains. She concluded by thanking the meeting for her reception.

Syphilitic Placenta. By ANGUS MACDONALD, M.D., Edinburgh.—Syphilitic disease of the placenta had of late attracted some attention on the continent, but had commanded little attention from the British profession. The paper embodied the result of a careful microscopic examination of two undoubted specimens of the disease. The chief difficulties that lay in the way of ascertaining the true nature of the disease were twofold. 1. It was liable to be mistaken for fatty degeneration of the placenta, and had been so mistaken by excellent observers, such as Kilian and Robin. 2. It was frequently almost impossible to arrive at a satisfactory proof of constitutional syphilis till the discovery by Wagner of Berlin of osteochondritis syphilitica. Microscopical and chemical examination of the placenta were sufficient to show that such cases were not fatty degeneration. It was easy, also, to prove in a fœtus born dead, and even macerated, whether it was constitutionally syphilitic or not. If the fœtus were syphilitic, there would be a band of tissue between the bone of the shaft and the cartilage of the epiphysis of the long bone, in a condition of inflammatory irritation. This band was bounded by very irregular outlines both towards the cartilage and towards the true bone, and consisted, according to the advancement of the disease, either, 1. Of cartilaginous cells hypertrophied and greatly increased by proliferation, as also prematurely infiltrated with earthy matter; or 2. Of the above, combined with premature sclerosis of the intercellular tissue, and premature osteogenic formation within the cartilage, and arrest of true bony transformation; or 3. The higher degrees of inflammation might come on, softening and interruption of the connection between bone and cartilage, and inflammatory exudation with even suppuration. The results of those changes might be seen both by the naked eye and the microscope, as the reddened or greyish yellow band was quite visible to the naked eye, and the hardened prolongations of premature calcified cartilage were easily seen and felt. The change in the placenta was equally distinct, but varied, 1. According as the father was primarily affected by syphilis; 2. According as the mother was first affected; 3. According as both were syphilitic early in the pregnancy. If the father were primarily affected, the villi were the site of the disease in the first instance. They were the seat of a peculiar cellular hypertrophy and multiplication, named by Frankel "disfiguring granulation-cell disease", and which consisted of an immense multiplication of the cellular contents of the villi and of the epithelial mantle of the villus, together with an increase of the thickness of the wall of the included vessel. This cellular multiplication and increase proceeded outwards from this vessel as a centre, and the rows of connective tissue nuclei were seen to be arranged in circles, reminding one of the appearance of an Haversian canal. In consequence of this cellular multiplication, the villi were enormously increased in size and weight, the vessels were ultimately completely obstructed, and by and by the hypertrophy was followed by atrophy and abortion of the villus. The unaffected portions of the placenta were liable to become congested; extravasations were likely to be hence formed, and the ultimate result was suffocation of the fœtus. If the

mother were primarily affected, the disease attacked the maternal placenta, and consisted essentially of increased growth of the connective tissue framework of the placental decidua, and enormous hypertrophy of the large cells of the decidua, leading to obstruction of the villi by compression. The affection described by Virchow, Slavjansky, and Kleinwächter as endometritis, placentalis nummosa, was probably syphilitic disease of the maternal placenta. If both father and mother were primarily syphilitic, or became so in the early months of pregnancy, both conditions exist conjointly. In two placentas examined by Dr. Macdonald, the history proved syphilis of father and of mother; the bones showed well developed osteochondritis syphilitica, and the placental tissue was affected by both forms of the syphilitic degeneration of tissue. From his researches, Dr. Macdonald drew the following conclusions. 1. A large number of intrauterine deaths from diseased placenta are due to the existence of constitutional syphilis in either or both parents, and the death is the result of progressively increasing defective blood-supply, owing to the changes described above. 2. The changes taking place in the placenta give the organ a pale appearance, and increase its size; and, in consequence, the appearance it presents is liable to be mistaken for fatty degeneration. This mistake is easily prevented by microscopical and chemical examination of the diseased organ. 3. The bones of the dead fœtus will (as they will show osteochondritis syphilitica, if the constitutional disease be present), afford a valuable and infallible means of deciding whether the corresponding placenta is syphilitic or not. 4. Medicines thought to be beneficial by their action upon the blood, as oxygen given in such cases, most probably are useful, if they really do good, as blood-depurators, and may be beneficially replaced by iodide of potassium and other accredited antisiphilitic measures. 5. On the whole, there is little good to be expected from premature labour in such cases, as the child, though born alive, is saturated by the disease. We may expect better results by antisiphilitic measures acting through the mother on the placenta and the child at the same time.—Mr. LAWSON TAIT (Birmingham) thought the view of the paper an error, and referred to his own recent paper on the subject. The change occurred in the arteries, and was analogous to the changes in vessels of the kidney described by Dr. Johnson. It was a conservative change.—Dr. SWAYNE (Clifton) made observations on the size of the placenta.—Dr. MACDONALD replied.

Note of Inquiry with reference to some Points in the Management of the Third Stage of Labour. By J. WALLACE, M.D., Liverpool.—In this inquiry, Dr. Wallace considered, first, the rules of guidance and practice generally followed; first, as regards the treatment of the placenta; and, secondly, that of the uterus subsequently. The position of the placenta was shown to be most frequently on the middle zone of the uterus; and, next, on the fundal zone; and, according to its position, was traced the mechanism of expulsion. Here it was pointed out that Smellie and others knew the true mechanism of expulsion and delivery of the placenta, which has been readily brought under the notice of the profession by Matthews Duncan, Lemsler, Caseaux, Leishman, and others, in contradistinction to the descriptions given by Baudelocque, Schultze, etc. The different methods recommended by various obstetric authorities of management of the placenta were referred to, and the author's views and practice stated. The paper was concluded by a reference to the uses and abuses of the binder, a routine habit of practice being condemned both in that and in the habit of giving ergot, opium, cordials, etc., after delivery. It was especially shown that the binder, as applied with pads, converted an abdominal organ, as the uterus is at that stage, into a pelvic one, and hence caused, instead of prevented, flooding, and was one of the main factors in producing subsequent uterine trouble in the way of flexions and displacements.

Melœna in the New-born Child. By J. HALLIDAY CROOM, M.B.
Vomiting in Connection with Pregnancy. By H. FLY SMITH, M.B., Oxon.—Pregnancy causes a generally exalted condition of the nervous system. Reflex action is readily exhibited. Nausea and vomiting in the early months of pregnancy is coincident with the development of the corpus luteum in the ovary. The gastric symptoms appear usually in the morning, because the blood has become tainted with an extra amount of carbonic acid gas breathed during the night. Exposure of the skin to fresh air acts reflexly on the morbidly excitable centre commanding the pylorus; closure of this valve causes the stomach to empty itself by way of the œsophagus instead of the duodenum. The vomiting may proceed to an obstinate and uncontrollable form, endangering life by inanition. This, too, occurs apart from any organic lesion, whether of the digestive track or other organ; the uterus and ovaries may also be apparently in a normal condition. Treatment directed immediately to the stomach has frequently failed. Certain observers having found that leeches to the cervix has been followed by remission of the gastric symptoms have, therefore, thought

that inflammation of the cervix originated the reflex action of the stomach. In some cases, redressment of a retroverted womb has succeeded. Dr. Graill Hewitt asserts that there is always in these cases flexion of the cervix. Dubois observed that, having dilated the cervix for the induction of labour, the vomiting forthwith ceased without interruption to the pregnancy. Dr. Copeman of Norwich has recently published three cases, when similar treatment was followed by a like success. All authors agree that, in extreme cases, drugs fail. It will appear, then, that the uterus itself should be attached with the view of subduing inflammation if it exist, or redressing the womb if it be displaced, or dilating the cervix as an empirically successful treatment.

Neuralgic Dysmenorrhœa. By CHARLES R. DRYSDALE, M.D.—The author thought that a salutary revolution was now setting in against the surgical doctrines held by Dr. Marion Sims and others upon dysmenorrhœa and its causes. Dr. Drysdale very rarely indeed witnessed any case where he had found any service to arise from operations on the uterus; whilst he had seen some cases of pelvic abscess and pelvic peritonitis occur from such interference. He was lately consulted by a patient, single, aged 32, who had suffered since the age of sixteen from dysmenorrhœa, and who on consulting two eminent specialists was advised by the one to have recourse to incision of the cervix, and by the other to wear a pessary. In this case, the uterine sound passed in its normal direction without difficulty, and the patient had no leucorrhœa nor prolapse of the organ, which was quite normal in size. There was no ulceration of the os uteri, although another eminent specialist had considered this as the cause of her dysmenorrhœa. The author held that there was still too great a tendency to expect to find an evident physical cause for all painful menstruation. Spasm and neuralgia were quite sufficient to account for the vast majority of cases. Membranous shreds, also, were frequent causes of obstruction to the monthly flow. An illustrative case was recorded. The rational treatment of dysmenorrhœa commencing at an early period, consisted not in the use of pessaries, or of incision of the uterus, surely; but in the use of cold baths in the morning, with short walks in the open air afterwards; in hot baths, a few days previously to the menstrual periods; and in palliative treatment of the paroxysms by means of antispasmodics at the epoch of pain. Marriage sometimes cured such cases at once; at other times, it was of no use.

Case of Rupture of the Unbilical Cord during Delivery, followed by Death of the Child. By W. HAINING, M.D., Chester.—The chief points of interest noted in this case were the following. The duration of the pregnancy, as fixed by well proved circumstances, could not have exceeded 274 days, whilst, according to the mother's showing, it must have been not more than 267 days. 2. Menstruation was prolonged for four, if not five periods after the occurrence of impregnation; and the continuance of the function, the cessation of which was regarded by the mother, aged eighteen years, as the only certain evidence of pregnancy, caused her to miscalculate her "time". 3. The labour which appeared to have been completed within two hours of the time at which the pains first called for attention, though not of the kind which they required, their nature not being apprehended. This time is unusually short for a primipara under ordinary circumstances. 4. The cord was of the usual thickness, but measured only eight inches in length; the length at the placental end being about five inches and a half. There was no hæmorrhage from either of the ruptured ends. 5. The death of the child was interesting medico-legally. It died twenty-three hours after its birth; there was no suspicion of foul play, and there had been no concealment of pregnancy. The only *post mortem* fact noted, was a bruise of the scalp over the left occipito-parietal suture, but there was no internal effusion of any kind. The birth took place in a house, in the presence of married women; but, had it occurred in a privy or water-closet, in the case of a woman who had never confessed her shame, she would, however innocent her intention might have been, have certainly been required to stand her trial upon a criminal charge.

THE DINNER.

THE annual dinner of the Association was held in the Music Hall on Thursday, August 5th, and was attended by a company numbering nearly five hundred. The hall was set out with thirteen tables, in addition to the one on the platform, and the tables as well as the orchestra were adorned with shrubs, bouquets, and flowering plants, arranged in tasteful groups. Sir Robert Christison, Bart., President of the Association, presided, and was supported on the right by the Right Hon. the Lord Provost; Dr. Copeman, Norwich; Dr. Lowe, President of the Royal College of Physicians; Surgeon-General Elliot; Dr. Waters, Chester; Professor Balfour, Dr. McClintock, Dublin; Prof. Spence; Mr. Alfred Baker, Birmingham; Professor Lister; Professor Macleod,

Glasgow; and on the left by the Rev. Lindsay Alexander, D.D.; the Right Hon. Lyon Playfair, M.P.; Principal Sir Alex. Grant; Dr. Falconer, Bath; Bishop Cotterill; Sir J. Cordy Burrows, Brighton; Dr. Matthews Duncan; Mr. Husband, Vork; Dr. Gueneau de Mussy, Paris; Dr. Warburton Begbie; Dr. Chadwick, Leeds; and Mr. Ernest Hart. The centres of the various tables were occupied by Dr. John Chiene, and Dr. Angus Macdonald, with Bailie Methven; Councillor Dr. Coghill, with Bailie Muirhead and Dr. Hutchison, New York; Dr. Brackenridge, with Bailie Tawse, Mr. Skinner, City Clerk, and the Rev. Dr. Bell; Dr. Littlejohn, with Treasurer Colston; Dr. John Smith, jun.; Dr. Grainger Stewart; Dr. Thomas Keith, with Professor Pacchiotti, of Turin; Dr. Keiller, Professor Simpson, Dr. Argyll Robertson. The following gentlemen were croquiers:—Professor Crum Brown, with Dr. Championnière, Paris; Dr. Batty Tuke; Dr. M'Kendrick, with Professors Dewar and Dr. Charles, Belfast; Dr. Cadell Dr. Gillespie, with the Master of the Merchant Company, Mr. Hugh Rollo, W.S., and Mr. Cripps. A number of ladies occupied places in the gallery.

The Rev. Dr. Lindsay Alexander said grace, and Bishop Cotterill returned thanks after dinner.

The CHAIRMAN proposed "Her Majesty the Queen".

The toast having been drunk with enthusiasm, four pipers of the Queen's Edinburgh Rifle Volunteer Brigade marched round the room playing the national music, which was received with great cheering.

The CHAIRMAN proposed "The Prince and Princess of Wales, and the other members of the Royal Family." He hoped His Royal Highness may have great enjoyment in his approaching visit to our Indian dominion, and that he may come back instructed in mind and improved in health, and with the assurance that his visit has helped to tighten the bonds that connect this country with that glorious land in the East. [*Applause.*]

The PRESIDENT intimated that apologies for absence had been received from the Lord Justice-General, the Lord Justice-Clerk, the Solicitor-General, Inspector-General Smart, the Lord Advocate, Surgeon-Major White, King's Dragoon Guards, and Surgeon-Major Lithgow, 79th Highlanders.

The CHAIRMAN gave "The Army, Navy, and Reserve Forces". A great deal had been said in the newspapers about the efficiency of our navy and army, and likewise of our reserve forces. In regard to the navy, all he could say was that he saw our jolly tars sometimes parading the streets, and he observed that they wore the same dress and walked about with the same rolling independent gait as ever, with their faces raised exactly as if they were about to board an enemy's ship a great deal bigger than their own. [*Laughter.*] He saw no difference between them and the tars he used to see in his young days, when our navy extended over the whole world, and no enemy dared to meet us; and he saw no reason, therefore, why our seamen now-a-days should not discharge their duty just as well as their predecessors. In regard to the fitness of our ships and their armaments, he had only to say he should pity very much any of our adversaries who should come into contact with a ball weighing 600 or 1,000 lbs. discharged from an 80 ton gun. [*Laughter.*] We were accustomed lately to hear complaints about the youth and want of stamina of our soldiers, and their inability to march long distances; but they were all well aware, without quoting what had happened in our own days, that the great victories of the French Revolution were gained by the young soldiers; while, as to the marching, they would not consider that so doubtful a matter, when they recollected the long walks of twenty miles or more they used to make when they were young men, and that too with pretty heavy bags upon their shoulders. Why our young soldiers could not do the same thing, he could not see. Respecting the reserve forces, he would only remark that their motto was "In Defence", and that they had served their purpose so well that since they came into existence no enemy had dared to land upon our shores. [*Applause.*] He coupled the toast with the name of Dr. Dickson, of the Royal Navy, and Surgeon-General Elliot.

Dr. DICKSON and Surgeon-General ELLIOT replied, the latter remarking that there was no reason to despair of our so-called "weedy" soldiers, for they possessed a fine physique and great power of endurance, as proved in the recent manoeuvres at Aldershot.

The PRESIDENT, in giving "The Clergy", said it would be observed that the toast was given in general terms. In Scotland they had a great variety of clergymen, all of whom claimed that their own particular denomination was "the Church". [*Laughter.*] They could not, therefore, in a general assembly like the present, drink "The Church", because any one clergyman might rise and say, "I am the Church!"—[*renewed laughter*—] and the poor chairman would not know what he was about. He therefore proposed the far more comprehensive toast of the clergy. There was a great connection betwixt the medical profession and that of the clergy. In ancient times the priests were the only

doctors, and even in later days the priests of the Catholic Church were the principal physicians. In these days a complete separation had very properly taken place betwixt the profession of theology and that of medicine; but, at the same time, the one was very well known to be an auxiliary to the other. Many a time they knew how desirable it was that the courage of a patient in an unfortunate crisis should be sustained by the equanimity which came over his spirit through the ministrations of a clergyman. He had had to request that aid; and never was it granted without his observing a beneficial result—so much so, that he should almost say they should have in the pharmacopœia "*sacerdotes*" as one of their remedies. They would often find it useful indeed to send a prescription—*Sacerdotis quantum sufficit, et quamprimum.* [Applause.]

Bishop COTTERILL, in responding, said he trusted that medical men realised now, as they did not do half a century ago, that the clerical office, when rightly administered, was really an aid to the medical profession. [Hear, hear.] Unfortunately in former times religion had been represented, most unhappily, as unfavourable to science, whereas science was its nearest ally; and, on the other hand, science had looked with some suspicion on religion. But he trusted that kind of feeling, not only as regarded the relations between medicine and the clerical office, but generally between science and religion, was gradually passing away. [Applause.]

Dr. LOWE proposed "The Houses of Parliament", remarking that in no other country in the world did institutions of a similar nature give such general satisfaction. He coupled with the toast the name of Dr. Lyon Playfair, M.P.

The Right Hon. LYON PLAYFAIR, on rising to respond, was received with cheers. He said the President of the Royal College of Physicians did all things well in Edinburgh, but he had made a very bad speech, for, in proposing that they should drink to the welfare of the Houses of Parliament, two great institutions in this country, he had forgotten them altogether, and proposed the health of a very little man. [Laughter.] He returned thanks on behalf of the Houses of Parliament which legislated for this country with confidence on this occasion, because, when the present Parliament was brought into existence, they were told by the distinguished man who is now at the head of the Government that the keynote of the Parliament was to be "*Sanitas sanitatum omnia sanitas*". [Applause.] How far the Parliament had fulfilled that promise, he had not now to tell them. He had criticised its action very freely that day in his presidential address; but one thing he might say, that whenever any subject relating to the public health of the community, to such subjects as this great Association had chiefly an interest in, and relating to all subjects connected with the social welfare of the people, he had always admired this, that the House of Commons, of which he had had the most experience, forgot altogether that it was divided into two great political parties—[hear, hear, and cheers]—and acted as one body in trying to frame measures most productive of good for the public interest. [Renewed cheering.] But, whilst he said that, there was another thing which had both amused and perplexed him until he found for it an explanation. There was a great theoretical terror in the House of Commons of the doctors. [Oh, and laughter.] There was a determination expressed very loudly that they would not place communities in this country under the despotism of medical men; but there was conjoined with that a very curious practical confidence in the doctors. The reason for that, after a little while, was not difficult to see. In the first place, when local authorities were entrusted with the carrying into effect of Sanitary Acts, one saw the explanation easily. The science and intelligence of the doctor was often, in regard to a knowledge of local evils, in advance of the authorities themselves; and they felt that the knowledge and science of the doctor often made him in reality the master, although he was only the servant, of the local authority. But that did not explain the difficulty in the House of Commons. The constant speaking against the doctors, coupled with the practical confidence reposed in them, as shown by the fact that every Act gave more and more power, and threw the motive power of all sanitary legislation into the hands of medical men, arose from this circumstance: communities found themselves diseased just as individuals did, and they were now appointing everywhere State physicians, just as an individual appointed his own physician; and they knew that when a patient was diseased he was extremely submissive to their will. He allowed the will of the doctor to overcome his own will; but when he became well he began to be refractory. He thought then that he knew a great deal better than the doctor, and would not follow the regimen which was necessary to keep him in health. And so it was with communities. They trusted the doctor when there were great maladies abroad, but they began to show their independence of them when they were sound. Parliament was an aggregation of communities, so that when they passed legislative measures they showed

that curious conflict between distrust and confidence. They said when everything was well that they would not allow themselves to be put under medical despotism, that they were not going to hand over the country to medical despots, but when they passed laws they threw all power into their hands. They might take, for example, the Artisans' Dwellings Bill which had just been passed. There was a great determination not to throw everything into the hands of the doctors, but the doctors had been made the primary motive power of the whole measure. So it was with every measure of a like nature which they passed; they showed practical confidence, whilst they had theoretical terror. That sometimes made men, inexperienced in the ways of the House, do things which those who had experience in legislative assemblies were astonished at. He would give them one example: there was no more clamant wrong connected with the medical interest just now than the injustice to which the medical officers of the army were exposed. [Hear, hear.] The medical officers of the army were good enough this session to give him several excellently prepared memorials setting forth their grievances in an extremely temperate manner. These memorials were placed in the hands of the War Secretary, with whom he had several conferences, and whom he found extremely anxious to study and master the subject. But the patience of the medical officers of the army, as was naturally to be expected, was a little exhausted, and they wished to appeal to the House of Commons. His own conviction, based upon the knowledge of those feelings of distrust and practical confidence in medical men, made him convinced that this would have a hardening, instead of a softening, effect with regard to their cause, and he did all he could to discourage such an appeal, because he was quite certain the Secretary of War would give it a full and kindly consideration, and that it was much better to make it an act of administration than an appeal to the legislature. That showed that they could not always trust the legislature in cases of prejudice. But that prejudice was certain to be removed. Medical men, when well educated, had obtained the respect of their patients wherever they settled; and so in time would the public officers of health, if they devoted themselves, as they were doing now, to the welfare of the public, with a single desire to prevent disease as well as to cure it. By their excellent conduct in these as in other respects, they would remove the prejudices which the legislature might have in regard to their profession, and they would receive that recognition and honour, as regards their position as officers of the State, which, perhaps, was given to them in a grudging manner. [Cheers.] He again thanked them for the honour they had done him in coupling his name with the toast of the Houses of Parliament. [Applause.]

The PRESIDENT next gave the "British Medical Association". In doing so, Sir Robert said there was no doubt that all acquainted with the British Medical Association would allow that it had been in this country a very great success. [Cheers.] It commenced as a provincial Association, but it gradually extended itself over England, reached the capital, and then became the British Medical Association. Wisely, it was not called the English Medical Association; for then, of course, they would not have had a Scotchman or Irishman in it. [Laughter and applause.] But, as he had said, all divisions of the kingdom had justice done them in naming the Association the "British Medical". He had often been amused at the facility with which in the south the term "England" was substituted for "Britain". The Duke of Wellington would never have said in his despatches that he did this with his English army. [Cheers.] But yet, to such a ridiculous extent had it gone, that when during the Indian mutiny, when the 78th and 64th Regiments—one a Scotch, and the other an English regiment—advanced against immense odds and carried everything before them, on one occasion the 78th charged a battery of artillery of the enemy, and in defiance of their opposition carried it, one of the newspapers—he would not say which of them, but a newspaper which professed to regulate a great deal of what goes on in the world, in describing the great gallantry of the Highlanders, said that nothing could resist English pluck. [Laughter.] The originators of this Association had great credit in choosing for it the comprehensive and, to his ear, euphonious sound of the British Medical Association, and much had they been rewarded. In the course of a few years, the numbers of the Association increased to about 2,500; and he understood now from Mr. Ernest Hart, who knew the fact well, that, since he became Editor of their JOURNAL, the number had increased to 6,100; and the result of their visit to Edinburgh would probably be the means of adding 500 Scotchmen to the Association. [Loud applause.] It was impossible for him to go over the various incidents that had marked the progress of this body. It was leaving its mark upon the country, upon medical history, and upon the sanitary history of the country—and he used the word sanitary in its largest possible sense. It would be endless were he to go over all the important measures in which they had taken part.

What he would advert to just now, however, was their enormous power, and the caution with which they should exercise it. [*Hear, hear.*] There was no member of the House of Peers, or member of the House of Commons, who had not got his doctor, and he doubted very much whether he had not got a doctor who was not a member of this Association. Now, if a man's doctor was worth his salt, the patient could not help giving him a very considerable part of his conscience. [*Laughter.*] He could not help it, fight as he might, and he begged to suggest that this was the cause why, as Dr. Lyon Playfair said, members of Parliament had a horror of doctors. They knew their great power over them. But it could not be denied that that power was just—[*laughter*—]but still a man scorned to be under the influence of another. The medical profession, as all admitted, was a very powerful body; and he ventured to question whether, since the days of the institution of the Jesuits, there was a body who possessed such great influence, or exercised it in so quiet a way. This was the reason why they should take care what steps they took for the improvement of medicine for the benefit of the nation at large. Every step they took depended upon their organisation. [*Hear, hear.*] It was quite impossible for a great Association such as this to discharge its own business in such a limited time. They had already seen that, during the history of the present meeting, they had been obliged to homologate a great number of the transactions of the Council without taking them into consideration. Sir Robert then proceeded to refer in eulogistic terms to the services rendered to the Association by the Local Secretaries, the Council, and the Staff of the JOURNAL of the Association. In concluding, he made allusion to the Benevolent Fund of the Association, for the relief of the decayed members of the profession, remarking that it was only proper that they should all become members of this branch. He had the greatest pleasure in giving "Health and prosperity to the British Medical Association".

The toast was drunk with enthusiasm.

Dr. FALCONER (Bath), in replying to the toast, referred with satisfaction to the work which had been accomplished at this meeting, and said that, even on the ground of an aid to scientific discovery, this Association could justify its existence. A larger sum of money had this year been granted by the Association for the prosecution of scientific inquiry than in the preceding year, and, therefore, they were now in a position to wipe out the complaint that had been frequently urged against them, that they had made use of their resources more for their internal management than for the promotion of scientific inquiry. In the Bill which had just passed through Parliament, the finger of the Association was clearly to be traced; and if the Association could press to a successful issue the Habitual Drunkards question, which would assume a new aspect from this date, and show how best to defend against themselves those unfortunate beings who could not resist the temptation to rob themselves of reason and physical power, they would have accomplished much. After referring to the hardship exercised by the Scotch Poor-law on the medical profession, and speaking of the good effected by the aid of the Association in England and Ireland in reforming the Poor-law system, he said he agreed with Sir Robert Christison on the responsibility attached to the Association, and advised the members to exercise the greatest care, wisdom, and foresight in using their power in Parliament, so that it might never be turned against them.

Mr. ERNEST HART (Editor of the BRITISH MEDICAL JOURNAL), being called upon from all quarters of the room, said he felt deeply honoured by being thus spontaneously called upon to respond to the name of the Association. The position in which they had, by their kindness, thus placed him was embarrassing, for he felt that, as he had opportunities of addressing them weekly from a position as absolute as that of a clergyman in his pulpit, it was hardly fair that he should trespass upon their attention at this gathering. He would acknowledge that the serious and responsible work of editing the BRITISH MEDICAL JOURNAL was a labour of love to him, and one that he felt to be the most interesting work of his life. For this work, he had readily sacrificed other opportunities of professional usefulness and advancement, and he felt that in the expression of kindly feeling he had experienced that evening this had been acknowledged. [*Cheers.*] He was deeply gratified at seeing how steadily the Association had progressed during the last seven years, in numbers and in power. It had extended itself far and wide, and had an influence which was constantly making itself felt in Parliament, the press, and in the public mind. [*Cheers.*] This extensive and extended influence enabled it to press forward any measure for the public good; and its power and the power of the JOURNAL was unexampled in the history of the press. [*Cheers.*] It only remained for the members to sacrifice their private ends to public duty, and then the Association would have a parliamentary power which could be used for the prevention of disease and the promotion

of the public good, which, rightly and discreetly used, would make the Association one of the great benefactors of the country. [*Cheers.*]

Mr. HUSBAND proposed the health of Sir Robert Christison. He said that the excellence of their Chairman recommended him to every class of society in Edinburgh. [*Cheers.*] It was well known that Sir Robert never spoke but he edified, instructed, and amused. When he remembered that their President was one of the first toxicologists of the day, that he had been one of the best therapeutists and practical physicians which Edinburgh ever produced, and when he also remembered that Sir Robert was renowned as a man of science, and that another association seemed to foreshadow the high honour of electing him president next year, he would say that such a man was an honour to their profession. [*Loud cheers.*]

The toast having been received with the utmost cordiality,

Sir ROBERT briefly replied, expressing himself as deeply gratified by the position in which he had been placed, stating that he never would forget the visit of the British Medical Association to this city.

Dr. MATTHEWS DUNCAN proposed "The Lord Provost, Magistrates, and Council", remarking that the Lord Provost had, in order to be present at their gathering that evening, put himself to great inconvenience by travelling from London.

The LORD PROVOST, after expressing regret for not being present at the opening of the Association's meeting on Tuesday, said that still his absence could scarcely have been missed when the gentlemen of the medical profession had been welcomed in such a friendly way by his friend Bailie Tawse. He proceeded to say that a charge had been committed to the Town Council of Edinburgh, not only to preserve the city's natural beauties—[*applause*—]but also to open up, by means of the City Improvement Act which they had received, many of the old and confined closes, so as to improve the social condition of the people.

[*Applause.*] A great deal had been done, but still a great deal of work remained to be executed. But Rome, they must remember, was not built in a day; and in time this city would carry out those aids to health which this Association so much desired. He next referred to the Bill which the Corporation received to introduce a new supply of water, which, when accomplished, he thought would double the present supply. [*Applause.*]

Dr. PRIESTLEY gave "The Universities and Medical Schools of Scotland", and, in doing so, said he could not look over twenty years of the history of the University of Edinburgh without feelings of the greatest regret. He now missed the names of the professors who had been his old masters—names such as those of Professors Davidson, Alison, Sir James Simpson, and Goodsir; and now the name of Professor Bennett was removed from the list, although they rejoiced that he was still in life. They were all, however, glad that there was yet a great phalanx of teaching power representing the University of Edinburgh as well as the other Universities of the country, and these were fittingly represented by Sir Alexander Grant. [*Cheers.*]

Sir ALEXANDER GRANT, in reply, took the opportunity of expressing the great pleasure which he felt in welcoming, on the part of his University, the British Medical Association to Edinburgh. It was an occasion to the University of great pride, in the first instance, because its senior professor, their well-beloved brother, had been chosen as their President—[*cheers*—]and, secondly, because the University of Edinburgh was the *alma mater* of many of the members now present among the members of the Association. [*Cheers.*] He might say that they of the outer world, who looked with such deep reverence upon what their medical advisers told them upon every subject, looked with some interest to this banquet, because it had given them much satisfaction to know that men of such high authority did not object to moderate indulgence. [*Loud laughter.*] There had been a rumour last week in Edinburgh that five hundred quails had been ordered for this banquet, which led to the opinion that the theory of those medical advisers who discouraged the use of all grosser kinds of meat was to receive sanction this evening. But he must say that those who felt some alarm as to that subject, had their minds immediately relieved on entering the hall, and taking up the *carte* which was laid before them. He hoped that, on their next visit to Edinburgh, the University authorities would have the pleasure of receiving the Association in rooms more worthy of such an University. [*Cheers.*]

Dr. MACLEOD, Glasgow, also replied, remarking that, if the Association visited Glasgow or Aberdeen, they would find they were not sluggards, and that they had endeavoured not to betray the great interests of the profession.

The other toasts were, "The Orators and Presidents of Sections", proposed by Dr. Edward Waters, and responded to by Mr. Spence; "Our Guests", by Professor Lister, replied to by M. Noel Gueneau de Mussy; "The Reception Committee and the Local Committee", by Sir J. Cordy Burrows, replied to by Drs. Gillespie and Batty Tuke.

The PRESIDENT, at the conclusion, said he would give one more toast, one consisting of three words only, which had been given at all medical gatherings at Edinburgh since the middle of last century. It was not known to some of the strangers, but he had got it from one of his oldest professors, Dr. Duncan. It was, "Floreat res medica", which was translated by the doctor as "Long live and ill health".

[Loud laughter.]

The assembly then broke up shortly before twelve o'clock.

PRESIDENT'S RECEPTION.

At nine o'clock in the evening of Tuesday, August 3rd, the President, Sir Robert Christison, held a reception in the Music Hall and Assembly Rooms. There was no attempt at decoration of the Assembly Rooms, but the space beneath the gallery of the Music Hall was arranged as a drawing-room; while refreshment buffets were placed in the east and west wings, and the orchestra was effectively decorated with palms, dracenas, ferns, and plants in bloom. As the company, which numbered upwards of 1,600 ladies and gentlemen, arrived at the rooms, they were received by Sir Robert Christison, Dr. Gillespie, Dr. Lowe, Dr. Batty Tuke, and Bailie Tawse. The reception over, an agreeable promenade and *conversazione* ensued in the Assembly Room, where Mr. Daly's orchestra played a programme of dance music; and also in the Music Hall, where the platform was occupied by the band of the 1st King's Dragoon Guards, who also played a programme of selected music. A very pleasant evening was spent.

CONVERSAZIONE.

In connection with the visit of the Association, the President and Fellows of the Royal College of Physicians gave a *conversazione* at the Museum of Science and Art on Wednesday, August 4th, which was attended by a very large assemblage. A general invitation had been issued to members and non-members attending the Association meetings—special cards being sent only to the municipal authorities, the Lords of Session, the officers of the Garrison, and a few other public functionaries; and the hearty manner in which the invitations were responded to may be judged from the fact that in course of the evening no fewer than one thousand five hundred and sixty-three ladies and gentlemen passed the turnstiles. The company on their arrival were received by Dr. Lowe, the President of the College, and Mrs. Lowe—the reception ceremony lasting over an hour. The suitability of the Industrial Museum for a gathering of this character has been often demonstrated, and on this occasion the brilliantly lighted halls, graced as they were with many elegantly dressed ladies, presented a gay and exhilarating scene. Refreshments were served in the south rooms, which were most tastefully decorated with greenhouse plants and flowers; and the whole of the arrangements were admirably carried out. The proceedings lasted until about half-past eleven o'clock. During the evening the bands of the 1st King's Dragoon Guards and Queen's Edinburgh Rifle Volunteer Brigade, which were stationed one at each end of the central hall, played an excellent programme of music. The band of the Dragoons opened the programme, and the pieces were afterwards played alternately by each band.

GARDEN PARTY.

On Friday, August 6th, on the invitation of Principal Sir Alexander Grant and the Senatus Academicus of the University, upwards of three thousand ladies and gentlemen attended a garden party in the Royal Botanic Gardens. Sir Alexander Grant, in his official robes as Principal of the University; Lady Grant; Professor Balfour, also in his official robes as Regius Keeper of the Gardens; and Mrs. Balfour, received the guests on their arrival, at the end of the entrance avenue, just in front of a fine specimen of the *Wellingtonia Gigantea*, planted as a memorial tree in 1861 by Sir Robert Christison. The gardeners attached to the gardens were employed to conduct visitors through the grounds, to point out the more notable plants, and indicate the views of greatest interest. Among the medicinal and economical plants which were specially exhibited were the following: *Drimys Winteri* (Winter's bark), *Bixa orellana* (Anneth plant), *Gossypium herbaceum* (cotton), *Theobroma cacao* (chocolate), *Corchorus capsularis* (jute), *Thea Bohea* and *T. viridis* (tea), *Citrus aurantium* (orange), *C. Limonum* (lemon), *Azle marmelos* (Indian ael), *Garcinia morella* (gamboge), *Guaiacum officinale* (guaiac), *Quassia amara* (quassia), *Magnifera indica* (mango), *Astragalus verus* (tracaganth), *Myrospermum Peruvicum* (balsam of Peru), *Tamarindus indica* (tamarind), *Acacia Arabica* (gum Arabic), *Caryophyllus aromaticus* (clove), *Eugenia pimenta* (allspice), *Eucalyptus globulus* (blue gum), *Cephaelis ipecacuanha* (ipecaecuan), *Cinchona calisaya*

(yellow bark), *Cinchona succirubra* (red bark), *Coffea Arabica* (coffee), *Richardsonia scabra* (white ipecaecuan), *Styrax officinale* (storax), *Ilex Paraguensis* (Verba, Inate, or Paraguay tea), *Isonandra gutta* (gutta percha), *Olea Europaea* (olive), *Convolvulus scammonia* (scammony), *Xagonium purga* (jalap), *Nicotiana tabacum* (tobacco), *Camphora officinarum* (camphor), *Cinnamomum cassia* (cassia), *Cinnamomum zeylanicum* (cinnamon), *Myristica officinalis* (nutmeg), *Zingiber manihot* (cassava), *Stillingia sebifera* (tallow tree of China), *Antiaris toxicaria* (upas aniar tree), *Artocopus incisa* (bread fruit), *Ficus religiosa* (pippul or sacred fig of India), *Brosimum utile* (cow-trees), *Piper nigrum* (black pepper), *P. cubeba* (cubeb pepper), *Zingiber officinale* (ginger), *Maranta arundinacea* (arrowroot), *Aloe vulgaris* (Barbadoes aloes), *A. socotrina* (Socotrine aloes), *Elais quincensis* (oil palm), *Andropogon Schanauthus* (lemongrass), *Saccharum officinarum* (sugar-cane), etc. In the walls of the class-room there were suspended large coloured drawings of medicinal and economical plants, such as aconite, squill, Calabar-bean, belladonna, henbane, capsicum, jalap, senna, asafetida, hemlock, sarsaparilla, squinting cucumber, etc. Living plants of *Dionaea muscipula* (Venus's flytrap); species of *Drosera* and *Drosophyllum* (sundews); and other insectivorous plants, such as species of *Sarracenia*, *Darlingtonia*, *Nepenthes* and *Cephaelotus*, were also exhibited.

In the Herbarium Hall, the large collections of dried plants were open for inspection, and on the tables was laid out a map representing Ben Lawers, with dried specimens of the principal plants stuck on, which are to be met with at different heights on that mountain. Specimens of the rarer Scotch plants were also exhibited, especially those species which are found only in single localities.

In the class-room adjoining the museum, a beautiful collection of models and fresh specimens of fungi were exhibited, amounting to over three hundred specimens. The table, which was thirty feet long, was covered with a convex bank of dry sand into which the fungi were stuck, and had a fine effect. Some of the most conspicuous kinds were as follows: 1. Edible Species—*Agaricus campestris*, *A. nudus*, *A. pomonae*, *A. procerus*, *A. rachodes*, *A. rubescens*, *A. pantherinus*, *Boletus edulis*, *B. scaber*, *Cantharellus cibarius*, *Clavaria coralloides*, *Coprinus comatus*, *Fistulina hepatica*, *Hydnum repandum*, *Hygrophorus niceus*, *H. pratensis*, *H. virgineus*, *Lactarius deliciosus*, *Lycoperdon giganteum*,* *Marasmius oreadus*, *Morchella esculenta*, *Russula alutacea*, *R. heterophylla*, *Tuber aestivum*, etc. 2. Poisonous Species—*Agaricus vereginosus*, *A. fuscicularis*, *A. fertilis*, *A. muscarius*, *A. semiglobatus*, *Boletus luridus*, *B. piperatus*, *B. satanus*, *Clathrus cancellatus*, *Coprinus micaceus*, *Laccarius piperatus*, *L. rufus*, *Phallus impudicus*,† etc. 3. Species which cause disease among plants; these included models of species of *Aecidium*, *Erysiphe*, *Mucor*, *Periza*, *Phelionitis*, *Polystigma*, *Puccinia*, *Sphaeria*, *Uredo*, *Valsa*, *Merulius tachrymans*, or dry-rot fungus in various stages of growth. Large coloured drawings of many of these and other fungi were exhibited on the walls of the room.

Leaving the houses, the visitors went to the arboretum, passing on the way the general collections of plants arranged according to their natural orders; and from the high grounds of the main avenue what are recognised as the finest peeps of Edinburgh were enjoyed. The *pinetum*, with its fine collection of the newest and best conifers, was surveyed, and visitors passed on to the rock garden. Between the rock garden and the herbarium is a beautiful lawn, and here gradually all the guests congregated. In the centre of the lawn was stationed the band of the Dragoon Guards and the pipers of the Queen's Edinburgh Rifle Volunteer Brigade, which performed a selection of music in the course of the afternoon. The promenade seemed to be generally enjoyed, and between five and six o'clock the terraces overlooking the lawn and the grass slopes presented a gay and animated appearance, the bright colours of the ladies' dresses harmonising well with the more sober attire of the gentlemen and the fresh greenery of the turf. Refreshments were served in the winter garden. Among those present, in addition to the members of the Association, were: Sir John Don Wauchope, Sir Douglas Stewart, Sergeant Bailey, the Bishop of Edinburgh, Provost Cazenove, Dean Montgomery, Rev. Dr. Lindsay Alexander, Rev. Dr. Sandford, Sheriff Hallard, Sheriff Nicolson, Sheriff Hamilton, the Lord Provost, Bailies Muirhead, Howden, Tawse, Methven, Treasurer Colston, Dean of Guild Craig, Councillors Turnbull, Sloan, Boyd, McLaren, Rowatt, Hall, Mossman, Wellstood, Donald, McDougald, Sinclair, Coghill, and Durham; Colonel T. B. Butt, Lieutenant-Col. Lindsay, Colonel Trouson, Colonel Playfair, Majors T. Cadell, V.C., Allan, 79th Highlanders, Smith, 1st K.D. Guards, Leith, 79th Highlanders; Captains Davies, Douglas, Phipps, Pittman, Benthall, Bryne, Hills, Campbell, Clays, and Everett, etc.

* This large puff-ball is delicious when young and properly cooked. The mature spores, however, when swallowed, have given rise to violent irritation of the mucous membrane.

† This species has been occasionally eaten when young without any bad results.

BRITISH MEDICAL ASSOCIATION:
SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st, Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, AUGUST 21ST, 1875.

PROGRESS IN SURGERY.

THE Addresses in Medicine and in Surgery, delivered at the recent meeting of the Association in Edinburgh, had an interesting feature in common, which gave them a special value beyond that which they possessed as containing the expressions of opinions of two representative men. Both Dr. Begbie and Mr. Spence extended their view beyond the present into the distant past of their respective departments of the healing art; and, while recognising the progress which medicine and surgery have made in modern times, vindicated the claims of the ancient practitioners of medicine and surgery to our respect and admiration for their honest and earnest endeavours to improve their art, even though, in so doing, they acted on erroneous or imperfectly known principles, or followed cumbrous and unwieldy methods in carrying their principles into practice. It would be very satisfactory if the perusal of these addresses would lead to a more careful study of the history of medicine and surgery. The value of such study in relation to surgery was well set forth by Mr. Spence when he said:

"I believe it is only by reviewing the advance in relation to the past, that we will be able to estimate what real progress our science has made, and in what that progress consists, whether in the discovery of something absolutely new, or in modifying and improving methods of treatment, the intrinsic value of which had not been fully appreciated, or which had fallen into disuse owing to the imperfect method in which the principle had been carried out."

No more appropriate illustration of this could be found than that which was selected by Mr. Spence as the first subject of his comments: the treatment of fracture of the thigh-bone. It must have been obvious from the first that extension and counterextension were necessary for maintaining the bone in its proper position; and hence, from the time of Hippocrates downwards, we find the ingenuity of surgeons exercised in devising the means of carrying out this object. But, as Mr. Spence observed, the body was treated too much as a mere machine, and too little regard was paid to what it could bear. The most interesting point in Mr. Spence's remarks on this subject was his demonstration of the fact that the practice of extension by weights and pulleys, which is deservedly coming into favour with modern surgeons, is not at all a new thing; for Hildanus, more than two centuries ago, described and figured an apparatus for permanent extension which, though rude, bears a striking resemblance to the modern weight and pulley apparatus. Mr. Spence did justice to the mechanical skill of this sagacious old surgeon, when he vindicated his extension-bed from the contemptuous sarcasm of John Bell, and remarked that it would have been better to endeavour to simplify and improve it, than to hold it up to ridicule as "lumber" "not unworthy of the chambers of the Inquisition". After describing the modern method of applying the extension-apparatus in its most simple and effective form, Mr. Spence concludes his remarks on the subject in words with which we heartily agree.

"Looking to the extension method, thus improved and simplified, I think we may fairly reckon it as progress in a most important department of surgery; but, whilst we congratulate ourselves on our advance, and replace the bed and weight of Hildanus in the *armamentarium antiquorum*, et us regard it not as 'lumber', but reverently, with the homage due to the perception of a true principle, however rude in design and execution the apparatus may be."

Following this vindication of the merits of ancient surgery in respect of the treatment of fractures of the femur, there come some practical remarks on the process of union in fractures, on refracture in badly set fractures, and on operations for the cure of ununited fractures. The chief point in Mr. Spence's remarks on the first of these topics is, that he denies the existence of, or necessity for, the so-called "provisional callus" in cases where the bones are kept in proper apposition and muscular action is prevented.

In speaking of the subperiosteal method, Mr. Spence, while acknowledging the claims of Ollier of Lyons in connection with this branch of surgery, called to the remembrance of his audience the labours of his former colleagues, Syme and Goodsir, as having contributed in no small degree to our advance. The practical application of the method he held to be of most value in cases of acute necrosis.

The brief remarks on the manual method of reducing dislocations of the hip, and the comparison of the "American method" with the plan made known by a French surgeon forty years ago, are interesting. Indeed, as Mr. Spence hinted, the manual method of reducing these dislocations is of still greater antiquity. He quoted Pouteau as stating that it was known to the ancients, and was mentioned by Hippocrates and Paulus Egineta. On referring to the translation of the works of the last named author by the late Francis Adams, we find the following, under the head of "Dislocation at the Hip-joint" (vol. ii, p. 498).

"When the luxation is recent, it may be managed in the way recommended by Hippocrates. We must then proceed immediately to the reduction; for dislocations at the hip-joint, when allowed to remain long, are wholly irremediable. In general, then, the reduction may be accomplished by rotating it, by bending the limb, and by extension. For, if the accident be recent and the patient young, we may sometimes succeed in reducing the limb by grasping and rotating the limb this way and that. When the dislocation is inwards, we may sometimes accomplish our purpose by bending the limb at the groin inwards frequently and strongly. If the dislocation does not yield to these means, we must have recourse to extension," etc.

Here we have another instance of the antiquity of things often regarded as new: the difference between the ancient and the modern practice being, that the more accurate anatomical knowledge possessed by the surgeons of the present day enables them to carry out the principle with a greater proportion of success than fell to the lot of the men of old time.

The observations of Mr. Spence on the various methods of bloodless surgery, on tumours, and on operations on the air-passages, have less of antiquarian interest than is attached to his remarks on other topics. At the same time, they are of much value as the expression of the results obtained by an observant practical surgeon; and his defence of the judicious employment of venesection, and his remarks on the distinction between croup and diphtheria, will have been read by our associates with interest as the expressions of his opinion on two important topics, which have become subjects of professional disputation in recent years.

The last, and perhaps the most interesting, matter treated of by Mr. Spence, was the treatment of wounds and surgical dressings. After recalling to the recollection of his hearers the old practice by which a wound was never allowed to heal by the first intention, but was put through a process of "digestion, mundification" (for which one is almost tempted to read *immundification*) "and carnification", he went on to show how, even when a more simple method of healing wounds was introduced, the idea that something must be done or a great fuss made had such a hold on men's minds, that such reformers of this department of surgical practice as Paracelsus, Coldbath, and Sir Kenelm Digby, were obliged to have recourse to incantations, sympathetic powders, and such like means of satisfying the patient that "some great thing" was being done. As regards the antiseptic method, of which his distinguished colleague Professor Lister is the chief exponent, Mr. Spence holds that it occupies too great a share of attention to the exclusion of conditions which he considers as equally if not more important. We do not propose, in this place, to enter on a consideration of the merits of the antiseptic method; but will merely remark

that, while the evidence in favour of the value of this plan of treating wounds is very strong, we must not, on the other hand, lose sight of the facts referred to by Mr. Spence in his address, and given in detail by Dr. Kirkwood in a recently published *Statistical Report of the Major Operations performed by Professor Spence in the Edinburgh Royal Infirmary; with Remarks by Professor Spence*. It is there shown that, during the two years from October 1872 to October 1874, in 30 amputations of the lower extremity there were 7 deaths; in 6 of the upper extremity, 5 deaths; in 23 cases of excision of joints, there was one death; in 31 cases of removal of tumours, 4 deaths; in 14 operations for necrosis, 4 deaths; and in 8 other operations (tracheotomy, etc.), 4 deaths. Further, Mr. Spence states that, during the three years 1861-63 the mortality in 105 capital operations of various kinds was only 7. These favourable results are attributed, not to any special antiseptic treatment, which he does not employ, but to attention to the conditions of the patient and to the cleanliness of the wound, conjoined with the use of simple dressing. Such facts as these must receive weighty consideration in any attempt to decide the real value of the antiseptic method.

Mr. Spence's Address was not, and, under the circumstances, could not be, exhaustive of all the topics which could be brought forward. But, in regard to those on which he treated, it possesses a twofold value; first, as conveying the opinions of a practical surgeon who has enjoyed large opportunities, and has made good use of them; and, secondly, as showing that much of what many of us are accustomed to regard as new belongs in fact to antiquity—some of it, perhaps, to the prehistoric age of medicine, and that modern advance in surgery consists in great part in the general recognition of the value of old principles, and the improvement and simplification of the methods by which they are applied in practice.

HAMPSTEAD ASYLUM.

THE Select Committee of the House of Commons appointed to inquire into, and report upon, the proceedings of the Metropolitan Asylums Board presented their Report to the House on the 27th ultimo.

The Committee find that the action of the Asylums Board "has been strictly in accordance with their duties, powers, and responsibilities, as derived from the Metropolitan Poor Act, 1867"; that, although some alarm existed in the neighbourhood of the Hampstead Asylum, and some risk was encountered by residents or pedestrians passing near, and loitering about, ambulances, nevertheless these evils have been, in the opinion of the Committee, exaggerated; that they are not of necessity incidental to the existence of contagious hospitals, "but are mainly due to the carelessness of persons entering or leaving the same"; and that, by efficient administration, the dangers inseparable from the existence of infectious hospitals "may be reduced to a minimum".

The Committee also find that, from the medical evidence on both sides, infectious hospitals are not necessarily dangerous to their immediate neighbourhoods, but only become so by bad management. Of the alternative site, No. 3, the Committee consider that it is too remote from the population to be benefited; and that owners of property and others would make objections similar to those of the Hampstead residents. The Committee pass a high eulogium on the conduct of the asylum managers in undertaking, at great risk to themselves, the work of providing for the treatment of contagious fevers. "The Committee cannot quit this part of the subject without expressing their strong sense of the great services which have been rendered to the metropolis by the managers; who, with a courage, and in a spirit of devotion scarcely less than heroic, applied their energies and abilities, not merely to the establishment and supervision of the asylums, but were in constant personal attendance therein during the worst periods of the epidemic."

In reading the evidence given before the Committee, the following points struck us as worthy of attention. In the majority of cases, the medical witnesses simply stated their opinion, without stating the grounds on which the opinion was founded. Of the very slight and

insufficient grounds on which some opinions are founded, the following is an example. A servant girl, whilst driving down Haverstock Hill, passed a small-pox ambulance, after which she was seized with small-pox; ergo, conclude the servant and the medical friend of the family, the small-pox was communicated from the ambulance. On the fallacy of such a mode of argument it is needless, we hope, to insist; but this is almost the only kind of argument which has been used against the hospital. Again, on the question of large and small hospitals, it was contended by Dr. Septimus Gibbon that the latter were preferable to the former, and that small-pox patients were treated more safely at home than in large hospitals. This opinion he founded on a comparison of death-rates, than which no more fallacious test of hospital salubrity could be found. The death-rate of a hospital is influenced unfavourably by a variety of circumstances which have nothing whatever to do with its salubrity; its situation as regards proximity to large manufactories, and consequent liability to the reception of severe accidents; pressure on the resources of the hospital involving the refusal of the minor cases; the extension of a hospital, by means of which minor cases are admitted; the proportion of medical and surgical cases, the mortality of the former, without any regard to sanitary conditions, being always much larger than the latter. It was at one time thought that the Paris hospitals were more unhealthy than the London hospitals, the opinion being founded on a comparison of death-rates. Inquiry showed that the number of beds devoted to surgical cases in the London hospitals exceeded the number devoted to medical cases; whilst in Paris, the exact reverse was the case. When the necessary correction for this was made, the medical mortality of the Paris hospitals was 13.52 per cent.; that of Guy's Hospital, 14.08; and the surgical mortality was at Guy's, 5.33; and at Paris, 5.48. The admission or rejection of infectious cases, phthisis, dead and dying cases; skin, syphilitic, and eye cases; lying-in cases, etc., all exercise an important influence on the death-rate, irrespectively of any sanitary or unsanitary conditions peculiar to hospitals. As Dr. Bristowe and Mr. Holmes say in their Report to Mr. Simon (Privy Council Report, 1863, p. 529), "A high death-rate indicates, as a rule, that a hospital fulfils efficiently the purposes for which it was designed; and that a low death-rate, on the other hand, indicates (*ceteris paribus*) comparative inefficiency."

In reference to the mortality in certain cases of small-pox treated in their own homes, Dr. Gibbon's statistics are not only valueless, but absolutely misleading, unless the state of vaccination and the revaccination, the age and the variety of the disease, be taken into account. As a rule, mild cases of illness are treated at home, and severe cases sent to the hospital.

Objection has been taken to the present site on the ground that the approaches are bad. Now, on the theory that ambulances spread contagion through the streets which they pass, it is obvious that the wider the streets the less the danger to the pedestrians on either pavement, or to carriage passengers on the road or street itself. In this view, the Mill Lane sites are very unsuitable as compared with the present site, inasmuch as the approach to the former is by a narrow lane, scarcely permitting the passage of two carriages freely; whereas the approach to the latter is by an unusually wide road, which will permit the passage of several carriages abreast. If, also, the ambulances spread contagion in the streets through which they pass, the less the number of streets to be passed, of course, the better; but the Hampstead residents, notwithstanding their own theory, desire the ambulances to pass through a greater number of streets.

The medical witnesses for Hampstead, at least the two ablest, Dr. Murchison and Dr. Ford Anderson, admitted that no danger would arise from the *existence* of the hospital, but only from the passage of visitors, nurses, and ambulances. But how, we beg to ask, would this be avoided by placing the hospital at Mill Lane? Visitors, nurses, and ambulances would still pass through Hampstead in going to and from the alternative site; and the ambulances from several of the districts to be benefited by the hospital would pass through a larger portion

of Hampstead in going to and from the alternative site than to and from the present site. Thus the Hampstead residents would, by their own action, increase the danger which they assert they desire to avert. Great danger has been predicted to pedestrians in Haverstock Hill from the existence of the Hospital on the present site; but the Hampstead residents, when they proposed site No. 1, forgot this same danger to the thousands of railway passengers who would have been compelled to pass under the very walls of the hospital; whereas Haverstock Hill is 300 feet from the present hospital.

THE QUARTERLY RETURN OF THE REGISTRAR-GENERAL.

DURING the first three months of the present year, the registered number of persons married in the United Kingdom was 114,258; and the marriage-rate was 14.2 per 1,000 persons living. In England, the rate was 14.3, and slightly exceeded the average. It was so low as 7.1 in Westmoreland, and 7.7 in Cambridgeshire, whereas it was 18.2 in Lancashire, and 18.8 in Northumberland. In Monmouthshire and South Wales, the marriages were 14 per cent. less than the average, one result of the extensive strike and lock-out in the coal and iron trade of the district.

During the quarter that ended on 30th June last, the births of 284,356 children were registered in the United Kingdom; the rate being 34.8 per 1,000. In England, the birth-rate for the quarter was 36.0 per 1,000, which was 0.2 below the average rate in the second quarter of the ten years 1865-74. The experience of the first six months of Compulsory Registration of Births in England (the new Registration Act having come into operation on the 1st January last) shows no appreciable effect upon the birth-rate, although it has been estimated that, during the ten years 1861-70, the average annual number of births that escaped registration was 13,614. Indeed, the births registered in England and Wales during the six months ending 30th June last were actually less by 2,141 than the number returned in the corresponding period of 1874, when the population of the country was undoubtedly less than it now is. The birth-rate during the quarter was but 29.5 and 30.0 in the principally agricultural population of the South-Western and South-Eastern Registration Divisions, whereas it was 39.8 and 43.8 in the manufacturing and mining population of the North-Western and Northern Divisions. In the eighteen large English towns, the rate was 1.3 above the average rate in all England; it ranged from 32.8 in Portsmouth and Norwich, to 43.5 in Sunderland and Oldham, and 45.8 in Salford. In fifty other large towns, the rate was 36.5; in Cheltenham, it was 21.7; and 25.5 in Exeter and Bath; whereas it was 46.8 in Wigan, and 47.2 in Gateshead. The estimate of the present population of Wigan has been revised.

During the three months ending on June 30th, the deaths of 175,689 persons of both sexes were registered in the United Kingdom; and the death-rate was 21.5. In England, 130,797 deaths were recorded, equal to an annual rate of 21.9 per 1,000, which exceeded by 0.5 the average rate in the corresponding quarter of the ten years 1865-74, and was higher than in the spring quarter of any year since 1866. The alternations of temperature during April were unusually severe, and the weather during the greater part of June was unseasonably cold. These meteorological conditions appear to have been especially unfavourable to the health of infants and elderly persons. As the death-rate from the seven principal zymotic diseases was considerably below the average, a large increase of deaths must have occurred in some of the other classes of disease. A complete examination of the causes of death throughout the country is not yet possible, but it may be safely assumed that there was an exceptional fatality from diseases of the respiratory organs. In London, for instance, the deaths during the quarter exceeded the average by 1.1 per cent. only; whereas the deaths referred to diseases of the respiratory organs were 22 per cent. above the average. The death-rate amongst the 13,500,000 persons residing in towns was 22.7 per 1,000; amongst the rural population of 10,000,000 it was 20.8 per 1,000. The urban rate was 0.2 below, whilst the rural rate

was 1.4 above, the average. The decline in the fatality of zymotic diseases favourably affected the urban death-rates, whilst the inclemency of the weather during the spring increased the death-rate of elderly persons, especially in rural populations.

In the eighteen largest English towns, the death-rate was 23.2; and ranged from 17.3 in Portsmouth and 21.2 in Wolverhampton and Sunderland, to 28.1 and 30.3 in Manchester and Oldham. Infant mortality per 1,000 was 111 in Portsmouth, and 137 in Salford and Sheffield; and ranged to 182 in Leicester, and 191 in Norwich. The zymotic death-rate was 1.4 in Portsmouth, and 2.1 in Newcastle-upon-Tyne; and ranged upwards to 4.5 in Norwich and Salford, and 5.8 in Hull. Among fifty other large towns, the lowest rates were 14.6 in Dover, 17.1 in Devonport, and 17.4 in Colchester; the highest rates were 28.3 in Rochdale, 28.5 in Stockport and Wigan, and 28.8 in Preston. The zymotic rate ranged from 0.5 in Dover and Cheltenham to 5.3 and 5.4 in Birkenhead and Wigan respectively.

There were 29,839 deaths of infants under one year of age, equal to a rate of 139 per 1,000; 67,847 deaths of children and adults between 1 and 60 years, giving a rate of 12.7; and 33,111 deaths of persons aged 60 years and upwards, equal to a rate of 74.2 per 1,000. The rates were above the average in the first and last classes; and 3,000 elderly persons died in England and Wales who would have survived had the death-rate amongst persons aged 60 years and upwards not exceeded the average in the five preceding corresponding quarters.

To the seven principal zymotic diseases, 15,419 deaths were referred; 4,063 resulted from scarlet fever, 3,640 from whooping-cough, 2,728 from different forms of fever, 2,463 from diarrhoea, 1,432 from measles, and 348 from small-pox. The zymotic rate was 2.6 against 3.1, the average rate in the five preceding corresponding quarters. Scarlet fever was especially prevalent in the East Riding of Yorkshire; and in Cowbridge, Flint, and Festiniog. Diphtheria prevailed in Sandwich, Hailsham, and Swinefleet near Goole. Whooping-cough was more than ordinarily fatal in London, Norwich, Birmingham, Wigan, Sunderland, and South Shields. Measles was less fatal than usual, but there were several local outbreaks of the disease. The death-rate from fever was lower than in any quarter since the end of 1869. In many counties, no death from small-pox was recorded; 73 deaths were referred to that cause in Birmingham, and 44 in Keighley—in which latter town the outbreak of the disease was remarkable for its intensity among the unvaccinated, and afforded a standing protest against the conduct of the Keighley guardians in refusing to fulfil the provisions of the Compulsory Vaccination Act.

The death-rates of 46 of the principal English watering-places during the quarter are given in this report, and, in the following districts, the zymotic rate exceeded 2 per 1,000; in Eastbourne and Seaford, 10 deaths were referred to whooping cough, 4 to fever; in Blackpool and Fleetwood, 3 deaths were due to diarrhoea, 2 to fever, 2 to scarlet fever, and 2 to whooping cough; in Folkestone, 15 deaths were referred to measles; in Whitby, 11 deaths were caused by whooping-cough, 2 by fever; in Aberystwith, 7 deaths were referred to measles; in Southport, 7 deaths were referred to whooping-cough, 4 to diphtheria, 2 to fever, and 2 to diarrhoea; and, in Llandudno, 2 deaths were referred to whooping-cough, 2 to fever, and 2 to diarrhoea.

The natural increase of population in the United Kingdom, produced by the excess of births over deaths during the quarter, was 108,667; and, in England, that increase was 83,853. The emigrants of British origin who left the United Kingdom during the quarter were 51,178, a smaller number than in any corresponding quarter since 1862.

The temperature during April was remarkably changeable; during May the weather was unusually warm, the mean temperature exceeding the average by 2.2 degs.; the first ten days of June were also warm, but, from the 11th to the 30th day of the month, the mean daily temperature was nearly 3 degs. below the average. The fall of rain during the quarter at Greenwich was 5.4 inches. The price of wheat and potatoes was low; but the price of meat, especially of mutton, showed a marked increase.

THE Library of the Royal Medical and Chirurgical Society was closed on Monday last, the 16th instant, and will be reopened on Thursday, September 16th.

It is stated in the *Pioneer of India*, under the date of Allahabad, July 21st, that "in eighteen or nineteen days, out of seventy-three persons attacked by cholera at Simla, fifty-five have died".

It is intended to form a section of Military Hygiene at the meeting of the Association of German Naturalists and Physicians, to be held in Gratz in September.

PROFESSOR M. J. WEBER, for some time co-director with Max Schultz of the Anatomical Institute in Bonn, died on July 28th, in his eightieth year. He was the author of a well known anatomical atlas.

STAFF SURGEON-MAJOR PORTER, late 97th Regiment, has been elected an Honorary Associate of the Order of St. John of Jerusalem in England, and presented with a cross of the order in recognition of his services in aid of the wounded in war.

THE CHOLERA IN SYRIA.

By latest advices received from Syria, it appears that the number of cases of cholera in Damascus and Antioch are happily on the decrease. At Damascus, from the 20th to the 26th of July, there were 680 cases and 531 deaths; and at Antioch, from the 19th to the 26th, there were 186 cases and 114 deaths. The cholera, it is stated, of the sporadic form, has appeared at Aleppo, where, from the 19th to the 26th July, 39 cases occurred with 20 deaths.

THE SANITARY STATE OF CONSTANTINOPLE.

OUR Constantinople correspondent writes:—Alarm is spreading itself amongst the Christian population of this city; and they are gradually awakening to the fact that we have the dread enemy cholera once more nearly amongst us. It is in vain that sanitary reformation and measures time after time have been suggested to the municipal authorities; but, heedless and apathetic, they have allowed the city and suburbs to remain in the same unsanitary state as ten years ago, when the cholera invaded us, sweeping off the inhabitants by thousands—the death-rate at the time, it will be remembered, was over 2,000 a day. We still have uncovered sewers, pestilential ditches, decomposing animal and vegetable *debris*, insufficient water-supply, etc.

THE FAMINE IN ASIA MINOR.

OUR correspondent in Constantinople writes:—Very unsatisfactory reports still continue to reach us from the famine-stricken districts of Asia Minor, relative to the health of the inhabitants who, it appears, are still suffering most severely, not only from actual want and starvation, but also from disease; the mortality from various causes being terrible. Typhus and bubo plague are endemic throughout the country. The Government are accused of endeavouring to ignore the present state of affairs, the consequence of which has been a fierce ebullition of public feeling both against the Government and their medical representatives, whose reports to the sanitary council lately published, have been most severely censured by the public press. Much has been done by private enterprise to relieve the most urgent wants of the people in the famine districts, about £26,000 having been subscribed for that purpose; but this is now nearly expended, and the demand for relief continues. The Italian Government authorities have ordered quarantine regulations to be enforced upon all vessels arriving at their ports from Syria, Alexandretta included.

OUT-PATIENTS AT LONDON HOSPITALS.

A CONTEMPORARY has recently called attention to the fact, that out-patients are kept waiting for hours at a time when they go to a hospital for advice. With regard to the subject of waiting in out-patient rooms until the honorary staff can get through the cases which present

themselves, we will merely point out, first, that, if a rich man pay a fee and apply to any eminent member of the profession in large practice, he will have to wait his turn, it may be for hours; and, perhaps, even then without success, as we have known instances where private patients who have not made a special appointment have been unsuccessful in their application on more than one occasion, although they could afford and were prepared to pay a liberal fee. Secondly, we very much doubt the wisdom of offering undue facilities to all classes of out-patients who apply for treatment at the London hospitals, by which they will be guaranteed instant attention. These out-patient departments are, under the present system, with all its disadvantages, too much abused in practice; and we cannot, therefore, endorse the hope expressed by our contemporary that steps will be taken to insure immediate attention to all applicants for relief. This subject is far too large an one to be treated piecemeal; and, until the whole system is reorganised, we cannot, in the interests of the poor themselves, support a suggestion which, in practice, will only tend to increase the pauper roll.

THE RIBERI PRIZE.

AT the meeting of the Royal Academy of Turin on August 6th, the Riberi prize of 20,000 *lire* (£800) was awarded to Professor Schiff of Florence, for his work entitled *Contributions to the Pathological Physiology of the Spinal Cord*. This is the fourth occasion on which the prize (a triennial one) has been awarded.

THE JOHN HUNTER MEMORIAL.

FOUR years ago, a proposal was made to commemorate John Hunter's long residence in Kensington, where for thirty years he carried on those labours which have immortalised his name, by placing a window in memory of him in the parish church; and a subscription was opened for the purpose of raising the necessary funds. The carrying out of the proposal has been delayed in consequence of the church being encumbered with a heavy debt, and of other local circumstances; but we learn with pleasure from a circular recently issued by the honorary secretaries, Mr. Frank Buckland of 4, Old Palace Yard, and Mr. John J. Merriman of 45, Kensington Square, that all difficulties have been removed, and that they propose to complete the subscription list by October 31st, so that the window may be in position, if possible, by February 14th of next year. The amount already subscribed is £80; and further subscriptions (limited to one guinea each) are solicited. A list of donors will be published after October 31st; and a drawing of John Hunter's house and grounds will be forwarded to each subscriber.

THE GREAT NORTHERN HOSPITAL.

THE Great Northern Hospital deserves credit for the manner in which it has dealt with the question of out-patient abuse. If other institutions, which, by reason of their position and their wealth, might have been expected to lead the way in this matter, had shown the same zeal, the difficulties connected with out-patient relief might by this time have been solved. The following extract from the recently published Report of the Great Northern Hospital shows the beneficial results which have flowed from a systematic inquiry into the circumstances of all applicants for out-patients' treatment.

"The Registrar of Out-patients commenced his duties on the reopening of the department (on October 19th, 1874). As mentioned in last year's Report, this officer was appointed to endeavour to check the abuse of out-patients' relief by a careful and yet liberal inquiry into the circumstances and position of applicants. The return of out-patients relieved for the past year is for eight months, in respect to physicians' and surgeons' patients, against six months for the year ending 30th June, 1874; the return for the other departments being for twelve months in respect to both years. From this return, it will be perceived that the system of registration has not by any means checked the stream of applicants, although it is believed that it has deterred people who are able to pay for medical relief from seeking gratuitous aid. The Registrar has visited the homes of 863 patients, and has found that only 37 have given wrong addresses. Such persons have not been readmitted. Further, 140 applicants, whose circum-

stances did not warrant their being admitted to the benefits of the charity have been referred to the local dispensaries. Taking, therefore, into consideration the result of the working of the department for the last eight months, the Committee are, on the whole, satisfied that the knowledge that the circumstances of the applicants will be inquired into and their homes visited has had a deterrent effect on imposture, and they believe that the abuse of out-patients' relief has been materially checked thereby."

We observe with pleasure that it is proposed to rebuild and enlarge the hospital. The extension of an institution which is conducted on such sound principles cannot fail to be a boon to the crowded neighbourhood in which it is situated.

THE DEAF AND DUMB IN AUSTRIA.

ACCORDING to the *Wiener Medizinische Presse*, the proportions of deaf and dumb persons per 10,000 inhabitants in the Austrian provinces are as follows: in Salzburg, 21.4; in Styria, 17.9; in Upper Austria, 10.9; in Silesia, 10.4; in the Bukowina, 9.5; in Moravia, 8; in Galicia, 6.9; in the Tyrol, 6.3; in Vorarlberg, 4.2. A large number are not in any public institution. Cretinism in many instances runs nearly parallel with deaf-dumbness, the proportion of cretins per 10,000 being: in Salzburg, 38.9; in Upper Austria, 18.3; in Styria, 16.9; in Silesia, 9.2; in the Tyrol, 7.6; in the Bukowina, 4.2; in Vorarlberg, 2.4; in Moravia, 2.2; in Galicia, 1.9.

EXCISION OF THE LARYNX.

THE operation of excision of the larynx has been lately performed in Berlin by Professor von Langenbeck. The patient was a man aged 57, who came into hospital on November 29th, 1874, suffering from symptoms of laryngeal obstruction and irritation, for the relief of which tracheotomy was performed the next day. Laryngoscopic examination showed much cedematous swelling of the epiglottis and aryepiglottic ligaments; and there was enlargement of the inframaxillary lymphatic glands on the right side. Extirpation of the larynx was recommended, but refused; and the patient left the hospital in January. On July 14th, he returned. Respiration had been carried on through a trachea-tube; but the spread of the disease had impeded deglutition to such an extent that he could only swallow fluids. On July 21st, extirpation of the larynx was performed, Trendelenburg's apparatus being applied to the trachea, and chloroform administered through it. A transverse incision was made above the hyoid bone, and a perpendicular one carried down from it; and the two flaps of skin having been turned aside, the diseased parts were removed. The specimen was shown by Dr. von Langenbeck at a meeting of the Berlin Medical Society. The anterior wall of the oesophagus and pharynx was divided, the larynx cut away, and the hyoid bone sawn through in the middle. The disease, which was cancerous, had involved the upper part of the larynx, the epiglottis, and the hyoid bone, to such an extent that it was difficult to distinguish the several parts. The inner surface of the cricoid and thyroid cartilages as far as the laryngeal pouches, and the inferior vocal cords, were free. The disease commenced close above the ventricles of the larynx, in the form of nodular masses which completely filled the upper part of the organ. The arytenoid cartilages and the aryepiglottic ligaments, the hyoid bone, and the base of the tongue, were all involved in the disease, and were removed. On July 28th, a week after the operation, the patient was free from fever, and his general condition was satisfactory. A solution of salicylic acid was used as an antiseptic.

THE GERMAN SANITARY CONGRESS.

THE following subjects will be discussed at the third meeting of the German Sanitary Association, to be held at Munich on September 13th, 14th, and 15th. 1. The determination of a plan for the investigation of the occurrence, as to place and time, of epidemics of typhus: reporter, Professor von Pettenkofer (Munich); co-reporter, Staff-Surgeon Dr. Port (Munich). 2. Hygienic requirements of new buildings, especially in the new quarters of large towns: reporter, Dr. Varentzapp (Frankfort); co-reporter, Engineer Bürkli-Ziegler (Zürich). 3.

The demands of public health in relation to food, in orphan-asylums, barracks, prisons, and almshouses for old persons, and also in public kitchens: reporter, Professor Voit (Munich). 4. The aims, means, and limits of sanitary police control over certain important articles of food, especially bread and meat: reporter, Dr. Heusner (Barmen). 5. Public slaughter-houses, and the introduction of a general regulation of the slaughtering of animals; also the compulsory examination of meat, with special reference to the obligation of the district authorities to recompense the butchers: reporter, Herr Gobbin (Görlitz); co-reporter, Dr. P. Börner (Berlin). 6. The formation of a general registration of deaths in Germany, with, if possible, medical certificates of the causes of death.

RECENT URBAN MORTALITY.

DURING last week, 5,382 births and 3,551 deaths were registered in London and twenty other large towns of the United Kingdom. The average annual death-rate was 24 per 1,000 persons living. In Norwich, it was 17; Edinburgh, Dublin, Sunderland, and Portsmouth, 18; Wolverhampton, 19; Bradford and London, 22; Oldham, 23; Sheffield and Manchester, 24; Liverpool and Bristol, 25; Glasgow, 26; Birmingham, 27; Leeds, 28; Hull, 31; Nottingham, 32; Salford, 33; Newcastle-upon-Tyne, 36; and Leicester, 40. The annual zymotic death-rate averaged 6.5 in the eighteen English towns, and ranged from 1.3 and 1.8 in Norwich and Oldham to 10.4 in both Birmingham and Salford, and 18.5 in Leicester. The fatality from diarrhoea equalled a rate of 3.7. No death from the disease was registered in Norwich; but the rate in the other towns ranged upwards to 7.8 in Birmingham and 14.7 in Leicester. The fatal cases of scarlet fever showed an excess in Bristol, and those of fever in Sheffield. In London, 2,395 births and 1,483 deaths were registered; the former were 128 above, the latter 210 below, the average. The annual death-rate was 22.5. Amongst the deaths were 1 from small-pox, 36 from measles, 87 from scarlet fever, 7 from diphtheria, 50 from whooping-cough, 22 from fever, and 147 from diarrhoea; in all, 350 deaths, which were 160 below the average. The 147 deaths from diarrhoea were 178 below the corrected average; 75 per cent. were the deaths of infants under one year of age. In greater London, 2,872 births and 1,738 deaths were registered, equal to annual rates of 35.6 and 21.6 per 1,000. In outer London, the general and zymotic death-rate were 17.5 and 2.9 respectively, against 22.5 and 5.2 in inner London. The mean reading of the barometer at Greenwich was 29.74 inches. The mean temperature of the air was 65.2 deg., or 3.1 deg. above the average; and there was an excess on each day of the week. The mean degree of humidity of the air was 84; the general direction of the wind was S.W.; and the horizontal movement of the air averaged 10.3 miles per hour. Rain fell on five days, to the amount of .21 of an inch.

PROMOTION, ETC., OF ARMY MEDICAL OFFICERS.—The promotion to the rank of Surgeon-Major of Surgeon C. H. Y. Godwin, which appeared in the *Gazette* of July 6th, 1875, is to be dated May 14th, instead of April 25th, as therein stated.—Surgeon F. Gillespie, M.D., to be Surgeon-Major, *vice* H. Titterton, M.D., retired upon temporary half-pay.—Surgeon-Major A. E. T. Longhurst, M.D., retires upon temporary half-pay.—Surgeon C. H. Swayne is transferred temporarily to the half-pay list, without half-pay.—Surgeon-Major West has been removed from the 2nd Battalion 11th Regiment to the 58th Brigade Depot.

INSPECTOR-GENERAL H. FRANKLIN, C.B., on the half-pay list, died at Folkestone on August 2nd, aged 82. He joined the Service as hospital mate August 13th, 1808; was promoted assistant-surgeon June 29th, 1809; surgeon, May 26th, 1814; surgeon-major, November 19th, 1830; deputy inspector-general, January 14th, 1842; inspector-general, June 25th, 1847; and retired upon half-pay November 29th, 1850. He served in the Peninsula from September 1808 to the end of that war, in 1814, including the battles of Vittoria, Pampeluna, Pyrenees, Nivelle, Orthes, and Toulouse, and siege of Badajoz (medal with six clasps). He served also in the American war, including the battle of Plattsburg. He served in India from April 1842 to June 1850, and was present at the battles of Chillianwallah and Goojerat, in the Punjab campaign (medal with two clasps and C.B.).

DR. HUGHES BENNETT.

At the presentation of the bust of Dr. Hughes Bennett to the University of Edinburgh on August 3rd, Dr. Andrew Clark of London spoke in the following terms, on behalf of the subscribers.

When some time ago it became known that Dr. Hughes Bennett had been compelled, unhappily by failing health, to resign his chair in this University, there arose in the minds of some of the pupils and friends a desire that the important work which he had done in this place should in this place find some abiding record and acknowledgment. Accordingly, it was agreed to offer a bust of Dr. Bennett to the University; and the University having graciously accepted the offer, I am here to-day to make formal presentation of our offering. Had this duty fallen into the hands of some one of higher rank and of greater eminence, the ceremony of presentation would have been invested with greater importance. Nevertheless, what it has lost in importance it has gained in fitness. I was once his pupil, and for a long time his assistant, in the pathological department of the Royal Infirmary. From him I got not only knowledge, but the love of work. He laughed me out of youthful conceits, provoked me into perseverance, and drilled me into habits of exact observation. To the habits of thought and work begotten and established under the influence of Dr. Bennett's teaching and example, I owe in great part such success as I have had in life, and I rejoice in this opportunity of making grateful acknowledgment of what I owe him. And now, in this place, where Dr. Bennett has dwelt for over thirty years, and where his history may be supposed to need no recapitulation, I might here bring my task of presentation to an end. But we may be too familiar with a man to know what he really is; we may be too close to his work to see it quite distinctly; and as this is an occasion when Dr. Bennett's work may be justly brought to mind by one sufficiently far removed from the sphere of it to see it undisturbed, I trust you will bear with me whilst, in a few plain words, I strive to set forth some of Dr. Bennett's claims to a place of lasting honour in this University and in the history of his art. It is no abuse of language to say that Dr. Bennett was a great teacher. Earnest, exact, methodical, practical, he had the power of communicating to others his love of work and his methods of working. Probably, he has made more original inquirers and given a greater impetus to exactness of inquiry in pathological histology than any other medical teacher in the empire. The cardinal points of his teaching, the points upon which he was never weary of dwelling, were minute care in observation and literal exactness in recording the results of it. He would never allow hypothetical assumptions to mingle with actual descriptions. He was not content to tell students how a thing was to be done; he made them do it. Loving knowledge for its own sake, and unceasing in his condemnation of an unreasoned empiricism, he nevertheless kept before the minds of his pupils the great fact that the end of all their studies was the acquirement of an art: the art of preventing disease, and of relieving human suffering. To Dr. Bennett we owe in this country the introduction of the use of the microscope in diagnosis; of the experimental methods of teaching normal and pathological histology, physiology, and pathology; and of great improvements in the manner of communicating clinical instruction. One who has thus taught for over thirty years must have taught for some purpose in his time, and I am well assured that among practitioners, professors, and investigators throughout this kingdom and its dependencies, the influence of Dr. Bennett's teaching and the example of his industry and boldness, are happily and fruitfully at work. But Dr. Bennett is still more than a great teacher. As a pathologist and as a physician, he has made his mark upon the theories and the practice of these days. For the last quarter of a century there have been few additions to our knowledge and few improvements in our art in which he has not taken some share. He is, indeed, the father of pathological histology in this country, and has managed to steer a middle and, as I think, a just course, between the extravagant extremes of Rokitsansky and of Virchow. By his studies of inflammation as a process of abnormal nutrition, he opened new paths of inquiry, and started trains of thought leading to discoveries of which as yet we cannot discern the end. He has shown that disease is not a new or a foreign thing, but a series of altered states; that the laws which regulate the evolution of normal products are the very same laws which, in different conditions, regulate the evolution of morbid products; that between physiology and pathology there is an unbroken continuity; and that, for all the purposes of our art and its progress, both are to be treated after the same fashion. Although Dr. Bennett's views of cancer have not been generally adopted, it cannot be doubted that his work on *Cancer and Canceroid Growths* was in

advance of the knowledge of the time, and that his hypothesis of the local origin of canceroid tumours, illustrated with much ingenuity and argued with great earnestness, was a substantial and fruitful addition to our stock of pathological ideas. By his discovery of the facts of the leucocythemic condition, and by the interpretation which at first he put upon them, he has brought to light the existence of a series of allied states of equal interest and importance. By his practical illustrations of the natural history of disease, he has given us in some instances a true criterion of the value of remedies; whilst, by his implacable opposition to indiscriminate bleeding and the use of other depressing agents in the treatment of inflammations, by his introduction into practice of cod-liver oil, and by his advocacy of restorative methods of treatment, he has sensibly prolonged the life of the consumptive, and diminished the mortality of many acute and chronic diseases. And we are indebted to Dr. Bennett not only for what he has done, but for what he has forborne from doing. He has made no sacrifices at the shrine of popularity for the sake of the favours which she might grant him. He has not degraded the exercise of his profession into a mere matter of money-making; and, looking back along the thirty years of his public life, I can see nothing but unswerving loyalty to the dignity of his art and the welfare of his brethren therein. Thus much have I said in words, I trust, of truth and soberness. But Dr. Bennett's enemies (and he is of doubtful honesty who has none) may allege that there is another side to the subject of my speaking. I am not blind to the fact, and I know that an indiscriminating eulogy would be unworthy of the place, the occasion, and the man. Too outspoken to be widely popular; too unsparing in his chastisement of faults from which he is himself free, to escape the resentment of those who suffer; too slow to recognise the virtue which sometimes lies even in antagonism, and too prone to see personal animosities in public opposition—I do not claim for Dr. Bennett an exemption from frailties and faults from which no human excellence is wholly privileged. But when all is said, and the worst is said, I am convinced that many a capping day will come and go, and many a physician and professor will have here his day and die, ere one shall appear amongst them worthier on all grounds of worthiness than Dr. Bennett is worthy of the place of honour which I now claim for him at your hands.

REPORT OF THE COMMITTEE OF COUNCIL UPON THE SUBJECT OF STATE MEDICINE QUALIFICATION.

1. It is desirable that every person holding any public appointment connected with medical attendance upon the poor should have a fair knowledge of the principles of Public Hygiene.
2. It is also desirable that every medical man should be competent (as proved by examination) to fill any such office, and that every candidate for admission into the medical profession should, therefore, have a fair knowledge of the principles of Public Hygiene.
3. It is desirable that every person holding the office of Medical Officer of Health should have passed through the ordinary curriculum of medical education, and should be possessed of such medical qualification as shall entitle him to registration in the *Medical Register*.
4. It is desirable that every corporation duly entitled to grant such qualifications as shall confer the legal right to registration in the *Medical Register*, should be further entitled to grant a special qualification in State Medicine also.
5. This qualification should include an adequate knowledge both of *Legal Medicine*, or *Medical Jurisprudence*, and of *Preventive Medicine*, or *Public Hygiene*, comprehending *Medical Police* and the management of medical institutions supported by national or local taxation.
6. Every one holding this qualification should be entitled to register it as an additional qualification (see *Medical Act, 1858*).
7. The General Medical Council should be empowered and required to prepare a scheme for the examination in State Medicine to be carried out by all licensing bodies. The scheme to specify: *a.* The number, qualifications, duration in office, duties and remuneration, of the examiners; *b.* The subjects of examination; *c.* The nature and methods of examination; *d.* The form of special diploma or special certificate to be granted by any Board of qualified examiners; *e.* The fees to be paid, if any, by candidates for examination; *f.* The places and times for holding the examination.
8. Each licensing body should be empowered to grant the diploma in State Medicine to qualified medical men now holding office of a certain standing, and to medical officers of the army and navy, after a practical *vis à voce* examination.
9. Until January 1st, 1880, matters should be permitted to remain *in statu quo*; and that after January 1st, 1880, no medical officer duly

appointed before that time shall be disturbed in his office or appointment in consequence of not holding such special diploma or certificate.

10. After a given time—say the first day of January 1880—no candidate for any appointment as Medical Officer of Health should be eligible for election unless he is able to produce a special diploma from some of the recognised authorities of having passed an examination in State Medicine, in addition to his diploma entitling him to practise medicine generally, and to be enrolled in the *Medical Register*.

THE RECENT CHARGE OF MANSLAUGHTER AT BOSTON.

THE following is Dr. G. M. Lowe's account of the *post mortem* examination in the case of Mary Elizabeth Wright, for the manslaughter of whom Mr. Wood of Boston was recently tried, as reported in the *JOURNAL* of July 31st.

On the 9th day of April, 1875, at the house of — Wright in Skirbeck Quarter, Boston, at 8.50 A.M., I made a *post mortem* examination of the body of Mary Elizabeth Wright, aged 32 years, who was confined (as I am informed) on April 6th, 1875, and died shortly afterwards. This examination was made in the presence of Dr. Morris of Spalding, at the desire of the medical attendant on the deceased, Mr. Wood of Boston. The body was well developed; the rigor mortis was strongly marked; the perinæum was uninjured; the cellular tissue of the thighs and abdomen was crepitant with air. On opening the thorax, the several organs within its cavity were perfectly healthy. The liver was pale, and rather large; the stomach and bowels were somewhat distended with flatus. Upon removing the contents of the abdominal cavity, the cellular tissue covering its posterior part and lying under the peritoneum, were distended with air, and crepitant on pressure. There was an effusion of blood in the cellular tissue under the peritoneum, on the left side, corresponding to the brim of the pelvis, both posteriorly and anteriorly; and there was also a slight effusion of blood on the right side within the pelvic cavity. The general surface of the uterus was pale, its substance flabby and uncontracted; in the neighbourhood of the right Fallopian tube, there was effusion of blood; blood was also effused under the peritoneal fold surrounding the right Fallopian tube and broad ligament generally; right ovary healthy. The left broad ligament was in a similar condition; but there was more extensive effusion of blood; left ovary healthy. The cellular tissue in the posterior part of the cavity of the pelvis was also infiltrated with blood. The uterus, with all its attachments, together with the bladder and rectum, with their peritoneal coverings, were then carefully removed. The uterus and vagina were then carefully laid open along their entire length. There was a slit through the utero-vaginal walls, extending three inches in length, commencing about one inch above the neck of the uterus, extending through it down the vagina, on the left side, and corresponding with the position of the effusion of blood in the pelvis previously described. The length of the uterus from cervix to fundus was nine inches. The internal surface of the uterus was pale, but healthy; its cavity was empty; and the placental attachment had been evidently in the neighbourhood of the right Fallopian opening. The uterus, with its parts, was then replaced in the body. The stomach was examined; its mucous surface was pale, and contained about two ounces of fluid; it presented no remarkable appearance, and was replaced with its contents within the body. The rest of the abdominal organs were pale, but healthy. I have no hesitation in stating that the rupture of the uterus was the immediate cause of death.

ASSOCIATION INTELLIGENCE.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT.

A SPECIAL meeting of the members of the district will be held in the Library of the County Hospital, Canterbury, at 3.30 P.M., on Thursday, September 2nd, "To further develop and carry out the details for the formation of an Ethical Committee, which was agreed to at the last meeting of the district, and which was then adjourned to a future meeting."

EDWARD WHITFIELD THURSTON, *Honorary Secretary*,
Ashford, August 17th, 1875.

WEST SOMERSET BRANCH: ANNUAL MEETING.

THE thirty-second annual meeting of this Branch was held at the Railway Hotel, Taunton, on Thursday, July 22nd, at 2.30 P.M. Fourteen members and two visitors attended. The retiring President, Mr. RAN-

DOLPH, shortly addressed the meeting, and then resigned the chair to Dr. CORDWENT, the President for the ensuing year.

Report of Council and Treasurer's Accounts.—The following report of Council was read by the secretary. The treasurer's accounts and balance-sheet, which had been examined by Dr. Meredith and found correct, were taken as read.

"1. Your Council have pleasure in reporting to the members of the West Somerset Branch, on this its thirty-second anniversary, that during the past year the work of the Branch has gone on in a most satisfactory manner. The meetings have been well attended, and the business carried on with much vigour and spirit.

"2. The year having been inaugurated at Milverton with the most agreeable of associations, under the presidency of Mr. Randolph, it will be recollected that important resolutions relative to Club practice were then passed (and which, it may be hoped, will in time be not unproductive of beneficial results, although none have as yet been observed). The interesting communications from the President, and the scientific paper of Mr. Parsons on Addison's Disease, will be fresh in the recollection of those who had the good fortune to be present on that occasion.

"3. At the autumnal and spring meetings, besides excellent papers on What is a Tonic? by Dr. Cordwent, and the Causation of Typhoid Fever, by Dr. H. J. Alford, the questions of the Treatment of Whooping-cough, and How best to deal with Habitual Drunkards?—led to spirited discussions; on the latter question, the following resolution was passed:

"That this meeting is of opinion that the legislature should be petitioned to enact some measure for dealing with habitual drunkards, and placing them under proper restraint."

"4. With a view to carrying into effect this resolution, your Council herewith submits a form of petition which is recommended by the Council for the adoption of this meeting.

"5. A communication having been received by Dr. Kelly from the General Secretary, asking that the list of representatives of the Branch in the Council for 1875-6 should be forwarded to him before June 10th, the subject was considered at a meeting of your Council on June 3rd, when the following resolution was passed; viz.:

"Resolved that the secretary be requested to send up the names of H. W. Randolph, Esq., and Dr. George Cordwent, and that this action of the Council be submitted to the next general meeting of the Branch for confirmation."

"6. The treasurer's accounts will be presented in their usual form, and it will be satisfactory to see that he holds a balance of £6 5s. in favour of the Branch.

"7. The number of members in the Branch is now fifty-two. Three new names have been added to the list during the past year; but, on the other hand, the loss of several who have either left the neighbourhood or withdrawn from other causes is to be regretted.

"8. Ten years ago, it was matter of congratulation that the number of members in the Branch had reached to thirty. While there is thus cause for rejoicing in the favourable view of the present strength of the Branch as contrasted with what it was in 1865, members should not fail to recollect that there are still a large number of their brethren who reside within the district who do not belong to the Association.

"The Council urges upon every member of the Branch to bear this in mind, and take action upon it during the ensuing year. If this be done at the next annual meeting, there ought to be found a good accession of strength to the Association, and more especially to its West Somerset Branch.

After discussion, it was resolved that the report of Council, together with the treasurer's accounts and balance-sheet, be received and adopted.

Representatives of the Branch in the General Council of the Association.—It was resolved that the President, George Cordwent, M.D., and H. W. Randolph, Esq., be the representatives of the Branch in the General Council for the ensuing year.

Honorary Secretary and Treasurer.—W. M. Kelly, M.D., was re-elected honorary secretary and treasurer.

Place of Meeting for 1876, and President-elect.—It was resolved that the annual meeting in 1876 be held at Bridgwater, and that Frederick Farmer, Esq., be President-elect.

Intermediate Meetings.—It was resolved that intermediate meetings should be held as usual during the ensuing year, about Michaelmas and Lady Day, at the discretion of the Council; and that such meetings take place at the Railway Hotel, Taunton.

Members of Council of the Branch.—It was resolved that the following, with the President, Past-President, President-elect, and Honorary Secretary be the Council of the Branch for the ensuing year:—H.

Alford, Esq.; W. Liddon, M.B.; John Meredith, M.D.; J. Pranker, Esq.; F. J. C. Parsons, Esq.; and W. L. Winterbotham, M.B.

Petition re Habitual Drunkards.—The petition, as recommended in the report of Council for adoption, was read by the secretary. It followed the form which had been issued by the Birmingham and Midland Counties Branch. It was resolved that the form now submitted be approved and adopted; that Mr. Randolph be requested to take charge of it and obtain the signature of members, and in due course, at his own discretion, have it presented to Parliament.

Cases and Papers.—The following were read.

A Case of Supposed Poisoning by Hemlock. By THOMAS CLARK, L.R.C.P. Ed., Dunster.—The poison was supposed to have been eaten by a cow, and two children were affected with the symptoms of narcotic poisoning after taking the cow's milk.

A Medico-legal Case. By J. MEREDITH, M.D.—The question was as to the cause of death in an infant aged 11 weeks, who, being under the effects of vaccination which had been performed eight days previously, was taken into the open air on a particularly cold day in December, and died suddenly while being held at the mother's breast. At the coroner's inquest, a verdict was returned that death had been caused by the intensity of the cold; but, after hearing details of the case as related by Dr. Meredith, the more general opinion of the meeting was, that the probable cause of death was suffocation.

A Case of Psoas Abscess. By J. MEREDITH, M.D.—The interesting details of this case were given with great minuteness. The leading points were: 1. Acute inflammatory symptoms; 2. A hard swelling in the right groin; 3. Matter pointing in the lumbar region; 4. Expectoration of matter from right lung and subsidence of the lumbar swelling; 5. The abscess extending below Poupart's ligament, and opened antiseptically at the outer margin of Scarpa's triangle; 6. Complete recovery.

Discussion followed the reading of all the above cases, and votes of thanks were passed to their authors.

Vital Conservancy in Disease.—The President, Dr. Cordwint, read a paper on Vital Conservancy in Disease. A vote of thanks to him for it was passed by acclamation.

Dinner.—An excellent dinner was served at a quarter past 5 o'clock, after which the usual toasts were given and responded to.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MAY 28TH, 1875.

SIR WILLIAM JENNER, Bart., M.D., D.C.L., F.R.S., President, in the Chair.

Hypertrophy of the Lower Parts of the Face.—Mr. BARWELL exhibited the patient, whose case he had narrated at the meeting of the Society on March 12th last. (The case was reported in the BRITISH MEDICAL JOURNAL of March 20th, p. 394.) On March 13th, Mr. Barwell placed a ligature around both facial arteries just below the wind on to the surface of the lower jaw; not only simply ligaturing the vessel, but dividing it and tying it above and below the point of division. The operation was followed by a severe attack of erysipelas, from which, however, the patient made a good recovery. The proceeding was attended for a time by a diminution in the hypertrophy; during the last month, however, which the man had passed in the country, the swelling had again increased, and his state was now much the same as before the operation. It was noted that there was much greater pulsation on the right side than on the left, the collateral circulation being more freely established, but this did not appear to have had any influence on the growth. The patient refused any further operative interference at present.

In reply to Mr. Hulke, Mr. BARWELL stated that both facial arteries were ligatured simultaneously.—The PRESIDENT considered that a slight diminution in the size of the lips had taken place; but, as there was distinct pulsation on the right side, it was clear that the hypertrophied tissues still received a considerable supply of blood.—Mr. BARWELL stated that the lips had increased slightly since the patient quitted the hospital. Within a week after the operation, slight pulsation was felt on the right side. The facial artery was certainly tied, and there was no second facial artery; but it was impossible to deal operatively with the collateral circulation. If any further treatment were to be adopted, he thought a small portion of mucous membrane might be excised; but the patient would not now consent to any such procedure.

Double Fistula in Ano: one treated by the Knife, the other by Elastic Ligature.—Mr. MAUNDER read notes of this case. The patient, a female, aged 24, had suffered from fistula in ano for some time; one

fistula on the right side having made its appearance two years ago; another on the left side twelve months previously to her coming under observation. These two fistulae were equidistant from the anus, and extended to about the same depth where they communicated with the bowel. The one on the right side was divided by the knife, and the elastic ligature was applied to the one on the left. The knife-wound was dressed with a strip of oiled lint, and no application was made to the other. For two or three days after the operation, the patient complained of severe pain, and this was especially referred to the left side. On the sixth day, the ends of the ligature were found lying in a deep groove, which they appeared to have cut in the tissues; and, on the ninth day, the ligature came away. On the twelfth day, the wound made by the knife was almost on a level with the surrounding parts, while that which was the result of the ligature was a deep groove, having very prominent callous edges like the margins of a chronic ulcer of the leg. On the twenty-second day, the knife-wound was completely cicatrised, but that made by the ligature was only partially healed, and still grooved. Five weeks after the operation, it was found that the groove left by the ligature was converted into a sinus, the edges having united; it was, therefore, again united, and complete union took place in about a fortnight, five weeks after the wound made by the knife had closed. Mr. MAUNDER remarked that, as a rule, it would be wrong to endeavour to establish a principle of practice from the experience of a single case, but the test of the efficiency of a method of treatment was absolutely trustworthy when two different operations were performed simultaneously upon the same patient, who was the subject of a similar complaint in corresponding localities. Under these circumstances, the history of the above case would induce him to declare in favour of the knife as a means of causing less pain and quicker restoration to health. The elastic ligature might be reserved for those who would on no terms submit to a cutting operation, as well as for those of hæmorrhagic diathesis.

Mr. HEATH thought there were cases of fistula seated high up, where, to obviate hæmorrhage, it would be more prudent to use the elastic ligature or similar means. The knife, however, was preferable in the vast majority of cases. He would never employ the elastic ligature for the removal of tumours, the experience of the first case in which the treatment was carried out in this country (that of Sir II. Thompson) being by no means encouraging.—Mr. HUTCHINSON understood Mr. MAUNDER to admit that there were exceptional cases where the ligature might be employed, but none where it could compete with the knife. He had seen but little of its use, but could confirm Mr. MAUNDER's statement as to the slowness of healing that followed its use.—Mr. HULKE had not used the ligature himself, but had seen it employed in three cases; and the extreme painfulness and slow progress made in each case had convinced him of the inferiority of the method.—Mr. THOMAS SMITH said that he had tried the elastic ligature on two occasions, the result being, that he would never resort to it again, unless prevented for very good reasons from using the knife.

Arterio-venous Aneurism in the Thigh caused by a Pistol-shot.—Mr. HULKE read notes of this case. The patient, a coach-builder, aged 44, was admitted into the Middlesex Hospital, complaining of great pain and weakness in the right lower extremity. The whole limb was swollen, its cutaneous veins were dilated, the leg was eczematous, and there was a small, very painful, superficial ulcer on the shin. He stated that, three years before, when in Missouri, a smooth-bore pistol exploded as he was putting it into his right trousers' pocket; he fell; and, from the sharp pain he felt in the knee, he thought that the ball had lodged in it. However, in a few moments, he was able to get up and stand. On stripping off his trousers, he found an entrance-wound below the right hip, but none of exit; and, an hour after the accident, he discovered the bullet under the skin, at the inner side of the thigh, whence a doctor cut it out. Its spherical shape was unaltered. The loss of blood from both wounds did not exceed a wineglassful; and more, he said, came from the cut made for the extraction of the bullet, than from the entrance-wound. In a couple of days, both wounds had closed. He went out the next morning after the accident; and, except on the first day, he did not strictly keep his bed, but, for about one month, he hobbled out with a stick or crutch, and then resumed his work. Two nights after the accident, when the wound had already closed, he was kept awake by pain in the thigh, and he then became aware of an unusual throbbing in it. This, his doctor said, was of no moment; he was to lie still till it stopped, which, however, had not yet happened. The limb grew weak and painful; and, at the end of a year, it often gave way under him in walking, making him stumble. His statement was borne out by the presence of a small scar (that of the entrance-wound) five inches vertically below the crista ili, and four and a half inches from the anterior superior iliac spine, level with the upper border of the great trochanter, and of a rather smaller linear scar, where

the ball was cut out, on the inner side of the thigh, seven and a half inches below the spine of the pubes. A line joining these two scars cut the axis of the thigh obliquely, and it crossed the course of the large femoral vessels at a point where the femoral vein usually passed from the inner side to behind the superficial femoral artery. From this spot upwards, the femoral artery and vein were greatly dilated; the vein was much more swollen than the artery, and it was most so under cover of the sartorius muscle, where the course of the bullet crossed it. At this spot, there was a very considerable sinuous bulging of the skin, which closely simulated an aneurismal pouch. The vein, in its whole extent, pulsated synchronously with the femoral artery, and, throughout its entire course, a loud rough murmur was audible. It was a continuous, rough, blowing sound, with a rhythmical swell, synchronous with the pulse in the artery. A strong purring vibration was felt along the course of the vein. The dilatation murmur and the palpable vibration were observable from the ham upwards to above the groin, as far as the external iliac vessels were accessible. Below the level of the lower sac, their intensity quickly diminished. All the cutaneous veins were unnaturally conspicuous. The pulse at the ankle was weaker than on the other side. Pressure on the femoral artery in the groin was immediately followed by a diminution of both vein and artery, and by the instantaneous cessation of the pulsation, murmur, and thrill. These symptoms left no room to doubt that a communication existed between the superficial femoral artery and its attendant vein, and their greatest intensity at a spot nearly opposite the lower of the two scars, indicated this to be the situation of the inoculation. For several weeks, careful pressure was made by using a Carté's compressor at the groin, alternately with a Skey's tourniquet put on a few inches below. For several days, also, direct compression upon the spot of inoculation was combined. These measures altogether failed to produce any permanent effect; and, notwithstanding every care in applying it, the pressure induced a slight attack of eczema in the groin, which overran the scrotum and penis, and provoked a slight lymphadenitis. The patient had now become weary of this treatment; but as his general health was deteriorated, he was sent into the country. He was not seen again for three months, when his leg was found to be more swollen, but there was no appreciable difference observable in the state of the femoral vessels. He remained in hospital six weeks, and again direct pressure, alone, and combined with pressure on the cardiac side of the inoculation, was tried, with perfectly negative results. He was then supplied with an elastic stocking reaching from foot to groin, and the uniform and efficient pressure of this was followed by the best results, enabling him to follow his occupation with but little inconvenience. There was no alteration in the condition of the aneurismal varix, but the circulation in the leg and the nutrition of the tissues had become manifestly better. Sphygmographic tracings, which were exhibited, showed the vibratile jarring character of the pulsation in the varix.

Mr. HEATH was not surprised to hear that pressure had not been beneficial. He related particulars of the case of a lady who, after striking her leg, had subsequently an apparent arterio-venous aneurism, formed by a communication occurring between the anterior tibial artery and an accompanying vein. In that case, pressure was tried without effect; and authors generally seemed to have had the same experience. An elastic stocking was then ordered. The patient had some trouble during a subsequent pregnancy, but was now well.—The PRESIDENT inquired if the colour of the limb were altered.—Mr. HULKE replied that the skin was a little bluish when the bandage was off. One interesting circumstance connected with these cases was, that not merely the vein but the artery also dilated. Roux published several cases of arterio-venous aneurism following venesection, in some of which the symptoms of aneurism did not appear for several years; in one case, six years. In all these cases, the artery was enlarged up to the trunk; and the radial and ulnar arteries were also largely dilated. He thought the phenomenon was due to the fact that the arterial met the venous current, and consequently could not advance so readily as in the normal condition.—Dr. POWELL thought the arterial enlargement due to the fact that the vessel had been wounded and inflamed, and then had gradually given way.—Mr. HULKE remarked, however, that the whole length of the artery was enlarged, not only the part injured.—Mr. PICK said that these cases usually occurred from accident, sometimes from ulceration. He alluded to the case of a girl, aged 13, in whom the veins of one leg were enormously dilated. Soon after birth, the veins of one limb were seen to be much larger than those of the other; and, at 13 years of age, one leg was nearly twice as large as the other. The veins were then so dilated, that they were thought to be about to burst. The worst were treated by being obliterated by needles passed beneath them. Afterwards, an elastic stocking was fitted, with which she went to the country.

A Doubtful Case of Cutaneous Disease.—Dr. DICKINSON made some observations upon the case exhibited by Dr. R. J. Lee at the Society on November 27th, 1874 (*vide* BRITISH MEDICAL JOURNAL of December 19th, 1874, page 792). Dr. Tilbury Fox, Dr. Duckworth, and himself had been appointed as a committee to inquire into the case. The disease was a skin-eruption, which, commencing at the heel, in three weeks travelled "like a comet" up the limb, and once or twice encircled the trunk; as the head of the line, which was dotted and red, advanced, the tail of the line gradually faded. Chloroform had been given to the child, and a small portion of skin excised; this was still to be examined microscopically. The operation had stopped the progress of the disease.—Dr. SOUTHEY asked if the disease were the result of fraud, or was it due to a parasite?—Dr. DICKINSON said the affection was undoubtedly due to disease, and not to art. The committee were inclined to think it parasitic. The line had advanced at its end regularly; the committee had cut out that end of the streak, and believed they had excised the head of a parasite, which had still to be minutely examined.

Acute Pemphigus.—Dr. SOUTHEY gave particulars of a case of this disease. The patient, aged 19, a well nourished young woman, was admitted into St. Bartholomew's Hospital with the history that she was a general servant, but that latterly she had led a somewhat irregular life. She had always enjoyed good health. On October 28th, she first presented herself at the hospital with a sore on the side of the hand, which had commenced as a blister. She stated that the sore was at first about the size of a threepenny-piece. On November 15th, she first felt very poorly; she was feverish and could not eat; had a sore throat, and an eruption all over her face and body. The rash came out with much irritation and tingling. It appeared first as small round raised spots, which varied in size from a pea to that of a cob-nut. On November 19th, when first seen by Dr. Southey, her body was covered by blebs or bullæ of various sizes, some of them surrounded by a halo of redness. On the face were several large ones, especially at the inner angles of both eyes, at the corners of the mouth, and on the chin. Others were seen on the dorsal and palmar surfaces of both hands and between the fingers. The arms and legs were especially affected at the flexures of the joints. On the back, chest, and abdomen, the blebs were large and oval, and in some parts confluent, measuring quite an inch across. Some looked quite transparent, others presented more opaque contents, while those which were pressed upon, or had been rubbed, contained a yellowish fluid. The fluid collected from a few in a test-tube was alkaline, and albuminous enough to coagulate entirely by heat. The mucous membrane of the mouth was sore and aphthous; the tongue was protruded with difficulty, and was covered with a yellowish white fur. Her throat was sore, so that she swallowed with difficulty; and there was a superficial aphthous sore situated about the middle of the hard palate, and extending to the velum palati. The heart and lungs were normal; the abdomen was empty and retracted, not painful on pressure. Pulse 117, soft, feeble, regular; respirations 24, regular; temperature 101.7 deg. Her skin was moist and perspiring. She was ordered effervescent saline draughts, with small doses of opium; milk and beef-tea, with stimulants. A solution of nitrate of silver (ten grains to the ounce) was injected into some of the larger bullæ, and the parts everywhere were swathed in cotton-wool, soaked in carbolic oil. Fresh bullæ came out every day; and the back, buttocks, and thighs presented superficial sores, which were excessively painful, and bled when the dressings were changed. On November 29th, she was placed in a warm bath at a temperature of 100 deg. Fahr., in which she remained five hours, the greater part of the time being spent in sleep. She took more food that day than on previous days; and, to the surprise of her nurses, after having been lifted into the bath in an almost inanimate condition, she managed to get out of it with only slight assistance. The following day she was kept in the bath twelve hours, and the next day ten hours. On the fourth day she was kept in the water six and a half hours. In consequence, however, of the water being allowed to get too cold while she slept, she became confused, slightly delirious, exhausted, and shivering when put to bed. Reaction, however, set in, and the following day she was found to be very prostrate, with a pulse of 120, very feeble, and temperature 100.2 deg. Fahr. She was breathing quickly, and complained that her throat was worse, and she was not so well. A sample of urine was obtained; it was high coloured; specific gravity 1045; it contained no albumen, but turned quite black and effervesced violently upon the addition of nitric acid. On December 4th, the carbolic acid dressing was discontinued, and Caron oil substituted. From this date the improvement became very manifest. Although restless, feverish, and difficult to manage, she gained strength day by day, and no fresh bullæ made their appearance. In a few weeks she was able to leave the hospital for Walton.

Mr. HULKE remarked that the nervous prostration in this case had

been supposed to be due to the carbolic acid; perhaps the colour of the urine was traceable to the same cause. In surgical cases, where carbolic acid was much used, the urine was often quite purple.—Dr. SOUTHEY remarked that, in such cases, the smell of carbolic acid remained in the urine. Indican, which was passed in large quantity in cases of great prostration, appeared to be abundantly present in the urine in this case.—Dr. GREENHOW said that the dark colouring of the urine, when due to carbolic acid, appeared spontaneously; whereas only by the addition of the strong acids was the dark colour of indican brought out. In almost every case of recovery from the collapse stage of cholera which he had seen, indican was present.—Mr. HUTCHINSON asked if Dr. Southey could state more carefully the quantity of serum in any of the bullæ; and was there any considerable amount of inflammatory material at the base of the bullæ? He had never seen iodide of potassium hydroa developed to a stage that could be mistaken for acute pemphigus. The bullæ of hydroa looked as if they would rival in size the bullæ of pemphigus, but they never did so. Again, in iodide hydroa, the bullæ had great inflammatory infiltration at their base, and were depressed at the centre. Then, too, the iodide in Dr. Southey's case was given only one day. Mr. Hutchinson mentioned a case of acute pemphigus. The patient was a man, aged 26, and Mr. Hutchinson had seen him at the beginning of his illness. He then had a curious group of vesicles over each eyebrow, with a good deal of erythema around. Bullæ then appeared upon the trunk, increased in size, and became as large as half-eggs. There was ulceration over the buttocks; and, in other particulars, the case resembled Dr. Southey's. He (Mr. H.) at first refused to acknowledge it was pemphigus; but, seeing that the patient emaciated rapidly, became very prostrate, and seemed about to die, arsenic was then given. No other bullæ appeared, and the patient at once rapidly improved, although no other alteration in the treatment was made. When the man was nearly well, the remedy being discontinued, a few fresh bullæ appeared. Arsenic was again given; the bullæ healed, and the patient became quite well. In another man, a very serious case of pemphigus, arsenic did not succeed, and the man died. This was the only case in which Mr. Hutchinson had found the remedy fail to cure the disease, and he regretted that in that instance he had not pushed it further. Within twenty-four hours after arsenic was given, the fresh eruption of bullæ usually ceased. The astonishing point in Dr. Southey's case was, that the patient recovered without specific treatment, for such he considered arsenic to be in pemphigus. He had never seen a case cured without definite specific treatment.—The PRESIDENT mentioned a case of chronic pemphigus, which resisted all treatment in the Children's Hospital. The child then went to the country, fortunately had measles, and rapidly recovered from pemphigus.—Dr. SOUTHEY said that some of the bullæ contained one drachm of liquid, and were as large in diameter as a shilling. They had no red rim around, nor induration, nor did deep ulceration ensue, except at the buttocks and other parts subjected to pressure, and in the face, where the girl picked out the bullæ. The body, after the attack, was left covered with pigmented stains; but scars remained only where pressure had produced them. No iodide of potassium was given after the first day in the hospital. He believed, if she had not been kept in the bath, she would have died. Morphia-injections gave no relief; but, when she was placed in the water, and pressure taken off her, then she rested in comfort. The bath was discontinued with the healing of the worst sores at the back of the body, because of the difficulty experienced in maintaining the water at a constant temperature.

GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.

MAY 11TH, 1875.

JOSEPH COATS, M.D., Vice-President, in the Chair.

Diseased Ankle successfully treated by Carbolic Acid Injections, etc.—Dr. STRETHILL WRIGHT presented a patient, to show the result of treatment in a case of long-standing disease of the ankle. The young woman had received an injury six years ago from a kick about three inches above the joint; this resulted in swelling and lameness, so that in three years she entered the Royal Infirmary, and was under treatment there for six months, but with little benefit. In June 1873, she had again to enter the infirmary, and remained for five months; amputation was then advised, but she declined. She entered the Barony Hospital in September 1874, with the ankle much swollen and very painful, especially at nights; five sinuses existed, and these communicated with one another and with bare bone, but the joint was not opened. At first, the treatment consisted in laying the sinuses open and dressing antiseptically; but no improvement occurred till the middle of December, when a new procedure was adopted. The swollen

and inflamed tissues were then injected with a solution of carbolic acid (1 to 40) by means of a syringe having a sharp point, about the thickness of a knitting-needle; the tissues were pierced and the injections made in various directions, but the joint itself was not pierced. A poultice of carbolic linseed-meal, covered with carbolic gauze, was applied, and the dressings were made under the carbolic spray. The process was repeated, at first daily, and afterwards at intervals of several days, and was continued for four months, and the limb was kept at rest in a splint for two months. This dressing was suspended six weeks ago, owing to an erysipelatous inflammation, and simple water-dressing was used, as the sore was now quite superficial. The pain subsided soon after the injecting treatment was begun. When she was shown to the Society, there was only a small superficial sore, the foot was quite movable, and the joint appeared natural. Dr. S. Wright referred to another case of diseased joint (the wrist), somewhat similar, but of shorter duration, and without sinuses, which had recovered under the same treatment pursued at the same time. He raised the question as to what this beneficial action could be due, especially in the second case, as the mischief could not have been due to any injurious influences from without. He was inclined to think also that the injections had been repeated oftener than was necessary.

Two Cases of Sympathetic Ophthalmia.—Dr. THOMAS REID showed two patients illustrating two very different forms of this disease. The first, a young man aged 20 years, was admitted to the Eye Infirmary on February 15th, 1875, with a wound in the left cornea, passing from the junction of the cornea with the sclerotic, at its lower and inner part, upwards and inwards for about two lines; the wound was occupied by prolapsed iris; this was snipped off, and atropine solution applied. Slight inflammatory symptoms persisted for about three weeks, and gradually passed off, leaving, however, a certain irritability. The patient being anxious to return to his work, he went home, but returned in a fortnight with sclerotic injection of both eyes, the lower margin of the right cornea hazy, the pupil normal in size, but with complete posterior synechia: this did not yield to atropine solutions of full strength, but the left pupil dilated readily. Calomel and opium were ordered, and atropine; but, as the symptoms were not passing off, he was admitted again into hospital in a week, and iodide of potassium was given in addition. Symptoms of well marked serous iritis now were present, both corneæ being studded with minute brownish dots. The inflammation gradually subsided, and the right pupil began now to yield. When he was shown to the Society, both pupils were fully dilated; the opacity and dotting of the cornea had cleared off as well as the inflammatory symptoms; the eyes, however, remained very sensitive to any irritation. The vision had not been perceptibly affected in either eye throughout the whole course of the disease. The medicines had now been stopped and tonics substituted. The second case, a boy aged 14, was admitted to the Eye Infirmary on December 9th, 1874, with a severe injury, from a fragment of iron, of the right cornea, extending from its centre vertically upwards for about two lines into the sclerotic, the eyeball being partially collapsed. He was at once put to bed, and extract of belladonna and a bandage applied; the inflammation, which was not great at first, gradually declined, and he was allowed to go home in three or four weeks, with instructions to avoid using his eyes, and to carry on the treatment. In a fortnight, he returned with symptoms of superficial inflammation (hyperæmia) of both eyes; the vision of the left eye being good, there being no ciliary pain on pressure on the injured eye, the pupil of the left being good and acting readily to light. It was then hoped that the symptoms were superficial, and might pass off; but it was explained to the parents that enucleation might be necessary. The boy was put to bed, and iodide of potassium was given in small doses. The eyes remained in much the same condition, one day better and another worse, the pupil on the left side acting freely; but, as the patient began to complain of occasional dimness of vision, enucleation was at once performed on February 17th, 1875. The operation was easily done, but was followed by considerable hæmorrhage and violent deep-seated pain in the cavity of the orbit. Next day, the pain had abated and the hæmorrhage ceased. The pupil, which was formerly rather dilated, became contracted, in spite of solution of atropine (four grains to one ounce), and at the ciliary attachment of the iris a deep livid ring appeared. Small doses of calomel and opium were given; but, on the third day after the operation, the vision declined, so that he was barely able to distinguish fingers. The iodide was increased, but the disease advanced; the pupil became more contracted, the iris became œdematous, and was traversed by a considerable number of highly congested blood-vessels; this gave the iris a pinkish appearance, and it bulged forwards without iridonecrosis. Vision was now extinct. The stump of the enucleated eye remained irritable. The eyeball, after being in chronic acid for a month, was laid open by a horizontal section from before backwards; the retina, as is

usual in such cases, was found completely separated from the choroid, with the exception of one point to the outside of the macula and near the entrance of the ciliary nerves and vessels; the separated retina was pressed forward, lying in folds against the zonule of Zinn and the partially dissolved lens, which remained *in situ*. Two cord-like prolongations were sent backwards, one to the entrance of the optic nerve, and the other to the point of adhesion to the choroid already noticed. The choroid on each side of this point of adhesion was considerably hypertrophied; the sclerotic at this point likewise projected inwards, with a corresponding depression on the outer surface. In the depression on the surface, a number of hypertrophied blood-vessels were observed. The radial fibres of the ciliary body were detached from the sclerotic towards the equator of the lens, as is usual in inflammation of the ciliary body. The anterior chamber was occupied by hypertrophied iris. The adhesion of the retina to the choroid, and the condition of the sclerotic, seemed to indicate that an injury might have been inflicted in this region by the fragment of iron; and, as it might have penetrated the ball, although there was no distinct cicatrix, a search was made in the stump six weeks after operation. It was found that the ocular conjunctiva had not cicatrised, and a fungous granulation occupied the centre; this was removed and a probe passed in various directions, but no foreign body was found. The wound now healed up. [On a more careful examination of the enucleated eye subsequently, a thin fragment of iron, half an inch in length and about three-sixteenths in breadth, was found imbedded deeply in the lower hemisphere close behind the lens, one of its extremities pressing on the inferior part of the ciliary processes. From this point backwards the retina adhered to the choroid, giving the section the appearance already referred to. This adhesion of the retina to the choroid did not extend to the upper hemisphere of the eyeball. The position of the foreign body within the eyeball accounts for the adhesion of the retina and the hypertrophy of the choroid, either by the extension of the inflammation backwards from the ciliary processes, or by direct injury to the parts at the time the accident happened, by the fall of the foreign body through the upper aspect of the ball to its lower.] Dr. Reid remarked that, in the first case, although the sympathetic affection involved the iris, yet, the vision being good, and the disease being much less dangerous than other forms of sympathetic inflammation, it was resolved to give the patient a chance of recovery without operation; but, although up to the present the disease had been amenable to treatment, and all trace of inflammation had nearly gone, the case still required to be watched lest a recurrence should take place. In the second case, the vision being but slightly impaired, and there being no evidence of iritis, the usual beneficial results from enucleation were anticipated; but a very manifest aggravation of the symptoms occurred after the operation. The facts seemed to point to some diseased condition of the ciliary vessels, and probably also of the nerves, at their entrance in the stump, as the parts within the injured eye itself seemed quiescent. He thought that sympathetic disease might thus be due to disease of the ciliary blood-vessels and to irritation of these nerves, in other parts of their course than their terminal distribution in the ciliary body itself. The lesson to be drawn from this unfortunate case was that, in all cases of injury to the eye, causing, from their nature, complete destruction of vision, enucleation at once should be insisted on.

Diabetic Cataract.—Dr. THOMAS REID also showed a patient with diabetic cataract, double and fully formed. The man was 22 years old; dimness of vision had appeared only about the beginning of April, and in three days became as bad as on admission. His health seemed to have been impaired for a year, and he had had diabetic symptoms for about that time. He had been put under treatment by regulated diet, and Walker's diabetic biscuits and rusks had been used with some advantage. Dr. Reid said that this form of cataract was frequently found in the milder forms of diabetes in young persons, as well as in the more severe. In the former cases an operation was justifiable, if the general health were moderately good; and he hoped to be able to operate in this case.

Paralysis of Accommodation of Eye in Diphtheria.—Dr. BARR and Dr. HECTOR C. CAMERON presented a boy who had been under their care. He was 11 years old, and had been seized with diphtheria on February 13th. He recovered satisfactorily; but in six weeks it was found that his vision was affected for near objects, but not for distant ones, and, on examination, this was clearly due to a paralysis of the accommodation. There were no other paralytic symptoms, except a slight degree of paralysis of the muscles of deglutition, with regurgitation of fluids swallowed, etc. His mother stated that, during an attack of whooping-cough, he had had an internal strabismus.—Dr. RENFREW referred to the case of a clergyman now under his care, whose family had been nearly all affected with bronchitis and measles, complicated,

in some at least, with perfectly distinct diphtheritic exudations and typhoid symptoms. He himself was laid down on May 3rd with sore-throat and hoarseness, and on the 4th he felt his sight weak, and by the 7th his sight was such that he could not see near objects; on the 8th, he consulted Dr. Reid, who made out paralysis of the accommodation, and recommended the use of convex glasses for a time. He was able to preach on the 9th without spectacles, and is now very much better. There were no other paralytic symptoms.—Dr. REID said that the case of the clergyman was one of much interest, owing to the early date at which this affection of the vision had appeared, and to the rapidity with which changes occurred in the power of accommodation. With regard to the boy, he inquired if he were hypermetropic, as he had found this diphtheritic affection chiefly occurring in those who were so; and the history of squint, during the illness from whooping-cough, pointed in the same direction. The clergyman referred to was not hypermetropic.

Old Ununited Fracture of Skull.—Dr. FOULIS showed a part of a skull in which an old ununited fracture existed; this passed from above the left external auditory meatus, transversely backwards across the squamous suture, to about an inch from the lambdoidal suture. It was united over nearly all its extent, leaving a mere groove to mark its seat; but, near the commencement, there was an oval gap left by the erosion of the margins, which were quite sharp; the gap was filled by fibrous tissue. Between the skull and dura mater, at and near the fracture, there lay a pale fawn-coloured tough laminated layer, seemingly an old clot. This had eroded the bone over it slightly.

Instrument to facilitate cutting Sections of Tissues hardened by Freezing.—Mr. W. J. FLEMING exhibited an instrument which he had devised, consisting of a Stirling's section-cutter surrounded by a chamber through which a current of weak spirit was caused to flow, the spirit having been previously reduced to a very low temperature by passing through a worm immersed in a freezing mixture. The advantages he alleged it to possess were its portability, and the facility with which it could be manipulated, while the frozen tissue thus remained in its position, and numerous sections could be made without its being touched in any way by the hands. He thought freezing was so valuable a method of hardening, that it only required an easily worked arrangement to bring it into more general use.

Obstruction of the Intestine.—Dr. JOSEPH COATS showed a specimen of obstruction of the intestine. He pointed out that a diverticulum which proceeded from the ileum, three or four feet above the valve, had become adherent by its apex to the mesentery of the ascending colon. Beneath the bridge thus formed, several loops of small intestine had passed in rather a complicated way, and one small portion which passed twice under the bridge showed the dark red colour and thickened appearance of complete strangulation. He remarked that the diverticulum was three or four inches in length, and had a somewhat blunt extremity, but that from this extremity there proceeded a fibrous band an inch or more in length, which formed the medium of attachment of the diverticulum. The preparation was removed from a boy about 9 years old, who had died with the usual symptoms of internal obstruction of the intestine.

Fruit-stone passed per Urethram.—Dr. HECTOR C. CAMERON showed a damson-stone passed from the bladder by a male patient, 43 years of age. His first symptoms were frequency of micturition, and a little pain in the perinæum; these began about twelve months ago. About November last, he had, for two or three days, violent pains just below the umbilicus, with vomiting and one or two rigors. On the cessation of this attack, he began to pass *gas per urethram*, and his urine became very turbid, but not distinctly feculent in odour. In a week, he was able again to follow his business, and continued to do so till about two months and a half ago, gaining flesh and feeling well, but all along passing *gas per urethram*, and often a little blood at the conclusion of micturition; he now began to pass fluid feces also *per urethram*, somewhat resembling meconium in appearance. At this point of the case, Dr. Cameron had seen the patient with Dr. Suttie, who had supplied the foregoing particulars. On sounding the bladder, nothing was elicited; but, on giving a sudden sharp stroke above the pubes, succussion-sound was very distinctly made out in the bladder, the percussion-note being at the same time tympanic. The rectum was natural in all respects, and, although filled with rather hard feces, thin feces were coming from the urethra. It was evident that the connection of the urinary organs was not with the rectum. A fortnight after this examination, he passed *per urethram* the fruit-stone shown to the Society; it had a slight crystalline deposit on its surface. With the view of allowing the opening in the bowel to heal up, the patient had been fed entirely by enemata, and feces had since ceased to come from the urethra; and, for several days together, flatus had also been sometimes absent.

Specimens and Instruments.—Dr. FOULIS presented a dissection of the cerebral arteries in a case of atheroma with cerebral hæmorrhage. —Mr. W. J. FLEMING presented a cheap hot and gas stage which he had devised for the benefit of students, the principle being the same as Stricker's, but the cost about five shillings.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

VACCINATION.—Mr. Edward Crickmay, vaccinator of the Dennington District of the Hoyné Union, has been awarded by the Local Government Board a further sum of £7 19s. for efficient vaccination.—Dr. John W. Watkins, Medical Officer of the No. 4 District of the Warrington Union, has been awarded the sum of £31 17s. for efficient public vaccination. This is the third time he has received an award.

THE FACTORY ACTS.—The following certifying surgeons have been appointed:—Edward Garraway, M.R.C.S. Eng., for Faversham, *vice* T. C. Spyers, M.D., deceased; Benjamin Barkus, M.D., for Gateshead, *vice* A. Rolf, M.R.C.S. Eng., deceased; Joshua Wm. Morison, L.R.C.P. Ed., for Pembroke, *vice* D. A. Reid, M.D., resigned.

THE LONDON SICK POOR.

AT the annual meeting of the Metropolitan Asylums Board, Mr. J. A. Shaw Stewart, for the Stockwell Asylums Committee, reported that there was no reason to fear any extraordinary pressure, in consequence of fever, upon the accommodation of the asylum. Attention had been called to cases among the upper and middle classes, and alarm had been felt; but, with regard to the poor, in the fortnight not a single case of either typhus or enteric fever had been admitted. During the fortnight, 71 cases had been admitted to the fever asylum; there had been 5 deaths and 39 discharges, leaving 71 cases, against 85 a fortnight ago. Of the 71, 69 were scarlet fever cases, and 1 was an enteric fever case. In the small-pox side, 5 cases of the disease had been admitted from the whole of the unions of London; 6 had been discharged, leaving 7 at present to represent all the cases in London under the Poor-law authorities. Mr. Barringer stated that at Homerton 54 cases of fever had been admitted during the fortnight; there had been 5 deaths and 4 discharges, leaving 133 under treatment, against 127 a fortnight since. With regard to the imbeciles, Mr. Wyatt reported that there were 1,804 at Leavesden, and 4 deaths only had occurred. Mr. Ward, for the Caterham Committee, reported that there had been 10 admissions and 8 deaths during the fortnight, leaving 1,820 patients. Mr. Galsworthy, in reference to the visit of the managers to the asylum, stated that it was found to be in an excellent condition in every respect; and that great credit was due to Dr. Cortis and the Committee, to whom a vote of thanks was passed. Mr. E. H. Currie stated that, at the new Clapton Asylum for imbecile children and others, there were now 262 patients. All the reports were adopted, and, after further business, the Board adjourned.

EXAMINATION OF LUNATICS.

DR. COUTTS (Banchory).—There is no rule as regards payment for certifying pauper lunatics in Scotland. Thus in New Deer, Aberdeenshire, the medical officer receives no fee for such certificates, whilst in Old Deer the parochial board pay their medical officer £2 for every lunatic sent to an asylum. Under these circumstances, we cannot state whether our correspondent is entitled to charge a fee for such certificates, unless we had before us a copy of the agreement he has entered into. If nothing has been stated respecting certifying gratuitously, in equity he would be entitled to a fee of £1; but whether the parochial board would pay, except upon compulsion, is a totally different matter, and it is for our correspondent to decide whether it is worth his while to enforce payment. In one respect our correspondent is entitled to consideration. We find by the last census that the population of the parish, of which he is joint medical officer, amounted to 5,927; and the total sum paid for medical relief, out of which medicines have to be found for the year 1873-74, reached the munificent sum of £45 13s.—verily a great deal of work for very little money.

DR. BILLING (Hailsham) asks the following questions. 1. Has any other medical man the right to enter my workhouse and examine my patients without my consent, or in consultation with me? 2. Have the magistrates the legal power to order the master of the workhouse to send for any other medical man?

* * * In order to answer our correspondent's two questions, it is necessary to reply to the second one first. In the case of a presumed lunatic pauper, the magistrates, whether stipendiary or merely justices of the peace, have the legal power of selecting the medical gentleman, who shall (on intimation given to them through the relieving officer by the workhouse or district medical officer) visit and certify as to the mental condition of such pauper; and, firstly, such medical gentleman has a right to enter such workhouse and examine the patient without the consent of the medical officer—indeed, under such circumstances the medical officer is

ignored altogether. But whilst there is no doubt that the magistrates have this power, it is generally arranged that as the medical officer has all the trouble of the case, that the duty should devolve on him of not only giving intimation, but of attending before the justices and getting the fee. We would advise the medical officer to address a temperate letter to the Board of Guardians stating his case; and as there will be no addition to the expense, it is not improbable that such an arrangement may be come to as will admit of the workhouse medical officer certifying in all cases that may come under his charge.

BIRTHS AND DEATHS REGISTRATION ACT.

MEDICAL OFFICER.—Section 28 of the Births and Deaths Registration Act (1874), provides that "every registrar, when and as required by a sanitary authority as defined by the Public Health Act (1872), shall transmit by post or otherwise a return, certified under the hand of such registrar to be a true return, of such of the particulars registered by him concerning any death as may be specified in the requisition of the sanitary authority". The section also provides that the registrar "shall be entitled to a fee of twopenny for every death entered in such return, which fee shall be paid by the authority requiring the return". The Act makes no provision for the furnishing of returns of births, or for payment for the same. Any returns of births, therefore, required by a medical officer of health must be obtained by mutual arrangement between the sanitary authority and the local registrar. Should such an arrangement be objected to either by the sanitary authority or the auditor, we can see no reason why a medical officer should not pay for the returns of the births himself, if he deem the returns to be useful to him, and he be willing so to do.

PAROCHIAL CHARGES.

We consider that the assistant overseer in the Tendring Union acted in strict accordance with his duty, in giving an order for attendance on a parturient woman, under the circumstances detailed in the paper sent us; and, consequently, he having discharged his duty properly, and representing the guardians, the union should have paid the fee to the medical officer. We should murmur, and they ought now so to do, that gentleman having been supported by the opinion of the county court judge. Should, by any mishap, the auditor in such case disallow such payment, the Local Government Board would remit the same. We would recommend Mr. Squire to again apply to the Board of Guardians for payment, and, should they refuse, as is most probable, to entertain the application, to submit the facts of the case for the consideration of the Local Government Board.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

TOURISTS' HAMMOCKS.

AT this time of the year, when tourists are on the move, it may not be out of place to illustrate the method introduced by Mr. Richard Davy for slinging Seydel's hammocks in vans. The upper hammock slung

in the railway-van is for young and active persons, as an educated agility is necessary for entering one of these hammocks suspended four feet from the ground. The elastic cord on each side of the upper hammock moderates lateral swing when the carriage is running fast. The lower hammock is for the aged and infirm. This mode of travelling continues to give great satisfaction to invalids; and we recommend any tourist to provide himself with one of these portable accessories.

It is intended in future to publish the number of vacancies in the Army Medical Department to be competed for at each examination.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, August 12th, 1875.

Price, Arthur, Surrey Villas, Thornton Heath, Croydon
Stephens, Charles, Upper Parliament Street, Liverpool

The following gentlemen also on the same day passed their primary professional examination.

Bain, David Stuart Erskine, Charing Cross Hospital
Todd, John, University College

UNIVERSITY OF EDINBURGH.—The ceremony of capping took place on August 1st. Professor Balfour, Dean of the Faculty of Medicine, introduced to the Chancellor the following candidates for degrees.

Doctor of Medicine.—*** indicates that the candidates received gold medals for their dissertations, and * that the dissertations were commended. [—John R. Black, Scotland, M.B. and C.M., 1872; Thomas Wilkinson Blackshaw, England, M.B. and C.M., 1872; Kenneth Mackenzie Downie, Scotland, M.B. and C.M., 1866; David Richard Edwards, Wales, M.B. and C.M., 1871; Richard Edward England, England, M.B. and C.M., 1871; Edward Flint, England, M.B. and C.M., 1870; John Brodie Henderson, Scotland, M.B. and C.M., 1870; ***Francis Imlach, England, M.B., 1872; Samuel M'Aulay Inkster, Shetland, M.B. and C.M., 1873; Thomas Scoresby Jackson, England, M.B. and C.M., 1870; Henry Ambrose Lediard, England, M.B., 1870; *William Livesay, England, M.B. and C.M., 1871; ***Herbert Coddington Major, Jersey, M.B. and C.M., 1871; Frederick Parlett Fisher Ransom, England, M.B. and C.M., 1873; ***William Stirling, Scotland, Baxter School in Natural Science, 1870, Falconer Fellow of 1871, M.B. and C.M. with first-class honours, and D.Sc. and Ettles Prizeman, 1872; John Burnley Walker, England, M.B. and C.M., 1873; *James Mauo Williamson, England, M.B. and C.M., 1872.]

Bachelor of Medicine and Master in Surgery.—[** Indicate that the candidate has passed the examinations with first-class honours; * indicates that the candidate has passed the examination with second-class honours.]—Alexander Alexander, Scotland; Ernest Aubin, Jersey; Edmund St. George Baldwin, Canada; John Barlow, England; Alfred George Bars, England; John Jas. Graham Brown, Scotland; Samuel Brown, Scotland; Thos. Sinclair Browne, Barbadoes; **William Watson Cheyne, Scotland; Edwin Millidge Chisholm, Scotland; Joseph Waterfield Chown, England; Thomas M'Rae Clark, Demerara; John Henry Clarke, England; Joseph Mantagu Cotterill, England; James Crabb (M.A. Aberdeen), Scotland; Frederic Hamilton Crowdy, Newfoundland; Charles James Davey, England; William Thomas Evans, England; John Ferens-Oliver, England; William Garton, England; Walter Gillies, England; Charles Glasier, England; Manuel Martinho Gonsalves, Demerara; John Rogerson Hamilton, Scotland; James Milner Helme, England; R. Brown Hogg, Scotland; James Holmes, Berwick; David Morton Jack, Scotland; Bertram Janisch, St. Helena; John Frederick Johnson, Ireland; John James Johnstone, Scotland; Abraham Emrys Jones, Wales; *Edward Owen Jones, Wales; *George Kirkwood, Scotland; Henry William Laing, Scotland; William Lamb, India; Charles Smith Lunan, Scotland; *Neil Macleod, England; Norman M'Leish (M.A. Edin.), Scotland; John Marchbank, Scotland; Alexander Dalton Murray, Scotland; Fraak Nankivell, England; Henry Robert Oswald, India; Archibald William Renny, Peru; Richard Isaac Richardson, Scotland; Charles Smart Roy, Scotland; Charles Snodgrass Ryan, Australia; Charles Edward Sanderson, India; John Sherburn, England; Magnus Retzius Simpson, Scotland; George Daniel Smith, England; John Smith, England; Otto Wien Smith, Scotland; Thomas Fair Heitherington Spence (M.A. Edin.) Scotland; George Skelton Stephenson, England; William Stewart, Scotland; Herbert Stanley Stone (B.A. New Brunswick), New Brunswick; Mark Johnston Symons Scotland; Alfred Crowdon Tunstall, England; **Adam Robert Turnbull, Scotland; George Richardson Underwood, Scotland; Arthur John Vause, England; William John Vereker-Bindon, Cape of Good Hope; *Arnold Hirst Watkins, England; Alfred Hardy Watson, England; Thomas Henry Watson, England; George Thomas Brown Watters, Scotland; Richard Wearing, England; James Hamilton Wilson, England.

Bachelor of Medicine.—James Aitchison, England; Ernest Gilbert Carey, India; William Carey, India; Joshua John Cox, Ireland; George Crichton (M.A. St. Andrews), Scotland; James Crompton Kames, England; Thomas Fraser, Scotland; John George Garson, Orkney; Thomas Harker, England; George Herbert Jameson, England; James M'Naught, England; James Rutherford Morrison, England; Walter Cameron Morris, Barbadoes; Thos. Duddingston Wilson (M.A. Edin.), Scotland.

The Ettles Prize for 1875, to the best graduate of the year, who has gone through all the examinations with the highest honours, was awarded to Adam Robert Turnbull, M.B., C.M., M.D. The Goodis Memorial Prize, established in memory of the services to science in the University of the late Professor Goodis, to be awarded triennially to the writer of the best essay on some branch of anatomy, human or comparative, normal or pathological, or for an essay on experimental physiology, was awarded this year for the first time, the successful competitor being Dr. James Foulis, and his thesis being "The Structural Development of the Ovary, and the Pathological Changes which take place in it." The Hope Chemistry Prize of £100 was awarded to Agornáth Chat-topádhya, B.S., of Bengal.

MEDICAL VACANCIES.

The following vacancies are announced:—

APPLECROSS, Parish of—Medical Officer. Salary, £154 per annum, with house. Applications on or before the 24th instant.
BOURNEMOUTH GENERAL DISPENSARY—Resident Medical Officer and Secretary. Salary, £120 per annum, with furnished apartments, coals, gas, and attendance.

CARNARVON UNION—Medical Officer for the Llandwrog District. Salary, £60 per annum.

DAVENTRY UNION—Medical Officer for the Workhouse and the First District.

DORE UNION—Medical Officer for the Koutchburgh District and the Workhouse.

DUDLEY DISPENSARY—Resident Medical Officer at Michaelmas.

EASTRY UNION—Medical Officer for the Eythorne District.

HAY UNION—Medical Officer for the Herefordshire District.

INVERNESS DISTRICT ASYLUM—Assistant Medical Officer. Salary, £70 per annum, with bed, board, and washing. Applications on or before the 11th instant.

KEVNSHAM UNION—Medical Officer for the Keynsham District.

LEEK UNION—Medical Officer for the Norton District.

LOUGHBOROUGH DISPENSARY and INFIRMARY—Resident House-Surgeon. Salary, 100 guineas per annum, with furnished rooms, fire, lighting, and attendance. Applications on or before the 24th instant.

LYMINGTON UNION—Medical Officer for the Hordle, Lymington, and Milford Parishes.

NORWICH DISPENSARY—Salary, £120 per annum, with unfurnished residence and apartments.

PEMBROKE UNION—Medical Officer for the First District.

PLOMESGATE UNION—Medical Officer for the Aldeburgh District.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road—House-Physician. An allowance of £100 per annum is made in lieu of board and residence. Applications on or before the 23rd instant.

ROYAL SOUTH HANTS INFIRMARY—House-Surgeon. Salary, £80 per annum, with board, lodging, and washing. Applications on or before September 6th.

ROVSFON UNION—Medical Officer for No. 5 District. Applications on or before September 6th.

STAINES UNION—Medical Officer for the Shepperton District.

UCKFIELD UNION—Medical Officer for the Maresfield District.

WARWICK COUNTY LUNATIC ASYLUM—Second Assistant Medical Officer. Salary, £200 per annum, with board, lodging, and washing.

WESTMINSTER GENERAL DISPENSARY—Honorary Surgeon. Applications on or before the 23rd instant.

WEST SUSSEX, EAST HANTS, and CHICHESTER GENERAL INFIRMARY and DISPENSARY—Assistant House-Surgeon. Salary, £20 per annum, with board, lodging, and washing. Applications on or before the 25th instant.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

DUKE, David, M.R.C.S.Eng., appointed Surgeon to the Royal South London Dispensary, *vice* J. J. C. Constable, M.D., resigned.

***DUNCANSON, J. J. Kirk, M.D.**, appointed Surgeon to the Dispensary for Diseases of the Ear, Edinburgh.

GODLEE, Rickman J., M.B., appointed Demonstrator of Anatomy at the Charing Cross Hospital Medical School.

***JOLLY, Robert, M.D.**, appointed Joint Professor of Anatomy at Queen's College, Birmingham.

MURRAY, William, M.B., appointed Medical Officer to the Pembroke Dispensary and Infirmary, *vice* D. A. Reid, M.D., resigned.

WILLIAMS, Neville, B.A., M.R.C.S.Eng., appointed House Surgeon to the Carnarvonshire and Anglesea Infirmary, *vice* R. Davies, Esq., deceased.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTHS.

THORNHILL.—At Bulman Village, Newcastle-on-Tyne, on August 15th, the wife of John Thornhill, Esq., Surgeon, of a daughter.

WARD.—On August 15th, at Saltburn, Twickenham Common, the wife of Martindale Ward, M.D., of a daughter.

CAMPBELL.—On August 15th, at 16, Wellesley Terrace, Liverpool, the wife of W. Macfie Campbell, M.D., of a daughter.

MARRIAGE.

PRINGLE—SMITH.—On August 17th, at Nolton Chapel-of-Ease, Bridgend, by the Rev. F. W. Edmondson, M.A., Rector of the Parish, Henry Turnbull Pringle, M.D., Medical Superintendent of the Glamorgan County Asylum, to Jessie Isabella, only daughter of the late Thomas George Smith of Bridgend, Glamorganshire.

DEATHS.

***WARD, John, Esq., Surgeon**, at Penistone, aged 60, on August 10th.—Friends are requested to accept this intimation.

FINNEY, Charles White, L.S.A., at Ockbrook, aged 61, on August 8th.

INGLIS.—On August 11th, at Worcester, Florence, wife of Alexander Inglis, M.D.

DR. THOMAS CHAMBERS, Senior Physician to the Chelsea Hospital for Women, was on August 3rd elected a Fellow of the Royal College of Physicians of Edinburgh.

BEQUESTS.—By the will of the late Mr. James Douglas Stoddart Douglas of Chilston Park, Kent, the West Kent Hospital and the Ophthalmic Hospital at Maidstone each receives a legacy of £200.—Mr. John Hodgkin of Lewes has left to the Lewes Infirmary £50, and to the Hospital for Sick Children, Great Ormond Street, and the Convalescent Branch £25 each.

The Kent County Ophthalmic Hospital, Maidstone, has been presented with ten framed engravings by Messrs. Henry Graves and Co. of Pall Mall, and Mr. Thomas Hyde Hills of Oxford Street: seven of the engravings are from pictures by the late Sir Edwin Landseer.

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAYGuy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAY ..St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAYSt. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.

FRIDAY.....Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.

SATURDAYSt. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

FRIDAY.—Quekett Microscopical Club (University College), 8 P.M. Mr. W. Cole, "Remarks on a Parasite of the Humble Bee (*Sphaerularia bombi*)".

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with Duplicate Copies.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

ERRATA.—In the article on "The Royal Hospital, Plymouth", at page 206 of last week's JOURNAL, the first sentence on column 2 should be as follows: "The average height of the windows from the floor is not more than four feet; ten out of a total of thirty-four being only three feet nine inches above the level of the ward-floors." In the same column, lines 9 and 11, for "ward" read "wall".

THE ADMISSION OF LADY MEMBERS TO THE ASSOCIATION.

SIR,—I am anxious to direct the attention of members of the Association to one or two points which deserve their careful consideration. Firstly, the great majority of the members of the Metropolitan Counties Branch were ignorant that females had been admitted as members of the Branch until the fact was revealed at the general meeting on Tuesday last. Secondly, the rules under which the entrance was effected were framed originally at a period when such a candidature can hardly have appeared a probable contingency. Thirdly, as this Association is the only really representative body of medical practitioners in the kingdom, the admission of females into it constitutes a recognition of their status by the profession at large.—Yours very truly,
J. A. GOODCHILD.

Ealing, August 9th, 1875.

THE LATE DR. A. D. KERR.

SIR,—In your impression of to-day, referring to the death of Dr. A. D. Kerr, at Millport, you say that Dr. Kerr had been in practice for some years in Greenock. He was only in practice in Greenock for one month.—I am, sir, yours faithfully,
JOHN S. WILSON, M.R.C.S.Eng.

A MEMBER OF THE VETERINARY COLLEGE.—For a long time it was supposed that the skeleton of the famous racehorse Eclipse was in the Museum of the College of Surgeons. This turns out to be a fallacy, and the supposed Eclipse has given place to Orlando, who was born in May 1841, and died in December 1868, when he was presented to the College by her Majesty the Queen.

CAPSICUM IN DELIRIUM TREMENS.

SIR,—Will some one of your correspondents kindly inform me the proper doses and mode of using the capsicum treatment in cases of habitual drunkenness?—Yours truly,
G. PERCIVAL HADLEY, M.D.

A DEMONSTRATOR.—The examinations for the present session have been brought to a close at the College of Surgeons. The Registration always takes place in October.

VEGETABLE DECOMPOSITION.

SIR,—I would feel most gratefully obliged if any of your numerous readers would kindly inform me, through your columns, of the names of the authors or works who have treated of the effects of vegetable decomposition upon health in a formal manner, as I am greatly interested in discovering such immediately.—Your obedient servant,
MEDICUS.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

CURIOUS ACTION OF GLYCERINE UPON BORAX.

SIR,—I had occasion to make an alkaline lotion for a case of acne a short time ago, which consisted of borax, bicarbonate of soda, chlorate of potash, glycerine, and water. After the ingredients were put in, and the bottle filled with water, I added half an ounce of glycerine, and corked the bottle. To my surprise, in a few seconds violent action began to take place, and I was obliged to remove the cork, for fear of an explosion. I could not understand what had taken place, and could only think that there was some acidity in the glycerine; but such was not the case; it was perfectly neutral to test-paper; and the other chemicals, I believe, were perfectly pure.

I then repeated the experiment in the following way, and a very interesting one it was, perfectly inexplicable to me, and of which I can gather no information from any work. I put into a test-tube about equal parts of powdered borax and bicarbonate of soda, with a little water; I then added some glycerine, which, of course, sunk through the solution of soda, and rested over the borax; chemical action immediately began, the glycerine gradually became dissipated, and the borax was dissolved. I have repeated the experiment several times, and have obtained the same result with the carbonate, although not to the same amount. The change is evidently at the expense of the glycerine; for, if only a few drops be added, the action soon stops, to be renewed with great intensity if a large quantity be then added.

I am not sufficient chemist to unravel the decomposition, and I thought by bringing it forward in your JOURNAL I might obtain the true explanation of the phenomena. I am, etc.,
FREDERICK LONG, L.R.C.P.Lond.

Wells-next-the-Sea, August 13th, 1875.

ERRATUM.—In the list of Fellows of the Royal College of Physicians of London, at p. 217 of last week's JOURNAL, the name "Barder, Charles Foster", should be "Barder, George Foster".

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Bristol Daily Post; The Daily Bristol Times and Mirror; The Derby and Chesterfield Reporter; The Lincolnshire Herald; The Glasgow Herald; The Sunderland Daily Echo; The Carnarvon and Denbigh Herald; The Manchester Guardian; The European Review; The Hackney and Kingsland Gazette; The Worcestershire Chronicle; The Birmingham Daily Post; The Brighton Daily News; The Sussex Daily News; The Glasgow Herald; The Cork Examiner; The Scotsman; The Cork Daily Herald; The Southampton Times and Hampshire Express; The Hampshire Advertiser; The Birmingham Morning News; The Chester Courant; The Metropolitan; The Live-Stock Journal; The Shield; The Grocer; The Shipping and Mercantile Gazette; The Advertiser; The Islington Gazette; The Penrith Observer; The Hastings and St. Leonard's Gazette; The Ilkley Free Press; The Leicester Daily Post; etc.

COMMUNICATIONS, LETTERS, ETC., have been received from:—

Mr. James Spence, Edinburgh; Dr. Smart, Haslar; Mr. W. Adams, London; Mr. H. C. Bartlett, London; Dr. Pirrie, Aberdeen; Mr. Allender, Edinburgh; Mrs. Hoggan, M.D., London; Mr. J. C. Sargeant, London; The Rev. J. A. Hatchard, Hastings; Dr. John Gregor, Edinburgh; Mr. W. R. Davies, Sandbach; Mr. F. H. Hodges, Leicester; Dr. W. H. Lowe, Edinburgh; Dr. J. J. REMARKS

ON

THE NECESSITY OF LEGISLATION FOR
THE CONTROL AND TREATMENT
OF INSANE DRINKERS.*

By A. PEDDIE, M.D., F.R.C.P.E., F.R.S.E., etc., Edinburgh.

IN addressing this Association on the necessity of legislation for the control and treatment of insane drinkers, I would commence by observing that this is no new question in Scotland. Before January 1858, when I contributed a paper on it to the Medico-Chirurgical Society of this city, it had been forced on the attention of many medical men and others by constantly recurring difficulties in the disposal of these unfortunate sufferers; and it had special prominence in evidence given in 1855 before the Scottish Lunacy Commission, and in the report of the Commissioners in 1857. At the meeting referred to, the question was most favourably discussed; and, when the paper was published, the subject was well ventilated, and viewed as a most important one, in almost all the newspapers and journals of the period. This agitation was followed, in March of the same year, by a most admirable lecture "On the Medico-Legal Relations of the Habit of Intemperance", delivered at a *conversazione* of the Royal College of Surgeons by our distinguished President Sir Robert Christison; and it was kept alive for several years by various able contributions in medical and literary journals. There thus arose in the public mind a feeling, and I think I may say an unanimous desire amongst medical men, that something ought to be done by legislation to meet the question at issue. On this side of the Border, therefore, we have noticed with best wishes the efforts carried forward on the other side during several years, mainly through the instrumentality and indefatigable exertions of the late Mr. Donald Dalrymple, M.P. And here I cannot allow the occasion to pass without expressing in a single sentence, from much private correspondence with Mr. Dalrymple, as well as from a knowledge of his public career and conduct, the high estimate I formed of his moral worth, intellectual endowments, and remarkable determination and strength of purpose, without regard to personal expense and labour, which he displayed in the face of many trying discouragements while seeking the settlement of this question.

Mr. Dalrymple's second Bill, founded on a large mass of evidence laid before the Select Committee of the House of Commons in 1872, and on the strong report of that committee, of which you, Mr. Chairman, were a member, lost its place in Parliament, in consequence of the change of ministry; and Mr. Dalrymple's death, which shortly afterwards occurred, seemed to threaten a serious delay of effort in the same direction. The subject, however, has lately been revived and warmly agitated by several of your Branch Associations, and by a most influential deputation who lately waited on the Home Secretary, with a view to the introduction of a measure in next session of Parliament on the basis of Mr. Dalrymple's Bill; and this, I trust, together with the earnest consideration of the subject at this meeting of the Association, will give a great impulse to the movement.

I cannot believe that a settlement of the question can now be long delayed, when an Association so large and powerful as the British Medical takes it up, and gives on it a decided utterance.

That some legislative enactment is required to meet the case of a large proportion of insane drinkers, psychologically termed dipsomaniacs or oinomaniacs—or, popularly, habitual drunkards—will be doubted, I imagine, by few, if any, assembled on this occasion. And I may further assume that little need be here said in considering who are to be viewed as insane drinkers. They may be briefly described as those—1. Who inherit the propensity to intemperance; 2. Who evince it as the principal manifestation of some form of cerebral disease; 3. Who are affected with it as a result of an injury of the head, or severe fevers, or other wasting bodily ailment, mental shock, heavy grief, reverse of fortune, and, indeed, from causes similar to those anteceding

some other insanities; 4. Those who acquire it through a course of vicious indulgence in stimulants.

In whichever way produced, or from whatever combination of causes, the distinguishing feature of this malady in its confirmed state is total loss of self-respect and self-control under an overwhelming craving for alcoholic drinks, although with little or no palatal relish for the same, which must be gratified at any cost, regardless of honour or truth, and, in fact, unaffected by appeals to reason or self-interest, the tears of affection, or suggestions of duty either to God or man.

I must also assume that it is not necessary at this meeting to point out particularly in what respects dipsomania differs from the *mania à potu*, or, as also called, the delirium ebriosum, or acute mania from alcoholic excess; or how it is distinguished from delirium tremens, the toxic mania of alcoholic accumulation, or from the hydra-headed forms of the vice of drunkenness. Of the latter, we have abundant examples everywhere around us, in which we have the most marked types of constant tipping without entire unfitness for the business of life in persons drinking from facility of disposition, from conviviality, and from the love of drink or the love of intoxication, but who have more or less power to abstain when they choose to do so.

That the phase of intemperance which so utterly annihilates self-respect and the power of self-regulation is indicative of affection of the brain-plasma primarily or from exoteric influence through alcoholic action—in other words, an abnormal cerebral condition, occasioning unsoundness of mind—cannot be reasonably questioned; and, as in origin it thus resembles other insanities, it presents also similarities and variety in its course, manifestations, and terminations. Thus, in this malady, the irresistible craving may spring up suddenly, often in successive attacks of singular periodicity, or from the mere taste of anything alcoholic quickly bringing the system under the full sway of alcoholic poisoning; or it may pass through a slow, stealthy, insidious course ere the action, if not the nutrition, of cerebral matter becomes changed.

It is developed in all classes and conditions of society; in the men of refinement and high mental culture as well as in the coarse-minded and ignorant; in the lady of rank and in the tradesman's wife; in all periods of life, in old age, in the adult, and even in early youth; in different constitutions and temperaments, manifesting various eccentricities of deportment and habits, wastefulness, destructiveness, perverted moral feelings and impulses, revenge, theft, violence, and invariably mendacity. It is occasionally cut short for a time by delirium tremens or acute mania, or goes on to drivelling dementia, chronic alcoholism, or some other form of insanity, if life be not brought to a close by accident or some superinduced disease.

Besides, while this alcoholic diathesis, as it may be called, is transmitted from generation to generation, idiocy, epilepsy, paralysis, and other forms of cerebro-spinal disease, are the frequent legacy of drunken parents to their children.

It is a remarkable fact, too, that, if there be any peculiar proclivity, any black spot in a man's moral nature, it is brought out under the weakening and perverting influence of alcohol. Hence, among the criminal class of dipsomaniacs, we have a variety of results, and often a most remarkable uniformity in crime committed by the same individual under successive states of inebriety. Thus one individual will invariably be guilty of assault, another of wanton destructiveness, such as smashing windows, another of theft, and not only so, but of stealing very frequently the same sort of articles. Did the limit allowed for this paper permit, it would be easy for me to treat of in greater detail, and to illustrate and verify with cases, the various points now indicated.

The mass of cases arising out of intemperance—purely the vice—carry with them their own pains, penalties, and checks, and must be judged of by the peculiarities of each individual case, and left to varied physical, moral, and religious teachings. But there is a link which connects, and a boundary-line which separates intemperance the disease from intemperance the vice. Here it is that legislative interference of any kind becomes, and very properly so, most delicate; and it is here that at first sight most formidable obstacles are supposed to exist against our present proposal. For the very worst cases of dipsomania, in which there is a manifest concrete of the malady, of irresistible desire for stimulants, with some other form of mental disease independent of alcoholism, the present law of lunacy clearly provides. The acute mania of drink is also, we would say, a fit disease for asylum treatment, if there be not convenience in private or in the strong room of a hospital; to which cases of delirium tremens also may be taken, when safe and judicious management cannot be carried out in private. But cases of well marked dipsomania, which are so serious to the unfortunate individuals themselves, and so perplexing and injurious to friends and society, are without help or hope, either in private or from the law of the land; there is nothing in the future but certain degradation

* Read before the Public Medicine Section at the Annual Meeting of the British Medical Association in Edinburgh, August 1875. [For discussion, see p. 267.]

and ruin to the individuals themselves, often to those closely connected with them, and injury to the community.

No doubt, the voluntary clause of the last Lunacy Amendment Act, 1866, was thought likely to meet, to some extent, the case of the dipsomaniac; but, while there has been latterly a gradual annual increase of voluntary admissions of the general insane, there has not been such of insane drinkers; and there are strong objections to the admission of such into lunatic asylums. It is not at all desirable that such should mingle with other lunatics in public or private asylums, or that a malady requiring special treatment should be brought under lunacy law arrangements. It is most undesirable also that asylums should be embarrassed and annoyed by the care of dipsomaniacs; for it is a necessity that an inebriate retreat should be a strictly temperance institution, which a general asylum cannot be, and consequently in such insane drinkers find opportunities, through other inmates, to obtain the supplies they crave; and so, by schemings and untruthfulness, produce endless misery and inconvenience in these establishments. That the habitual drunkard of this class, therefore, absolutely requires special care, is clear; but, as in cases of legislation a definition must generally precede the proposed legislative provisions, he may be briefly defined as a person of unsound mind whom the habit of intemperance is such to render, notwithstanding the plainest considerations of interest and duty, unable to control himself, and incapable of managing his own affairs, or such as to render him in any way dangerous to himself or others.

If the above be a true description of the condition of the person indicated, surely it is the manifest duty of a good and wise Government to exercise its paternal functions in providing for the control of his person and the interim management of his affairs, with the view of promoting the well-being of the unfortunate individual, instead of permitting him to go to wreck and ruin. Indeed, the neglect of law to provide such a check and remedy seems inconsistent and unjust, when we consider that, while it permits the insensate drunkard to endanger his life, to waste his property, and deprive his family of that which they are entitled to expect from his hands during life, or to fall to them at his death, it holds him responsible for any act he may commit. No doubt the law assumes that he drinks voluntarily with his eyes open to the consequences, and that his practices are, therefore, an aggravation of his guilt; but such is not the case; for he drinks, as has been shown, involuntarily by a power from within impelling him forwards with irresistible force, without any power of reflection as to ultimate consequences.

From the nature of the malady, it is evident that, unless there be separation from the persons through whom, and places where, the morbid craving can be gratified, and well regulated restraint placed on the habits, little can be expected in the way of treatment. Such separation is necessary in most cases of insanity; but still more is it required in the case of insane drinkers, who, although unfit for attention to the proper duties of life, are full of devices (often most ingenious and clever) to obtain their desire (with them the one object of their life); and so cunning and deceitful are they in scheming for it, that they outwit the most vigilant attendants (women being in this respect even more talented than men); so that at best any good arising from ordinary restraint is extremely temporary. In certain early cases, and in short fits of periodical drinking, it may be at long intervals of time, perhaps it might be advantageous were it declared lawful to take the control of the person in his own dwelling. But in general real benefit can only be obtained from a sufficiently prolonged detention in a home or sanatorium, or by whatever name it may be called, where all arrangements are adapted, not merely for firm and kindly supervision, but for overcoming restlessness and discontent. This will be best accomplished, in the first instance, by pleasing the palate in the way of good culinary arrangements, so as to counteract the craving for stimulants; by attention to other bodily comforts, and by providing occupations and amusements during all weathers and seasons within doors and in the open air. In due time, by these means and a judicious exercise of the system of trials of freedom on probation, and every other possible agency, physical, mental, moral, and spiritual, an endeavour would be made to restore to a healthy condition the disordered brain and shattered nervous system; to create new desires and nobler aims; to inspire self-esteem, and develop and strengthen the power of self-control, so as to fit for a return to society and the duties of life.

In order to call into existence houses or institutions such as would be suitable for the upper and middle classes of society, a law to empower restraint and detention is manifestly essential. A few such institutions on a small scale have existed in Scotland, but have laboured under most discouraging difficulties from want of authority to receive and retain a sufficient number of inmates, and for a sufficient length of time, to become remunerative. This has stood in the way of liberal

investment for suitable premises, ground furnishings, staff of service, etc. Thus the important essentials for efficient treatment have been necessarily defective; and the result is, that the care of a very small fraction only of insane drinkers has been undertaken, and cure somewhat rare. The inmates with partially restored sanity from enforced deprivation of stimulants become restless; and, knowing that they cannot be detained, legally demand liberty, and take leave, or else work on the minds of friends or guardians by entreaties or threats, and get it. If, however, the state will sanction, under proper checks, both voluntary admissions and compulsory commitments in cases of genuine dipsomania, permitting prolonged detentions until real benefit is derived, a sufficient number of homes or retreats, or by whatever name they may be called, for the cure of persons in the upper and middle classes, would certainly spring up, both through private enterprise and the efforts of companies or associations formed for the purpose, somewhat similar, indeed, to many existing and thriving lunatic retreats and asylums, affording accommodation and means of treatment very different in efficiency from those inebriate institutions which have in times past struggled under cramping difficulties. Now, into such houses as these, many unfortunate persons would enter voluntarily, as they do in some of the American inebriate institutions, knowing that, if they did not thus surrender themselves for treatment, they would be compulsorily committed; and then, when they are under control, the law, as I have already hinted, could prolong it for such time as might be deemed necessary to accomplish the humane ends in view.

There are two other grades of society, however, for which some provision would be necessary for control and reformation, namely, the working classes, with a certain portion of the poor, who, or their friends, were unable to pay much, if anything, for board; and for criminal drunkards. The former would be boarded—classified, of course—in Sanatoria; and the latter in Reformatories, classified too.

In regard to the Sanatoria, I do not think it would be asking too much of a wise Government to assist in establishing tentatively three or four such in central districts of the country, by grants of a few thousand pounds to each. I believe that these institutions would be additionally supported, and, perhaps, in time become self-supporting, through payments made for board paid by the better portion of the working classes or their friends; by work done in the institution; by legacies and donations; and, perhaps, by sums paid from parochial boards for the care of pauper inebriates. Knowing the downward course of habitual drunkards in this class of society, and how families are dragged into squalid poverty, and demoralised; and how neighbourhoods and the general interests of society suffer through crime and local taxation, it would, I am confident, be a good investment of Government and parish money, yielding indirectly, if not directly, a tenfold return.

The same may be said, also, as to reformatories, into which criminal drunkards only should, I think, be sent—those who have sunk to the lowest depths in the social scale, and are dangerous to society. Many of them are truly dangerous characters, and almost constantly resident in police cells and prisons for crimes committed under the influence of drink or to obtain drink. Of course, the upholding of such institutions, removed from ordinary prisons, must fall on prison boards and local taxation; but here, too, as might be expected, a return could be obtained in moral and social good and pecuniary compensation. Direct commitments to such reformatories by the magistracy might in many cases be most advantageously made without passing the individual through a prison; while in other cases he would be transferred thither from a prison by a warrant, for which the desired legislation would provide. Here, the punitive element could not be altogether separated from the reformatory; but other important agencies could thus be brought successfully to bear on this wretched class of persons. To this end, no better counteractive to idleness and drinking habits could be employed, nothing better fitted to generate self-esteem and strengthen in them the power of self-control, than the cultivation of industrial habits, especially with the stimulus of obtaining some immediate as well as ultimate benefit for good conduct and for work done. However, for the full elucidation of these plans, I beg to refer you to a paper of "Suggestions for Legislation (in Scotland) for Habitual Drunkards", handed by me to the Select Committee of the House of Commons in 1872, as explanatory of evidence given before them, and by whom it has been published in the appendix of their report. This document also points out how the management of persons' affairs could be attended to while in retirement from the active duties of life.

In the foregoing remarks, I have viewed this question chiefly from the platform of the physician; but I have claimed for it, also, that of the lawyer, the political economist, and the moralist; but I would consider it also from the standpoint of religion. The views taken of it hitherto, in some quarters, have apparently been through the dark atmosphere of sin; looking at the habitual drunkard as culpable for not

governing his will and restraining his passions by the precepts of the Gospel; and looking on its agitators, perhaps, as actuated by materialistic leaning, and losing sight of moral influences and the discipline of the church, which last, however, cuts the inebriate off from its pale, and too often casts him adrift to his fate. If these conjectures are so, surely this must be attributable to want of discrimination respecting the true position of dipsomaniacs, contrasted with other drunkards, on whose conduct in their state of liberty, or, rather, license, religious precept, or the example of the wise and good, cannot have the slightest influence. It has been said, without any exaggeration, that were immediate eternal punishment and a glass of intoxicating liquor put in a dipsomaniac's choice, he could not resist choosing the latter. As, therefore, spiritual benefits usually flow and operate through human agencies and instrumentalities, we believe that facility for legal control will be the likeliest medium for the transmission of a precious changing influence. Only by enforced abstinence from the accursed thing, as well as by other means, already detailed, brought to bear for months, or, perhaps, even years, on the unhappy subject of this propensity, can we hope to see him return to society, as it were, "clothed and in right mind".

But some others of the general public who look down on a wretched habitual drunkard with mixed feelings of pity and disgust, on account of the shame and disgrace of his position, may speak of his fate in terms like these, "Poor fellow, he killed himself with drink!" or of another, with a shrug of the shoulders, "He is fast going to the bad through drinking habits". They will then say doubtfully, in regard to the question of legislation, Do you ever cure a dipsomaniac? From evidence given (Mr. Mould's) before the Select Committee of the House of Commons, it appears that cases of perfect cure are certainly rare compared with the number of persons said to have been treated; but it must be kept in mind that we have as yet no law enabling us to bring a person early enough, and keep him long enough, under treatment. There has not hitherto been a chance of accomplishing more than mere temporary benefit among the few cases in which there has been any attempt at treatment. Let us, however, obtain sufficient but carefully guarded permissive powers, and I believe that the result would be very different. But here we are immediately met with another question: How can you carry out such powers to any extent? Can you ever hope to send any considerable portion of the habitual drunkards in the kingdom into inebriate institutions? In such a remark, there is an evident confounding of dipsomania with other forms of drunkenness. As distinguished in the foregoing remarks, the number must be very considerable; but what a blessing it would be to have even a few hundreds of the worst cases placed in several tentative institutions, safely controlled and treated, with the hope of a moderate percentage in reformation and cure; nay, while they are merely protected from themselves, protection will be afforded to their families and society; and if so for these, why need we despair of having a larger percentage of cures in cases of sufficiently decided, but of a more recent and promising, character, treated in institutions into which many may be induced to enter voluntarily to avoid being sent compulsorily? The number of reported cures, even in lunatic asylums and retreats in England, seem to be greater than our experience in Scotland; and the reported results in the American and Canadian inebriate institutions, fostered by State arrangements, are still more encouraging. I am convinced, indeed, that if a proper system of treatment, applicable to the different orders of society, were established, we might have as fair a percentage as is accomplished in acute and chronic cases relatively among the general insane, if not a higher one.

But here, objectors to the proposed legislation, as a last resource, betake themselves to the old argument: Is not this a free country; and has a man not a right to do with his own, or with himself, as he chooses, taking the consequences of his conduct? No; the State regards the suicide either as a criminal or as insane; and the dipsomaniac, as we have shown, having lost the power of his reason in governing his will, must therefore be regarded as under a mental malady, and treated as such. But, besides, it is not the rightful privilege of any man to waste the means of those dependent on him; perhaps to ruin, as well as disgrace, his family and friends, or place them in personal danger, or offend a neighbourhood, or invade the liberties and privileges of good citizenship. To quote from what I have said elsewhere: "The liberty of the subject is a precious trust, but the well-being of society is still more sacred. The absence of law to meet the case of the insane drinker is in reality a license for evil, since no precaution is taken to prevent most grievous infringements of the liberties of others. It certainly is an overstrained delicacy in legislation which shirks interference with a class of cases which lead to so much private misery and public expenditure, as the records of our courts of law and the church, and our prisons, poor-houses, and lunatic asylums, amply prove."

It seems to us, therefore, that it is the bounden duty of a wise Government to help those who cannot help themselves, and to protect those who are sufferers from such misery and mischief; and, as it legislates in other insanities, it is unquestionably within its province to legislate in this; and, moreover, since it legislates regarding restrictions in the use of intoxicants, it cannot be without its province to deal with the abuse of them. We trust that ere long our Government will, in these respects, take a leaf out of the statute-books of Sweden, of the United States, and of our own colonies in Canada, Australia, and New Zealand.

ON THE CONTROL AND RESTRAINT OF HABITUAL DRUNKARDS.*

By G. F. BODINGTON, M.D., Kingswinford.

I HAVE little doubt, from recent observation, that the balance of opinion amongst medical men in general is now largely in favour of legislative measures for the control and restraint of habitual drunkards. Several circumstances may be cited to prove this. Not many weeks since, a deputation went to the Home Secretary, to present to him a memorial strongly urging the Government to proceed to legislation on the subject in the next session of Parliament. This memorial bore the signatures of a number of the most eminent physicians and surgeons both in this and the southern metropolis, as well as in other parts of the kingdom. The prayer of this memorial was warmly advocated in Mr. Cross's presence by Sir Thomas Watson and others. The leading organs of the medical press are in favour of legislation, and the rank and file of the profession throughout the country hold, there is good reason to believe, the same view. I can vouch for this, at least, in Birmingham and the surrounding district. The Birmingham and Midland Counties Branch lately appointed a committee to promote legislation for the control and restraint of habitual drunkards; and the experience I gained as honorary secretary of this committee enables me to say, that in and around Birmingham the profession is nearly or quite unanimous in favour of restrictive measures. A petition to Parliament has been drawn up, and the Committee has, so far as I know, met with no refusals when canvassing for signatures. On the contrary, the members of the Branch are eager to sign. The same feeling, there can be little doubt, pervades the other Branches of the Association. Some of them, as is well known, are actively exerting themselves in the matter. In short, there is, as the phrase goes, a "movement" in the Association in favour of legislation on the subject in question. Outside the Association also there seems to be a very general opinion in the profession, so far as I can learn, that a remedy is requisite for this crying evil, which medical men only can fully appreciate, but which they are powerless to remove. From these circumstances, it is fair to conclude that the profession at large is, for practical purposes, of one mind upon this topic, and requires, I take it, no more convincing. If the passing of a Drunkards' Act depended on their vote, it would be passed forthwith. There is, therefore, not much need of further argument addressed to members of our own profession.

When, however, we discuss the matter with the general public, we find the aspect of the case, as seen from a lay point of view, changed; and it is signally changed as seen from the lawyers' point of view. Society, especially the legal section of it, says: "What, shut up men of sound mind who have committed no crime? You can't do it; it will interfere with the liberty of the subject." The lawyers tell us there is no precedent for such a step, that no such power is known to the law as the power sought to be obtained in this instance, and that to grant such a power would be a violation of fundamental constitutional principles. The only exception, they say, is found in the Lunacy laws, the exception which proves the rule; no man can have, or ought to have, his liberty curtailed, unless he be charged with crime or be mad, and the proposals that have been made in Mr. Dalrymple's Bill and elsewhere are most dangerous and unallowable innovations.

This is not a fanciful picture; the objection is current to my knowledge. You know, sir, that

"God sends country lawyers an' other wise fellers
To start the world's team wen it gits in a slough".

I am able to say, from personal communication as well as from second-hand information, that the objections now sketched out constitute, with the "country lawyers and other wise fellers", a very serious difficulty and obstacle, which the advocates of restraint must be ready to face and to combat. The answer to it is not hard, if the spectre of legal

* Read before the Public Medicine Section at the Annual Meeting of the British Medical Association in Edinburgh, August 1875. [For discussion, see p. 267.]

protection can be laid. I would ask all, who object on such grounds as I have named, this question, Whose liberties, and rights, and privileges, are invaded the most, in the case in question, the liberties and privileges and rights of the wretched drunkard, or those of his miserable victims, his suffering and oppressed family? If the scales be held evenly, which way will the balance turn? The answer can hardly be doubtful.

I suppose it is the lot of every asylum proprietor to be asked frequently to receive men or women, heads of families, who, not being insane, are yet incapable of self-control or of managing their affairs, and who by their drunken habits bring disaster and ruin upon those whom they ought to support and protect. As you all know, such cases cannot be received into asylums. I have a vivid recollection of the utter disappointment and even despair that I have sometimes witnessed when friends or relations have learnt, to their astonishment, the impossibility of placing even the most desperate cases under control, and that no remedy exists against an evil that saps the foundations of the peace, prosperity, and indeed very existence, of families and homes.

It is not my object now to picture the enormity of this evil, with which this auditory is perfectly familiar—quite as familiar as, or, perhaps, more so than, myself. My present aim is to point out that we shall not procure legislation without much difficulty and opposition in Parliament, possibly also amongst the constituencies. We cannot afford to ignore this opposition, and we must be prepared with such a bulk and weight of evidence as will carry conviction not only to our own minds, but to the minds of opponents. That work has yet to be done. The public at large is not aware of the depth and extent of the evil. Could they fully realise, as we do, in all its horrors, the misery which habitual drunkards inflict on their families, a wave of indignation would rise, and they would save us all further trouble by insisting with one voice upon instant remedial measures.

Protection to the oppressed and the suffering is the principle to be invoked. Mr. Mill, in his work on *Liberty*, has the following passage: "As soon as any part of a person's conduct affects prejudicially the interests of others, society has jurisdiction over it, and the question whether the general welfare will, or will not, be promoted by interfering with it, becomes open to discussion." That passage, I think, may be taken as our text in the argumentative campaign that will have to be fought. It must be shown, as it can be shown, and not shown merely, but thrown into the most vivid relief, that "the general welfare" under the present want of system suffers seriously, nay vitally; and that the seclusion of a definite number of drunkards—if it be a hardship at all—is, at least, a fleabite in comparison with the tyrannies, the cruelties, and the oppression which those drunkards practise upon their families, and the wrongs they inflict on society at large.

If it be urged that it is unjust to deprive a person of liberty, to inflict upon him the severe punishment of prolonged imprisonment for no crime, for an offence which is at the worst a vice, and which, on the showing of the advocates of seclusion, is often a disease, the answer is that the law does already concede the principle involved, for it punishes with fine or temporary imprisonment temporary offenders; why, then, should it shrink from dealing with chronic offenders? If the law sees no wrong in immuring a man who is "drunk and disorderly" for one night, why should it hesitate to immure men who are "drunk and disorderly" all their time?

Further, it may be answered, that the interests of society imperiously demand that whatever inconvenience or unhappiness may fall upon the individual in this instance, it must be endured for the sake of the general good. It will be found, however, I fully believe, that, in the long run, a greater aggregate amount of happiness and comfort by far will be secured to the drunkard himself by shutting him up, than by leaving him to pursue without control his wretched career of debauchery, degradation, disease, and death. It is, in short, a mercy and charity to a confirmed drunkard to cut him off by any means whatever from the source of his supplies.

A point arises in connection with this subject which will have to be well remembered. There is much confusion in the public mind as to the terms used, and these will have to be clearly elucidated and defined. The following extracts from an article in the *Birmingham Daily Post*, of July 3rd, 1875, illustrate the difficulty. The writer says: ". . . Everyone will assent to the proposition that habitual drinking is a very serious evil. Dr. Dalrymple, however, proposed to regard it as a form of insanity, and to treat those who indulged in it precisely as if they were lunatics, and that appears to be the course recommended by the gentlemen who have now taken the question in hand. Their proceedings, therefore, demand attentive consideration, for it would be no light matter for the public to undertake the care and custody of the innumerable people who are given to hard drinking. There appears, however, to be a distinction, fanciful or real, drawn between persons who merely practise drinking as a vice and those who are incited to it

by some irresistible impulse. The latter are termed dipsomaniacs, a term implying that they are mad on the subject of drink. The deputation did not seem to observe the distinction, for the memorial spoke of dipsomaniacs as if the word signified habitual drunkard, but some of the members evidently held that there was a difference. . . . The advocates of seclusion have certain adverse arguments to answer before the premises on which they rest their case can be altogether admitted. Theirs may, perhaps, be the correct position; but, before inducing the Government to act on their advice, they will have to give clear proof that there is a distinguishable condition of dipsomania; that it is not capable of being confused with ordinary drunkenness; that it prevails among such a moderate number of persons as institutions of reasonable extent might accommodate; that it is capable of being actually cured by forcible restraint; and that the cure can be effected within a specified period."

That is an example of the kind of argument that will have to be met. The confusion between drunkenness as a disease and drunkenness as a vice must be cleared up. For my part, I look upon all *habitual* drunkenness as a disease, and I would boldly call it all dipsomania. It is in its character as a disease that we, as physicians, are entitled to deal with it. I would sink the notion of its being a mere vicious propensity. When fully developed, there are not two kinds of habitual drunkenness. The cases are, one and all, cases of dipsomania, of irresistible, uncontrollable, morbid impulse to drink stimulants. No doubt, this disease may originate in various ways; it may originate, as we are informed, from vice; it may take its start from bad example, from bad habits in early life, or it may spring from hereditary causes, attacking, as it sometimes does, young men or mere boys. The causes, indeed, are very numerous; but, whatever the causation, whether it be an hereditary malady, or acquired, it is, when developed, one and the same disease, dipsomania as it has been called, running in parallel lines in many respects with insanity, and demanding similar treatment.

A definition of this disease, however, will be demanded of us for practical legal purposes. I do not know that a more sufficient one can be required than the one given in Mr. Dalrymple's Bill. The vexed question of vice or disease is there very properly left out, and an habitual drunkard is defined thus: "A person shall be deemed an habitual drunkard who, in consequence of the habitual intemperate drinking of intoxicating liquor, is dangerous to himself or to others, or incapable of managing his affairs." There is also a supplementary definition, but this is the main thing, and seems to me to answer the purpose. It meets the difficulty that Mr. Cross suggested to the deputation that went to him, with regard to the great numbers that would probably have to be taken in charge. If we put before the public or the legislature such a description or definition, and propose to deal only with persons so defined, we shall, I believe, in due time make good our case. Above all, we shall make way by showing, as I think can be shown, that it is cheaper—for your true Briton loves a cheap bargain—cheaper, I say, to separate the drunkard from society, utilising, it may be, his labour, than to allow him to go about, lord of his free will, but a waster of his own and others' substance, an unproductive creature, a spendthrift, a drone in the busy human hive.

The lay mind wants something tangible, something, as they style it, practical, and will but tardily take in the idea, that dipsomania is a disease demanding that the victims of it should be shut out from society and bereft of liberty, for months or even years, while in a condition of body and mind which, to uninstructed common sense, seems sound and sane.

Such ideas they will look upon as "viewy", fanciful, and theoretical; the "fads of physicians" they will call them. Hence, it is necessary to use such arguments as I have used in this paper, and to put them prominently in the foreground, arguments based on the grounds of expediency, general utility, the protection of person and property, and the safety of society. The more we push forward arguments of this kind, the more way we shall make with Parliament and the public, and advance the cause we have in hand.

MR. ALBAN H. G. DORAN, F.R.C.S., has been elected surgeon to the Westminster General Dispensary, in the vacancy occasioned by the resignation of Mr. William Rose.

ASSOCIATION EXCURSIONISTS.—After the recent meeting in Edinburgh, a large number of the members and their friends took part in an excursion under the guidance of Mr. Thomas Cook, and visited Oban, the pass of Killiekrankie, the Caledonian Canal, Staffa and Fingal's Cave, Iona, Glencoe, Loch Lomond, Loch Katrine, the Trossachs, Stirling Castle, etc. At the conclusion of the tour, a vote of thanks to Messrs. Cook, for the ability and attention shown to the party during the excursion, was unanimously carried.

FORTY-THIRD ANNUAL MEETING
OF THE
BRITISH MEDICAL ASSOCIATION.

Held in EDINBURGH, August 3rd, 4th, 5th, and 6th, 1875.

PROCEEDINGS OF SECTIONS.

SUBJOINED are abstracts of most of the papers presented to the several Sections of the Association at the Annual Meeting. The papers themselves, as opportunities occur, will be published in full in the JOURNAL.

SECTION B.—SURGERY.

Wednesday, August 4th.

THE Chair was taken by the President, JOSEPH LISTER, Esq., F.R.S.

Demonstration on the Treatment of Club-Foot. By W. J. LITTLE, M.D., London.—Dr. Little first alluded to Stromeyer's great discovery of subcutaneous tenotomy, published in 1831. In 1836, he himself, by the study of specimens in the museums at Berlin, came to the conclusion that contraction of the tendo Achillis was not the only cause of distortion; but that the anterior and posterior tibials were also effective. Accordingly he had, as early as 1837, divided the tendons of these muscles in cases where it seemed necessary. After showing how the average age at which patients were operated on had gradually decreased from eighteen years to a few weeks or even days, Dr. Little went on to consider the causes of imperfect cures or relapses of the deformity after an apparent cure. These he considered to be the following. 1. Omission of operation at an early period. The earlier the period of operation, the more perfect would be the cure. Operation might be practised the day after birth. 2. The undue importance attached to the division of the tendo Achillis alone. 3. The treatment by instruments where the patient's foot was kept too long in a fixed position. By this, the healthy use of the joint was lost. 4. The entrusting of the after-treatment too much to attendants, instead of to the surgeon himself. The excellence of the results would be in proportion to the amount of personal attention paid by the surgeon. Not a single day should pass without his reapplying the apparatus. 5. The insufficient estimate of the difficulties sometimes met with by the operator, and his consequent neglect to inform the parents of the true nature of the case. He was in the habit of informing parents that the after-treatment of the case would be required to be attended to by them until their child had arrived at an age when it was responsible for itself. 6. Improper use of apparatus in those cases where the cure had not been completed before the patient was able to walk. In relapsed cases, he deprecated redivision of the tendon, or resection of the muscle itself. The heroic proposal to divide all the tissues *en masse* between the skin and tarsal arch was unnecessary and useless. Even although there was no risk of bleeding, and though the divided nerves united again, still there would probably be pain and risk. He had endeavoured from an early period to simplify the mechanical appliances employed, whether or not any cutting operation in each particular case be needed. During the last ten years, he had gradually advanced to the present state of his experience that every case of congenital varus in an infant under nine or ten months of age requires absolutely no other mechanical appliances than a roller bandage and one or more padded metallic splints successfully adapted to the limb, in proportion as its form and position improve, and that more elaborate apparatus based upon Scarpa's or Stromeyer's modified Scarpa's shoe, or upon steel and India-rubber springs, with leg-irons, is only required when either ill-fortune, inattention, or neglect has prevented the treatment from being carried out early or in a thorough manner. He laid down the following rules. Whether or not any division of tendons be deemed necessary, commence the treatment at the earliest period the health of the infant, the state of the mother, and other circumstances, permit, even within twenty-four hours or the first week of birth. If in doubt as to need of operation, "take farther advice", or try gentle mechanical treatment only, by means of his splints, for a few weeks. Whether or not any operation be performed, remove and reapply the splint at least once in each twenty-four hours, and whenever it appears to be seriously displaced. Practise and teach the nurse to effect, daily or oftener, gentle manipulations, pressings and stretchings of the distorted parts towards the desired form and position, and guard against the ankle losing any portion of its natural movement; overcome thoroughly the inversion of the foot and the contraction of the sole before attempting to bring down the heel, especially if resort be

had to operation. However favourably the case may progress, do not permit the part to assume for a moment any portion of the former evil position, from which the treatment may have gradually rescued it, or allow the child on any pretence to be placed on the foot before full natural eversion and bending can be readily effected by the attendant and anatomically or spontaneously by the child. A well treated successful case of severe congenital varus can apply the sole and heel properly to the ground with the toes turned out, and walk at the age of twelve to sixteen months as well as a sound child. In conclusion, Dr. Little showed how he considered a cure of club-foot could be effected before the child was twelve months old, so that not only should the foot be perfect in shape, but also in function. This consisted in the application of a well-padded straight splint, at first exactly moulded to the deformity. Gradually, each day, the angle was to be changed, until the foot, from the position of *varus*, assumed that of *valgus*. It should be kept at this for a few days. While this process was going on, the movement of the foot at the ankle should be performed each day. If necessary, the tendo Achillis might be divided, and a splint with a screw used. By this means, the surgeon could, in twelve months, obtain a perfect cure, and thus avoid all unnecessary expense to the parents, or annoyance to the patient. The author exhibited a series of his splints for the cure of congenital club-foot in infants, and of other apparatus, for incompletely cured, relapsed, and neglected cases, employed from the time of Scarpa to the present day.

President's Address.—The PRESIDENT delivered an address.

Note on a Peculiar Variety of Hydrocele of the Cord. By FURNEAUX JORDAN, F.R.C.S. Eng., Birmingham.—A young gentleman, aged 23, presented himself with an enlargement in the scrotum, a little larger than a walnut, spherical, and well defined, situated midway between the external ring and the testis. The cord was distinctly felt above the swelling, but slightly thickened. The enlargement was translucent, was very movable, was a little larger in the evening, and a little less in the morning. There was an impulse on coughing, at which time a fine rustling stream of fluid could be felt passing through a second tube from the abdomen to the enlargement. When firm and persistent pressure was made, a stream of similar character could be felt passing from the swelling to the abdomen. There was at no time any sign of protruding bowel. Mr. Jordan believed that, in its anatomical characters, and in its mode of formation, the enlargement was similar to the "encysted hydrocele of the cord", except that a fine tubular communication with the abdomen still remained unobliterated. The treatment recommended was a light truss, to cut off the communication with the abdomen.—Mr. RIVINGTON (London) took exception to the nomenclature of the case. It was not an encysted hydrocele of the cord, because it seemed to communicate with the peritoneal sac. It looked like one of the varieties of congenital hydrocele of the cord.—Mr. O. PEMBERTON (Birmingham) thought it was simply a portion of peritoneum containing peritoneal fluid, to which the term hydrocele did not apply. Puncture would have led to a communication with the peritoneal sac.—The PRESIDENT thought that it might be diffused hydrocele of the cord where there was fluid in its cellular tissue, communicating with the cellular tissue of the iliac fossa. It thus could be induced with difficulty; and, when the patient stood up, a rushing sound was heard from the fluid making its way back. He thought that it was a misnomer to call it congenital hydrocele, as the tube opened into the peritoneum.—Dr. PIRRIE (Aberdeen) thought that the case was analogous to one he had met with. In it, there was nothing in the scrotum; but two little tumours could be felt in the cord. They did not communicate with one another; nor did the upper one open into the peritoneum. He therefore believed them to be two hydroceles of the cord, due to the irregular contraction of the tubular prolongations. He thus held that there was an accumulation of fluid before closure. They differed from Mr. Jordan's case in having no communication with the peritoneum.—Mr. F. JORDAN was afraid he had been less distinct in his paper than desirable. In the programme it was described as hydrocele of the cord.—Mr. RIVINGTON objected to the term "encysted".

Excision of the Thyroid Gland. By P. HERON WATSON, M.D., Edinburgh.—Dr. Watson noticed the opinions of surgical authorities on the subject, and described five cases in which he had operated, one of them being fatal. He recommended attention to the following particulars. 1. The external incision should extend from the larynx to the sternum, if the tumour be large and spread widely in a lateral direction. 2. The vessels—arteries and veins—should be secured as they are divided. 3. The fascia should be opened as widely as the skin; and, if the tumour be large, the soft parts may be divided transversely as far as the sternomastoid muscles. 4. The delicate investing fascial sheath of the thyroid body should be left undivided until the vessels included in it have been tied. 5. After the mediate ligature of the thyroïdal vessels in the cel-

lula sheath, the capsule of the thyroid gland should be opened by scratching through it in the middle line, and the attachments of the goitre carefully divided by blunt-pointed scissors curved on the flat. There should be no tearing away of the gland. 6. If bleeding occur after the separation of the tumour, from any of its vascular attachments, the vessels, if they are to be secured, should be tied *en masse* along with the cellular sheath.—Mr. LENNOX BROWN (London) felt that the operation for goitre was one of which he could not approve, simply because it was unnecessary. In none of the cases did there seem to be dysphagia or difficulty in breathing. The first case was typical, viz., a young lady with a goitre about the size of a China orange. When an incision was made from the larynx to the sternum, the cicatrix caused a worse deformity than the goitre itself. But there were other means of removing the gland equally certain, and leaving no mark. There were four varieties of goitre, viz., simple, fibroid, cystic, and fibro-cystic. In the simple, counterirritation by the red iodide of mercury was sufficient. In the fibroid, injection of iodine into the substance of the gland produced most wonderful results, without any resulting deformity. In the cystic, he used to inject iodine. He now, however, tapped, injected with perchloride of iron, and plugged the cannula. In about forty or fifty cases, there had been only one death. In the fibro-cystic form, setons were of great value; or Maisonneuve's darts of chloride of zinc might be used. He therefore believed that the operation was unnecessary; and, although it was brilliant enough, it was better to try milder measures, remembering the aphorism of Hippocrates, viz., "to cure the patient with as little harm as possible".—The PRESIDENT said that he had only seen Dr. Watson's unsuccessful case. The principle, however, seemed a sound one. An improvement he had made was to subdivide the part ligatured, and ligature each half. The larger the tumour was, the greater the risk. If it were large and overlapped the carotid sheath, it was important to tie the tissues with the vessels at such distance that, when the fascial sheath was divided, there should be no risk of hæmorrhage from the ligature slipping. He therefore passed an aneurism-needle from the middle to the side, and divided the ligature. He next passed a needle along one of the threads, and, pushing it through the tissues, cut the thread. He then withdrew the needle, and tied the ligatures. The gland could then be dissected out without bleeding. In the first case, the gland enveloped the trachea, and overlapped the carotid sheath. The second was extremely vascular, was principally on one side, and largely overlapped the carotid vessels. One vein, during the operation, was so large as to look like the internal jugular. The operations were performed antiseptically. There was no suppuration in one case, and only a little tension in the other. Hemp was used for the thyroid vessels, as the catgut was hardly strong enough. Dr. Thomas Keith, however, had shown him some, kept for five years, which was exceedingly strong, and, by twisting it in strands, it could be used for any purpose. In both the cases operated on there was severe dyspnoea.—Dr. WARSON said that, perhaps, he did not go into symptoms sufficiently, so as to settle, to the satisfaction of some, the propriety of operating. In all his cases, there were difficulty in deglutition, stridor of breathing, and affection of the general health. The operations were certainly not undertaken as a *dernier ressort*, just as it was not the custom in tracheotomy to operate at as late a period as possible. In goitre, if they waited until the patient was suffocating, there would be a risk, not only of disfigurement, but of death. The disfigurement was large when the incision was made; but, even after twenty-four hours, there was great contraction. In one case, an incision of seven inches contracted to an inch and a half. In regard to Maisonneuve's *flèches*, he had heard of a case where the incision for their introduction was followed by severe bleeding. This was arrested by lint strips. After the separation of each slough, bleeding also took place; so that the patient was in great danger, and ultimately recovered, with various cicatrices, to which no linear one could be compared. He had employed injection with iodine in many cases without admirable results. In cystic goitre, whether unilocular or multilocular, he would not operate until he had tried tapping. In all his cases he had done so. In his first, he had tapped and injected; but other cysts appeared. He therefore deemed it inexpedient to wait and operate as a *dernier ressort*. In the cases operated on, both his colleagues and himself were satisfied as to the necessity of operation.

A Case in which Adams's Operation for Subcutaneous Division of the Neck of the Thigh-bone was performed on Both Sides in the same Patient for Straight Ankylosis. By EDWARD LUND, F.R.C.S.Eng., Manchester.—In the case related by Mr. Lund, both hip-joints were ankylosed in the straight position, so that the patient could not sit down. Subcutaneous division of the neck of the thigh-bone was first performed on the left side, and twelve weeks afterwards on the right side. The result of the operation was, that the patient acquired excellent power

of motion in both hips; he could support the weight of his body on either leg; and he had greatly improved in all respects.—Mr. WILLIAM ADAMS (London) felt sure that no one could congratulate Mr. Lund more than himself in having been so fortunate as to obtain useful mobility at both points. He had aimed at such results, but without getting them. In his own cases, there had been extreme deformity, where motion could not be obtained even when the patient was under chloroform. In about twelve or fifteen cases now operated on, there had been only one failure, and it was in St. Thomas's Hospital, where the patient was a strumous child, with little ankylosis. As a rule, the cases to be operated on were, beginning with the best, rheumatic, pyæmic, traumatic, and serofulous. The last should be excluded. If the cases were carefully selected, the results would be good. Mr. Bryant had operated on two cases, with successful results.

Two Cases of Aneurism, one of the Carotid and one of the Femoral Artery, treated by the Wire Compress. By J. DIX, M.R.C.S.Eng., Hull.—The wire compress here spoken of was introduced to the profession by Mr. Dix ten years ago, as a substitute for the ligature. The full details of the method, with illustrative cases, were published in the *Edinburgh Monthly Journal* for September 1864. At that time, he had only used it for wounded blood-vessels; but he also spoke of its applicability to arteries in their continuity, and explained the process for aneurism. He now related two cases in which it was so used on the carotid and on the femoral artery. Both were successful. In the latter, the incision, five inches long and an inch and a half deep, healed by first intention. The operation is as follows. The artery is cut down on, and the wire is drawn under the artery by the aneurism-needle in the usual way. Each end of the wire is then attached to a needle, and so brought out through the tissues by the side of, but clear of the wound, so that the ends are about half an inch from each other. A piece of cork is placed between the points of exit of the wire, and pressed firmly down in the course of the artery; and over this the wire is tightly twisted till the circulation is stopped. In each of the cases related, a feeble current of blood was admitted into the sac for three days, and only on the fourth day was it entirely cut off. In twenty-four hours afterwards, consolidation of the aneurism had taken place. The wire is removable at any time, and in these cases was removed on the sixth and seventh days. This the author considered one of the greatest advantages of his method, as it allows the gradual establishment of the collateral circulation, and greatly diminishes the risk of gangrene, if not removing it altogether. It does not cut the inner coats of the artery, nor cause ulceration of its outer coat; its blood-channel is intact, and hæmorrhage cannot possibly occur. Bleeding (the greatest danger from ligature) is entirely abolished; and gangrene, the next most fatal risk, is much diminished. The wire compress has other advantages over the ligature. Thus it is not a foreign body in the wound, and therefore does not excite suppuration and impede breathing. It is applicable to all arteries alike.—Dr. PIRRIE (Aberdeen) said that a great deal had been brought forward on acupressure. Since 1854, he had used no other method of arresting hæmorrhage in any operation, unless in those on the tongue, upper jaw, and deep tumours of neck. His belief in it was unshaken; and acupressure, defined as "metallic compression, removable at pleasure", he believed to be one of the greatest improvements in modern surgery. In regard to its use in aneurism, there was no time to discuss it, although he would have been most happy to do so.

On the Modern Treatment of the Advanced Stages of Constitutional Syphilis. By WILLIAM ACTON, M.R.C.S.Eng., London.—The author spoke of the ravages produced in syphilitic patients in the time when it was the custom to administer mercury in excess, and to the reaction against this practice in the form of the so-called expectant treatment. He then gave an exposition of Ricord's views on the treatment of syphilis; and enunciated the following laws as those which should guide the practitioner in the management of the disease:—1. That mercury is most successful in the treatment of secondary symptoms; 2. That iodide of potassium is to be principally depended on in tertiary symptoms; 3. That a mixed treatment is applicable in cases of advanced constitutional syphilis. In conclusion, he made some remarks on the necessity of preventing syphilis, and described the result of observations which he had made on prostitution in Edinburgh, where he found the evil to prevail to an excessive extent.

Tracheotomy in Croup and Diphtheria. By GEORGE BUCHANAN, M.A., M.D., Glasgow.—This paper contained an argument for operating on the suffocative stage and type of the above diseases founded on Dr. Buchanan's own experience, which was summarised as follows: total cases of tracheotomy in croup and diphtheria 46, cured 17, died 29; croup 16 cases, cured 6, died 10; diphtheria 30 cases, cured 11, died 19.

The Treatment of Patent Urachus. By J. J. CHARLES, M.D., Belfast.

Case of Perforation of the Abdomen per Vaginam; with Remarks. By ALEXANDER E. McRAE, M.D., Penicuik.

A Case of Partial Rupture of the Popliteal Artery, and Complete Rupture of the Popliteal Vein, for which Primary Amputation of the Thigh was performed. By W. RIVINGTON, F.R.C.S.Eng., London.—The patient was a healthy young man, aged 19, who was riding on the front seat of an omnibus, when a runaway horse and cart dashed at the omnibus, and a corner of the cover of the cart struck him on the left knee, driving it forcibly backwards. On his admission into the London Hospital soon after the accident, there was much contusion of the knee, but no signs of fracture or dislocation. The swelling of the part increased, and the patient complained of loss of sensation in the leg; the temperature of the limb also fell. Pulsation could be barely felt in the posterior tibial artery. On auscultation, a low clicking sound was heard in the course of the popliteal artery; and the diagnosis formed was probable rupture of the artery. This diagnosis was concurred in the next day by Mr. Hutchinson; and amputation was performed by a modification of Teale's operation. The patient ultimately did well. On examination, there was found to be extensive effusion of blood in the areolar tissue of the limb. The posterior ligament of the knee-joint was slightly torn; and the plantaris muscle was torn from its attachment to the femur. The popliteal vein was completely severed; and the inner and middle coats of the artery were separated from the external. The ligamentous and cartilaginous structures of the joint were injured; and the external condyle of the femur was nearly separated by a fissure, while a small triangular piece of bone lay loose and projected into the joint. The upper part of the tibia was also fissured. The history of the case was followed by some practical comments.

Demonstration on Stricture of the Urethra. By F. N. OTIS, M.D., New York.—Dr. Otis said that a stricture of the urethra might be caused by any inflammation which spread below the mucous membrane so as to cause a deposit of tissue in the submucous coat, and consequent obstruction of the calibre of the canal. This obstruction might vary from a slight constriction to complete obliteration. By some, it was considered that where a No. 8 or 9 instrument of the English scale passed, there could be no stricture. This he considered entirely wrong. By means of his urethrometer, he was enabled to ascertain the calibre of the urethra. In a series of about five hundred cases, he had established the fact that there was a constant relation between the circumference of the flaccid organ and that of the urethra itself. He went on to show how the slightest constriction of the urethra produced friction; and that this, leading to irritation, caused, when it became chronic, gleet. Gleet he considered as the indication of a stricture. There might be, of course, stricture without gleet. His plan was to dilate the urethra, after ascertaining its calibre and the position of the stricture. The dilatation was to be carried at least two degrees beyond the ascertained normal calibre of the canal. By means of a fine knife two millimètres in breadth, the stricture was then divided internally. By this means, it could also be ascertained accurately whether there were more than one stricture, so that they could be dealt with in the same manner.

Demonstration of Conjunctival Transplantation from the Rabbit to the Human Subject. By J. R. WOLFE, M.D., Glasgow.—Dr. Wolfe first described the nature of the affection in which this transplantation was necessary; viz., in adhesions between the apposed surfaces of the conjunctiva due to injury. Previous attempts to remedy this had been mechanical, and therefore useless. In 1872, he devised this method of transplantation; and it was now practised by Becker, Von Graefe, and others. Details as to how it was done were, therefore, needed. Two patients whom he had under treatment were shown. 1. F. B., aged 9, had his right eye burned with lime in January last, the cornea being rendered almost entirely opaque, with the exception of the small upper and outer segment. The pupil was thus completely covered with the adherent lower eyelid. Dr. Wolfe first turned the transparent portion of the cornea to account by making an artificial pupil upwards and outwards. Eight days ago, he operated for the cure of the symblepharon. Some of the ligatures were still in the new conjunctiva from the rabbit. 2. Peter C., aged 20, a quarryman, was operated on on January 23rd, 1873. The patient had his face and both eyes injured from a gun-powder explosion. His left eye was completely blinded by a symblepharon. Dr. Wolfe made an iridectomy upwards, and then remedied the symblepharon from the conjunctiva of the rabbit. A fortnight ago, he presented himself again for the treatment of his everted eyelid of the right eye, when Dr. Wolfe found that a small bridge had formed in the new conjunctiva, which he separated, and supplied a new conjunctival flap.

Thursday, August 5th.

On Ligature of the Common Femoral Artery; and especially on Ligature by an Antiseptic Material. By OLIVER PEMBERTON, F.R.C.S. Ed., Birmingham.—Mr. Pemberton began by referring to a case described by him in his Address on Surgery at the meeting of the Association in 1873, in which, as he then supposed, he tied the common femoral artery for an aneurism in Scarpa's space. The operation was successful as regarded the main issue; but, the patient having since died from another cause, Mr. Pemberton had found that the circumflex ilii, the epigastric, and the profunda femoris arteries, were given off together above Poupart's ligament; and that he had tied the superficial femoral artery. The portion of vessel (five-eighths of an inch) between the point of ligature and the origin of the above-named branches was firmly plugged. He then went on to argue that it was the surgeon's duty in such cases to tie the common femoral artery in preference to the common iliac; because it produced less danger to the patient, and because there was yet an artery left to tie in case of failure. He did not regard the risk of secondary hæmorrhage, insisted on by Mr. Erichsen, an objection to the ligature of the common femoral; and he believed that this risk might be diminished or even removed by the use of an antiseptic catgut ligature, applied in such a way as to close the artery without cutting it through. He believed that the objection as to the point of origin of the profunda was of no real importance if the vessel were not cut through.—Mr. LUND (Manchester) wished to know when the hempen ligature came away, and whether it was drawn through, showing that there had been division of the artery. In the other case, did the ligature undergo solution, or remain as a fibrous band?—Mr. PEMBERTON said that the hempen ligature came away thirty days after operation. As the loop of whipcord was intact, it must undoubtedly have cut its way through the tissues of the vessel.—Mr. DIX (Hull) said that it was remarkable, he thought, that the artery he mentioned in his paper read on the previous day as not being ligatured for fear of secondary hæmorrhage, was the common femoral. The point on which he wished most particularly to dwell was the comparison of the catgut ligature with his own method by means of the wire compress. The advantages of the catgut ligature were, he thought: 1, that it was not a foreign body; 2, that it did not damage the internal coats; 3, that it did not require to be detached by ulceration as in the case of the silk ligature. It, however, might give way too soon; and in one case the clot had been carried to the brain on the second day. But by his method the wire could not yield too soon, nor become detached. Above all, the circulation was not cut off too quickly. The circulation was at first feeble, allowing deposition of lymph. Then, when the wire was tightened, the clot was completely consolidated. The wire could then be taken away without fear of secondary hæmorrhage.—Mr. RIVINGTON (London) asked how Mr. Dix was sure that the wire did not cut through the vessel.—Mr. DIX said that, in the case of carotid aneurism, there was pulsation when the wire was removed.—Mr. FURNEAUX JORDAN (Birmingham) congratulated Mr. Pemberton on his paper. At St. Bartholomew's Hospital, he had seen Sir James Paget apply a ligature to the common femoral in a stump where there was bleeding due to sloughing.—Dr. PIRRIE (Aberdeen) thought that their present experience did not warrant them in giving a definite opinion on the merits of acupuncture and the catgut ligature. Everyone knew that from limited statistics any conclusions could be drawn. It was their present duty to collect facts. There was a remarkable unanimity among the members of the profession in regard to ligature of the common femoral being undesirable; while that of the external iliac was highly successful.—Mr. LISTER (Edinburgh) did not suppose that Mr. Pemberton meant that a hempen ligature would be without risk when applied on an arterial trunk near a large branch. The origin of the branches of the common femoral varied extremely; and it made all the difference, whether the ligature was applied close to a large branch or a quarter of an inch above it. As to the catgut ligature not cutting through the internal and middle coats, he always applied it so as to do so. At his antiseptic demonstration, he had pointed out how the ligature was not properly prepared, as his own directions were wrong. He had prepared it rightly himself; but it was by accident. The catgut ligature, when rightly prepared, could be used without risk. He had tied the femoral artery four times, and the carotid once with it, successfully; and his colleague Mr. Amundale had had the same experience with regard to the femoral, the carotid, and the external iliac. In none of these cases had there been any giving way.—Mr. PEMBERTON, in reply, said that in his first case there was an abiding coagulum; and in the second, where he had tied the artery one inch below Poupart's ligament, there was no severance of the tube of the artery. Ligature of the external iliac was successful; but Mr. Lister should not forget cases where the aneurism recurred. It

certainly was not good to have recurrence, or to tie the artery again above the former ligature.

On a New Operation for the Obliteration of Depressed Cicatrices after Glandular Abscesses or Exfoliation of Bone. By WILLIAM ADAMS, F.R.C.S. Eng., London.—The operation consists of the following steps: 1. Subcutaneously dividing all the deep adhesions of the cicatrix by a tenotomy-knife introduced a little beyond the margin of the cicatrix, and carried down to its base: 2. Carefully and thoroughly everting the depressed cicatrix, turning it, as it were, inside out, so that the cicatricial tissue remains prominently raised: 3. Passing two hare-lip pins or finer needles through the base, at right angles to each other, so as to maintain the cicatrix in its everted and raised form for three days: 4. Removing the needles on the third day, and allowing the cicatricial tissue, now somewhat swollen, succulent, and infiltrated, gradually to fall down to the proper level of the surrounding skin. Three cases, in which this operation had been performed by Mr. Adams, at periods varying from eleven, nine, and three years from the present date were adduced in illustration. In the last two cases described, one resulting from glandular abscesses in the neck, and the other from necrosis of the inferior maxillary bone, all traces of the depression were removed, and the cicatricial tissue alone could be seen; but it was perfectly on a level with the surrounding skin. In texture and in appearance this cicatricial tissue had so much improved, having lost its shiny, membranous and vascular character, and become thickened and of an opaque white colour, that it closely resembled the surrounding skin. In the first case, which had resulted from a bullet-wound, and a portion of the malar bone had been carried away, although the depression could not be entirely obliterated, very great improvement had resulted from the operation. The permanency of the operation was placed beyond all doubt by the two last cases described, one nine, and the other nearly three years since the operation; and the completeness of the obliteration of the depression; and the improvement of the cicatricial tissue surpassed Mr. Adams' most sanguine expectations.—Mr. LUND (Manchester) had a case some time ago in a young gentleman who lost a portion of the bone below the orbit, a depressed cicatrix being left. He had operated without Mr. Adams' improvements; and, when he saw the case last, the cicatrix had fallen back to its old state. The patient wished to be again operated on; and, although he was unwilling then to do so, yet he might with Mr. Adams' needles give him a further chance. He would like to know what dressing Mr. Adams used. He thought that, in such cases, the cavity might be nicely filled up with blood-clot, the uses of which they had seen in Mr. Lister's demonstration. It would be important to prevent suppuration in the line of the needles.—Mr. ADAMS did not use any dressing except collodion in one instance. In only one case had he any bleeding. The needles were removed on the third day, with a little suppuration in one case, but none in the others. The only difficulty he had was in avoiding veins.—Dr. HARDIE (Manchester) had found a difficulty in operating on depressed cicatrix by one puncture. At Mr. Adams's suggestion, he had so treated a case of depressed cicatrix over the malar bone large enough to admit the little finger. It had been unsuccessful; and he had, therefore, dissected the cicatrix out, and by wire sutures brought the edges together. A small linear cicatrix only remained after three years; and there was no recurrence as in Mr. Lund's case.—Mr. ANNANDALE (Edinburgh) had listened with great pleasure to the paper. Mr. Adams had been very successful in his two cases. From his own experience, he should have hesitated to interfere with the cicatrices so freely, from fear of sloughing. It was interesting and curious that, in Mr. Adams's cases, there were no such bad results. On the whole, he preferred Mr. Hardie's method, if it did not remove too much.—Mr. LISTER thought that the plan was undoubtedly ingenious; and there could be no harm done if, in the dissection, no veins were wounded. The operation was subcutaneous, and the pins pressed on sound tissue. Experience would show if the cure were permanent. He himself would prefer to dissect out the skin, and, using button-sutures, get primary union with a linear cicatrix.—Mr. ADAMS had cut out the cicatrix in one of his cases. There was necessarily, however, a scar.—Mr. LISTER did not quite understand how there was no scar in Mr. Adams's cases. He thought there must be an improved scar.—Mr. ADAMS explained that the scar became thicker and less conspicuous, because more like the surrounding textures.

A New Rhinoplastic Operation. By J. HARDIE, M.D., Manchester.—Dr. Hardie read a paper on a case of loss of nose, for which he had devised a new operation. The patient was a girl aged sixteen, who had lost her nose in early childhood, from disease. The whole of the organ had been destroyed, with the exception of small portions of both alæ and of the columna, and the margin of the resulting cavity was covered by thin white cicatricial tissue. The principal difficulty to be overcome was

that of securing sufficient prominence to the new substitute. It was evident that if the latter consisted of soft parts alone, it would in a short time become nothing more than a mere covering over the cavity: it was therefore necessary to provide a bony support for the superstructure of soft parts. It was thought that this end might have been attained by partially detaching the nasal process of each superior maxilla, and connecting them in the middle line. On further reflection, however, this method was discarded, as it appeared unlikely that a sufficiently long piece of bone could be obtained to serve instead of both bones and cartilages. It was then determined to endeavour to utilise a portion of one of the patient's fingers for the end in view. Accordingly, an incision was made along the middle of the palmar surface of the last phalanx of the left forefinger, with a transverse incision at its base. Two flaps of skin were then raised, one at each side of the finger. These were then stitched to the previously denuded margins of the cavity, and the arm was carefully supported by means of long strips of adhesive plaster passed round the neck and under the elbow. Union took place on one side by adhesion, on the other by granulation. The arm was retained in its position for the period of three months, in order to secure a complete vascular supply from the face to the finger. Division of the finger was accomplished gradually, with the same end in view; and when the bone was divided with the bone-pliers, effecting complete separation, both ends of it bled. The patient did not suffer from the prolonged constraint. The transplanted phalanx retained its vitality unimpaired. Further operative details were subsequently had recourse to to unite the alæ and columna with the free end of the finger, and to remove the nail. When these steps were completed, the transplanted finger itself presented a very fair substitute for the nose; but in the course of a few weeks it had receded to some extent into the cavity, so that it would still be necessary to carry out the original intention of covering it with a portion of skin. It was thought, however, that, in suitable cases, the finger itself might be used to form an adventitious nose without further covering. In the event of the operation being again undertaken, it was recommended to use a longer portion than one phalanx, to adopt means for narrowing the orifice of the cavity, and to be careful that the finger did not become twisted from a perpendicular line during the process of union.

On the Treatment of Strumous Enlargements of the Glands by Hypodermic Injections. By MORELL MACKENZIE, M.D., London.—The author commenced by stating that his paper had reference principally to disease of the cervical glands, for it was in that situation that it was most important to get rid of the enlargement without disfigurement. Practitioners had always found great difficulties in dealing with these cases, as treatment often exaggerated the deformity. The author stated that, as the results of his experiments with many different solutions, he had found the dilute acetic acid the most valuable remedy. As a rule, he injected once a week; but, where several glands were affected, the injections could be made more frequently. It was desirable, if possible, to cure by absorption; but sometimes suppuration could not be prevented. In these cases, the pus should be drawn off by a fine aspirator. Suppuration was apt to be followed by thickening of the walls or outer portion of the glands. In these cases, the oleate of mercury (ten per cent.) was most valuable. The author then proceeded to quote in detail some of the thirty-six cases which he had treated with acetic acid. He concluded by stating that he did not believe that the cure of these cases rendered the patient more liable to phthisis. He had seen many cases of phthisis develop where glandular enlargements had existed untreated; but he knew of none where pulmonary disease had followed the cure of such cases. On the other hand, he thought that phthisis was more likely to follow the spontaneous breaking down of glandular tissue.

Two Cases of Punctured Fracture of the Frontal Bone treated by Trephining: and resulting, one in total, the other in partial, Loss of Vision. By KELBURNE KING, M.D., F.R.C.S., Hull.—In the first case, the accident arose from the kick of a horse in the left side of the forehead. A punctured fracture of the bone was the result. For some time, no serious symptoms arose. But, a month after the accident, Dr. King trephined the bone, on account of head-symptoms, and removed three portions of the internal plate of the skull which projected through the membranes into the substance of the brain. Abscess and hernia cerebri followed; but eventually the patient recovered, with, however, loss of vision from atrophy of both optic nerves. The second case was that of a sailor, who fell into the hold of a ship, and received, among other injuries, a punctured fracture of the left side of the forehead. Three weeks after the accident, Dr. King trephined the patient. Notwithstanding this, a most serious train of symptoms set in, including paralysis of all the limbs, except the left arm; hyperæsthesia of the legs; blindness, deafness, loss of speech, and delirium. This patient eventually recovered, with blindness of the right eye, caused by atrophy of

the optic nerve.—Mr. NAPPER (Cranleigh) said that, as the result of experience of two cases, he believed that trephining, though easy at the time, yet presented after-difficulties. In one case, suppuration occurred under the dura mater, and the patient died. In a similar case, he would not hesitate to make free incisions.—Mr. W. ADAMS (London) felt doubtful as to whether the fractures should have been termed punctured. They were rather depressed and comminuted. Punctured fractures were produced by a spike, pitchfork, bayonet, etc., but not by the kick of a horse.—Mr. LISTER (Edinburgh) remarked on the interest of the cases. The double vision with one eye was very remarkable. The practical lesson was to show the importance of Syme's rule of trephining in such cases, without waiting for symptoms. As to the terminology, if a fracture were caused by great violence, and the external hole were small, it could be termed punctured. It was unnecessary, however, to stick too closely to terms.—Dr. KING said there would be some hesitation in trephining a lad who rode two miles for advice after the accident. As the result of his experience, however, he thought it would be good to trephine in all cases of punctured fracture. In regard to whether it should be termed a punctured or depressed fracture, it was really a matter of fact; and he should therefore have brought the specimens with him. All the mischief was caused by the splintering of the inner table, and he thought punctured fracture a good name.

Conservative Aural Surgery. By JAMES P. CASSELLS, M.D., Glasgow.—Defining aural surgery as surgical common sense rightly applied, Dr. Cassells insisted that, inasmuch as all intelligent surgery was conservative in its aims, aural surgery was so likewise, because aural surgery was simply general surgery, *plus* special knowledge. But this claim did not rest on inference alone; for it was capable of proof that aural surgery possessed this principle, and that it did not exist as a scientific pursuit if it lacked it. While he admitted that the principle did not always arrest the passing attention in general surgery, it was otherwise in the surgical treatment of the diseases of the organs of special sense, because normal function in them depended upon the complete integrity of their tissues. Apart from this, however, there were special reasons why aural surgery was pre-eminently conservative; these were: 1. Diseases of the ear did not tend of themselves to natural cure, but to become progressively worse, and more serious in their consequences; 2. Of these diseases, only those were preventable and curable that admitted of surgical treatment. These conclusions were the outcome of his own experience and observation. Regarding the congestive diseases of the ear as those in which surgical treatment was demanded, he considered them the only ones in which the conservative principle was applicable, and that early incision of congested tissue was the foundation of conservative aural surgery. Accepting exanthematous catarrh of the tympanum and its appendages as typical of these congestive affections of the organ, he sketched its natural history, and pointed out the two stages in its progress in which aural surgery, as a preventive and preservative method of treatment, was specially indicated: urging its adoption upon the attention of those present, on the grounds that this disease, in its initial stage, was capable of being arrested, and that, in its later stages, its ravages were limitable by the proceeding which he recommended to their notice. While he directed attention specially to this disease as the one in which aural surgery, as a conservative measure, was applicable, he desired to say that its application was not confined to it, but was called for in all the congestive affections of the external ear as well, out of which many serious complications arose. He then referred to paracentesis of the membrana tympani as the operation representative of conservative aural surgery, because this principle was first noticed in connection with the treatment of the disease, the history of which he had sketched, by the operation which he had just named, and which he now recommended to the profession, with certain modifications based upon and suggested by a more perfect pathological and clinical knowledge. He then glanced at the history of the operation, which was, indeed, the history of the origin of the principle of conservatism in this department of medical science; and concluded by saying that the aims of aural surgery, whether exhibited in simple incision of congested tissue, or in the more pretentious operation of paracentesis of the membrana tympani, were to prevent and to preserve, and that it was misapplied if employed for any other object.—Mr. LUND (Manchester) asked the form and direction of the incision in the membrana tympani, and the kind of knife used.—Mr. RIVINGTON (London) said that Dr. Cassells' proposal was no novelty, as it was merely an extension of the plan of cutting through the membrana tympani when fluid was effused into the tympanic cavity. It rested with the general practitioner to carry out the suggestion, as the aural surgeon only saw the case when the mischief was irreparable. They should, therefore, examine the state of their patients' ears during the stages of scarlatina. Specialists were now endeavouring to press their specialism on the general practitioner; and this would certainly

be a benefit to the public.—Mr. LENNIX BROWNE (London) agreed with Mr. Rivington as to his views on specialists. The latter did not see cases until the mischief was done. They were, therefore, grateful to Dr. Cassells for directing attention to a means of preventing those sequelæ of which otorrhœa was the most favourable, and was even expected. He agreed with him as to incision where there was pus; but he doubted if the general practitioner would incise before fluid collected. The incision by the knife had the advantage over the perforation by ulceration of healing rapidly.—Dr. CASSELLS, in reply, related the case of the child of a medical man brought to him after reading one of his papers. The hearing in one ear was gone; but, by this operation, that of the other was saved. He did not lay claim to originality, as the operation had been introduced by Saunders, the father of English aural surgery. He himself had pointed out the definite stages at which the operation should be done. In scarlatina, the incision should always be made before the fluid accumulated, so as to get resolution. When in general practice, he had always acted on this rule. As to the operation, he did not, from want of time, give precise details. They could be found in the *Glasgow Medical Journal* for 1872. The incision should be made from top to bottom, in the middle of the posterior half of the membrana tympani, behind and parallel to the handle of the malleus, as fluid collected behind in the mastoid cells.

Provincial Surgery in Scotland, illustrated by cases treated in the Alloa Hospital. By PETER BROTHERSTON, F.R.C.S.Ed., Alloa.—The hospital has been in existence for the last six years, and is situated on rising ground, a little to the north of the town of Alloa. The population of the town is about ten thousand, and that of the county fourteen thousand; and the building has been found completely adequate to the wants of the locality. The surgical hospital consists of two wards, with six beds each; and a small room for seclusion, with two beds, an operating room, kitchen, nurses' apartments, etc. There has been no difficulty in procuring funds for its maintenance; and the erection of similar institutions was urged wherever needed, from consideration of the favourable results that have been here obtained. During the six years of its existence, there have been treated in it nine fractures of the radius and ulna; four fractures of the neck of the humerus; two fractures of the humerus; ten fractures of both bones of the leg, fourteen fractures of the thigh, and one compound fracture of the thigh, all of which recovered. Of ten amputations of the thigh, eight recovered. Of four excisions of the knee, only one did well. Of four amputations of the leg, two amputations of the arm, three amputations of the forearm, twenty-four amputations below the carpus, four excisions of the mammae, one case of lithotomy, one case of extirpation of the testicle, all of which recovered, as well as the ordinary amount of smaller cases, I need not specify. The average annual expenditure has been about £250; and the whole original cost of the institution was £1,270, including furniture, etc. There was built in connection with the surgical hospital a house for the treatment of infectious diseases; and it is, in all its arrangements, entirely separate. It consists of two wards, containing in all fourteen beds. This separate building is partly maintained by the Burgh and Parochial Board, each contributing £10; and it has been found of the greatest service, on several occasions, when Alloa was threatened with an invasion of small-pox and typhus fever.—Dr. G. H. B. MACLEOD (Glasgow) remarked on the interest of the paper as showing the immense benefits of such provincial hospitals. As the surgeon, however, of an infirmary once fed from Alloa, but now hardly getting a single case from it, he hardly saw the advantages as strongly as Mr. Brotherstone did.

New Operation for Ununited Fractures. By MATTHEW HILL, F.R.C.S., and M.R.C.P.Ed., Bootle, Liverpool.—The operation devised by Mr. Hill for the cure of ununited fractures consists, like Dieffenbach's, in driving ivory pegs into the fragment, but is different in all other respects. The old operation entails a large wound in the soft parts and exposure of the bone, in short, renders the fracture "compound": in the new operation this is avoided, the pegging being done subcutaneously. The necessary tools are an Archimedean-screw drill-stock with two or three drills, and ivory stilettes about four or five inches long. The drill and stilettes are similarly graduated in half inches, and the ivory is, moreover, grooved like a director in order to facilitate its introduction alongside the drill, and afterwards to allow the escape of inflammatory fluids, which might otherwise be pent up in the bony fragments. The *modus operandi* consists in entering the drill through a puncture made by a tenotome; the boring of the bone is next proceeded with, the graduations enabling the operator to calculate his depth to a nicety. The ivory stilette is now filed transversely half way through, at a distance from the point corresponding to the depth of the hole in the bone; it is next slid down beside the drill, which is then withdrawn, the stilette slipped into its place, lightly hammered, and with a sharp twist broken off at the notch, flush with the surface of

the bone. The remainder of the ivory is now withdrawn, and the puncture sealed with a strip of plaster. It is obvious that as many pegs may be introduced in this manner as is thought desirable; in the author's case three were introduced without causing any subsequent mischief or the formation of abscess. The punctures healed kindly and by the "first intention".—Dr. G. H. B. MACLEOD (Glasgow) said that the operation was undoubtedly something new, and he only regretted they did not know the end of the case. For his own part, he had seen such admirable results from the antiseptic treatment of open wounds, that he preferred to cut down on such cases antiseptically. Mr. Hill's method, however, was most ingenious.—Mr. J. D. MORRISON (Edinburgh) drew attention to his modification of the Archimedeian screw, by which only one hand was needed, and greater delicacy of touch secured.—Mr. LUND (Manchester) had tried the method of drilling bones, but had become disheartened. He used a five-sided broach. Mr. Morrison's ingenious instrument would be a great help.—Mr. ANNANDALE (Edinburgh) had found the common bradawl or pricker of the joiner to work as well as any apparatus. It was cheap, in addition, only costing about threepence.—Mr. HILL, in reply, said that the drill-stock was a minor point. The important fact in the operation was its being done subcutaneously.

On Section of the Cornea in certain Diseases of the Eye of Inflammatory Origin. By J. VOSE SOLOMON, F.R.C.S.E., Birmingham.—The late Mr. Guthrie recommended that large collections of pus in the anterior chamber should be treated by a free vertical incision through the cornea. Mr. Solomon tried this plan in a case in 1852; but the result was unsatisfactory, probably because the operation was too long deferred. In 1873 and 1874, he successfully treated by free incision several cases of extensive hypopyon, abscess, and diffuse purulent infiltration of the cornea. The general results of his treatment were, immediate relief from pain; preservation of the curve of the cornea, and consequently lessened astigmatism; the prevention of synechia anterior and staphyloma; and limitation of the resulting leucoma. The cicatrix formed merely a thin white line. Several illustrative cases were described.

On the Treatment of some Diseases affecting simultaneously the Voice, Speech, and Hearing. By LENNOX BROWNE, F.R.C.S. Ed., London.

Subcutaneous Operation for the Relief of Fibrous Ankylosis of the Knee-joint. By C. F. MAUNDER, F.R.C.S. Eng., London.—The patient was a man, aged 33, who was admitted into the London Hospital, on May 12th, 1875. About three years ago, the right patella was broken into three pieces. The knee had been stiff ever since, and he had injured it on two other occasions. Amputation had been suggested. He walked like a man with a wooden leg, swinging the right limb in a half circle. The joint was the seat of firm fibrous ankylosis; the fragments of the patella, and the tibia and femur, being immovable one upon the other. On May 19th, the patient being under the influence of chloroform, Mr. Maunder forcibly flexed the leg, the adhesions breaking audibly. There was considerable swelling and ecchymosis afterwards; but no good resulted. On June 2nd, the fragments of the patella and their fibrous bond of union were severed from the fibrous tissue occupying the joint. A strong tenotomy-knife was entered on the inner side just above the patella; and, the desired section being made, the wound was closed in the usual way, as in tenotomy; and then the leg was forcibly and freely flexed. On the fourth day, passive movement was commenced, and the patient was encouraged to practise flexion and extension of the leg. On July 27th, he was able to perform both these movements, and walked with a scarcely perceptible halt.

On Egyptian Ophthalmia and Cataract Complications; with Cases.

By J. R. WOLFE, M.D., Glasgow.—For the last six years, Dr. Wolfe had adopted a new method of treating that intractable disease. The results were highly satisfactory, and he related the following cases: 1. Granulation with pannus of four years' standing; complete cure; central opacity of cornea remedied by formation of new pupil; 2. Granulation with double cataract, of nine years' duration; cured, and double extraction successfully performed; 3. Granular lids with pannus, complicated with traumatic cataract; pannus cured, and cataract successfully extracted. The method of treatment which he adopted consisted of: 1. Scarification of the whole conjunctival *cul-de-sac* once or twice a week; 2. Daily application of the syrup of tannin (two drachms to one ounce).

Friday, August 6th.

Professor PIRRIE, and afterwards Mr. ANNANDALE, occupied the Chair.

Remarks on the Varieties of Wry-neck, and its Treatment. By W. J. LITTLE, M.D.—The author described three groups of cases met with in practice: 1. Those caused by rheumatic and strumous disease of

the bones, ligaments, and glands of the cervical region, and by cicatrices of burns and wounds; 2. Those having a congenital origin, which exhibit more or less rigid contraction and structural shortening of one portion or the whole of the sterno-cleido-mastoid muscle, and which present considerable analogy with congenital club-foot; 3. Spasmodic wry-neck, induced in middle life from derangement of the cerebro-spinal nerve-centres. The treatment of cases due to past or present vertebral disease, and of burn and cicatrix cases, demands more or less elaborate mechanical aid; whilst those arising from congenital contraction often require subcutaneous division of one or both portions of the sterno-cleido-mastoid, and the subsequent use of a common roller and plaster bandage with a leather-padded collar only, made higher on the contracted side. Photographs illustrating each of these forms of wry-neck before and after treatment were exhibited.—Mr. FOLKLER (Hanley) asked how the incision was made.—Dr. LITTLE replied that he divided the tendon about one inch above the clavicle, where there was the deepest arch below it. Care should be taken that the assistant did not pull too hard.—Mr. GRAHAM asked if, in spasmodic cases, there was any return after operation. In one case he had operated on, there was no return twelve months afterwards.—Dr. LITTLE had had a case of recurrence two months after operation. In these cases, according to Langenbeck and Stromeyer, the knife acted as a narcotic. He did not mean to question the accuracy of Mr. Graham's observation, but yet congenital wry-neck often appeared like the spasmodic form. In the unmistakably spasmodic cases, division did little good.—Dr. PIRRIE (Aberdeen) had listened with great pleasure to Dr. Little's paper.

Notes on the Modern Methods of Extracting Cataract. By C. B. TAYLOR, M.D., Nottingham.—Since patients suffering from cataract were operated upon by extraction, no method, when successful, had yielded more brilliant results than Daviel's process of removing the lens by making a flap of one-half of the cornea. The fatality, however, attending this operation, even in the most competent hands, had led to its abandonment, and the substitution of various alternative measures. One of the first of these was advocated by Mooren, who proposed to avoid prolapse of the iris by excising a portion of this membrane some weeks prior to the removal of the lens. This rendered the extraction much safer, but it involved two operations, and the risks attendant upon the large flap remained; hence Schulte began to extract through a small linear incision, lifting out the lens with a spoon; this was abandoned for the more scientific methods introduced by Von Graefe and the author simultaneously [See original paper by the author in *Ophthalmic Review*, 1865.] These methods reduced the immediate loss from upwards of ten per cent. to about three per cent., and diminished the partial failures one-half. The pupil, however, was sacrificed, and in order to combine the advantages of a perfect pupil with the safeguard of an iridectomy, the author excised only a small portion of the periphery of the iris, leaving the pupil untouched. This operation yielded excellent results in the author's hands in upwards of thirty cases, and had been highly commended from results in his own practice by Mr. Brudenell Carter. The process, however, was delicate and tedious. To avoid the flap, retain the advantages of a linear incision, and still save the pupil, Dr. Kuehler of Darmstadt extracted through a wound made directly across the centre of the cornea. Mr. Bader of Guy's Hospital also practised a similar incision, only a little below the pupil; and Mr. Liebreich made one a little lower still. Dr. Vincente Chiralt, Lebrun, and Warlomont had adopted, in succession, exactly the same form of incision as Mr. Liebreich, but placed it above the pupil. The author had nevertheless obtained excellent results in some cases with both the lower and upper forms of incision; and his experience had been, that the nearer the wound approached the corneo-sclerotic junction, the less risk there was of any of the evil results enumerated above. After many trials, and a careful study of numerous cases, both in this country and on the continent, he concluded that the safest form of incision was a transverse one at about the upper third of the cornea. At first, a portion of iris was excised as a part of the operation; but, subsequently, the author proposed to dispense with the iridectomy in certain cases; and afterwards, in consequence of the greater facility and consequent diminished risk attending the various steps of the operation, a section at the lower third of the cornea was adopted. In this way a shallow slit-like flap was formed, comprising only one-third of the cornea, and lying in the corneo-sclerotic junction. This permitted the ready exit of the lens through the natural pupil, and left no trace afterwards; being close to vascular tissue, it healed rapidly; any prolapse of the iris was readily replaced at the time, and if the pupil were maintained in a contracted state by the instillation of Calabar bean, the prolapse did not return. The wound healed in twenty-four hours, after which atropine might be used if desirable. The operation was singularly safe, and successful as to the appearance of the patient and the power of vision.

The Treatment of Spina Bifida. By J. MORTON, M.D., Glasgow.—Dr. Morton's paper on spina bifida referred to the hopelessness with which such cases were regarded previously to 1871, and stated that many still regarded them as necessarily fatal. In the autumn of that year, a case presented itself in the wards of the Glasgow Royal Infirmary, which induced him to consider whether he could not abandon the do-nothing system, and it was treated successfully by injecting the iodo-glycerine solution. Since that time, six other cases had been so treated with a like result by Dr. Morton and others. All the lumbar and dorsal cases treated by Dr. Morton himself had been fortunate. In only three other cases had the iodo-glycerine injection been used, and these succumbed, not from any direct effects of the operation; one was otherwise hopelessly deformed and paralytic, and probably not a fit case for any interference; another died from debility; the third, under Dr. Morton's own care, died from convulsions due to the draining away of the cerebro-spinal fluid, which might readily have been prevented had the child been resident in the hospital. So far as was known, these were all the cases in which this mode of treatment had been employed. Collodion, either common or flexible, was used to close the apertures necessarily made, and had always answered the purpose. Hitherto seventy per cent. of the cases had been cured, taking even the worst view of the cases; but, discounting the paralysed and deformed ones, there might be about eighty per cent. The mode of managing them was described.—Mr. MEADE (Bradford) asked if the early cases had been kept in view, so as to see that there was no paralysis or other after-effects.—Dr. MORTON said that he had done so, and found no bad effects following. It was curious, that in none of the cases given was there any paralysis.—Mr. GRAHAM said that the general experience was, that one out of three cases operated on died. The results under Dr. Morton's treatment were most gratifying, and he hoped that the good effects would continue.—Mr. ANNANDALE (Edinburgh) congratulated Dr. Morton on his success. From a large experience of his own and others' cases, especially those of the late Professor Syme, he had come to the conclusion that interference generally caused death. Indeed, latterly, Mr. Syme did not operate. In some cases, he had seen spontaneous cures; but the success of Dr. Morton's plan was most gratifying.—Dr. PIRRIE (Aberdeen) felt indebted to Dr. Morton for his valuable paper. He had listened to it with great interest. Hitherto his opinions had been similar to those of Mr. Annandale. Dr. Morton's plan, however, opened up quite a new field. In regard to pathological specimens of spina bifida, he might mention that, in the Association Museum, a very fine specimen of its occurrence in the lumbar region was shown by him. In it a vesicular process of the sacral nerves could be seen passing through the fissure, to become adherent to the posterior wall.

A Case of Strumous or Tubercular Disease of the Breast simulating Scirrhus. By R. H. MEADE, F.R.C.S. Eng., Bradford.

Further Observations on the Electrolytic Dispersion of Tumours. By JULIUS ALTHAUS, M.D., London.—He stated that it was now pretty well ascertained what electrolysis could do, and what it could not do; and that its sphere of usefulness was not likely to be much curtailed or enlarged by future researches. Regarding the mode of application, he remarked that the voltaic current was conveyed to the tumours by means of gold needles, which acted either in fixed rows or singly, in any direction that might be required, by means of the serres-fines conductor; and that either the influence of the negative pole alone, or that of both poles simultaneously, was utilised. Electrolysis was very useful in certain forms of nævus; and the author pointed out its advantages over excision, the injection of perchloride of iron, nitric acid, the subcutaneous ligature, and the galvanic cautery. Cystic bronchocele yielded readily to it, and solid bronchocele more slowly. A remarkable case of the latter affection was related, in which the patient's life was in imminent danger from pressure of a rapidly growing tumour on the pneumogastric nerve. Sir William Fergusson had refused to operate, but the patient got ultimately quite well under the author's care. Sebaceous tumours yielded readily to electrolysis, which was likewise useful in recurrent fibroid and secondary cancer. It was not possible by this means to eradicate the cancerous diathesis, or to prevent the tendency to death; but it was most effectual for the relief of the pain; promoted sleep and appetite, and soothed and strengthened the system generally. Dr. Althaus related a case of secondary cancer of the breast, in which the suffering had been intense; but where the last few weeks of life were rendered perfectly comfortable by the use of electrolysis, the patient ultimately sinking from congestion of the lungs, brought on by exposure. The author wound up by requesting his hearers to use electrolysis more largely in suitable cases than had hitherto been done, and showed the instruments which he generally employed for his operations.—Dr. JOHN DUNCAN (Edinburgh) said that Dr. Althaus had the largest experience of anyone as to this mode of treat-

ment, which, he believed, would come still more into use. He himself had considerable experience of its use in the treatment of aneurism and nævus. In certain cases of aneurism, it was admirable. In aortic aneurism, however, it was disappointing, as, although it gave relief, yet it did not cure. It was certainly best in cirroid aneurism, or aneurism by anastomosis. He had referred to the treatment of nævus by this plan; but for the plethora of papers in this Section, he would have made a written communication on this subject. The method was perfectly safe and certain. It had the disadvantages of leaving a scar when performed too quickly, and of being tedious when done too slowly. Its use should be limited to cases where it was important to have no scar, such as the face and other exposed parts. Where a scar did not matter, something more rapid should be used. In the treatment of other tumours by it, he had little experience. He found it extremely tedious when done slowly; and, when done quickly, there was risk of sloughing. This was nothing mysterious. When done slowly, there was destruction of texture and then absorption. But, when it was too quickly performed, the destroyed texture came away as sloughs. He had used with advantage a needle in which the part in contact with the skin was insulated, and only that below the skin free from such a protection. In this way, there was no risk of slough or scar. He could confirm what Dr. Althaus had said as to its giving relief from pain in certain cases, especially in vascular cancer. In a case of pulsating sarcoma of the neck (primary), which he had seen through the kindness of Dr. George Balfour, there was great pain; so that the patient could not sleep for more than ten minutes. After the operation, however, he got rest for four nights. This fact he could not explain; but, from his experience of this and another case, he thought that the irritation of the electrolysis increased growth; and, therefore, the surgeon had to choose between causing increased rapidity of growth and giving relief to the patient.—Dr. J. C. HUME could confirm what Dr. Duncan had said as to the use of an insulated needle. His experience was limited to two or three cases of nævus in the face. In the first, the nævus occupied the extremity and length of the nose. Unfortunately, the child died from bronchitis. In the second case, the nævus extended over the whole of one cheek. Although the treatment was protracted, yet the cure was satisfactory. At present, he had another case under treatment, where the bridge of the nose, one cheek, and both eyelids were affected. In none of these cases was there any scar left.—Mr. LENNIX BROWNE (London) was so well acquainted with Dr. Althaus's treatment, that he could bear testimony to its effects on nævi and the softer forms of enlargement of the thyroid body. Its advantages in treating the latter form of disease, viz., preventing hæmorrhage and leaving no scar, he had omitted to mention, when speaking on this subject at a former meeting of the Section.—Dr. BUCHANAN (Glasgow) did not feel qualified to give a general opinion as to this method. But, in regard to nævi, he believed that, in the vast majority of cases, excision was the safest, easiest, and best plan. There were few instances in which it was not applicable.—Dr. ALTHAUS said that reply was hardly necessary, as most of the speakers had agreed with him. He was especially pleased with Dr. Duncan's remarks. In regard to electrolysis causing increased rapidity of growth, they should remember that Dr. Duncan's case was a primary cancer; whereas it was in secondary cancer that it was most applicable.

Tertiary Sore-Throat. By C. R. DRYSDALE, M.D., London.—Tertiary sore-throat was readily divisible into two forms: 1, the ulcerative; 2, the gummy. The ulcerative form of tertiary sore-throat was seen chiefly on the tonsils, or posterior wall of the pharynx, and was comparatively rare. It might occasion discomfort in swallowing, and pain in the ear. It might be extensive enough to remove the whole of one tonsil. The gummy tumour of the soft and hard palate was the commonest, perhaps, of all the symptoms of tertiary syphilis. Gummy tumour of the velum commenced by the deposition of small masses of gummy material in the substance of the soft palate, which at an early stage made the soft palate feel to the touch as if it contained small bodies, such as cherry-stones or split-peas, in its substance. In a short time, the inflammatory stage supervened, and the mucous membrane over the infiltrated part became dusky-red, glistening, or varnished in appearance. To the touch, the parts felt greatly thickened, and were sometimes twice or thrice as thick as in the normal condition. The velum became immovable at the infiltrated part. The disease was often insidious in its approaches. Patients not unfrequently came to the practitioner with perforation of the soft palate, who had never known the danger they were incurring by their neglect of the very slight symptoms in the throat. When inflammation had once set in, the disease went on with great rapidity. The infiltrated part became softened, and a slough came rapidly away, so that perforation or complete division of the soft palate into two lateral flaps might occur in two or three days. It was, on this account, of the greatest importance that

practitioners should be habituated to diagnose at once the characters of the tertiary sore-throat; since any delay in remedies exposed the patient to two grave infirmities. The first of these was the loss of voice, which was in proportion to the extent of perforation of the velum; and the second was the regurgitation of food, and especially drinks, by the nostrils, when the perforation of the velum was not very small. The loss of the voice was sometimes almost total. The regurgitation of liquids was often a serious matter, producing emaciation and death from asthenia. Perforations of the hard palate from gummy deposit were also common, and produced the same effects; and were amenable to the same remedy. In the treatment, caustics should not be used in the inflammations connected with gummy sore-throat. Nor should such tumours be touched with the knife. What was indicated was the administration of the iodide of potassium at once, in large doses of fifteen grains four times daily. Mercury in such cases was powerless, or nearly so; and was only to be tried when the iodide failed, which it did in rare cases.

The Surgical Treatment of Lymphatic Tumours of the Neck. By S. MESSENGER BRADLEY, F.R.C.S., Manchester.—Mr. Bradley limited his paper to the consideration of certain nuchal lymphatic tumours, which he divided into three classes: 1. True hypertrophies, with or without a strumous diathesis, and showing no tendency to break down or undergo pathological change; 2. Strumous hypertrophies, consisting of cellular hyperplasia plus caseous deposit, which, after a time, soften either in patches or entirely, until the gland becomes a mass of soft strumous matter; and 3. Hard non-infectious lymphomata. Mr. Bradley said that, as a rule, these cases were lumped together and treated generally, indiscriminately and unsatisfactorily by the local application of iodine and the internal administration of cod-liver oil, etc. It was his wish to substitute an arm of precision for this hit or miss method; and, from an extensive trial, he was able to say that, by a proper selection of cases, this could be done. For several months he had injected the harder lymphatic tumours with a few drops of tincture of iodine, with the almost invariable result of causing a rapid diminution, going on to complete absorption of the gland. He had even succeeded in producing absorption of some encapsulated tumours situated on the salivary glands by this means, but confined himself at present to recommending this mode of treatment in hypertrophies of the lymphatic glands. As a rule, two or three injections of from five to fifteen minims of the simple (P.B.) tincture of iodine, was sufficient to effect a cure. No other treatment was necessary. This plan had the advantage of being comparatively painless, safe, and speedy. It was not applicable to all lymphatic tumours, and, if used indiscriminately, would fall into disfavour and disrepute. To avoid this, he laid down the following rules for the surgical treatment of these nuchal tumours: 1. *Cases to be treated by Injection of Iodine:* a. True hypertrophies of cervical glands without scrofula; b. Strumous hypertrophies of cervical glands before they have broken down; c. Hard (non-infectious) lymphomata; d. All encapsulated tumours, as a tentative operation. 2. *Cases to be treated by Incision:* Lymphatic tumours that have, either with or without previous injection of iodine, broken down into pus. 3. *Cases of Cervical Tumours to be treated by Extirpation with the Knife:* a. Strumous glands which form tumours riddled with soft patches, and resting on a base of suppurating cellular tissue, with a large area of blue skin; b. Encapsulated tumours which have resisted the treatment by injection.

Severe Cerebro-Spinal Symptoms produced by a Fall at Football. By P. M. BRADWOOD, M.D., Birkenhead.—The symptoms were produced by fall on his back suffered by a young lad through missing a drop-kick at football. He thought the case worthy of the attention of surgeons, as being a rare instance of severe nervous symptoms being caused by a slight accident.

On Extirpation of the Tongue. By JOHN C. HIRSCHFELD, M.B., Banff.—The author briefly commented on the various operations for the removal of the tongue, and recommended the following plan, as obviating the risk of hæmorrhage, and removing various objections to other proceedings. The patient having been put under the influence of an anæsthetic, the lingual arteries are tied. The vessel is exposed by making an incision an inch and a half or two inches in length above and parallel to the great cornu of the hyoid bone, turning up the sub-maxillary gland, and dividing the fibres of the hyoglossus muscle. The mouth is then opened by depressing the lower jaw; and the tongue is then cut off close to the hyoid bone. If the mouth be small, the aperture may be enlarged by cutting from the angle of the mouth into the cheek. The author believed that epithelial cancer of the tongue had comparatively little tendency to spread.—Dr. JOHN DUNCAN (Edinburgh) said that the principle of preliminary ligature of both lingual arteries was a sound one. But it must be remembered that, in almost any operations near the lingual, it could be easily exposed, and an aneurism-

needle passed or pressure applied by means of the finger. He thought that the risk of hæmorrhage after the *érasaur* or galvano-cautery was magnified. He had not used the latter in removal of the tongue; but had found it of great advantage in removing, without risk of hæmorrhage, syphilitic growths of the genital organs.—Dr. GRAHAM had used the galvano-cautery in extirpation of the tongue without hæmorrhage or any untoward result. His plan was to sever the lateral attachment of the tongue to the mucous membrane by means of scissors. A straight incision was then made from the chin to the hyoid bone. Two needles were next applied, so as to graze the top of the hyoid; and then, by means of a platinum loop, the whole organ could be easily removed.—Mr. ANNANDALE (Edinburgh) understood Dr. Hirschfeld to say that the epithelial form of cancer, which chiefly affected the tongue, had little tendency to spread. He did not think that this was the case. He had operated in many instances, and found that the tendency to spread was very great. It most frequently began in the lateral half of the organ, and then implicated the muscles and mucous membrane. It was, therefore, advantageous to operate completely. This could best be done by dividing the jaw. When the disease was limited, the galvano-cautery could be used; but there was risk of a portion of the disease being left behind. Although the galvano-cautery ensured less risk of hæmorrhage and left a safer wound, yet he preferred first dividing the jaw, so as to expose the tongue in all its connections. The galvano-cautery or *érasaur* could then be used.—Dr. HIRSCHFELD, in reply, said that he believed the preliminary ligature of the linguals to be a great help in preventing all hæmorrhage.

The Nourishment of the Head of the Femur after Intracapsular Fracture. By F. OGSTON, jun., M.D., Aberdeen.—After an introductory description of the state of parts in an old ununited intracapsular fracture, and a short review of the theories which had been brought forward to account for the healthy state in which the head of the femur is frequently found after this injury, a third method was indicated as an efficient one; viz., that the head of the femur is supplied with an abundant supply of blood by the capsule reflected along the neck. This view was supported by quotations, by diagrams, and by reference to injections of this structure, showing that blood-vessels pass through the reflected capsule and pierce the head of the femur, and that this connecting band remains uninterrupted in those cases where the head of the bone is found well nourished, while it is wholly ruptured when the head of the bone is found to be wasted. The statement of Hyrtl, that vessels do not reach the head of the femur by the round ligament, was shown to be incorrect, since in one of the cases quoted the injection entered it by this channel.

On Fibrous Tumours of the Auricle. By J. J. KIRK DUNCANSON, M.D., Edinburgh.—The auricle is subject to a variety of diseases, and growths of various kinds are found affecting different parts of it, arising from the different structures of which it is composed. They may be tumours containing hydatids, masses of fatty matter; or they may be steatomatous, sebaceous, encysted or fibrous tumours. Hypertrophy of the lobule, as well as tubercles of a gouty nature, spread over the auricle, may occur in subjects of a gouty diathesis. Elephantiasis has been known to attack the auricle, and cancer of an epithelial nature affects the auricle independently of any other seat in the body. Fibrous tumours of the auricle occur in the lobule of the ear. They have been most frequently met with in the ears of the negroes of the Brazils, and some African tribes; but they are to be met with in all countries where the practice of piercing the lobule of the ear for the wearing of earrings or other ornaments is customary. Various reasons are given for their occurrence by different authors. According to some, they arise from the act of piercing the lobule of the ear in certain constitutions; others say they are caused by the irritation of the articles worn, such as brass earrings. Shortly after the lobules of the ears have been pierced, or not until some irritation by the articles worn, pain and swelling supervene. These are followed by a more defined swelling in the track of the puncture, and this swelling may become a well marked fibrous tumour. Paget says there may be, perhaps, some doubt whether the growth be a proper tumour, or a cheloid growth of the cicatrix tissue, formed in the track of the wound; but it has the aspect of a distinct fibrous tumour, and the skin appears unaffected; they are recurrent. According to Billroth, these tumours consist chiefly of spindle-shaped cells and connective tissue, and are merely an hypertrophy of the cicatrix, similar to tumours growing from cicatrices on other parts of the body (keloid). St. John Roosa calls them fibro-cartilaginous, and says they are a simple hypertrophy of the normal structures. They occur more frequently in the African than in the Caucasian race.

Anæsthetic Agents.—On the proposal of Mr. ANNANDALE, the Section passed a resolution recommending the appointment of a Committee to inquire into and report on the use of anæsthetics. (See JOURNAL, August 14th, page 214, col. 2.)

SECTION D.—PUBLIC MEDICINE.

THE papers in this Section have been arranged in the following groups, of which one was taken up on each day that the Section met.

- A. Contagion and Infectious Diseases.
- B. Medical Legislation, Meteorology and Disease, Statistics of Disease, etc.
- C. General Sanitary Arrangements; Drainage, Water-supply, Ventilation.

Wednesday, August 4th.

GROUP A.—CONTAGIOUS AND INFECTIVE DISEASES.

The President, the Right Hon. LYON PLAYFAIR, M.P., took the Chair at 2 P.M.

Contribution to the Life-history of Contagium. By P. M. BRAIDWOOD, M.D., and F. VACHER, Esq., Birkenhead.—Having carefully reviewed the literature of the subject up to date, including the papers in the recently issued reports of the medical officer of the Privy Council, the authors proceeded to give particulars of their own investigations. The questions, it was the purpose of these researches to elucidate, were thus stated: (a) What is contagium? (b) In what manner is it generated or communicated? (c) What are the conditions on which its life or activity depend? The results of inoculations on eighteen subjects with water containing the soluble constituents of vaccine lymph were recorded. It was explained that diffusion was effected in the manner adopted by Dr. Burdon Sanderson, but the diffusates were more concentrated than those used by previous investigators; and the authors submitted that, by testing the effects of the diffusate first, and in no case vaccinating till a given time after making the abortive insertions, they avoided a possible source of error with which the method of procedure of M. Chauveau and Dr. Sanderson was chargeable. Of seventy-two punctures inoculated with the diffusate, seventy-one failed entirely. As proving that the exception to M. Chauveau and Dr. Sanderson's experiments was valid, the authors tried the effects of vaccinating with lymph pure and diluted simultaneously, and found that the maturing of vesicles at the points treated with pure lymph tended to prevent the formation of vesicles at the points treated with the artificially weakened virus. The conclusion arrived at on this point was, that there is the strongest indirect proof (there can be no direct proof till we can wash off all trace of plasma from the bodies it suspends) that the contagium of the virus with which we are most familiar, consists of particles neither soluble in water nor in watery liquid. The next series of experiments reported were for the purpose of determining some of the conditions affecting the activity of the type—contagium. They consisted of animal vaccinations, retrovaccinations of cows and heifers, inoculations with lymph preserved by different methods for various lengths of time, and vaccinations with mixtures of lymph and various so-called antiseptics or germicides. As regards the results obtained from this last group of experiments, it was stated that combinations of vaccine and carbolic acid solution for sixty-four insertions yielded nine vesicles; that sulphuric acid vaccine failed to produce vesicles; that ozonised and chlorinised vaccine also entirely failed; that vaccine mixed with a saturated neutral solution of quinine retained its activity; that a mixture of lymph and liquor potassæ permanganatis (B. P.) gave doubtful results; that chloralum on being mixed with lymph did not affect its activity. The third series of observations referred to the local manifestations incidental to vaccination. The authors vaccinated a heifer at several points, and day by day removed successive portions of skin where vaccine had been inserted. Sections, vertical and oblique, were then made and tinged with carmine, these being subjected to examinations with high and low powers. The preparations and drawings from them were exhibited.

On the Nature of Contagion. By T. J. MACLAGAN, M.D., Dundee.—The author first referred to what is known regarding contagion, and then proceeded to show that the view which gave the best explanation of co-existent facts is that which regards it as consisting of minute living organisms, probably of albuminous composition, possessing the power of organic development; always reproducing their own kind; capable, under favourable circumstances, of preserving their vitality for a considerable period; but speedily perishing when separated from these conditions and freely exposed to the atmosphere.—The PRESIDENT said that long ago he was a strong advocate of the chemical theory of contagion; and the most beautiful specimen of inductive reasoning we possessed was Baron Liebig's chapter on contagion and miasm. Modern research, however, had given little support to this view. The very specific character of contagion—its power of reproduction—was an argument in favour of the germ-theory. It was as certain that whatever produced scarlet fever would produce scarlet fever, as that a dog would produce a puppy, or a rose-tree would produce a rose-tree.—Dr. CARPENTER (Croydon) pointed out that, in

the dilution of the vaccine lymph with distilled water, the small quantity of alkali in that water might have rendered the vaccine material inactive, and hence followed the want of results which might have followed with the addition of some chemical agent such as carbolic acid. As to contagion, he thought it was to be traced to some organic germ, which might, under certain meteorological or physical conditions, develop into one or other of the diseases to which the human body was liable.—Mr. J. A. WANKLYN (London) pointed out that, though the water used to dilute the lymph referred to in the first paper was not perfectly pure, the experiments were all the more cogent, inasmuch as they proved that contagia were destructible by water. This fact of the germ-forms losing their power was of very great importance; and, if they admitted the accuracy of these experiments, they must admit the possibility of destroying every poison-germ by dilution. As to the nature of contagion, while not defending the chemical theory, he held that, unless they could discriminate germs, the germ-theory had no vitality in it.—Dr. MACNAMARA (Calcutta) was doubtful as to diseases being alone capable of reproducing themselves; for scarlet fever was never found in India, or cholera in Australia, although both countries were in communication with the West and with each other.

Scarlet Fever: How to Prevent its Spread. By J. M. FOX, M.R.C.S.E., Amnaside, Cockermonth.—The paper commenced with a statement that facts in sanitary science are sometimes brought to light with greater distinctness in small towns, where observation may be more complete and conditions are less mixed, than in larger urban areas. An epidemic of scarlet fever during 1874 in Cockermonth had impressed the writer with the conviction that, in order to prevent the spread of this complaint, it is essential that local sanitary authorities should, under the advice of their medical officer, have the full statutory power: 1. To fine the parents or guardians of children attending any school from an infected house; 2. To close all schools, public and private, during such time as their order may direct; 3. To order the disinfecting and lime-washing of such premises. He also considered that all dame-schools and other schools, public and private, should, in regard to all matters affecting health, stand to the local authority precisely as lodging-houses and slaughter-houses do; and that it should not be lawful for any school, public or private, after the passing of a statute to that effect, to be opened without a certificate signed by the Chairman of the Local Authority, defining the number of children to be accommodated in such school, and otherwise approving its general sanitary arrangements. The paper strongly urged the Association to use its influence, in order to obtain these additions to sanitary law. These recommendations were illustrated by reference to the epidemic of scarlet fever in Cockermonth alluded to above. The town had a good sanitary character, being well situated and having a good system of sewerage and a faultless water-supply. There were but two deaths in the year from typhoid fever, one from typhus, and nine from diarrhoea, five of which occurred in the workhouse. There were two deaths of adults from diphtheria, one in a house saturated with scarlet fever poison, and the other that of a butcher living near a slaughter-house now closed. All the other slaughter-houses were well kept, being under frequent inspection. Not a single fatal case of scarlet fever, and very few of illness, were found amongst adults; indeed, out of thirty-four deaths, only four occurred under one year of age, the remaining thirty being between the ages of two and seven and a half years. It seemed clear, therefore, that the disease did not follow the track of any known sanitary defects, and that children, not young infants, were the sole objects of its attack. It was admitted that the health of children is a test of general hygienic conditions; but not to that degree that any such conditions are known which mark out children exclusively as their victims. Public conveyances and pawn-shops were kept under rigorous oversight, and were in no case believed to have been the means of propagating the disease. The difficulty of sending young children to a hospital for infectious complaints was felt. The fact that this cannot be done in many cases without sending the mothers also, proves that this is not quite the kind of separation to be sought in dealing with this complaint. Regarding this difficulty, and the age of the sufferer from scarlet fever, what is rather wanted is the prevention of the assemblage of children in all schools, especially public schools and dame-schools. In the new code of regulations published by the Education Department in 1874, there is a clause, page 6, specifying that, "if a school have closed during the year under medical authority, on account of a local epidemic, a proportionate reduction is made from the number of meetings and attendances required", for the purpose of a money capitation grant. If this provision exist, why not the power authoritatively to make use of it? and if there is the power to close public schools, why not private infant schools also, whose sanitary condition is usually much worse?

Is Enteric Fever ever spontaneously Generated? By CORNELIUS B. FOX, M.D., Chelmsford.—The author remarked that the question of paramount interest and importance to all engaged in the practice of the highest branch of the profession, namely, preventive medicine, has been one which seems to have divided the most distinguished physicians into two parties, one section giving an affirmative, and the other a negative answer. Sir William Jenner, in an excellent address delivered before the Clinical Society on January 12th, 1875, pointed out, whilst discussing the etiology of the fever, that the best mode of settling this much debated query would be to study every isolated case occurring in out-of-the-way country places. Dr. Fox, as medical officer of health over the central, eastern, and southern portions of Essex, had, with this object in view, investigated thoroughly during the past two years every isolated case in his district, many parts of which are only connected with the outer world by the most primitive methods of communication. He recorded a summary of 27 isolated cases in this extensive area, which he has, in a sceptical frame of mind and animated with the sole desire of ascertaining the truth, carefully subjected to an exhaustive scrutiny. Of these 27 cases of enteric fever, three were clearly traceable to pre-existing ones. He divided the remaining 24 into two classes—the “doubtful”, and the “decidedly untraceable”—and placed 16 under the former, and 8 under the latter heading. The “doubtful” class comprised those respecting which there was a shadow of a doubt. Details were given of two of the most interesting of the eight “decidedly untraceable” cases, namely, the outbreaks of Asheldham and Langford. In the first, the apparent cause was excremental pollution of water, and in the other an excremental pollution of air. The Langford outbreak was one of the most striking cases that had yet been made public, showing the strongest probability of the development of the fever from faecal fermentation, all other possibilities of origin having been eliminated. The arguments which had been employed by both the parties of the controversy were examined and discussed, the reply of those believing in the spontaneous origin of the fever to the principal argument of their opponents being considered unsatisfactory. The researches of Chauveau, Burdon Sanderson, Beale, Klein, Bastian, and Hallier, the theory of the omnipresence of typhoid germs, the views as to the dissemination of the disease by other articles of food besides milk, and the suspicion of a connection with the consumption of meat from fevered or diseased animals, were only briefly alluded to; the object of the author being to limit himself strictly to the point raised by his question as presented to the public health physician in his work in rural districts. The experience of Dr. Fox tended to show—1. That enteric fever is sometimes spontaneously developed; 2. That it spreads by contagion in the overcrowded dirty dwellings of the poor, whilst it is rarely communicated from the sick to the healthy in capacious, airy houses where cleanliness in all things is the rule; and 3. That the immunity in the latter case is ascribable to the prevention of air, water, and food pollution by the poison, and to the dilution of the poison, and perhaps its destruction by the natural or artificial disinfectants, if the air be impregnated therewith.

Typhoid Fever in the Isle of Skye. By JAS. BROWN, L.R.C.P., Uig.—The object of the paper was, without entering into any description of the symptoms or treatment of typhoid fever in Skye, to expose at least two evils, which were asserted to be the causes of the frequent outbreaks there. After showing that the outbreaks could not be attributed to bad water, since the water in Skye was excellent, the author asserted the two chief causes to be: 1. The almost universal habit among the crofters of lodging their cattle under the same roof as themselves; 2. The scantiness of sleeping accommodation, large families being crowded into two, and sometimes one, apartment. Besides these evils, there was the practice of keeping piles of manure in front of the cottages, and having peat-fires in the centre of the room, with no means of egress for the smoke save the door and window, and a small hole in the roof. The difficulty of remedy was the tenacity of the islanders to old customs. The remedy suggested was to remove the cattle, and lodge them outside, by which an additional apartment would be at once available for the accommodation of the family. In most of the cases of typhoid fever, a tendency to relapse was observed, which was attributed to the constant presence of the exciting cause—impure atmosphere. The lungs were frequently attacked in these cases of relapse, and great discomfort was, of course, occasioned by the foul atmosphere. Again, owing to scantiness of accommodation (in evidence of which the remarks of Lord Young in the late Snizort case at Inverness were adduced), isolation was impossible; and the fever could not be confined to only one or two members of the family. The paper concluded by declaring the readiness of the proprietors to afford every facility for the erection of separate dwellings for the cattle. The remedy would be inexpensive, owing to the abundance of stone, the only considerable expense being the roofing of the houses.

On a Village Outbreak of Enteric Fever traceable to a Specifically Polluted Water-supply. By DAVID PAGE, M.D., Kendal.—In December and January 1874-5, a sudden outbreak of enteric fever took place in Staveley, a village of Westmorland, midway betwixt Kendal and Windermere. Twenty-five attacks and four deaths, the cases being well marked, and, with three exceptions, of a severe type, were recorded in connection with the outbreak, which, in its chief extent, fell with remarkable incidence upon those houses dependent for their water-supply upon a rivulet flowing through a portion of the village. Although subject to almost constant pollution from drains and gutters at various points above the houses referred to, the water of this brook had been used with impunity for years. At the beginning of November, an elderly man came from Kirkoswald, in Cumberland, where enteric fever had recently prevailed, ill of the fever, and was laid up in one of a row of seven cottages situated hard by the edge of the brook, some 800 yards higher up its course. He died on January 9th, and, during his illness, there was positive evidence of the discharges having been thrown into the stream. Between November 25th, the date of the next case, and January 21st, out of forty-two families who either habitually or at times drank the water, thirteen, or nearly one-third, were attacked with typhoid fever. Two incidents of peculiar value, from the clue they afforded to the determination of the incubation-period of typhoid fever when spread by means of a specifically contaminated water, happened in the progress of the outbreak. On November 14th, a girl, whose parents resided in one of the houses by the edge of the stream, came home on a short visit from a farm-house in the valley of Longsleddale, seven miles away. She returned to the farm-house on the evening of the following day, and, on December 2nd, was seized with typhoid fever exactly eighteen days afterwards. Her brother at home in Staveley was similarly seized on December 9th. Both were severe attacks. In the other instance, a pump, which had hitherto been kept in working order, in spite of the intense frost of December, was frozen hard on the night of the 29th. The nearest pump was 160 yards distant, and several families resorted to the stream. Out of seven who used the water, four were attacked on January 10th, one on the 11th, and one on the 12th. The pump was thawed on January 1st, so that the use of the water was limited to a couple of days; besides which, in each instance, it was averred that the supply had been taken on one day only from the stream. Calculated from the earlier date or the later, the period of incubation in these six cases would be from ten to fourteen days. The cessation of the outbreak was coincident with the alarm created by these nearly simultaneous attacks, which led to the abandonment of the stream for the time, the last case referable to the use of water from that source occurring on January 21st. In three families only of the thirteen did multiple cases occur; viz., in two, two cases respectively, and three cases in the third. Of the eighteen cases directly traceable to the water-supply, three only were adult males, the rest being women and children. As the male population were chiefly employed in the bobbin-mills in the neighbourhood, their immunity might be in part explicable by their greater absence from home. Regarding the remaining seven cases of the twenty-five, three were solitary cases. One was that of a woman who had occasionally waited upon one of the other sufferers; the other two lived outside the village, under circumstances which excluded any connection with local sanitary defects; but both had been in the habit of frequenting the village, and might in that way have contracted the infection, although it was impossible to trace its origin in this direction. The other four cases occurred in the farm-house in Longsleddale, to which the fever had been brought by the girl whose case was mentioned. The cases were severe; two children and two adults were attacked, two of the cases ending fatally. There were no local circumstances which could in the remotest manner account for the spread of the fever, inasmuch as the water was derived from a spring issuing from the rocky hill-side above the house, and there was strong evidence to show that the manner of infection was by the actual swallowing of solid particles of excreta. In conclusion, the author cited several examples of the occurrence of typhoid fever under conditions which illustrated the difficulties in the way of making sure that the negative evidence upon which the question of the spontaneous origin of the fever necessarily depended was complete evidence, and without prejudice to either side offered a contribution of facts to the etiology of the disease. 1. Water polluted with excremental matters had been used with immunity for years. 2. This water, on the addition of the dejections of a typhoid patient, became the carrier of the contagion. 3. The incubation-period is not necessarily shortened, but may even be of prolonged duration, equally in the spread of typhoid fever by the agency of water as of air.—Dr. BRITTON (Halifax), from numerous cases that had occurred in his neighbourhood, had come to be of opinion that enteric fever might arise spontaneously.—Dr. CARPENTER (Croydon) said they wanted more facts

before they could determine as to the spontaneous or non-spontaneous origin of typhoid fever. Some time ago, he had a large number of cases, the sources of which he was unable to find, and he then came to the conclusion that they had arisen *sua sponte*, although that scarcely represented the state of his mind at the present time. The germs of disease might have lain dormant for many years in the situations where they were placed. He remembered a practitioner in Oban informing him of some such cases occurring in Mull. A proprietor of that island ordered the removal of some old houses which had lain in a state of ruin and uninhabited for many years. Eight men were employed in digging the walls, and every one was attacked with small-pox, the germs of that disease having lain in these houses all those years. Now, if the germs of small-pox had lain dormant for many years, why not those of typhoid fever? As to the incubation of typhoid, he knew that in the Croydon outbreak it varied from five days to over two months. That outbreak in Croydon, during which there were 500 cases, he had traced to the effects of an intermittent supply of water coming after a constant supply. A hydrostatic vacuum was thus caused, and all the noxious gases from the surrounding soil were absorbed by infiltration.—Dr. ROSS (London) ascribed much of the typhoid in large towns to emanations from cow-houses, cesspools, and walls soaked in sewage which had escaped from broken drains or overflow-pipes.—Dr. MARSHALL (Greenock) said that one cause of enteric fever had, he thought, been overlooked. In certain states of health, the enteric system of the patient itself created poisons which might poison the patient. Gases or germs might be germinated in the body in certain states of health from the low state of digestion, and a sudden exposure to cold might set this poison-manufactory agoing.—Mr. STEPHEN ALFORD (London) said that, in the high parts of London, typhoid fever was constantly sent up the drains from the low districts, the flow of water downwards driving the noxious gases upwards. The question of trapping drains thoroughly was a much more important one than the spontaneity or non-spontaneity of enteric fever.—Dr. A. P. STEWART (London) said that it was a curious fact that many of the most destructive epidemics of typhoid that had occurred had not arisen in crowded cities, but in rural districts, where there was pure air and seemingly plenty of pure water. He narrated the case of a friend of his, who went to inspect a boarding-school previously to sending his two daughters thither. Everything he liked well, but the drain, which passed within three feet and a half of the well. When he spoke of this, he was informed that the water of the well had been drunk for years, and that no disease had ever occurred. To satisfy himself, he twice had samples of the water taken and analysed, and it was found to be perfectly pure. He sent his daughters to the school; but, in two or three weeks, typhoid fever broke out, and of four deaths which occurred one was that of his youngest daughter. The water of the well was then found to be putrid from the sewage which had found its way into it.—Mr. BARTLETT (London) mentioned that he had analysed the water in his house nine times before he found a trace of contamination; and this contamination had been caused by what Dr. Carpenter had pointed out: the hydrostatic vacuum, resulting from an intermittent supply, drawing in noxious gases.—THE PRESIDENT, in bringing the discussion to a close, referred to the interesting and important nature of the subject. However different opinions might be held as to the spontaneous origin of enteric fever, there was one thing they could all practically do, whether as medical officers of health or in private practice; viz., war against filth in all its forms. "By taking as a text, in their broadest sense, the words of the prophet, "Wash and be clean", they could do a great deal to prevent the spread of enteric fever and all other kinds of infectious diseases.

An Outbreak of Enteric Fever in the Village of Killamarsh, Derbyshire. By A. MACKINTOSH, M.D., Chesterfield. — Dr. Mackintosh sketched the geographical and geological features, and the sanitary conditions of the locality, and then gave a history of the outbreak. He believed it to have arisen *de novo* through drenching sewage-water and inhaling sewage-emanations. He could not observe evidence of contagion in any case.

On the Propagation of Typhus Abdominalis. By EDWARD WATERS, M.D., Chester.

On the Ages at Death from Small-pox, Measles, and Scarlatina. By J. W. TRIPE, M.D., London.—The calculations were made from 2,516,468 deaths from all causes in England during the five years 1868-72, and embraced 48,435 deaths from small-pox, 47,341 deaths from measles, and 112,412 deaths from scarlatina. The deaths were given for every year of life under 5; then for 5-15 years, 15-25, 25-45, 45-65, and 65 and above. Dr. Tripe showed that, out of each 1,000 deaths from these diseases, 149 occurred from small-pox, 200 from measles, 65 from scarlet fever, during the first year of life; that, in the second year of life, the mortality from small-pox decreased to 53, whilst that from

measles increased to 376, and from scarlet fever to 147, in each 1,000 deaths from these diseases. Up to five years of age, the mortality from small-pox remained about the same in each year of life, whilst that from measles much increased, and that from scarlet fever increased in the third year to 165 per 1,000, and then decreased to 120 in the fifth year. The proportions of deaths from these diseases during the first five years of life were as follows: from small-pox, 350; from measles, 920; and from scarlet fever, 646; whilst from all causes the rate was 407 in each 1,000 deaths. Above five years, there were, therefore, 650 deaths from small-pox, only 80 from measles, and 454 from scarlet fever, per 1,000 at all ages. This remarkable difference was attributable, in Dr. Tripe's opinion, to vaccination affording but an imperfect protection against an attack at later periods of life, as compared with an attack of the disease itself. Dr. Tripe thought, however, that even if an individual should not have had any of these diseases, he became less susceptible to infection as age increased; and that this diminished susceptibility occurred very early in life as regards measles, later on (above 15) as regards scarlet fever, whilst it did not take place for small-pox until about 40 years of age. The extraordinarily small proportion of deaths above 5 years from measles, above 15 from scarlatina, and above 45 from small-pox, formed the data on which this opinion was founded.

On some Points connected with Cottage Hospitals. By JAMES COOPER, F.R.C.S. Ed., Cromer.—The following questions were discussed in this paper. Are cottage hospitals likely to injure the old established hospitals? To what extent should they be self-supporting? In what way should they be provided with medical attendance? Should medical men give their services gratuitously?

Thursday, August 5th.

GROUP B. MEDICAL LEGISLATION: METEOROLOGY AND DISEASE: STATISTICS, ETC.

President's Address.—The President, the Right Hon. LYON PLAYFAIR, M.P., delivered an address, which was published at page 173 of the JOURNAL for August 7th.

On the necessity of Legislation for the Control and Treatment of Insane Drinkers. By A. PEDDIE, M.D., Edinburgh. [See p. 253.]

On the Control and Restraint of Habitual Drunkards. By G. F. BODINGTON, M.D., Kingswinford. [See p. 255.]

Sir ROBERT CHRISTISON, after thanking Dr. Peddie and Dr. Bodington for their papers, said he desired to submit a resolution. A well considered resolution on this subject, brought forward under the auspices of the Association, ought to have great weight. Therefore they should be careful what they said, but at the same time very resolved to carry it out. He moved:

"That excessive intemperance is in many cases a symptom of a special form of insanity, which requires special treatment, with a view, first, to the recovery of those affected, and second, to the protection and advantage of them and of society. That in the present state of the law such treatment is not attainable, and that it is desirable that legal provision should be made to render it attainable."

The subject, he said, was one which occupied his attention at a very early stage of his professional career, in consequence of his occupying the Chair of Medical Jurisprudence for ten years. At that time he lived with his brother, who was a member of the Scotch bar. At their common table, he used to meet several of the most eminent members of the Scotch bar, and there was not one of these gentlemen who did not scout the idea of putting habitual drunkards under restraint. What they urged was, that they could not distinguish between a habitual drunkard who was suffering from disease and one who was suffering from the effects of vice. But in course of time several of these gentlemen came to see instances of habitual drunkenness in relatives and friends. Gradually conviction stole upon them; and he believed that now, among Scotch lawyers generally, there was a feeling that some sort of restraint should be placed on habitual drunkards. Recently he had charge, along with Dr. Peddie, of the representation which was being got up by Mrs. Dalrymple for presentation to the Home Secretary, and in the course of a day and a-half he got that document signed by the professors of Metaphysics, of Moral Philosophy, of Political Economy, and, what he considered of more consequence than all these, the professor of Scotch Law—[hear, hear, and applause]—and not only by him, but by a former Solicitor-General for Scotland, now Dean of the Faculty of Advocates. [Applause.] A great deal had been said in print and in the papers as to the difficulty of distinguishing between habitual drunkenness the result of vice, and habitual drunkenness the result of disease. He suspected they must acknowledge that this unfortunate condition was not very often purely the result of disease. He had seen it so, but by far the greater number of cases arose in

consequence of the persons having gradually yielded to the vice. They must consequently face this fact—not try to evade it—and show the Government and the Legislature that the cases in the end were not different—that there was no difference in their features and in the results to the drunkards themselves, to their families, and to society at large. When, in the little society to which he had alluded, he was asked, “How are you to distinguish between moderate excess and such excess as you consider bordering on insanity?” his reply was, that he was always very cautious about giving definitions. He was once asked in the witness-box to give a definition of insanity or unsoundness of mind. He knew very well that this was but the introduction to a dexterous cross-examination, and he replied that that was a problem on which twelve judges in England had exercised their ingenuity and had failed; that many men had written on the subject and failed; that, therefore, it was not to be expected that he should succeed; but that, if counsel would bring a case before him, he should not only satisfy himself, but satisfy his questioner, whether it was a case of insanity. [Laughter and applause.] His reply to the doubters on the question under discussion was the same: Bring before me a case, and I will tell you whether it is to be accounted for by disease or not. He was rather inclined to borrow a name from the pure English, and call this *drink-craving*; that was the real essence of the thing—the man had such a craving for drink that he could not resist it. It would, he dared say, be often difficult to distinguish, but they could always decide on examination. [Hear, hear.] Then, if they did make a blunder, and introduce among drink-cravers a man who was not so bad, was any harm done to him? No, but a great advantage, for they took him in time; no harm was done to his friends, whom he was ruining, and no harm to the public: in fact, it was one of the extraordinary cases where an error could do no harm. [Hear, hear, and laughter.] He hoped the Association would adopt the resolution, and go forward to the Legislature. They had a righteous cause; and, in his long experience, there never had been any right thing, notwithstanding all difficulties at first, that was not eventually carried in the House of Commons if they could get some zealous member to bring it forward. [Applause.]

Mr. HUSBAND (York) seconded the resolution. As medical men, they did not require to be satisfied that there were such persons as habitual drunkards, but the public mind and the Legislature required to be educated on the point. There was no one who had had large opportunities of practice but must have felt this to be one of the greatest difficulties of his professional life, and more especially when women were the subjects of the vice. He never knew an intelligent medical man who had any doubt as to the propriety of placing such people under restraint. He hoped that on some member of the House of Commons the mantle of Mr. Dalrymple would fall, and that a proper measure would ere long pass. [Applause.] The Council of the Association were, he said, taking steps in the matter, and at next annual meeting it was hoped they would present a full report. [Applause.]

Dr. MORRIS (Baltimore), as a trustee of an institution for receiving inebriates in America, said Americans were not a people who would bear restraint very well, and it might be supposed that they would be the last in the world to submit to a law of this kind. But in several States there were such laws for the restraint of drunkards—laws apparently stringent, but not actually so in operation. When any man or head of a family was known as a habitual drunkard, and any two respectable householders went before a judge and declared that the man was committed to the inebriate asylum, as it was called, and kept there for a certain term—generally a year. The very fact of the existence of the law was a deterrent to drinkers. He would say, Do not let this bugbear of restraint of personal liberty have any weight with you, for we Americans, who know what liberty is, or at least think we do, do not find that it interferes with us. [Applause.] The institution to which he referred took in three kinds of inmates: first, those who paid nothing; second, those who paid a moderate sum, such as working classes could afford, from 18s. to 25s. a week; then the educated and wealthier classes, who paid a fair price. The original institution was too near the city, and patients frequently strolled thither and got spirits. Now they had bought a farm five miles from town, and they intended to build a new institution on the cottage system, and to classify the inmates. The institution worked admirably; it was not self-supporting, but they got a small contribution from the State and subscriptions from the public. They could not make an absolute cure under two years, for it required that time before the molecular structure of the brain tissue, destroyed by habitual drinking, was entirely reconstructed. They had thirty-three per cent. of cures, and when a reconstructed and rebuilt clerk or merchant left the institution and went about amongst his friends, the merchants put their hands in their pockets and paid for that reconstruction by subscriptions.

Dr. JOSEPH ROGERS (London) said it continually happened that persons were sent to the poorhouses in England, Ireland, and Scotland, who were suffering simply from the effects of drink. After a few days they recovered, and as soon as they were able to crawl over the door they demanded and got their liberty. He thought power should be given to enable the authorities to detain such habitual inebriates. He thought that there were too many brewers and publicans in the House of Commons. [Applause.] That was the true explanation why no proper redress could be got from the present Parliament.

Dr. J. C. REID (Newbiggin) said that one of the evils of the Scotch Lunacy Act of 1843 was to do away with the power which the Scotch had possessed from time immemorial of sending their drunkards to one of the islands in Loch Lomond. [Hear, hear.] All the talk as to the restraint of drunkards interfering with the liberty of the subject was balderdash. The liberty of the subject was interfered with from the date of his birth. [Laughter.] One could not be born but an Act of Parliament stepped in and said he must be registered; then he must be vaccinated by order of Parliament; and when he grew older, and wanted to take a sleeping partner into the concern, he could not be married in England after twelve o'clock. [Laughter.] What was worse still, he could not be decently laid away in his coffin without an Act of Parliament interfering with the liberty of the subject. But the law was too lenient, and would not interfere with the liberty of the subject who was an enemy to himself, to his family, and the public weal. [Hear, hear.] He hoped the time was not far distant when the law in regard to chemists and doctors would be made to apply to publicans. If a chemist sold poison and a person died, he was held responsible; and if a surgeon made a mistake, he was held liable in an action for malpractice. Why should the publican be freed from the same liability? Make the publicans responsible, and there would be far fewer unhappy homes. [Applause.]

Mr. LITTLE (London) believed the love of strong drink was engendered very much among certain classes by the miserable condition of their dwellings and by overcrowding.

Dr. A. P. STEWART (London) said great harm was done by the statements made in regard to the identity of habitual drunkenness and disease. If they went before Parliament on the ground that it was a disease, they took up perilous ground indeed. If they said a man was a maniac, they would be told to send him to a lunatic asylum; and if they did that, more harm would be done than good. He approved of Sir Robert Christison's proposal to invent a new name. For nearly three hundred years the power, originally given by James I, had existed of interfering with the liberty of the subject because he was drunk; that was, the magistrate imprisoned a man for a day or two for being drunk. Let the principle be extended to continued restraint, and they would touch the evil.

Dr. CARPENTER (Croydon), in reference to the committee appointed by the Council of the Association to report on the subject, said that Committee would be glad to get all the information possible, and he hoped members would send in all they could.

The PRESIDENT said he had acted on the Committee upon Habitual Drunkards with his friend Mr. Dalrymple. He entered the Committee in an extremely doubtful state of mind, his feeling being hostile to the proposal; and this he had told Mr. Dalrymple. He then thought they must look chiefly to education and diffusion of knowledge among the people as the means of preventing drunkenness, and that restraint was a very questionable mode of procedure. But he confessed that the evidence brought forward led him to a different conclusion before the labours of the Committee were closed, and he signed the report advocating certain forms of restraint as being necessary in the case of habitual drunkards. It was because the public were not sufficiently educated on this matter, and because they had not shown sufficient interest in it, that the House of Commons was unable at present to legislate. The Association would do great good by the resolution it might adopt, but that was not sufficient. The members must educate the public, and the House of Commons must feel that it would be supported by the public in legislating on the subject. The present mind of the House of Commons was, that there were great difficulties connected with the subject, and that they must look these difficulties in the face. But he was afraid the House was like the Highland clergyman of whom Dr. Norman Macleod used to tell, who said that, whenever he saw a difficulty, he looked it fully in the face, and then passed by on the other side. [Laughter.] If, however, the public took up the question for themselves, the House of Commons, finding public feeling supporting them, would soon pass a measure. [Applause.]

The resolution was then carried by acclamation.

State Medicine in Relation to Education. By HENRY J. YELD, M.D., Sunderland.—In his introductory remarks, Dr. Yeld pointed out that the legislation of recent years has placed the children of the working

classes in a much better position, as to the sanitary and other conditions under which their education is carried out, than those of the middle classes, and affirmed that, in the matter of education, there has been class legislation, and not legislation for the general welfare of the community. The object of this paper was to bring prominently before the public the unsanitary and other conditions under which many thousands of the children of the middle classes and upper section of the lower classes are educated. For this purpose, he first stated what may be considered as the necessary requirements for healthy and efficient education: 1. The school buildings should be perfect in their sanitary arrangements, and in every other respect; 2. Education should be physical as well as moral and mental; 3. To meet this requirement, a playground should be attached to every school; 4. Persons engaged in tuition should possess a certificate of their competency to act as teachers, and should have some knowledge of the laws of health. After a few remarks upon each of these points, he proceeded to show to what extent the schools now existing throughout the country, for the education of the children of the middle classes, fail to meet these requirements, taking the hundred private schools in the borough of Sunderland by way of illustration. On inspection, only twelve of the hundred were schools specially built for the purpose of education, the remainder being rooms in dwelling-houses used as school-rooms; thirty schools were overcrowded and defective in their sanitary arrangements; while, with regard to their ventilation, in 90 per cent. the only means of ventilation was by the windows, and in most instances by a single window, there being no special means provided whereby the air might be kept pure. To several schools there was no water-closet or other accommodation attached, and only five schools had playgrounds adjoining. Lastly, with a view of placing these schools on a more satisfactory basis, and more in accordance with the spirit of the age, he proposed that an act of Parliament be passed or order in Council (if sufficient) be issued, providing: 1. For the registration of all persons acting as teachers throughout the country; and that, from and after a fixed date, no person be registered without producing a certificate of competency from an educational examining board. 2. For the registration of all schools, not directly or indirectly under the control of the Privy Council, at the office of the local authority. 3. That, at the time of such registration, a certificate shall be produced, signed by the surveyor and medical officer of health of the local authority, stating that the premises proposed to be registered are in every way adapted for the purpose of education. 4. That the number of children allowed to be educated in such school shall be fixed by the local authority. 5. That the medical officer of health, or other officer of the local authority, shall have power to inspect such schools, from time to time, at any hour between 9 A.M. and 5 P.M. 6. That with a view of encouraging the erection of efficient schools, the Privy Council shall have power to make grants of money towards the erection of such schools on such conditions as may be determined upon.

The Anomalies and Deficiencies of Parochial Medical Relief in Scotland. By JOSEPH ROGERS, M.D., London.—Dr. Rogers began by remarking that, in 1869, a Select Committee of the House of Commons was appointed for the purpose of inquiring into the working of the Scotch Poor-laws. This Committee, of which Mr. Crawford was chairman, collected during that year and the following a voluminous mass of evidence. In the year 1871 they agreed upon their report, and in the following year Mr. Crawford brought in a bill, which was based upon the Committee's report, but was, however, lost upon the second reading. Since the rejection of the Bill, no steps had been taken to remedy the evils that were shown to exist; and, as an amendment of the system of medical relief was embraced in that Bill, it occurred to him that he might revive the subject. After giving a sketch of the systems of Poor-law medical relief in England and Ireland, he pointed out that in 1873 the gross poor relief in Ireland amounted to £927,730, or 3s. 5½d. per head of population, although that sum included an outlay of £155,362 spent on medical relief; this latter amount constituting the sixth part of the total outlay, for a population of 5,344,151; whilst in the same year there was expended on the poor in Scotland £873,075 for a population of 3,360,068, or 5s. 2½d. per head of population, of which sum only £34,000 was expended on medical relief, or in round numbers about the twenty-sixth part, against the sixth part expended in Ireland. Of this sum of £155,362 spent on medical relief in Ireland, £24,279 went for medicines and medical appliances; if a proportionate sum were expended in Scotland, the outlay for medicines alone would cost the parochial medical officers £15,264. To make the matter more clear, he contrasted certain Irish with certain Scotch towns. Belfast has a population of 202,641; the medical relief in 1873 cost £4,078; gross relief amounted to £30,042. Edinburgh, with St. Cuthbert's combination, has a population of 209,917; it spent in medical relief in the same year £1,558 5s. 2d., or not half that of Belfast, while

the poor relief expenditure was £52,455, or £22,000 more. He also gave the following tables as showing contrasts.

	Population.	Medical Relief.			Gross Relief.		
		£	s.	d.	£	s.	d.
Glasgow.....	170,553	2,377	0	0	40,875	0	0
Barony.....	234,115	2,057	0	0	43,623	13	2
Dundee.....	86,527	564	12	11	14,971	8	3
Newry.....	72,079	2,100	0	0	8,267	0	0
Armagh.....	72,384	1,638	0	0	6,489	0	0
Greenock.....	59,795	721	19	4	9,698	0	0
Londonderry.....	58,758	1,910	0	0	4,747	0	0
Aberdeen.....	47,077	246	6	10	12,512	16	0
Dunbarton.....	45,990	1,069	0	0	4,587	0	0

The author next inquired whether any proof could be adduced showing the benefits arising from finding the medicines and paying a reasonable fair stipend for services. Bonhill, Dumbarton, has a population of 9,408; the medical officer gets a stipend of £78:19:7; all medicines are found. The poor relief amounts to £1,597. In the adjacent parish of Cardross the population is 7,080; £46:8:2 only is paid for medical relief, out of which medicines have to be found; the poor-rate amounts to £1,390, or only £200 less than in Bonhill with 2,328 more people. In Cardross, last year, the poor relief had risen up to £1,469, nearly £100 in excess of Bonhill, medical relief remaining as before. As an instance of great disparity in payments for services, he quoted Old and New Deer, Aberdeenshire. New Deer had a population in 1871 of 4,853, of which number 152 were registered poor and their dependents, and 50 were casual poor and their dependents, total 202, with 7 lunatics. Medical relief cost £30, medicines being found by the medical officer; the total gross relief amounted to £803:9:2. Of this number of paupers 7 either died or were otherwise got rid of in the course of the year. Old Deer has a population of 5,085; there were 257 registered poor and dependents, 94 casual poor and dependents, and 24 lunatics: of this number 30 died or otherwise disappeared; and the total poor relief was £1,624:10:7. Although the population, pauperism, gross relief, sickness, and mortality, was so much greater than in New Deer, the stipend out of which everything had to be found was only £9:10:1 more than in New Deer. He would ask, what chance does there exist that the sick poor in Scotland get proper medicines when they have to be supplied from such stipends? The system of medical relief in Scotland had a deteriorating moral effect on all connected with it. Referring to the enormous extent of some of the rural districts, he remarked that the whole of Sutherlandshire, with an area of 1866 square miles, and a population of 26,000, is divided into five medical districts—Assynt, Eddrachillis, Golspie, Helmsdale, and Tongue, including several minor parishes. The district of the medical officer of Assynt extended 14 miles in one direction, and 28 in the other. The whole sum paid for medical relief in this county amounts to £595, out of which horses and drugs have to be found. He could not give much information as to the interior arrangements of the various poorhouse hospitals; but if the description given of Barnhill Poorhouse, Barony—in a very able and evidently truthful report, forwarded to the House Committee by the medical officer—were typical of their general condition as receptacles for sick people, it was clear that there existed as great a necessity for a sweeping alteration in their arrangements, as he had shown to be necessary in the treatment of the out-door sick.

Mr. ERNEST HART (London) moved:

“That in the opinion of this Section the interests of the sick poor of Scotland would be furthered and the system of poor-law medical relief would be placed on a more satisfactory footing, if the following measures of reform were adopted universally throughout Scotland—viz., that the cost of medicines be supplied by every Parochial Board, exclusive of the salary of the medical officer; that medical officers be removable from office by the Board of Supervision only; that the Parochial Boards be required to superannuate such medical officers at the proper time; and that the Parliamentary grant in aid of medical relief be placed on the same footing as in England and Wales. That this resolution be reported by the Chairman of this Section to the general meeting of the Association; and that the aid of the Association and of the Scottish Branches in particular be requested in support of an effort to give legislative effect to the above recommendations.”

Nearly all the defects pointed out in the Scotch Poor-law had, he said, been removed in Ireland and England; and although, on the surface, such a measure appeared to involve greater expenditure, in the long run it promoted economy in health, life, and money.

Dr. A. P. STEWART (London) seconded the resolution, which, after some remarks from various Scotch Poor-law medical officers condemning the present system, was adopted unanimously.

On the Steadiness of the relations between Weather and Mortality in London. By ARTHUR MITCHELL, M.D., F.R.S.E., Edinburgh.—The object was to show that the distribution of deaths from many of the particular causes of death over the different weeks of the year, as deduced from the records of a long series of years, was substantially the same as that for each quinquennial period, or for each single year, composing the long series. This was shown to be true even of epidemic diseases like small-pox and scarlet-fever. It was further shown that such divergences as occurred in the distribution of the deaths over the weeks of the year, between one year and another, or one period of years and another, answered to corresponding divergencies in weather. Deaths from diarrhoea, which were greatly under seasonal influence, were used to illustrate this. The general conclusion was, that the relation of deaths from many diseases to weather was so steady as to constitute a feature in their natural history.

The Influence of Weather on the Death-rate from different Diseases and at different Ages in London and in Twenty-four Large Towns of Great Britain and Ireland. By ALEX. BUCHAN, A.M., F.R.S.E., Edinburgh.—This paper was illustrated by a large series of diagrams showing by curves the weekly mortality of London from the more prominent diseases, and the weekly mortality of the other large towns from all causes, from diarrhoea, and of infants under one year of age. The results for all the large towns show during the winter months an excess above the average mortality. As regards the English towns, the excess is greatest at Norwich, Wolverhampton, and Nottingham; and least at Bradford, Leeds, Salford, and most other towns in the north. In Scotland, the winter excess is greatest at Aberdeen, and least at Leith and Greenock. At Dublin, the largest monthly mortality, 22 per cent. above the weekly average, occurs during February and March, being from a month to six weeks later than the time of the maximum of the English and Scottish towns. In all the English towns, the minimum mortality of the year is in the spring months, the amounts below the averages of each town being greatest at Norwich, Wolverhampton, Birmingham, Leicester, and Nottingham. In Scotland, on the other hand, autumn is the healthiest season. In Glasgow and Edinburgh the deaths fall about 20 per cent. below the average in the month of September. During the period of high temperature in summer, every one of the large towns of England shows an excess of deaths above the average, with the single exception of Bristol, at which place, while there occurs an increased mortality at this season, it only comes near to, but never quite reaches, the average. Taking any two consecutive weeks which indicate the highest mortality, the excess per cent. above the average is for Wolverhampton, 6; Manchester, 8; Portsmouth, 12; London, 14; Hull, 20; and Leicester, 47. The excess above the average at Leicester is thus eight times as great as that of Wolverhampton. In Scotland, no town exceeds its average during the hottest weeks of the year; but, on the contrary, the death-rate everywhere is under the average, and, in most cases, very considerably so. As regards London, it has been shown by Dr. Arthur Mitchell and the author (*Journal of Scottish Meteorological Society*, vol. iv, pp. 229 and 238), that if the deaths of infants under one year of age be taken from the total mortality, the summer excess disappears from the curve; and, it is further shown that, if deaths from diarrhoea be deducted from the whole mortality, the summer excess disappears equally as in the former case. These results hold good for every one of the large towns for which the required data have been published. Looking, then, at the large towns of England, Bristol has the least excess of infant mortality, the highest average of any week being only at the rate of eight calculated on an annual mortality of 1,000 of the whole population. In London, the rate rises to 10 in the end of July and beginning of August; and in Liverpool it rises to 16, a rate which is also reached by the deaths in Leeds, Hull, and Sheffield, and closely approached by a number of the other English towns. At Leicester, however, it shoots up to 22 and 24 in the second and third weeks of August. The season of minimum infant mortality is everywhere during the spring months in the sixteen large towns of England. The smallest spring mortality occurs at Portsmouth, the smallest summer mortality at Bristol; the largest summer mortality at Leicester, and the largest mortality during the other nine months of the year, at Liverpool. From the beginning of November to the summer solstice, the mortality from diarrhoea is everywhere small, being double, however, in Liverpool and Manchester as compared with London and Portsmouth. The following is a list of all the large towns of Great Britain arranged in the order of the greater or less prevalence of fatal cases of diarrhoea during July, August, and September, the figures being the average weekly death-rate for the thirteen weeks, calculated on the annual mortality per 1,000 of the population. In England: Leicester, 9.56; Salford, 7.15; Leeds, 7.02; Manchester, 7.00; Liverpool, 6.28; Sheffield, 6.20; Birmingham, 5.78; Hull, 5.56; Nottingham, 5.36;

Norwich, 5.02; Newcastle, 4.61; Bradford, 4.42; Wolverhampton, 4.03; Sunderland, 3.89; London, 3.45; Portsmouth, 2.94; and Bristol, 2.38; in Scotland: Dundee, 2.14; Glasgow, 1.90; Greenock, 1.75; Paisley, 1.71; Leith, 1.45; Edinburgh, 1.23; Perth, 1.08; and Aberdeen, 0.96. The summer temperature of the Scottish large towns is several degrees lower than that of the English towns, and we see that every one of the Scottish towns has a mortality from diarrhoea lower than the lowest mortality of any one of the English towns. The diarrhoea mortality of each town is found from year to year to rise proportionally with the increase of temperature, but the rate of increase differs very greatly in different towns. This points to other causes than mere weather, as determining the absolute mortality; and it is the investigation of these causes, which may arise from topographical, social, or sanitary conditions, peculiar to each town, which calls for instant and most serious attention. In order to work out the problem of the relation of the weather and mortality of our large towns, it is indispensable for the comparison of the different towns with each other, that the system of meteorological observation be uniform at all places, particularly as regards the hours and modes of observing the temperature, humidity, and movements of the air, and rainfall; and it is further indispensable that several meteorological stations be established in each of the large towns.

On Deaths by Accident in the Navy and Army. By Inspector-General WM. R. E. SMART, C.B., M.D., Haslar.—The collation of statistics through thirteen years showed, that these stand as 3 in the navy and 1 in the army against .707 in the metropolis per 1,000. The admission for treatment from all causes amounts to 132.9 per 1,000 in the navy against 114.3 in the army; the excess in the former being made up of hurts, which stand as 29.5 in navy to 9.3 in army per 1,000 men. The deaths from this cause are nearly in the same ratio, between 10 and 11 per 1,000, in both services, to the admissions "hurt." The inference was, that slighter injuries are treated among seamen than among soldiers; and that the increased ratio to mean strength or per 1,000 force, 3 in the navy to 1 in the army, is made by the greater number of injuries and not by their greater severity; which is not borne out by comparative lists of recorded injuries of a directly fatal nature, which are strongly against the navy. Reasons for this were assigned. The excess of total mortality in the army per 1,000, 16.6 against 11.6 in navy, is made up by the death-rates of diseases, which stand as 15.3 army against 8.4 navy; showing the greater salubrity of ships than that of barracks and camps. To fill the death-rate by accident of 3 in the navy against 1 in the army per 1,000 men, there fell in battle .16, 1.72 died by drowning, and 1.16 by other accidents; and, in the army, in battle .137, by drowning .426, and by other accidents .435. After stating that medical hygiene had already affected very much in lowering the death-rate by disease in both services, Dr. Smart descanted on the possibility of similar results regarding the death-rate by accidents, and suggested the good that might be anticipated if combatant officers of both the public services were instructed in the laws of hygiene in their colleges and schools.

On the Numerical Ratio of Disease in the Adult Male Community deduced from the Sanitary Statistics of Her Majesty's Customs, London, for the years 1857-74. By WALTER DICKSON, M.D., R.N., London.—The registration of disease is an acknowledged desideratum in public medicine. A more accurate and complete knowledge of the rate of sickness, and its incidence on various classes of the population, would throw light on some important social and economic questions, one of the most urgent of which, at present, is the true position of the numerous benefit societies established by the working classes for mutual aid in sickness, and comprising, according to high authority, four millions of persons, and holding eleven millions sterling of property. Very many of these institutions are known to be in a most unsatisfactory financial condition, in consequence of miscalculation as to the claims which they may be called on to meet. Mortality rates are ascertained with mathematical precision; but the ratio of industrial incapacity, by reason of illness, is as yet but imperfectly known in those classes of the community whom it most interests. The army, navy, police, prison, and Poor-law records do, or might, yield valuable information; but the bodies of men of whom they treat are too fluctuating, and their circumstances too exceptional, to furnish reliable representative data for this purpose. In the sanitary statistics of the Customs' officers of the Port of London will, it is believed, be found a fairly correct estimate of the health-condition of the middle-class, middle-aged male population. They are, for the most part, resident in London, and occupied from eight to twelve hours in daily labour, attended, in most instances, with considerable fatigue and much exposure to the weather. They form a permanent force, leaving it seldom except on promotion, death, or invaliding; and resemble in all essentials the majority of the well-doing industrious section of the community, who have to earn

their daily bread and maintain families in a position removed alike from luxury and from indigence. These officers are all under medical surveillance during their service of thirty or forty years; and the records of their sickness and results have been kept with as much fulness and accuracy as the nature of the subject will allow. Their age ranges from 21 to 65; the mean age at present is 38. Although embracing a limited number, the records extend over so long a period that they may be considered as typical of a large force. The numerical ratios of 28 years (which is equivalent to that for one year of 32,000 men), are, mean daily number incapacitated, 27 per 1,000; admissions to sick-list in year, 700 per 1,000; mean duration of each case, 15.5 days; time lost per man annually, 11 days, exclusive of Sundays, 9.5 days; mortality from disease, 11.5 per 1,000, and from accident, 1.3 per 1,000; in all, the deaths are 12.8 per 1,000; superannuations or invalidings, 8 per 1,000; death and invaliding combined, 21 per 1,000; recoveries so as to resume duty, 979 per 1,000. Of the various classes of disease, the ratio of those of the respiratory organs amounts to 27 per cent. of all the cases, 20 per cent. of the time lost, 11 per cent. of deaths, and 18 per cent. of the superannuations; phthisis yields 1.4 per cent. of cases, 8 per cent. of time lost, 31 per cent. of deaths, and 9 per cent. of superannuation; rheumatism and gout show 14 per cent. of sickness, only 0.4 per cent. of death, but 33 per cent. of superannuation; diseases of the heart exhibit 1 per cent. of cases, 2 per cent. of time lost, 13 per cent. of the deaths, and 1.5 per cent. of superannuations; diseases of the digestive organs give 17 per cent. of cases, 13 per cent. of time lost, 9 per cent. of deaths, and 7½ per cent. of superannuations; diseases of the nervous system amount to 7.5 per cent. of the cases, 9 per cent. of time lost, 9 per cent. of deaths, and 20 per cent. of superannuations, 10 per cent. being for insanity; skin and other surgical diseases give 11.5 per cent. of cases, 10 per cent. of time lost, but hardly any deaths or superannuations. Zymotic diseases occur in the small proportion of 6 per cent. of the whole amount of sickness, and 7 per cent. of the whole mortality; and no instance has occurred in many years of any officer having contracted such illness on board ship, a remarkable proof of the extreme healthiness of the port of London in regard to its vast foreign traffic, and of the satisfactory health of the Customs' force. Phthisis and heart-disease are the most fatal diseases, causing one half of the whole mortality. The former claims 4 per 1,000 men as its annual victims, of the mean age of 41 years. Heart-disease destroys 1.5 per 1,000, at the average rate of 48 years. Accidental injuries constitute 10 per cent. of the cases, 11 per cent. of the time lost, and 9.5 per cent. of the mortality. Drowning causes 4.7 per cent.; fractures, etc., 3 per cent.; and suicide, 1.8 per cent. of the whole number of deaths. These deaths from violence amount in all to the rate of 1 per 1,000 of the force.

On the Mortality of Adolescence. By JOHN BEDDOE, M.D., F.R.S., Clifton.—This paper was founded on a statistical basis, and chiefly on the figures published by Mr. Charles Ansell, junior, of the National Life Assurance Society. The author showed grounds for believing that puberty had an influence in increasing mortality, especially among young females of the upper class, the rates of girls of the lower class and of boys of both classes being less affected; and he touched briefly on some questions of hygiene suggested by these facts.

The Causes of Invaliding among Convicts in the Government Prisons of England. By D. NICOLSON, M.B., Portsmouth.

Tobacco, and its Effects on the Health of Males. By CHARLES R. DRYSDALE, M.D., London.—The author said that the result of a paper by him read at Norwich had shown that, although very many, far too many he thought, eminent physicians and surgeons made use of tobacco, yet none could be found bold enough to say that the practice of smoking, chewing, or snuffing was consistent with health. The population of the British isles used some fourteen millions sterling yearly in the purchase of tobacco, pipes, etc. Nevertheless, there had always been able medical objectors to the *sainte herbe*. The alkaloids contained in tobacco, or in tobacco-smoke, were very poisonous; and, when smoke was taken into the mouth, a portion of such alkaloids dissolved in the saliva, entered the circulation readily enough. Smoke breathed in small rooms, or railway carriages, also poisoned to a certain extent all who inhaled it, whether smoking or not. The first cigar or pipe showed the effects of acute tobacco poisoning, producing nausea, vomiting, hiccough, dyspnoea, prostration, coldness of the extremities, cold sweats, and intermittent pulse. Chronic poisoning by tobacco, the ordinary disease seen in practice, was tested by Blaton, who administered two or three grains of tobacco daily to dogs with their food. The animals lost appetite, had diarrhoea, swelled gums, loosening of teeth, irregular action of the heart, paralysis of the hind legs, blindness, and deafness. Black teeth and spongy gums, with fetor of breath, were common in smokers. An affection of the tongue and epithelioma of the lips was common enough in smokers. Tobacco

amaurosis was too well established to be denied; and Mr. Critchett alleged that the wealthier young men of this day very frequently injure their sight grievously by their great smoking. Palpitation of the heart was common among smokers and chewers, as well as paleness, and occasionally intermittent pulse. Decrepitude came far too quickly upon great smokers; and Dr. Drysdale attributed, in some cases, the occurrence of rickety children to the use of tobacco by the male parent. Brodie said of tobacco, that it tended to make the race degenerate. Sir William Jenner said smoking tended to produce palpitation, prolapse of the rectum, and impotence. Miller and Jolly alleged that chronic tobacco-poisoning caused palsy and insanity. Bertillon had shown that smoking was most injurious to the functions of the brain in youth. Kostral showed how many diseases are produced by tobacco in the Austrian State Factory. Fortunately, said Dr. Drysdale, our European women do not smoke. They prefer good breath and clean teeth to fetor and black stumps, and do not like to become dreamy, nonchalant, and fractious, like the chronic votaries of the pipe or cigar.

On the Evils of Medical Men undertaking the Duties of Nurses. By A. FREER, M.R.C.S. Eng., Stourbridge.—The growing disposition of the richer classes to have their medical attendants to nurse them during acute but ordinary illnesses, should be watched with regard to the interests of both doctor and patient. Why in such illnesses should the medical man assume the duties of a nurse? If the attendance of a medical man be demanded during several nights, this should be given, not by him in charge, but by some one free from the anxieties of general practice. The surgeon, who has been away for a time, returns to the bedside able at a glance to appreciate changes. Absence makes the eye grow clearer; and the first look at the invalid after a night's absence must not be lightly foregone. If the medical man stay in the house of the invalid all the time, the friends are tempted to put undue pressure upon him to prescribe some fresh remedy at every change for the worse. Perhaps, in the night, the patient is stirred up anew to receive a fresh attention. If the medical man suggest nothing more, disappointment is felt by the friends. They do not understand, as he does, that time itself is a remedy without which all others may be in vain. It is a happy thing that improved knowledge of disease is to us increased power; for, as luxury advances, people are becoming more impatient of the restraints of illness, and expect more from medical men than they used to do. But these must not be willing at every call to come down from the hill of observation into the battlefield to do the work of subalterns; but if this be forced upon them to a greater extent in the future, it is to be hoped that the notions of the public as to remuneration for unnecessary detention keep pace with such serious claims.

The Training of Nurses in Provincial Hospitals. By EDWARD WATERS, M.D.

Friday, August 6th.

The Section met in the Chemistry Class-room; Dr. LYON PLAYFAIR, M.P., in the Chair.

GROUP C.—GENERAL SANITARY ARRANGEMENTS: DRAINAGE: WATER-SUPPLY: VENTILATION.

The Sanitary State of Rome. By LAUCHLAN AITKEN, M.D., Rome.—It was, he said, useless to deny that the sanitary reputation of Rome was of the worst possible character; and it had been, and was, so much the custom to write and speak of its unhealthy state, that they need feel no surprise if many still associated the name with ideas of danger or disease. Many visitors came under the influence of that feeling; he might have said nearly all, except perhaps a few sentimental young ladies, who found a gloomy satisfaction in believing that all the treasures of antiquity and all the wealth and beauty of nature to be found there, could only be visited at an amount of risk which made them think their doing so little less than heroic. Proceeding to inquire if this distrust were thoroughly warranted, he referred to the excessive mortality in Rome in 1872, when the death-rate was 37.1 per 1000, due to an epidemic of small-pox which had spread over Europe from the war-stricken provinces of France; a great increase in the deaths from diphtheria and croup, the effects of the inundation of the Tiber at the end of 1870, when two-thirds of the houses were flooded; and the overcrowding of the poorer quarters, due to the influx of labourers and artisans, who eagerly poured into the newly constituted capital, in the hope of better wages and steady employment. But, since 1872, there had been a gradual improvement. The effects of the flood had ceased to tell on the death-rate; better accommodation had by degrees been provided for the new-comers. Work had been easily got by all steady men, wages had been high, and provisions, though dearer, had not attained a price which seriously interfered with the poorer classes; and, since the advent of the Italian government, the city authorities had borrowed largely, and spent money to improve its sanitary state.

Among other things, the drains in the so-called English quarter had been thoroughly repaired or entirely rebuilt. The cleansing work was better performed, and, if the scavengers still seemed to take things rather easily, yet every one who knew Rome only a few years ago now readily admitted how much pleasanter to the eye and nose it had become. Outside the city walls, too, there had been progress, though not to a corresponding extent. Garibaldi's plans were not impracticable, and would probably have the desired effect. Meantime, many of the proprietors were engaged in planting the Campagna with fast growing young trees. From the reports issued by the Statistical Office at the Capitol, it appeared that, in 1872, the proportion of deaths to the population was 40.5 per 1000; in 1873, 34.1; in 1874, 33.9; and for the first five months of this year, 35.1. Those figures, however, presented a fictitious mortality, as they included in the returns from the hospitals and city the deaths of many persons not belonging to the community of Rome. After making the due deduction, the mortality assumed very different proportions, being, in 1872, 37.1 per 1000; in 1873, 29.1; in 1874, 26.2; and in the first five months of 1875, 29.1. A great part of the deaths among those who had no fixed residence in Rome occurred in the hospitals; and, indeed, the admissions of immigrants from other provinces of Italy into those institutions greatly exceeded those of the poorer classes of Rome. The patients in the hospitals belonged mainly to the central and southern provinces of Italy, the majority being peasants, who arrived at fixed seasons to till the Campagna or to reap the harvest, while others were masons or bricklayers, who established themselves in Rome when work was plentiful, but who had not yet been included in the population. The fluctuating population was almost entirely male, and, as the occupations of the peasants exposed them to the malaria during the worst season, the deaths were enormous. They were said to be 6 per cent. annually; but that was probably under the truth. No doubt also the unhealthy state of the hospitals had much to do with the excessive mortality; the deaths in the hospitals, indeed, amounted to nearly half the mortality. Although the death-rate in the hospitals of those not belonging to the community was high, it did not seem to be so among other strangers in the city. Referring to Roman fever, he remarked that a great many deaths were registered from this cause which were really not caused by it. He had never seen any case among visitors to Rome during the winter months which could be so described. In conclusion, he said that a modern Roman had nearly as good a chance of life, and was no more likely to die from a preventable disease than the citizens of Edinburgh; and it was possible that, by the statement he had made, part at least of the fear of a visit to the Eternal City might be dispelled.—The PRESIDENT said that personally he had not a very good word to say for Rome. He went there, and on the third day took that fever. During his convalescence, he thought a good deal as to what was the cause of the fever. He did not know that he came to a better conclusion than anyone else. But one thing struck him. In ancient cities, such as Rome and Jerusalem, the *debris* of many thousand years, which had accumulated and raised the level of the surface, contained a large quantity of organic remains, which lay dormant until excavations were made, when the oxygen of the air commenced an incipient putrefaction, and produced malaria. At all events, he knew exactly the time when he was struck. It was while looking at some new excavations which were being made in the Palace of the Cæsars. He thought it would be very interesting if Dr. Aitken were to obtain an instrument for ascertaining the exact amount of organic matter in the air by means of permanganate of potash, and examine the air before an excavation had commenced, and after it was in progress. Some interesting conclusions could be obtained in that way. The enormous mortality among workmen in the hospital had been mentioned, and it was quite possible that the workmen were stricken down while excavating ruins, making new sewers, or taking out the foundations of new houses.—Mr. W. J. COOPER (Richmond) pointed out that great mortality also occurred in Jerusalem among the Jews. The sewage of centuries had sunk into the *debris*, and when it was disturbed, malaria set in, and the mortality was very great in consequence. In 1854, an old clay pit was opened in Broad Street, London, which emitted a very foul smell. Cholera came shortly afterwards, and Golden Square, adjoining, was almost depopulated.—Dr. GRIGOR (Rome) thought the unhealthiness of Rome as a winter residence was very much magnified. The community was small, and any fatal case made a great noise. He was satisfied that Rome had as little typhoid fever as Edinburgh, or any town he knew, in proportion to the population. He did not think a great deal of typhoid was generated in Rome; what they had was an ague or malarious fever. Typhoid was imported from other cities. He believed that the malaria among the workmen was due, not so much to excavations as to the poor constitutions of the men, caused by their poor living and wretched lodgings.

On the Sanitation of Houses, especially with reference to Drainage. By W. EASSIE, Esq., C.E., London.—The evils of improper drainage were best observed in houses that had been from time to time added to. One was then able to trace the first awakening up of the inmates, when the patrimonial cesspool had filled up and choked the drains. When this happened in villages, all that was done was merely to partially empty the receptacles and clean out the drains. And when this had occurred several times, a new dumb-well was sunk and the drains led into it, the old pit being covered up with a stone. It was cheaper to do this than to fill it up; and, besides, this procedure did not necessitate the absence of the family. It was the same in towns, and lately Mr. Eassie laid bare in a West End London house three cesspools which had been dug in proximity, and abandoned in rotation as they filled up with ordure and filth. Four cart-loads of night-soil were removed, which could not have seen daylight for half a century. The reason why these ancient nuisances were found inside houses in towns and cities was not because they could not be accommodated outside the house, but because the slops from the kitchen and bath and laundry wastes were insufficient to flush the more solid wastes outside the walls. In nearly every case, too, the drains were of brick, laid with uneven bed, and through the joints of which the fluids percolated. For instance, a cottage was drained into a cesspool in the kitchen, and, when that was full, another was dug, until the place was honeycombed with them, the subsoil saturated, and the well poisoned. A common privy was used in the yard, and this performed the same evil functions. Fly-and-bye water-closets were introduced, and earthen pipes, and the cesspool for these was dug in the garden, with a lower one for an overflow, and both cemented down air-tight fashion. There was no ventilation, except through the trapping-water of the syphons. Drainage into a cesspool was not necessarily dangerous, provided only that the waste-pipes of the sinks delivered outside over a trap; provided, too, that the soil-pipes were carried roof high, and a foul-air withdrawing-cowl fixed upon them, all would be well. It might, in some cases, be absolutely necessary also to ventilate the cesspool by an upright shaft, or a ventilating charcoal trap in the stone cover; and it might even be wise occasionally to ventilate the march of the drain. Where a common privy was used, an earth or ash-closet ought to replace it. Where a parish sewer was put in the main road, and the value of the land enhanced so much as to make it worth while to enlarge a building, sometimes half of the house was drained into the sewer and the other half into the old cesspools. The old cesspools had not, however, been dug up in the basement of the house nor the urine catch-pit in the stables. It was very easy to so arrange the plan of a house that the whole of the wastes might deliver immediately outside the house, and to have nothing but the outside wall between the water-closets, lavatories, and sinks. When it was advisable to drain the basement, it could be disconnected from the main road by interposing over the junction a ventilating shaft. The sinks and lavatories should all deliver over an open chamber. The walls of a house should be built hollow, and protected from rising damp also by a proper damp-proof course.—Dr. CARPENTER (Croydon) said there were three canon laws that ought to be observed with reference to the disposal of sewage—(1.) That in sewers in connection with houses, stagnation should not be allowed; (2.) that there should be free ventilation, the air, however, not being allowed to pass inside the dwelling-house; and (3.) that there should be no communication between the sewage and the water-supply.

On Mortality in relation to Dwellings. By GEORGE ROSS, M.D., London.—Dr. Ross commenced his paper with questioning the correctness of the ordinary statement that "the mortality of a population is in a ratio to its density", and affirmed that "high density is not necessarily a cause of a high mortality". He pointed out that life in great cities might be made as healthy as in the best regulated villages, if the authorities would use the resources at their command. There need be no stagnant water, nor festering heaps of dirt, no decaying vegetation, nor other nuisance in cities, if proper cleansing were systematically resorted to; and houses might be built, even for the humblest, upon plans that would secure ample ventilation, and promote the health of the occupiers. He then described the condition of houses in towns as they now exist, and pointed out their characteristic evils; affirming his belief that the chief cause of the high mortality of an urban population is the bad construction and squalor of their homes. The new Act for the improvement of the dwellings of the working classes would, it was hoped, remove the worst of these evils. Dr. Ross then explained a series of tables to show the direct influence of unwholesome houses in producing disease and premature death. He gave a list of thirty-two streets in St. Giles's district; and showed that, in one street at the top of the list there was, in the course of a year, one death in every house from diseases caused by filth and bad ventilation, viz., zymotic diseases, tuberculous diseases, and asthenic bronchitis. From that high average,

there was a gradual declension until, in a square at the bottom of the list, there was only 1 death in 41 houses from the same diseases. Again, as regards population, Dr. Ross showed that the mortality from the same diseases was more than thirteen times greater in the street than in the square. In Chapel Place, a court of small cottages, the death-rate in 1870 was 69.7 per 1,000, and all the deaths were caused by the diseases named. In Queen Street, the death-rate was 48.7 from the same diseases. The death-rate of other places was given, and Dr. Ross described the peculiarities of the several courts to account for the difference of mortality. The mortality in Chapel Place from zymotic diseases was 16.4; in Queen Street, 9.7; in Church Lane, 8.4; in Dudley Street, 6.2; and in Wild Court, 5.6 per 1000 living. Dr. Ross then compared the death-rate in three blocks of buildings, under the management of the Society presided over by Lord Shaftesbury. These blocks were similar in size, had the same careful attention, and were occupied by a similar class of people, and only differed materially as regards their structure and surroundings; and he showed that, in one year, the death-rate was, in one block of the model houses, 4.6 per 1,000; in another block of adapted houses, 18.2; and in the third—a very bad old block, but adapted according to the prevalent notions for promoting health—36.5 per 1,000. The sanitary condition and mortality of portions of the Whitechapel District were then detailed, the facts being collected from Mr. Liddle's Reports. The results were similar to those in St. Giles's district. The wretched habitations in Farthing Alley and Rose Court were described—houses consisting of two and three rooms in narrow courts, without proper sanitary conveniences, and without the possibility of ventilation. Dr. Ross stated that there were many acres of this kind of property in Whitechapel. Dr. Ross then reverted to his original proposition that mere density was not necessarily a cause of disease, and illustrated his argument by a reference to the high density of population in model dwellings, and the associated low death-rate. He also stated that already in some parts of the metropolis the density ranged from 600 to 2000 persons to the acre. The difference in the mortality was caused chiefly by the difference in the construction of the houses and sanitary arrangements. It was not density, but dirt, that had to be guarded against. The defects of site, construction, and arrangement, that make houses unhealthy, were then briefly stated, strong emphasis being placed upon the evils arising from the bad foundations of houses. Dr. Ross insisted that all dwelling houses should be built on concrete or other impermeable material; as all porous soils, including gravel, let in the water, and made houses unwholesome. Brick houses, after a certain period, became unfit for habitation on account of the absorbing power of the brick, which retained miasmatic poisons, and kept up a succession of attacks of zymotic diseases. Many of the remarks in this part of the paper were evidently made in allusion to the powers for condemnation given to medical officers of health in the new Act of Parliament. Dr. Ross concluded his paper with a list of suggestions in respect of the sanitary requirements to be observed in the erection of new dwellings for the working classes.

Sanitary Remarks on Trap and Soil-Pipes. By A. FERGUS, M.D., Glasgow.—Dr. Ferguson said he had for some years been investigating diseases connected with excremental pollution; and, at the Birmingham meeting of the Association, he had drawn attention to the danger arising from decayed soil-pipes. Finding that the perforations were always in dry portions of the pipes, and made from the inside, he concluded they were caused by sewer-gas—an inference sustained by chemical analysis of the powdery corroded matter, and by the fact that ventilated pipes lasted longer than close ones. The specimens he exhibited had all been well trapped; and as tension sufficient to force gas through the trap was too rare to account for such an action, he was forced to the conclusion that the gas was either generated in the trap itself, or was absorbed by the water at the outer end, and given off at the inner end, or that both of these things took place. That diffusion by the latter means was likely—indeed, inevitable—he had proved by frequently repeated experiments with model traps, when a little gas (without pressure) on one side, was always found to diffuse itself through the water, and, in a very short time, to indicate its presence by chemical tests on the other side. This happened whether the gas was light or heavy, and the most thorough ventilation only made its passage a little slower. He had recently been giving increased attention to the other source of gas—viz., generation in the trap itself. He invariably found that part of the fæces floated on the surface of the water on the house side of a trap or cesspool. Flushing only agitated without removing them, and then they decomposed until dissolved. The gas so generated must either pass up the rain-pipe (if connected) or into the house; and was more likely to do the latter, on account of the higher temperature. He gave minute particulars of a representative case in a good locality in the West End of Glasgow, where typhoid fever, casually introduced,

was spread in this manner. The true sanitary remedy was that no excretal matter should be allowed to pass into the drains at all; it should be dealt with separately, and, within twenty-four hours of being voided, should either be returned to the earth or subjected to chemical or other action, rendering decomposition impossible.

On the Sanitary Improvements of Country Villages. By G. WILSON, M.D., Leamington.

On the Comparative Merits of the Water Carriage and Dry Systems of Sewage from a Sanitary and Economical Point of View. By G. A. KENYON, M.B., Chester.—This paper set forth the conclusions arrived at by an impartial inquiry into the respective advantages and disadvantages of water-closets, versus dry methods of removal of excrement for urban communities. These conclusions were, in short, to the effect, that if removal at intervals of one week or less is to be insisted on, then the only advantages that can be pleaded in favour of dry systems is, the saving of the water that would otherwise be required to flush the closets; and that the quantity of water thus saved may be taken to be equal to one-seventh or one-sixth of the smallest amount needful for the convenient satisfaction of the other requirements of the community; an amount that would seldom be of serious importance. The experience of towns (Coventry, Warwick, Bristol) in which the use of water-closets is universal, was quoted to show that no serious difficulty is encountered from misuse by the poorer inhabitants. The danger of introducing sewer-gases into houses may be entirely avoided by keeping the water-closets, like all other closets, actually or virtually outside the houses. Although recently a great amount of success has been met with in disposing of the contents of the pails in one large town, yet the working expenses are so great as to exclude the idea that, on this account, the pail system has any advantage over water-closets; whilst there is, as a matter of fact, a good deal of nuisance connected with their use, and not the same security from the risk attending the deposit of infectious evacuations or discharges which is afforded by the water-closet. If removal once in three months were sufficient, there would be attainable, at a smaller expense, a great improvement in the old state of things in a town; by filling up all underground middens or cess-pools, excluding rain, distributing ashes, and so arranging, that any excess of moisture, such as would be occasioned by inadvertently emptying slops therein, should escape along a surface channel to the yard-gully. Thus, there need be no drain inside, and no ashes could get into the sewers; nor would the interior remain wet; and there would be a warning afforded which would tend to prevent a repetition of misuse.

The Drainage and other Sanitary Conditions of Rural Districts. By J. A. DAVENPORT, Esq., Nantwich.—In the course of a paper, in which the question of rural drainage was dealt with, Mr. Davenport said that, of the systems of dealing with house-slops and liquid refuse, one which seemed to answer in the district with which he was connected, was that of subirrigation carried out either in the gardens or fields adjacent to the dwellings, sometimes in connection with a little tank, and sometimes without; where there was no tank, the slops were thrown to a trapped grid, below which there was a strainer to prevent any matter from passing, likely to choke the drain; where it was necessary to prevent pollution of the soil, larger sanitary pipes should be used; but, where the liquid was dealt with, common pipes were used (sometimes with sockets), and at every two or three feet, spur pipes branched out for three or four pipes' length; these drains were placed ten or twelve inches below the surface, and the liquid soaked from them into the soil. It was necessary, however, to provide subsoil drains at as great a depth as possible in order to relieve the soil of the excess of purified water; sometimes it was preferred to allow the water to drain into a little tank first, properly placed, to be kept for garden purposes; and then the overflow was simply dealt with on the above system. Sometimes he had utilised a deep ditch, running the overflow irrigating drain parallel to it, and allowing the liquid to filter through the intervening soil. If the upper drains should become choked, it would be but a small matter to take them up and relay them; but he had in his district a block of eight or ten houses that had been drained on this system for two years past, and all was working well up to the present with no signs of choking. Most of the work was roughly done, and under conditions rendering a good result a matter of some doubt. Still, so far, it was as satisfactory as might be expected. The difficulties in persuading and arranging as to this particular system had been great; for ordinary people did not quite comprehend it. The only principle that he had considered it safe to act upon, was to deal with all foul liquids by the soil; get them properly on to it or through it by some means as quickly as possible; and, in suggesting any rural drainage, he always kept this end in view; and the system sketched out, or some little variation of it, which might be frequently necessary, looking at the varying conditions under which such work had to be carried out, would

generally be found to furnish a fair solution of the difficulty. The ventilation of the drains should in all cases be insisted on. Field's flush tank would be a great addition to any system of garden subirrigation. Greater difficulties with these subirrigating systems might be experienced where the soil was excessively stiff, but the ashes from the house and the refuse from the garden burnt, together with other substances tending to lighten it being mixed therewith, would in some degree tend to remove the difficulty. Probably for villages, etc., no better method of dealing with their sewage could be adopted than that provided by the automatic sewage meter-tank.

Drinking and Table Waters. By C. H. BARTLETT, Ph.D., F.C.S., London.—The paper commenced with remarks on the necessity of a sufficient supply of aqueous fluid for the due performance of the functions of animal life, and the fundamental part water performs in the transformation of food into the animal tissues and in the elimination of the waste products of the system. The agency of water in the processes of fermentation and decomposition was then considered; and the advantage of accurate observation of the quantities imbibed in health and disease was pointed out. The author then commented on the value of microscopic research as leading to a new method of pursuing medico-chemical investigations which might pave the way to the identification of the specific poisons of infection. He then noticed the precautions required to prevent drinking water from disseminating disease. Chemically pure water was unattainable and unnecessary. The geological sources of water-supply, as affecting its wholesomeness, were considered; and the reason was given why the water from surface-wells and alluvial soil is generally unfit for drinking. The nature of different organic impurities in water was described; and the means of discriminating those which were dangerous from others less objectionable were mentioned. Remarks were made on metallic poisons in solution, and on the fallacy of the usual standard of estimation. Autumn was the period when well-water was most liable to dangerous impurities. The author described the means of prevention of lead-poisoning, by the use of tin piping and a new filtering medium which removed both lead and organic matter. The dangers of common aerated waters made with impure chemicals, and the necessity for a great alteration in the ordinary apparatus for their manufacture, were pointed out.

On Ventilation, with Model of Apparatus. By G. GOLDIE, L.R.C.P.Ed., Leeds.

The Expense of Ventilation and Warming as Sanitary Requirements. By JAMES A. RUSSELL, M.B.

On the Mineral Constituents of Drinking-Water. By J. A. WANKLYN, Esq., London.—Mr. Wanklyn said that within the last ten years the problem presented by the organic matters in water had been solved. Chemists would do well to return to the inorganic materials in drinking-water. It was a well established fact that, by filtration on the large scale, the organic matter in drinking-water might be so far removed that the water might be made to reach the standard of purity attained by good drinking-water; but, if there were objectionable mineral matter in the water, there was no remedy but to change the source of supply. To this statement, however, there was an exception in favour of the Clark process, whereby an excessive charge of carbonate of lime was reduced. It might be asked, Do not the mineral matters taken in food so far outweigh that in drinking-water as to reduce it to insignificance? An inquiry into the mineral matter actually present in the food led to a decidedly negative answer. Bread contains the mineral matter of the flour and the salt commonly used in making it. Assuming that one pound of flour is consumed by an individual in a day, the mineral matter supplied by the flour will be about 50 grains; and these 50 grains comprise 25 grains of phosphate of potash, 12 grains of phosphate of magnesia, a little phosphate of lime, a little silica, etc. To the pound of flour the baker adds about 70 grains of salt. The quantity of water drunk in all shapes during the day may be set down at about half a gallon; and those Londoners who drink the water of the Thames will, therefore, take daily 8 or 10 grains of mineral matter derived from the drinking-water. Putting on one side the common salt, which was artificially added, the mineral matter of the food did not by any means overwhelm the mineral matter in the drinking-water. The question had often been asked, whether the carbonate of lime present in many hard waters might not be needed by the animal economy. If the only other source of lime were the flour consumed as bread, there might, indeed, be need for the lime in the drinking-water. According to the recent analysis made in Mr. Wanklyn's laboratory, there is very little lime in flour, one pound of which contains only $1\frac{1}{2}$ grain of lime. He believed that a comparison of the mineral contents of the ordinary dietary of a population with the character of the water-supply would furnish most valuable information. The mineral required in the largest quantities by the animal economy was common salt, at least 150 grains of which were required daily by a

man. He believed that salt-famines must occur, and that whole populations must occasionally suffer from deficiency of that material; and he once recommended a water-supply with 80 grains of salt to the gallon, in a case where the population appeared not to get sufficient salt from other sources. He knew no considerable water-supply to any town in this country from which any considerable fraction of the daily dose of salt could be derived; but the various beverages often contain much salt. Beer, which is notoriously charged with a considerable amount of salt, was a good example in point. A few years ago, Webb's soda-water came into great favour; and, when this soda-water was examined, it was found to contain a large proportion of salt. Apollinaris water was a highly salted drink. The strange liking which many persons had for the water of sewage-wells, such water being notoriously charged with salt, afforded another illustration. Bearing these facts in mind, the conclusion was, that water-drinkers should add a little salt to the water—20 to 50 grains of salt per gallon. Passing from the salt and carbonate of lime, which might be looked upon as in a sense nutritious, there were in drinking-water other matters, some of which were not nutritious, being to a certain degree poisonous, or being medicinal. To this class Mr. Wanklyn would assign soluble compounds of magnesia. No water-supply should contain more than a very small proportion of magnesia; probably the limit should be set at not much over 1.0 grain (carbonate of magnesia) per gallon of water. In Thames water, he found 0.7 grain of carbonate of magnesia per gallon; in the Kent Company's water, 1.3 grain. A curious example of a magnesian water was afforded by the St. Ann's Well of Buxton, the water of which, according to the very careful analysis of Playfair, contained 4.7 grains of carbonate of magnesia per gallon.

Vote of Thanks to the President.—Dr. A. P. STEWART (London) moved a vote of thanks to the President, Dr. Lyon Playfair, whose presence had done honour to the Section. [*Loud applause.*] One of the few real statesmen, he said, sent to the House of Commons after the passing of the late Reform Bill was Dr. Lyon Playfair, whose ability was soon recognised by all, and who secured a power and position in the House which, he believed, would be strengthened in the future. Dr. Playfair had been of great advantage to the community, especially on those matters to which his life had been devoted, and to whose success he had so materially contributed. [*Applause.*]

Dr. CARPENTER (Croydon), in seconding the motion, hoped that Dr. Lyon Playfair would be able to carry out those maxims which were put forward by the leader of Her Majesty's Government and by the leader of the Opposition—viz., *Sanitas sanitatum, omnia sanitas*; and *Salus populi suprema est lex* [*applause*—for hitherto what had been introduced had been defective to a considerable extent. [*Hear, hear.*]

Dr. LYON PLAYFAIR said it had been to him an immense pleasure, and a great aid and encouragement, to have met so many Medical Officers of Health from different parts of the kingdom; because, although they had corresponded and co-operated together, still the presence of so many gentlemen interested in this great subject—which the leader of the present government had justly said was the great subject of the future—encouraged a legislator to go on with his arduous labours; because he felt assured that there were in the section practical men who could give practical suggestions which would enable this subject to be forwarded. [*Applause.*]

SECTION E.—PSYCHOLOGY.

Wednesday, August 4th.

The President, Dr. W. H. LOWE, delivered an address, which was published at page 176 of the JOURNAL for August 7th.

The Disorders of Speech in Insanity. By F. S. CLOUSTON, M.D., Edinburgh.—A discussion ensued, in which Dr. White (Aberdeen) and Dr. A. Robertson (Glasgow) took part.

Observations on the Unilateral Phenomena of Mental and Nervous Disorders. By ALEXANDER ROBERTSON, M.D., Glasgow.—After some preliminary observations, unilateral mental phenomena were first considered. These consisted of illusions and hallucinations, and possibly also of the peculiarities supposed to be due to the separate and independent action of the hemispheres. The observations of French writers were specially noticed. Cases of one-sided hallucinations of hearing were quoted from Gall, Griesinger, and Schrodor van der Kolk. But these cases appeared to be nearly exceptional in the experience of these observers. The writer then submitted the results of his examination of 250 insane patients, both in respect of these and other sensorial or psycho-sensorial disturbances. Of thirty-four patients who entertained clear and well-defined illusions or hallucinations of one or other of the senses, in five "voices" were heard only in the left ear, and in five others in the left ear more than the right; in one, they were audible in the right ear alone; and, in two, they were stated

to be more distinct in that ear than the other one. The disorders of the other senses were then referred to, and afterwards details of the cases of unilateral auditory hallucinations were given. The phenomena were most apt to occur in the milder and more ephemeral forms of insanity, and particularly when it had been caused by strong alcoholic liquors. The frequency with which the hallucinations were associated with the left ear was very striking, and it was pointed out that the cases quoted from the above named authors were also on the left side. The pathology of the phenomena was then considered at some length, and also the indications derived from modern research in the anatomy, physiology, and pathology of the nervous system as to their anatomical seat. The seeming dual action of the hemispheres was then illustrated. Thereafter, unilateral motor phenomena were discussed, the observations being restricted to the convulsive class; and a number of conclusions were stated, some of which were published by the writer in 1869. First, convulsive movements may begin in different parts of the body in the same case, even though there is no reason to think there is any appreciable change in the cerebral lesion. Second, in unilateral convulsions, the so-called bilateral muscles are often implicated, but the twin muscles of the otherwise sound side in most cases do not contract so firmly as those on the side first convulsed. The physician may, therefore, often ascertain for himself in a case of general convulsions the side on which the convulsive movements first began (and, consequently, the hemisphere affected), by simply grasping the limbs of the two sides, and comparing the degree of firmness of their respective muscles. Thirdly, there may be *alternate* conjugate deviation of the eyes during the same convulsive seizure. Fourthly, as a general rule, the higher up the lesion is situated the more apt the convulsions are to become bilateral. Fifthly, when convulsions begin on one side, there is frequently a distinct and sometimes a prolonged interval before consciousness is involved; and it is occasionally retained throughout the whole seizure. Sixthly, there is a decided increase of temperature in the convulsed members. All these conclusions were illustrated by cases. With respect to unilateral sensory phenomena, it was submitted that there seems less disposition for the "irradiation of sensations" from one to both sides, than for the extension of one-sided into general convulsions. The greater regularity of the motor than the sensory symptoms was also dwelt on and illustrated. In surveying the different classes together, it was observed that one-sided disorders of motion and sensation had their analogues in unilateral hallucinations, and just as the partial might become general in the one case, they might also do so in the other. A striking illustration of the gradual merging of illusions of vision into insanity was submitted. Lastly, some observations were made on the irregularity in the order of succession of these phenomena as compared with normal physiological sequences.—M. DUPUY (Paris) referred to his own experiments on the effects of cauterising one cerebral hemisphere, in which he had found paralysis of the same side of the body as a result; while a subsequent cauterisation of the opposite hemisphere appeared to have a counteracting effect, the paralysis then disappearing.—Dr. Clouston, Dr. Vellowlees, Dr. Deas, and Dr. Bramwell, continued the discussion.

Notes of an Unusual Case of Epilepsy. By P. MAURY DEAS, M.B., Macclesfield.—This was a case of epilepsy, complicated with mania, but also presenting some unusual and anomalous symptoms, occurring in a strong and apparently healthy young woman. The epilepsy had existed six years. Before that, she was subject to "aggravated hysteria". Maniacal symptoms first showed themselves eight months ago. She was under treatment in the Northampton Asylum for four months, and in the Cheshire County Asylum for the last six weeks. On admission, the left foot was found to be contracted and distorted, exactly like a bad case of talipes varus. The patient, who was very rational at times, said she had a bad attack of fits last Christmas, while in service, and when she came to herself she was in the union, and her foot distorted as it was now. The day of her admission she had several fits, and the following evening had a succession of several fits from 7 P.M. to 4 A.M. The noticeable points in the fits were: 1. Violent rhythmical movement of the head from side to side, to the number of one hundred a minute, and attended by a peculiar short respiration, like a bark; 2. Tonic spasms of the muscles of the limbs, which were strongly flexed; 3. The spasms in about three minutes extending to the trunk, and ultimately producing actual opisthotonos; 4. Increasing congestion of the face and neck until, at the maximum of the spasms, the face assumed the characteristic epileptic lividity, with complete closure of the glottis; when, just as choking seemed imminent, sudden relaxation took place, followed by stertor, blowing respiration, and foaming at the mouth; 5. After the fits had lasted some time, the right foot was observed to be becoming contracted during the spasms; and by the morning it was permanently distorted similar to the left one. She became maniacal after this for ten days, with fits at intervals. During one series of fits, the left hand

became contracted and distorted also, but came right in a few days. The treatment consisted of stimulating injections, bromide of potassium, and blisters to the nape of the neck. The most interesting point, perhaps, in the case, was that, under chloroform, the contraction of the right foot was reduced. A splint was subsequently applied for a week, and now the limb was as well as ever. The left foot had since been treated in the same way. It was already much improved, but, from the longer continuance of the contraction, the result in this case must be more doubtful. The questions arose, Was this a case of true epilepsy? Could it be a form of hysteria? or had the "aggravated hysteria", from which she had suffered, gradually developed into epilepsy? or was it probable that there was organic disease? Dr. Deas was led to think that the case must be classed as one of epilepsy, from the following considerations. 1. There was an undoubted "discharge" during the fits. 2. The patient had a sensation of "aura". 3. There was complete unconsciousness during the fits. 4. There were closure of the glottis, venous congestion, frothing at the mouth, and stertorous breathing. 5. There were none of the ordinary signs of hysteria. The patient complained much of pain in the head, especially in the intervals of a series of fits; she sometimes asked to have it cut open, or that she might be killed. Dr. Deas thought it possible that there was a source of irritation in the brain of an organic nature, but whether of the nature of deposit, tumour, or other change, it was impossible to say. This view was consistent with the marked predominance of tonic spasm, and the prolonged contraction of groups of muscles.

Emotional Aphasia. By D. DE BERDT HOVELL, F.R.C.S.E., Clapton.—This affection, which might be distinguished from that more frequently bearing the name, by being usually of temporary duration and not the result of organic disease, was illustrated by the case of a lad, sixteen years of age, who, with an interval first of six, and next of eight weeks, lost the power of speaking, but not of thinking or writing; on the first occasion for twenty-four hours, on the next for forty-eight, and the third for one hundred and twenty hours. He recovered perfectly each time. The attack was brought on, in the first instance, by fatigue of speech from prolonged effort of talking, combined with excitement and anxiety. It was contended that this was an instance of aphasia proper, *i.e.*, according to the Lexicon, of speechlessness, from fright or emotion, and that the disease to which the name is usually applied would be more properly described by aphemia, if that were a classical word, but, that not being so, by the aphasia atactica of Dr. Ogle. In explanation of the symptoms, it was assumed that the vaso-motor nerves were the seat of the disorder.—A short debate followed, in which Mr. Lennox Browne, Drs. Down, Gairdner, and Clouston, took part.

Thursday, August 5th.

Statistics of Lunacy in Town and Country. By JOHN SIBBALD, M.D., Edinburgh.—Dr. Sibbald exhibited several tabular statements illustrating the statistics of lunacy. He pointed out that the problems to be solved before these could be properly understood were of great complexity. The figures which he had collected in the tables shown were intended to illustrate one branch of the subject. They showed, among other things, that the number of pauper lunatics in Scotland persistently chargeable to country parishes is larger than the number chargeable to towns, being 206 per 100,000 for the country, and 177 per 100,000 for the towns. On the other hand, the number annually added to the roll of pauper lunatics from among the residents of country parishes is smaller than the number occurring among the residents of towns, being 35 per 100,000 in the one case, and 56 in the other. He showed that this is probably accounted for by a large number of patients requiring only temporary treatment being sent to asylums in towns, who would be allowed to remain at home in the country. He adduced arguments and figures to show that the apparently enormous increase of lunacy in late years was only an apparent increase, and that there is no proof statistically that there is a larger proportion of actual insanity in the population now than there was thirty years since.

Unilateral Convulsions and Hemiplegia, depending upon a circumscribed Lesion of Cerebral Convolutins. By BYROM BRAMWELL, M.B., Newcastle-on-Tyne.—Mary Conway, aged 37, was admitted to hospital May 23rd, 1875. Eight years ago, she received a severe blow on the left side of the head. (The skull was fractured.) Three years ago, she had four right-sided unilateral convulsions, brought on, she thought, by fright. For the past three years, she had felt "pins and needles" in the forefinger and thumb of the right hand, and had not been able to use her needle as well as formerly. On May 10th, she went to bed very drunk, and vomited all the following day. On May 11th, she had a severe convulsion, and continued to have fits. A week after the fits commenced, "she lost the power of her right arm and leg". She looked fifty years of age. The pupils were equal,

cases, 616 males and 653 females were sane, and 430 males and 351 females insane. From the comparative table of the effects of various diseases on the weight of the brain, in the sane and the insane of both sexes, it appeared that, taking the total numbers, the encephalon was heaviest in the insane, the difference being in the males three-fourths of an ounce, and in the females an ounce and a quarter. The average weights were as follows, taken from the whole of the cases :

	Sane.		Insane.	
	M.	F.	M.	F.
Cerebrum	41.4	36.4	41.8	37.5
Cerebellum	5.1	4.6	5.4	4.7
Pons and medulla	1.0	1.0	0.9	1.0
Encephalon	47.5	41.9	48.2	43.2

Tables were then given, showing the average weights in diseases of the nervous system, pulmonary diseases, cardiac diseases and dropsy, abdominal diseases, and typhus. Diseases of the nervous system were most numerous amongst the insane males, amounting to nearly 47 per cent. of their whole number; this excess was due to the frequency of general paralysis, a disease, as the symptoms indicate, usually accompanied by softening and sometimes by induration of the spinal cord as stated by Dr. Boyd in 1848, confirmed by the microscopical observations of Mr. Gulliver, and since by other observers. The encephalon was $2\frac{3}{4}$ ounces below the average weight. In pulmonary diseases, the encephalon was below the average weight in males and insane females. In cardiac diseases, the encephalon was considerably above the average weight in all classes, also in abdominal diseases, except in sane males, in whom it was the average weight. In fevers, too, the encephalon was above the average weight, so that cerebral wasting seems to accompany chronic diseases, cerebral and pulmonary.

The Psychology of Muscle. By J. S. NAIRNE, L.F.P.S., Glasgow.—According to the author of this paper, man has a psychologic and a pneumatologic nature. The latter is hidden. Muscle is entirely responsible for the former; and the identity of the nerve-centres with muscle, *i.e.*, as muscle is asserted. The psychologic phenomena are vital and intellectual; the powers are sensory and motor; and consciousness is an attribute of muscle, but not necessarily of it alone. This consciousness is progressive with organ, and at last amounts to knowledge. The senses are the highest muscular organs of knowledge, and beyond them and without them there is no remembering perceptive power. The being, the phenomena, the powers, are in all cases the result and necessity of definite equilibrium; without which equilibrium there is nothing.

Friday, August 6th.

The Hypodermic Injection of Morphia in Insanity. By J. MCDIARMID, M.B., Murchly.—After some preliminary remarks, the author spoke of the superiority of the hypodermic to the stomachic administration of morphia. The physiological reasons were the greater exactness of the dose, the easy administration in rebellious patients, and the unanimous consent of experimenters. The usefulness of hypodermic injection of morphia in insanity was commented on, and its use in melancholia, acute mania, recurrent mania, chronic mania, and general paralysis was illustrated by cases. The habits of filthy dements were improved under the hypodermic treatment. There was delayed action in some patients. Constipation was not caused by this method of giving morphia. Vomiting after subcutaneous injection was not frequent. Hypodermic injection of morphia was unsuitable in maniacs suffering from heart-disease, and was to be employed only as a *dernier ressort*. The use of atropia in combination with morphia subcutaneously was described; and also the doses of morphia required in the various forms of insanity. The results obtained by this method were compared with those of cannabis Indica, chloral, bromide of potassium, and opium and morphia by the mouth.—Dr. CLOUSTON (Edinburgh) said the effects of morphia in cases of insanity might be divided into three classes: first, what might be called its specific effect on melancholia; secondly, its quieting effect in cases of mania; and thirdly, its sleep-producing effect in all cases. In regard to the first of these—the specific action of morphia in melancholia—he performed a number of experiments some years ago, treating the patients with morphia, and administering doses of from half a grain to two grains. During the progress of his experiments, he had weighed the patients every week, had taken the temperature of their bodies, and had their diet carefully attended to. He did not administer the morphia hypodermically; but he supposed that, so far as its special effect on melancholia was concerned, that was of little account. The result of his observations was not in accordance with those of Dr. McDiarmid. Of twenty-two patients with whom he had experimented, the great majority lost weight during the treatment, while the appetite at the same time seemed to diminish. In only three of the cases was there anything like that

effect following the dose which had been so much lauded by various writers. Then, again, his experiments as to the quieting properties of morphia in cases of mania were certainly neither more hopeful nor more satisfactory than those connected with melancholia. In nearly every case, indeed, he found that the dose took away the appetite of the patient; and for this reason he did not consider morphia so beneficial as bromide of potassium and other remedies. In regard to the mere sleep-producing effect of the morphia, he thought the chief objections to it were the dryness of the mouth that was apt to be experienced in the morning, and the excitement occasionally brought on instead of sleep. On the whole, the results of his experiments in relation to the action of morphia on insane patients were such that he had almost universally discontinued its use.—Dr. MCDIARMID pointed out that the results spoken of by Dr. Clouston might be attributed to the fact, that that gentleman had administered about three times as much morphia as had been done in the experiments which he had conducted.

Experiments on the Brain of Monkeys, with especial Reference to the Localisation of Sensory Centres in the Convolutions. By DAVID FERRIER, M.D., London.—The experiments on which the following conclusions are based were supplementary to those of the electrical irritation of the brain of monkeys, already published in the *Proceedings of the Royal Society*. They were recorded in detail in the Croonian Lecture read before the Royal Society in May last. In the absence of Dr. Ferrier, Dr. Lauder Brunton gave a brief summary of the main results. The method followed was the comparison of the effects of electrical irritation with those following localised destruction of parts of the brain by means of the actual canterly or scalpel. The two sets of experiments supported and explained each other. The most important fact demonstrated by this series of experiments was the localisation of regions of special sense in the convolutions; and this, along with localisation of centres of motion proper, served to clear up the true significance of the reactions to electrical stimulation. 1. Destruction of the frontal regions of the brain, which gives no reaction to electrical stimulation, is without effect on sensation or voluntary motion, but causes marked impairment of intelligence and of the faculty of attention. 2. Destruction of the grey matter of the convolutions bounding the fissure of Rolando causes paralysis of voluntary motion on the opposite side of the body, sensation remaining unaffected; while lesions circumscribed to areas, previously localised by the author, caused paralysis of voluntary motion limited to the muscular action excited by electrical stimulation of the same regions. 3. Destruction of the angular gyrus causes blindness of the opposite eye, the other senses and voluntary motion being unaffected. This blindness is only of temporary duration, provided the angular gyrus of the opposite hemisphere remains intact. When both are destroyed, the loss of visual perception is total and permanent. 4. Destruction of the superior temporo-sphenoidal convolutions abolishes conscious reaction to auditory stimuli, the other senses and voluntary motion remaining unaffected. The results of destruction, taken with the effects of electrical stimulation of this region, indicate that it is the centre of auditory perception. 5. Destruction of the hippocampus major and hippocampal convolution abolishes the sense of touch on the opposite side of the body. 6. Destruction of the *subiculum cornu ammonis*, taken with the results of electrical stimulation, indicates that this is the seat of the sense of smell for the same side of the body. 7. Destruction of the grey matter of the lower part of the temporo-sphenoidal lobe in immediate relation to the region of olfactory perception abolishes the sense of taste. 8. Destruction of the optic thalamus causes complete anaesthesia of the opposite side of the body. 9. Ablation of the occipital lobes produces no effect on the special senses or on the powers of voluntary motion, but is followed by a state of depression, with refusal of food, not to be accounted for by mere constitutional disturbance. In one case, which survived the operation for three weeks and was then killed, the appetite returned: a phenomenon probably to be accounted for by compensatory association. The sexual appetite, however, was exhibited during the first few days after the operation, as judged by the behaviour of the animal to a companion monkey. 10. Ablation both of frontal and occipital lobes in one monkey did not interfere with the powers of sensation or of voluntary motion.—Dr. ROBERTSON (Glasgow) thought those experiments, though doubtless very interesting, should not lead us too hastily to conclusions, as Dr. Ferrier's observations were much disputed, and the monkey's brain was not the same as a man's.—Dr. SAUNDEY referred to Veyssiéres's experiments on the localisation of common sensibility.—Dr. DUPUY (Paris) gave the results of his own observations, which differed from those of Dr. Ferrier.—Dr. CATON (Liverpool) had repeated many of those experiments, and could confirm Dr. Ferrier's statements. He had only just been made aware that Dr. Ferrier had been doing anything to localise special sense, and was very pleased to find that the centre, assigned by Dr. Ferrier to the sense of

sight, was one which he had localised by an entirely different method, viz., that of noting the variations in the electrical currents of the brain as caused by functional exercise.—Dr. FRASER and Dr. SMITH followed, and the latter expressed the general sense of the meeting in thanking Dr. Lauder Brunton for ably explaining Dr. Ferrier's views.

SECTION F.—PHYSIOLOGY.

Wednesday, August 4th.

DR. BURDON SANDERSON, F.R.S., President, took the Chair at 2 P.M.

Transference of the Long Tendon of the Biceps Muscle from the Scapula to the Humerus in Chronic Disease of the Shoulder. By JOHN STRUTHERS, M.D., Aberdeen.—Dr. Struthers explained how the tendon, say in a rheumatic shoulder, being no longer of any use, was removed from the upper bone and joined on to the lower bone, by which its use was thereby to some extent preserved. The steps of this process were narrated, and the subject was further elucidated by the exhibition of specimens. Adhering to the lower bone by the effects of excited action, the part of the tendon within the joint, having become functionless, was seen in various stages of passing away, while the attachment of the lower bones, on which the muscle pulled, became gradually stronger till the adaptation was completed. Dr. Struthers remarked that this might be called a pathological process; but pathological processes were also physiological processes; and, he expected that in future, the study of these processes would throw much light on questions connected with the origin and adaptation of healthy structures.

Experiments on Change of the Bodily Temperature consequent on Section of the Cord in the Cervical Region. By J. BURDON SANDERSON, M.D., LL.D., F.R.S., London.

The Electric Currents of the Brain. By RICHARD CATON, M.D., Liverpool.—After a brief *résumé* of previous investigations, the author gave an account of his own experiments on the brains of the rabbit and the monkey. The following is a brief summary of the principal results. In every brain hitherto examined, the galvanometer has indicated the existence of electric currents. The external surface of the grey matter is usually positive in relation to the surface of a section through it. Feeble currents of varying direction pass through the multiplier when the electrodes are placed on two points of the external surface, or one electrode on the grey matter, and one on the surface of the skull. The electric currents of the grey matter appear to have a relation to its function. When any part of the grey matter is in a state of functional activity, its electric current usually exhibits negative variation. For example, on the areas shown by Dr. Ferrier to be related to rotation of the head and to mastication, negative variation of the current was observed to occur whenever those two acts respectively were performed. Impressions through the senses were found to influence the currents of certain areas; e.g., the currents of that part of the rabbit's brain which Dr. Ferrier has shown to be related to movements of the eyelids, were found to be markedly influenced by stimulation of the opposite retina by light.

The Digestive Principle of Insectivorous Plants. By LAWSON TAIT, F.R.C.S. Ed., Birmingham.—Mr. Tait communicated the results of certain experiments he had made, for the purpose of separating the digestive principle or ferment, on which the remarkable power possessed by certain plants, as pointed out in Mr. Darwin's recent interesting work, is dependent. Mr. Tait showed that it was possible to separate this principle from the plant for experimental purposes. As to the precise method of its action, he was still engaged in inquiry; but, so far as his researches had gone, he was able to confirm the view taken by Darwin, that the chemical processes concerned in animal and plant digestion were identical.

The Effects of certain Drugs upon the Intracranial Circulation. By J. M. FOTHERGILL, M.D., London.—Dr. Fothergill stated that, in producing effects upon the intracranial vascularity, there were two factors: (1) a direct effect upon the circulatory system; and (2) an effect upon the cerebral cells by which they attracted more blood, or less blood to themselves. These factors existed in varying proportions in different drugs; and according to the exigencies of each case, one or other agent should be chosen, as opium in cases of insomnia from pain, chloralhydrate rather when the sleeplessness takes its origin in a high blood-pressure. Whether the agent administered depresses or stimulates the nerve-centres, its action can usually be intensified by giving it along with drugs which act directly upon the circulation, as opium with antimony, and quinine, which affects the encephalic blood-vessels; with digitalis, which raises the blood-pressure generally.

On a Case of Death from Suffocation in a Diver, illustrating some Effects of Increased Pressure on the Pulmonary Circulation. By R.

BEVERIDGE, M.D., Aberdeen.—The death of this man occurred almost immediately after his first descent for the season. There was no defect in the apparatus, and his companion who descended with him was unaffected; it could not, therefore, be due to deficient supply of air. On a previous occasion, this man had, under similar circumstances, nearly lost his life. It also was his first descent for the season. It was usual for divers on descending for the first time to experience a feeling of oppression and a sensation as if the head would burst. This, as a rule, passed very quickly away, and nothing further was observed in the way of discomfort till after leaving the water, when there was very often a sensation of giddiness, sometimes an attack of sickness, and in many cases a flow of blood from the nose and mouth. Most men after a few trials became accustomed to the work and suffered no inconvenience, but some did not do so, and always suffered in some way on leaving the water. These symptoms were undoubtedly due to the varying pressure on the vessels on the lungs, and in the above case had produced complete stoppage of the pulmonary circulation. This view was confirmed by the *post mortem* examination. The heart was large, pale, and flabby; its cavities were empty of blood; the lungs were intensely gorged with dark fluid blood. The air-tubes, beginning at the fauces, were much congested, dark purple in colour; and the smaller bronchi were partially filled with dark frothy blood. Other organs were also loaded with dark blood. The heavy pressure (in this case doubled) would cause partial stoppage of the lung-circulation, throwing back the venous blood on the right side of the heart, and thus inducing insensibility and suffocation, while the quick taking off of the pressure could allow all those vessels to fill to the utmost, thus producing the great gorging of all the bronchial surface, and the complete emptying of the cavities of the heart. In the discussion that ensued, several gentlemen expressed doubts as to the cause of the man's death, suggesting that, although one of the diving-bells was safe, the other might not have been so, and that this might not have been ascertained on account of the connecting-tube being out of order.

Thursday, August 5th.

Physiological Acoustics. By J. G. MCKENDRICK, M.D., Edinburgh.—Dr. McKendrick gave a demonstration on physiological acoustics, with the view of illustrating the results of the researches of Helmholtz regarding the quality of musical sounds. After pointing out that Helmholtz had discovered that a musical note consisted, not of one tone, but of a series of tones, Dr. McKendrick proceeded to show this by means of an ingenious contrivance devised by Dr. Koenig of Paris. In a series of interesting experiments, it was shown how a tone could be decomposed, as it were, into its fundamental harmonics, and in this way an actual flame-picture of it be obtained.

Effect of Division of the Sympathetic Nerve of the Neck in Young Animals. By WILLIAM STIRLING, D.Sc., M.D., Edinburgh.—Dr. Stirling said that the division of the sympathetic nerve in the neck, for instance, of a young rabbit or dog was, in the first place, followed by the ordinary symptoms of the operation. As the animal grew, however, it was found that the ear of the side in which the nerve was divided grew more than that on the other side. The hair of the ear upon this side became stronger than on the opposite side; and, lastly, the temperature of the affected part continued higher than that of the other side for several months together.

Anatomy and Physiology of the Semicircular Canals. By A. CRUMBROWN, M.D., Edinburgh.—The main object of the paper was to elucidate the theory that these canals may afford our sense of equilibrium and rotation. After stating the conviction that we possess a sense of rotation quite distinct from all our other senses, Dr. Crumbrown proceeded to show that this sense must necessarily have a special peripheral organ physically constituted so as to be affected by rotation. The structure of the semicircular canals of the internal ear was, he considered, such as to fit them to act as such a peripheral organ; and this view was supported by the experiments of Flourens and Goltz. The bony canals in question being filled with liquid, rotation of the head about an axis at right angles to the plane of a canal would produce motion of the contents, and this might be expected to irritate the terminations of the nerves in the ampulla.

On Injection of the Kidney in Bright's Disease, in Relation to Albuminuria and Hematuria. By J. COATS, M.D., Glasgow.

A New Histological Process for Staining Tissues. By FRANCES ELIZABETH HOGGAN, M.D., London.—Mrs. Hoggan said that the process in question recommended itself principally on account of the property it possessed of staining the substance of the cell as well as the nucleus and nucleolus, and because it gave the best results where carmine and ammonia failed. It consisted in first pouring over the specimen (after treating it with water and with methylated spirit) a one-per-cent. solution of perchloride of iron; and, in a few minutes

afterwards, a few drops of a two-per-cent. solution of pyrogallic acid—both solutions being made in distilled water. A practical demonstration of the process was given by Mrs. Hoggan.

The Action of Stimulants and Narcotics. By THOMAS P. LUCAS, L.R.C.P.Ed., London.—This paper opened with a notice of nerve-force. The author expressed the opinion that vitality is dependent upon an exhibition of this force. He adduced several proofs to show that it is most closely allied to electricity, and designated it as *nervo-electricity*. He divided this *nervo-electricity* into three parts: (1) that with which the nerve-fibres, muscles, and tissues generally are always charged, and which is spent in the rigor mortis—the residual; (2) the radiant *nervo-electricity*, or that which is continuously passing from the body with the eliminated heat—the complementary; (3) that which is called forth and discharged in the exhibition of every vital phenomenon—the supplementary *nervo-electricity*. The second portion of the paper was devoted to a notice of the action of drugs on the cerebro-spinal and sympathetic nerves, in order to show that stimulants act through the former, and narcotics by means of the latter. A number of proofs were adduced to show the action of narcotics upon the sympathetic. Instances were given to prove that stimulation (narcotisation) of the sympathetic induces general relaxation, contraction of the blood-vessels, and congestion of the capillaries, and consequent coma and death. On the other hand, severe stimulation (narcotisation) paralyses the sympathetic; the result of which is that the cerebro-spinal exercise their powers unchecked, and more or less prolonged rigidity of the muscles ensues. Again, those medicines which stimulate the cerebro-spinal (stimulants), cause increased activity in the parts stimulated; but if pushed to a great degree, they exhaust, and, by a provision of nature, narcotisation sets in; if the stimulation be still further pushed, exhaustion of the vital organs takes place, and death is instantaneous. In conclusion, the paper went to show that, by watching the action of drugs upon animals, by pushing the trial to the extreme limits, and by noting the *post mortem* appearances, we could ascertain the nerves on which such drugs act. Thus, in disease, we should be able to apply remedies in a scientific manner, not by an imaginary law of *similia similibus curantur*, but by a demonstrated law, *contraria contrariis curantur*.

The Magnetic Conditions of Arterial and Venous Blood considered in relation to the influence that Arterial Blood exerts in promoting the Functions of Life; and the consequent Value of Magnetism as a Therapeutic Agent. By R. C. SHETTLE, M.D., Reading.—In this paper, the author referred to the experiments he had brought before the Royal Society, in which he had demonstrated the fact that a grand distinction exists in the physical properties of arterial and venous blood with regard to magnetism, and that the magnetic properties of arterial blood are dependent upon the oxygen absorbed in the blood, with the amount of which they are in direct proportion. He next went on to show that, as chemical action and electric action are in direct proportion to each other, and the direction of the electric current is in the same direction as chemical action, and as by another law the amount of electric force generated is in direct relation with the amount of magnetic disturbance, it follows that, if the arterial blood is able to sustain life by virtue of the chemical action of oxygen, it is equally able to perform the same work by virtue of the magnetic disturbance to which the motion of the corpuscles gives rise; and, inasmuch as magnetic influences are exerted at sensible distances, and chemical action depends upon the contact of bodies, it also followed that in these operations of life chemical action must be secondary to and directed by magnetic action. He next pointed out that it is to the influence of the magnetism of the earth acting upon the molecules of matter in the circulating fluid in certain conditions that the corpuscles and various other organic principles owe their existence, and that the different characters which the blood-corpuscles assume in the four great divisions of the animal kingdom result: 1. From the food upon which the animal lives; and 2. From its habits of life; and, inasmuch as they result from the mode in which matter acts upon force and force upon matter, they naturally acquire properties peculiar to the animal in which they have been formed, and these peculiarities they again impart to successive generations of corpuscles. And, in accordance with this law, they would be liable to certain modifications by a

change in the habits or food of the animal in which they existed. The proper selection of food becomes, therefore, a matter of great importance with regard to health, every form of matter taken into the system having its own specific magnetic influence: 1. Over the blood-corpuscles; and 2. Through them over the nerve-currents; disorder or disease resulting from the imperfect manner in which organic principles are formed and combined either from insufficiency of force or impurity of matter acted upon. With regard to the treatment of disease by medicines, he showed by the above law that, as a rule, all drugs act by virtue of the magnetic characters they impart to the blood. Iron, one of our best and most universal tonics, strengthens the system by adding to the magnetic character of the blood, so inducing more powerful currents of electricity in the nerves. Magnetic bands applied externally are frequently of the greatest service, either alone or in conjunction with internal remedies, as they increase the polar influence of the part over which they are placed. The author concluded his paper by pointing out that the doctrine hitherto held has been that oxygen supports animal life by its chemical properties under the influence of a mysterious vital force (the laws of which must necessarily be as unknown as they are mysterious). With reference to the theological bearing of the subject, he showed that the fact of vital activity being referred to magnetic action only testified to the simplicity and unity of purpose which pervades all the works of the Creator, the grandeur of which becomes apparent not only in the phenomena of terrestrial magnetism, but also in the application of the same force to all the phenomena of life.

SELECTIONS FROM JOURNALS.

MIDWIFERY AND DISEASES OF WOMEN.

THE UNMANAGEABLE VOMITINGS OF PREGNANCY.—The *Journal de Médecine et de Chirurgie* quotes a communication from M. Tarnier respecting a case in which, in a multipara in the third month of pregnancy, serious unmanageable vomitings were arrested by the simple application of a plug of wadding to the vagina. He collates with this fact three cases published in the BRITISH MEDICAL JOURNAL, in which Dr. E. Copeman saw very serious vomitings arrested by the dilatation of the neck of the uterus. In the first case, the digital dilatation of the neck was to have been followed by puncture of the membranes to induce abortion at six months. A fortunate delay demonstrated to Dr. Copeman that dilatation had a great influence on the arrest of the vomitings. Pregnancy went on in due course, and the patient was delivered at the proper time. In a second case, the result was intentionally sought and obtained in the second month of pregnancy. In a third, pregnancy had reached the eighth month. The vomitings were also stopped, and the patient was delivered eighteen days afterwards, when she had already regained some strength. The plug and the dilatation of the neck are two mechanical methods which, in the opinion of the writer who comments on these cases in the *Lyon Médical*, are very rational, though undoubtedly acting by a different mechanism. The plug prevents the shaking about of the womb; the dilatation of the neck detaches the membranes over a certain space, and prevents the twitchings or distension of the internal orifice.

PATHOLOGY.

MALFORMATION OF ABDOMINAL ORGANS.—R. Wünsche describes, in the eighth volume of the *Jahrbuch für Kinderheilkunde*, new series, a case of congenital occlusion of the pylorus, with occlusion of the duodenum at its passage into the jejunum, absence of the gall-bladder, and atresia of the sigmoid flexure. The duodenum was dilated into a large sac, almost twice the size of the stomach, which was normal; it contained a quantity of thin brownish-yellow fluid. The jejunum and ileum were of the calibre of a quill, and quite empty; the large intestine was not much stronger, and contained a little mucus. From the liver, which was of normal texture, a rather wide hepatic duct passed into the duodenum; the ducts of Wirsung and Santorini were also abnormally dilated. The child in which these malformations occurred died six days after birth. Two other children of the same parents had, it was said, previously died at the same age.—*Centralblatt für die Medicin. Wissensch.*, May 15th, 1875.

BRITISH MEDICAL ASSOCIATION:
SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st, Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, AUGUST 28TH, 1875.

DIURETICS.

THERE exists no class of remedies so intimately wrought in with physiological knowledge for their rightful application in practice as diuretics. The well worn formulæ evolved by experience and largely used in a routine way by practitioners usually contain various forms of agents which increase the bulk of urine; but in their synthesis empiricism has received no aid from physiological research. Such formulæ, then, really are happy guesses; the guess having some direction given to it by close observation and comparison of different cases. They are creditable to the careful watchfulness of our predecessors in medicine, and demonstrate how much we owe to empiricism during long ages, ere science came to plant her finger-posts along what had been but wandering tracks, found and kept by few, and lost by the majority, who wandered on in aimless helplessness. In order, then, to comprehend the action of various diuretics, it is necessary to remember the structure and function of the kidney, its relations to the vascular system, as well as its depurative action.

One of the chief functional uses of the kidney is to excrete water. For this end, it is in peculiar and intimate relations with the circulation. In the kidney, the renal artery, itself but a short branch from the main trunk, breaks up rapidly into numerous minute arteries. These again suddenly break up into very fine and minute vessels, with extremely thin walls, through which the water of the blood escapes readily into the uriniferous tubules, and so passes away. In consequence of this rapid subdivision of an artery of considerable size springing off from the aorta, the flow of water in the kidney is in very close relationship to the blood-pressure within the arterial system. If a draught of water be swallowed, it passes readily from the stomach into the blood-stream, the bulk of blood is increased, there is increased blood-pressure, and a rapid flow of urine follows. Every variation in the condition of the elastic arterial system is readily felt in the kidney. If there be much tension, then the flow in the tubules is free; when the blood-pressure is low, the secretion is languid. In practice, it is a matter of great moment to recognise what Traube has so much insisted upon, namely, the relations of water-excretion to the condition of the vascular system. Every day we see this, that is, if we are prepared to look for it. The on-come of cold weather, and especially the first days of frost, increase the bulk of urine, and the calls to empty the bladder, very distinctly in most people. The cold contracts the vessels of the skin, and so raises the blood-pressure in the arteries, and an increase in the bulk of urine results. When the first warm days of spring induce free action in the skin, it is noticed that there is a palpable diminution of the bulk of urine. In the same way, we note how the bulk of urine falls in heart-disease; less and less is the volume of water passed, as the failure of the heart becomes more and more pronounced; the first effect of remedial agents in heart-disease, and the most cheering evidence that they are doing good, is the increased flow of urine. As soon as our agents affect the circulation and increase the blood-pressure in the arteries, the effect is visible in the flow of urine. Thus, in the administration of digitalis, squill, and similar drugs, we increase the bulk of urine by the effect of these agents upon the circulation. More careful experiments have been performed in connection with digitalis than with any other vascular diuretic;

and we know that, while this drug is so pre-eminent a diuretic in cases of failing circulation, it does not increase the bulk of urine in healthy persons; indeed, in toxic doses it produces arrest of the renal secretion. Of old, practitioners said that diuretics relieved the circulation, and that digitalis relieved the failing heart by getting rid of much water from the blood and so reducing its bulk. Even yet there are some who say that digitalis always acts best upon the heart when its diuretic effects are most distinct. This is a curious but not incomprehensible inversion of the facts of the case. Really, the flow of urine is the most satisfactory evidence of the effect of the drug upon the circulation.

So much for the relations of the vascular system and the flow of water through the kidneys. While recognising clearly the relations of bulk of urine to blood-pressure, it must also be borne in mind that the vaso-motor supply of the renal vessels is large, and functionally very active. By means of rapid dilatation of the renal vessels, a large flow of urine can be attained without much change in the blood-pressure. In cold weather, there is every reason to believe that not only is the general arterial tension increased by the contraction of the cutaneous vessels, but that there is an active dilatation of the renal vessels. This is rendered probable by the known relations of the kidney and the skin, and the effect of certain agents. For instance, draughts of fluids, especially if alkaline or alcoholic, in cold weather increase the flow of urine; in summer they increase the perspiration. Those who take potash persistently, and their number in these meat-eating days is legion, especially comparatively young men, note how their draughts of potash-water drench them with perspiration in warm weather. When the skin is acting freely, the amount of fluids consumed has but little effect upon the bulk of urine. In cold weather, when the skin is marbly and dry, the amount of fluids consumed exerts but little influence over the cutaneous transpiration. The play back and forward betwixt the skin and kidneys is very interesting and instructive. Some agents act upon the vessels of the kidney, dilating them, doubtless through the medium of the vaso-motor nerves, and so increase the flow of urine. These are diuretics in the truest sense—simple diuretics. It is obvious that such agents may be profitably combined with others which increase the blood-pressure. Such a combination is probably attained by the union of juniper and digitalis. In many instances, such a combination would be very desirable. It must not be asserted too positively that the vascular diuretics do not exert some special action upon the renal vessels; that, in fact, while producing a contracting effect upon the blood-vessels generally, they dilate the blood-vessels of the kidneys. If, indeed, they produced contraction in the renal vessels in strict proportion to their effect upon the rest of the vascular system, they would not produce an increased flow of urine: the effect upon the renal vessels would exactly neutralise their action upon the vascular system generally. It is necessary to be very clear upon this point, else it is impossible to read aright the effects of chronic Bright's disease upon the bulk of urine. It is well known that in the earlier and middle stages of granular kidney there is a great flow of urine. It is also well known that during these stages there are high blood-pressure, a low pulse-curve with the sphygmograph, accentuation of the aortic second sound, and hypertrophy of the left ventricle. There are, indeed, all the evidences of a high blood-pressure and a large flow of urine. When the heart begins to fail, then the bulk of urine falls step by step with the cardiac failure.

There are cases, however, where all these evidences of the state of increased arterial tension exist without there ever being a notable increase in the bulk of urine. What are, then, the lessons taught us by such cases?

They are these. While in the majority of cases there is increased blood-pressure due to an hypertrophied condition of the muscular portion of the vascular system, the renal vessels are not equally affected, and thus the increase in the blood-pressure produces an effect upon the urine; in other cases, there is hypertrophy of the muscular walls of the renal arteries sufficient to neutralise the rise in the blood-pressure, and so there is no increase in the bulk of urine. Clinical observation would

tend to show that the latter class of cases is much rarer than the former. The rule certainly is that the condition of vascular tension and the bulk of urine are intimately related to each other.

In those cases, then, where we wish to excite a large flow of urine, it is well to combine together in one prescription agents which dilate the renal vessels with agents which raise the blood-pressure. Some diuretics, and especially the various salts of potash, are actual depressants of the circulation, and in many cases, especially when the heart is weak, it is desirable to counteract the property by combining potash with squill or digitalis; in many cases of atonic gout this is very necessary.

The kidneys are also largely associated with the elimination of nitrogenised waste. The products of histolysis, and the waste of albuminoids split up in the liver to form glycogen—the cinders of the body-combustion—are cast out of the system by the kidneys and the skin. As in the excretion of water, so in the elimination of azotised waste, the kidneys and the skin preserve their intimate relation. When we wish to increase the elimination of solids by the urine, we do not, or at least ought not, to give a diuretic which possesses its diuretic effect by means of its action upon the vascular system. This is useless. But, instead, we give potash, buchu, and other agents which act upon the kidney itself. By these means, we increase the elimination of urine-solids. In many cases, especially in those cases of Bright's disease where there is a large flow of urine of low specific gravity—not a mere case of dilution of urine-solids, but a positive decrease of the solids, with increase of the bulk of water—it is desirable to give potash in infusion of buchu. In the scanty urine of advanced heart-disease laden with lithates, such-mixture would produce no good results, probably, in most cases, only depress the heart's action further; while vascular diuretics are the agents required by such a condition. In that form in which azotised waste is most permanent in the body—viz., lithic acid—potash increases the bulk of urine-solids by rendering the lithic acid soluble, so that, as lithate of potash, it drains away in the water of the kidney. There are thus diuretics which increase the bulk of urine-solids, and diuretics which possess the property of increasing the amount of solid excreta in the urine. They are totally distinct agents, not to be confounded with each other, not to be substituted for each other, but often to be combined together with advantage. Whenever, then, we wish to act upon the kidney, we must first clearly recognise what it is we wish to achieve, and then to prescribe accordingly. If there be a condition of urine laden with lithates, then potash is indicated. If at the same time the vascular system be atonic, and the heart act feebly, then it is desirable to give squill or digitalis as well. It is not inconsistent to give a vascular diuretic with one which increases the excretion of urine-solids; but it will not do to give one for the other, as if they could be substituted for each other. With either, or with both, may be given a simple diuretic which induces renal hyperæmia.

In the earlier stages of chronic Bright's disease, when there is a full well-sustained pulse, potash may be given alone without depressing the circulation too much. In fact, a certain amount of depression of the circulation is not without its advantages; and a lowering of the bulk of urine is commonly accompanied by a positive increase in the amount of urine-solids, not a mere relative and proportionate rise in the specific gravity. Indeed, it would seem that there is certain antagonism betwixt those branches of the renal artery which Virchow has shown to pass to the cortical substance and the glomeruli, and those which pass in an opposite direction to the vasa recta and the pyramids. When the one set are dilated, there is a large flow of water, and a small escape of urine-solids; when the others are dilated, there is a small flow of dense urine. In health, we are all subject to variations in the volume and character of the urine. In chronic renal disease, these changes are more pronounced still, and the variations in the renal secretion are such as to force themselves upon the attention of the individual. It seems probable that vascular diuretics act upon the cortical division of the branches of the renal artery, as we find under

their use a great increase in volume of urine, without increase in bulk of urine-solids. So also it would appear that agents which increase the elimination of urine-solids act upon the pyramidal vessels, at the same time decreasing the bulk of urine. Thus we find a condition of high arterial tension, with a large flow of pale limpid urine, give way to a condition of lessened arterial tension and a small bulk of dense urine: a change very common in the subjects of chronic renal disease. Also, we know that a discharge of lithates in the urine commonly precedes the breaking of a common cold and restored activity of the skin; a dilatation of the pyramidal vessels apparently anticipating the relaxation of the cutaneous vessels. On the other hand, with the corded vessels of an acute hysterical attack, we find a large flow of limpid urine, very free from solids. There is some association, not yet satisfactorily recognised, but glimmering faintly, betwixt conditions of arterial tension and the two sets of vessels in the kidneys. By vascular diuretics we act upon one, and by eliminant diuretics we act upon the other.

The anatomy and physiology of the kidney must be borne in mind whenever it is desirable to give a diuretic; and the form of diuretic to be administered must be recognised in every case, and adapted to the end we wish to attain. Agents classed as diuretics cannot be given indiscriminately and substituted for each other. They can, however, often be combined with advantage, and a vascular diuretic may often be united to a diuretic of another form with benefit in a large class of cases.

ALLIANCE BETWEEN QUALIFIED AND UNQUALIFIED PRACTITIONERS.

DURING the past week, at an inquest and in a police-court, evidence was given of two instances in which such an understanding existed between unqualified and qualified practitioners as, at least, to amount to a treaty of alliance, that is not only discreditable to the profession, but dangerous to the public. At an inquiry held by Mr. Humphreys, the coroner for East Middlesex, as to the cause of the death of an infant, it appears that there is a so-called dispensary at 20, Bethnal Green Road, kept by an unqualified practitioner, who, on examination, called himself a "student of medicine", although he admitted that he had never been a student in a hospital, or attended any medical lecture; over his door, however, he was described as "surgeon and accoucheur", and, in his window was announced, "home visitation 2s. 6d. per week, medicine and advice 1s. per week". It was stated at the inquest, that all interest in this establishment had been now handed over to a qualified practitioner, who attends at the surgery two or three times a week; the unqualified "student" still, however, occupies the premises as Dr. Bathrom's assistant. Such an arrangement savours too much of a partnership between a qualified and an unqualified practitioner to be satisfactory from a professional or a public point of view. If a qualified practitioner allow his unqualified assistant to see patients at his own residence, their relations assume those of a kind of partnership. We may, remark, moreover, that Dr. Bathrom's name, which was referred to at the inquest, does not appear in the *Medical Register* for 1875.

The other case to which we would refer, was heard before Mr. Bridge, the police magistrate, at Hammersmith. An unqualified practitioner in Kensington was summoned at the instance of the Board of Guardians for signing a medical certificate, under the Vaccination Act, alleging that a certain child was not in a fit state to be vaccinated. Two certificates were produced, one purporting to be signed by Percy Leslie, M.D., and the other bore the signature "W. C. Smith, for Percy Leslie, M.D." The defence was, that the defendant acted as assistant to Dr. Leslie, and signed the certificates by his authority. It was proved, however, that there was a brass plate bearing defendant's name on the gate of the house where he resided, while Dr. Leslie lived in Westminster. Dr. Leslie, in his examination, stated that the defendant had been his assistant in Westminster, but had not so acted for a year. Dr. Leslie, however, admitted that he had, since defend-

ant had been in Kensington, been frequently at his house, and that "no doubt the defendant was constantly in the habit of signing himself certificates for him". In the present period of antivaccination agitation, it is very satisfactory to find, not only that the Kensington guardians decided to prosecute in the case, but that they succeeded in getting a conviction. The defendant was fined £10, and ordered to pay two guineas additional for costs, with the alternative of two months' imprisonment.

M. WURTZ has been nominated Professor of Organic Chemistry in the Faculty of Sciences of Paris. He consequently resigns the office of Dean of the Faculty of Medicine.

A NEW chair of General Anatomy has been created in the College of France, and M. Ranvier has been appointed professor. The choice is an excellent one.

A DIPLOMA of honour of the Vienna Exhibition has been awarded to Dr. Liebreich of Berlin, for his discovery of the properties of chloralhydrate.

LIKE all thoughtful and strong men, Sir Robert Christison has the faculty of arousing antagonism, as well as of producing conviction. His review of the history of the Edinburgh University was full of prickles for the Town Council, who were present officially, and who could not at the time vindicate their administration. An indignant voice has been raised in the Council, however; and, if Sir Robert Christison is not shrivelled in the flame of civic wrath, it is probably because the cool waters of Loch Earn supply a special antidote.

OTHER passages in the President's address have excited attention across the Channel; and the *Dublin Medical Press*, discussing the emigration of Irish students to Scotland, which, it affirms, is disastrous to the Irish school of surgery, is to be found in the fact that "the Queen's College (Ireland) student is obliged to seek in Scotland, and cannot obtain either in Ireland or England, an education level as low as that of his own University". It says:

"Taking the aggregate of all the courses of lectures required by the Queen's University, the Scotch Colleges, and the Irish College of Surgeons, we find that, while the students of the latter must produce certificates for nineteen different courses and twenty-seven months' hospital, they are admitted to examination at the Queen's University on fourteen professional courses and twenty-four months' hospital, and at Edinburgh on eleven courses and the same hospital attendance. It is plain, therefore, that a Queen's College student must go to Scotland for any degree outside the Queen's University which he may desire to have; because if, having taken out the courses necessary for his Q. U. degree, he wishes to present himself at the Irish College or at the University of Dublin, he is obliged to spend another winter in Dublin, and pay for five extra courses."

The Irish scheme of conjoint examination would have relieved the Irish school of surgery of the severe underselling competition of which complaint is now made. The fact that the University of Edinburgh itself suffers a good deal from the same kind of competition, affords a pretty strong commentary on Sir Robert Christison's argument against an uniform minimum examination.

ANOTHER class of persons who will be aroused by the sayings of Sir Robert Christison are the antivivisectionists. Very early in this debate, we expressed a willingness to find space for any worthy contribution to the arguments against vivisection. Dr. Macaulay, the editor of the *Leisure Hour*, writes to us *à propos* of Sir Robert Christison's address, to express a wish to combat some of the fundamental propositions on which his brother medical men are wont to rely in defence of the practice of experimentation on animals. We shall be very glad that he shall do so, and can promise him open lists and chivalrous laws of combat.

SCARLET FEVER AT HURDSFIELD.

A SOMEWHAT serious outbreak of scarlet fever has occurred at Hurdsfield, near Macclesfield, among the children attending one particular school, no fewer than sixteen out of seventeen cases having occurred among the pupils of the school in question. It is stated also that an application was made to the vicar for the purpose of temporarily closing the place in order to have it thoroughly disinfected; but that he declined doing so. The sanitary authorities are actively engaged in the adoption of remedial measures.

THE TRANSIT OF VENUS.

A HANDSOME recognition of the services of Dr. Henry Draper in connection with the recent observations on the transit of Venus has been made by the United States Government. It consists of a gold medal made at the United States Mint at Philadelphia. On the obverse is the motto, from Virgil, "Pamam extendere factis hoc virtutis opus est", and in the centre a figure of the heliostat which was used by Dr. Draper in training the photographers. On the reverse is the inscription, "Veneris in sole spectandæ curatores, R. P. F. S. Henrico Draper, M.D., Dec. viii, MDCCCLXXIV." The phrase around the edge of the reverse, "Decori decus addit avito", conveys a tribute of praise to the literary and scientific attainments of Dr. Draper, sen. The Transit Commission have also sent Dr. Draper a handsomely bound set of resolutions illuminated in mediæval style, with a telescope, camera, etc.

UNIVERSITY OF ABERDEEN.

DR. SMITH-SHAND, lecturer on clinical medicine in the Aberdeen Royal Infirmary, has been appointed to the chair of the practice of medicine in the University of Aberdeen, vacant by the resignation of Dr. Macrobin.

THE WORCESTER INFIRMARY.

IN consequence of the resignation of Dr. Inglis, and the complaint by the medical staff "of the injustice inflicted upon him by the vote of censure for a single unavoidable absence from duty in the face of fourteen years' service, together with the interpretation put upon the rules", a subcommittee has been appointed, upon the motion of the Earl of Beauchamp, "to inquire into the rules relating to the honorary medical staff, and to report what amendments, if any, it may be desirable to make therein." A letter on the subject appears in another page.

ZIEMSSSEN'S CYCLOPÆDIA OF THE PRACTICE OF MEDICINE.

WE have received the tenth volume of Ziemssen's Cyclopædia of Medicine, containing Schröder's Diseases of the Female Sexual Organs. The volumes of the German edition of this great work are not being issued in regular succession—some of those treating upon subjects of greatest interest having the precedence, although numbered to conform to the plan of the entire work. It has been concluded to follow the same course with this translation; and in compliance with the expressed wish of many subscribers, the tenth volume is now published before the fourth. Volume IV will follow on Dec. 1st, and Volume V on March 1st, 1876. The publishers announce that the rumours of an intended change in the plan of publication are entirely without foundation. This work will be obtainable only by subscription for the entire set of volumes. This Cyclopædia is now being published in the English, German, Dutch, Italian, and Russian languages.

DRUGGISTS' PRESCRIPTIONS.

DR. DIPLOCK took occasion recently to make some well-timed remarks while holding an inquest on the body of a child, who met with her death through improper treatment at the hands of a druggist. The child had been ailing for some time past, and was taken by the mother to a local druggist. Deceased got worse, and when too late a properly qualified medical man was called in, who found that the child was suffering from congestion and inflammation of the lungs, from which she died in a few hours. The coroner, in summing up the case to the jury,

said that it was very much to be regretted that druggists were allowed to prescribe for children in the way they systematically did, without knowing anything about the real illness from which the little ones were suffering. There was a child suffering from a cold which, by active treatment, would have been probably got rid of, and yet, owing to the neglect of the parents in not calling in proper medical assistance, and to the ignorance of a local druggist, the cold had resulted in inflammation of the lungs, and terminated fatally. In his experience as coroner, he had known druggists make the most absurd mistakes in reference to the symptoms of patients brought to them. In one case, a child was suffering from a fracture of the skull, for which a druggist prescribed a mustard poultice on the chest, and another prescribed chalk mixture for effusion on the brain. As a rule, the druggist prescribed for the children, who got worse, and when they were *in articulo mortis* a doctor was called in, who could give no certificate, and an inquest followed. It was high time that strict measures were taken to stop the system. The jury returned a verdict in accordance with the facts, and thanked the coroner for his remarks, which they endorsed.

CAPTAIN WEBB.

THE unprecedented exploit of Captain Webb stands almost unrivalled as an instance of human prowess and endurance. It places Captain Boyton's achievement completely in the shade as an exploit, though its practical utility to the species may be much less. It is not merely that Captain Webb is a daring and accomplished swimmer, of unusual powers of endurance, as regards sustained muscular efforts, the great question is, by what arrangement or modification of his heat-producing and heat-conserving processes did he manage to sustain his twenty-two hours' immersion? It is notorious that J. B. Johnson's attempt to swim the Channel two years ago ended in complete failure, after an hour's immersion; and yet J. B. Johnson is a no ordinary swimmer, and a stalwart fellow, possessing good powers of endurance. There must exist in Captain Webb's case strong contractile power in the vessels of the skin, by which his body-heat was conserved and his stores of force thus rendered available for muscular effort. Combustion within the body produces heat and mechanical effort, and when the powers are taxed to produce heat, or the temperature falls, muscular effort fails partially or absolutely. But, though wearied, he fulfilled his task; and if his immersion be followed by no pyrexia, then Captain Webb's heat-regulating powers must be regarded as of no ordinary character. How far and to what extent the porpoise-oil prevented heat-loss, and so aided in the result, is a factor that can only be appraised when others have tried it, and seen how far it will enable them to undergo the heat-loss of prolonged immersion. That it will have an effect is certain, as in cold regions it is usual to grease the body thoroughly in order to retain its heat. But, admitting all this, there would still appear to be peculiarities in the vaso-motor nerves which make the difference, and which has made Captain Webb's achievement *un fait accompli*.

UNREGISTERED PRACTITIONERS.

A SHORT time ago, we called attention to some very unsatisfactory cases which had occurred in the northern counties, where patients had died while under the treatment of unregistered practitioners. Another case of the same kind has just taken place at Plawsworth, near Durham. A young man, after having been unwell for a fortnight, was so ill on the 5th instant that he was unable to leave his bed. His mother summoned Mr. Hall of Holmside to attend him on the 6th, and that gentleman saw him a second time on the 10th. On the evening of that day, the patient died. Half an hour before this event took place, Mr. Blackett was called to see him, but he was dead before he could arrive. Under these circumstances, the case came before the coroner. When Mr. Joseph Hall was examined, he said, "I am a medical student, under the tuition of my father, Perceval Hall of Holmside. My father is a medical practitioner, but not registered. He practises under the Statute of Limitation, and has done so about thirty years. I visited the deceased for the first time on the 7th instant, and he complained of pains in the joints. I found he was suffering from rheumatic

fever, and there were extensive swellings of the joints. I did not apprehend any immediate danger, for, had I done so, I would have called in some medical gentleman. I did not look upon it as a serious case, and was surprised when I heard the patient was dead." Mr. Blackett, who was ordered by the coroner to make a necropsy, was prevented from doing so by the friends. But looking at the details of the case which had been mentioned, he gave it as his opinion that deceased died from inflammation of the pericardium. Death will sometimes occur suddenly in the course of an attack of rheumatic fever, notwithstanding the most careful and attentive treatment; but this case reveals a degree of lawlessness which is far from being satisfactory. Neither Mr. Perceval Hall or his son appears to be in a position to give certificates of death; and the coroner's order for a *post mortem* examination was set at naught. The foreman of the jury thought there was no occasion to hold an inquest upon the case; but the coroner was of the contrary opinion, and we entirely agree with him. Though there may have been no doubt as to the cause of death, there was great need to check the irregular proceedings connected with the attendance of unregistered practitioners, and the refusal of a necropsy under the coroner's warrant.

DR. TOLER MAUNSELL.

WE regret to announce the death of Dr. Toler Maunsell of Dublin. Dr. Maunsell was an able and prolific writer on medico-political and sanitary subjects. He was also the honorary secretary to the Irish Poor-law Medical Association, and in that capacity laboured zealously in the interests of his brethren.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT the last meeting of the Council, when the resignation by Mr. Henry Hancock of his seat as a member of the Court of Examiners was read, the following resolution was unanimously passed: "That the best thanks of the Council be and are hereby tendered to Mr. Hancock for the efficient manner in which he has discharged his duties as a member of the Court of Examiners." Mr. Hancock was elected a member of the Council in 1870. The library and museum will be closed on and after Wednesday next, for the necessary repairs and cleaning, and will be reopened on October 1st.

THE ANTIVACCINATORS AGAIN.

THE zeal of the antivaccinators is worthy of a better cause. They lose no opportunity of disseminating their misleading assertions. We have before us in a couple of halfpenny post-cards, which are apparently now being circulated by thousands, and which say much for the astuteness, but very little for the honesty, of those who put them forward. Can anything be more disingenuous than to say, "Great risk is incurred of contaminating their (*i. e.*, the infant's) blood with loathsome and incurable maladies? In 1874, 351 infants and children under five years of age died of syphilis in London alone." And then follows a reference to Mr. Hutchinson's paper in the pages of a contemporary. The reader will observe how dexterously vaccination and infantile syphilis are associated, as if there were some necessary connection between them; and with what candour allusion is made to Mr. Hutchinson's researches, which were (if we remember rightly) undertaken at the request of the Medical Department of the Privy Council, the central authority for the regulation of vaccination, and which have, no doubt, been frequently and carefully weighed by Mr. Simon. Again, how misleading is it to say, "Death from pyæmia or erysipelas often follows the operation; 139 children under five years of age died in London of erysipelas in 1874." Here is the same want of a *sequitur* as in the previous quotation. But what matter the rules of logic so long as the cause of the antivaccinators is advanced? If, as we presume, these post-cards present an epitome of the case against vaccination, the Acts which make it compulsory are not likely to be repealed. That it requires to be practised with care we are all well aware, and to this point the attention of the Medical Department of the Privy Council is especially directed; but, when properly performed, the lapse of time only serves to establish its value as a protection against small-pox.

ASSOCIATION INTELLIGENCE.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT.

A SPECIAL meeting of the members of the district will be held in the Library of the County Hospital, Canterbury, at 3.30 P.M., on Thursday, September 2nd, "To further develop and carry out the details for the formation of an Ethical Committee, which was agreed to at the last meeting of the district, and which was then adjourned to a future meeting."

EDWARD WHITFIELD THURSTON, *Honorary Secretary*.
Ashford, August 17th, 1875.

BORDER COUNTIES BRANCH: ANNUAL MEETING.

THE annual meeting of the above Branch was held at Dumfries on Friday, July 23rd, 1875, in the Board Room of the Dumfries and Galloway Royal Infirmary. Previously to the meeting, the members were entertained at a *déjeuner* by Dr. W. A. F. Browne.

Dr. GREEN of Kendal took the chair at one o'clock, and there were sixteen other members present.

Report of Council.—Dr. SMITH, Secretary, read the following report of Council.

"The Council have much pleasure in presenting the seventh annual report to the members of the Border Counties Branch.

"At the commencement of the year, there were sixty-five members on the list; and during the year thirty-five new members have been elected. Four members have resigned, and one member has died; so that the number at present on the books is ninety-five.

"The chief feature in the history of the Society during the past year has been the great success which has attended the change in the title of the Society and the alteration in its rules which was effected at the last annual meeting. Through these alterations, members of the profession residing in the Border Counties of Scotland have been enabled to avail themselves of the privileges of membership of a Branch of the British Medical Association, and twenty-nine have availed themselves of this privilege. One of the ordinary meetings of the year has been held at Dumfries and the other at Carlisle, and both these meetings have been of a successful and agreeable character; the average attendance being higher than at any previous meeting during the past two or three years.

"The Council are glad to find, from an examination of the treasurer's books that there is a large surplus available after all the expenses of the year have been paid, and they recommend that the example of last year be followed, and a donation of £5 be given to the British Medical Benevolent Fund.

"To the great regret of the Council, the senior Secretary has intimated his intention of withdrawing from the official position which he has held during the last seven years. In taking this step, Dr. Barnes is carrying out a purpose which he has repeatedly expressed to the Council during the past three years, but which he has hitherto been induced to forego at their request. The Council desire to express their sense of the great obligations they are under to Dr. Barnes, and to tender him their thanks for the efficient manner in which he has conducted the business of the Branch.

"The balance in hand at the commencement of the year was £12 : 10 : 8; and the receipts consist of seventy-three subscriptions for the year, eight arrears for previous years, and twelve subscriptions for 1875-76 paid in advance, amounting to £11 : 12 : 6; total, £23 : 17 : 2. The disbursements amount to £15 : 14 : 9, leaving a balance in hand, June 26th, 1875, of £8 : 2 : 5."

Medical Benevolent Fund.—The recommendation of the Council that a donation of £5 be made to the British Medical Benevolent Fund was adopted by the meeting.

President's Address.—The retiring President vacated the chair, and introduced the President for the year, Dr. W. A. F. BROWNE, who delivered his inaugural address. It was devoted to the consideration of new, or newly described, nervous diseases. The general paralysis of the insane, although now one of the most formidable and fatal maladies seen in asylums, was stated to have remained unnoticed or unrecorded until 1822 and 1826, when described by Bayle and Calmeil in their works on *Méningite-Chronique* and *La Paralyse des Aliénés*. Dipsomania, or the involuntary craving for stimulants, involving perversion of the moral sense and enfeeblement of will, seemed to have been introduced to the notice of medical men as a specific disease, in Esquirol's memoir *Monomanie d'Irresse*, in 1838. Now generally recognised, and included in the question, "What shall we do with our drunkards?"

this affection was engaging the attention of philanthropists, even of Parliament as well as that of our profession. Typhomania, or Luther Bell's disease, first announced by the observer whose name it bears, was defined as neither typhoid fever nor mania, but a form of alienation marked by sudden prostration of strength, and as sudden restoration or death, as presenting no symptoms of inflammatory action, and as curable by diffusible stimulants. Absinthism, or toxic epilepsy, resulting from the abuse of some preparation of absinthe, was diagnosed chiefly by delirium, fear, fury, and convulsions, being distinguished by the last symptom from insanity following poisoning, etc., by alcohol. This distinction had been established by experiment upon the lower animals by M. Magnan, Paris, who had written a monograph upon the subject. Inquiry had been going on in France upon the origin and features of absinthism since 1859-64, and the former had been traced to the habits acquired by the soldiery in Algiers.

New Members.—The following gentlemen were elected members of the Association and Branch: Frederick Skaife, L.R.C.P.Ed., Wigton; Robert Scott, M.B., Dumfries; Wm. Jackson Kennedy, L.R.C.P.Ed., Sanguhar; Alexander Dall McDonald, M.D., Dumfries; James Rae Anderson, M.D., Eskbank, Canonbie.

Election of Office-bearers.—The following were elected office-bearers for the ensuing year: *President-elect*: H. Barnes, M.D. *Honorary Secretaries*: S. Lockie, M.D., Carlisle; and John Smith, M.D., Dumfries. *Council*: J. A. Campbell, M.D.; J. Crerar, M.R.C.P.Ed.; J. Gilchrist, M.D.; T. F. F'Anson, M.D.; W. S. Kerr, M.D.; W. Reeves, M.D.; W. Scott, M.D.; M. W. Taylor, M.D.; R. Tiffen, M.D. *Representative in the Parliamentary Bills Committee*: W. Reeves, M.D. Dr. Green was elected permanent vice-president.

Medical Fees.—Dr. SMITH (Dumfries) introduced the subject of fees proper to be charged in medical and surgical practice, and moved the appointment of a committee to frame a suitable scale. The motion was adopted, and a committee appointed with instructions to report to the next meeting.

This concluded the ordinary business of the meeting, and the members afterwards dined together at the King's Arms Hotel.

CORRESPONDENCE.

THE WORCESTER INFIRMARY.

SIR,—It is a trite saying that one half the world does not know how the other half lives; and I confess myself to have been hitherto in ignorance of the view taken by the medical profession of the recent proceedings of the executive committee of the Worcester Infirmary.

An impression appears to prevail that one of the honorary medical staff has been censured by the committee for non-observance of the rules under urgent circumstances which compelled his unavoidable absence from duty, and reflections have further been cast upon his colleagues for apparently acquiescing in the propriety of the treatment I have described.

There is a melancholy reason for refraining from more than a brief attempt to correct the misapprehension which has arisen. The sad event to which I refer has gained Dr. Inglis the deep sympathy of all who know him, and makes me reluctant to touch, even in the lightest manner, on the facts of the case; yet it is fair to the executive committee to say that, unless the committee of such an institution have before them some statement of exceptional circumstances requiring infringement of rules or some plea of justification on the ground of urgency, they necessarily find themselves in a position of great difficulty when invited to deal with a complaint that rules have not been complied with.

The executive committee probably regret that no such plea of extenuation was alleged; and if hereafter they refrain from recommending the governors to make alteration in the rules which have occasioned comment, their conduct will, no doubt, be dictated by a conviction that the rules, if prudently and wisely understood on both sides, do not impose upon the honorary medical staff, to whose talents and unbought services the infirmary is so largely indebted, any rigid or inflexible yoke. As practical men, they also probably are of opinion that it is difficult, if not impossible, to express under a common formula those exceptional circumstances which are beyond rules, and which ought in each of such cases to be the subject of individual judgment and explanation.

I have the honour to remain your obedient servant,
ONE OF THE EXECUTIVE COMMITTEE.

August 24th, 1875.

THE TRAINING OF IDIOTS.

STR.—I beg to offer a few remarks upon the subject of Sir Charles Trevelyan's resolutions, recently submitted to the Council of the Charity Organisation Society, with reference to idiot institutions. I learn from the *Charity Organisation Reporter* of June 23rd that these resolutions, together with a draft Bill upon the same subject by Canon Hopkins, were, after a (briefly reported) discussion by several gentlemen interested in existing institutions, referred to a Committee for further consideration.

It is not my intention to occupy your space with observations upon the proposed scheme for the association of pauper and non-pauper idiots and imbeciles, in institutions partly charitable and partly maintained by government aid or out of the poor-rates. Suffice it to say that such a plan, though working well in America, has hitherto not found much favour in this country; and it appears to me at least worthy of consideration, whether separate pauper institutions, both educational and custodial, might not with advantage be established throughout the country, upon the model of those already set up in the metropolitan district, leaving to voluntary effort the necessary provision for idiots and imbeciles of the non-pauper classes. However this may be, the Charity Organisation Society deserves the thanks of the community for pointing out the inadequacy of existing arrangements for the unhappily large proportion of idiots and imbeciles amongst our population. Accurate statistics as to the present number of *pauper* idiots and imbeciles, as distinguished from lunatics, it is not easy to obtain, owing to the looseness of the nomenclature used in the returns from unions (a subject I would respectfully commend to the attention of parish medical officers); but the number was estimated at over ten thousand in 1866; and for these, except in the metropolitan district and in the county of Warwick, there is absolutely no specific accommodation.

With these few remarks upon the general scope of the resolutions, I pass to the consideration of some points of detail of more immediate interest to our profession. First, with regard to the educational grant mentioned in Resolution 4. It is certainly well that training schools for idiots should be regarded as places for *education*; but I fear there is some risk of the term being understood in this connection in too limited a sense. There are grades in the education of idiots never dreamt of in the philosophy of Her Majesty's Inspectors of Schools; but the education of the muscles and the senses, and the utilisation of this education in practical industrial training, are assuredly as worthy of government recognition as is mere proficiency in the "three r's". Then, with regard to Resolution 6, there can be no question that some of the provisions of the Lunacy Acts, especially the forms of medical certificate and of various returns to the commissioners, require modification to adapt them to the case of idiots; but, in the Bill drafted in connection with this resolution, much more sweeping alterations are contemplated. Amongst other things, it is proposed that idiot asylums which do not contain more than two hundred and fifty patients may dispense with a *medical* superintendent, the present law requiring such an officer to be resident in every institution containing more than one hundred patients. Surely there is no good reason for this very salutary rule to be relaxed. It should never be forgotten that the idiot is truly an "insane person", and a person often *unsound* not only in mind, but in body also. If a *pupil*, he must still be regarded as a *patient*; and the operations of the schoolmaster must be subordinate to those of the physician. The success that has hitherto largely attended the training of idiots and imbeciles may be said to be in the main due to the scientific recognition of the physical basis of mental defect, and to the judicious application of physiological principles to the subject. The Americans, practical people as they are, have not failed to see the necessity of *medical* superintendence for their idiot institutions, both large and small; and the general opinion of those entrusted with the organisation of such establishments may be gathered from the report to the legislature, of the Trustees of the Illinois State Institution for the Feeble-minded, with reference to the appointment of their first medical superintendent, Dr. C. T. Wilbur. After referring to him as "a gentleman of medical attainments and experience—indispensable qualifications for a superintendent of such an establishment as ours, which is, as well as educational, to a very great extent sanitary in its nature"—they go on to say: "Though idiocy may not be essentially a disease, yet diseases and deficient organisation are so frequently connected with it, that it requires careful, constant, and skilful treatment, and the facilities and appliances of a well regulated hospital, and such gymnastic exercises as are most conducive to physical and mental culture and development." This was in 1866; now, it would be almost safe to say that the progress of inquiry tends to show that idiocy is essentially a disease, the origin and correlations of which demand all the skill and research of a well-trained physician. The contributions to the patho-

logy of the subject by Drs. Langdon Down, Ghabham, and Ireland, in this country, are sufficiently well known to the profession; but much remains to be made out, and the work is of such a character as to require and repay close and special attention. I am aware that different opinions exist amongst medical men as to the ultimate economic value of idiot-training; but I suppose all will agree that the grouping of idiots in establishments apart from the general community is *pro tanto* an advantage. Taking, for the sake of argument, merely this lower view of the subject, the opportunity should not be lost to the profession, as it is to be feared would probably be the case in an institution under non-medical management, of the scientific study of idiocy. Family history, constitutional tendencies, symptoms of physical disease often much masked by the mental condition, all these have to be weighed in the balance before a just opinion can be arrived at as to prognosis and treatment: and last, but not least important, the revelations of the *post mortem* room must be thoroughly scrutinised in connection with abnormalities observed during life.

In conclusion, I would beg leave to commend to those who are laudably promoting the establishment of new idiot institutions, the words of Lord Derby at the festival commemorative of the completion of the Royal Albert Asylum. "The greater part of the value of an asylum," says he, "as of a hospital, consists in its usefulness as a school where a particular complaint there treated may be studied, not merely that we may know how to cure it, or how to alleviate it when it comes before us, but that, if possible, we may trace it back to its source, and so guard against it in future.....If we are to look to it as a work of humanity and charity, an asylum such as this is admirable..... Being wanted, it is good that we should have it; but it will be better still if within its walls, and within the walls of other establishments such as this, a lesson can be learnt which shall render their application superfluous and obsolete in the future."—I am, sir, yours, etc.,

G. E. SHUTTLEWORTH, B.A., M.D., etc.,
Medical Superintendent, Royal Asylum for Idiots and Imbeciles of the Northern Counties, Lancaster.

MILITARY AND NAVAL MEDICAL SERVICES.

INDIAN MEDICAL SERVICE.—The following candidates for her Majesty's Indian Medical Service were successful at the competitive examination held at Burlington House on the 9th August, 1875. Thirty candidates competed for ten appointments. All were reported qualified.

Order of merit.	Names.	Order of merit.	Names.

NAVAL MEDICAL APPOINTMENTS.

- ANDERSON, Staff-Surgeon W., to the *Pembroke*, for Haslar Hospital.
- BENNETT, Staff-Surgeon W. R., to the *President*, for temporary service.
- BROWNLOW, Surgeon T. D.A., to the *Sapphire*.
- CLINTON, Fleet-Surgeon W. F., to the *Minotaur*.
- EVANS, Staff-Surgeon William J., to the *Diamond*.
- FELTHAM, Surgeon C., to the *Undaunted*.
- FINCANE, Fleet-Surgeon D., M.D., to the *Resistance*.
- FISHER, Staff-Surgeon William S., to the *Vestal*.
- HARAN, Fleet-Surgeon T. J., to the *Fisgard*, additional, for duty at Somerset House.
- HORROCKS, Surgeon J., to the *Minotaur*.
- INMAN, Staff-Surgeon William, to the *Arab*.
- IRVINE, Surgeon G. J., to Haslar Hospital.
- LAMBERT, Staff-Surgeon J., to the *Lily*.
- LOW, Surgeon George W., to the *Implacable*, for service in the *Sealark*.
- O'CONNOR, Staff-Surgeon D., to the *Sapphire*.
- PEARSON, Surgeon W., to the *Warrior*.
- SCOTT, Surgeon A., M.D., to the *Black Prince*.
- TERRY, Staff-Surgeon S., to the *Duncan*.
- WALSH, Fleet-Surgeon J. C., to the *Sultan*.
- WARD, Fleet-Surgeon John A., to the *Sultan*.
- WATSON, Fleet-Surgeon A., M.D., to the *Serapis*.
- WOODS, Surgeon Henry C., M.D., to the *Serapis*.

OBITUARY.

ALEXANDER FLEMING, M.D. Edin., F.R.C.P., BIRMINGHAM.

WITH sincere regret we announce the death of Dr. Alexander Fleming, which occurred at Buxton, on the 21st instant, in the fifty-second year of his age. He was born in Edinburgh, and educated in the University of his native city. In 1844, he graduated as a doctor of medicine, with the highest honours, a gold medal being awarded for his inaugural thesis. After taking his degree, he spent some considerable time in the hospitals of Paris, Vienna, and Prague, whence he returned to Edinburgh, and edited for some years, in conjunction with Dr. Day and Dr. W. T. Gairdner, *The Edinburgh Monthly Journal of the Medical Sciences*. He subsequently resided for a few years in Cork, where he held the professorship of *Materia Medica* in the Queen's College, and was also one of the examiners in the Queen's University in Ireland. About eighteen years ago, he came to Birmingham, and was immediately appointed professor of *Materia Medica* in the Queen's College, and physician to the Queen's Hospital. In 1859, he was elected a Fellow of the Royal College of Physicians of London. At the end of 1871, signs of chronic renal disease appeared, and he shortly afterwards relinquished private practice, and went to the south of France, where he chiefly resided during his illness. In 1873, he resigned his office at the Queen's Hospital, and was at once elected, in recognition of fifteen years' service, consulting physician. At the time of his death, he was also consulting physician to the Women's Hospital, and to the Ear and Throat Infirmary. Since the amalgamation of the two medical schools of Birmingham, Dr. Fleming was an active member of the Council of Queen's College. He took a prominent part in the foundation and subsequent management of the Institution for Trained Nurses—a much needed and very successful establishment. When the Association held its annual meeting in Birmingham, in 1872, Dr. Fleming was appointed to deliver the Address in Medicine. His failing health obliged him to decline the request of the Council, and his place was filled by Dr. Wilks. Dr. Fleming was well known as a contributor to medical literature. The following are the more important of his writings: *A Treatise on Aconite; Medical Education, with especial reference to the course for the degree of M.D. in Queen's University, Ireland; The Classification of Medicines; Clinical Notes in Therapeutics, taken in the Hospitals of Vienna, Paris, and Prague; Treatment of the Habit of Opium-eating; Lead-poisoning and its Treatment, etc.* His researches concerning aconite won him early fame.

Dr. Fleming was a prudent and painstaking physician. He will long be remembered as a most admirable clinical teacher. He was very exact and methodical in his observation of disease, and he had a rare facility in making students understand the details of a difficult case. He always taught diagnosis by the well-known "method of exclusion". His knowledge of the action of medicines was wide and extensive, his therapeutic resources were vast and varied, and he thoroughly believed in the virtues of the remedies he used. He was very gentle to his patients, and he always showed a kindly and almost affectionate interest in the welfare of his pupils. Dr. Fleming enjoyed a very large consulting practice in Birmingham and the Midland counties.

DAVID PETER EVANS, M.B., BELPER.

MR. D. P. EVANS of Belper died on Tuesday, July 20th, at the age of 53, after a month's painful illness terminating in abscess (pyæmic) of the brain. He was the fifth son of the late Mr. David Evans (who for upwards of forty years was one of the most distinguished surgeons in the midland counties), and brother to the late Dr. Evans of Birmingham. Another brother is Mr. S. H. Evans, who has lately retired from the practice of his profession after a long and honourable career at Derby. Mr. Evans received his education at King's College, London, and in 1845 took the degree of M.B. at the University of London, coming out in the first class. His funeral was attended, it is calculated, by at least 1,500 people of all ranks.

UNIVERSITY INTELLIGENCE.

UNIVERSITY OF CAMBRIDGE.

CERTIFICATES IN STATE MEDICINE.—The examination in State Medicine for certificate of proficiency will commence on October 5th. Candidates are required to send their names to Professor Living, Cambridge, before September 15th. Any person whose name is on the *Medical Register* may present himself for the examination, provided he is twenty-four years of age.

MEDICAL NEWS.

Organic Chemistry, and *Materia Medica* and Pharmaceutical Chemistry.

First Class.

Wilkinson, Arthur Thomas (Exhibition and Gold Medal), Owens College School of Medicine

*Henderson, George Courtenay (Gold Medal), University College

Second Class.

Goodchild, Francis, St. George's Hospital

Third Class.

Miller, Richard Shalders, University College

* Obtained the number of marks qualifying for the Exhibition.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, August 19th, 1875.

Bruce, Robert, 121, Old Street, St. Luke's
Chant, Thomas, Bridgewater
Clark, Wm. Theobald Blanton, Malmesbury, Wiltshire
Joseph, Sidney Westbrook Jorwerth, St. Leonard's-on-Sea
Willans, William Blundell, Singapore

The following gentlemen also on the same day passed their primary professional examination.

James, Thomas, Middlesex Hospital
Morris, Clarke Kelly, St. Thomas's Hospital

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At examination meetings of the College, held on Tuesday, Wednesday, and Thursday, July 13th, 14th, and 15th, 1875, the following gentlemen obtained the License to Practise Medicine.

Alexander, Thomas	MacNamara, Joseph
Barker, Arthur Edward James	O'Meara, Michael Aloysius
Deeley, Ambrose William	Townsend, Charles Bryan
Elliott, Robert Andrew	Warnock, Hugh Thomas
Hunt, Daniel De Vere	Wood, Edwin Stanley
Jones, John Thomas	Youelle, Michael
MacGrath, William Michael	

The following candidates obtained the License to Practise Midwifery.

Banks, Alfred	MacGrath, William Michael
Barker, Arthur Edward James	O'Carroll, Martin
Deeley, Ambrose William	Townsend, Charles Bryan
Drapes, John Benward	Warnock, Hugh Thomas
Drummond, David	Wood, Edwin Stanley
Jevers, Philip Glover	Youelle, Michael
Jones, John Thomas	

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH: DOUBLE QUALIFICATION.—The following gentlemen passed their first professional examination during the recent sittings of the examiners.

James Griffith Macaskie, Berwick-on-Tweed; Ernest Aylward, Hastings; Andrew Douglas Ramsay Thomson, Dalkeith; Hugh Murray, Sutherlandshire; Harrison Hartley, Yorkshire; John Michael de Verde Ratton, Dublin; Edward John Baxter, Middlesex; Thomas Henry Smith, Stockton-on-Tees; Daniel Stenhouse, Aucherarder; Wm. Ellis Mumford, West Indies; Henry Crawford McBryan, Dublin; Francis Henry Wood, Wakefield; John Elletson Richards, Yorkshire; James Watson, Lanarkshire; John Albert Howard, Taunton; Alfred Wyatt Crane, France; William Alexander Logie, Kirkwall; Alexander Tratman Bremner, Gloucestershire; Harry Pell Hderon, Manchester.

The following gentlemen passed their final examination, and were admitted L.R.C.P. Ed. and L.R.C.S. Ed.

Robert Green Douglas, Northumberland; George Herbert Bentley, Bombay; Jeremiah Scott, County Cavan; Arthur Gregory Sandberg, Yorkshire; Jas. Alexander Dyer, Fifehire; Arthur Wugley Bateman, London; Thos. Bowes Shaw, Yorkshire; Maryat Hahneimann Green, London; George Taylor Schofield, Hull; John Parker Breton, County Tipperary; Charles Gibson, Newcastle-on-Tyne; Edwin Godfray, Jersey; Bryan Charles Waller, Yorkshire; William Cranston, County Cavan; John Macdonald, Skye; Roderick Ross, Lewis; Wm. Frederic Bailey Eadon, Shetfield; Wm. Dudley Power, Cork; Wm. McCarthy, Crnk; Robert Harvey, India.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—The following gentlemen passed their first professional examination during the July examinations.

George Gibson Hamilton, Falkirk; Robert Davies Evans, North Wales; John Macnaught, Glasgow; Louis Windham Fox, Bristol.

The following gentlemen passed their final examination, and were admitted Licentiate of the College.

Joseph Montagu Cotterill, Brighton; Henry Wm. Laing, Bridge of Earn; Frank John Cannon, London; David Makin Kennedy, Liverpool; Frederic Hamilton Crowdy, Newfoundland; Thos. Duddington Wilson, Edinburgh; Chas. Sidney Richardson, Dover; Herman John Groesbeck, Cincinnati, Ohio; Andrew Smith, Fifehire; Charles Thornton Champneys, Glasgow; Henry Miller Shand, Aberdeen; John Stevenson, Edinburgh; Thos. R. Macdonald, Skye; John James Underwood, Cumberland.

MEDICAL VACANCIES.

THE following vacancies are announced:—

BOURNEMOUTH GENERAL DISPENSARY—Resident Medical Officer and Secretary. Salary, £120 per annum, with furnished apartments, coals, gas, and attendance.

CARNARVON UNION—Medical Officer for the Llandwrog District. Salary, £60 per annum.

DISPENSARY FOR SICK CHILDREN, Manchester—Assistant Medical Officer. Salary, £180 per annum. Applications on or before September 15th.

DORE UNION—Medical Officer for the Koutchurch District and the Workhouse.

DUDLEY DISPENSARY—Resident Medical Officer at Michaelmas.

EASTRY UNION—Medical Officer for the Eythorne District. Salary, £30 per annum, and fees. Applications on or before the 31st instant.

HAY UNION—Medical Officer for the Herefordshire District.

HOSPITAL FOR SICK CHILDREN, Manchester—Assistant Physician. Salary, £300 per annum. Applications on or before September 15th.

INVERNESS DISTRICT ASYLUM—Assistant Medical Officer. Salary, £70 per annum, with bed, board, and washing. Applications on or before the 11th prox.

LEEK UNION—Medical Officer for the Norton District.

LYMINGTON UNION—Medical Officer for the Hordle, Lymington, and Milford Parishes.

NORWICH DISPENSARY—Salary, £120 per annum, with unfurnished residence and apartments.

PEMBROKE UNION—Medical Officer for the First District.

PLOMESGATE UNION—Medical Officer for the Aldeburgh District.

ROYAL CORNWALL INFIRMARY—House-Surgeon, Secretary, and Dispenser. Salary, £200 per annum, with furnished rooms, gas, coals, and attendance. Applications on or before September 1st.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road—House-Physician. An allowance of £100 per annum is made in lieu of board and residence. Applications on or before the 31st instant.

ROYAL PORTSMOUTH, PORTSEA, and GOSPORT HOSPITAL—House-Surgeon. Salary, £120 per annum, with board and residence. Applications on or before the 31st instant.

ROYAL SOUTH HANTS INFIRMARY—House-Surgeon. Salary, £80 per annum, with board, lodging, and washing. Applications on or before September 6th.

ROYAL SOUTH LONDON DISPENSARY—Honorary District Surgeon. Applications on or before the 31st instant.

ROYSTON UNION—Medical Officer for No. 5 District. Applications on or before September 6th.

STAINES UNION—Medical Officer for the Shepperton District.

UCKFIELD UNION—Medical Officer for the Maresfield District.

WARWICK COUNTY LUNATIC ASYLUM—Second Assistant Medical Officer. Salary, £100 per annum, with board, lodging, and washing.

WEST SUSSEX, EAST HANTS, and CHICHESTER GENERAL INFIRMARY and DISPENSARY—Assistant House-Surgeon. Salary, £20 per annum, with board, lodging, and washing. Applications on or before the 28th instant.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

BURNES, Alex. G., M.B., C.M., appointed Physician to the North London Hospital for Consumption and Diseases of the Chest.

CADDY, Henry, M.R.C.S. Eng., appointed Senior House-Surgeon to the Royal Southern Hospital, Liverpool, *vice* W. Williams, M.D., resigned.

*DAVIES, Edward, M.R.C.S. Eng., appointed Consulting Surgeon to the Swansea Hospital.

GWATKIN, Owen, M.R.C.S. Eng., appointed Junior House-Surgeon to the Royal Southern Hospital, Liverpool.

*JONES, A. Emrys, M.B., C.M. Edin., appointed Resident Medical Officer to the Hulme Dispensary, Manchester.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTH.

PLATT.—On August 21st, at Priory Villas, Kilburn, the wife of *William Henry Platt, L.R.C.P.E., of a daughter.

DEATH.

*FLEMING, Alexander, M.D., F.R.C.P., of Birmingham, at Buxton, aged 51, on August 21st.

TESTIMONIAL.—Mr. Owen T. Evans, of Brymbo, M.R.C.S. Eng., has been entertained at a complimentary dinner, and presented with an address and a purse of £60, on leaving the neighbourhood.

OPERATION DAYS AT THE HOSPITALS.

MONDAY Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAY Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAY .. St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAY St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.

FRIDAY..... Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.

SATURDAY St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with Duplicate Copies.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

DR. TOMKINS.—Candidates for the Fellowship of the College of Surgeons of England have now to undergo an examination in Medicine, unless already in possession of a recognised medical license.

SIR,—Will a Member of the Association be good enough to inform me what is the best disinfectant to get rid of the offensive smell from the discharge from a cancerous breast?
Yours obliged,
TRICEPS.

ERRATA.—In the paragraph on Auscultation of the (Esophagus, in last week's JOURNAL, page 228, column 2, the remarks at the end in confirmation of the value of Dr. Clifford Allbutt's paper, attributed to Dr. Crichton of Perth, should have been stated to have been made by Dr. Crichton of Tavistock.

UNQUALIFIED ASSISTANTS.

SIR,—I am glad to perceive a portion of your columns devoted to a discussion of this growing evil, and that, in a proper spirit of fair play, the unqualified are allowed to air their grievance, which is, that they are not sufficiently recognised. Their champions in these columns have endeavoured to demonstrate that a part is greater than the whole, and that they must know more of the practical part of our profession than those who have had the advantages of the very practical teaching now adopted at the schools. These worthy persons (I doubt not many of them are) who are practising *sine diploma*, as they euphemistically style it, might often add *sine curriculo*. They are clamouring for a dangerous precedent. I had a short time ago a *locum tenens* sent me by an agent as unqualified but thoroughly competent. I found soon after his arrival that he had never spent a day in a hospital. Such help as this, in a manufacturing district where accidents were frequent, had to be at once dispensed with; and though there are, doubtless, many of them efficient and useful men, I think we should consult the dignity of our profession, no less than the safety of the public, by having as little to do with them as possible. And though no objection can be taken to a qualified practitioner availing himself of the services of an unqualified assistant under his direction, and giving him only temporary charge of any case, nothing, I should think, can be more reprehensible than the plan—very common, I fear, in some places—of putting such men in charge of branch practices, and in position away from the immediate control of the principal. Such conduct as this is unworthy of members of this great Association, including as it does so many of high standing and position in our ranks, and whose motto should be, *Sans peur et sans reproche*.—I am, yours truly,
August 1875. SCRUTATOR.

SIR,—In answer to a request in the JOURNAL of April 24th, I beg to state that my present address is "No. 369, Calle Florida, Buenos Ayres".

I am, sir, your obedient servant,
Buenos Ayres, South America, June 30th, 1875.

W. N. HIRON.

A METROPOLITAN TEACHER.—We have heard that the annual registration of students at the College of Surgeons will, in all probability, be discontinued after October next; the registration by the General Medical Council serving all the purposes. The College of Physicians long since discontinued it.

L.R.C.P. (Dublin).—We shall not probably differ in opinion in the end; but we should be better able to decide the ultimate questions if the argument were stated with less irrelevant and discursive attack upon collateral subjects of difference.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, no later than Thursday, twelve o'clock.

THE CASE OF THE LATE MR. P. E. MERRYWEATHER.

SIR,—In forwarding to you a list of the donations we have received since you last published the contributions to this fund, we feel it will be a subject of much satisfaction to those who have kindly aided in this matter to know that the amount raised has done great and permanent good. Besides supplying immediate wants, it has enabled Mrs. Merryweather to take a good house, where she is already prospering, and maintaining and providing for the education of her children. She is very grateful indeed to all who have so kindly extended the helping hand in the time of her great need. The appeals in the medical journals have brought assistance even from distant Kurrachee.—We have the honour to be, sir, yours faithfully and obliged,

CLAS. J. HARE, M.D. Cantab., F.R.C.P.,

W. A. ATWOOD, L.K.Q.C.P.,

57, Brook Street, Grosvenor Square, W., August 21st, 1875.

Table with 2 columns: Donor Name and Amount (£ s. d.). Includes entries like 'Donations already acknowledged', 'Waggett, John, M.D.', 'Nodes, Mr.', 'Poppl-ton, R. D., Esq.', etc., totaling £240 7 6.

H. (St. Bartholomew's).—We understand that the vacancies in the Court of Examiners of the College of Surgeons will be filled up in October.

MR. HINNELL (Bury St. Edmunds).—We know nothing of the hospital to which our correspondent refers.

MR. WORTH (Nottingham).—Yes; but we must beg our correspondent, in consideration of the demands on our space, to be as concise as possible.

CORONERS AND THEIR JURIES.

SIR,—My attention has been called by a medical friend to a letter signed H. H. P., in your issue of the 24th July. I shall be obliged if you will allow me to correct some of the writer's mistakes, not unusual, by the way, on the part of medical men. Any one who takes the trouble to read Blackstone, or other such authorities, will be aware that the office and court of the coroner are amongst the most ancient and important in the country. The coroner is a magistrate and "principal conservator of the peace", and as such a judge, and possessed of the same judicial powers in relation to his own court, as the Lord Chief Justice of England. It is true that some medical coroners, forgetting their proper dignity and position, indulge in the discussion of medical and social ethics to delighted audiences of jurymen and reporters. Legal coroners, I flatter myself, never so indulge. But when H. H. P. presumes to assert that neither a coroner nor his jury have the right, judicially and before the court has broken up, to express opinions, or make presentments, upon matters fairly arising out of the inquiry, he either ignores the universal practice of judges, magistrates, and grand juries, in this behalf, or he puts a slur upon an institution which he deems humbler, and spares offices which he supposes to be higher, in public estimation, and, therefore, not safe to be attacked. I will only remind him that the coroner's duty is not so much to ascertain the cause of death, which any medical man could do by a dissection; but to ascertain, by a formal public inquiry, by sworn evidence before a sworn jury, "if any be culpable". For H. H. P. to say that no opinion to this effect is to be expressed short of a verdict of manslaughter, especially now that, through the wretched policy of modern days, deadlands have been abolished, is an opinion which, I trust, will meet with no favour among your readers generally.

Yours, etc., A LAWYER.

Will the writer of a letter signed M. D. Erlangen, which appeared in our issue of the 14th instant, kindly forward us his address in confidence?

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

INQUIRR (Chester).—1. Circulars are unusual and objectionable. Our correspondent's object would be gained by enclosing to each patient an ordinary visiting card with his new address, writing on it "change of residence", or something of the kind 2 and 3. To both these questions, our answer is in the negative.

L. S. A.—The Apothecaries' Society is disposed to defend the rights of its members; but, in point of fact and of law, they have not now any exclusive privileges.

M. A., M.D.—It is right to put the M.D. on a door-plate; but it would be a mistake to put both M.A. and M.D. The M.A. is an honorary style, which has no professional privileges or relation to public function.

AN EDINBURGH VISITOR.—We do not know where best Mr. Lister's antiseptic preparations and appliances may be obtained in London. Probably some of the leading druggists or surgical instrument makers, whose names may be found in the advertising columns of this JOURNAL, will supply them.

ARMY MEDICAL OFFICER.—Mr. Lyon Playfair may, we think, be fairly trusted to advise the medical officers earnestly and judiciously.

VOTING AT THE MEDICAL BENEVOLENT COLLEGE.

H. S. (Greenwich).—More must be done before the cause is won. An influential member of the governing body of the Medical Benevolent College wrote to us after the publication of the leader in the JOURNAL to which you refer, stating his belief that the cause was won, and that henceforth it was only a question of time. After the vacation, it will probably be desirable that a special meeting of the governors be summoned for the purpose of considering the question; and, if necessary, we shall take steps in the matter.

MEMOR FIDES.—The use of the Unguentum Zinci Benzoiati was, we believe, due to the late Mr. Alexander Ure of St. Mary's Hospital. It was for a long time in general use before it was brought into the Pharmacopœia.

X. Y. Z.—We have no means of knowing, other than those which our correspondent himself possesses. If we were to comment upon the matter, we might be liable to misinterpretation. Degrading practices of any kind bring their own punishment.

DR. H. W.—No medical man is bound to attend a patient, unless, indeed, no other medical relief is within reach, and the case is urgent.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Bristol Daily Post; The Daily Bristol Times and Mirror; The Derby and Chesterfield Reporter; The Lincolnshire Herald; The Glasgow Herald; The Sunderland Daily Echo; The Carnarvon and Denbigh Herald; The Manchester Guardian; The European Review; The Hackney and Kingsland Gazette; The Worcestershire Chronicle; The Birmingham Daily Post; The Brighton Daily News; The Sussex Daily News; The Glasgow Herald; The Cork Examiner; The Scotsman; The Cork Daily Herald; The Southampton Times and Hampshire Express; The Hampshire Advertiser; The Birmingham Morning News; The Chester Courant; The Metropolitan; The Live-Stock Journal; The Shield; The Grocer; The Shipping and Mercantile Gazette; The Advertiser; The Islington Gazette; The Peasant Observer; The Hastings and St. Leonards Gazette; The Ilkley Free Press; The Leicester Daily Post; etc.

COMMUNICATIONS, LETTERS, etc., have been received from:—

Dr. Thomas Chambers, London; Mr. E. Oliver, Manchester; Mr. T. C. Eager, Woking; Dr. G. F. Burder, Bristol; Dr. E. J. Tilt, London; Dr. W. Macfie, Edinburgh; Dr. C. E. Underhill, Edinburgh; Mr. J. E. Ingpen, London; Dr. W. Hitchman, Liverpool; Dr. John Alexander, Paisley; Mr. A. Speedy, London; Mr. R. H. A. Huoter, Dalston; Dr. B. T. Moore, London; Mr. E. L. Hussey, Oxford; Dr. H. D. Foote, Rotherham; Mr. T. L. Webb, Ironbridge; Dr. P. Eade, Norwich; The Registrar-General, Dublin; Dr. T. J. Walker, Peterborough; Mr. J. Hudson, Clapham; Mr. Henry Cadly, Liverpool; Dr. E. Slade-King, Ilfracombe; Dr. W. A. Satchell, Kew; Mr. J. H. Barnes, Liverpool; Dr. J. Sawyer, Birmingham; Mr. L.H. Elenkarne, Buckingham; Mr. H. M. Jay, Chippenham; Dr. C. J. Hare, London; Dr. R. W. Crighton, Tavistock; Mr. A. Davies, Swansea; Mr. A. H. Allen, London; Dr. O. T. Woods, Hatton, Warwick; The Director-General of the Army Medical Department; Mr. R. H. Smith, Manchester; Dr. Joseph Bell, Edinburgh; Dr. J. W. F. Smith-Shand, Aberdeen; Mr. R. Hordley, Hartshill; Mr. W. E. Wyllis, Great Yarmouth; Dr. McCall Anderson, Glasgow; The Military Secretary, India Office; Dr. Carroll, New Brighton; Mr. John Liddle, London; Mr. H. Hailey, Newport Pagnell; The Secretary of Owens College, Manchester; Dr. T. J. MacLagan, Dundee; Mr. J. Ashburner Thompson, London; Mr. R. Laidlaw, Glasgow; Dr. Branwell, Newcastle-on-Tyne; Mr. Francis Vacher, Birkenhead; Dr. J. R. Kealy, Gosport; Dr. G. E. Shuttleworth, Lancaster; Mrs. Fleming, Buxton; Mr. C. H. Collins, Chew Magna; Our Dublin Correspondent; Mr. R. A. H. Wood, Liverpool; Mr. J. L. Green, Tisbury; Dr. C. C. Wimberley, Coventry; Dr. J. J. K. Duncanson, Edinburgh; Dr. J. Candy, Devonport; Mr. W. F. Tonkyns, Yeovil; Mr. B. D. Taplin, Malvern; Dr. T. F. J. Messer, Helensburgh; Mr. H. Mitchell, Colchester; Mr. J. Bankart, Exeter; Mr. G. H. Smith, Edinburgh; Mr. R. P. Cotton, London; Mr. Woodie, Stirling; Mr. J. V. Lucas, Ahmedabad; Mr. R. H. B. Nicholson, Hull; Mr. T. P. Salt, Birmingham; Mr. J. B. Walker, Golcar; Mr. H. Swinson, Leamington; Mr. E. N. Smith, Paddockhurst; Dr. G. M. Humphry, Cambridge; Mr. F. Heywood, Manchester; Dr. E. T. Tibbits, Rugeley; Dr. E. M. Sherritt, Clifton; Dr. W. J. Kennedy, Dalkeith; Mr. J. H. Roberts, Denbigh; Mr. A. S. Cooks, Stroud; Mr. Kenworthy, Bowden; Dr. Fraser, Edinburgh; Dr. W. R. S. Jefferis, Lochmaben; etc.

AN ADDRESS

ON

THE PRESENT STATE OF ANATOMICAL SCIENCE.

*Delivered to the Anatomical and Physiological Department of the
Biological Section of the British Association:
Bristol, August 25th, 1875.*

BY JOHN CLELAND, M.D., F.R.S.,

Professor of Anatomy and Physiology in the University of Galway;
Vice-President of the Section.

I SHALL not venture to occupy the time of the Section with any *résumé* of such information in anatomy and physiology during the past year, as such information is readily accessible in the pages of journals and year-books. I shall content myself with making some comments on the condition of anatomy at the present time in a few important particulars.

I had intended to speak also of some subjects connected with physiology; but I find that I cannot do so without lengthening my remarks to a greater extent than might be desirable. I shall be content, therefore, so far as that science is concerned, to mention that, although experimental physiology is probably less cultivated in this country than in any other in which biology is studied, it has been practically decided by Parliament that it is quite time to put some check on investigation in that direction; for, as every one knows, a Royal Commission has been appointed to inquire into vivisection. In the scientific world, all are agreed, whatever opinions may prevail in other sections of the community, that the man who would wantonly inflict pain on a brute beast is himself a brute, and deserving to be roughly handled; and because there is no difference of opinion on that subject, and because no experimental science can well prosper if one man is to judge for another what experiments are justifiable to institute or to repeat, or are likely to give important results, I do deplore the clamour which well-meaning persons have raised, and regret that it has been so far yielded to.

In anatomy, the most important progress in recent years has been made in those departments which abut most closely on physiology; namely, the microscopy of the tissues and development. The whole conception of the nutrition of the body has become altered in comparatively recent years by the additions to our knowledge of the nucleated corpuscles, which are the living elements of which it is composed; and principally by the recognition of the secondary nature of cell-walls, the close connection or even continuity of the nerves with other tissues, and the identity of the white corpuscles of the blood with amœboid or undifferentiated corpuscles outside the vessels. The origin of every living corpuscle from corpuscles pre-existing is no longer difficult to imagine, but may, I incline to think, be almost looked on as proved. The history of each may be traced back through conjugated germs to the corpuscles of preceding generations in uninterrupted succession, and the pedigree of the structural elements is seen to differ in no way from that of individual plants or animals. It is true, indeed, that no absolute proof exists that new living corpuscles originating by mere deposit are not added to the others; but the evidence against such a thing taking place is exactly of the same description as that which exists against spontaneous generation of independent organisms; viz., that things previously unexplained by the theory of parentage are explained now, while, on the other hand, there is no sufficient evidence of the origin of life by any other mode.

The advance of histology in recent years is owing in part to the facility of obtaining good microscopes at moderate prices having brought the study within the reach of a great and increasing crowd of observers. At first, the progress of histology was influenced by the steps of improvement in the manufacture of microscopes; but now, for a number of years back, we have been in possession of instruments thoroughly suited for the investigation of tissues; and I think it will be generally admitted that the highest powers which have been manufactured are not those which have advanced discovery most, or are most likely, in the present state of science, to yield the richest harvest. We appear to be more dependent now on new methods of preparation. Thus, if we go back for a considerable number of years, we cannot but remember what a valuable addition glycerine proved when it came first into use, and what a harvest of discovery followed the introduction of chromic acid. More recently, the methods of transparent injection, of preparing sections by imbedding, the freeing of

tissues, the use of carmine and other pigments for staining, the resort to metallic depositions by the use of osmic acid, silver and gold, and a variety of other additions to our means of preparation have produced results of an astonishing kind, which have changed the whole aspect of histology from that which it wore when I myself first took an interest in the subject.

Leaving histology, I shall devote the rest of my remarks to the morphology of the vertebrata. Here I am less disposed to indulge a gratulatory vein. No doubt, within the last dozen years, we have had work to be grateful for. Worthy of a prominent place in this, as in other departments of anatomy, is the encyclopædic work, the *Lectures*, of Milne-Edwards, invaluable as a treasury of reference to all future observers; while the memoirs of Gegenbaur on the carpus, on the shoulder-girdle, and on the skulls of Selachian fishes, and Kitchen Parker's memoirs devoted to mature forms, may be taken as examples that morphological problems suggested by adult comparative anatomy have not lost their attraction to men capable of elaborate original research. And I the more willingly select the names of these two writers, because, on one subject on which they have written, the shoulder-girdle, I am compelled to differ from their conclusions, and to adhere rather to those of Owen, so far as the determination of the different elements in fishes is concerned; and by stating this (although the subject cannot be now discussed) I am enabled to illustrate that the appreciation of the value of elaborate and painstaking work is a matter totally distinct from agreement with the conclusions which may be arrived at in the investigation of complicated problems, although wisdom and penetration as to these must ever command admiration.

But, when one looks back on the times of Meckel and Cuvier, and on the activity inspired by the speculations of the much abused Oken, the writings of Geoffroy St. Hilaire, the less abstrusely speculative part of the works of G. C. Carus, and the careful monographs of many minor writers; when one reflects on the splendid grasp of Johannes Müller, and thinks of the healthy enthusiasm created in this country for a number of years by Owen's *Archetype and Homologies of the Vertebrate Skeleton*, and then contemplates the state of vertebrate morphology at the present moment, it seems to me that its homological problems and questions of theoretical interest do not attract so much attention as they did, or as they deserve.

There can be no doubt that a great and curious influence has been exercised on morphology by the rise of the doctrine of the origin of species by natural selection. Attention has been thereby directed strongly for a number of years to varieties; and probably it is to this doctrine that we owe the larger number of observations made on variations of muscles, nerves, and other structures. Particularly elaborate have been the records of muscular variations, very praiseworthy, interesting to the recorders, very dry to most other people, and hitherto, so far as I know, barren enough of any general conclusions. So much the more credit is due to those who have worked steadily in faith that beauty will emerge to gild their results some day.

But the doctrine of natural selection has had a further effect in anatomical study, aiding the reaction against the search for internal laws or plans regulating the evolution of structures, and directing attention to the modifying influences of external agencies. This effect has happened naturally enough, but it has been far from just; rather is it a pendulum-like swing to another extreme from what had previously been indulged in. The doctrine of natural selection starts with the recognition of an internal formative force which is hereditary; and in the development of the doctrine, the limits of hereditary resemblance have been greatly studied; and further, it will be observed that one of the fundamentals of the doctrine is, that the formative force alters its character gradually and permanently when traced from generation to generation in great tracts of time. Now I am not going to enter on a threadbare discussion of the origin of species in this company; suffice it to say that, while the existence and extensive operation of such a thing as natural selection seems to have been convincingly proved, it is a very different thing to allege that it has been the sole, or even the principal agent in producing the evolutions of living forms on the face of the earth. So far as anatomy is concerned, it is a secondary matter whether the link between the members of the evolving hosts of life have been genetic or not. But I wish to point out that, even pushing the Darwinian theory to the utmost possible extreme, the action of external agents infers the existence of something acted on; and the less directly they act, the more importance must be given to the hereditary or internal element. We are, therefore, presented with a formative force, which exhibited itself in very simple trains of phenomena in the first beginnings of life, and now is manifested in governing the complex growth of the highest forms. We are set face to face with that formative force, and are obliged to admit its inherent capability of changing its action; and that being the case, it is more of an assump-

tion to declare that the changes are all accidental and made permanent by accident of external circumstance, or to consider that it has been the law proper to this force to have been adequate to raise forms, however liable to modification by external circumstances—to raise them, I say, from the simple to the complex, acting through generations on the face of the earth, precisely as it acts in the evolution of a single egg into an adult individual? This is that formative force which has been elaborately shown by Mr. Darwin, in launching his theory of "pangenesis", not only to be conveyed through whole organisms and their seed, but to pervade at all times the minutest particles of each; and I merely direct attention to the fact that its extension over the whole history of life on the globe must be granted, and ask if, in the range of forms which furnish at the present day an imperfect key to the ages which are past, there is not exhibited a development comparable, in its progression to definite goals, with what is shown in the life of a single plant or animal. For my own part, I am fully convinced of an unity of plan running through animal forms, and reaching, so far as the main line is concerned, its completion in the human body. I confess that I think that there is evidence that animal life has reached its preordained climax in humanity; and I cannot think it likely that, as myriads of years roll on, descendants differing *in toto* from man will be developed. To argue the subject would be to enter on the largest subjects of morphological anatomy, and on speculations on which agreement could not be expected. Even, however, in the nature of the variations in the human race there seems to be some evidence that the progress of evolution is to be traced from man, not to other animal forms yet to appear, but, through his psychical nature, into the land of the unseen. Those variations, keeping out of view differences of bulk and stature, which appear to have some relation to geographical position, are principally to be found in the head, the part of the body most closely connected with the development and expression of the mental character; and I may mention that when, some years ago, my attention was directed to the variations of the skull, the only part whose variations in different races I have had opportunity of studying with any degree of minuteness, I became satisfied that in uncivilised races there might be distinguished skulls which had undergone hereditary degeneration, others which had reached the most advanced development possible for them; and a third set, notably the Kafirs, with large capabilities for improvement in the future. Indeed, it is beyond doubt, that there is a limit for each type of humanity beyond which it cannot pass in the improvement of the physical organisation necessary for mental action.*

There are also some curious indications in human structure of the formative force nearing the end of its journey. In the details of the skeletons of other animals, one sees the greatest precision of form; but there are various exceptions to this neatness of finish in the skeleton of man, and they are found in parts specially modified in connection with the peculiarities of his development, and not requiring exactness of shape for physiological purposes; while, on the other hand, physiognomical mould and nicety of various physiological adaptations are found in perfection. Look at the variations in the breast-bone, especially at its lower extremity, which is never shapely, as it is in the lower animals. Look at the coccygeal vertebrae; they are the most irregular structures imaginable. Even in the sacrum and in the rest of the column the amount of variation finds no parallel in other animals. In the skull, except in some of the lowest forms of humanity, the *dorsum sellæ* is a ragged, warty, deformed, and irregular structure, and it never exhibits the elegance and finish seen in other animals. The curvature of the skull and shortening of its base, which have gradually increased in the ascending series of forms, have reached a degree which cannot be exceeded; and the nasal cavity is so elongated vertically, that in the higher races nature seems scarcely able to bridge the gap from the cribriform plate to the palate, and produces such a set of unsymmetrical and rugged performances as is quite peculiar to man; and to the human anatomist many other examples of similar phenomena will occur.

Questions of homology are matters which must be ever present in the study of structure as distinct from function—both the correspondence of parts in one species to those in others, and the relations of one part to another in the same animal; and perhaps I shall best direct attention to the changes of opinion on morphological subjects in this

* I allude to the circumstances, that, under the influence of civilisation, the length of the base of the skull does not increase, but positively decreases; that the proportion of the extent of the arch to the base has strict limits; that the curvature of the base in some uncivilised races falls slightly short of the normal; that in others it transcends the normal by a peculiar process of degeneration between the sphenoid and ethmoid; and that increased capacity of the cranial cavity in the progress of civilisation is obtained almost entirely by increase of breadth and by the rounding out of those flat surfaces above and below the temporal ridges which give savage skulls a rooflike appearance. See "Inquiry into Variations of Skull" (*Phil. Trans.*, 1870).

country during the last twenty-five years, by referring shortly to the homological writings of three eminent anatomists—Professors Owen, Goodsir, and Huxley.

For the first time in English literature, the great problems of this description were dealt with in Professor Owen's work already referred to published in 1848; and it is unnecessary to say that, notwithstanding the presence of unquestionable errors of theory, that work was a most valuable and important contribution to science. The faults in its general scope were justly and quietly corrected by Goodsir at the meeting of this Association in 1856 in three papers, one of them highly elaborate; and in these he showed that the morphology of vertebrate animals could not be correctly studied while reference was made exclusively to the skeleton. He showed the necessity of attending to all the evidence in trying to exhibit the underlying laws of structure, and especially of having constant regard to the teachings of embryology. Among the matters of detail which he set right, it may be mentioned that he exposed the untenability of Professor Owen's theory of the connection of the shoulder-girdle with the occipital bone, and pointed out that the limbs were not appendages of single segments corresponding with individual vertebrae. Referring to the development of the hand and foot, he showed the importance of observing the plane in which they first appear, and that the thumb and great toe are originally turned toward the head, the little finger and little toe toward the caudal end of the vertebral column. But he probably went too far in trying to make out an exact correspondence of individual digits with individual vertebral segments, failing to appreciate that the segmentation originally so distinct in the primordial vertebrae becomes altered as the surface of the body is approached: a truth illustrated in the vertebral columns of the plagiostomatous fishes, in the muscle-segments over the head in the pleuronectids, and in the interspinal bones bearing the dorsal and anal fin-rays of numbers of fishes, but so far, as I know, not hitherto sufficiently appreciated by any anatomist.

Goodsir also exploded, one would have thought for ever, the erroneous theory of the correspondence of the mammalian tympanic plate with the quadrate bone of birds and the suspensorium of fishes, directing attention to the neglected but just appreciation by St. Hilaire of the homological importance of the ossicles of the ear, and to the embryological work of Meckel and Reichert. But undoubtedly he fell into great mistakes of his own in matters of detail connected with the exceedingly difficult question of the correspondence of the bones of the skull, the principal of these probably being an unfortunate notion that the *great frontal* of fishes was a bone which disappeared from the skulls of mammals, a notion which spread its influence over his determination of a number of other elements, and introduced a confusion which made his paper on the skull hard to understand.

In 1858, Professor Huxley delivered his Croonian Lecture on the Vertebrate Skull; and in 1863, his lectures at the Royal College of Surgeons on the same subject. He profited by the wisdom of Goodsir, and studied the works of Rathke, Reichert, and other embryologists. But, rightly or wrongly, he took a step further than Goodsir. He assumed from the first that the homologies of adult structures could be determined by development, and that by that study alone could they be finally demonstrated. As regards the skull, the constitution of which always remains the central study of the vertebrate skeleton, his writings marked the introduction of a period of revulsion against not only the systems of serial homologies previously suggested, but even against any attempt by the study of the varieties of adult forms to set them right. Mr. Huxley has added materially to the previously existing number of interpretations as to what elements correspond in different animals; and, in doing so, has found it necessary to make various additions to the already troubled nomenclature. Those who consider these changes correct will, of course, see in them a prospect of simplicity to future students; but to those who, like myself, have never been able to agree with them, they are naturally a source of sorrow. Among the changes referred to, may be mentioned the theory of the "*periotic bones*". That theory I venture to think a very unfortunate one, introducing a derangement of relations as wide-spread as did Goodsir's theory of the frontal bone. And do not think me presumptuous in saying so, seeing that this theory is in antagonism with the identifications of every anatomist preceding its distinguished originator, not excepting Cuvier and Owen; nor is it easy to discover what evidence it has to support it against the previously received decision of Cuvier as to the *external occipital* and *mastoid* of fishes. Without entering into the full evidence of the subject, it may be stated that, so far as this theory affects the *alisphenoid* in the skull of the fish, it must be given up, and the determination of Professor Owen must be reverted to, when it is considered that in the carp the third and fourth nerves pierce what that anatomist terms the *orbisphenoid*, the bone which is *alisphenoid* according to the theory which terms the *alisphenoid* of Owen the *prootic*. A proof still more

striking is furnished by *Malapterurus* and other Silurids, in which the bone in question is pierced by the optic nerve. That being the case, the prootic theory will be seen to have arisen partly from giving too much importance to centres of ossification, and partly from considering the nerve-passage in front of the main bar of the *alisphenoid* of Owen as corresponding with the *foramen ovale* of man rather than with the *foramen rotundum* and sphenoidal fissure. A spiculum, however, separating the second from the third division of the fifth nerve, and having therefore the precise relations of the mammalian *alisphenoid*, does exist in the carp and other fishes. But in reptiles Professor Huxley's determination of the *alisphenoid* is right, and Professor Owen's clearly wrong; for in the crocodile the *alisphenoid* of Huxley and others is perforated by the sixth nerve, so that it cannot have any claim to be called *orbitosphenoid*. I must, however, maintain against Professor Huxley's view of Professor Owen's determination of the *nasal* in fishes, notwithstanding that Professor Owen has failed to appreciate the exact relation of that bone to the nasals of mammals, and has thereby laid his position open to attack. The arguments on that point Professor Huxley was good enough to lay before the public fourteen years ago, by kindly reading for me before the Royal Society a paper, which subsequently appeared in its *Transactions*; and I am not aware that anyone has since attempted to controvert them.

I shall not trouble you further with such matters of detail; but it will be clear from what has been said that the beginner in comparative anatomy must at the present day find himself at the outset, in the most important part of his osteological studies, faced with a diversity of opinion and confusion of nomenclature sufficient to produce much difficulty and to have a repelling effect on many minds. Such difficulties might well be encountered with enthusiasm where a belief existed that behind them lay a scheme of order and beauty; but not many will spend time investigating such intricate details if they doubt the interest of the general conclusions likely to be reached by mastering them. On this account, it is a great pity that the scepticism generated partly by the difficulties of the subject, and partly by reaction from the dogmatism of the admirers of Oken, does too frequently discourage the investigation of the serial homologies of the parts entering into the segments of the skull, and the determination of the nature and number of those segments. It is a pity that so much clamour has been made for a number of years against the expression "vertebral theory of the skull", because fighting against words is but stupid warfare at the best, and because all that was really meant, and that could be justly stated, could have been brought into prominence without objecting to a time-honoured phrase. It is questionable if anyone who ever used the convenient term "vertebral theory" meant to indicate more than a certain community of plan on which were built the segments of the skull as well as those of the spinal column; that, in fact, the two constituted one complete chain, of which the first few segments were so different from the rest that, till Oken pointed the fact out, it was not recognised that they were segments lying in lineal continuity with the rest. But the matter has recently stood thus: that to some minds, in the imperfect state of our knowledge, one thing seemed essential to a segment comparable with the rest, and to others something else seemed requisite; and the oddity of the position of affairs is this, that the objectors to the phrase "vertebral theory" have been as crotchety in setting up imaginary essentials to a segment as their neighbours. On the one side, we were taught to expect certain definite osseous elements in each segment, to which definite names were given; while, on the other, in opposition schemes, centres of ossification have been built on as matters of primary consequence, although a glance at the modifications in the vertebral column proper might convince anyone that they are things of the very slightest importance morphologically. Also those who have objected to speaking of cranial vertebrae, have put great importance on the point at which the *chorda dorsalis* terminates, although it has been long known that in one animal the *chorda dorsalis* runs right on to the front, that in others it fails to enter the skull at all, while in the majority it passes for a certain distance into the base. Johannes Müller, on such grounds, concluded, thirty years ago, that the presence of *chorda dorsalis* was not necessary to constitute a cranial vertebra; and there seems no reason to doubt that he was right. Looking at the early embryo, the cerebro-spinal axis is seen to be one continuous structure; and the walls of the canal containing it are likewise manifestly continuous, not at first distinguishable into a spinal and a cranial portion. Looking at the adult condition, in the higher classes the vertebrae of the tail are seen dwindling into mere bodies developed round the *chorda dorsalis*, and giving off rudimentary processes without separate centres of ossification, while towards the head the bodies diminish and the arches enlarge; and in the skull the *chorda*, round which the bodies in the rest of the column are developed, comes to an end, and the neural arches are enormously enlarged and have additional centres of ossifica-

tion, precisely as in the mammalian thorax costal centres of ossification are found which do not exist in the costal elements of cervical vertebrae. It would, therefore, be quite as justifiable to object to the term vertebra as applied to a joint of the tail because it has no *lamina*, or none with separate centres of ossification, as to object to its applicability to segments of the skull because the *chorda* is absent, or the osseous elements different in number from those found usually in the segments of the trunk.

However, it is gratifying to observe that, among the most recent additions to morphological anatomy, there is a highly suggestive paper by Professor Huxley, appearing in the Royal Society's *Proceedings* for December last, and entitled "Preliminary Notes upon the Brain and Skull of *Amphioxus lanceolatus*", in which the learned professor, who has for many years been the most determined opponent to the mention of cranial vertebrae, declares, so far as I can comprehend his meaning, that the region of the head represents no less than fourteen segments, all of which he terms *protovertebrae Amphioxus*. This determination of correspondence is made the more remarkable by being followed up with a suggestion that the numerous protovertebrae lying in front of the fourteenth in *Amphioxus* are represented only by muscles and nerves in the higher vertebrates.

I hail this paper as being practically at last an ample acknowledgment that there is no escape from admitting the correspondence of the region of the head with the segments of the trunk; but the details of the new theory scarcely seem convincing; and I might have preferred to leave its discussion to others, were it not that the notions which it opens up are far too important to allow it to be passed over in any account of the present state of opinion on the subject of vertebrate morphology. The argument in this new theory runs thus: that the palate-curtain of *Amphioxus* is homologous with that of the lamprey, and that the palate-curtain of the lamprey is attached below the ear; that, therefore, all the seven segments seen in front of the palate-curtain of *Amphioxus* are represented by parts in front of the ear in the lamprey and the other Vertebrata. Again, the branchial arches of the higher Vertebrata are assumed to be of the nature of ribs; and in none of the Vertebrata next above *Amphioxus* "are there more than seven pairs of branchial arches; so that not more than eight myotomes (and consequently protovertebrae) of *Amphioxus*, in addition to those already mentioned, can be reckoned as the equivalents of the parachordal region of the skull in the higher vertebrates". Everything, observe, depends on the segment to which the palate curtain of *Amphioxus* belongs. Now, I have already pointed out to you that the segmentation of the vertebrate body is not perfect; and there is no method by which the alimentary canal, of which the mouth and palate are the first part, can be divided into segments corresponding with the cerebro-spinal nerves. Most certainly we cannot judge that a portion of a viscus belongs to a particular segment from its lying underneath some other structure in definite relation, like the ear, to the cerebro-spinal system; for then should we be obliged to grant that one-half or more of the heart belongs to segments in front of the ear, since it is undoubtedly so situated in a chick of the thirty-sixth hour. But the branchial arches are in front of the heart, and, according to the theory which we are considering, are behind the ear; thus the principle assumed in the starting-point of the theory is taken away.

Again, it is important to observe that the branchial skeletal arches cannot be ribs, for they lie internal to the primary circles of the vascular system formed by the branchial arteries and veins, while the ribs are superficial to both heart and aorta. If the ribs are represented at all in the branchial apparatus (and I doubt it very much), it is by the cartilages superficial to the gills in sharks, rays, and dog-fishes; and it would seem impossible for any one who has dissected them to doubt that those cartilages are homologous with the branchial skeleton of the lamprey, which they somewhat resemble. In fact, if the external and internal branchial openings of the lamprey be enlarged, its gills are reduced to a form similar to those of the shark.

There is nothing in this, however, which interferes seriously with the proposed theory of the skull. It is merely a point in the argument which I have thought right to clear. More important it is to remark that, on the supposition that numerous protovertebrae are represented in the region of the head, there are most serious difficulties interfering with the idea that they are, as Professor Huxley states, represented only by muscles and nerves in the higher Vertebrata; and that there is any correspondence between "the oculo-motor, pathetic, trigeminal, and abducens nerves with the muscles of the eye and jaws", and the regular nerves and muscle-segments of the fore part of *Amphioxus*. Even in the lamprey, the eyeballs are supplied with muscles similar to those to which, in other vertebrates, the oculo-motor, pathetic, and abducens are distributed; and I find in the large species that, notwithstanding this, the series of regular muscle-segments is continued over the head—

not, indeed, in the same way as in *Mivine*, but in a highly instructive and curious manner. The five foremost muscle-segments have their upper extremities attached considerably in front of the nasal opening by a short tendon, which touches its fellow in the middle line; and, extending thence in an outward and backward direction, they pass behind the eyeballs, the first two running in front of the first gill-pouch, and the third lying over it. Therefore, in this instance, as surely as the nostril is in front of the eye, so surely the upper extremities of these muscle-segments are shifted forwards out of their morphological place, probably in connection with the great protrusion of the jaws for the physiological purpose of forming a sucker. There is no escape from granting this shifting, even were it possible to believe that the eyeball could be further forward than the nostril; for, while the fifth muscle-segment can be traced in front of the nostril, the sixth occupies the interspace between the skull and first vertebra, so that, if the muscle-segments are taken as a guide, the whole skull, forward to the nostril, belongs to one intersegmental space: a view which is clearly absurd. The succeeding intermuscular septa correspond each with a cartilaginous vertebral arch; and it is interesting to observe that the branchial cartilages are not placed one for each septum, like the fibrous representatives of ribs detectable within the septa; for the second cartilage is opposite the sixth septum, the third opposite the ninth, the fourth opposite the eleventh, the fifth opposite the thirteenth, and the sixth and seventh opposite the fourteenth and fifteenth septa; and this is one reason for doubting that even these superficial branchial cartilages, though attached to the vertebral column, are to be regarded as ribs.

It may be noticed as a wholesome symptom in anatomical speculation, that the new theory which has led to these remarks is founded on arguments drawn altogether from comparison of different species, and not from embryology: a very remarkable circumstance, as coming from one who so lately as last autumn reiterated in this Section his slowness to believe in reasonings founded on adult forms, and even on "later development". The wisest know so little, that humanity must be content to gather information from every possible source, and leave no set of ascertained facts out of view in attempting to arrive at generalisations. If we had before us all the adult anatomy of every species that ever lived on the earth, we should only then have the record completed from which to frame a full system of morphology; and, as matters stand, we must translate embryological phenomena with the aid of the series of adult forms, as well as translate the teachings of the adult series with the aid of embryology.

Falling back on my proposition, that the segments of the vertebrate body are nowhere complete, and that segmentation at one depth may exist to a greater extent than at another, I may mention certain embryological phenomena in the brain which have received too little attention, and which to some extent warrant belief in a larger number of segments in the head than is usually admitted; although I do not see that they are necessarily at variance with that theory of seven segments in every ossified skull which I indicated in 1862. In the chick, in the middle of the second day of hatching, already is the third cerebral vesicle divided into a series of five parts, separated by slight constrictions, the first part larger than those which succeed, and the last part narrowing to the spinal cord. The auditory vesicle lies opposite the constriction between the fourth and fifth parts. At the end of the second day and during the third, these divisions assume dimensions which give them a general appearance exceedingly similar in profile to the protovertebræ of the neck. In the following day they exhibit a more complex appearance, and after that the first compartment alone remains distinct as cerebellum, while the divisions between the others disappear in the thickening of the cerebral walls. In their first two stages, Mr. Huxley, whom I have already referred to so often, has figured these crenations, but he has not, so far as I know, described them.

I may also direct attention to another embryological point, to which I referred last year at Belfast as a probability. I speak now from observation. That which is termed the first cerebral vesicle in the early part of the second day of hatching of the chick, is an undifferentiated region of the brain from which a number of parts emerge successively from behind forwards. As early as the thirty-sixth hour the optic nerves can be traced, separated from the rest of the vesicle by distinct elevations of the floor of the brain, reaching inwards to the constriction between the first and second vesicles: and as early as this date the first trace of bilidity of the brain in front may be discerned—that bilidity which, to my thinking, is only one of several instances of longitudinal fission in the fore part of the head, the trabeculæ presenting another instance of the same thing, and the cleft between the maxillary lobe and the part of the head above it a third; while in the muscular system such longitudinal cleavage or fission is common even in the trunk. In a chick of the third or fourth day, when rendered very

transparent, the optic nerves can be seen extending from beneath the front of the optic lobes; while in front of the optic lobes there are placed in series from behind forwards a posterior division of the first vesicle, an anterior division, the cerebral hemispheres, and the olfactory lobes. Thus there is a large supply of material presented in the brain for the study of segmentation: the difficulty to be overcome by future inquiry and careful collation of all available facts is to determine the value of the parts placed one in front of another.

Perhaps I have occupied time too long with matters involving a large amount of technical detail; but I trust that I may have, in some measure, illustrated that both in aim and in accomplished work anatomy is no mere collection of disconnected facts, no mere handmaid of the physician and surgeon, nor even of physiology. I do not doubt that it is yet destined, as dealing with the most complex sequences of phenomena, to take the highest place among the sciences as a guide to philosophy. One cannot help noticing the increased importance now given to natural history studies as a part of education; and it is worth while to note that it is most of all in anatomy and physiology that the close connections of matter with mind are brought under review—physiology exhibiting the relations of our own mental being to our bodies, and anatomy revealing a body of organised nature, whose organisation points to a source of beauty and order beyond.

The people of Bristol do well to rally round their medical school. They do well to furnish it with buildings suitable for the prosecution of all the natural history studies which adhere to medical education; and they do well to join with that school a complete college of literature and science. Let us hope that they will make it worthy of so wealthy and historic a city. But if they will have their medical school the success which in so flourishing a locality public enthusiasm may well make it, and if they will have it aid as well as be aided by a school of general education, let them follow the system latterly adopted in Oxford and Cambridge, long carried out in the Universities of Scotland, and recognised, though not in all instances sufficiently provided for, in Ireland. Let anatomy, human and comparative, receive its place as an important and fundamental science. Let thorough and adequate provision be made for its being taught as a science; and see that it do not, as in too many medical schools which shall be nameless, degenerate to the etymological and original meaning of the word, a mere cutting up of carcasses.

ON TRACHEOTOMY IN CROUP AND DIPHThERIA.*

By GEORGE BUCHANAN, M.A., M.D.,
Professor of Clinical Surgery in the University of Glasgow.

THE prevalence and fatality of diphtheria of late years, as may be seen by a perusal of the Registrar-General's returns, has drawn the attention of the profession to the etiology of that disease, and has recently given rise to a controversy as to the identity or non-identity of croup and diphtheria. Many able papers have appeared in the pages of the BRITISH MEDICAL and other journals on this subject, and to them I refer those interested in the question; but there is one point of resemblance which is of the utmost importance in a practical point of view. Although the two diseases may be as distinct as to cause, course, and sequelæ, as scarlet fever is from simple tonsillitis, yet both are characterised by the effusion, on the mucous membrane of the air-passages, of a tough false membrane. This membrane may differ in its nature and in situation, at least at the commencement, but the tendency in both cases is to obstruct the breathing and cause suffocation.

This seems so self-evident that I must almost apologise for mentioning it; but I have been so often met with the objection that, because the primary disease causing the effusion is diphtheria and not croup, therefore it is hopeless to interfere, as the operation will not cure the specific disease, that I have considered it not out of place to introduce it. We might as well refuse to open an abscess of the tonsil which was about to choke a patient suffering from scarlatina, because the operation will not cure the fever, as refuse to relieve a patient from instant death from suffocation because the operation is not a cure for diphtheria.

Now, the point I wish to bring out is, that there is a stage both in croup and in diphtheria at which it becomes evident that recovery is hopeless and death from suffocation certain. It is quite true that it is exceedingly difficult to say when that stage has arrived, and mistakes may sometimes occur; but I believe practically it is better to err on the safe side, and acknowledge the inefficacy of treatment, rather than delay till it is too late to resort to the last resource. Tracheotomy *per se*, though

* Read before the Surgical Section at the Annual Meeting of the British Medical Association in Edinburgh, August 1875.

a difficult, is not a dangerous, operation; and I, for one, would be inclined to urge its performance before the strength of the little sufferer has been brought to the lowest ebb by the struggles which result from the approaching suffocation.

I wish, however, clearly to guard myself from being supposed to advocate tracheotomy in all circumstances of approaching death from croup or diphtheria. I have elsewhere explained my views on this subject, but I cannot avoid referring to them again.

The diseases in question, but especially diphtheria, when they prove fatal, cause death in one of two ways: either by exhaustion or by suffocation. Hence, we may say there are two varieties, viz., the asthenic and the sthenic. In the great majority of instances, croup is a sthenic inflammation attended with effusion of lymph in the trachea, and proves fatal by suffocation. In some cases, however, the attack is attended with such a depression of the vital powers that the patient sinks apparently from the virulence of the disease. This, however, is a rare case. But in diphtheria there are two well marked types: the sthenic, which closely resembles an attack of sthenic croup, except that the effusion of lymph begins on the fauces and extends through the glottis into the trachea; and the asthenic, which more closely resembles scarlet fever, and in which the effusion covers the whole of the mucous membrane of the fauces, tonsils, and even the pharynx, and in which the false membrane soon becomes foul, putrid, ichorous, and contagious.

In the former of these types, the danger is suffocation; in the latter, it is vital depression, death from asthenia.

Now, with regard to the treatment of these affections at the early stage, I wish here to make no reference; the scope of my remarks is the duty of the medical attendant, when medical treatment has failed, or is clearly failing, to arrest the disease. And I think that it is very important that medical practitioners, especially those commencing practice, should be supported by the opinion of those qualified to advise them in such a delicate matter as this, seeing it is a most painful and disagreeable task to advise parents to submit their children to such a repulsive proceeding.

I believe, then, that I am justified in calling on all those who have seen much of these diseases to unite with me in asserting that, when medical treatment has been fairly tried and when it is proving unavailing, and when death seems imminent from suffocation, not from vital depression or exhaustion, it is the duty of the medical attendant to perform, or advise the performance of, tracheotomy.

I know that here I shall be met with the objection that some cases which seemed hopeless have ultimately recovered; but these isolated examples are very few in number, and are counterbalanced out of all proportion by others in which delay, owing to repugnance to the operation and a hope that symptoms will improve, has deprived the patient of that chance of life which the surgeon can offer.

In pressing this view on my medical brethren, I am aware that I am adding nothing new to what has been frequently advanced by those who have had occasion to operate much in croup and diphtheria, but every year convinces me that it is the duty of those whose experience qualifies them to speak with authority on the matter, to reiterate their convictions, even if it be in nearly identical terms.

Last December, I was called to a case of croup, and when I arrived I found the child, a girl seven years of age, in the last stage of suffocation. The two medical gentlemen in attendance declared that the patient was beyond the reach of surgery. One of them, who had never seen the operation, strongly dissuaded me from making the attempt; the other, who had at one time been one of my clinical students, on hearing my wish to give the child a chance, persuaded the parents to consent. The little patient was livid, and though I did not use chloroform, as I usually do, it did not wince when I made the incision through the skin. The result was that the child is now alive, and in the enjoyment of excellent health.

To one who sees the operation for the first time, the hopelessness as to the attempt is only equalled by the surprise and gratification at the result.

But, while I am so strongly advocating the operation in the circumstances referred to, there is one condition in the suffocative form of those diseases which contraindicates tracheotomy, and which, if discovered, should prevent anyone from performing it. When the suffocation depends not only on obstruction of the trachea, but also on effusion of false membrane or the glutinous fluid which precedes it, into the smaller bronchial tubes, then the case is not one for operation. The difficulty, then, is to discover when the false membrane which causes the obstruction to breathing is limited to the trachea and larynx and when it has invaded the bronchia. Percussion and auscultation ought to assist in the diagnosis, but the restless tossing of the child and the noise of the breathing always make this a difficult proceeding.

There are two signs which appear to me to be valuable guides: one

is the amount and loudness of the stridor, which is always great in proportion to the patency of the small tubes and obstruction in the trachea.

But the most valuable test is a view of the naked chest. When the obstruction is in the trachea, while the bronchial tubes are free, the respiratory movements are continued with exaggerated energy, but the chest will not respond to the muscular efforts. The result is that at each inspiration the flexible parts of the thoracic walls are drawn in with great force, the intercostal spaces are hollowed, and the ensiform cartilage sucked back. But when the small bronchial tubes, and, perhaps, the air-cells, are stopped with the viscid or membranous effusion, the muscular efforts are more feeble and the chest remains puffed out, and the whole aspect is that of a child thirsting for breath, but with the lungs already full and themselves unfit for respiration. In this latter case, I never operate; in the former, with every hope of success.

This is not the place to enter into details with regard to the operation, which vary in many respects in different cases; but one thing may be impressed on the young operator by one who has had considerable experience; and that is, that tracheotomy is not the simple plunge of a knife into the trachea that many suppose, and that can be easily effected in the bloodless neck of a subject on a dissecting-room table. It requires coolness and patience on the part of the operator. Sometimes the trachea can be exposed by very little dissection; at others, numerous obstacles come in the way, especially in young children. Among these may be mentioned overabundant cellular tissue and fat, turgid veins, isthmus of the thyroid gland, which is very large in infancy, and protrusion into the wound from below of the thymus gland, a frequent cause of surprise and annoyance to those who are not forewarned. In consequence of these possible complications, the operation must be done slowly and systematically, obstacles turned and held aside, bleeding vessels secured; and the golden rule is that the trachea is never to be opened till its white rings are seen clearly at the bottom of the wound.

The following table contains an account of my operations of tracheotomy in croup and diphtheria, and the respective results.

CASE I. Croup; aged 6. Cured.

II. Croup; aged 3½. Death in three hours.

III. Croup; aged 3. Death immediately.

IV. Croup; aged 1¼. Death in sixteen hours.

V. Diphtheria; aged 2. Death immediately.

VI. Diphtheria; aged 2½. Death in six hours.

VII. Croup; aged 1½. Death in eight hours.

VIII. Croup; aged 3. Death in twenty-four hours.

IX. Diphtheria; aged 4. Cured.

X. Diphtheria; aged 2½. Cured.

XI. Diphtheria; aged 1¾. Death in twenty-four hours.

XII. Croup; aged 5. Cured.

XIII. Diphtheria; aged 2½. Death in forty hours.

XIV. Croup; aged 5. Cured.

XV. Diphtheria; aged 5. Death in twenty-eight hours.

XVI. Diphtheria; aged 5½. Death in five days.

XVII. Diphtheria; aged 6. Cured.

XVIII. Diphtheria; aged 3. Death in four days.

XIX. Diphtheria; aged 3½. Death in seven days.

XX. Diphtheria; aged 2. Death in five days.

XXI. Diphtheria; aged 2½. Cured.

XXII. Diphtheria; aged 6. Death in two days.

XXIII. Diphtheria; aged 5. Cured.

XXIV. Diphtheria; aged 8. Death in thirteen days.

XXV. Croup; aged 1½. Death in six hours.

XXVI. Croup; aged 5. Cured.

XXVII. Diphtheria; aged 5. Death in five days.

XXVIII. Diphtheria; aged 7. Cured.

XXIX. Croup; aged 5. Death in three days.

XXX. Diphtheria; aged 5. Cured.

XXXI. Diphtheria; aged 2. Death in two days.

XXXII. Croup; aged 2½. Death in two days.

XXXIII. Diphtheria; aged 5. Death in six days.

XXXIV. Croup; aged 9. Cured.

XXXV. Croup; aged 4. Death in three days.

XXXVI. Diphtheria; aged 8. Death in eight days.

XXXVII. Diphtheria; aged 7. Cured.

XXXVIII. Diphtheria; aged 7. Death in three days.

XXXIX. Diphtheria; aged 5. Cured.

XL. Diphtheria; aged 5. Death in two days.

XLI. Diphtheria; aged 4. Death in three days.

XLII. Diphtheria; aged 6. Cured.

XLIII. Diphtheria; aged 4. Death in two days.

XLIV. Croup; aged 7. Cured.

XLV. Croup; aged 9. Death in four days.
 XLVI. Diphtheria; aged 6. Cured.
 Total cases of Tracheotomy, 46. Cured 17; Died 29.
 Tracheotomy in Croup, 16. Cured 6; Died 10.
 „ Diphtheria, 30. Cured 11; Died 19.

The average result is precisely the same, viz., one child is saved out of every two and two-thirds operated on; and, as the operation was always done when there seemed no hope of recovery otherwise, it may safely be stated that the lives of these seventeen children were saved by tracheotomy.

UNUSUALLY RAPID ACTION OF THE HEART.

By JOHN CAVAFV, M.D.,

Assistant-Physician to St. George's Hospital.

DR. FARQUHARSON'S interesting paper on this subject, published in the *JOURNAL* of June 12th, recalls to my mind a very similar case which came under my notice some years ago, and which deserves, I think, to be recorded.

A groom, aged 32, was admitted into St. George's Hospital, under the care of the late Dr. Fuller, on March 15th, 1871. He had suffered from acute rheumatism seven years before, but had presented no cardiac symptoms till his present illness, the history of which was as follows. He had been in the service of a French family, with whom he was shut up in Paris during the siege. In October, his master's horses were killed for food, and he was consequently discharged. Since that time, he had lived very poorly, barely supporting himself by odd jobs of various kinds, and for the last two months had been subjected to great privation. He could obtain no meat, and only small quantities of bread and wine. He grew thin, and became subject, for a fortnight before his admission, to violent palpitation and præcordial pain on the least exertion or excitement. The fits of palpitation would often last a whole night. He left Paris on March 13th, with only two pounds of bread, and, on reaching Charing Cross, was penniless and destitute. He begged a lodging, and was offered food, but could not eat. The next morning, he swallowed a cup of tea, but this was immediately vomited. Violent pain and palpitation came on, and continued with barely appreciable intervals of rest, till he was admitted into the hospital on the following day.

He was then sweating profusely; there was great dyspnoea, and the heart's action was extremely rapid. The pulsations were counted as follows: at 1.30 (by Dr. Barelay), 228; at 2.15 (by myself), 216; at 2.20 (by the house-physician), 208; a little later (by Dr. Dickinson), 200; at 3 (by Dr. Whipham and myself), 176. A few minutes later (by Dr. Jones), the pulse suddenly became very weak, irregular, and intermittent, and dropped to 100-108. He was fed with small quantities of egg and brandy mixture every hour. The feeding was continued during the night, which was quiet, with the exception of one comparatively slight attack of pain and palpitation, and, at 11 on the following day, I found the pulse irregular, 100 to 108, with occasional intermission, and a harsh systolic murmur was now audible at the apex. Next day, the pulse had fallen to 82, and he steadily improved. He gradually became able to take food, the palpitation diminished in force and frequency, and by April 12th he was well enough to go to the Convalescent Hospital at Wimbledon. The treatment consisted of egg and brandy mixture, gradually diminished and replaced by food; bark and ammonia, and latterly citrate of iron and bromide of potassium in effervescing ammonia draught. No digitalis was given.

In this case, there are, it will be seen, many points of similarity to that published by Dr. Farquharson. There was valvular disease, the murmur was inaudible during the very rapid action of the heart, and there was a sudden fall (preceded in my case by a gradual diminution) in the number of pulsations, accompanied by irregular and intermittent action. With regard to the causation of palpitation, it seems probable that, in the great majority of instances, it is due to paresis of the inhibitory fibres of the pneumogastric, and not to stimulation of the accelerator nerves. Palpitation occurs chiefly in anæmic and otherwise weakened patients; in the case before us, it came on after insufficient food and consequent exhaustion, and it is difficult to suppose that, in cases such as these, there can be increased nervous action of any kind. I am aware that, in exophthalmic goitre, the palpitation and increased action of the heart are considered by some to be owing to stimulation or irritation of the accelerator nerves. But even here the majority of symptoms—dilatation of arteries, flushing, heat, sweating, etc.—point to paralysis of the sympathetic, or at least of the vaso-motor nerves. Friedreich has suggested that the increased action of the heart is secondary to vaso-motor paralysis, the coronary arteries being thus dilated, and the heart in consequence receiving an increased blood-

supply. It should, however, be remembered that dilatation of arteries means diminution of blood pressure, and that this always increases the frequency of the heart's contractions. A high blood-pressure, on the contrary, stimulates the centre of origin of the pneumogastric, and thus diminishes the frequency of the pulse.

THE LATE DISCUSSION ON PUERPERAL FEVER, AND ON ITS TREATMENT BY INTRAUTERINE INJECTIONS.

By EDWARD JOHN TILT, M.D.

WHEN, in opening the discussion, Mr. Spencer Wells stated that he came to learn and not to teach, those who hold him in high esteem thought this was only the usual artifice of the orator, seeking to moderate expectations so as to ensure the success of a final effort; and great was our surprise, when his turn came to close the debate, to find that he had trotted us out to show our paces, without having any definite object in view. Henceforth this discussion will be memorable among others; for, although the business of the Society was suspended for four consecutive meetings, and although the discussion was well carried on by many men well prepared by length and quality of observation, and who did their best to put their thoughts in small compass, no one gave them their proper place and weight in a general *résumé* of the debate; for this was left undone by Mr. Spencer Wells, by the President of the Society, and by the principal organs of the medical press.

I have no intention to do the work that should have been done by others; but, before responding to an appeal made to me by a correspondent in the issue of the *British Association Journal* of July 17th, that I should more fully state the best means to evacuate the foetal contents of the womb, I propose to make a few remarks on puerperal fever. I am glad of the opportunity to rectify the apparent one-sidedness of the remarks I made at the Obstetrical Society; for it is obviously advisable, when a speaker has to treat a vast subject in fifteen minutes, that he should devote the time to the elucidation of some undervalued point of practice rather than to the delivery of a mere syllabus of his views of the subject.

I am not aware that I am indebted to the discussion for any new views on puerperal fever; but it has deepened the conviction I already entertained, and I hold—1. That, during the puerperality, the blood is in such a state "of trembling equilibrium", to use Dr. Richardson's happy expression, that the unknown poison of puerperal fever may be developed within the blood by cold, or mental emotion, or zymotic influence, while the lochia remain perfectly normal. I say *may*, for sometimes even the poison of scarlet fever follows its usual course in a puerperal patient without causing puerperal fever, and without in the least interfering with the healthy tenor of the puerperal processes. 2. That, the womb and lochia being in a healthy condition, cold, mental emotion, or zymotic influence may render the lochia putrid, and thereby develop a poison which, soaking into the surface of the womb and its sinuses, is taken up by the uterine lymphatics, which pass it into the blood, so as to cause puerperal fever. 3. That the seat of placental attachment, a bruised portion of the womb, or any rent in its tissue, may inflame unhealthily, and thus produce pyrogenic fluids, which may be taken up by the lymphatics and cause puerperal fever, as already mentioned. 4. That fragments of placenta, of the membranes, and blood-clots, if retained in the womb, decompose, and produce septic fluids which may cause puerperal septicæmia. 5. That, as with other patients, so with puerperal women, when attacked by zymotic influence, the whole of their secretions may be vitiated, so that scarlatina, for instance, may poison the lochia, if it find them healthy, or intensify the virulence of the poison if it find them already made putrid by any of the causes previously enumerated. 6. That, just as other poisons often pass through the lymphatics into the blood without inflaming them, so the poison of puerperal fever may pass through the uterine lymphatics into the blood and into the peritoneum without inflaming the lymphatics sufficiently to fill them with pus; extensive purulent lymphangitis being rather the exception than the rule, unless certain epidemic influences prevail.

For all that relates in the previous propositions, to the mode in which the lymphatics convey from the womb the poison which, on coming in contact with puerperal blood, lights up puerperal fever, as well as for the explanation of the very early advent of puerperal peritonitis and the subsequent occurrence of puerperal cellulitis, pelvic abscess, and ovaritis, I refer the reader to my paper on Lymphangitis in Pelvic Pathology, in the sixteenth volume of the *Transactions* of the Obstetrical Society of London. Those who take interest in this mo-

mentous question will find a satisfactory attempt to establish the differential diagnosis of puerperal lymphangitis and puerperal phlebitis in a recent communication of Dr. Siredey.*

I do not share the dislike that some entertain for the term puerperal fever, and, however much they may object, it will be the term used by medical men to their patients, so long as they speak English, while the scientific name will vary according to the notion entertained by the profession respecting the nature of the complaint.

Drugs were not mentioned at the late discussion, yet it was eminently practical; for, as each speaker laid most stress on what he considered the chief cause of puerperal fever, the auditors were urged to renew their efforts to shield puerperal women from cold, mental emotion, zymotic influence, and to prevent the stagnation of foul fluids in the womb by ascertaining more carefully the state of the lochia.

Vaginal Injections.—It is customary with many practitioners to tell the nurse to inject a weak solution of Condy's fluid, or of carbolic acid, or of chloride of lime, into the vagina by means of an India-rubber syringe, when the lochia are said to be offensive. The plan is highly commendable; but I think it would be well, if it were accepted as a rule of practice, that, whether the lochia be fetid or not, a vaginal injection should be made every morning, about the third or fourth day after parturition; that is, when the blood-flow from the womb has greatly diminished. The cervix is always bruised and often lacerated, the fourchette often torn, and almost always so in primiparæ; it is therefore advisable to bathe the parts with a warm fluid, as well as to remove foul secretions. I have already advocated the practice as a means of preventing uterine inflammation; and it would also provide for the early removal of whatever is foul in the vaginal fluids. I can recommend nothing better for this purpose than a solution of a drachm of acetate of lead in a pint of warm water, with the addition of a dessert-spoonful of laudanum, if there be pain, or of Condy's fluid, should the lochia be at all offensive. The womb will better relieve itself of its contents if the patient be shifted from back to side, and her position thus changed several times a day; and by letting her micturate in the usual way, much sooner than we usually do, after parturition, according to the practice of Dr. Goodell of Pennsylvania University.

Intrauterine Injections.—Nothing that I may have said or written should be construed as meaning that it is the common practice on the Continent to use intrauterine injections when the contents of the womb are supposed to be fetid during puerperality. There is no mention of intrauterine injections in the accounts of the epidemic of puerperal lymphangitis, by which the Great Maternité of Paris was decimated from 1827 to 1832, nor in the two that occurred in 1842-44 at the Hôtel-Dieu of Rennes, graphically described by Dr. Botrell. As far as I am aware, Dr. Dupierris, a Cuban practitioner, is the first who had recourse to intrauterine injections; but principally with the view of preventing *post-partum* flooding. Dr. Wynn Williams has lately stated that he has made intrauterine injections to cure puerperal fever by the removal of fetid secretions from the womb for the last twenty years. Professor Stoltz, once Dean of the Strasburg, and now of the Nancy Faculty of Medicine, assures me he has done so with singular advantage for the last fourteen years. Dr. Fontaine,‡ who now practises in Madrid, has made three hundred intrauterine injections soon after parturition. Dr. Despine§ of Geneva has done so in thirty cases. Dr. Lucas-Championnière informs me that lately, at the Paris Maternité, a patient of Dr. Hervieux was rapidly cured of *post partum* purulent metritis by intrauterine injections; and that, during last winter at the Hospital of Anger, Dr. Guichard made intrauterine injections in fifteen cases, in which the lochia were fetid, and that pus was found in the lymphatics of those who died. If I had time to search the journals, I should find a certain number of cases in which French or English practitioners have resorted to the same practice. Several of the speakers in the late discussion have likewise done so; and, while many testified to the remarkable coincidence between the abatement of uterine factor and the amendment of alarming symptoms of puerperal fever, none mentioned peritonitis or any other untoward symptom having been caused by the practice.

I have recommended intrauterine injections during puerperality only when the lochia are fetid, as a curative measure; but I have suggested to those practising in India, that it would be worth while trying whether the plan would not be useful there, as a means of preventing *post partum* flooding, dysentery, and defective uterine involution. I did so because

when practising in Cuba some thirty years ago, Dr. Dupierris,* finding that his patients frequently died of *post partum* hæmorrhage, and that tetanus supervened if he checked flooding by the introduction of ice into the womb, adopted the plan of injecting a solution of iodine into the womb, immediately after removing from it the placenta and the clotted blood. This plan prevented flooding, and had also the advantage of preventing that form of puerperal fever that depends on fetid uterine secretions. The success of the plan was so great, that it was adopted by several Cuban practitioners, and it seems to have stood the test of time; for Dr. Dupierris published an account of it in 1870, substantiating his assertions by numerous cases.

When employed as a means of curing puerperal fever, I should like it to be accepted as a rule, that it is the duty of a medical man to make disinfecting injections into the womb, whenever symptoms of puerperal fever coincide with fœtor, however slight, of the vaginal secretions, unless the fœtor can be explained by lesions of the vagina itself.

Instruments Required.—To prevent accidents, it is always advisable to use an instrument with a double current when making intrauterine injections in the *unimpregnated* womb; but, during the first eight days of the puerperal period, during which intrauterine injections are most wanted to remove fetid secretions, the cervical canal is sufficiently wide to permit the free escape of small fragments of decomposed tissue with the outflowing stream of water; I therefore think a No. 9 or 10 gum-elastic catheter, in the extremity of which can be fitted the nozzle of an India-rubber bottle, is as good an instrument as can be used; it is one easily obtainable, and none other has been used by some of those who speak best of the practice. The use of so simple an instrument as a gum-elastic catheter ensures the possibility of its being burnt to avoid chance of spreading infection to another patient. The little instrument sold for injecting perchloride of iron into the womb would do very well. I have used the ordinary patent India-rubber syphon syringe for the same purpose, and that portion of the tube that screws on can in like manner be burnt at the end of the case. I place the woman on her back, with her thighs well separated and the edge of the bason well under the nates, the bed having been previously protected by a square of mackintosh. The tube of the instrument should be pushed well up to the fundus, and the fluid should be injected very gently and evenly.

Professor Stoltz uses an instrument with a double current action, the two tubes being enclosed in a third about the size of the index-finger; and he assures me he has never found a difficulty in passing this tube through the cervix during the first week of puerperality. No such instrument is to be found at the instrument-makers'; but Mr. Coxeter has made one at my suggestion. It may be objected that fragments of septic tissue may lodge inside this instrument, remain there, if it be carelessly washed, and thus transfer contagion to another woman; but I think that due care would prevent such an occurrence; for the instrument would carry within itself the antidote to the poison it encountered, and, before using it, the nozzle could be steeped in a strong solution of the disinfectant to be afterwards used in a more diluted state.

Fluids to be used.—A solution of Condy's fluid of chloride of lime might be made available, if nothing better were at hand. A strong solution of alcohol has been frequently used by Dr. d'Espine and several French practitioners; but it seems to me that its disinfecting action is indirect, and that the alcohol acts by contracting the womb and closing the uterine sinuses, while the fetid contents of the womb are diluted and evacuated. There is also a certain amount of alcohol in the lotions that have been most extensively used in association with carbolic acid and with iodine.

I do not know the strength of the alcoholic solution of carbolic acid that has been always used by Professor Stoltz; but Dr. Guichard washes out the womb with a pint of tepid water, in which he puts an ounce of a solution made by adding to ten ounces of water six ounces of alcohol and an ounce of crystallised carbolic acid. It would be well to begin with this dose of half a drachm of carbolic acid, and to increase it cautiously, if at all; for carbolic acid is a powerful remedy. One of carbolic acid to 200 of water is Dr. B. Hicks's proportion.

I believe tincture of iodine is the best disinfectant for intrauterine injections; for iodine is well borne by fistulous passages, closed cavities, and even by the peritoneum. Tincture of iodine, by its action on the nerves of the womb, is a powerful hæmostatic, while its antiseptic properties are undeniable; so it is doubly useful when there are putrid contents to purify and uterine sinuses to close; and I have no doubt it will ultimately supersede the perchloride of iron in cases of *post partum* hæmorrhage. I have repeatedly injected one of water

and two of tincture of iodine into the womb in cases of chronic internal metritis. It has occasionally caused severe uterine tormina, which subsided in a day or two. My friend Dr. Emmet of New York, after operating on the interior of the womb, injects it or soaks it with tincture of iodine; and, since he has adopted this plan, he has not had a case of septicæmia. Dr. Fordyce Barker, to check severe hæmorrhage following abortion, lately injected an ounce of the undiluted tincture of iodine (and the American tincture has double the strength of ours) with perfect success and no ill-effects; so it is not likely that any would follow the injection of a very strong solution of iodine into the womb soon after labour. I have then injected four drachms of the tincture in half a pint of tepid water, Dr. Wynn Williams has been in the habit of using three drachms to the same quantity of water; but Dr. Dupierri's practice has been to inject into the womb, immediately after the removal of the placenta, four drachms of tincture of iodine (double the strength ordered in the *British Pharmacopæia*), ten grains of iodide of potassium, and one ounce of distilled water.

It remains to be seen which is the best plan, either to inject the tincture of iodine little diluted, so as to act strongly on the womb, or to largely dilute the tincture, so that it may wash away fragments of putrid tissue.

I had been aware that Dr. Braxton Hicks had already treated this subject, I should have contented myself by referring to his trustworthy teaching,* which shows that he has been long aware that puerperal fever is likely to arise from the retention of foetid uterine fluids. These remarks of mine may not be, however, altogether useless; and most acceptable were those made by Dr. Wynn Williams, in the *JOURNAL* for August 7th, on the washing out of the puerperal womb.

CASE OF INVERSION OF THE UTERUS, OF THREE MONTHS' STANDING.†

By J. H. EWART, L.R.C.P.,
Surgeon to St. Mary's Hospital, Manchester.

ELIZABETH V., aged 22, married, was attended by a midwife in her first confinement on March 27th, 1874. She was at full term, and the labour went on well to the end of the second stage; there was then, according to her account, some difficulty with the afterbirth, which the midwife endeavoured to overcome by pulling at the cord. Eventually a surgeon was called in, and he and his assistant attended the patient up to the time of her admission to St. Mary's Hospital, Manchester on the 6th July, 1874, *i.e.*, for upwards of three months. She stated that she lost an alarming quantity of blood at the time of her confinement, and that she had had more or less hæmorrhage ever since. Sometimes she had lost a very considerable amount of blood; the last occasion on which this occurred was about a fortnight before her admission. Various injections had been given to her for the purpose of controlling the loss; no vaginal examination, however, was made after the confinement.

On admission to the hospital, the patient presented a most blanched appearance. She complained of no pain; the appetite was pretty good; the pulse 100, feeble. A small pear-shaped tumour, bleeding readily when touched, was found in the vagina.

On the following day (8th July), the patient was placed under the influence of chloroform, for the purpose of further examination. The tumour was smaller than I should have expected an inverted uterus to be; it bled very readily; on passing a finger into the rectum and pressing the fingers of the other hand at the same time deeply above the pubes, no intervening substance could be felt. The absence of the uterus from its normal position was further demonstrated by passing a sound into the bladder, and again by the impossibility of introducing the uterine sound by the side of the tumour, the neck of which was tightly constricted. Being now satisfied that the case was one of inversion of the uterus, I tried digital pressure, and persisted in it for some length of time. (I regret I did not notice the time accurately.) Considerable force was used; as much, indeed, as I deemed justifiable. I therefore desisted, with the intention of employing the elastic stem-pessary described by Dr. Barnes in the first volume of the *Obstetrical Transactions*, and in the event of that failing, of incising the neck, as recommended in the same communication. Some of those present, however, thought that further efforts should be made with the hand, and I reluctantly gave my consent. Pressure was accordingly resumed; and

after some time the operator announced that he had succeeded in reducing the inversion. It was obvious to the onlookers that the success was due to the exertion of extreme force; and, on examination, two fingers could be passed into a rent in the anterior vaginal wall just where it formed the cervix uteri. There was also some laceration of the perinæum, but at what stage of the proceedings this happened is uncertain. After the operation, the patient's pulse was pretty good, and her general condition was not alarming.

July 9th. She complained of soreness, and a little abdominal pain. Temperature normal; pulse 110.

July 10th. She felt chilly; had no pain. Temperature 98; pulse 104.

July 11th. She felt better. Temperature normal; pulse 100.

July 12th. There was a good deal of whitish discharge. Temperature normal; pulse 100.

August 8th. Since the last note, the patient had not had a single bad symptom; the vaginal rent had healed, a very slight thickening marking its site; the uterine sound passed two inches in the normal direction. The woman then became an out-patient, and preparations of iron were prescribed for her on account of her extreme anæmia. She subsequently went to Southport for six weeks; and on October 21st, she again presented herself at the out-patient room, looking much improved in colour and general appearance. She had menstruated twice since leaving the hospital. The uterus was normal in position; the sound passed rather more than two inches; the os was somewhat flabby, and presented the appearance of a little superficial ulceration, which soon yielded to the application of nitrate of silver; the situation of the vaginal rent could not be discovered.

I saw my patient after some time, when there were signs of commencing phthisis; after this, I lost sight of her, and am now unable to obtain any trace of her.

Inversion of the uterus is not a very common occurrence, only fifteen cases having been reported in the English journals since the year 1871. It does not seem necessary to enter into the details of these cases; suffice it to say, that nearly all of them are said to have been due to traction on the cord.

In the *BRITISH MEDICAL JOURNAL* for January 28th, 1871, Dr. Tylecote reports a case of spontaneous inversion twenty-four hours after labour. Dr. Braxton Hicks relates a similar case in the *JOURNAL* for August 31st, 1872; and also another where the inversion followed delivery by forceps; and in the first volume of the *Obstetrical Journal* (page 319) Mr. J. Prankerd narrates a case where inversion occurred during the effort of straining at stool seven days after labour. With regard to the possibility of spontaneous inversion, and for an explanation of this phenomenon, I beg to refer my hearers to Dr. Hicks' paper in the *BRITISH MEDICAL JOURNAL* for 1872.

The treatment of these fifteen cases varied; most of them were reduced by pressure of one kind or another; two died before medical aid could be procured; in two, the uterus was removed as a last resource in order to save life; and in two others Dr. Barnes succeeded in reducing the inversion by the method to which I have already alluded, and the value of which cannot be overestimated.

Dr. Barnes has clearly pointed out how an inverted uterus *ought* to be treated; it has fallen to my lot to bring before the profession a case which teaches how it *ought not* to be treated; for the satisfactory termination of the case does not prove that the treatment was one to be recommended.

How many women would have recovered after such severe injuries? and what would have been the result if the rent had occurred posteriorly instead of anteriorly? Now, how are such accidents to be avoided? We are directed to use as much force as is justifiable: what is the measure of justifiable force? What amount of strain will the vaginal walls bear? Speaking from my experience in the case here recorded, I would urge that the utmost care, care even approaching timidity, be used in the application of manual pressure to chronic cases, and that, in the event of failure by this method, recourse be had to the air-pessary, or even incision of the neck, inasmuch as such an operation must be far less serious than rupture of the vaginal wall.

INVERSION OF THE UTERUS.

By WILLIAM KELLY, M.D., Physician to the Taunton and Somerset Hospital.

In the abstract of Mr. Ewart's case of successful reduction of an inverted uterus of three months' standing, as given at page 231 of the *JOURNAL* of August 21st, the author is stated to have said "that, in any future case, he would firmly discountenance the treatment adopted in the case here recorded".

* On *Post Partum* Douching of the Womb (*BRITISH MEDICAL JOURNAL*, November 13th, 1869).

† Read before the Obstetric Medicine Section at the Annual Meeting of the British Medical Association in Edinburgh, August 1875.

I have recently had under my care a case very parallel to that related by Dr. Ewart, with one important exception; viz., that the inversion was *not* reduced. I append a brief account of the case.

The patient, aged 24, had been delivered of her first child by a midwife in December last. She was admitted into the Taunton and Somerset Hospital on March 22nd, suffering from extreme exhaustion and uterine hæmorrhage, the latter having continued more or less from the time of her confinement. She had received medical treatment before coming to the hospital, but no vaginal examination had been made. The state of inversion being ascertained, she was put under chloroform, and for more than an hour efforts were made with considerable force to effect reduction; but they were ineffectual. Some amount of constitutional disturbance followed, and a second attempt was not made for a month (after the next catamenial period had passed over); this proved equally unavailing with the first. The patient having soon recovered from the effects of this second operation, and the uterine hæmorrhage with its attendant exhaustion having also disappeared, she was anxious to leave the hospital, as the displaced uterus caused her little inconvenience. She was, however, prevailed upon to submit to a third attempt at reduction; but, this being followed by no better results than those which had gone before, her husband removed her from the hospital, and the case has now been lost sight of.

In employing taxis, I followed, or rather I endeavoured to follow, the directions given by Marion Sims in his *Clinical Notes on Uterine Surgery*; i. e., after pushing the body of the uterus up within the cervix, he says the reduction should be completed "by compressing the fundus laterally, and deeply imbedding the thumb in the cornu uteri, by which means we slide one-half of the organ at a time through the os internum, instead of the whole fundus, which presents a greater diameter". The first stage was easily got over; but all the sustained pressure I could employ failed to open the internal ring (for that was the form the part assumed) for the passage of the fundus. I varied the position of the patient, and I also used alternately both my right and my left hand.

CLINICAL MEMORANDA.

THE TREATMENT OF CHLOROFORM-POISONING.

As I have always taken a deep interest in all that pertains to the induction of anæsthesia by means of chloroform, I have perused the remarks of Mr. Messenger Bradley of Manchester with interest. The state in which he has described his patient to have been is an unusual one; it is a state of collapse preceding chloroform-sickness, complicated with a fit; and, although the phenomena are sufficiently alarming, they invariably pass off with the advent of the sickness, if not before. I would call attention to the rigidity of the jaws: "his teeth were closed". The patient is never fully under the influence of chloroform—complete paralysis of the sensorium—so long as a single muscle of the body is capable of contraction, either spasmodically or otherwise; and I have long observed that the last muscle to lose the power of contracting is the orbicularis palpebrarum. As soon as this muscle ceases to resist the finger in raising the right upper eyelid, *cæteris paribus*, one may consider the patient fully anæsthetised, and ready for the severest operation in surgery.

Although I have frequently seen similar phenomena to those of Mr. Bradley, I am not prepared to say they have been the same. I have never observed closure of the jaws. Clenching of the teeth or closure of the jaws is not a symptom of deep anæsthesia under chloroform, and is only possible in the first stage, or when the patient is returning from complete anæsthesia; therefore, in itself it is not a dangerous, but rather a favourable symptom. In chloroform-poisoning, as a rule, whenever there is muscular contraction or rigidity, I should consider my patient's life safe. I was once asked in a Medical Society, "Are you not afraid when the patient kicks violently?" to which I replied, "No; I am more afraid when he ceases kicking." In any dangerous case which I have seen, the lower jaw has always fallen or become relaxed. This I believe most certainly to be the rule; therefore, taking into consideration the frothing at the angles of the mouth, the lividity of the lips, and the temporary arrest of the respiratory and circulatory organs, I conclude that the lad had taken an epileptic seizure, or something very like one, whilst under the influence of the anæsthetic, and most likely when he was beginning to come to himself, as it occurred towards the "completion of the operation".

The treatment I do not object to; only I should have been inclined to trust most to encouraging vomiting, if there were any threatening of the same, by turning the patient on his side, with his face looking somewhat downwards, which at once protrudes the tongue and saves

the laceration from the use of a vulsellum; tickling the fauces with the fingers, the jaws being forced open if necessary; and giving him plenty of air in the horizontal, and not in an inverted, position. Time and quiet will do the rest, as in an ordinary attack of epilepsy. It is worthy of note, that the lad had had chloroform on a previous occasion "without any bad symptom". As to artificial respiration in such a case, is it of any use? I doubt it, simply because of the fit, if fit it were. No amount of artificial respiration will ever overcome an epileptic seizure; it simply comes right of itself. It is just possible that in this case, as in many others, the *post hoc* may be mistaken for the *propter hoc*. The indication to my mind would be to induce or precipitate the sickness, which has relieved, if not saved the life of, many an epileptic. The sickness failing, artificial respiration was the sheet-anchor.

I only offer these remarks as suggestions from the study of Mr. Bradley's interesting case. I think it would be well that every such case were so probed and digested: good is sure to come out of it. It is said that prevention is better than cure; and I beg to suggest, for the future guidance of those who have the responsibility of administering chloroform, never to give it on any account except on an empty stomach. No food should be taken for at least four hours beforehand. Although this rule is well known and generally appreciated, there is no rule of practice so universally neglected or so constantly broken. Surgeons will give brandy and water beforehand, and chloral, and laudanum, and mixed anæsthetics; they will do anything and everything but the right thing in order to obviate sickness and other consequences of the administration of chloroform. For the future, if they will only make sure that no kind of food, solid or liquid (water or a mild cup of black tea excepted), be taken by the patient for at least four hours before taking any anæsthetic, I will guarantee less sickness and a decided fall in the number of accidents from anæsthetics in general, and chloroform in particular.

I trust that Mr. Bradley will kindly take these remarks in the purely suggestive spirit in which they are meant, and that humanity may profit by them.

THOMAS SKINNER, M.D., Liverpool.

RHEUMATISM WITH HIGH TEMPERATURE AND FATAL CEREBRAL COMPLICATION.

W. H. S., a hosiery, aged 35, of arthritic diathesis, regular habits, and healthy appearance, usually excitable, had lately been subject to additional excitement, consequent on his having opened a new business and being about to be married. He had lost two sisters and one maternal aunt from rheumatic fever and its complications. On August 5th, he felt pains in his knees; and on the 7th he put himself under my care, labouring under acute rheumatism. He was put in bed between the blankets; the affected joints were wrapped in cotton-wool; and bicarbonate of potash was administered every four hours. Slight pericarditis showed itself on the fourth day of the attack, but it yielded to small blisters. A draught containing half a drachm of solution of muriate of morphia procured comfortable rest at night. On the tenth day, although his pains were better, his tongue cleaning, and his appetite slightly improving, he was restless and languid. On the eleventh day, when seen at 6 P.M., he complained of feeling very weak, and had had a little delirious once or twice during the day. He had also had frequent micturition, passing more urine than previously. The pain and swelling of the joints were very much better; the perspiration was not quite so profuse. A careful examination of the heart showed no fresh complication. His temperature, which throughout the illness had varied from 101 to 103 deg., was not taken at this visit. His pulse was about 100, and his tongue cleaning. Later in the evening, feeling very restless, he asked his mother, who was nursing him, to send for his draught, which he took at 10 P.M.; and shortly afterwards both he and his mother dropped asleep. Three hours afterwards, at 1 A.M. on the twelfth day, Mrs. S. was roused by the noisy breathing of her son; and, finding she could not awaken him, she sent for me. I found my patient quite unconscious; the pupils were moderately contracted, as in natural sleep; respiration was catching and irregular; pulse weak, about 120; skin intensely hot; temperature in the axilla, 110½ deg.; in the palm of the hand, 109 deg. By applying towels wrung out of cold water, and fanning, the temperature of the surface was lowered; but the intense heat in the axilla and the palms of the hands continued; and, as the respirations became worse and the pulse flagged, it rose to 111½ deg. in the axilla. The patient died at 3 A.M., only two hours from the first observation of the serious symptoms. The decomposition of the body after death was extraordinarily rapid. The symptoms in this case correspond in every point with those observed in the other cases, now tolerably numerous, in which, during the last five or six years, the coincidence of fatal cerebral rheumatism

and very high temperature has been recorded; and its chief interest lies in the occurrence, although in very slight a degree, of its premonitory symptoms, nervous prostration, slight delirium, and frequent micturition; and in the very rapid development of the serious symptoms. I have notes of two cases, one a man who died in the Queen's Hospital at Birmingham in 1860, with fatal cerebral complications and burning hot skin; and the other a lady who died here under my care in 1862, with a similarly suddenly fatal so-called metastasis to the brain; and in each of these, I doubt not, had the clinical thermometer been in use, a similar high temperature would have been registered.

THOMAS JAMES WALKER, M.D., Peterborough.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

UNIVERSITY COLLEGE HOSPITAL.

CASE OF EPITHELIOMA OF THE THUMB ORIGINATING IN A CHRONIC WART.

(Under the care of Mr. ERICHSEN.)

THE fact that apparently simple warts may, after years of quiet vegetation, develop malignant characters, is now generally recognised, and the only remarkable points about the following case are the youth of the patient and the situation of the growth.

A young man of dark complexion, short stature, and fair *physique*, aged 21, was admitted into University College Hospital on January 14th, under the care of Mr. Erichsen. He had been employed at a skin and leather warehouse, had always lived well, had enjoyed good health, and had never had syphilis. His father had died at 40, of consumption; and his maternal grandmother of cancer. His mother was alive, and aged 44. He was one of a family of nine children, of whom six were living. A brother had died of acute rheumatism; the other two in infancy.

About six years previously, the patient had noticed a small wart on the back of the phalangeal joint of the left thumb; it bled occasionally when rubbed, and grew slowly larger, but did not trouble him for four years. It then began to spread rapidly towards the nail and round the outer side of the distal phalanx. He then came to the hospital, and the growth was apparently destroyed with caustic. After a few months, however, it reappeared, and soon extended further than before. In February 1874, nitric acid was again applied, but ineffectually; for, on the readmission of the patient eleven months afterwards, nearly the whole of the distal phalanx of the thumb was covered by a nodular growth with a sloughy ulcerated surface; only a small part of the inner aspect of the thumb was free. Over the metacarpo-phalangeal joint were three smaller nodules of a similar nature.

On January 20th, Mr. Marcus Beck amputated the thumb opposite the middle of the metacarpal bone; and on February 3rd the patient was discharged, the wound being almost healed.

TWO CASES OF STRANGULATED HERNIA IN OLD PEOPLE.

(Under the care of Messrs. C. HEATH and BECK.)

CASE I.—*Very large strangulated Umbilical Hernia: Partial Reduction by Taxis: Rupture of Intestine and Death.*—A very stout old woman, aged 62, was admitted into University College Hospital under Mr. Christopher Heath on April 19th. She had been married thirty years, had had three children, and, with the exception of two attacks of acute rheumatism, had generally enjoyed good health. She stated that a lump had first appeared at the umbilicus after a severe strain about three years previously. This lump gradually increased in size, and, about a year after its first appearance, the patient strained herself again in lifting a fender, and the hernia became strangulated, but was soon reduced. On the evening of the 17th, it again became strangulated, and she had not been able to return it since.

On admission, the patient was pale, depressed, and anxious-looking. She complained much of sickness and of pain in the abdomen. Over the centre of the abdomen was a large lobulated tumour, which could scarcely be grasped by the two hands. The larger part of the mass consisted of two lobes, right and left, above the umbilicus; below and between them was a third, smaller and softer. The tumour was tender on pressure, for the most part resonant on percussion; and there was no impulse on coughing.

The patient having been etherised, Mr. Heath attempted to reduce

the tumour. The aspirator was then introduced in two places, when fluctuation was perceptible, and some brownish fluid drawn off. Flatus also escaped: but still reduction could not be effected. An elastic bandage was therefore applied round the tumour, with ice over it. A hypodermic injection of morphia was given, and enemata of brandy and beef-tea ordered to be given regularly. Next morning, the patient seemed easier. She had not been sick since the operation, and was in no pain; but the tumour continued in the same state, and her pulse was very feeble. The bandage was reapplied. Soon afterwards, she began to sink rapidly, and died in a state of collapse.

NECROPSY.—On opening the hernial mass it was found that the small lower lobe consisted of a sac containing omentum, which was quite distinct from the main bulk of the tumour. The upper and larger sac was much lobulated; it contained nearly the whole of the ileum, together with part of the jejunum and about a foot of the transverse colon. The coils of intestine were firmly adherent to each other and to the wall of the sac. The latter contained also a considerable amount of dark feces, which had escaped from a large rupture of the colon. The contained intestines were of a very dark purple colour, and softened. Lying just outside the neck of the sac, was another foot of small intestine, also very dark and congested, but still glazed; it was separated from the healthy gut beyond by a sharp line of demarcation. There was abundant evidence of general peritonitis.

CASE II. *Femoral Hernia strangulated for five and a half days: Gangrene of the Gut: Operation and Death from Exhaustion.*—A needlewoman, aged 67, was admitted under the care of Mr. Marcus Beck on the afternoon of February 5th. She stated that, eight or nine weeks before, she had first noticed a small lump in the left groin; it grew somewhat larger, but gave her little inconvenience; and she did not trouble herself about it. On the morning of January 31st, whilst lifting, she suddenly felt great pain in the groin, and nearly fainted. This passed off; but she continued very uncomfortable all day, and soon became very sick. Becoming worse next day, she sent for a doctor, who gave her medicines, but who eventually sent her to the hospital. The bowels had acted last on January 29th. Lately, the vomiting had been stercoraceous.

The patient was a very emaciated, aged-looking woman. In her left groin was a tumour larger than a hen's egg, having a distinct neck at the saphenous opening. It was very tender; the skin over it was red and oedematous; and there was no impulse on coughing. The patient was vomiting occasionally, and complained of great tenderness over the abdomen. She was at once put under chloroform. Mr. Beck then dissected down to the neck of the tumour, and opened the sac. It contained a knuckle of intestine, part of which was of an ash-grey colour, and evidently gangrenous. The sac contained also gas and feculent fluid, which were found to have escaped from two minute openings in the sloughing gut. This was accordingly laid open; and, all constriction having been relieved, the healthy margin of the gut was attached to the skin on each side of the wound, and a dressing of oiled lint applied.

The operation was perfectly successful. On the 8th, the patient's pulse was 100, and of fair strength. Her tongue was clear and moist, and feces passed freely by the wound. The peritonitis also subsided. But, after going on well for some days, the patient's strength failed again rather rapidly, and she died on the evening of the 14th, of old age and debility, accelerated by the shock she had undergone.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.

CASES OF ACCIDENT.

(Under the care of Mr. JABEZ HOGG.)

CASE I. *Traumatic Cataract: Extraction: Detached Retina.*—Joseph T., aged 13, was admitted on January 14th, 1875. He stated that, three years ago, a stone struck his left eye. The eye was red and painful for a week afterwards, but the sight was apparently good. Shortly his vision became misty, and it had been gradually getting worse since. On admission, there was a dense, uniform, white cataract, and he could only see light and shade with his left eye. His right eye was normal. Under ether and chloroform (given alternately), Mr. Hogg proceeded to tear the lens through with two needles. The capsule proved to be tough, and the lens not fluid. Atropine (four grains to an ounce) was instilled, and a bandage applied to both eyes. He had no pain afterwards, and slept well. Atropine was instilled daily. The right eye was uncovered on the second day, and a shade worn on the third. On January 23rd, the torn capsule had reunited, and therefore Mr. Hogg determined to remove it. This was done under chloroform and ether, by separating adhesions between the iris and lens with a

needle, and withdrawing the lens almost entire with a sharp hook. A little remained in the pupil. A very small quantity of fluid vitreous humour escaped. The atropine, pad, and bandage, was used. The pupil cleared completely, no inflammation followed, but vision was not greatly improved. He was discharged on the 31st.

On March 16th, he again appeared as an out-patient. His vision was no better, and was unimproved by glasses. On an ophthalmoscopic examination being made, the retina was found to be completely detached, only a dark metallic reflection being obtained.

CASE II. Blow on Eye: Detached Retina: Extirpation.—George S., aged 4, was admitted on January 20th, 1875. Eighteen months ago, he fell and struck his right eye against the corner of a piece of furniture; the eye at the time did not appear to be much injured, nor was vision much impaired until three months afterwards. It had, however, been red and painful for the last week. On admission, some conjunctivitis existed; the cornea was normal; the iris did not contract on exposure to light, but dilated under atropine. The pupil had a yellow appearance. On careful examination, the lens was seen to be clear, whilst just behind it an uniformly bright yellow substance appeared, slightly vascular at its periphery. The iris bulged slightly forward, and the globe was somewhat tense. Under methylene, Mr. Hogg extirpated the eye in the usual manner. There was considerable hæmorrhage, which was soon checked by cold water and a firm compress. It did very well, healing up nicely. The patient was discharged on January 24th.

On examining the eyeball, the retina was found completely detached, except just at a point near the entrance of the optic nerve; it was also thickened and opaque. The vitreous body was entirely absorbed, and, between the retina and the choroid, a large quantity of a greenish-yellow fluid (*hydrops retinalis*) had been secreted. The choroid was much atrophied and nearly transparent. A small hard cartilaginous nodule of the size of a pin's head existed on the choroid opposite the yellow spot. The lens was quite clear. On a microscopic examination being made, the yellow fluid appeared to consist of serum containing a large number of circular pigmented granules loosely cohering, and mixed up with numerous cholesterine crystals.

CASE III. Traumatic Cataract: Needle Operation: Panophthalmitis: Extirpation.—Robert H., aged 31, was admitted on February 10th, 1875. He said that, four years ago, he was struck with a boxing-glove on his right eye. His sight remained good for two years, but since then it had been gradually becoming worse. On admission, he had an uniform white cataract in his right eye, and with it he could barely distinguish light. The eye was quite quiet, and only slightly painful. His health had been indifferent for some time. Without chloroform, the lens was broken up. Atropine was instilled, and a pad and bandage applied to both eyes. On the second day, acute iritis set in. In a few hours, the anterior chamber was half full of pus. He complained of violent pains in the eye and head, and was very sick. Notwithstanding the administration of remedies and paracentesis corneæ, together with a generous diet and stimulants, the inflammatory action continued, and general suppuration of the globe commenced. The acute symptoms having subsided, on March 8th he was sent into the country to improve his general health; on the 16th, he was readmitted. The eye was now quiet, with commencing atrophy of the globe. On the 18th, Mr. Hogg removed the eye in the usual way under chloroform. It healed up rapidly; the œdema of the lids subsided, and he was discharged on March 30th.

On examining the eye, the cornea was found to be opaque and enormously thickened; the iris was infiltrated with pus and partly adherent to the cornea; the vitreous humour, however, was inspissated, infiltrated with pus and lymph, and containing large vessels in its anterior. The lens was broken up and mixed with pus; the retina was thickened, and attached firmly to the choroid.

CASE IV. Traumatic Cataract: Needle Operation.—Frederick L., aged 14, a bootmaker's apprentice, was admitted on March 1st. Whilst engaged at his work three weeks ago, his hand slipped, and the awl he was using was thrust into his right eye. It had penetrated the cornea, leaving only a small cicatrix at the outer part, and wounded the lens. On admission, the eye was quiet and the lens uniformly opaque. He could just distinguish light with it. Without chloroform, Mr. Hogg, with a short straight needle, broke up the lens; atropine was instilled into the eye, and a pad and bandage applied. Atropine was continually applied, and no inflammation followed. On the second day, the lens appeared to be well broken up, and a large quantity of it was lying in the anterior chamber. On March 23rd, as a good deal still remained in the pupil, Mr. Hogg again cut it up. The pupil cleared very much after this, but still a good deal of capsule remained undissolved, and on April 13th a small incision was made at the inner margin of the cornea with a bent needle; and, on passing in a curette, the aqueous humour gushed out, carrying with it large fragments of lens-substance.

The pupil gradually cleared, a little capsule remaining at the outer part only. On the 26th, this was nearly absorbed, and his vision was improved on dismissal. He again appeared as an out-patient on June 3rd, and had *perfect* vision.

REVIEWS AND NOTICES.

A MANUAL OF DIET IN HEALTH AND DISEASE. By T. KING CHAMBERS, M.D., F.R.C.P., Consulting Physician to St. Mary's Hospital, etc. Pp. 352. London: Smith, Elder, and Co. 1875.

THERE exists a marked tendency in the present day to bring the hygienic conclusions reached by scientific observation within the sphere of the general reader, so that they may be "understood of the people". That such practice is desirable cannot be disputed, since a large portion of the general public take much interest in matters concerning their health, and expound their views with much earnestness, if not always with very profound knowledge. Scraps of information gathered from the remarks of their medical men, often widely different and utterly incompatible, in spite of much stretching and speculative piecing; crumbs from more formal consultations, and some research amidst popular works, whose information is of a very questionable character, form the material for much general conversation and some proselytising on small matters. That people should feel an interest in the matter of food is very natural, as diet has formed a part of medical advice probably from its earliest development in the suggestions of the old matrons of the hordes of primitive man, or of the medicine man or priest, down to the most recent physiological dieting of the diabetic. Minds, too, were much exercised on the subjects of the sustaining and the lowering treatments practised by rival medical men, each the inspired prophet of a small coterie, so well described by George Eliot. Then, Mr. Banting's scheme for the reduction of obesity and superfluous and deforming adipose tissue, by a regulated system of diet, usurped public attention for a time, and endeared itself to the corpulent of all ages, of both sexes, and of all grades of society. The great truths that fat was formed from the excess of hydro-carbonaceous matter consumed as food, and that the avoidance of such material in the diet would lead to a consumption of the fat garnered up in the system, then took hold of the public mind, and thus some elementary facts were introduced into public opinion. However mischievous in its consequences—and most mischievous consequences have followed the adoption of Bantingism as a means of reducing excessive weight—this scheme has laid part of a solid foundation of information amidst the public at large.

The comparatively recent, but already actually antiquated, notions of regarding the amount of nitrogenised matter in any article of food as forming the measure of its value for nutritive purposes, have given way to a sounder knowledge on the part of physiologists; which from them, in suitable form and shape, is passing swiftly into the recognition of the well informed portion of the public. Such corrected knowledge is very desirable, and this work of Dr. CHAMBERS is admirably calculated to serve the end he has in view of giving sound and trustworthy information on the subject of diet to both lay and professional readers. There is one serious omission in it, however, and that is the physiological destination of our food after it is digested. Here the work falls short of the more elaborate treatise by Pavy. If, however, the work is wanting here, the omission is ably compensated by the amount of practical information given throughout its pages. The writer is evidently perfectly at home in his subject, and every page reveals that the work is the outcome of the fulness of knowledge, and not a mere compilation written to order.

In the commencing chapter, the writer introduces in pleasant guise the subject of "what is the Natural Food of Man", and shows that it is at once no particular form of food, and yet is everything almost upon which he can lay his hands. The arrangement of the viscera of man permits his consuming the most varied forms of food, and in so far as a compromise betwixt the arrangements of the carnivora and the herbivora, much aided, however, by the general intelligence of the creature. It would appear, however, that such modifications are not confined to humanity; "and our cats have accommodated themselves to a mixed diet, assimilating their form to that of herbivora by a considerable increase in the length of their bowels over those owned by their cousins of the mountains". As a consequence of his internal arrangements, man can combine various forms of food to constitute his diet, and mix fat with farina, and the red flesh of other animals with vegetables, in order to get combinations which will best enable him to manifest so much force daily without loss of weight. There are two

points to be attended to in the choice of food: the supply of material convertible into force, and the maintenance of the body-weight. These are put strikingly as follows.

"Suppose, for instance, a gang of a hundred average prisoners to excrete, in the shape of breathed air, urine, and feces, daily $71\frac{1}{2}$ lbs. of carbon and $4\frac{1}{4}$ lbs. of nitrogen, which is pretty nearly the actual amount of those elements contained in the dry solids of the secretions, as estimated in current physiological works. Nitrogen and carbon, to that extent at least, must be both supplied. Now, if you fed them on bread and water alone, it would require at least 380 lbs. of bread daily to keep them alive for long; for it takes that weight to yield the $4\frac{1}{4}$ lbs. of nitrogen daily excreted. But in $380\frac{1}{2}$ lbs. of bread there are $128\frac{1}{2}$ lbs. of carbon, which is 57 lbs. above the needful quantity of that substance. If, on the other hand, you replaced the bread by a purely animal diet, you would have to find 354 lbs. of lean meat to give them the needful $71\frac{1}{2}$ lbs. of carbon; and thus there would be wasted 105 lbs. of nitrogen, which is contained in the meat, over and above the $4\frac{1}{4}$ lbs. really required to prevent loss of weight. In the former case, each man would be eating about 4 lbs. of bread; in the latter, $3\frac{1}{2}$ lbs. of meat *per diem*. If he ate less, he would lose his strength. In the former case, there would be a quantity of starch; and in the latter, a quantity of albuminous matter, which would not be wanted for nutrition, and would burden the system with an useless mass very liable to decompose and become noxious."

This is a distinct way of putting the necessity of a mixed diet for the wants of man. The excess of albuminous matter involved in a meat dietary is not, however, so entirely waste and useless as the author would seem to infer. It is quite true, undeniably true, that but a comparatively small amount of nitrogen is required to maintain the tissues of man in their integrity; nevertheless, the economy of man is such that he can not only live, but lead a very active life, upon a purely albuminous diet, as is seen in the Indians of the Pampas. They live upon meat and water; nor is there reason to suppose that they are careful to see that their meat is fairly accompanied by fat. The albuminous principles which are assimilated have two different destinations; one, a well recognised one; the other, less generally known. The first is the growth and repair of the tissues, the second is the production of glycogen. By far the greater part of the azotised food of man is split up in the liver into glycogen and waste. The glycogen is the fuel of the body, chiefly burnt up in the muscles, and forms the force-producing material of the body. The glycogen furnished by the splitting up of the albuminoids in the liver is useful, but the nitrogenised waste is a source of trouble. The urea and uric acid we excrete are mostly the products of azotised waste from the liver, and only to a small extent the products of histolysis, of tissue-waste—that is, in health; in pyrexia it is different. Glycogen is largely produced by saccharine and farinaceous foods. The liver is the storehouse of glycogen, which is given out gradually but unintermittingly into the blood, and, probably, in the form of lactic acid in union with soda, forms the fuel of body-combustion. It is of much importance that this process be understood, not only from its importance in the treatment of diabetes and in the dietary of the gouty, but even in the requirements of ordinary life. It is, then, to be regretted that Dr. Chambers has not gone sufficiently into the destination of food, especially albuminous food.

His remarks on the choice of food, the characteristics of good as compared to bad qualities of food, in flesh, in fish, in vegetables, are excellent and to the point. This portion of the book is especially valuable to those who cater in the market or the store, and buy the different articles consumed in a household. A similar conclusion is forced upon one by the perusal of the section on wine, as to form, character, and utility. He states that some of the cheaper wines, especially of Bordeaux, are perfectly made, and that such is the case is clinically corroborated by their wholesomeness and freedom from disagreeable after-effects when taken by the gouty. The author is of opinion that the occasional use of wine in social festivities is not to be restricted, and the "moderate use will not shorten, but both cheer and lengthen life". All alcoholic beverages, he insists, should be carefully chosen and good of their sort. "However little a man's purse allows him to drink, let it be good", is the concluding sentence of the consideration of alcohol in the part devoted to health.

The chapter on Digestion, and of the aid that can be given to digestion by cooking, when properly performed, is good, as might be expected, and so much to the point, that the reader must not have in any *résumé* here an excuse for neglecting the perusal of the chapter in its entirety. These practical applications of knowledge to the dietetic matters of common life form a strong point in Dr. Chambers's book, and the sum total of impressions produced is the well grounded impression that the author must be a very agreeable person to dine with. Not only would the food and wines be all that could be desired, but

the pleasant conversation, which he insists upon as desirable for perfect digestion, would also not be wanting.

In the second part, the special dietetics of health are reviewed. The importance and value of milk both for children and adults receives due recognition. Some very practical remarks as to the choice of a wet nurse precede an account of how she should be fed in order to secure the best nutrition for the child she suckles. "The time for weaning should be fixed, partly by the almanac, partly by the growth of the teeth." In the dietary of young persons, stress is laid upon the necessity for plenty of puddings, bread, butter, fruit, etc.—sugar is not mentioned, all reference being superfluous—as the staple of the nursery commissariat. Meat once, or, at most, twice a day only should be the rule; while in health, no wine or beer, except as a festive treat, no coffee, or other exciting drink should be given. "Between puberty and full growth, the principal thing we have to guard against is overloading the stomach", consequently, the writer infers, the necessity for plain food, so as not to be too tempting for young people. "A diet which in an old man may be wasted for lack of solution, and which would therefore be a starvation diet to him, may in a young person be richly ample. On the other hand, the easily soluble but scanty diet on which the old man might flourish, would not suffice for his active, growing grandson." "Young people, too, should not be brought up to the habit of taking physic", is a rule which should be written up over the door of every nursery.

A new feature in Dr. Chambers's book is the consideration of the dietary suitable to various forms of life-occupation, each with its own requirements. Thus we find a chapter on the Diet in Commercial Life. The principal meals should be breakfast and dinner; breakfast before, and dinner after, the work of the day. But a break in the middle of the day for luncheon is very important. The habitual use of stimulants in the middle of the day is to be deprecated. Nevertheless, where an unusual amount of cerebral exertion has been gone through, a cheerful glass of wine or beer will often prevent over-fatigue. Let not, however, the demand or the supply grow a daily habit, is the word of warning which the writer appends. For literary and professional men, the diet of youths is advised—frequent small supplies of easily soluble mixed food. There is no more fatal habit to a literary man than that of using alcohol as a stimulant betwixt meals. The temptation is greater, perhaps, to a literary man than to any other in the same social position. He writes; and not only is such a man tempted to take stimulants, as is said here, but it might have been added that the exhaustion is ultimately all the more, and the craving to take more stimulants after work is over is still more pronounced. Then follows some account of the habits and dietary of several well known literary characters, of much interest.

The chapter on Athletic Training is one to which most readers will turn with keen interest; nor will their perusal go unrewarded. They will find there the rules of training, both as to exercise, to diet, and to fluids. The systems of Oxford and Cambridge for the training of their crews are both given, in the winter and summer training. No fairly representative abstract is possible; the chapter must be perused as a whole.

Then follows a chapter on Hints for Healthy Travellers, in which the ripe experience of the writer reveals itself in directions not only of rational, but of the most practical character, the outcomes of acquaintance with the subject treated of. Doubtful water is one of the things against which a warning is given. Garlic is a constituent of foreign dishes apt to offend the bowels of a Briton. Olive-oil is better than butter in hot climates; and milk that has been boiled is less likely to originate typhoid fever than unboiled milk. The suggestion that travellers should provide a store of captains' biscuits, in order to render them independent of the bread of the aborigines, is doubtless a sound one. A hint how to avoid the pestiferous places of retirement in continental hotels will be grateful to many; viz., to coax the landlady into the loan of the key of her private establishment. In the country, the worship of *Clascina sub Jove* is advised. If the tourist ride much, a warm bath betwixt leaving the saddle and sitting down to table is recommended. There are other remarks one would wish to quote if the space permitted. The chapter on Climate must be left unquoted for this reason.

The effects of starvation, poverty, and fasting, must be left out of this notice, in order to admit some allusion to Dietetics in Sickness, which subject forms Part III. This section is especially valuable to the professional reader, while it gives much that is instructive to the well-informed lay reader, and of which a more general knowledge in the abstract would serve greatly to facilitate the medical attendant's remarks being attended to when given in the concrete. In the treatment of acute fevers, Dr. Chambers follows Hippocrates in thinking the matter of food of some importance, that he gives formulæ for many preparations. Some of them are real additions to the means of meeting disease, for

which every reader will feel personally grateful. It is, indeed, in this division, that the merits of this work are so conspicuous, and which give it such a high practical value. "The great art of duly nourishing fever-patients consists in giving a frequent, almost continuous, supply of liquid food." The feeder and spouted cup, for cases of great prostration, are recommended. The directions as to the kind of food, its preparation, etc., are excellent; and the directions for the cookery for fever-patients will probably be copied into countless household recipe-books. The dietary for sickness and for indigestion is very sensible; and the latter is, of course, very perfect. There is much, too, that is valuable in the chapter on diet in gout and in rheumatism; though here, as also in the remarks on diet in albuminuria, the absence of the physiological consideration of food leaves the matter unsatisfactory. The practical advice is just as sound in most cases, however, as if this omission had been, as it doubtless in future editions will be, attended to. The diminution of azotised food, the adoption of mineral waters, the avoidance of rich generous wines, are all duly insisted upon. The children of the gouty must attempt at least to escape their inheritance by "a life of strict abstemiousness and muscular activity; 'to scorn delights, and live laborious days'. They must not compound for temperance in alcohol by indulgence in dainty meats, sweet pastry, soft beds, or idleness."

"Would you enjoy soft beds and solid dinners,
Then, gallants, board with saints and bed with sinners."

is advice the direct antithesis of which should be given to those in whom gout is an inheritance.

The recommendations as to diet in gravel, stone, and diabetes are good and trustworthy. But the advice to give albuminous material freely in albuminuria is of very questionable character. In some cases, it may be indicated; in most, it is best to give it in but limited quantity.

Then follow chapters on diet in deficient evacuation, in hysteria, in alcoholism, in insanity, in consumption, and in diseases of the circulatory organs. In the first are recipes for suitable food. In consumption, the dietary is directed to be liberal, and to contain large quantities of the most easily digestible forms of fat; and many forms of such food are given. There are, too, valuable remarks as to how fish-oils may be taken so as not to be intolerably nauseous. The great benefit of climate upon assimilation is insisted upon. In affections of the circulatory organs, diet is of much importance. The avoidance of soups is recommended, if they are followed by flatulence. The necessity for a nitrogenised diet in those who are likely to have atrophic degeneration of the heart is thus put:—"Atrophic degeneration is warded off by keeping up the redness and fluidity of arterial blood." This may be so; but it is matter for question. Alcohol in diseases of the heart is condemned. It quickens the beat, causes capillary congestion and irregular circulation, and mechanically dilates the cavities. Indeed, the remarks of Dr. Chambers on the subject of alcohol, in its use and its abuse, are about the fairest, the justest, and most impartial it has fallen to our lot to be acquainted with. Its use is advocated in distinct and forcible utterances, while the prejudicial results of indulgence in it are demonstrated with equal distinctness. The unfitness of the drunkard for the duties of the *prolétaire* is clearly and uncompromisingly asserted. Two of the rules given for the use of alcohol may be quoted. (a) Let it never be taken as a stimulant or preparative for work, but as a defence against injury done by work, whether of body or mind. For example, it is best taken with the evening meal or after toil. (b) Let the increase in the desire for and power of digesting food, be the guide and limit to the consumption of all alcoholic liquids.

We have criticised this book very openly, perhaps chiefly because its general excellence is such that small blemishes become very apparent, and form blots where ordinarily they would be but slight stains. In the plan of the work, in its execution, and in its pleasing literary garb, Dr. Chambers's manual deserves to take its place amidst our standard treatises, and will be welcomed by the profession; while, with lay readers, it ought to be, and is likely to be, an universal favourite. No more trustworthy and welcome book has been issued from the press for several years. The profession may congratulate itself as well as Dr. Chambers on the success of his rather difficult achievement.

A CLINICAL CONTRIBUTION TO THE TREATMENT OF TUBAL PREGNANCY. By T. GAILLARD THOMAS, M.D. New York: Appleton and Co.

EVERYONE who is called upon to deal with cases of extrauterine foetation will feel personally indebted to Dr. THOMAS, for this graphic description of a case in which he succeeded perfectly in removing the foetus with safety to the mother. The author justly observes that

"No condition which develops itself in connection with gestation is attended by greater or more inevitable dangers than that in which the impregnated ovum attaches itself to tissues outside of the uterus". Any contribution from such an authority is, therefore, well worthy of consideration. Few cases of extrauterine foetation have, during their early and progressive stages, been brought to a favourable conclusion by surgical means. After alluding briefly to the various means resorted to for this object, he describes minutely the process adopted in the case under consideration. The attempted removal of the placenta gave rise to severe hæmorrhage, necessitating the injection into the sac of a solution of persulphate of iron. A discussion upon the advantages or otherwise of leaving the placenta to come away subsequently is recorded in the fourteenth volume of the *Transactions of the Obstetrical Society of London*, many of the Fellows advocating non-interference with the placenta. It would have been exceedingly interesting to test this practically in the present case: still *finis coronat opus*—the case recovered: "the remaining portion of the placenta came away spontaneously on the fifteenth day". Dr. Thomas lays great stress upon the recognition of *ballottement*, as aiding materially in forming a positive diagnosis, he having observed this in no fewer than three out of four cases. Every practitioner should read this pamphlet.

ON PARALYSIS FROM BRAIN-DISEASE IN ITS COMMON FORMS. By H. CHARLTON BASTIAN, M.A., M.D., F.R.S. Physician to University College Hospital, etc. London: Macmillan. 1875.

IN this little volume by Dr. BASTIAN we have, collected and arranged, his series of lectures delivered last year on the above subject in University College Hospital, and which have already received publication in the pages of a contemporary; and it is with considerable pleasure that we see thus placed in a convenient form the observations and experience of one specially able to deal with so complex and important a subject.

The lectures are eight in number. The first five are devoted chiefly to the consideration of the hemiplegic state, and other symptoms, both primary and secondary, attending rupture of intracranial vessels, their occlusion by embolism and thrombosis, and the pathological results entailed by these lesions. In the sixth, the differential diagnosis of brain-lesions is discussed. In the seventh, the function of the cerebellum is considered, and the symptoms induced by apoplexy of the various parts of the organ; and, lastly, in the eighth lecture, the prognosis and treatment of paralysis from brain-disease in its different forms are discussed. It is expressly stated by the author, in his preface to these lectures, that it has been his object to deal with the subject as succinctly as possible, and thereby promote the usefulness of his work for students and "busy practitioners". With this object in view, we think that he has acted wisely. It is a difficult matter to curtail observations, and more especially difficult in considering diseases of the nervous system, the symptoms of which are too often almost bewildering in their complexity. While thinking, therefore, that, in some instances, and more especially on the subject of differential diagnosis, a somewhat more extensive consideration might with advantage have been afforded, and more reference made to the results of recent experiments on animals, we nevertheless think that the observations of Dr. Bastian are sound and well selected, and that his work will recommend itself to very many. Dr. Bastian deserves credit for the candour and care with which he never fails to impress the possibility of error in diagnosis, the sources of fallacy which are continually present from complexity of symptoms, and from the fact that, with regard to the function of many portions of the brain, we are still in a state of doubt and uncertainty. How often does it happen to many besides students to see their diagnosis, which ought to have been correct according to the rules laid down by systematic writers, completely set aside by *post mortem* examination!

With regard to the functions of the different parts of the cerebral hemispheres, however, we are sorry to see advanced the doctrine that the posterior lobes are more especially concerned with the manifestation of the higher intellectual faculties, and to find that Dr. Bastian should give the weight of his opinion in favour of a doctrine the fallacy of which we consider fully demonstrated.

The remarks on treatment are, we think, practical, sagacious, and clinically useful. With regard to medicines, in the premonitory stage of apoplexy, bromide of camphor and ergot are recommended. In the apoplectic condition, reliance is placed on bromide of potassium, and, in the outbursts of convulsions arising from the presence of organic lesions, chloroform-inhalation is recommended. Several plates, illustrating the anatomy of the convolutions of the brain and the vascular supply to the various parts, add additional value to these lectures, the style of which throughout is clear and forcible. We are glad to welcome Dr. Bastian in the field of clinical work; it is hardly to be

doubted that the habit of research and the dialectical skill which he has shown in the investigation of difficult subjects which lie at the base of medical science and progress will make his work as a practical physician, long and steadily pursued as it has been in excellent fields of study, fertile in good results in the advancement of the pathology, diagnosis, and treatment of the classes of disease to which he is devoting particular attention.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

IMPROVED HYPODERMIC SYRINGE.

MESSRS. L. BLAISE and Co. (late Savigny and Co.) of St. James's Street, London, have brought under our notice an improved hypodermic syringe. The advantages claimed for this instrument over others hitherto made consist, for the most part, in its peculiar construction, which allows of its being kept clean with very little trouble, and its improbability of getting out of order, and its non-liability to breakage.

As represented in the above illustration, the glass-cylinder is encased in a metal mounting or jacket, fenestrated to show the graduation for minims. No cement is used to fasten the parts to each other, but in its stead there are washers at each extremity of the cylinder, which not only secure the exclusion of air, but effectually prevent the annoyance of the glass becoming loose. Should, however, by accident, the glass cylinder be broken, an extra one is supplied with each instrument, which may be replaced by any one. The instrument can be taken apart for cleaning by simply unscrewing the nut through which the piston plays. The piston is made longer than the cylinder to allow of the washer being pushed through far enough to be oiled, etc., without the trouble of getting at it in the old way. The needles or cannulated points are made much finer than those usually employed, an advantage in lessening pain in their introduction. The superiority of this instrument has been pronounced by the leading members of the medical profession. It is made either with sterling silver mountings or of plated metal with gold or steel needles, and is fitted into a case with a small vial. The instrument is so constructed that the piston may be worked with a screw or plain action. It is most suitable for hospital use. After employing this instrument, and testing the extent to which it is really an improvement, we should be disposed to prefer it to any other.

CYSTO-URETHROSCOPE.

THE larger of the instruments figured here was devised by Mr. Reeves to aid in the diagnosis and treatment of vesical and urethral affections in females. Their simplicity and the ease with which they can be used are naturally strong recommendations. The cysto-urethroscope—the larger figure—is merely a large silver aural speculum, with a wide lateral opening, and is applied in the following way. An ordinary surgical probe being passed into the bladder, the little finger, well oiled, is insinuated along it with a gentle rotatory motion; and, on its entering the bladder, the probe is withdrawn, and the finger rotated to stretch the parts; it is then withdrawn to just within the meatus, and the instrument, provided with its guide, well oiled, is easily introduced, as the little finger is taken away. When the guide is withdrawn, urine will escape, and that which remains in the bladder must be mopped out with small pieces of sponge on long holders. Ordinary daylight or a reflecting mirror will give a good view of the parts. By rotating the instrument, the whole of the urethra can be inspected, and any fissure or ulcer either incised or cauterised; and by raising, depressing, or inclining laterally its end, nearly the whole of the surface of the bladder

can be plainly seen, and treatment carried out. The largest size that Mr. Reeves has at present used will admit the little finger; but larger ones may be applied, if needed, without damage. Sometimes the fibrous ring surrounding the external urethral orifice will require to be notched before introducing the finger. Incontinence need not be feared, as it has not resulted in the cases in which Mr. Reeves has had occasion to explore the bladder and urethra.

The smaller instrument is for daily use in the out-patient room or in the wards, and will demonstrate the existence of mischief in the urethral mucous lining. Both instruments have been in use since January, and many continental, American, and English practitioners have expressed their satisfaction with them.

THE FLEXIBLE CLINICAL STETHOSCOPE.

THE many difficulties that attend the use of the ordinary stethoscope in dispensary practice, and especially the inconvenience and dangers connected with its application in some of the most urgent cases among the lower classes, would seem to have suggested to the inventors of this instrument the idea of lengthening the tube indefinitely, while they

secured the proper application of the chest and ear-pieces by various ingenious modifications. The result is, that they have produced a stethoscope which promises to be not only convenient, agreeable, and safe, but superior to the common instrument, under ordinary circumstances, in several important respects. The principle on which it has been constructed is, that air is the conducting medium in all tubular stethoscopes, and that the law of acoustics, that the intensity of sound varies inversely as the square of the distance, does not apply to tubes. The stethoscope accordingly consists of a piece of silk-covered tubing two feet in length, of nearly uniform calibre, this being provided at the one end with an ear-peg, and at the other with a chest-piece. The ear-peg is made of a well polished piece of vulcanite, which may accurately fit the external opening of any ear without entering it and causing tinnitus; it presents a minute lateral perforation, which is intended to prevent the air from impinging unpleasantly upon the membrane when the chest-piece is moved, and so relieve the confusing noise produced on its application. By leaving the perforation uncovered, the observer avoids these inconveniences; and, when the instrument is applied, and he is about to listen, he closes the aperture with the finger, and the sounds are transmitted to the ear. The chest-piece is screwed to the tube, and so its shape and size may be varied at pleasure. The same may be said of the length of the tube. Besides the advantages already mentioned, the following may be fairly claimed for this stethoscope; viz.: 1. The ease with which patients may be auscultated in otherwise inaccessible positions; 2. The comparative safety from infection; 3. The possibility of carefully regulating the pressure on the chest-pieces, especially in the case of aneurism, blood-vessels, etc., and in children and sensitive patients; 4. The construction of the ear-peg; 5. The ease with which the observer may use his eye and ear at the same time. The stethoscope has been designed by Drs. Reid and Morison of Canonbury, and constructed by Messrs. Arnold and Sons, Smithfield.

BRITISH MEDICAL ASSOCIATION:
SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st, Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, SEPTEMBER 4TH, 1875.

MURDEROUS LUNATICS.

RECENT occurrences have again called attention very forcibly to those difficult considerations which arise whenever criminal responsibility and mental disease are viewed in their mutual relations, and have also brought to light some altogether unlooked-for combinations. The singular spectacle has been lately seen, of juries acquitting prisoners as insane in deference to common sense and medical testimony, and in defiance of the plainest and most emphatic judicial directions; and the not less unusual exhibition has been witnessed, of medical men specially skilled in insanity calling for increased stringency in the application of the law to lunatics. Dr. Manley, the Medical Superintendent of the Hants County Asylum, following the lead of Dr. Kirkman of the Kent County Asylum, has, in a letter to the *Times*, fairly raised the question whether recognised lunatics should be absolutely exempt from punishment for crime, and has not hesitated to show his own strong inclination to return an answer to the inquiry the reverse of that which it has hitherto practically received.

The fact that a man is an inmate of a lunatic asylum does not of itself totally incapacitate him for the performance of civil acts. He can still, under certain circumstances, make a will and enter upon a contract. Does, then, the same fact, taken alone, render him altogether irresponsible for criminal conduct? Can he not, under any circumstances, commit a murder or perpetrate a fraud? Theoretically, it is held that he can transgress the law, and that the mental aberration which has justified the deprivation of his liberty is not necessarily of such a nature as to place him beyond the reach of punishment; for inmates of asylums who have committed murder are brought to trial for their offences. But, practically, to all intents and purposes, it is held that a certified lunatic residing in an asylum is legally irresponsible. No instance can be recalled in which such a lunatic has been convicted and subjected to punishment; and no difficulty has ever been experienced in securing the acquittal of such a lunatic, when arraigned for crime. While copious and conclusive evidence of mental aberration has been demanded whenever the defence of insanity has been set up in the case of an uncertified lunatic accused of crime, little or no evidence, beyond the fact of confinement in an asylum, has been required when the same defence has been advanced on behalf of a certified lunatic similarly accused; and no doubt, as a general rule, it is well that an entirely different weight of testimony should be deemed necessary to establish the irresponsibility of a presumptive and of an accredited lunatic. When a person charged with violation of the law has, prior to that violation, been formally pronounced insane, and has had his liberty restricted, there can be no suspicion that the plea of insanity is resorted to as a mere cloak for vice, or a shield from penalties. Then experience has clearly established that, in a vast majority of instances, the crimes committed by lunatics in asylums are the direct offspring of their lunacy, and are symptoms of disease, and not manifestations of depravity. They result from blind exuberant violence, from hallucinations of the senses, from definite delusions, or from a morbid impulse, the veritable character of which is shown by its mode of development and by collateral indications of mental derangement. So frequently is this the case, so generally has it been observed that lunatics in asylums

are irresponsible for their actions, that the principle has been extended and made universal, and all lunatics in asylums have come to be regarded as unaccountable agents.

We are now told, however, that this generalisation, which predicates irresponsibility of all asylum lunatics, is too wide; and that there are many of them who, although of unsound mind, are yet regulated by rational motives, and are as capable as sane men of appreciating the nature of an illegal act, of foreseeing its consequences, and of exercising self-control. We are told that insanity may be partial, and may be confined to certain regions of the mind, leaving those who suffer from it free from durance, and of vigorous will in all the ordinary relations of life. We are told that the insane may be deterred from crime by the dread of punishment; and that they are now presuming upon the immunity from punishment which they have hitherto enjoyed, and are giving license to their evil passions—to jealousy, rage, and revenge—safe in the knowledge that they are insane.

No doubt there is much truth in all this. There are but few lunatics who are always and altogether irresponsible. It is a trite observation, that the present humane administration of our lunatic hospitals is only possible because their inmates can apprehend the meaning of rewards and punishments, and can deliberately choose between them, preferring, as a rule, tobacco, beer, associated amusements, and smiles of approval purchased by good conduct, to the withdrawal of privileges and closer seclusion as the results of recalcitrant behaviour. It is well known, also, that some lunatics are vicious as well as mad, and that these sometimes basely take advantage of their situation, and exhibit cool and calculating villany. There is, perhaps, scarcely an asylum medical superintendent in England who has not been menaced by some lunatic under his care, who has not had to reflect upon the cogent reasoning contained in some such statement as the following. "If you do not liberate me, I shall kill you; and of course I shall be none the worse for so doing. I am a lunatic, and am not answerable for what I do; and the only consequence which can follow a murder committed by me is a change of residence from my present domicile to Broadmoor, which is, I am told, a much better place than this." We give our asylum medical officers credit for courage enough to make them indifferent to such threats even in the mouths of reckless, determined, crafty men; but at the same time we are bound to admit that it is scarcely fair that they should be deprived of any legitimate protection when beset with such dangers, and that it is not conducive to public safety that they should be submitted to the temptations connected with such a situation. The lunatics who employ such threats are almost invariably monomaniacs, who are shrewd and cunning, but who harbour in some corner of the mind dark vindictive feelings, probably directed against persons in prominent positions. The liberation of these lunatics is practically in the hands of the asylum medical officer; and it is not an impossible thing that such an officer, in a moment of weakness or panic, might avoid an ever-present personal risk by incurring a remote hazard for some one else. It is not an impossible thing that a point might be stretched, and a lunatic entrusted with freedom when incapable of rightly using it.

One of the most convincing arguments against the abolition of capital punishment was, that such a step would expose the officers of justice to inordinate and unsupportable danger; for it is clear that, in the absence of the penalty of death, criminals of the worst type, whose misdeeds already merited the highest terms of penal servitude, could incur no worse fate than that in store for them by resisting, and even slaying, those charged with their arrest; and that it would often be worth the while of more trivial offenders to run the risks connected with killing those in whose custody they were. The fear of death has a deterrent fascination upon debased minds which, in justice to our policemen and detectives, to say nothing of other considerations, we cannot dispense with. We are assured that, even upon diseased minds, it has a similar inhibitory influence; and we are asked whether we are warranted in withholding from our asylum officers the security which the maintenance of that fear would confer upon them. In prisons

in which comparatively rational beings are confined for stated times, with every conceivable inducement to good conduct, it is found necessary to resort to the lash, to strait-waistcoats, to dark cells, to penitential dietary, and to the punishment of death, in order to preserve discipline and ensure safety. In asylums, on the other hand, in which the most turbulent and explosive specimens of humanity are incarcerated for indefinite periods, under the most aggravating circumstances, no punitive measures are permitted more impressive than a siesta in a rather luxurious bed. We confess we have often marvelled at the success which has attended the reign of the law of kindness in such institutions, and we should be the first to deplore any alteration in the policy which has converted them from dens of terror and brutality into homes of beneficence and gentleness. But the question is not whether any departure should take place from the present code of internal management of these establishments, but whether their inmates should remain beyond the pale of law, and the reach of retributive justice. It is found expedient occasionally to expel somewhat precipitately from the community at large an intractable and blood-stained member. Might it not be advisable, from time to time, to deal similarly with a rational madman who has presumed too far upon the privileges of his class? If it can be shown conclusively that a lunatic confined in an asylum, who is in possession of adequate powers of self-control, has committed a premeditated murder, instigated by some rational motive altogether independent of his particular mental aberration, there can be no good reason why that lunatic should not be treated like any ordinary criminal. But the difficulty of fulfilling the conditions enumerated in the foregoing paragraph of proving adequate self-control, of demonstrating a rational motive, and of showing the absence of connection between the criminal act and the mental disease, must always be enormous. It would seem to be almost impossible satisfactorily to bring home a crime to an acknowledged lunatic. Even in the case of the man McKaye, who killed the late Mr. Lutwidge, with the avowed intention of being removed to Broadmoor, after the flesh-pots of which he hankered, and who was pronounced responsible for his actions by two of the Commissioners in Lunacy, not a moment's hesitation was felt in returning a verdict of not guilty. Public sympathy will always, in some measure, set towards a man, even although a criminal, who has been visited with the direst of human calamities, and no good result could follow the execution of a person regarded with more of pity than condemnation. Then, if we are to punish lunatics by death, why should we not punish them also in other ways? If they can be guilty of murder, they can be guilty also of assaults, larcenies, and minor offences; and it would come to this: that every lunatic asylum would require to have a stipendiary magistrate attached to its staff.

But, if murderous lunatics are not to be executed—and we confess we see almost insuperable obstacles in the way of such a consummation, however devoutly it might be wished for on some grounds—neither need they be encouraged to give way to homicidal violence. We would suggest that the dietary at Broadmoor Asylum, which is said to be unusually liberal, should be reduced to a level with that in use in pauper asylums, and that never again should batches of evangelists be sent forth from Broadmoor with tidings of its sumptuousness into all our county asylums. Grub is a paramount consideration in the lunatic as in the school-boy mind, and it is surely not advisable that an improved *menu* should be held out as a premium upon murder. Then convicts who have become insane during their term of punishment are known to be the most dangerous, insubordinate, and treacherous of criminal lunatics, and it is surely not advisable that they, at the expiration of their sentences, should be sent to carry corruption and all ill-feeling into our county asylums, where no special provision for dealing with them exists, while the more tractable and harmless criminal lunatics detained during Her Majesty's pleasure are accommodated at Broadmoor, which is essentially a criminal asylum.

THE library of the Obstetrical Society will be closed from September 6th to September 18th, both days inclusive.

It has been decided to hold the next annual meeting of the British Association for the Advancement of Science in Glasgow, under the presidency of Sir Robert Christison.

SEVERAL cases of sunstroke, of various degrees of intensity, occurred in Berlin towards the end of the week terminating on August 14th—the weather being at the time remarkably warm.

SIR DUNCAN GIBB has, we regret to learn, resigned the office of Physician to Westminster Hospital, in consequence of the state of his health.

THE library and museum of the Royal College of Surgeons were closed on Wednesday last for one month, for the purpose of repairs, cleaning, dusting, etc.

A SOMEWHAT serious outbreak of scarlatina is reported to have occurred at the School of Military Engineering, at Chatham, amongst the children.

THERE is, we hear, an erroneous impression that the intended testimonial to Mr. Prescott Hewett is limited to old St. George's students. There is, however, no such limitation; Mr. Rouse of St. George's Hospital is acting as Honorary Secretary to the Fund.

THE *Gazette* announces that the Queen has appointed Sir James Alderson, Knt., M.D., and Arthur Farre, M.D., to be two of Her Majesty's Physicians Extraordinary. The eminent position of the two physicians named in the *Gazette* is fitly recognised by this mark of royal favour.

The Twelfth Annual Meeting of the British Pharmaceutical Conference has just been concluded at Bristol, having been held simultaneously with the meeting of the British Association, and appears to have been very successful and useful.

AMONG the leading papers read at the meeting enumerated by the *Pharmaceutical Journal*, was an account of a successful attempt by Mr. Symons to accomplish the hitherto unsolved problem how to prepare a more homogeneous liniment than the ordinary liniment of turpentine with acetic acid. Mr. Symons uses castor-oil for the purpose.

DR. TILDEN read a paper on the crystalline constituents of Barbadoes and Socotrine aloes. Dr. Tilden disagrees with Rochleder's suggestion that the aloins form a homologous series, but believes zanoloin to be identical with socaloin, and barbaloin (in the anhydrous state) isomeric with it, whilst nataloin is widely separated from the other crystalline principles. The possible application of salicylic acid in pharmacy was the subject of a paper by Mr. Bengel. A number of pharmaceutical preparations were exhibited, all of them more or less prone to decomposition. Many of them which contained from a quarter to half a grain of salicylic acid to the ounce appeared perfectly good, although they had been prepared about four months. The freshly expressed juice of conium, hyoscyamus, and taraxacum, proved to be exceptional in this respect. Some experiments with albumen had shown that salicylic acid does not prevent, and only slightly retards, the action of pepsine. In the discussion which followed, the antiseptic properties of boracic and benzoic acids were referred to. Finally, a report was made by Dr. Wright on new derivatives from the opium alkaloids, a subject that seems to be practically inexhaustible.

REFERRING to these and other researches, Mr. Groves, in the President's address, took occasion to say that it is, he supposed, hopeless to expect to find in the ranks of hard-worked medical men experimenters able and willing to cope with the great amount of this kind of work which may be said to be daily and hourly accumulating. Take such a series of investigations as those of Wright on the Alkaloids, where, in a single page, we may find described perhaps half a dozen bodies of de-

finite composition, distinctive crystalline form, and endowed with potencies differing both in kind and degree each from the others. What proportion of substances such as these are adequately tested, how many are not tested at all, possibly to the great loss of medical science? Parliament has more than once voted £2,000 to defray the cost of investigating the sources of certain diseases of an infectious character; and it would, Mr. Groves thinks, not be amiss to ask it to supplement the grant in future years with another £2,000 to defray the cost of the physiological testing of new remedies proposed for the treatment of disease generally.

THE *Edinburgh Medical Journal*, referring to the recent meeting of the British Medical Association, says:

The Edinburgh meeting of the British Medical Association in 1875 has come and gone; and in looking back upon it, we believe it must be considered a most successful one. It was very largely attended; the weather was most favourable; there was a plethora of excellent papers in all the sections; the arrangements for entertaining as well as instructing the visitors were most complete. Everybody seemed anxious to please and be pleased; in short, it was not only a most agreeable holiday, but also an excellent opportunity for comparing notes as to medical and surgical progress. However much Edinburgh men may regret that our visitors came at a time when the New Infirmary is only half finished, and the new University buildings not begun, we would fain hope that they still saw enough to teach them that Edinburgh, as a medical school, is second to none. In the addresses, at least, no falling short of its ancient power could be noticed. Sir Robert Christison, bearing his weight of years and honours lightly, poured forth his stores of experience on the subject of medical education. Dr. Begbie, in his thoughtful, scholarly, and polished oration, showed that the school of educated physicians, of which Britain has always been proud—from Sydenham and Graves, Latham, Alison, Watson, and Stokes—has young men to trust to in the future. Mr. Spence gave us the outcome of his great experience and thoughtful conservatism in his review of the progress of surgery. Dr. Matthews Duncan was as plain-spoken, clear, and incisive as ever; while Rutherford and Lister, McKendrick and Dewar, in their lectures and demonstrations, showed that the spirit of true scientific work, which seeks for truth for its own sake, is still active and fruitful. We may seem to speak chiefly of our own men—for on them, of course, lay the burden and heat of the day—but the excellence of the papers, and spirit of the discussions, showed that our visitors were in no way behind their hosts. There were almost too many claims on the time. Each evening had its entertainment; and with the President's reception on Tuesday, the *conversazione* of the Royal College of Physicians on Wednesday, the dinner on Thursday, and the garden party on Friday, it was high time that the Saturday should be devoted to sea-breezes and out-door amusement; thus ending a pleasant and successful week.

CURIOSLY enough, as the proceedings of the Association increase in importance and scientific value, so do they seem to lose interest in the eyes of our oldest metropolitan medical contemporary. The Edinburgh meeting was the largest medical gathering ever assembled in this kingdom, with the single exception of our last London meeting; and it was, without any exception, the most important meeting of the Association yet held in respect to the number and value of the papers read, of the demonstrations given, and of the proceedings in the sections. The report published, however, in our excellent contemporary, is the scantiest which it has furnished for many years, while of the sectional proceedings it gives none at all. However, the most useful friends of any prosperous and rapidly growing institution are those who regard it with disfavour, and treat it to jealous criticism. No armour can be considered trustworthy which is not subject to the constant searching out of its weak points. It is in the cold atmosphere of keen hostility that a hardy tree, such as this Association, will flourish best.

To be really useful or creditable, however, criticism should be based upon some broadly correct knowledge of elementary facts. It cannot really serve any honest purpose, for instance, to decry the Council of the Association as "self-elective". Any one who knows anything at all about the matter knows that the Council consists of a total number of nearly three

hundred members, elected annually by the branches at their general meetings, the elections being independent, local, and wholly made by the branches themselves. The constitution of the Council is largely changed every year. The Committee of the Council consists of the leading officials of the Association, of the honorary secretaries elected by the branches, of the past presidents of the Association, who have from time to time been selected by the profession in the locality which invites the Association, and of twenty members added by the General Council just mentioned. Upon what does our well meaning critic, therefore, rest, when he describes the Council of the British Medical Association as "self-elective"? It may have many faults, but certainly no wilder invention could have been devised with which to reproach it than this.

THE debate which occurred at the recent meeting of the Association as to the selection of next year's place of meeting has had an echo in letters which we have received from two respected members of the profession. The general meeting having, however, arrived at a conclusion, and remitted the execution of it to the Committee of Council, it has seemed to us that any further communications on the subject should, in the first instance, be addressed to the President of Council, to whom we have accordingly forwarded them. A letter which appeared last week in a contemporary on the subject had, he informs us, been recalled by telegram on the previous Wednesday, and was published notwithstanding its recall.

WE very much regret to hear that Dr. Spencer of Clifton has been disabled by illness from fulfilling the duties of Secretary to the Physiological Section of the Meeting of the British Association, for which post his medical and scientific accomplishments and culture had marked him out. Dr. Spencer contracted fever in the course of his hospital duties; with a characteristic courage and sense of social duty, he had himself removed to the Fever Hospital, where he has been successfully treated, and is, we are glad to hear, now convalescent. Dr. Martyn of Bristol, whose interesting research on "Prickle Cells" we lately published, acted as one of the Secretaries of the Physiological Section in substitution of Dr. Spencer.

THE parliamentary return of the names, ages, and nationalities of persons who have served in the British Merchant Service during the last two years as surgeons, whose names do not appear in the *Medical Register*, and which has just been published, contains the names of 224; and, amongst some respectable and duly qualified members of the profession, are others who are a disgrace to it, one of whom is particularly *wanted* by the police authorities.

MEDICAL CERTIFICATES AND INQUESTS.

THE recent "Births and Deaths Registration Act, 1874" requires that "in the case of any person who has been attended during his last illness by a registered medical practitioner, that practitioner shall sign a certificate stating, to the best of his knowledge and belief, the cause of death". Notwithstanding this general enactment, it appears clearly desirable that medical practitioners should refuse to sign such certificates in cases of death from violence, or even of suspected violence, until the case has been referred to the coroner, and that officer has notified his decision that an inquest is unnecessary. We have every reason to believe that this would be the course of action observed in such cases by nineteen out of every twenty medical practitioners. Circumstances connected with a recent inquest held at Brislington, in Somersetshire, on the body of a man who died from injuries received through being knocked down by a train in a tunnel, show, however, that misconceptions exist as to the duty of practitioners to give medical certificates in cases of death from violence. It may be useful, therefore, briefly to note the circumstances of the case. The deceased was knocked down on the night of the 12th ultimo, and the next day Mr. Lodge, a local practitioner, was called in, only an hour or two, however, before the man died. On the request of a neighbour or relation of the deceased, Mr. Lodge gave a certificate to the effect that death was caused by "injuries

in the abdomen". If this certificate had followed the usual course, it would have been taken to the local registrar, who, had he done his duty, would have reported the circumstances of the death to the coroner, and have delayed the registration of the death until the coroner's decision as to holding an inquest was known. As a matter of fact, through a succession of blunders, the body of this man was buried before either the registrar or the coroner heard of the death; and the body had eventually to be disinterred by order of the coroner before the inquest could be held. At the inquest, the coroner, very naturally, blamed Mr. Lodge for having given a medical certificate in such a case, and expressed great surprise when this practitioner, in answer to a question, stated that if a man were brought to his surgery with a bullet wound through his head, he did not see why he should not give a certificate of the cause of death. It is to be hoped that very few medical practitioners hold the same opinion on this point as Mr. Lodge expressed, or else the security of life from wilful injury, which depends in great measure upon the efficient performance of the duties of coroner, would soon become endangered through the want of co-operation on the part of the medical profession in using their influence to encourage the holding of inquests in all cases of death from violence, as well as in all cases of sudden death in which the real cause of death can only be conjectured. In the case of which we are speaking, Mr. Lodge, in giving a certificate to the effect that the deceased died from "injuries to the abdomen", was stating an absolute fact, but, in so doing, he committed two serious faults. In the first place, he usurped the functions of the coroner, in assuming that the death was the result of pure accident and not of manslaughter, or of attempted suicide: and, secondly, his certificate as to the cause of death was for the purpose of the death-register lamentably incomplete, as it failed to give any information as to the cause of the injuries to the abdomen. The Registrar-General instructs all his registrars to inform the coroner of all deaths from violence, previously to their registration, in order that an inquest may be held, or that the coroner may decide that it is unnecessary to hold one. If medical practitioners, however, give certificates of the cause of death in such cases, facilities are thus afforded for the registration of deaths from violence, without reference to the coroner, which would soon become highly dangerous to society.

MIDWIVES IN FRANCE.

MIDWIVES in France can only practise in the departments for which they are specially licensed. The tribunal of Brive (Corrèze) lately decided that a prefect could provisionally license a midwife to practice in another department than that in which she had been examined. The court of appeal at Limoges, however, quashed the decision, and declared, in the case under consideration, that the authorisation given by the prefect was of no force, and that the midwife had transgressed the law.

LEPROSY.

PUBLIC interests seem to require increased attention to the circumstances under which leprosy is being imported into this country. The number of cases of that most horrible disease under observation by British physicians in this country is apparently increasing. Dr. Laycock, the eminent professor of medicine in the University of Edinburgh has, in a recent report in the *Edinburgh Medical Journal*, pronounced the opinion that facts indicate that it is a communicable disease; but that the specific poison has evidently a long period of latency, and requires special conditions of health for its manifest activity. The number of cases reported is such that, as Dr. Laycock emphatically points out, it is hardly possible to exaggerate the importance of the question of communicability. Professor Laycock adds: "If our returned leprosy countrymen can be *facti* of contagion, and spread a disease the most incurable, most prolonged, and most distressing of any known, what an infliction upon our country will follow upon their unguarded intercourse with the healthy. The more frequent occurrence of leprosy in Great Britain will afford our experimental physiologists opportunities

of determining whether the disease can be communicated to lower animals or not. It is, however, an inquiry, the cost of which should be borne by government or the public. Domestic animals, like swine and cattle, would be the proper subjects of experiments, and not small animals like guineapigs and rabbits. As the animals infected by leprosy products would necessarily have to be numerous, and have to be watched over a series of years, it is plain, private effort cannot be available."

PATENT MEDICINES.

WE entirely agree with the President of the Pharmaceutical Conference as to the propriety of grappling with that monster evil, the unrestricted sale of the so-called patent medicines. With him, we would make them in fact what they are in name; their composition should be divulged to the commission, and some control thereupon exercised upon the publication of advertisements respecting them. It would not, of course, do to license puffs of any kind, but the power of preventing the more scandalous and destructive of the lies from being obtruded on one's attention from every hoarding and almost every publication should be vested in some one. Care for the public health demands some interference; for example, with the sale of certain hair-restorers, which, vaunted as not being dyes and uninjurious, are found when chemically examined to contain poisonous combinations of lead. Indeed, there is, he says truly, scarcely a chemist or a doctor who could not adduce from his own experience instances of their injurious action on the persons of their customers or patients. Another glaring instance which he mentions is that of the "sure cure for the opium habit": it was found to contain per dose two grains of sulphate of morphia, to be taken three times a day.

HYDROPHOBIA.

TWO cases of hydrophobia are related to have occurred last week. The first took place near Accrington, where a child, aged two years, was bitten three months ago by a dog, which subsequently became mad, and was destroyed. The wound soon healed, and the child's health was not affected until it was seized with hydrophobia, from which it died. The next case was that of a collier at Burslem, who was bitten about seven months ago, while giving some medicine to a dog. The wound was cauterised, and quickly healed. He was lately seized with all the symptoms of hydrophobia, and died in great agony in two days. Large doses of chloroform which were administered appeared to produce little effect.

THE WORCESTER INFIRMARY.

THE Executive Committee have reported that there is no reason for any alteration of the rules, "feeling confident that no unfair pressure will ever be put upon any member of the honorary medical staff in consequence of unavoidable absence from duty." The medical staff, however, have intimated their intention of bringing the subject before a general meeting of governors. In the meantime, the election of a successor to Dr. Inglis is to be proceeded with. We are glad to learn that the medical staff are determined, as far as it is in their power, to prevent the matter from being left in the present uncertain and unsatisfactory footing, with no guarantee against the recurrence of such proceedings as those lately instituted against Dr. Inglis. We trust that, while the settlement is pending, the good taste and loyalty of other medical men will prevent them from coming forward as candidates for the vacant post.

MORTUARIES.

IN view of the great want of mortuaries which exists in the metropolis, and the legal difficulties which arise in the removal of a dead body from one parish into another, Dr. Joseph Rogers, Vice-President of the Poor-Law Medical Officers' Association, has suggested a plan which will, by legalising the union of parishes for mortuary purposes, remedy the evils. To call upon every parish to erect a mortuary would, in certain cases it is stated, entail a needless burthen; but there can be no

reason, unless there be legal difficulties, why a number of small parishes should not be incorporated so as to obtain jointly the benefits of these necessary buildings. As a preliminary step, Dr. Rogers has placed the following notice on the minute book of the Strand District Board of Works. "That, with the view to the more effectually and economically securing the establishment of mortuaries in the different parishes of the metropolis, this Board do memorialise the Metropolitan Board of Works, urging that Board to apply for powers in the next session of Parliament, authorising that body to undertake their erection in such parts of the metropolis as may be considered necessary."

A NEW HOSPITAL IN PARIS.

A NEW hospital, to be named the Ménilmontant Hospital, is to be opened towards the end of the year in the part of Paris from which it derives its name—one of the poorest quarters. It is situated between the Lariboisière and Saint-Antoine Hospitals, and will contain 150 beds. It consists of isolated pavilions. The wards are large, and none will contain more than twenty-two beds; there are numerous rooms with one, two, three, or four beds. Each ward has its own staircase; and in the centre of each pavilion is a separate staircase for conveying provisions. The pavilions are surrounded with open galleries, for the use of convalescents in fine weather. Independent of the hospital, there is a lying-in institution consisting of isolated wards.

NORMAL OVARIOTOMY.

A THIRD case of normal ovariectomy, and the second in this city, is reported to have been performed by Dr. T. T. Sabin, at St. Luke's Hospital (*New York Journal*). The patient, an unmarried girl, twenty-five years of age, had suffered for eight years from the most intense dysmenorrhœa and ovarian neuralgia, for which numerous operative and other measures had been tried in vain; the left leg, (the left ovary was the one affected) was unable to bear the weight of the body, and the patient finally became so anxious for relief from the constantly returning harassing ovarian, uterine, and pelvic pains, as to earnestly desire the removal of the ovary, which operation was performed August 8th, 1874, in the usual manner. The patient recovered without difficulty. One month after the operation, all ovarian pains had left her: she could walk easily, and the second menstruation since the operation was entirely normal and painless. The ovary was found to be perfectly normal.

THE BRITISH ASSOCIATION.

WE publish in another column the valuable address delivered by Professor Cleland in the department of Physiology and Anatomy at the meeting of the British Association in Bristol. We give also a compiled abstract report of the proceedings of that section. We should much have wished, had space allowed, to print Professor Rolleston's very able address in the anthropological department. It was full of varied interest, and had the mingled charm of erudition, scientific acuteness, and modern ethical application, which pervades most of his writings. Professor Rolleston dealt largely with craniology, and he prefaced his remarks with these words: "The largest result which craniometry and cubage of skulls have attained is, to my thinking, the demonstration of the following facts; viz., first, that the cubical contents of many skulls from the earliest sepultures from which we have any skulls at all, are larger considerably than the average cubical contents of modern European skulls; and, secondly, that the female skulls of those times did not contrast to that disadvantage with the skulls of their male contemporaries, which the average female skulls of modern days do, when subjected to a similar comparison."

ANTIVACCINATORS AT MONTREAL.

MONTREAL has been recently the scene of some disgraceful rioting on the part of the antivaccinators. It appears that, of late years, small-pox has been very prevalent in the city, especially amongst the French Canadians; and, in consequence, the provincial government passed an act to empower the municipalities to enforce vaccination. This, how-

ever, has been strenuously resisted by the French section of the community, under the leadership of Dr. Colene and other *savans*; and a mob of 7,000 roughs assembled a few Sundays since, who stoned the aldermen and gutted the house of one of the vaccination supporters, and in other ways conducted themselves in an irrational manner. The police were utterly powerless against the rioters, whilst, as a natural collateral incident, a severe small-pox epidemic still prevails.

THE INUNDATIONS IN THE SOUTH OF FRANCE.

By a decree of the President of the French Republic, dated April 7th, the following nominations to the Legion of Honour have been made, in recognition of services rendered during the late inundations of the Garonne. 1. Madame Sister Pénin, *supérieure* of the hospital de la Grave at Toulouse. She gave proof of the most rare devotion during the inundation. It was in great part due to her intelligent superintendence, her calmness and firmness, that the numerous inmates of the hospital could be rescued from the dangers which threatened them. 2. Dr. Bonnemaïson, chief physician of the Hôtel-Dieu at Toulouse. He displayed courage in personally taking part in, as well as superintending, the removal of the patients from the wards. Eighteen years of professional service. 3. Dr. Goujon, mayor of Vaudreuil and member of council of the *arrondissement* of Louviers (Eure). Has been in medical practice thirty-six years. He obtained a medal of honour for his conduct during the cholera epidemic of 1849; and distinguished himself during the inundations of the Seine in 1873. 4. Dr. Menot, promoter of the societies for the protection of infants, medical inspector of the canton of Montsauche (Allier); twenty-two years of useful and disinterested professional service; has distinguished himself during epidemics; has obtained numerous medals through his works, the principal object of which has been to diminish mortality in early life. 5. Dr. Colson, chief physician of the hospitals at Beauvais; thirty-two years of public service. Gold medals have also been awarded to: 1. Dr. Basset, 2. Dr. Labede, 3. Dr. Rippoli, professors in the school of medicine at Toulouse; and 4. Dr. André, assistant-surgeon of the Hôtel-Dieu—all of whom bestowed their care on the victims of the inundation. Silver medals have been awarded to M. Sabady, *interne* of the hospital de la Grave, and MM. Bonneau, Labat, Alibert, and Albert, *internes* of the Hôtel-Dieu; who watched over the evacuation of the wards and the placing of the patients in safety. Honourable mention for having taken an active part in the organisation of assistance has been recorded in favour of the medical profession in general in Toulouse, and MM. Bezy, Robes d'Orbecastel, Bret, and Chevalier, students of the school of medicine.

RECENT URBAN MORTALITY.

DURING last week, 5,353 births and 3,647 deaths were registered in London and 20 other large towns of the United Kingdom, and the average rate of mortality was 25 deaths annually in every 1,000 persons living. In Oldham, the rate was 16; Bristol and Bradford 21; London, 22; Edinburgh and Portsmouth, 23; Glasgow, Dublin, Sunderland, and Manchester, 25; Liverpool, Nottingham, Wolverhampton, and Norwich, 26; Leeds, 29; Salford and Birmingham, 30; Hull and Sheffield, 32; Newcastle-upon-Tyne, 35; and Leicester, 40. The annual zymotic rate ranged from 3.0 and 4.7 in Oldham and Portsmouth, to 15.0 and 18.5 in Salford and Leicester. Scarlet fever prevailed in Bristol. The death-rate from diarrhœa rose last week, and ranged from 0.8 in Bristol, to 13.8 and 16.6 in Wolverhampton and Leicester; in the latter town, the death-rate from this disease during the past five weeks has averaged 14.4 per 1,000. In London, the births exceeded by 66, whereas the deaths were 45 below, the average for the week. The annual death-rate was 21.8 per 1,000 persons living. The 1,440 deaths included 1 from small-pox, 22 from measles, 71 from scarlet fever, 10 from diphtheria, 53 from whooping-cough, 24 from different forms of fever, and 215 from diarrhœa; or 396 deaths altogether. During the twenty-two days ending on August 27th, the mean temperature of the air at Greenwich exceeded the average by 3.6 degrees; and the deaths from diarrhœa rose con-

tinuously week by week during that period. In outer London last week, the general and zymotic death-rates were 17.9 and 4.9 per 1,000 respectively, against 21.8 and 6.0 in inner London. Rain fell on Saturday to the extent of 0.34 of an inch.

SELF-HELP.

A MOVEMENT has been set on foot at Ashburton for the purpose of establishing a cottage hospital for that town. In the course of some excellent remarks, Sir R. Torrens said, he thought that "Every endeavour should be made to enlist the sympathies of those most to be benefited, viz., the working classes. He was sorry there were not more of these present, and he felt they should not succeed unless they could enlist their sympathies. He would like to see the working classes of this country much more independent and self-reliant, and out of their earnings—which were much greater now than formerly—make provision for sickness while in health."

A NEW CONVALESCENT HOME AT MARGATE.

THE new seaside convalescent branch of the Orphan Working School at Margate was formally opened on Monday by Her Royal Highness Princess Mary and the Duke of Teck, and a large gathering of local and other celebrities. This branch building, which is handsomely constructed, is owing to the exertions of the late active secretary, Mr. Joseph Soul, and is intended as a sanatorium for the benefit of invalids from the parent institution. The need of such an adjunct was well expressed by Earl Granville, when he stated that "It was a melancholy fact the extent to which these orphans inherited the tendency to disease of their parents, which rendered them more liable to weaker systems than those whose parents lived to a longer age; and the fact that they belonged to the poorer classes, who were unable to secure for them the advantages enjoyed by the rich, rendered it more necessary that the philanthropically disposed should look after them."

EXTREME DOSES.

IT is just as well to hear what our pharmaceutical friends have to say from time to time on this subject, if only as a reminder to the careless. Mr. Groves, in his address at Bristol, briefly observed that it is much to be regretted that the action taken in the matter by the Conference last year towards rendering the indication of extreme doses compulsory on the prescriber, as is done in Germany and elsewhere, has hitherto been fruitless, much to the annoyance and discomfort of both dispensers and prescribers, and also, it is to be feared, to the danger of patients—not so much of their getting a poisonous dose as of their getting a safe one, and less than the prescriber intended. We must not give up the idea, however, but, when the time comes for the revision of the *Pharmacopœia*, urge it forcibly upon the General Medical Council, and upon the Government if necessary. The latter suggestion is rather a strong one, and possibly constituents might think two or three times before acting on it. Mr. C. Boorne, however, in commenting on the address, said:

"There is a point touched upon in the address which I should like to refer to; the importance of it was impressed upon me as a young man by an incident which occurred in my apprenticeship. I am referring to what the President said about prescriptions of extreme doses. When I was an apprentice, I was required to dispense prescriptions, and those of some careless prescribers. One day I was called upon to dispense three drachms of potassio-tartrate of antimony; and, on reference to the prescriber, it turned out that it should be the liquor. Some time afterwards, while yet a raw recruit, I was left in charge of a business while the master took an excursion into the country. I remember being called up at three o'clock one morning, when a prescription was brought to me to dispense. It included three grains of hydrochlorate of morphia. I felt great difficulty about it. The prescription was brought to me by a gentleman's servant; he could tell me nothing more than that his master was ill; he could not tell me who wrote the prescription. After some consideration, I did what I do not mean to justify: I put in two grains. I went to bed, but not to sleep, with lively apprehensions of a coroner's inquest; for I might have killed the gentleman by giving him too much, or I might have defeated an effort to save his life by not giving him enough. I afterwards learned that

the medical man intended it to be three grains, because it happened to be a case of delirium tremens. If there had been opposite to the doubtful line a note of admiration, or something to indicate that the apparently extreme dose of three grains was really meant, it would have been a great relief to my own mind as a young dispenser. In the absence of any such assurance, the pharmacist is often placed on the horns of a dilemma."

We have already, in discussing this subject, indicated the advisability of prescribers specially indicating, by writing the words instead of a symbol, by an evident underline, or by some similarly distinct means, that any extreme dose which they may have reason to order is advisedly and intentionally prescribed. It would be useful in many cases in saving anxiety and possible injury to the patient, the dispenser, and the prescriber. The precaution is, we believe, becoming frequent.

SCOTLAND.

THE new asylum at Riccarton, near Paisley, for the accommodation of the lunatic poor, will be shortly ready for occupancy. The building is situated on an eminence commanding extensive views of the surrounding country. The estimated cost is about £12,000.

PAISLEY.

WE understand that Dr. Alexander, who was recently appointed House-Surgeon to the Paisley Infirmary, has resigned his appointment. During his brief official life of six months, he has gained the confidence and esteem of all with whom he has been brought into contact. It is unfortunate for the infirmary that, from various reasons, it has had, during the past three years, no less than five house-surgeons.

THE REGISTRAR-GENERAL'S RETURNS.

IN the second quarter of 1875, the births, deaths, and marriages in Scotland differed little in number from the last ten years' average for that quarter. The estimated population in the middle of this year being 3,495,214, the 32,294 births represent an annual birth-rate of 3.70 per cent.; the 19,518 deaths, an annual death-rate of 2.23 per cent.; the 6,638 marriages, an annual ratio of 0.76 per cent. The death-rate is the lowest observed in the quarter since 1871. The excess of births over deaths was 12,776; but there were 5,234 Scotch people among the known emigrants from the principal ports of the United Kingdom, and there are no means of ascertaining how many other persons found their way from Scotland to England, Ireland, and the Continent. A registrar in Linlithgow county notices a marked decrease of marriages, in consequence of the depressed state of trade among the mining population; but a Banffshire registrar observes a considerable increase of marriages among farm servants, and says that the high rate of wages, and in many cases the comfortable dwellings now given on farms, lead to a settling down early in life. The registrar of Aberdour, Aberdeen County, says:—"The only marriage he registered in May was arranged for the 15th of that month; but, on that morning, the bridegroom attempted to commit suicide by shooting himself. He recovered so far as to wish the marriage solemnised on the 16th, and this was done accordingly; but he died on the 18th. Two of the births registered in April were twins; one, a boy, born on Lady-day, and the other, a girl, on April 16th; but this last died on June 12th. The registrar of Kirkcubright does not forget that the census showed the large disproportion of 1,858 females and only 1,488 males in his district, and he sees little chance of a change in its luck when he finds that he registered nineteen births in the last quarter, and that thirteen of the new-comers were girls."

THE ROYAL INFIRMARY AND HEALTH COMMITTEE OF GLASGOW.

OUR Glasgow correspondent writes:—"There is at present a dispute between these bodies, which has unfortunately assumed something of a personal tinge. The discussion, as it appears in the public prints, seems to be between Dr. Russell, acting through the Committee of

Health, and Dr. Thomas, the Superintendent of the Royal Infirmary. The principal matter in dispute is briefly this. It has been discovered by Dr. Russell, that the local authority of Partick has been sending cases of enteric fever into the Royal Infirmary. It is hardly necessary to remind our readers, that the country is divided for sanitary purposes into a number of districts, each of which is governed by a local authority. The local authorities have the power of compulsorily removing cases of infectious disease and isolating them in hospitals. They have power to erect hospitals for their reception, and two or more neighbouring districts may combine to erect a common hospital; or they may take advantage of an existing hospital for the isolation of their cases. Partick is engaged in erecting such a hospital; but, in the meantime, without consulting the local authority of Glasgow, it has sent a number of cases into the Royal Infirmary, which is built in one of the most thickly populated parts of the city. That is to say, while the local authority of the city is taking its cases of typhoid fever out of the city to Belvidere, and keeping the excrement out of the city sewers, a contumacious local authority is busy importing into the city cases of this disease, and treating them in a hospital where drains are connected with sewers which pass through the heart of the city. This is what the Royal Infirmary directors have allowed, and this is what Dr. Russell through his committee has protested against. The superintendent of the infirmary endeavours to divert attention from the point at issue by a variety of pleas. He makes much of the position of the infirmary as a hospital supported by subscribers outside the city as well as inside; but we fail to see that this applies to cases sent by a public body outside the city. It may be a matter for discussion whether the infirmary is bound to receive cases of typhoid fever sent in by subscribers from outside the city or inside it. But a local authority outside the city stands in no such relation, and ought not to have been allowed to interfere with the district of a neighbouring local authority without communicating with it. Another plea set up by the infirmary is, that the patients in the city fever hospitals are not so well treated as in the infirmary. To this the crushing reply is made, that since these hospitals have been opened, the mortality at Belvidere has been every year considerably less than that of the infirmary for the same diseases. The sums total show a mortality for Belvidere of 12 for typhus and 11.3 for typhoid, while that of the infirmary is 17 and 15.6 respectively. The infirmary directors do not appear so much to deny these facts as rather to assert that, from the principle on which the medical attendance is conducted at the two places, the results ought to be in favour of the infirmary. It is as if they were determined that, if the facts did not agree with the principle, it was so much the worse for the facts. And so we find the superintendent, even after the publication of these statistics, in a patronising tone advising the committee to give it up and adopt the infirmary style of proceeding. Dr. Russell also maintains his principle of attendance to be the best, and adduces statistics in support of his position. Meanwhile, the question has been referred to the Board of Supervision, whether one local authority is at liberty to import into the district of another such authority cases of infectious disease, without in any way communicating with the said authority. It ought to be added, that the local authority of Glasgow have been quite prepared to treat the Partick cases as they have been treating cases from Maryhill and Hillhead, provided that these districts were erecting suitable accommodation within their own limits. They are actually in combination engaged in erecting a hospital for these three districts, so that, this condition being complied with, Partick would have found no difficulty in sending its cases to Belvidere.

IRELAND.

SIR DOMINIC CORRIGAN, Bart., has been appointed President, and Dr. Aquilla Smith Vice-President, of the Council of the newly formed Pharmaceutical Society of Ireland.

DR. CHARLES H. LEET has been reappointed Medical Representative of the Apothecaries' Hall of Ireland, in the General Medical Council.

A RUMOUR was extensively circulated that scarlatina had broken out among the children in Birr Barracks, King's County, and that the arrival of the 50th Regiment had been indefinitely postponed owing to this cause. The report, however, has been contradicted, there not being a vestige of any epidemic disease in or near the barracks.

BELFAST ROYAL HOSPITAL.

AT a quarterly meeting of the committee of this institution held last week, Dr. Ross was re-elected physician, and Dr. J. Walton Browne visiting-surgeon, in the room of Dr. Samuel Browne, J.P., resigned. Not more than one-half the sum required to complete the Convalescent Home has yet been subscribed; but, as a suitable site, free of all expense, has been obtained, it is hoped that the amount still required (about £3,000) will soon be forthcoming. In reference to Dr. Browne's resignation, the following resolution was unanimously adopted by the Board of Management:—"That this Board cannot accept Dr. Browne's resignation as visiting-surgeon to the hospital, after a connection with this institution of twenty-five years as surgeon and clinical instructor, without expressing their sense of the great loss it will sustain by his retirement; and they beg to tender him their best thanks for his unremitting energy and unwearied attention at all times to the interest of this charity; and also that he be placed on the consulting staff of the hospital."

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

MEETING IN BRISTOL, AUGUST, 1875.

SECTION D.—DEPARTMENT OF ANATOMY AND PHYSIOLOGY.

President: JOHN CLELAND, M.D., F.R.S.

Physiological Action of Light.—The report of a committee appointed at the meeting at Bradford in 1873 to investigate the physiological action of light, was read by Dr. J. G. MCKENDRICK. The members of the committee were Professor Balfour (Edinburgh), Professor Dewar (Cambridge), and Dr. McKendrick (Edinburgh). The investigation was begun by Professor Dewar and Dr. McKendrick about three years ago, and a paper on the subject was read at the Bradford meeting, when the committee was appointed, and a grant of £25 made to assist in carrying on the investigations. The results arrived at by the committee are as follows. 1. The impact of light on the eyes of mammalia, birds, reptiles, amphibians, fishes, and crustaceans, produces a variation amounting to from 3 to 10 per cent. of the normal electro-motive force existing between the surface of the cornea and the transverse section of the optic nerve. 2. This electrical variation may be traced into the brain. 3. Those rays that are regarded as most luminous produce the largest variation. 4. The electrical alteration is due to the action of light on the retinal structure itself, as it is independent of the anterior portion, eliminating, therefore, the natural supposition that the contraction of the iris might produce a similar result. It is possible by experiment to discover the physical expression of what is called in physiological language "fatigue". 5. The method employed in this research may be applied to the investigation of the special organs of the other senses. One of the principal difficulties in arriving at the exact relation between the electrical variation and lights of different luminous and colour intensity was the continually diminishing sensibility of the retina to the stimulus, owing to the abnormal condition of the eye when separated from the body and deprived of blood. This difficulty was overcome by placing the animal under the influence of woorara or hydrochlorate of chinoline, both of which substances deprive the animal of sensation and motion; thus experiments can be made upon the living eye without removing it from the body or in any way injuring the animal. It was found that, on applying the electrodes of the galvanometer to the cornea and to the surface of the skin, large deflections were obtained, sensitive to light, and showing a remarkably constant alteration. In the early part of the investigation, it was found that sometimes the initial effect of light was to produce an increase, and at other times a diminution, of the natural current circulating through the optical apparatus; but no explanation was then offered as to the

cause of this apparent anomaly. It has now, however, been demonstrated by a large number of experiments that the variation is related to the primary direction of the current. If, for instance, the cornea be positive to the surface of the brain, the initial effect of light is an increase; if, on the other hand, some portion of the brain be positive to the cornea, the initial action is a diminution of the natural current, thus showing that the current, superadded or induced by the action of light, is always in the same direction, only in one case it is added to, and in the other subtracted from, the natural current. The committee have also examined the action of polarised light and of the various coloured rays of the spectrum, with the result of showing that in all cases the yellow rays produced the greatest effect. They have also found that the extreme violet rays and the low red rays produce no alteration. The committee then attempted to measure accurately the electro-motive force of the living eye. This they did by means of Mr. Latimer Clarke's method of the comparison of electro-motive forces. From a large number of observations, it has been found that the electro-motive force of the nerve currents dealt with in these experiments on the eye of the frog amounts to about 1-350th part of a Daniell's cell. This was compared with the electro-motive force of the muscle and nerve of the frog: the muscle gave about 1-35th, while the nerve gave 1-480th part of a Daniell's cell. Lastly, the committee have recently made a series of elaborate experiments, by means of an instrument called a chronograph, devised by Regnault, as to the time required for the action of light upon the eye of the frog. It has been found to occupy about 1-10th of a second, thus remarkably agreeing with the conclusions arrived at by various Continental physiologists as to the time occupied by the action of light on the human eye. The result of this investigation shows that the electrical variation observed in the action of light is what occurs in the eyes of all members of the animal kingdom.

Microphotographs.—Mr. H. B. BRADY exhibited a series of microphotographs, chiefly from physiological and pathological preparations, taken by a new and simple process, devised by Mr. Hugh Bowman of Newcastle. The apparatus was also shown and described. It consisted of a simple mirror of speculum metal, placed at an angle of forty-five degrees in front of the eyepiece of the microscope, and directed downwards. The image was received upon a collodium plate set in the frame of a common photographic camera, and the photograph taken in the usual way. About eleven seconds was stated to be a sufficient exposure for the purpose.—The PRESIDENT, while admitting the utility of the invention, said that some difficulty would arise in its practical application, since, in looking at a preparation, it was often necessary to move the focus from point to point in order to obtain a complete examination.

Vascular Plexuses in the Elephant and some other Animals.—A paper on this subject was read by Mr. E. C. MIALL. It related to the physiological significance of certain plexuses of vessels in the elephant, as illustrated by some dissections undertaken by Mr. Miall and Mr. Greenwood.

Protoplasm and Adipocere.—A paper was read by Dr. J. GOODMAN on Protoplasm and Adipocere, or the Origin and Ultimate Termination of Animal Structure. The author endeavoured to show that the animal body, with all its complex organs and seemingly dissimilar structures, is formed either of corpuscles or fibrinous material, which alone can be denominated the true protoplasm of the body; and that dead animal matters are capable of resuscitation by contact with water, so that they will form corpuscles. Thus, an individual suffering from disease and taking no nutrition, may be sustained for weeks by the mixing of the effete matters from the frame with the aqueous fluid drawn by the absorbents.

Intestinal Secretion.—A second report was presented by the Committee on Intestinal Secretion—Dr. LAUDER BRUNTON and Dr. PYE-SMITH. The report detailed a number of experiments, which the committee had undertaken, and which were considered to prove the absence of influence on intestinal secretion through the splanchnic nerves, the pneumogastries, the sympathetic above the diaphragm or the spinal marrow; and the probable influence of the ganglia contained in the solar plexus, though certainly not of the two semilunar ganglia exclusively. Also the independent occurrence of hæmorrhage and of paralytic secretion appeared, in the view of the committee, to point to a separate nervous influence on the blood-vessels and the secreting structures of the intestines.

The Origin of the Lymphatics.—A paper by Dr. GEORGE and Dr. FRANCIS ELIZABETH HOGGAN, on the origin of the lymphatics, was read by the latter; and a large series of camera lucida drawings illustrating the subject was subsequently described by the former. The paper was merely offered as a preliminary abstract of what could be said on this very abstruse subject; and the authors alleged that they had discovered those "ultimate radicles" of the lymphatic system which

many histologists are at present seeking with the greatest skill and patience. Special reference was made to the lymphatic radicles in voluntary muscle of mammals, in involuntary muscle of batrachians, in the skin of fishes; and to the development and condition of lymphatic radicles and of lymphatic sinuses.

The Anatomy of the Skin.—A paper on this subject was read by Dr. MARTYN. In a recent paper, the author had described the structure and growth of the cuticle with reference to disease, and he now had to confirm the view which those appearances led him to predict, as holding good for ordinary and healthy epithelium also. Twelve years ago, Max Schultze observed that the lowest of the cells forming, in many layers, the cuticle were often covered with spines or grooves. His brother confirmed this in fishes, and other observers had done so in many diseases of the skin. In endeavouring to make out the real nature of this structure, Dr. Martyn, by the employment of unusually thin sections, staining, and the highest available powers of the microscope, had discovered that the cells which appeared "spinous" or "echinate", when isolated from their connection, if they could be at any time seen in single layers, were simply united together by delicate bands. These were so constantly seen broken across, that they assumed the form of tubercles or "prickles". As repeated observations confirmed this, the name "conjoined epithelium" had been proposed for this form or stage in the cell-life. These observations, of which drawings were engraved in the *Microscopical Journal* for August, were made on cancer of the skin. Dr. Martyn said that the conjoined epithelium was also to be found in (1) the human skin; 2. The front of the eye in the pig; 3. The lips of at least one fish (*Zens faber*). The difficulty of making the structure clear in a healthy animal cuticle was: 1. The intense cohesion of those very cells, so that, in trying to stretch one usually broke the uniting bands; 2. The necessity for using a high power, the one-twelfth, from 800 to 1,000 diameters being required to make sure of the nature of the bands. The interest of the subject lay in this direction. All the cells of which living things at any moment consisted were produced by division of a parent either into two equal parts (fissiparous), or by budding off a small bit (gemmiparous). Epithelial cells grew so, too, and, in "conjoined" epithelium, the division-process was lingering on. Many cells divided like an hour-glass; but here the points were very numerous. Protoplasm, of which cells at first consisted, varied constantly in form, as the amœba, or the white blood-cell. While alive, in a formative sense, it moved. The old outer firm wall, or shell of matter which formed around cells, and which was called cell-wall, had ceased to have this formative life, whatever functional powers it might have. Cells of many striking shapes were found in the organic world—star-shaped, spindle-shaped, caudate, and so on. In the early discoveries of cell-growth, innumerable mysterious vital powers were attributed to cells, amongst which was that of projecting processes: long wandering arms pervading intercellular tissue or other structures. As Dr. Martyn endeavoured to show some years ago, the form of the cell was almost invariably the result of ordinary force. It was a form which the cell was forced to take by the dragging out of the points at which it was in the act of dividing. This idea was now familiar, and the conjoined epithelium was a good illustration. A good subject for investigation would be those cases in which cells are covered with ciliary processes, probably from splitting of hardened and formed outer material.

The Physiological Action of the Chinoline and Pyridine Bases.—A paper on this subject by Dr. J. G. M'KENDRICK and Professor DEWAR, was read by the former gentleman. The following is an abstract. It is well known that quinine, cinchonine, or strychnine yield, when distilled with caustic potash, two homologous series of bases, named the pyridine and chinoline series. Bases isomeric with these may also be obtained by the destructive distillation of coal, or from Dippel's oil, got from bone. Greville Williams has pointed out that chinoline obtained from coal-tar differs in some respects from that yielded by cinchonine. In this research, the authors endeavoured to ascertain (1) the physiological action of the various members of the series; (2) whether there was any difference in this respect between the members of the series obtained from cinchonine and those got from tar; and (3) whether, and if so, how, both as regards extent and character, the physiological action of these bases differed from that of the original alkaloidal bodies. The bases in both series are difficult to separate from each other; but this has been done as far as possible by repeated fractional distillation. The salt employed was the hydrochlorate. This, dissolved in water, was introduced by a fine syringe under the skin of the animal. The action of chinoline was tested on frogs, mice, rabbits, guinea-pigs, cats, dogs, and man; but as the effects were found to be similar in all of these instances, the majority of the observations were made on rabbits. The experiments with the other substances were made on rabbits and frogs. The physiological action of hydrochlorate of chinoline was first

examined. Its action was then compared with that of the hydrochlorates of the chinoline series of bases distilling at higher temperatures, including such as lepidine, disoline, tetrahiroline, etc. In the next place, the physiological action of the pyridine series was studied, beginning with pyridine itself, and passing upwards to bases obtained at still higher boiling-points, such as picoline, lutidine, etc. Lastly, the investigation was directed to the action of condensed bases, such as dipyridine, parapicoline, etc.; and the effects of these substances were compared with those produced by the members of the chinoline series and among themselves. The following are the general conclusions.

2. There is a marked gradation in extent of physiological action of the members of the pyridine series of bases, but it remains of the same kind. The lethal dose becomes reduced as we rise from the lower to the higher.

3. The higher members of the pyridine series resemble in physiological action the lower members of the chinoline series, except (1) that the former are more liable to cause death by asphyxia, and (2) that the lethal dose of the pyridines is less than one half that of the chinolines.

4. In proceeding from the lower to the higher members of the chinoline series, the physiological action changes in character, inasmuch as the lower members appear to act chiefly on the sensory centres of the encephalon and the reflex centres of the cord, destroying the power of voluntary or reflex movement; while the higher act less on these centres, and chiefly on the motor centres, first, as irritants, causing violent convulsions, and at length producing complete paralysis. At the same time, while the reflex activity of the centres in the spinal cord appear to be inactive, they may be readily roused to action by strychnine.

5. On comparing the action of such compounds as C^9H^7N (chinoline) with $C^9H^{13}N$ (parvoline, etc.), or $C^8H^{11}N$ (colidine) with $C^8H^{15}N$ (conia, from hemlock), or $C^{10}H^{10}N^2$ (dipyridine) with $C^{10}H^{14}N^2$ (nicotine, from tobacco), it is to be observed that the physiological activity of the substance is, apart from chemical structure, greatest in those bases containing the larger amount of hydrogen.

6. Those artificial bases which approximate the percentage composition of natural bases are much weaker physiologically, so far as can be estimated by amount of dose, than the natural bases; but the kind of action is the same in both cases.

7. When the bases of the pyridine series are doubled by condensation, producing dipyridine, parapicoline, etc., they not only become more active physiologically, but the action differs in kind from that of the simple bases, and resembles the action of natural bases or alkaloids having a similar chemical constitution.

8. All the substances examined in this research are remarkable for not possessing any specific paralytic action on the heart likely to cause syncope; but they destroy life either by exhaustive convulsions, or by gradual paralysis of the centres of respiration, thus causing asphyxia.

9. There is no appreciable immediate action on the sympathetic system of nerves. There is probably a secondary action; because, after large doses, the vaso-motor centre, in common with other centres, becomes involved.

10. There is no difference, so far as could be discovered, between the physiological action of bases obtained from cinchonine and those derived from tar.

11. Dr. McKendrick also described the physiological effects of various methyl and ethyl compounds of chinoline. He alluded to the researches of Professor Crum Brown and Dr. Thomas R. Fraser on the action of methyl and ethyl strychnia as examples of a complete change in physiological action being produced by a change in chemical constitution. He and Professor Dewar had found the ethyl and methyl compounds of chinoline to have an action very different from chinoline alone. They were found to be much more active than chinoline alone, and to produce effects similar to those of the higher members of the chinoline series. He then indicated the important considerations suggested by this investigation; and said it was not too much to anticipate that the chemist may yet be able to build up compounds having effects resembling those of such valuable remedies as quinine, morphia, etc.—

12. Dr. PYE-SMITH said it was gratifying to find that so important a branch of science was being investigated by two such eminent men as Dr. McKendrick and Professor Dewar. Some of the bases to which reference had been made would, no doubt, prove useful medically and physiologically, especially in the latter capacity. With regard to cinchonine, he had made some experiments with it on the human frame; and he was led to the conclusion that the further it was kept from patients the better it would be. It was certainly cheaper than quinine, but it had many objectionable characteristics. He was glad to hear of the promised advantages of chinoline, which, if realised, would help them out of the difficulties attending the administration of woorara to the mammalia.

VACCINATION.—Mr. Thomas Taylor of Bocking, Essex, has been awarded an extra vaccination gratuity, amounting to £15 17s. Mr. J. Comyns Leach of Sturminster Newton has received, for the second time, a grant of £8 10s. for efficient vaccination.

ASSOCIATION INTELLIGENCE.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT.

The next meeting of the above Branch will be held at the Pavilion Hotel, Folkestone, on Thursday, September 16th, 1875, at 3 o'clock; Dr. HENRY LEWIS of Folkestone in the Chair.

Dinner at 5 o'clock precisely. Charge, 6s. 6d., exclusive of wine.

Gentlemen who wish to make communications to the meeting are requested to inform me at once, in order that a notice thereof may be included in the circular convening the meeting.

EDWARD WHITFIELD THURSTON, *Honorary Secretary*.
Ashford, August 29th, 1875.

NORTHERN COUNTIES (SCOTLAND) BRANCH.

The annual meeting of this Branch will be held at Elgin, on Saturday, September 18th, at 12.30 P.M. Dr. VASS, of Tain, President-elect.

Particulars by circular.

J. W. NORRIS MACKAY, *Honorary Secretary and Treasurer*.
Elgin, September 2nd, 1875.

SOUTH MIDLAND BRANCH.

The autumnal meeting will be held at Northampton, on Wednesday, September 22nd; HENRY TERRY, Esq., President-elect.

Gentlemen intending to read papers are requested to forward their titles forthwith to Dr. Bryan.

J. M. BRYAN, M.D. } *Honorary Secretaries*.
W. MOXON, Esq. }

Northampton, September 1st, 1875.

MIDLAND BRANCH.

A MEETING of the above Branch will be held at Matlock Bath, on Thursday, September 23rd. Several papers have been promised. Further information in next week's JOURNAL.

F. W. WRIGHT, *Honorary Secretary*.
Derby, September 1st, 1875.

NORTH OF ENGLAND BRANCH.

The autumnal meeting of this Branch will be held at the Queen's Hotel, Sunderland, on Thursday, September 23rd, at 3 P.M.; S. E. PIPER, F.R.C.S., President.

The following papers have been promised.

1. Dr. J. W. Eastwood. The Prevalent Practice of Advertising Medical Works in the Non-Medical Press.

2. Dr. C. Gibson. Certain Forms of Blood-Diseases.

Gentlemen who are desirous of reading papers will oblige by communicating with the Secretary.

Dinner at the Queen's Hotel, at 4.45 P.M. Tickets, exclusive of wine, seven shillings and sixpence.

G. H. PHILIPSON, M.D., *Honorary Secretary*.
Newcastle-upon-Tyne, September 1st, 1875.

MEMBERS PRESENT AT THE EDINBURGH MEETING.

The following names of members and visitors attending the meeting were entered in the book provided for that purpose in the Reception Room. The number of members of the Association who were present exceeded one thousand.

Acton, Wm., Esq., London; Adams, T. R., M.D., Croydon; Adams, W., Esq., London; Ady, John E., Esq., Edinburgh; Ady, J. C., Esq., Purmah; Affleck, J. O., M.D., Edinburgh; Agar, S. H., L.K.Q.C.P., Henley-in-Arden; Ainslie, Wm., Esq., Edinburgh; Auchison, J., Esq., Wall-end-on-Tyne; Aitken, J., M.D., Govan; Aitken, L., M.D., Rome; Alcock, J., Esq., Burslem; Aldred, H. A., M.D., London; Alexander, A., M.B., Caithness; Alexander, W., M.D., Duodonald; Alexander, W. B., Esq., Edinburgh; Alford, Stephens S., Esq., London; Allan, Alexander, Esq., Jersey; Allan, D., M.D., Boar Bridge; Allan, James, Esq., Edinburgh; Allbutt, T. Clifford, M.D., Leeds; Alsop, Thomas O. F., M.B., Royal Infirmary, Edinburgh; Althaus, Julius, M.D., London; Anderson, D. H. B., M.D., Army Medical Department; Anderson, Mrs. E. Garrett, M.D., London; Anderson, H. S., M.D., Selkirk; Anderson, James, M.D., I'ridge of Allan; Anderson, James, Esq., Musselburgh; Anderson, James, Esq., Ulverstone; Anderson, J. T. W., Esq., Edinburgh; Anderson, J. W., M.D., Glasgow; Anderson, John, M.D., Ulverstone; Anderson, Robert, M.D., Seaton; Anderson, Thomas, M.B., District Asylum, Edinburgh; Anderson, T. M'Call, M.D., Glasgow; Annandale, Thomas, Esq., Edinburgh; Andrew, Edwyn, M.D., Shrewsbury; Andrianaly, Madagascar; Arbuckle, Hugh W., M.D., Thorne; Archibald, D., M.D., St. Andrew's; Archibald

John, M. B., Biggar, Arlidge, J. T., M.D., Newcastle-under-Lyme; Arras, William, Esq., Wetheral; Artott, George, Esq., Lockerbie; Arthur, Hugh, M.D., Andrie; Atwell, G. Haines, Esq., Altrincham; Athill, Louisa, M.D., Dublin; Atkinson, E. T., Esq., Richmond; Atkinson, George P., Esq., Pontefract.

Baldon, H. C., Esq., Edinburgh; Baard, G. Dallas, Esq., Linlithgow; Baker, Alfred, Esq., Birmingham; Baker, James, Esq., Scarborough; Baker, J. C., M.D., Liverpool; Baker, J. Wright, Esq., Derby; Balfour, A. H., Esq., Portobello; Balfour, A. M. B., Portobello; Balfour, J. H., M.D., F.R.S., Edinburgh; Balfour, Thomas A. G., M.D., Edinburgh; Ball, Alfred, Esq., York; Ballantyne, Alexander, M.D., Dalkeith; Banks, Alexander, Esq., Edinburgh; Barbour, George F., Esq., Bunsick; Barety, A., Nice; Barnes, Arthur R., Esq., Faversham; Barnes, Henry, M.D., Carlisle; Barnes, Robert, M.D., London; Bartlett, H. Critchett, Esq., London; Barr, Thomas, M.D., Glasgow; Bassett, John, M.D., Birmingham; Batten, Thomas, Esq., Coleford; Baxter, W., Esq., Kilmarnock; Beaton, George T., M.B., Newcastle-on-Tyne; Beddoe, John, M.D., F.R.S., Bristol; Bedford, H. C., Esq., Cape of Good Hope; Begbie, J. Warburton, M.D., Edinburgh; Begley, W. C., M.D., London; Belcombe, Rev. Francis E., Edinburgh; Bell, Rev. D., M.D., Goolie; Bell, James M., M.D., Kettle; Bell, J. H., M.D., Bradford; Bell, Joseph, Esq., Edinburgh; Bell, Robert, M.D., Glasgow; Bennett, E. A., Esq., Nelson-in-Marsden; Bennett, E. H., M.D., Dublin; Bennett, H. N., Esq., Dublin; Bennett, J., Hughes, M.D., F.R.S.E., Edinburgh; Bennett, J. N., Esq., Mile Crux House; Bennie, Jas., Esq., Currie; Bernard, Walter, L.K.Q.C.P., London; Beveridge, Robert, M.B., Aberdeen; Berne, J. F., Esq., Paris; Berne, J. F., Esq., Mauritius; Bilton, Lewis, Esq., Edinburgh; Bindon, W. J., Verker, Esq., Edinburgh; Bishop, John, M.D., Edinburgh; Bishop, Thomas, M.D., Paris; Blair, Sheriff, Inverness; Blandford, Jos. W., Esq., Durham; Blanchard, Geo., Esq., Edinburgh; Blair, Wm., M.D., Jedburgh; Blancy, Roland, Esq., India; Blech, A., M.B., Edinburgh; Block, Oscar, Copenhagen; Bluet, John, Esq., Chesterfield; Blumer, Luke, M.D., Sunderland; Bodington, G. F., M.D., Kingswinford; Borthwick, Alexander, M.D., Dumfries; Bott, John, Esq., Huddersfield; Bott, Thos. B., M.D., Bury; Boucher, Georges, Esq., Mauritius; Bowes, Richard, Esq., Richmond, York; Bowie, John, Esq., Edinburgh; Bradley, Charles, Esq., Nottingham; Bradwood, P. M., M.D., Birkenhead; Brakenridge, David, M.D., Edinburgh; Bramwell, B., M.B., Newcastle-on-Tyne; Bramwell, J. W., Esq., North Shields; Bramwell, J. P., M.D., Perth; Branford, W. H., Esq., Edinburgh; Bratton, James, Esq., Shrewsbury; Bremner, Bruce A., M.D., Edinburgh; Bremner, Allan S., Esq., Edinburgh; Bridger, John, Esq., Cotenham; Bridgman, I. T., Esq., Berkeley; Briggs, Henry, M.D., Burnley; Britton, Thomas, M.D., Halifax; Broadbent, Lewis G., M.D., Hamburg; Broadbent, S. W., Esq., South Hetton; Durham; Broadbent, W. H., M.D., London; Brodie, David, M.D., Liberton; Brooke, Sir William, Nice and London; Brooks, James W., M.D., New York; Brotherton, Peter, Esq., Aloa; Brown, Alexander, Esq., Coldstream; Brown, Alexander Crum, M.D., Edinburgh; Brown, Colville, M.D., Berwick-on-Tweed; Brown, Henry, Esq., Northallerton; Brown, James, Esq., Isle of Skye; Brown, Joseph J., M.B., Edinburgh; Brown, Robert, M.D., Tranent; Brown, T., Sinclair, M. B., Barbadoes; Brown, Wm., Esq., Carlisle; Browne, Lennox, Esq., London; Bruce, Robert, M.D., Edinburgh; Bruce, Wm., M.D., Dingwall; Bruce, W. T., Esq., Halifax, Nova Scotia; Brumell, Matthew, Esq., Morpeth; Brunton, T. Lauder, M.D., F.R.S., London; Bryson, Jas. M., Esq., Edinburgh; Buchan, Alex., Esq., Edinburgh; Buchanan, A. M., M.D., Glasgow; Buchanan, Andrew, M.D., Glasgow; Buchanan, George, M.D., Glasgow; Bullus, Wm., Esq., Staffordshire; Burn, John, M.D., Edinburgh; Burns, John J. D., M.D., Rochester; Burrows, Sir Cordy, Brighton; Butler, Thomas M., Esq., Guildford.

Cadell, Francis, M.B., Edinburgh; Cadell, Major T., Cockenzie House; Caldwell, John, Esq., Shotts; Cameron, Hector C., M.D., Glasgow; Cameron, John, M.B., Lochgilphead; Cameron, R. M., Esq., Edinburgh; Campbell, J., Esq., Dundee; Campbell, J. A., Esq., Garland; Campbell, Peter, M.D., Edinburgh; Campbell, Wm., Esq., Hastings; Campbell, Wm., Esq., London; Campbell, Wm., Watson, M.D., Dunse; Candy, John, M.D., Devonport; Cattie, James, M.D., Edinburgh; Carey, Ernest Gilbert, Esq., India; Carey, Wm., Esq., Edinburgh; Carlyle, W. J., M.D., Langholm; Carmichael, J., Esq., Edinburgh; Carmichael, Jas. M.D., Edinburgh; Carmichael, Wm., Esq., Edinburgh; Carmichael, W. S., M.D., Edinburgh; Carmichael, W. M., Esq., Australia; Carnegie, John, M.D., Chesterfield; Carpenter, Alfred, M.D., Croydon; Carphin, J. R., Esq., Edinburgh; Caruthers, J. B., M.D., Edinburgh; Carter, T. A., M.D., Leamington; Cash, A. M., M.B., Edinburgh; Cassells, J. P., M.D., Glasgow; Cathcart, Charles W., Esq., Edinburgh; Caton, Richard, M.D., Liverpool; Caverhill, T., Esq., Haddington; Chadwick, Charles, M.D., Leeds; Chalmers, D. Short, Esq., Edinburgh; Chambers, Thomas, M.K.C.P., London; Champney, C. Thornton, Esq., Glasgow; Championniere, J., M.D., Paris; Chapman, J., Esq., Edinburgh; Charles, J., M.D., Belfast; Charlesworth, James, Esq., Hanley; Charteris, M., M.D., Glasgow; Chavoin, Silmours, Esq., Edinburgh; Cheyne, W. Watson, M.B., Shetland; Chiene, John, Esq., Edinburgh; Chisholm, Wm., Esq., Edinburgh; Christie, Thomas E., M.D., Ealing; Christison, Sir Robt., Bt., M.D., D.C.L., Edinburgh; Church, H. M., M.D., Edinburgh; Church, W. J., Esq., Weymouth; Clark, Andrew, M.D., London; Clark, James, M.D., Chasetown; Clark, Robt., Esq., Edinburgh; Clarke, V. C., M.D., London; Clarke, W. M., Esq., Bristol; Clouston, T. S., M.D., Edinburgh; Clume, J. Leopold, Esq., Jamaica; Coats, Joseph, M.D., Glasgow; Cochran, John, M.D., Edinburgh; Cockroft, Wm., Esq., Middleham; Coghill, J. G. Sinclair, M.D., Edinburgh; Coldstream, John, Esq., Edinburgh; Colston, Jas., Esq., Edinburgh; Constable, John, M.D., Leuchars; Cooke, W. H., M.D., Aldridge, Walsall; Coombs, Rowland H., Esq., Bedford; Cooper, Jas., Esq., Cromer; Cooper, W. J., Esq., Richmond, Surrey; Copeman, E., M.D., Norwich; Corbin, M. A. B., Esq., Guernsey; Coimack, Sir John Rose, M.D., Paris; Cornwall, James, Esq., Fairford; Cossar, Thomas, M.D., King's Lynn; Cotton, H. J., M.B., Edinburgh; Courtenay, G. T., Esq., Tranent; Coventry, James H., Esq., Prestwick; Cowan, Fred. S., Esq., Bath; Cowan, Samuel, Esq., Bath; Cowell, George, Esq., London; Cox, D. Charles, Esq., Penicik; Cox, John, D., Esq., Innerleithen; Cox, Joshua J., Esq., Innerleithen; Cox, Sir James, M.D., Kuelan; Crabb, James, M.B., Fdmburgh; Craig, Archibald, M.B., Pathhead-Ford; Craig, W. M.D., Fdmburgh; Crawford, D., Esq., Aberdeen; Crawford, R., Esq., London; Crease, James R., Esq., South Shields; Cresswell, Pearson, R., Esq., Dowlaits; Crichton, George, M.B., Perth; Crichton, James S., M.D., Arbroath; Crickmay, Edward, Esq., Laxfield; Crighton, R. W., M.D., Tavistock; Cripps, Edward, Esq., Cirencester; Cripps, Edward C., Esq., Cirencester; Croom, J. Haldimay, M.B., Fdmburgh; Cullingworth, Charles J., Esq., Manchester; Cumming, Wm., M.D., Edinburgh; Cunningham, James, M.D., Edinburgh; Cunningham, W. Murray, Esq., Glasgow; Cunningham, D. J., M.B., Edinburgh; Cunningham, M. R. J. B., M.D., Edinburgh; Currie, John, M.D., Lydney; Cuthbert, Clarkson, M.D., Edinburgh; Cuthbertson, David, M.D., Denny; Cuthill, James, M.D., Denny; Daldy, T. M., M.D., London; Dalgleish, W. Scott, Esq., Edinburgh; Darily,

Clement, Esq., Mauritius; Davidson, Alexander Dyce, M.D., Aberdeen; Davies, Andrew, Esq., Swansea; Davies, David, Esq., St. Andrew's; Davies, Ebenezer, Esq., Swansea; Davies, John, M.D., Maesteg; Davies, Robert, Esq., Abergele; Davies-Colley, T., M.D., Chester; Davis, F., Esq., Cymer; Davis, H. L., Esq., Wales; Davis, R. A., M.D., Lichfield; Dawson, Adam, Esq., Fdmburgh; Day, W. H., M.D., London; Deas, Peter James, M.B., Macclesfield; Deighton, Christopher, M.D., Clapham; Deiham, J. S., M.D., South Shields; Denton, F. R., Esq., Leicester; Desmond, L. E., M.D., Liverpool; Dewar, Alexander, M.D., Meitose; Dewar, James A., M.D., Arbroath; Dick, John, Esq., Edinburgh; Dickson, Alex., M.D., Glasgow; Dickson, Rev. T., Miller, Cloughton; Dickson, Walter, M.D., London; Dickson, Wm. James, M.D., Falkland; Dix, John, Esq., Hull; Dolman, A. H., Esq., Derby; Douglall, Joseph, Esq., Edinburgh; Douglas, Captain C., Edinburgh; Douglas, Henry, M.D., Dunfermline; Douglas, Mordey, Esq., Sunderland; Douglas, R. Green, Esq., Edinburgh; Dow, Wm. B., M.D., Dunfermline; Downie, R. M., M.D., Bengal, India; Downie, Thomas, M.D., Blantyre; Dowse, Thomas S., M.D., London; Drew, John, M.B., Stung; Drummond, F. W., M.D., Royston; Drysdale, John, M.B., Uphall; Dunbar, Henry, M.D., Kirkcaldie; Duncan, Alexander George, M.B., Grimsd; Duncan, A. Jas., M.D., Dundee; Duncan, J. Matthew, M.D., Edinburgh; Duncan, John, M.D., Edinburgh; Duncan, J. J. Kirk, M.D., Edinburgh; Dunlop, John, M.D., Edinburgh; Dunn, Robert, Esq., London; Dunsinure, James, M.D., Edinburgh; Dunsinure, James, jun., M.D., Edinburgh; Dupuy, M. F., Paris; Durand, Rudolph, Esq., Mauritius; Duhan, James, Esq., J. P., Mayfield; Durant, Christopher M., M., Ipswich.

Eagles, Woodfield, Esq., Aylesbury; Eames, J. Alex., M.D., Cok; Eames, J. C., M.B., Manchester; Essie, Wm., Esq., London; Elliott, Robert, M.D., Carlisle; Elliot, W. A., M.D., Ipswich; Evans, Charles, Esq., Eskwell; Evans, John, M.D., Sunderland; Evans, Thos. D. F., M.B., Edinburgh; Evans, Thomas, M., Newport; Everett, D., Esq., Worcester; Ewart, T. C., Esq., London; Faircloth, Richard, Esq., Newmarket; Fairless, W. D., M.D., Stockton-on-Tees; Falconer, R. REPORTS OF SOCIETIES.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH

JULY 7TH, 1875.

RUTHERFORD HALDANE, M.D., President, in the Chair.

Exhibition of Patients.—Dr. GRAINGER STEWART showed: 1. A sailor who had been paralyzed in consequence of spinal curvature, had improved under treatment so as to return to sea, but, after long exertion in bad weather, had again become paraplegic. He was again much improved by treatment. 2. He also showed a man suffering from sclerosis of the posterior columns of the cord. The muscular sense, which gives the power of appreciating weight, was lost in the limbs, and the cutaneous sensibility nearly gone. 3. He also showed a case of muscular atrophy in a blacksmith, chiefly confined to his forearms and legs. It had been progressing slowly for twenty years. 4. He also exhibited a case of bronchiectasis, which illustrated the symptoms well, especially the peculiar factor of the sputum; and 5. A young girl who appeared in tolerable health, but who was suffering from advanced disease of the kidney.

Exhibition of Specimens.—Dr. HALDANE exhibited the parts removed from a very remarkable case, which he had seen once only before death. The history was briefly as follows. A healthy militia sergeant had had diarrhoea, etc., and had been sent in from the regimental hospital. He was jaundiced, and vomited dark matter, stained with blood. The urine, which was exceeding scanty, was highly albuminous. The liver was not diminished in size. The symptoms were those of acute yellow atrophy of the liver. No treatment could be of use, and he died a few hours after admission, with his mind clear to the last. The necropsy showed the liver to be 4lbs. in weight, not much altered. The kidneys were enlarged and contained tubercular abscesses. There was no ulcer of the stomach, but the pancreas was enlarged, softened, and infiltrated with blood. He believed the case was one of great rarity and obscurity.

Mr. ANNANDALE showed a good specimen of cartilaginous tumour of the tibia, treated by amputation; a case of necrosis of the tibia; two-thirds of a cancerous tongue, along with diseased submaxillary glands, which he had recently removed; an epithelial growth on the penis, in a man aged 32, which he had recently removed without removing the whole organ; and a head of a femur excised in early hip-disease.

Mr. J. CHIENE showed a loose cartilage excised from a knee-joint, under carbolic spray.

Dr. ANGUS MACDONALD showed an intestinal concretion removed by Dr. TURNER of Keith, from the rectum. It was a gall-stone incrustated with hairs from a caryopsis, mixed with saline matter.

History of a Completed Case of Recurrent Tumour. By JAMES SPENCE, Esq.—This paper was a most careful and complete account of a case of extreme rarity. The facts were briefly as follows. Mrs. E. consulted the late Dr. MacLagan in 1832. She was then twenty-two years of age, and showed a tumour of three years' standing in the left loin; firm, elastic, and as large as a jargonelle pear. This tumour was removed. In 1834, and again in 1836, other tumours, similar in character, appeared in the scar, and were removed by Dr. Douglas MacLagan. Not till 1857 was she again under treatment, when Professor Syme was asked by Dr. Douglas MacLagan to see her, with a view to the removal of another tumour which had made its appearance in the scar about a year before. It was now about the size of half an orange, elastic, irregular, and, on its most prominent part, presented a pink transparent appearance. The tumour and scar were now again widely removed, along with a portion of lumbar fascia. Her general health was excellent; nor was there a symptom of cachexia. The wound healed well, and the tumours never returned. Sir James Paget and Dr. Haldane, who at the time examined the tumour, described its structure as fibrous tissue, containing nucleated cells of an elongated oval form. In November 1868, the patient returned with a tumour of the size of half a small melon on the right mamma, the nipple of which was retracted. There was no glandular involvement. Her health was good, and she looked well. In August 1870, she returned with a tumour in the vicinity of the scar of the last operation, but not in it. This tumour was as large as a small lemon. This was removed, and, on her convalescence from the operation, she had symptoms of stricture of the œsophagus, which, however, seemed to pass off, and were supposed to be nervous in origin. In June 1871, after a visit in the country, she caught cold, had bronchopneumonia and pericarditis, was unable to swallow, had an ulcerated tumour in the axilla, and died exhausted very rapidly. The *post mortem* examination was made by Dr. Wylie. The body was somewhat emaciated; face pale and sallow.

Zeigler, W., M.D., Edinburgh.

Over the right mammary region there was a linear curved cicatrix, five inches long, extending from the junction of the third costal cartilage with the sternum to the inferior margin of the pectoralis major in the axilla. An inch and a half lower down was a second curved cicatrix, two and a half inches in length. From the outer end of the longer cicatrix a gaping wound extended into the axilla, measuring three inches in length, and two inches in breadth at its widest part. The bottom and edges of the wound presented a gray phagedenic appearance, and were coated with a dirty greyish green discharge, which, under the microscope, was seen to be made up of a large amount of fatty debris, mixed with degenerated granular pus-cells. The tissue forming the base of this wound was tough and fibrous, being composed for the most part of connective tissue, which, under microscopical examination, appeared very abundantly nucleated, much more so than ordinary connective tissue; this was especially noticeable after treatment with acetic acid. The nuclei were small and oval in shape. Above the wound, the lymphatics along the course of the axillary artery were slightly enlarged. On the skin of the back, over the inferior angle of the left scapula, there was a small pedunculated tumour about the size of a filbert. This tumour was simply a hypertrophy of the cutaneous structures, especially the cutis vera. The outer surface of the pericardium was loaded with a deposit of fat. The parietal layer of the pericardium was everywhere adherent to the visceral layer, the adhesions being recent. The heart was quite healthy. The left pleural sac contained three pints of clear yellow serum. The pleura itself was dotted all over with numerous small white nodules of a fibrous consistence, varying in size from a millet-seed up to a pea. The microscope showed these to be formed of fibrous tissue very abundantly nucleated, similar to that forming the base of the axillary wound. The left lung was much diminished in size from compression. At the root of the lung, the walls of the greater bronchial tubes were much thickened, and the tissue around indurated, this being due to the presence of an excess of connective tissue. The right lung and pleura were healthy; at the root, however, the larger bronchial tubes presented the same thickening and induration noticed in the left lung. The tracheal and bronchial mucous membrane were congested. About two inches above the cardiac orifices of the stomach was a stricture of the œsophagus with indurated and thickened walls, firm and fibrous on section. The length of the stricture was one inch and a half, the indurated wall was half an inch in thickness, reducing the lumen of the passage to half its natural size. Opposite this stricture, the œsophagus and the aorta were bound together by very dense fibrous adhesions. The thickening of the œsophageal wall at the point of stricture showed nothing but the elements of ordinary connective tissue. In the uterus were three tumours, which microscopical examination showed to be simple fibrous growths. Mr. Spence then quoted briefly, and commented on, two other cases under his observation along with the late Professors Goodsir and Syme respectively, but showed that they in their termination as malignant growths really seemed to have been mere modifications of medullary sarcoma, while in looking back on his own, he summed up thus: "In conclusion, taking into account all the vital manifestations, I cannot classify this case as malignant; whilst, conversely, some of the circumstances, such, for instance, as the development of secondary growths in the mamma, axilla, and pleura, and the superabundant development of connective tissue, nucleated in greatly larger amount than usual in various organs, seem to withdraw it from the simple class. I am, therefore, strongly inclined to consider it a tumour *sui generis*, the type of a class whose peculiarity is the tendency to recurrence without constitutional degeneration."—An interesting discussion ensued, in which Messrs. Annandale and Bell, and Drs. Mathews Duncan and Wyllie, took part. Mr. Spence replied.

Contribution to the Pathology of the Ovary. By J. FOULIS, M.D.—The author gave a short statement of the views of Waldeyer on the development of the Graafian follicles and cells of the membrana granulosa, in which he laid stress on the fact that, whereas Waldeyer's investigations showed that both the cells of the membrana granulosa and eggs were derived from the germ epithelium on the surface of the ovary, his own investigations appeared to show that the eggs alone were derived from the germ epithelium, and the cells of the membrana granulosa were derived from connective tissue corpuscles of the stroma of the ovary. Having this fact as a basis for investigating the origin of cystic tumours of the ovary, Dr. Foulis stated that, as the result of numerous observations on the origin of cysts in the diseased ovary, he was able to demonstrate that, though many of the cysts of an ordinary cystic tumour of the ovary were simply over-distended Graafian follicles, in the walls separating these there was a growth of new cysts quite unconnected with presenting Graafian follicles, which might go on to an unlimited extent, and that the epithelium of these was produced from connective tissue corpuscles. He then drew attention to the very interesting fact that, in addition to the production of the epithelium of the cysts, the connective

tissue corpuscle of the stroma, by general and excessive proliferation, might give rise to sarcomatous growths in the ovary; and that, through the escape of epithelial elements from the diseased stroma and cysts into the peritoneal cavity, secondary sarcomatous growths might arise on the peritoneum, which, by constant irritation, resulting in the pouring out of ascitic fluid, ultimately exhausted the patient. Dr. Foulis showed drawings of the little masses of sprouting cells which he had discovered in ascitic fluids surrounding ovarian tumours, and by the presence of which he had diagnosed malignant ovarian tumour and peritonitis in two cases whose histories had already been given to the Society; and he now gave short notes of three additional cases in which he had discovered the same little masses of sprouting cells in ascitic fluid, and in two of these cases a *post mortem* examination verified the diagnosis made during life, viz., malignant ovarian tumour and peritonitis. The third case was that of a woman still alive, and in the ascitic fluid present an enormous quantity of the little masses of the sprouting cells were found. He then laid great stress upon the importance of a careful examination of ascitic fluids in cases where ascites complicated ovarian disease, and pointed out how rarely it was possible to get fluid by tapping from malignant tumours themselves, which were generally semi-solid. He ended by saying that it remained for future observation, to settle the question whether little masses of sprouting cells are ever found in ascitic fluids surrounding other malignant tumours of the omentum, peritoneum, etc., structures in which fibrous connective tissue exists in quantity.

The Society had the opportunity, through the kindness of Professor Laycock, who was unavoidably absent, of examining a most interesting case of tubercular leprosy in a young man of European extraction. The peculiar character of the voice was well marked.

CORRESPONDENCE.

THE LATE DR. MAUNSELL.

SIR,—The premature death of Dr. Maunsell of Dublin, announced in your last week's issue, is the heaviest blow and greatest discouragement which the cause of Poor-law medical reform has sustained since the day when poor Richard Griffin broke down. To me, Dr. Maunsell's death is especially unfortunate; for he constantly afforded me most valuable aid in procuring statistics, notably as regards the administration of dispensary medical relief.

On my first visit to Ireland six years since, undertaken for the purpose of studying the working of the system followed in that country, Dr. Maunsell was my companion and guide; indeed, without his assistance, it would have been well-nigh impossible for me to succeed in obtaining any information. He was the originator of the Irish Poor-law Medical Officers' Association, and, in his capacity of honorary secretary, devoted himself with untiring energy to the realisation of its objects; viz., the improvement of the status and emolument of his colleagues, and their superannuation.

I doubt not that some effort will be made in the sister isle to show how much his great services have been appreciated; but, in this country, I feel we owe him something also: there can be no doubt that, to his writings, much of the success which has attended the efforts made to ameliorate the position of the Poor-law medical service is justly due, notably as regards superannuation allowance. That he has left his wife and young family in very indifferent circumstances, there can be no doubt; and I, therefore, do hope that members of the profession in the United Kingdom will evince their sense of his public work in their behalf by contributing to a fund for their benefit. For this purpose, I shall be most pleased to receive any sum that may be forwarded to me.—I am, sir, yours obediently, JOSEPH ROGERS.

33, Dean Street, Soho, August 30th, 1875.

THE RECENT CHARGE OF MANSLAUGHTER AT BOSTON.

SIR,—In common, no doubt, with other members of the profession, I have anxiously awaited your publication of some farther particulars of the above case, and more especially of an account of the *post mortem* examination of the deceased. The latter appears in your issue of the 21st instant. Having compared it with the evidence previously published, I desire to make an inquiry of the professional witness for the prosecution in your columns.

I wish to make this inquiry publicly, because I conceive the matter to be of public interest. A laceration of the uterus during labour which terminates fatally, is almost always likely to lay the accoucheur in at-

tendance under some suspicion of malapraxis. Most often such a suspicion originates with ignorant or uninstructed persons; but, although the attendant may demand an inquiry in self-defence, that cannot be carried beyond its first stage of investigation, unless the charges brought be supported by expert evidence. Laceration of the uterus is an accident which occurs during labour not so unfrequently but that every accoucheur may justly apprehend it; it most often occurs spontaneously; it will, nevertheless, most likely lay him under suspicions which may perhaps be publicly avowed: and in that case he may be called upon to defend himself under the disadvantage of the adverse evidence of an accoucheur at least as competent as himself, and less directly interested in the issue. It, therefore, becomes a duty to criticise any evidence which has been given in a court of law in a case which it seems probable may at any moment become one's own.

In the instance to which I am now referring, Dr. G. M. Lowe, who was entrusted with the dissection of the deceased, and who was called by the prosecution, is reported to have given evidence on two occasions. I refer to the *Lincolnshire Chronicle*, in which paper the only detailed account has, so far as I am aware, been published. At the preliminary examination before the magistrates, Dr. Lowe is reported to have said that he did not consider the rupture existed before delivery; and, in his cross-examination, that the rupture took place during delivery, and that he believed this from the appearances found on dissection of the body. Upon this evidence, the accused was committed for trial. Dr. Lowe is said to have deposed that, in this instance, the position of the rupture was remarkable, and that it was not the result of natural causes, because it was situated below the position of the fetus *in utero*, and must have been caused by it in its exit from that organ.

Now, if there be one fact which is better ascertained of rupture of the uterus than others, I believe it to be this: that the laceration, whether the result of violence used to deliver, or of spontaneous causes, may occupy any position; but that the lower part of the uterus is the more usual position in the latter case. The most trifling reflection, indeed, serves to show that the lower part—the cervix—must be the seat of injury in a certain number of cases arising spontaneously; for one cause of laceration—and not a very uncommon one—is the nipping of a part of the cervix between the foetal head and the pelvis, either from some deformity of the latter, or an undue magnitude of the former. But the opinion above repeated may be gathered from the text-books or any monograph on the subject; and Dr. Leishman, in his recently published work, assigns to the various positions of laceration their proper order of frequency, in the sentence appositely quoted by you a week or two since.

Considering that it is perfectly well known that laceration of the uterus does frequently occur spontaneously about its neck, and that it must occur there in some instances, I supposed—and, no doubt it is so—that the evidence to which I have referred was not given but upon some very good grounds; the results involved were too serious, and the time available for consultation and research was too long, for it to be otherwise. Nevertheless, I have had the curiosity to analyse about twenty cases of rupture of the uterus during pregnancy or labour, reported to the journals during the last few years; and, though hastily gathered by running through the index of each volume, and forming but a rough test, after all, I think your readers may be interested in the result of their examination. In three cases, the position of the rupture is not noted; in one, it is left doubtful. Of sixteen remaining, the cause was traumatic in five:—1. By fall before labour; from fundus to cervix; 2. During version; posterior wall; 3. During version; anterior superior wall perforated by a foetal extremity; 4. During craniotomy; by spicula of bone; 5. During version; transverse at cervix, and a perforation by finger of midwife. In eleven cases, the rupture was spontaneous:—1. Perpendicular, several inches; 2. Transverse at neck; 3. By fright before labour; several inches long; above the os; 4. Transverse at neck; 5. Perpendicular, involving the vagina; 6. Posterior wall; fundus to cervix; 7. Middle line, involving cervix and vagina; 8. Posterior wall, to right side; 9. From a diseased patch; 10. Posterior wall, perpendicular upwards from cervix; 11. Perpendicular, anterior wall. Of three instances of laceration during version, then, in only one was the cervix involved; and then the rupture was transverse, and not, as in the unfortunate case under consideration, vertical; while, in the list of spontaneous ruptures, in six the rupture was vertical (as in the present case), and in two the vagina is said to have been implicated.

For the reasons already given, I desire to ask Dr. Lowe to afford the profession generally an opportunity of consulting the same authorities or experience which enabled him to state that a rupture, perpendicular in direction, and involving the cervix of the uterus and the vagina, occupies a remarkable position; and to share the knowledge which

enabled him to speak confidently of the cause of this laceration from its position, or from its appearance, or both, as the case may be. As I said above, these opinions, delivered after two months or more of deliberation, in a case so serious to the accused, and of so much interest to the profession in general, are, no doubt, based upon grounds, at all events, apparently sufficient. Perhaps I ought already to be acquainted with them. I am, etc.

J. ASHBURTON THOMPSON.
Islington, August 24th, 1875.

THE PENGE MURDERS.

SIR,—On July 23rd, I visited Frederick Hunt, the Penge murderer at the request of Dr. Ferguson, his medical attendant, with the view of ascertaining the condition of his mind.

The facts of the case have already been reported in the daily papers. The prisoner had been for some time before the commission of the murders in a depressed state of mind, owing to his having resigned an appointment as a clerk, and having entered upon more precarious employment as an accountant.

On the morning of March 23rd, the prisoner awoke at about three o'clock, and at about five o'clock cut the throats of his wife and child, and administered doses of laudanum and brown sugar to two other children; failing, however, to persuade his fourth child, the eldest boy, to take any of the poisonous mixture.

I examined the prisoner very carefully, with the object of testing his state of mind; and I could arrive at no other conclusion than that he was insane both at the time he committed the act and also at the time he was under my observation. I arrived at these conclusions from the following facts, which, though apparently but feeble indications of insanity when taken singly, are nevertheless very convincing proofs of mental aberration when taken altogether. Hunt stated that on March 21st he awoke at three in the morning, which had happened every morning for two or three weeks previously, and which was not his usual habit; and heard voices talking to him. He was distinctly awake at the time when these hallucinations were manifested. He denied altogether that he dreamt he heard these voices. As I had no reason to doubt that he conscientiously spoke the truth throughout the whole of our conversation, and as I do not believe that he knew how his answers to my questions would or would not tell in his favour, I can only conclude that these hallucinations and other symptoms noticed were genuine symptoms of insanity. When the idea of killing his wife presented itself to him, he was utterly unable to shake it off.

Hunt was very much attached to his wife and children, and they had never offended him in any way. There was apparently no motive whatever for the commission of the crime. At the time of the murder, he stated that he did not in any way realise the extent of the crime he was committing. He did not perceive that he was doing wrong. It appeared to him that he must murder his wife and children for their good. The idea of killing his wife made him weary of life. He could not shake it off; and, to use his own words, "the wind howled; the earth looked black; everything his children said to him seemed to be quarrelsome; and his wife would not speak to him."

He seriously contemplated committing suicide for some days before the act of murder; for he carried a bottle of laudanum about with him, with the intention of taking it, which intention was subsequently carried into effect.

He had no suspicion nor jealousy of his wife, nor of any other person. The idea of killing his wife and children came upon him suddenly upon waking. He fancied that the deed must be done, and that he could not bear to see them living before him another day.

After committing the murder, he made no attempt to escape. He was perfectly indifferent as to what would be done to him. He acknowledged covering up the bodies after the act, but denied that he was afraid of being discovered, or that he did it in any way to conceal what was done.

His memory was much affected. He could not remember what he did with the razor he used at the time of the commission of the murder; he did not remember whether or not there was a light in the room at the time of the act; whether or not there was any blood on his clothes; nor how long before the act he bought the laudanum; nor whether he had walked or ridden in a cab to the shop; nor in what part of Oxford Street the shop was situated in which he bought the laudanum.

He committed the act of murder at about 5 A.M., and left the house at 7.30; but he was unable to remember what he did in the meantime. There was no reason for believing that this defect of memory was assumed, as Hunt appeared anxious to answer all my questions conscientiously. He exhibited no remorse for what he had done, and stated that he did not at the time realise the enormity of the crime he was committing.

In addition to these facts, the family history of the prisoner indicated a strong hereditary tendency to insanity. Hunt's brother died insane, having been confined more than once in Bethlem Hospital; his sister committed suicide; and his father is considered to be an eccentric man.

Other minor circumstances in the case pointed to the same conclusion. His appetite had been uncertain for some days before the murder. At one time, he was ravenous; at another time, he abstained from food, under the delusion that he was unable to pay for a dinner. He had also suffered from a sensation in his head, as if, he said, his brain had not proper scope. His manner and aspect were those of a person about to suffer from an attack of acute mania. He had a peculiar twitching of the side of the face; and the cross wrinkles on the forehead, often noticed in the insane, were well marked.

It appeared, on inquiry, that the prisoner had always been a steady religious man, and had always held a high character amongst his neighbours and employers.

Under these circumstances, the jury without any hesitation found the prisoner not guilty on the ground of insanity, and the usual order was made as to his custody.—I am, etc., H. SUTHERLAND, M.D.

PUERPERAL FEVER.

SIR,—Following very closely, and with the greatest interest, the reports of the late discussion at the Obstetrical Society, on the Relation of Puerperal Fever to the Infective Diseases and to Pyæmia, I must confess myself still partially unsatisfied with the outcome of the same, at least, in so far as it affects the practical question between attendant and parturient. The closing epitome of Mr. Spencer Wells: "For a time, I will give up practice; I will not run the risk of damaging the patient who has entrusted her life to my care", might, at first sight, appear to be unnecessary, and as almost implying a reflection on the good sense and professional honesty of our body, were it not for the great divergencies of opinion as to pathological etiology which undoubtedly exist.

To be on the safe side, we may premise, however, that if only a large majority of those practising midwifery would, even before this discussion, have admitted the advisability of the course suggested by Mr. Wells, still the difficulty of following this course will appear to many to lie in the vagueness of the expression "For a time". What we who practise midwifery, year in and year out, wish to be assured of is not so much the advisability of abstaining "for a time", but how long a time is to be accepted as reasonably and practically satisfying the condition. It will be quite evident to all that, whether or not we grant the issue which has been raised as to what I may, perhaps, call the correlative interchangeability of the various infective diseases in the puerperal state, we must at the same time stipulate for the recognition of periods likely to be safe for the life of the patient and the honesty of the practitioner in the constantly varying round of his daily cases. In short, How long is "for a time" to be? This may involve the whole question of the life and duration of infective particles; but every day we act upon the assumption that, as regards a given individual, generator or carrier, this is limited. And I suppose there is very little reason for assuming that this limitation need to be extended as regards the puerperal woman.

When we find that medical officers of health are inclined, as I think rightly, to advise on this as on other points concerning the *salus populi*, we have a presumptive right to demand that they do not shelter themselves behind a certain ignorance lurking in the expression "for a time"; not that I wish to cavil, but where facts are found partly wanting, opinion may sometimes take their place as representing, at least, the outcome of the empirical experience of the individual or the community. Therefore, I ask through your pages that those, and they are many, eminent men who are competent to express an opinion, may come to the rescue of those "lesser lights" who have to bear the anxiety of practice and the "bitter cruelty" of reflections on their professional *bona fides* after an untoward issue.

This "bitter cruelty" is no fancy of mine, but an expression of experience, if not personal, at least nearly so. When the public mind first became exercised on this question by the prosecution of the Coventry midwife, I endeavoured to find in the text-books some definite expression of opinion on this question of time. But I found none except in Tanner's *Practice of Medicine*, where "at least three weeks" from the date of the last attendance on a "puerperal fever" case is named. I wrote to our excellent guide at Guy's, Dr. Braxton Hicks, and he most courteously replied that Dr. Lever always considered three weeks as sufficient time, and that he himself saw no reason for doubting that that would be amply sufficient for all practical purposes. Armed with this opinion from an authority of world-wide reputation, it is, to say the least, not satisfactory to be told by a clergyman that the

opinion is iniquitous and wrong according to present knowledge, and by a noble lord that he is surprised at such a time being named, as he always had understood from a medical man, now ten years dead, that three months was the least time that he would allow to elapse before going near even a *pregnant* female professionally; and that he is given to understand that "in these cases the blood is always poisoned". I presume he means that the practitioner's blood is *always* poisoned! Now, sir, add your entreaty to mine that our elders may disabuse the public mind of such a "pestilent heresy", which affects the honour and reputation of men, to whom among men the minimum of gratitude often represents the maximum of anxious service.

Doctors grow old betimes; but, if this vague danger is to hang like another Damocles' sword over every head, I, for one, will forswear the obstetric part of my craft, and never attend another parturient woman.

Your obedient servant, FREDERICK E. MANBY, F.R.C.S.Eng.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

DIPHTHERIA IN NORTH DEVON.

THE investigation of the history of local epidemics is one of the most important functions of Medical Officers of Health. If a medical inquest were held in every case of typhoid fever and diphtheria, and other of the large class of "filth-diseases", there is reason to believe that the word "preventable" would have a living meaning in the popular mind when applied to disease, such as it has not now; and by the force of innumerable examples, having all the power of domestic proof, and personal conviction, the prevalent sources of preventable disease, now regarded with supreme indifference or regarded as belonging to the dominion and sphere of activity of the expert only, would be gradually uprooted by the common consent of individuals as well as of communities. Mr. Wynter Blyth, Medical Officer of Okehampton district, makes an interesting contribution, in his recent report to the local authority, to the history of diphtheria in North Devon.

"The North of Devon appears threatened with an invasion of diphtheria; and although I am happy to say that the Okehampton Union is, so far as I know, free from this disease, I avail myself of this opportunity of giving you a connected history of diphtheria in North Devon, which I am the better able to do through the kindness of Dr. Slade-King, of Ilfracombe, who has afforded me some valuable information. Diphtheria appeared in Ilfracombe on the 21st of April, 1873. The first case was effectually isolated, and did not spread. The second case, which is said not to have been in any way dependent upon the first, occurred on the 14th of October, 1873. No information whatever was given to the sanitary officials, and, therefore, no precautions were taken. The children at the house to which the corpse was removed were all affected more or less, and they conveyed it to the private and public elementary schools, from which almost every case could subsequently be traced. 'In one case', says Dr. Slade-King, 'a child died, the room was cleansed, but not perfectly disinfected; another child came to the same room three weeks after, contracted the disease, and died. Contact in private and public elementary schools seems to have been the great cause of the spread of the disease. No adults died, very few were attacked.' There was one very curious thing noticed in Ilfracombe, and that is, that nine-tenths of the cases occurred in the high levels. I people would explain it as owing to sewer-gas floating upwards, but, as I shall shortly mention, every one of the cases in the country that I have as yet seen, also occurred on high ground. 'Isolation of the case, disinfection on a large scale, removal of delicate children to a distance from the town, and partial closure of schools, were the only precautions which seemed to reduce the spread of the disease.' 'The last death in Ilfracombe occurred on September 26th, 1874. It is at the present time, and for some time has been, perfectly free from diphtheria.' The first case of diphtheria brought under my own notice occurred at High Bickington on the 7th of April, 1873. Precautions were taken, and it did not spread. The next case I had information about was in the Bideford Union, nearly a year after, viz., at the beginning of February 1874, and on the high land around Clovelly. One or two fatal cases occurred. On April 19th, it again appeared in the Torrington Union, this time at Cott's Corner, in the parish of High Bickington, but it disappeared without spreading. On the 10th of June it was at Bickleigh, in the Bideford Union, and as no information of its presence was given to the sanitary officers until too late, it was imported from there to the new college at Westward Ho! and two or three cases occurred in the college, but the prompt action of the college authorities in separat-

ing the sick from the healthy, etc., prevented it from becoming the serious affair it would have become in any place under bad management or surrounded by unhealthy conditions. The last cases I have visited occurred in the parish of St. Giles, in the Torrington Union, where there have been one or two deaths. But whether at High Bickington, at Bickleigh, at Clovelly, or at Ilfracombe, unless it could be distinctly traced as carried by actual contact, it has occurred exclusively on lofty, airy, and open situations. I must, at the same time, say that hitherto in each case in my own district the drinking water has been undoubtedly polluted. So far, then, as I have gone, there are two fairly constant companions of diphtheria—high situations and polluted water. Subsequent observation will, perhaps show whether these are mere unimportant coincidences or not."

POOR-LAW MEDICAL APPOINTMENTS.

BAINES, Egerton C. A., M.R.C.S., appointed Medical Officer to the Nettlebed District of Henley-on-Thames Union, *vice* W. S. J. H. Munro, M.D., resigned.
 BUTLER, Edmund Fitzgerald, L.R.C.S.I., appointed Medical Officer and Public Vaccinator for the Boston District and the Workhouse of the Boston Union, *vice* W. H. Radley, M.R.C.S. Eng., resigned.
 CRAWFORD, James, M.D., appointed Medical Officer for the Manningham District of the Bradford Union, Yorkshire, *vice* E. Sugden, M.R.C.S. Eng., deceased.
 CLARK, Wm. W., M.D., appointed Medical Officer to the Workhouse and the Wellington District of the Wellington Union.
 DAVIES, John, M.D., appointed Medical Officer for the Ebbw Vale District of the Bedwely Union, *vice* Alexander Brewer, M.R.C.S. Eng., resigned.
 DAVIS, Henry H., M.R.C.S., appointed Medical Officer for the Llandysil District of the Newcastle-in-Emlyn Union, *vice* T. Jones, M.R.C.S., deceased.
 GUFFY, Thomas S., M.D., appointed Medical Officer for the Constantine District of the Falmouth Union, *vice* E. H. Ekykn, M.R.C.S., resigned.
 GRIFFITHS, D., M.B., appointed Medical Officer for the Llandiloyabont District of the Swansea Union, *vice* T. M. Jones, M.R.C.S., resigned.
 HAIR, James, M.D., appointed Medical Officer for the Eighth District of the Lenden and Winstree Union, *vice* H. D. Palmer, M.R.C.S., resigned.
 HOPE, John, M.D., appointed Medical Officer for the Chobham District of the Chertsey Union, *vice* S. M. Ward, M.B., resigned.
 THOMAS, Richard K. G., M.D., appointed Medical Officer and Public Vaccinator for the Tiverton West District of the Tiverton Union, *vice* J. Reddrop, M.R.C.S. Eng., resigned.
 WILLIAMS, David W., M.D., appointed Medical Officer to the Workhouse, Portsea Island Union, *vice* T. Diver, M.D., resigned.

OBITUARY.

EDMUND BURTON RAVENHILL, M.R.C.S., L.S.A.,
 WOLVERHAMPTON.

WE regret to announce the sudden death of this young and talented practitioner. Mr. Ravenhill was the second son of the Rev. T. H. Ravenhill, M.A., Vicar of Arlingham, Gloucestershire. He received his medical education at the Queen's College and the Queen's Hospital, Birmingham. At the College, he gained several distinctions. At the Queen's Hospital, he held in succession, each for six months, the offices of Resident Surgeon's Assistant, Resident Physician's Assistant, and Resident Obstetric Assistant, to all of which appointments he was elected after competitive examination. He became a member of the Royal College of Surgeons and a Licentiate of the Society of Apothecaries in 1870, and he was shortly afterwards elected to the house-surgeoncy of the South Staffordshire General Hospital at Wolverhampton, which post he held with credit for nearly four years. About a year ago, he engaged in private practice, and he soon afterwards married. Mr. Ravenhill had lately become subject to attacks of gastrointestinal catarrh, and his health had been much impaired by his devotion to his work. For a few days before his death, he had suffered from occasional but slight vomiting and abdominal pain, but there was nothing in his condition to cause anxiety to his relatives. He died very unexpectedly, probably from syncope, on August 23rd, in the twenty-seventh year of his age. Mr. Ravenhill had a promising career before him. His kind manner and gentle disposition had endeared him to many friends.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, August 26th, 1875.

Dobbie, Robert John Algernon, Budleigh Salterton
 Laird, John, 4, Palace Street, Piccadilly
 Lewis, Edwin Alatic, Lorraine Road, Holloway
 Oldham, Samuel, Burslem, Staffordshire
 Sargent, Arthur Francis, Lancaster Place, Belsize
 Upton, Alfred, Peiworth, Sussex
 Worswick, Frederick Henry, Hulme, Manchester

The following gentlemen also on the same day passed their primary professional examination.

Archer, Robert Kendray, Westminster Hospital
 Cox, William Laird, St. Mary's Hospital
 Creswell, William George, Queen's, Birmingham

At the recent examination for the prizes in Materia Medica and Pharmaceutical Chemistry, the successful candidates were:—1. Fredk. Freer Leslie Robertson, St. Bartholomew's Hospital, the Gold Medal; 2. Neville Scott Whitney, University College, the Silver Medal and a Book.

MEDICAL VACANCIES.

THE following vacancies are announced:—

BLACKBURN and EAST LANCASHIRE INFIRMARY—House-Surgeon. Salary, £100 per annum, with board, lodging, and washing. Applications on or before the 14th instant.
 BOURNEMOUTH GENERAL DISPENSARY—Resident Medical Officer and Secretary. Salary, £120 per annum, with furnished apartments, coals, gas, and attendance.
 BRISTOL LUNATIC ASYLUM—Assistant Medical Superintendent. Salary, £100 per annum, with furnished apartments, board, and washing. Applications on or before the 16th instant.
 CARNARVON UNION—Medical Officer for the Llandwrog District. Salary, £60 per annum.
 COLCHESTER UNION—Medical Officer for the Second District. Salary, £75 per annum.
 DISPENSARY FOR SICK CHILDREN, Manchester—Assistant Medical Officer. Salary, £180 per annum. Applications on or before September 15th.
 DUNDEE ROYAL INFIRMARY—Resident Medical Assistant. Salary, £70 per annum, with board, lodging, and washing. Applications on or before the 15th instant.
 HOSPITAL FOR SICK CHILDREN, Manchester—Assistant Physician. Salary, £300 per annum. Applications on or before September 15th.
 INVERNESS DISTRICT ASYLUM—Assistant Medical Officer. Salary, £70 per annum, with bed, board, and washing. Applications on or before the 11th prox.
 MARTLEY UNION—Medical Officer for No. 4 District. Salary, £85 per annum, and fees. Applications on or before the 9th instant.
 NORWICH DISPENSARY—Salary, £120 per annum, with unfurnished residence and apartments.
 PEMBROKE UNION—Medical Officer for the First District.
 QUEEN'S HOSPITAL, Birmingham—House-Physician. Salary, £50 per annum, with board, lodging, and washing. Applications on or before the 23rd instant.
 ROYAL SOUTH HANTS INFIRMARY—House-Surgeon. Salary, £80 per annum, with board, lodging, and washing. Applications on or before September 6th.
 ROYAL UNITED HOSPITAL, Bath—House Surgeon. Salary, £60 per annum, with board and residence. Applications on or before the 22nd instant.
 ROYSTON UNION—Medical Officer for No. 5 District. Applications on or before September 6th.
 ST. GILES-IN-THE-FIELDS and ST. GEORGE, BLOOMSBURY, Parishes—Medical Officer. Salary, £250 per annum.
 SHEPTON MALETT UNION—Medical Officer for the Fourth District. Salary, £32 per annum.
 STAINES UNION—Medical Officer for the Shepperton District.
 STROUD GENERAL HOSPITAL—House Surgeon.
 WARWICK COUNTY LUNATIC ASYLUM—Second Assistant Medical Officer. Salary, £100 per annum, with board, lodging, and washing.
 WIMBORNE and CRANBORNE UNION—Medical Officer for No. 1 and 2 District and Workhouse. Salary, £85 per annum for No. 1, and £75 for No. 2, with £20 additional for the Workhouse. Applications on or before the 23rd instant.
 WORCESTER GENERAL INFIRMARY—Physician. Applications on or before the 25th instant.
 YORK DISPENSARY—Resident Medical Officer. Salary, £130 per annum, with furnished apartments, coal, and gas. Applications on or before the 16th inst.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

FOWLER, George, M.R.C.P. Ed., appointed Physician to the North London Hospital for Consumption and Diseases of the Chest.
 *REID, Douglas A., M.D., appointed Consulting Surgeon to the Pembroke Dispensary and Infirmary.
 SHERRIN, John, M.B., appointed Assistant House-Surgeon to the Hull General Infirmary.
 WALTER, William, B.A., M.D., appointed House-Physician to the North Staffordshire Infirmary, Stoke-upon-Trent.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTH.

LYNES.—On August 26th, at 9, Priory Row, Coventry, the wife of *Edward Lynes, M.D., of a son.

DEATH.

HENRY, George, L.R.C.P. Ed., at the residence of his brother (Emerson W. Henry, M.D.), Lowther Street, Whitehaven, aged 29, on August 27th.

THE Clayton Hospital and Wakefield General Dispensary is to be removed to a new site, and £8750 has already been subscribed towards the cost of the land and new building; for which the Committee ask of the public £15,000. Amongst the subscriptions are two of £1000, and several of £500.

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.
 PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with Duplicate Copies.
 AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.
 CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.
 WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.
 COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

DR. BROUGHAM (Sheffield).—The following is the by-law on the subject. "No Fellow or member of the College of Surgeons shall advertise or publish any matter or thing prejudicial to the interests or derogatory to the honour of the College, or disgraceful to the profession of surgery; and any Fellow or member who may in any manner offend herein shall be liable to be removed, by resolution of the Council, from being a Fellow and member or member of the College." (Section xvii, par. 2.)

DOCTORS OF EDINBURGH AND ERLANGEN.

SIR,—Adverting to the letter of "M.D. Erlangen, L.R.C.P. London", in this day's issue of your admirable JOURNAL, may I be allowed to observe, in the interests of truth and justice, that the whole question of registration or recognition of foreign degrees is still in a most unsatisfactory state, and must yet be fairly adjusted? The General Medical Council, as you are well aware, promised, at its recent session, "to take into consideration whether, with a view of furthering the desire of extended accomplishment in medicine and science among the members of the medical profession, it may be advantageous to make it lawful for the Council to insert in the Medical Register (after the name of a person registered on other qualifications, etc.) the appropriate title indicative of a degree obtained after study and examination in a foreign University". Surely it cannot be supposed, in the year 1875, that "science and medicine" are restricted to the British Isles. Erlangen is proving the contrary by her *Cyclopaedia*, etc. Why, therefore, should the M.D. of Edinburgh be inserted in the Register by the Council, and that of Erlangen be ignored or rejected, in the following circumstances? "Candidates settled in foreign parts, who have complied with all the regulations for the degree of M.D. Edin., but who cannot appear personally to receive the degree, may, on satisfying the Senatus to that effect by production of official testimonials, have the degree conferred on them *in absentia*." (Statute xviii.) Now, sir, in common with Pereira, Ashwell, Lever, Waller, Brande, Davies, and several others, the degree of M.D. was conferred upon myself "in absentia", agreeably to the enlightened recognition, as I conceive, of British diplomas and "official testimonials" from Lawrence, Brodie, Cooper, Bright, Addison, Babington, etc.—in short, the best blood of "science and medicine" in this country—together with the exhibition of half a dozen published octavo volumes pertaining to physis or physical science, more than thirty years ago; and is it just that not only the *Medical Register*, but the *Medical Directory*, should be closed against the insertion of such medical degrees, and granted long before the passing of the Medical Act, whilst, in the face of fair play, or rather with open injustice to foreign graduates, physicians' licences, surgeons' diplomas, and honorary doctors' degrees, obtained in Great Britain and Ireland without personal examination, are recognised and registered by hundreds upon hundreds? Having subsequently graduated in "medicine and science" at a Prussian or Italian University, after residence and examination, the question at issue does not specially interest myself—a man, moreover, far advanced in the "sere and yellow leaf" from matter to spirit; but I think the editors of the BRITISH MEDICAL JOURNAL, pioneers of progress in science and medicine, ought in this, as in other subjects, to be the advocates of right rather than expediency, scientifically and ethically.—I am, etc.,

WILLIAM HITCHMAN, M.D.

Liverpool, August 1875.

MR. WILLIAMS.—Dr. Thomas Mayo, a former President of the College of Physicians, was the brother of Mr. Herbert Mayo of King's College.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

MEDICAL PRACTICE IN AMERICA.

SIR,—In reply to the inquiries of H. G. D. in your issue of July 24th, I may inform him (1) that neither legislators nor patients in the United States trouble themselves about the source of a medical man's diploma, there being no system of registration, nor any difference recognised between the degrees of regular, homoeopathic, "eclectic", or any other schools. Nothing but the title of "Dr.", however, is known to the American public; M.D. being the degree granted by all our colleges, and no lesser qualification existing. (2) The medical man's social status is second to none other; but, as I have already hinted, we have no distinction between pure physicians or pure surgeons and general practitioners, the whole profession standing on an equal "M.D." footing. (3) With thirty-odd medical schools turning out many hundred graduates *per annum*, the profession is decidedly overstocked in every section of which I have knowledge, though, of course, here as elsewhere, "there is always room high up".—Yours, etc.,

New York, August 4th, 1875. AN AMERICAN M.D.

BETA.—We know nothing of "goeiss" as a remedy for cancer: but our correspondent may safely put it down as utterly useless.

ARREST OF SPEECH IN AN INFANT AFTER A BLOW ON THE HEAD.

SIR,—A few days ago a patient consulted me for a skin-affection on her son, a fine little boy four years and a half old, and told me the following about him. When he was eighteen months old, he received a fall, from which he had a contusion of the skin and a small tumour in the temporal region (left side). He gradually recovered. Before the accident, he was just commencing to prattle a few simple monosyllables, but since then has not been able to speak, and has scarcely ever tried.

If any of your readers have met with a similar case, and can recommend anything to remedy the disability, I will be glad to know of it.—Yours truly, Brynmawr, August 18th, 1875. B. J. GLISSAN, Physician, etc.

GEOLOGIST.—Professor Clark of Cambridge is a son of the gentleman you mention. The Bishop of Chichester, when dining one day with George IV at Brighton, was asked by his Majesty if there was not more than one of his name at the University of Cambridge. "Yes," said his Grace, "there were three—viz., Stone-Clark, Professor of Mineralogy; Tone-Clark, Professor of Music; and Bone-Clark, Professor of Anatomy."

THE PARLIAMENTARY BILLS COMMITTEE OF THE BRITISH MEDICAL ASSOCIATION.

SIR,—At my recent visit to Edinburgh, I was much pleased to see the rapid growth made by the Association during the last few years. It has become an institution of great national importance, exercising a powerful influence on the legislature of this country, which has and will hereafter be attended with the most beneficial results. There was a subject which had been taken up with advantage by the Parliamentary Bills Committee—viz., the superannuation grants to union surgeons, to which I wish to direct attention. Much good has followed their efforts in this matter: I therefore suggest that they shall carry out the good work they have begun, and get the allowances to gaol surgeons put on a more satisfactory basis. The present Prison Regulation Act acknowledges the justice of such grants being made, but does not enforce it. The section (15) states that on a recommendation of the visiting justices, a grant "may" be allowed, etc.; but when recommendations have been made by the visiting justices, the allowances have not always been granted at the sessions or by the municipal corporate bodies—indeed, in some instances they have been refused. I would suggest that in the next Prison Regulation Bill the word "shall" be substituted for "may", which will do justice to medical men who have become incapacitated by long service or confirmed sickness, and will be equally satisfactory to visiting justices.

I hope you will see the reasonableness of the above suggestion, and induce the Parliamentary Bills Committee to use their efforts in getting it carried out.—I am, etc., A GAOL SURGEON.

* * * Our correspondent's letter will be brought under the notice of the Committee. The superannuation of Poor-law medical officers is, however, at present also permissive, and not compulsory. The Parliamentary Bills Committee have under notice certain palpable grievances of the medical officers of the Convict Service.

DR. E. HOLLAND has favoured us with a smoothly written, pleasantly versified, account of a trip which he made "From Waterley to Balloch Strand" after the Edinburgh meeting of the British Medical Association.

"When Scotland's capital—their labours o'er—
 Bid Æsculapian, fatigued, explore
 The matchless beauties of her darning land."

We are much obliged to him for the opportunity of reading his MS., and if he will inform us where to send it, it shall be restored to him.

DR. E. SLADE-KING (Ilfracombe).—1. We believe that Reynolds's *System of Medicine* will be found the most useful and complete work of the kind at present available for your purpose. 2. The Cambridge Examinations in State Medicine are readily available to all p 5sons whose names are on the *Medical Register*, and are at least twenty-four years of age. The Examination is divided into two parts. The first comprises physics; the principles of chemistry, with analysis of air and water, microscopical and chemical; the laws of heat; the principles of pneumatics, hydrostatics, and hydraulics, with especial reference to ventilation, water-supply, drainage, construction of dwellings, and sanitary engineering generally. The second part comprises the laws of the realm relating to public health; sanitary statistics; origin, propagation, pathology, and prevention of epidemic and infectious diseases; effects of overcrowding, vitiated air, impure water, and bad or insufficient food; unhealthy occupations, and the diseases to which they give rise; water-supply, and disposal of sewage and refuse nuisances injurious to health; distribution of diseases within the United Kingdom, and the effects of soil, season, and climate. We would advise our correspondent to write to Professor Liveing, University of Cambridge, for fuller information; but we can recommend, amongst other works, Parkes's *Manual of Hygiene*, Mr. Simon's *Reports to the Medical Department of the Privy Council*, Hart's or Wilson's *Manual of Public Health*, Eassie's *Sanitary Arrangements for Dwellings*, Professor Corfield's Lectures, and Dr. Meymott Tidy on the *Adulteration of Food*. Mr. Wanklyn's manuals of analysis are very valuable. Any bookseller can procure these works.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the *BRITISH MEDICAL JOURNAL*, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, no later than *Thursday*, twelve o'clock.

OFFENSIVE DISCHARGE FROM CANCER.

SIR,—In reply to Triceps, there is nothing in my experience to equal the common aqua picis, once belonging to the Dublin *Pharmacopœia*. For his purpose, let him put a teaspoonful or two of good Norway tar into a large wine-bottle, having previously filled it three-fourths full of boiling or very hot water. Shake well for a few minutes, and it is ready for use. When the water is exhausted, it may be renewed by adding fresh boiling or hot water, which may be repeated as often as the original tar serves to impregnate the fresh water strongly with its peculiar odour. It may be applied on pledgets of charpie or muslin—the thinner the fabric the better—and it may be renewed by means of a sponge, simply squeezing the sponge over the offensive surfaces; or, still better, diffuse it over the surface of the cloth or of the diseased structure, by means of an odorator. The patient can do this herself; all that is necessary is to attach an India-rubber tube—the same as an infant's feeding-bottle—which will reach the mouth of the patient. She will, by the use of this simple and inexpensive wash, keep herself and the atmosphere of the room perfectly sweet; indeed, the power of tar or oil of tar as a deodorant is simply next to magic, and is not to be equalled by any of the advertised specifics. It would not pay to advertise it; but I have used it now in carcinoma uteri and other external cancers for the past twelve or thirteen years, by injection or as above directed, and I pronounce it unsurpassable.

Messrs. Symes and Co., of 14, Hardman Street, in this town, have lately prepared for me a very elegant substitute; it is the best oil of tar rendered miscible in hot or cold water. Ten or fifteen drops or more to a pint of water make an excellent deodorant lotion, wash, injection, or enema. In the latter case, it is perfectly invaluable in wards of hospitals, as the stool is quite deodorised before its exit, and the ward is thereby kept sweet.

Symes and Co. prepare a deodorant powder, which some prepare; it is chiefly composed by whitening and oleum picis, very dilute.—I am, etc.,
LIVERPOOL, August 28th, 1875.

THOMAS SKINNER, M.D.

P.S.—As a lotion or enema, it is to be used cold or tepid. If in any way smart, dilute with water.

SIR,—In answer to your correspondent Triceps, I beg to state that I have had under my care a lady with epithelioma of the right breast for seven years, that it at one time assumed very formidable dimensions, and the odour was intolerable; but by dressing it in the following manner it has lessened in size, and, excepting when sloughing takes place, emits little or no effluvia. The part is washed with warm water, in which a few grains of permanganate of potash are dissolved, and dried with a soft rag. The strongest liquor carbolis detergens is applied with a camel-hair brush; it is then covered with unguentum carbolis detergens, spread upon lint.—Yours obediently,
FRANCIS TOULMIN.
Upper Clapton, August 31st, 1875.

SIR,—Triceps will find that a weak solution of sulphurous acid will effectually remove all the offensive smell from the discharge from the cancerous breast.—I am, sir, yours truly,
E. O., F.R.C.S.

DR. DAVY.—Glycerine was discovered by Scheele, and the late Mr. Startin is stated to have been the first to use it therapeutically.

K.—If you will send the MSS., we shall be enabled to give you an answer.

CAPSICUM IN DELIRIUM ET POTU.

SIR,—In answer to Dr. Hadley's question as to what is the mode of administering capsicum in *delirium et potu*, I would say that I have found that the best way to do so is in the form of pills; about four grains of the best powdered capsicum made up into a pill, with extract of gentian. One pill to be taken every two hours, till quietude is obtained. The more I use this drug in such cases, the more am I impressed with its great usefulness.—I am, yours faithfully,
L'HEUREUX BLENKARNE.
Buckingham, August 21st, 1875.

SIR,—Dr. Hadley will find ten minims of the tincture of capsicum taken in an ounce and a half of water before meals, or whenever depression or craving for alcohol arise, very useful. The powder may also be given in twenty or thirty grain doses, made up into a bolus with honey, and the dose repeated in three hours if it fail to procure sleep.—Yours faithfully,
HENRY M. JAY.
Chippenham, August 23rd, 1875.

A METROPOLITAN TEACHER.—It is quite true that Mr. Hancock has sat for the last time as a member of the Court of Examiners of the College of Surgeons. "Honest and true Hancock," says an esteemed correspondent, a teacher and surgeon to one of our large hospitals, "a man so thoroughly trustworthy." We believe he will for the present retain his seat at the Council.

THE PROBABILITY OF A SECOND ATTACK OF MEASLES.

SIR,—In your impressions of June 5th, 12th, and 19th, recently arrived here, I have read some letters pertaining to the above subject. Permit me to record a few facts which occurred in my own family, which will tend to show that a second or even third attack in life is by no means impossible. In the early part of 1867, my wife was attacked with well marked measles for the third time in my knowledge. The third attack occurred two days after her confinement. Her baby had measles sharply, as also our son, then aged about two years. At that time measles were epidemic in the town we were living in. In the early part of 1872, measles were again prevalent in the town we were living, and both my children had another well marked attack of measles. They are both at school now, my son going to a public school next year (owing to my absence from England, and the fact of their mother's death), and I shall view with anxiety the possibility of their exposure to a third attack.

One more remark with regard to the outbreak in 1867. Although, as I said, measles were prevalent in the town we were residing in, I may mention that in 1866, during the early months of her pregnancy, my wife, with a mother's care, nursed another of her children, who succumbed to measles. She was never, as far as I could ascertain, exposed to any contagion subsequently. Could the disease have lain dormant for so long a period as nearly seven months in her pregnant condition? This is a point which may be worthy of consideration.—Enclosing my card, I beg to remain, sir, yours truly,
F. R. C. S. Eng., R. N.
Esquimaux, British Canada, August 5th, 1875.

DR. O'FLAHERTY.—During the collegiate year ending 5th of April last, 45 candidates were admitted Fellows of the Irish College of Surgeons, 123 gentlemen received letters testimonial, and 22 licentiates obtained the diploma in midwifery.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

H. L. AND A MEMBER.—The Library and Museum of the College of Surgeons will be closed as usual during the month of September. The works of John of Arden and Gaddesden are in the Library. Write to Mr. Chatto, the obliging librarian, who will give you the information.

T. C., ABELAIDE.—The man is an arrant quack.
"Hold thy hand, health's dear maintainer;
Life, perchance, may burn the stronger;
Having substance to maintain her,
She, untouched, may last the longer.
When the artist goes about
To redress her flame, I doubt
Oftentimes he snuffs it out."—QUARLES.

GLYCERINE AND BORAX.

SIR,—I should think the chemicals used by your correspondent in his mixture must have been impure, for, in cases of aphtha, I am often in the habit of prescribing, with great success, borax and glycerine (ʒij c. ʒj), but have never observed any such explosion whilst dispensing them.—Yours, etc.,
M. R. C. P. Edin.
August 23rd, 1875.

MR. ASHBURTON THOMPSON.—We fear we should not have at command for some time the space required.

A. R. A.—Professor John Marshall, F.R.S., a member of the Council and Court of Examiners of the College of Surgeons, was elected Professor of Anatomy to the Royal Academy in 1873, in the vacancy occasioned by the death of Professor Partridge, F.R.S.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Bristol Daily Post; The Daily Bristol Times and Mirror; The Derby and Chesterfield Reporter; The Lincolnshire Herald; The Glasgow Herald; The Sunderland Daily Echo; The Carnarvon and Denbigh Herald; The Manchester Guardian; The European Review; The Hackney and Kingsland Gazette; The Worcestershire Chronicle; The Birmingham Daily Post; The Brighton Daily News; The Sussex Daily News; The Glasgow Herald; The Cork Examiner; The Scotsman; The Cork Daily Herald; The Southampton Times and Hampshire Express; The Hampshire Advertiser; The Birmingham Morning News; The Chester Courant; The Metropolitan; The Live-Stock Journal; The Shield; The Grocer; The Shipping and Mercantile Gazette; The Advertiser; The Islington Gazette; The Penrith Observer; The Hastings and St. Leonards Gazette; The Ilkley Free Press; The Leicester Daily Post; etc.

REGULATIONS

OF

THE GENERAL MEDICAL COUNCIL AND MEDICAL LICENSING BODIES.

SESSION 1875-76.*

THE GENERAL MEDICAL COUNCIL.

Recommendations and Opinions on Preliminary Examination.—Testimonials of Proficiency granted by the National Education Bodies, according to the subjoined list, may be accepted, the Council reserving the right to add to, or take from, the list. I. *Universities of the United Kingdom.* Oxford, Cambridge, Durham, and London: Examinations for Degrees in Arts. Oxford, Cambridge, and Durham: Local Examinations (Senior); Certificates to include Latin and Mathematics. Oxford: Responsions; Moderations. Cambridge: Previous Examination. Durham: Examination for Students in their Second and First years; Registration Examination for Medical Students. London: Matriculation Examination. Aberdeen, Edinburgh, Glasgow, and St. Andrew's; Examination for a Degree in Arts; Preliminary Examination for Graduation in Medicine or Surgery. Edinburgh: Examination of (Senior) Candidates for Honorary Certificates under the Local Examinations of the University of Edinburgh. Dublin: Examination for a Degree in Arts; Entrance Examination. Queen's University (Ireland): Examination for a Degree in Arts; Entrance Examination; Examination for the Diploma of Licentiate in Arts; Previous Examination for B.A. Degree. II.—*Other bodies named in Schedule (A) to the Medical Act.* Royal College of Surgeons of England: Examination conducted, under the superintendence of the College of Surgeons, by the Board of Examiners of the Royal College of Preceptors. Society of Apothecaries of London: Examination in Arts. Royal College of Physicians and Royal College of Surgeons, Edinburgh: Preliminary Examination in General Education, conducted by a Board appointed by these two Colleges combined. Faculty of Physicians and Surgeons of Glasgow: Preliminary Examination in General Literature. Royal College of Surgeons in Ireland: Preliminary Examination; Certificate to include Mathematics. Apothecaries' Hall of Ireland; Preliminary Examination in General Education. III.—*Examining Bodies in the United Kingdom, not included in Schedule (A) to the Medical Act.* Royal College of Preceptors: Examination for a First Class Certificate. The Examiners for Commissions in the Military and Naval Services of the United Kingdom; Certificate to include all the subjects required by the General Medical Council. IV.—*Colonial and Foreign Universities and Colleges.* University of Calcutta, Madras, or Bombay: Entrance Examination; Certificate to include Latin. University of McGill College, Montreal, of Toronto, of King's College, Toronto, of Queen's College, Kingston, of Victoria College, Upper Canada, of Dalhousie College and University, Halifax, of Fredericton, New Brunswick, or of Sydney: Matriculation Examination. University of King's College, Nova Scotia: Matriculation Examination; Responsions. University of Melbourne: Matriculation Examination, Certificate to include all the subjects required by the General Medical Council. Codrington College, Barbadoes: English Certificate for Students of two years' standing, specifying the subjects of Examination; Latin Certificate, or "Testamur". Tasmanian Council of Education: Examination for the Degree of Associate of Arts, Certificate to include Latin and Mathematics. Christ's College, Canterbury, New Zealand: Voluntary Examinations, Certificate to include all the subjects required by the General Medical Council. Cape of Good Hope: Third Class Certificate in Literature and Science, granted by the Board of Public Examiners. South Australian Institute, Adelaide: Preliminary General Examination.—N.B. A Degree in Arts of any University of the United Kingdom, or of the Colonies, or of such other Universities as may be specially recognised from time to time by the Medical Council, is considered a sufficient Testimonial of Proficiency. The Licensing Boards are recommended not to accept the certificate of proficiency in general (preliminary) education from any of the Bodies, the names of which are contained in the list annually circulated, unless such certificate testify that the student to whom it has been granted has been examined in—1. English Language, including Grammar and Composition.† 2. Arithmetic, including Vulgar

and Decimal Fractions; Algebra, including Simple Equations. 3. Geometry; First Two Books of Euclid. 4. Latin, including Translation and Grammar. And in one of the following *Optional Subjects*:—Greek; French; German; Natural Philosophy, including Mechanics, Hydrostatics, and Pneumatics.—Students who cannot produce any of the testimonials referred to in the first recommendation are required to pass an Examination in Arts, established by any of the bodies named in Schedule (A) to the Medical Act, and approved by the General Medical Council.—Certificates of proficiency are received from all bodies legally authorised to examine in General Education in Great Britain and Ireland, and from the several Licensing Bodies enumerated in Schedule (A) to the Medical Act in Great Britain and Ireland, shall bear evidence that the candidates have been examined and approved in at least the above subjects.—In the case of certificates received from similar educational and licensing bodies in other parts of the empire and foreign countries, satisfactory evidence shall be given to the Medical Council, or Branch Councils, that such certificates are equivalent to those recognised in the United Kingdom.

Registration of Medical Students.—Every medical student shall be registered in the manner prescribed by the General Medical Council. No medical student shall be registered until he has passed a Preliminary Examination. The commencement of the course of Professional Study recognised by any of the qualifying bodies shall not be reckoned as dating earlier than fifteen days before the date of registration.—The registration of medical students shall be placed under the charge of the Branch Registrars. Each of the Branch Registrars shall keep a Register of medical students according to a form, containing the Date of Registration, the Name, the Preliminary Examination and Date, and the Place of Medical Study.—Every person desirous of being registered as a medical student, shall apply to the Branch Registrar of the division of the United Kingdom in which he is residing, according to the annexed form,* which may be had on application to the several qualifying bodies, medical schools, and hospitals; and shall produce or forward to the Branch Registrar a certificate of his having passed a preliminary examination, as required by the General Medical Council, and a statement of his place of medical study.—The Branch Registrar shall enter the applicant's name and other particulars in the Students' Register, and shall give him a certificate of such registration.—Each of the Branch Registrars shall supply to the several qualifying bodies, medical schools, and hospitals, in that part of the United Kingdom of which he is registrar, a sufficient number of blank forms of application for registration.—The several Branch Councils shall have power to admit special exceptions to the foregoing regulations, for reasons which shall appear to them satisfactory.—A copy of the Register of Medical Students, prepared by each of the Branch Registrars, shall be transmitted, on or before December 31st in each year, to the Registrar of the General Council, who shall, as soon as possible thereafter, prepare and print an Alphabetical List of all students registered in the preceding year.—The several qualifying bodies are recommended not to admit to the final examination any candidate (not exempted from registration) whose name had not been entered in the Medical Students' Register at least four years previously.—In the case of candidates from other than schools of the United Kingdom, the Branch Councils shall have power to admit exceptions to this recommendation.

Age for License to Practise.—The age of 21 shall be the earliest age at which a candidate for any Professional License shall be admitted to his final examination; the age shall, in all instances, be duly certified; and a return of any exceptions in this recommendation allowed by the Licensing Bodies, together with the reasons for such exceptions, shall be transmitted to the Branch Council of that part of the United Kingdom in which they have been granted.—No License shall be obtained at an earlier period than after the expiration of forty-eight months subsequent to the registration of the candidate as a medical student.

in correct English on a given theme, attention being paid to spelling and punctuation as well as to composition. 2. To write a portion of an English author to dictation. 3. To explain the grammatical construction of one or two sentences. 4. To point out the grammatical errors in a sentence ungrammatically composed, and to explain their nature. 5. To give the derivation and definition of a few English words in common use. Provided always that an examination may be accepted as satisfactory that secures, on the part of the candidate passing it, a sufficient grammatical knowledge of English.

* *Form of Application for Registration as a Medical Student.*—I hereby apply to be registered as a Student in Medicine, in conformity with the Regulations of the General Council of Medical Education and Registration of the United Kingdom, for which purpose I submit the following particulars. (Name of applicant (to be written in words at length); Surname; Christian name; Preliminary examination; Date of preliminary examination; Place of medical study; Applicant's signature; Address; and Date of Application. To the Registrar of the Branch Council for—)

N.B.—The above form of Application, duly and legibly filled up, must be forwarded to the Registrar, post free, and be accompanied by a Certificate of the applicant's having passed a Preliminary Examination, as required by the General Medical Council, and a statement of his place of Medical Study.

* To save space, we omit those portions of the Recommendations of the General Medical Council and of the Regulations of the Examining Bodies, which are not of direct importance to medical students.

† The General Medical Council will not consider any examination in English sufficient that does not fully test the ability of the candidate—1. To write a few sentences

Professional Education.—The course of Professional Study required for a License shall comprehend attendance during not less than four winter sessions, or three winter and two summer sessions, at a school recognised by any of the Licensing Bodies mentioned in Schedule (A) to the Medical Act.—The following are the subjects, without a knowledge of which no candidate should be allowed to obtain a qualification entitling him to be registered:—1. Anatomy; 2. General Anatomy; 3. Physiology; 4. Chemistry; 5. Materia Medica; 6. Practical Pharmacy; 7. Medicine; 8. Surgery; 9. Midwifery; 10. Forensic Medicine. "Chemistry" should include a knowledge of the principles of Chemistry, and of those details of the science which bear on the study of Medicine. "Medicine and Surgery" should include a knowledge of Systematic and Clinical Medicine and Surgery, and also of Morbid Anatomy.

Professional Examination.—It is desirable that the different Licensing Bodies should combine their examinations, when this is practicable.—The professional examination for any License should be divided into two parts; the first embracing the primary or fundamental branches directly connected with the Practice of Medicine and Surgery; the former not to be undergone till after the close of the winter session of the second year of professional study; and the latter, or final examination, not till after the close of the prescribed period of professional study.—The examination in Physics, Botany, and Natural History may be undergone at an earlier period than the first professional examination.—The professional examinations to be conducted both in writing and orally; and that they be practical in all branches in which they admit of being so.—Excellence in one or more subjects should not be allowed to compensate for failure in others.—If a candidate be rejected for failure in any one subject, he should be re-examined in all.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

MEMBERS.

ANY person who shall have satisfied the College touching his acquirements in general Science and Literature, and his knowledge of Medicine, Surgery, and Midwifery, and who shall comply with the Bye-Laws and Regulations of the College, may be proposed to the College to be admitted a Member. (For synopsis of Regulations, see page 324.)

Every candidate who has prosecuted his studies abroad, whether in part or to the full extent required (except such as shall be exempted), shall nevertheless bring proof of his having attended, during at least twelve months, the medical practice of a hospital in the United Kingdom containing at least 100 beds.

Every candidate for the Membership of the College (except such as shall be exempted) will be required to pass the following examinations.

First Examination; Monday: *Evening*, from 7 to 10, by written questions on Anatomy and Physiology. Tuesday: *Evening*, commencing at 7 o'clock, *vis à vis*, on Dissections and Preparations.

Second Examination; Monday: *Evening*, from 7 to 10, written questions on Surgical Anatomy, and on the Principles and Practice of Surgery. Tuesday: *Morning*, Practical examination, either at the College or in the surgical wards of a Hospital. *Afternoon*, from 1 to 4, on Materia Medica, and on Chemistry in its application to Pathology, Pharmacy, and Toxicology. (This examination will be partly written and partly practical.) *Evening*, commencing at 7 o'clock, by written questions on Midwifery and the Diseases peculiar to Women. Thursday: *Evening*, *vis à vis* examination, commencing at 7 o'clock.

Third, or Pass Examination; Thursday: *Afternoon*, from 2 to 6, by written questions on Medical Anatomy and on the Principles of Medicine. Friday: *Afternoon*, from 2 to 6, by written questions on the Practice of Medicine, including the Principles of Public Health, and on Psychological Medicine. Saturday or Monday: Practical examination at the College or in the medical wards of a Hospital. Tuesday and Wednesday: Examination on *vis à vis*.

Every candidate must give fourteen days' notice in writing to the Registrar of the College, of his intention to present himself for examination, at the same time transmitting the following certificates. *For the Preliminary Examination:* Evidence of having passed an Arts Examination; and, in the case of those who shall have commenced professional studies after 1861, evidence of having previously obtained a Degree of Arts from some University of the United Kingdom, or of the Colonies, or from some other University specially recognised by the Medical Council, or that he has passed examinations equivalent to those required for a Degree in Arts; of having been duly registered as a medical student; and of having completed the second winter session of professional study at a recognised Medical School. *For the Second*

Examination: Evidence of having completed four years of professional study; of having attained the age of 21 years; of instruction and proficiency in vaccination; and of having attended not less than twenty labours. *For the Pass Examination:* Proof of having attained the age of 25 years; a testimonial from a Fellow or Member of the College; evidence of having completed the required course of professional study.

Blank forms of the required certificates of attendance on hospital practice and on lectures may be obtained on application at the College.

Third or pass examinations for the membership will be held on Thursday, October 21st, 1875, January 20th, April 20th, July 20th, and October 19th, 1876. The first and second examinations are generally held at the commencement of the same months.

LICENTIATES.

For synopsis of Regulations, see page 324.

Of the four years, one winter and two summer sessions may be passed in either of the following ways: 1. Attending the practice of a hospital or other institution recognised by the College; 2. Receiving instruction as the pupil of a legally qualified practitioner holding any public appointment which affords opportunities, satisfactory to the examiners, of imparting a practical knowledge of Medicine, Surgery, or Midwifery; 3. Attending lectures on any of the required subjects of professional study at a recognised place of instruction.

Professional studies commenced before the candidate shall have passed an examination in the subject of general education will not be recognised by the College. The course of Lectures on Botany may be attended prior to the commencement of professional studies; and any candidate producing satisfactory evidence that Botany formed one of the subjects of his preliminary examination will be exempt from attendance on this course. The Principles of Public Health must be comprised in the course of Lectures on Medicine, or in that on Forensic Medicine. The attendance on Lectures on Medicine and Surgery must not commence earlier than the second winter session; and the attendance on Lectures on Clinical Medicine and Clinical Surgery must not commence until after the first winter session.

Every candidate for the License, before he is admitted to examination, must sign a declaration, stating whether he has or has not been rejected within three months by any of the Examining Boards included in Schedule (A) to the Medical Act.

Candidates must pass the following examinations.

First Examination, on Anatomy and Physiology. First day: *Evening*, from 7 to 10, by written questions. Second day: *Evening*, commencing at 7 o'clock, *vis à vis*, on Dissections and Preparations. Second or Pass Examination. First day: *Evening*, from 7 to 10, by written questions on Surgical Anatomy, and on the Principles and Practice of Surgery. Second day: *Morning*, Practical examination at the College or in the surgical wards of a Hospital. *Afternoon*, from 1 to 4, on Materia Medica, and on Chemistry in its application to Pathology, Pharmacy, and Toxicology. (This examination will be partly written and partly practical.) *Evening*, commencing at 7 o'clock, written questions on Midwifery and the Diseases peculiar to Women. Third day: *Evening*, from 7 to 10, written questions on Medical Anatomy, and on the Principles and Practice of Medicine, including the Principles of Public Health. Fourth day: *Morning*, the candidate's practical knowledge will be tested, either at the College or in the medical wards of a Hospital. *Evening*, commencing at 7 o'clock, *vis à vis*, on Medicine, Surgery, and Midwifery.

Every candidate intending to present himself for examination is required to give fourteen days' notice in writing to the Registrar of the College, at the same time transmitting the following certificates. *For the First Examination*—Evidence of having passed an Arts examination; of having been duly registered as a medical student; and of having completed the second winter session of professional study at a recognised Medical School. *For the Second or Pass Examination*—Evidence of having completed four years of professional study; of having attained the age of 21 years; of proficiency in the practice of vaccination; and of having attended not less than twenty labours. A testimonial of moral character is required of every candidate. Blank forms of the required certificates of attendance on hospital practice and on lectures may be obtained on application at the College.

Licentiates of this College shall not compound or dispense medicines, except for patients under their own care.

Examinations of candidates for the College License will take place as follows. *First Examination*, commencing on the first Mondays of October and December, 1875, and February, April, July, October, and December, 1876. *Second or Pass Examination*, commencing on the second Mondays of the same months.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

DIPLOMA OF MEMBER.

For synopsis of Regulations, see page 324.

1. *Preliminary General Education and Examination.*—Candidates who commenced their professional education on or after the 1st of January, 1871, will be required to produce one or other of the following certificates:—1. Of graduation in Arts at an University recognised for this purpose; viz., Oxford; Cambridge; Dublin; London; Durham; Queen's University in Ireland; Edinburgh; Glasgow; Aberdeen; St. Andrew's; Calcutta; Madras; Bombay; McGill College, Montreal; and Queen's College, Kingston, Canada. 2. Of having passed an examination for Matriculation, or such other examination as shall from time to time be sanctioned by the Council of this College, at an University in the United Kingdom, or at a Colonial or Foreign University recognised by the Council of the College.* 3. Of having passed the preliminary examination for the Fellowship of this College. 4. Of having passed the preliminary examination of the Royal College of Surgeons in Ireland or of Edinburgh, or of the Faculty of Physicians and Surgeons of Glasgow. 5. Of having passed the examination in Arts of the Society of Apothecaries of London, or of the Apothecaries' Hall of Ireland. 6. Of having passed the first-class examination of the Royal College of Preceptors. 7. Testamur of the Codrington College, Barbadoes. 8. Degree of Associate of Arts granted by the Tasmanian Council of Education, with a certificate that the student has been examined in Latin and Mathematics. 9. Of having passed the voluntary examinations of Christ's College, Canterbury, New Zealand; the certificate to include all the subjects required from time to time in the Preliminary Examination of the College. Candidates who shall not be able to produce one or other of the foregoing certificates will be required to pass an examination in English, Classics, and Mathematics, conducted by the Board of Examiners of the Royal College of Preceptors, under the direction and supervision of this College.†

11. *Professional Education.*—Professional studies prior to the date at which the candidate shall have passed an examination in general know-

* The following are the Examinations at present recognised under this Clause (No. 2), viz.: Oxford—Responsions or Moderations; Local Examinations, Senior and Junior, the Certificates to include Latin and Mathematics. Cambridge—Previous Examination; Local Examinations, Senior and Junior, the Certificates to include Latin and Mathematics. Dublin—Entrance Examination. London—Matriculation Examination. Durham—Examination of Students in Arts in their second and first years; Local Examinations, Senior and Junior, the Certificates to include Latin and Mathematics; Registration Examination for Medical Students. Queen's University in Ireland—Two years' Arts Course for Diploma of Licentiate in Arts; Preliminary Examinations at end of B.A. Course; Local Examinations, the Certificates to include Latin and Mathematics; Matriculation Examinations. Edinburgh, Aberdeen, Glasgow, and St. Andrew's—Preliminary or Extra Professional Examinations for Graduation in Medicine. Calcutta, Madras, and Bombay; McGill College, Montreal; Bishop's College, Montreal; University College, Toronto; University of Trinity College, Toronto; Victoria College, Toronto; University of Laval, Quebec; King's College, Windsor, Nova Scotia; University of Fredericton, New Brunswick; Dalhousie College and University, Halifax; University of Sydney; University of the Cape of Good Hope; Bellevue Hospital Medical College, New York—Matriculation Examinations. Queen's College, Kingston—Matriculation Examination; Preliminary Examination of Students in Medicine. University of Melbourne—Matriculation Examination, with a Certificate that the Student has passed an Examination in Latin. Adelaide—South Australian Institute.

† The following are the subjects of the examination during the year; viz.—Part I. *Compulsory Subjects.* 1. Reading aloud a passage from some English author. 2. Writing from dictation. 3. English Grammar. 4. Writing a short English composition; such as a description of a place, an account of some useful or natural product, or the like. 5. Arithmetic. No candidate will be passed who does not show a competent knowledge of the first four rules, simple or compound, of Vulgar Fractions, and of Decimals. 6. Questions on the Geography of Europe, and particularly of the British Isles. 7. Questions on the outlines of English History; that is, the succession of the Sovereigns and the leading events of each reign. 8. Mathematics: Euclid, Books I and II; Algebra to Simple Equations inclusive. 9. Translation of a passage from the second book of *Cæsar's Commentaries de Bello Gallico.*—Part II. *Optional Subjects.* Papers will be set on the following six subjects; and each candidate will be required to offer himself for examination on one subject at least, at his option; but no candidate will be allowed to offer himself for examination on more than four subjects:—1. Translation of a passage from the first Book of the *Anabasis* of Xenophon. 2. Translation of a passage from X. B. Sabotini's *Picciola*. 3. Translation of a passage from Schiller's *Wilhelm Tell*. Besides these translations into English, the candidate will be required to answer questions on the grammar of each subject, whether compulsory or optional. 4. Mechanics: the questions will be chiefly of an elementary character. 5. Chemistry: the questions will be on the elementary facts of Chemistry. 6. Botany and Zoology: the questions will be on the Classification of Plants and Animals. The quality of the handwriting and the spelling will be taken into account. N.B. Each candidate (who has not already paid the amount) is required to pay a Fee of £2 on the morning of the first day of the examination, prior to his admission thereto. The next examination will be held in December. The exact dates of the examination are duly advertised when fixed in the Medical Journals; and candidates are required to send in the prescribed forms of application not less than three weeks before the commencement of each examination. A candidate, in order to qualify for the Fellowship, is required, in addition to the subjects included in Part I, to pass in Greek, French, or German; and in one, at his option, of the remaining subjects in Part II.

ledge, in conformity with the regulation in the preceding section, are not recognised.—The following will be considered as the commencement of professional education:—1. Attendance on the practice of a Hospital, or other public institution recognised by this College. 2. Instruction as the pupil of a legally qualified surgeon, holding the appointment of Surgeon to a Hospital, General Dispensary, or Union Workhouse, or where such opportunities of practical instruction are afforded as shall be satisfactory to the Council. 3. Attendance on Lectures on Anatomy, Physiology, or Chemistry, by lecturers recognised by this College. *The commencement of professional study otherwise than by attendance on lectures in recognised Medical Schools, or by attendance on the practice of recognised Hospitals, will not be admitted until a certificate thereof shall be furnished to the Secretary for registration at the College, by the practitioner whose pupil the candidate shall have become, or by the medical superintendent of the Hospital or other institution to the practice of which he shall have entered, and will date only from the reception of such certificate by the Secretary; the certificate to be accompanied by proof of having passed the preliminary examination in general knowledge.*

Blank forms of the required certificates may be obtained on application to the Secretary, and all necessary certificates will be retained at the College.

111. *Certificates, etc.*—1. Certificates will not be received on more than one branch of science from one and the same lecturer; but Anatomy and Dissections will be considered as one branch of science. 2. Certificates will not be recognised from any hospital in the United Kingdom, unless the surgeons thereto be members of one of the legally constituted Colleges of Surgeons in the United Kingdom; nor from any School of Anatomy and Physiology or Midwifery, unless the teachers in such school be members of some legally constituted College of Physicians or Surgeons in the United Kingdom; nor from any School of Surgery, unless the teachers in such school be members of one of the legally constituted Colleges of Surgeons in the United Kingdom. 3. No metropolitan hospital will be recognised by this College which contains less than 150, and no provincial or colonial hospital which contains less than 100 patients. 4. The recognition of colonial hospitals and schools is governed by the same regulations, with respect to number of patients and to courses of lectures, as apply to the recognition of provincial hospitals and schools. 5. Certificates of attendance upon the practice of a recognised provincial or colonial hospital unconnected with, or not in convenient proximity to, a recognised medical school, will not be received for more than one winter and one summer session of the hospital in attendance required; in such cases, clinical lectures will not be necessary, but a certificate of having acted as dresser for the period of at least six months will be required. 6. Certificates will not be received from candidates who have studied in London, unless they shall have registered at the College their cards of admission to attendance on lectures and hospital practice within fifteen days from the commencement of the session; nor from candidates who have studied in the provincial schools in England, unless their names shall be duly returned from their respective schools.* 7. Candidates who shall have pursued the whole of their studies in Scotland or Ireland will be admitted to examination upon the production of the certificates required respectively by the College of Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, and the College of Surgeons in Ireland, from candidates for their diploma. Candidates who shall have pursued the whole of their studies at recognised foreign or colonial universities will be admitted upon the production of the several certificates required for their degree by the authorities of such universities. 8. Members or Licentiates of any legally constituted College of Surgeons in the United Kingdom; Graduates in Surgery of any university recognised for this purpose by this College; and 9. Graduates in Medicine of any legally constituted college or university recognised for this purpose by this College, will be admitted to examination on producing their diploma, license, or degree, together with proof of being 21 years of age. In each of these cases—7, 8, and 9—the candidate will also be required to produce a certificate of instruction and proficiency in Vaccination, and satisfactory evidence of having been occupied, after having passed the preliminary examination, at least four years, or four winter and four summer sessions, in the acquirement of professional knowledge.

1V. *Professional Examinations.*—The First or Primary Examination is partly written and partly demonstrative. The Second or Pass Examination is partly written, partly oral, and partly on the practical use of surgical apparatus and the practical examination of patients. A candidate having entered his name for either the primary or the pass exami-

* At the first registration in October, candidates will be required to produce a certificate of having passed one or other of the preliminary examinations in general knowledge recognised by this College.

TABULAR VIEW OF THE REGULATIONS OF THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, AND OF THE SOCIETY OF APOTHECARIES IN LONDON.

	ROYAL COLLEGE OF PHYSICIANS OF LONDON.	ROYAL COLLEGE OF SURGEONS OF ENGLAND.	APOTHECARIES' SOCIETY.
	MEMBERS.	FELLOWS.	LICENTIATES.
AGE REQUIRED	Twenty-five.	Twenty-five.	Twenty-one.
EVIDENCE OF PRELIMINARY EDUCATION BEFORE COMMENCEMENT OF PROFESSIONAL STUDY.	A Degree in Arts of a recognised University, or evidence of having passed examinations equivalent to those for a Degree in Arts.	Degree in Arts of recognised University; or evidence of examination in Arts required for Graduation in Medicine at Universities; or to pass an examination in English, Classics, and Mathematics.	Examination in Arts by the Society's examiners; or certificate of having passed an examination in Arts recognised by the Medical Council.
DURATION OF PROFESSIONAL STUDY.	Five years, of which four must have been passed at a school or schools recognised by the College.	Six years; in the case of members of the College, two years in addition to the certificates for the diploma of member.	Three winter and two summer sessions.
COURSES OF LECTURES, ETC., REQUIRED.	Two winter sessions.	Lectures during two winters; dissections three winters.	First two winter sessions.
<i>Anatomy and Dissections.</i>	Two winter sessions.	Lectures one winter; and Practical Physiology another session.	First two winter sessions.
<i>Physiology</i>	Two winter sessions.	One course.	First winter session.
<i>Chemistry</i>	Six months.	Three months.	First summer session.
<i>Practical Chemistry</i>	Three months.	Three months.	First summer session.
<i>Materia Medica</i>	Three months.	Three months.	Three months.
<i>Practical Pharmacy</i>	Three months.	Not required.	First summer session.
<i>Botany</i>	Six months; including instruction in hospital <i>post mortem</i> room.	Lectures, three months; demonstrations in <i>post mortem</i> room of hospital, three winters and two summers.	Third winter session.
<i>Morbid Anatomy</i>	Two winter sessions.	One winter and one summer session.	Last two winter sessions.
<i>Medicine</i>	Three winter and three summer sessions, after second winter session.	One winter and one summer session.	Third winter session.
<i>Clinical Medicine</i>	Two winter sessions.	One winter session.	Not required.
<i>Surgery</i>	Two winter and two summer sessions, after second winter session.	Two winter and two summer sessions. Observation and examination of patients at least twice a week for three months.	Not required.
<i>Clinical Surgery</i>	Not required.	Three months; not less than ten labours.	Second summer session; twenty cases of labour.
<i>Practical Surgery</i>	Three months; not less than twenty labours.	Not stated.	Not stated.
<i>Miscellany and Diseases of Women.</i>	Three months.	Three months.	Second summer session.
<i>Clinical Study of Diseases of Women.</i>	Medical practice, three winters and three summers; surgical, three winters and two summers.	Surgical practice, four winters and four summers; medical practice, one winter and one summer.	Medical practice, beginning with second winter session to end of period of study.
<i>Forensic Medicine.</i>	Clinical clerk, three months; dresser, three months.	House-surgeon or dresser, six months.	Clinical clerk, six weeks at least.
<i>Hospital Practice</i>	Instruction and proficiency in Vaccination, Moral character from a Fel. or Mem.	Instruction and proficiency in Vaccination. Comparative Anatomy, one course.	Having been examined at class-exam. Instruction in vaccination, Moral conduct.
<i>Hospital Appointments</i>			

NUMBER OF EXAMINATIONS; FIRST EXAMINATION; WHEN IT MAY BE PASSED; SUBJECTS; DATES WHEN EXAMINATIONS ARE HELD.	THREE.	TWO.	TWO.	TWO.	TWO.
SECOND EXAMINATION; AT WHAT PERIOD IT MAY BE PASSED; SUBJECTS; DATES WHEN EXAMINATIONS ARE HELD.	<p>After end of second winter session. Subjects: Anatomy and Physiology.</p> <p>After four years of professional study in Surgical Anatomy and Surgery; Materia Medica; Chemistry in its application to Pathology, Pharmacy, and Toxicology; Midwifery and Diseases of Women; Examination of Surgical Patients.</p> <p>Third Examination: After completion of required course of study. Subjects: Medical Anatomy, Medicine, including Public Health and Psychology; Examination of Medical Patients.</p>	<p>After third winter session; in Anatomy and Physiology; May and November, and such other times as Council may appoint.</p> <p>After six years of professional study; in Pathology, Therapeutics, Surgery, and Medicine (Medicine not required from candidates holding approved diplomas, degrees, or licenses, or from those intending to obtain a medical qualification; in the latter case, the diploma of the College is not issued until proof of having passed the medical examination is produced). January, April, May, July, November.</p>	<p>After second winter session; in Anatomy and Physiology; January, April, May, July, November.</p> <p>After end of fourth year of professional education; in Surgical Anatomy, Surgery, and Medicine (Medicine not required from candidates holding approved diplomas, degrees, or licenses, or from those intending to obtain a medical qualification; in the latter case, the diploma of the College is not issued until proof of having passed the medical examination is produced). January, April, May, July, November.</p>	<p>After second winter session; in the <i>British Pharmacopæia</i>, Latin Prescriptions, Anatomy and Physiology, General and Practical Chemistry, Botany, and Materia Medica. Every Wed. & Th.</p> <p>At end of medical studies, in Medicine, Pathology, Therapeutics, Midwifery and Diseases of Women and Children, Forensic Medicine and Toxicology. Every Wednesday and Thursday.</p>	<p>Certificate of qualification to practise, £6 6s.; half retained in case of rejection and accounted for at subsequent examination. First examination, £3 3s., retained in case of rejection and accounted for subsequently.</p> <p>After rejection at first examination, candidate cannot be again admitted till after three months; after examination for license not till after six months.</p>
FEE PAYABLE.....	<p>£15 15s.; £5 5s. at first examination, not returned in case of rejection, but candidate admitted to one subsequent first examination without additional fee. After rejection at second examination, fee returned, minus £3 3s.</p>	<p>If a member, £5 5s. at each examination, retained in case of rejection. If not a member, £26 5s. (over and above charges for stamps), of which £5 5s. is retained in case of rejection.</p> <p>After rejection at first examination, candidates not again admitted for six months; after second examination, not till end of one year, unless Court of Examiners shall otherwise determine.</p>	<p>After rejection at primary examination, candidate must dissect for three months; after second examination, must attend Surgical Hospital Practice and Lectures on Clinical Surgery for six months.</p> <p>After rejection at primary examination, candidate must dissect for three months; after second examination, must attend Surgical Hospital Practice and Lectures on Clinical Surgery for six months.</p>	<p>£22; £5 5s. at first examination; after two failures at this examination, candidate must pay an additional £5 5s. before being again admitted to that examination. After rejection at Pass Exam., £5 5s. retained; and after two failures, an additional £5 5s.</p>	<p>Graduates in Medicine of British Universities, licentiates and members of Colleges of Physicians & Surgeons in the United Kingdom or of Apothecaries Hall in Ireland; candidates who have passed the first professional examination of other boards; candidates apprehended before August 1, 1858, or who commenced hospital attendance on or before October 1, 1861.</p>
REJECTED CANDIDATES.....	<p>After first examination, not admitted within three months; at second examination, not till end of six months. In first case, certificate of professional study in interval required; in second, hospital attendance & clinical lectures. After third examination, not readmitted (except by special permission) within one year.</p>	<p>Candidates who have passed examinations in Anatomy and Physiology of other licensing body; who have obtained Degrees in Medicine or in Surgery at a recognised University; who have passed an examination in Surgery at a College of Surgeons; Registrars of medical practitioners, with qualifications obtained before January 1st, 1861.</p>	<p>Candidates who have degrees in Arts of a recognised University in the United Kingdom are required to study for five years only. Members of College, after eight years, admitted to second examination, on production of certificate of fitness signed by three Fellows.</p>	<p>Candidates who have studied in Scotland or in Ireland, or at recognised Foreign or Colonial Universities, members or licentiates of the other Colleges of Surgeons in the United Kingdom, and Graduates in Medicine or Surgery of a recognised University.</p>	<p>Graduates in Medicine of British Universities, licentiates and members of Colleges of Physicians & Surgeons in the United Kingdom or of Apothecaries Hall in Ireland; candidates who have passed the first professional examination of other boards; candidates apprehended before August 1, 1858, or who commenced hospital attendance on or before October 1, 1861.</p>
CANDIDATES EXEMPTED FROM CERTAIN PORTIONS OF THE EXAMINATIONS OR ADMITTED UNDER SPECIAL REGULATIONS.	<p>Candidates who have passed examinations in Anatomy and Physiology of any other licensing body; who have obtained Degrees in Surgery, or have passed examination in Surgery of a College of Surgeons; or who have obtained degrees in Medicine; or who are above forty years of age, provided in each case that the evidence and testimonials are satisfactory to the censors.</p>	<p>Candidates who have passed examinations in Anatomy and Physiology of other licensing body; who have obtained Degrees in Medicine or in Surgery at a recognised University; who have passed an examination in Surgery at a College of Surgeons; Registrars of medical practitioners, with qualifications obtained before January 1st, 1861.</p>	<p>Candidates who have degrees in Arts of a recognised University in the United Kingdom are required to study for five years only. Members of College, after eight years, admitted to second examination, on production of certificate of fitness signed by three Fellows.</p>	<p>Candidates who have studied in Scotland or in Ireland, or at recognised Foreign or Colonial Universities, members or licentiates of the other Colleges of Surgeons in the United Kingdom, and Graduates in Medicine or Surgery of a recognised University.</p>	<p>Graduates in Medicine of British Universities, licentiates and members of Colleges of Physicians & Surgeons in the United Kingdom or of Apothecaries Hall in Ireland; candidates who have passed the first professional examination of other boards; candidates apprehended before August 1, 1858, or who commenced hospital attendance on or before October 1, 1861.</p>

nation, who shall fail to attend the meeting of the Court for which he shall have received a card, cannot present himself for examination within three months afterwards.

DIPLOMA OF FELLOW.

For synopsis of Regulations, see page 324.

SOCIETY OF APOTHECARIES, LONDON.

For synopsis of Regulations, see page 324.

No certificates of lectures or of anatomical instruction delivered in private to particular students, apart from the ordinary classes of recognised public medical schools, can be received by the Court of Examiners.—All students are required personally to register the several tickets of admission to lectures and medical practice within the first fifteen days of the months of October and May.

Examination in Arts.—Examinations in the subjects of preliminary education will be held at the Hall of the Society on Friday and Saturday, January 29th and 30th, April 23rd and 24th, September 24th and 25th, 1875.—Candidates will be examined in the following branches; and no candidate will be approved unless he show a competent knowledge of each branch:—1. The English Language; 2. The Latin Language; 3. Mathematics; 4. One of the following subjects, at the option of the candidate: (a) Greek; (b) French; (c) German; (d) Natural Philosophy.* Candidates applying to be admitted to any examination must pay the fee (One Guinea) at least one week before the examination; and must sign their names in the candidates' book between 10 A.M. and 4 P.M., not later than the previous Thursday. If a candidate fail to pass the examination, the fee will not be returned to him; but he will be admissible to either or both of the two next following examinations in Arts without the payment of an additional fee, upon giving the usual notice, and signing the candidates' book. Certificates in Arts granted by any of the bodies whose certificate is recognised by the Medical Council will be accepted as equivalent to having passed the above examination.

Professional Examinations.—The Court meets every Wednesday and Thursday; and candidates are required to attend at 4.30 P.M. each day. Every candidate intending to offer himself for examination must give notice on or before the Monday previous to the day of examination, and must at the same time deposit all the required testimonials, with the fee, at the office of the beadle, where attendance is given every day, except Sunday, from 10 to 4 o'clock; Saturdays, 10 to 2.

The examination of candidates for the License is divided into two parts, and is conducted partly in writing (on Wednesday), and partly *visà voce* (on Thursday).

Modified Examinations.—1. All Graduates in Medicine of British Universities will be admitted to a clinical and practical examination in the practice of Medicine and Midwifery. 2. Licentiates of the Royal College of Physicians of London or of Edinburgh; of the Royal Colleges of Physicians and Surgeons, Edinburgh; of the King and Queen's College of Physicians, Ireland; or of the Faculty of Physicians and Surgeons, Glasgow; and of the Apothecaries' Hall, Dublin, will be admitted to a clinical and practical examination in the Practice of Medicine, Midwifery, Forensic Medicine, and Toxicology. 3. Any candidate who has passed his first examination for the License of either of the Colleges of Physicians in the United Kingdom, or of the Colleges of Physicians and Surgeons of Edinburgh jointly, or of the Faculty of Physicians and Surgeons, Glasgow, or of the Apothecaries' Hall of Dublin; the first professional examination for the Degree of M.B., or Master in Surgery in the Universities of Oxford, Cambridge, or London; or the second part of the professional examination for the Degree of M.D., or Master in Surgery in the Universities of Edinburgh, Aberdeen, St. Andrew's, and Glasgow; or the first examination for medical and surgical degrees in the Irish Universities, will be admitted to a single examination in Anatomy and Materia Medica (to those candi-

* The following is the Syllabus of Subjects for Examination in 1876. 1. The English Language. The leading features of its History. Its Structure and Grammar. English Composition.—2. The Latin Language. January Examination: Virgil, *Æneid*, Book IV. April Examination: Horace, *Odes*, Book I. September Examination: Cicero, *De Senectute*. Re-translation of easy sentences. Grammatical Questions will be introduced into the Latin Paper, and each Candidate will be expected to give satisfactory answers to these.—3. Mathematics: The Ordinary Rules of Arithmetic; Vulgar and Decimal Fractions; Addition, Subtraction, Multiplication, and Division of Algebraical Quantities; Simple Equations; The First Two Books of Euclid.—4. (a) Greek: Xenophon, *Anabasis*, Books I and II; Grammatical Questions. (b) French: Molière, *L'Avare*; Translation from English into French; Grammatical Questions. (c) German: Fougère, *Undine*; Translation from English into German; Grammatical Questions. (d) Natural Philosophy: Mechanics, Hydrostatics, and Pneumatics. [The Books recommended for study in this subject are Smith's *Statics* and Smith's *Hydrostatics* (Rivington and Co.), or Newell's *Natural Philosophy*.]

dates who have not undergone an examination in those subjects), Practice of Medicine, Pathology, Therapeutics, Midwifery, Forensic Medicine, and Toxicology, which examination will be partly written and partly *visà voce*. 4. Members of the Royal College of Surgeons, England; Licentiates of the Royal College of Surgeons, Edinburgh; and Licentiates of the Royal College of Surgeons, Ireland; and all candidates who have passed the first Anatomical examination of the Royal College of Surgeons, London; the Royal College of Surgeons, Edinburgh; the Royal College of Surgeons, Ireland, are exempt from writing on Anatomy and Physiology only in their first examination. 5. Candidates who were apprenticed before August 1st, 1858, and those students who commenced their hospital attendance on or before October 1st, 1861, will be admitted to a *visà voce* examination on the following subjects: In translating physicians' prescriptions, in such parts of Chemistry and Materia Medica as bear upon the Practice of Medicine, and on Toxicology, in Forensic Medicine, Visceral Anatomy, the Practice of Medicine, including Diseases of Women and Children, and in Midwifery.

All candidates, unless registered, will be required to produce their diplomas.

No rejected candidate for the License can be re-examined until the expiration of six months from his former examination. A candidate rejected on his first professional examination can be admitted to re-examination after three months; and no rejected candidate as an assistant until the expiration of three months.

Prizes.—The Society of Apothecaries annually offer two prizes for proficiency in the knowledge of Botany, and two prizes for proficiency in the knowledge of Materia Medica and Pharmaceutical Chemistry. The prizes consist of a gold medal awarded to the candidate who distinguishes himself the most; and of a silver medal and a book to the candidate who does so in the next degree. The examination in Botany will be held at the Hall of the Society on the third Thursday in June, at 10 A.M., and will be conducted by printed papers and *visà voce* questions. The examinations in Materia Medica and Pharmaceutical Chemistry will be held at the Hall of the Society on the third Wednesday in August, at ten A.M., and will be conducted by printed papers and *visà voce* questions.

The Society's Botanic Garden at Chelsea is open daily (except Sundays) from 10 A.M. to 5 P.M. Tickets of Admission may be had on application at the beadle's office at the Hall.

UNIVERSITY OF OXFORD.

DEGREES IN MEDICINE.

EVERY student must reside either in one of the Colleges or Halls, or in a Licensed Lodging-House, for three years. During these three years, he has to pass two examinations in Arts and one in either Mathematics, Natural Science, or Law and Modern History; when, if he obtain a first, second, or third class, he can take his B.A. degree; if he do not gain such honours, he has to pass a third examination in *Literis Humanioribus*. A student deciding to graduate in medicine must, after passing the requisite examination for the degree of B.A., spend two years in study prior to a scientific examination for the degree of Bachelor of Medicine, unless he shall have taken a first or second class in the natural science school, when he may go in at the first opportunity for the first M.B. Examination. Two years after passing this examination, and after four years of professional and scientific study, he may go in for the second or practical examination for the M.B. degree. These four years of medical study may be spent either in or out of Oxford, in an approved medical school.

The M.B. Degree confers the License to Practise. For the Degree of Doctor in Medicine, a dissertation has to be publicly read three years after taking the M.B. Degree.

The medical examinations take place annually in Michaelmas Term. Scholarships of about the value of £75 are obtainable at Christ Church, Magdalen, and other Colleges, by competitive examination in natural science. Every year a Radcliffe Travelling Fellowship is competed for by anyone who, having taken a first-class in any of the Public Examinations of the University, or having obtained some University Prize or Scholarship open to general competition, proposes to study medicine. The Travelling Fellows receive £200 a-year for three years, half this period being spent in study abroad.

UNIVERSITY OF CAMBRIDGE.

BACHELOR OF MEDICINE.

A STUDENT proceeding to this degree must—(1) Reside in the University two-thirds of each of nine terms; (2) Pass the previous examina-

tion, which may be done in the first or second term of residence; or he may pass an examination equivalent to previous examination under the Oxford and Cambridge Schools Examination Board before he comes into residence; (3) Pursue medical study for five years, unless he have obtained honours in the Mathematical, Classical, Moral Sciences, or Natural Sciences Tripos, in which case only four years are required.

There are three examinations for the degree of Bachelor of Medicine, conducted partly by written answers, and partly *viva voce*. The examinations include chemical analysis, practical histology, the recognition and description of specimens (healthy, morbid, and microscopical), dissections, and the examination of patients.

The subjects of the first examination are—1, Mechanics and Hydrostatics; 2, Chemistry, with Heat and Electricity; 3, Botany. The student may present himself for this examination at any time after passing the previous examination. He must produce certificates of having diligently attended one course of lectures on Chemistry, including manipulation and one course on Botany.

The subjects of the second examination are—1, Elements of Comparative Anatomy; 2, Human Anatomy and Physiology; 3, Pharmacology. Before presenting himself for this examination, the student must have completed two years of medical study. He must have attended hospital practice during one year, have practised dissection during one season, and must produce certificates of having diligently attended a course of lectures on each of the following subjects: 1, Elements of Comparative Anatomy; 2, Human Anatomy and Physiology; 3, Materia Medica and Pharmacy; 4, Pathology.

The subjects of the third examination are—1, Pathology and the Practice of Physic (two papers, including questions in Surgery and Midwifery); 2, Clinical Medicine; 3, Medical Jurisprudence.—Before presenting himself for this examination, the student must have completed the course of medical study, must have attended hospital practice during three years, and must produce certificates of having attended one course of lectures on each of the following subjects: 1, Principles and Practice of Physic; 2, Clinical Medicine; 3, Clinical Surgery; 4, Medical Jurisprudence; 5, Midwifery: also of having been clinical clerk for six months at least at a recognised hospital: or of having, subsequently to the completion of his attendance on hospital practice, attended to practical medicine, with special charge of patients in a hospital, dispensary, or parochial union, under superintendence of a qualified practitioner, unless he himself be duly qualified.

After these examinations have been passed, an Act must be kept in the schools. The candidate reads a thesis, composed by himself, on some subject approved by the Regius Professor of Physic; the professor brings forward arguments or objections for the candidate to answer, and examines him *viva voce* as well on questions connected with his thesis as on other subjects in the faculty of a more general nature. The exercise must continue at least one hour.

DOCTOR OF MEDICINE.

This may be taken by a Bachelor of Medicine in the ninth term after his inauguration. He is required to produce certificates of having been engaged five years in medical study, to keep an Act similar to that for M.B., and write an extempore essay. He pays ten guineas for the Act.—A Master of Arts may proceed to the degree of M.D. in the twelfth term after his inauguration as M.A., without having taken the degree of M.B. He must pass the three examinations for M.B., and keep the Act for the M.D. degree. He must produce certificates of having been engaged five years in medical study, and the same certificates of attendance on lectures and hospital practice are required as of the candidate for the degree of M.B.

MASTER OF SURGERY.

The subjects of the examination for this degree are—1, Surgical Anatomy; 2, Pathology and the Principles and Practice of Surgery; 3, Clinical Surgery; 4, Midwifery.—Before admission to his examination, the candidate must have passed all the examinations for the degree of M.B., and must produce certificates of having attended the surgical practice of a hospital for three years, of having been house-surgeon or dresser for six months, and of having attended—1, a second course of lectures on Human Anatomy; 2, one course of lectures on the Principles and Practice of Surgery; 3, lectures on Clinical Surgery during one year; 4, ten cases of Midwifery; 5, of having practised Dissection during a second season.—The examination takes place at the same time as those for M.B., and in a similar manner. The candidate is required to perform operations on the dead body, and to examine patients in the hospital.

UNIVERSITY OF LONDON.

DEGREES IN MEDICINE AND SURGERY.

THE following Examinations for Degrees in Medicine will be held in the University of London in 1876. They will commence on the following days.

Preliminary Scientific Examination: Monday, July 19th.

Bachelor of Medicine (M.B.) First Examination: Monday, July 26th.

Bachelor of Medicine (M.B.) Second Examination: Monday, November 1st.

Bachelor of Surgery (B.S.): Tuesday, November 23rd.

Master in Surgery (M.S.) and Doctor of Medicine (M.D.): Monday, November 22nd.

The certificates in each case must be transmitted to the Registrar at least fourteen days before the commencement of the examination.

The fee for each examination is Five Pounds.* If a candidate withdraw or fail to pass either of the examinations, the fee is not returned; but he is admitted without further payment to two subsequent preliminary scientific, first M.B., second M.B., or B.S. examinations, or to one subsequent M.S. or M.D. examination, provided that he give notice to the Registrar at least fourteen days before the commencement of the examination.

BACHELOR OF MEDICINE.

Every candidate for the degree of Bachelor of Medicine is required—
—1. To have passed the Matriculation Examination, or to have taken a degree in Arts in one of the Universities of Sydney, Melbourne, Calcutta, or Madras (provided that Latin has been one of the subjects in which he has passed). 2. To have passed the preliminary Scientific Examination.† 3. To have been engaged in his professional studies during four years subsequently to matriculation or graduation in Arts in one or more of the medical institutions or schools recognised by this University; one year, at least, of the four to have been spent in one or more of the recognised institutions or schools in the United Kingdom. 4. To pass two examinations in Medicine.

First M.B. Examination.—The candidate must have passed the preliminary scientific examination at least one year previously, and must produce certificates—1. Of having completed his nineteenth year. 2. Of having been a student during two years at one or more of the medical institutions or schools recognised by this University; and of having attended a course of lectures on each of the three following subjects: Descriptive and Surgical Anatomy; General Anatomy and Physiology; Comparative Anatomy; Pathological Anatomy; Materia Medica and Pharmacy; General Pathology; General Therapeutics; Forensic Medicine; Hygiene; Obstetric Medicine and Diseases peculiar to Women and Infants; Surgery; Medicine.‡ 3. Of having dissected during two winter sessions. 4. Of having attended a course of Practical Chemistry. 5. Of having attended to Practical Pharmacy, and having acquired a practical knowledge of the preparation of medicines. Candidates are examined in Anatomy; Physiology; § Materia Medica and Pharmaceutical Chemistry; Organic Chemistry. Candidates must show a competent knowledge in all the subjects. The examinations are conducted by printed papers and *viva voce* interrogation, by demonstration from preparations and specimens, and by dissections.

Examination for Honours.—Any candidate who has been placed in the first division may be examined for Honours in (1) Anatomy, (2) Physiology, Histology, and Comparative Anatomy; and (3) Materia Medica and Pharmaceutical Chemistry, and Organic Chemistry. If, in the opinion of the examiners, sufficient merit be evinced, the candidate who distinguishes himself most in each of these three divisions receives

* For the degree of Doctor of Medicine, the fee will continue to be Ten Pounds to all such as, having taken their M.B. degree under the former regulations, shall not have paid the fee of Five Pounds at the Preliminary Scientific Examination.

† Candidates for the Degree of M.B. are strongly recommended by the Senate to pass the Preliminary Scientific Examination before commencing their regular medical studies. For the Preliminary Scientific Examination, candidates are examined in Mechanical and Natural Philosophy; Inorganic Chemistry; Botany and Vegetable Physiology; Zoology. They must show a competent knowledge in all the subjects of examination, and in Practical Chemistry. Candidates who matriculated previously to January 1861, are not required to pass the Preliminary Scientific Examination in any other subjects than Chemistry and Botany; and they may pass the Preliminary Scientific Examination and the First M.B. Examination in the same year, if they so prefer.

‡ The subjects numbered 2, 3, and 4, must be attended after passing the Matriculation Examination, or taking a Degree in Arts.

§ Any candidate is allowed, if he so prefer, to postpone his examination in Physiology from the First M.B. Examination at which he presents himself for examination in the remaining subjects until the First M.B. Examination in the next or any subsequent year; but such candidate is not admitted to compete for honours on either occasion; and he cannot be admitted as a candidate at the Second M.B. Examination until after the lapse of at least twelve months after having passed his examination in Physiology.

an exhibition of £40 *per annum* for the next two years, payable in quarterly instalments; provided that, on receiving each instalment, he declare his intention of presenting himself at the second M.B. examination within three years from the time of passing the first M.B. examination. Under the same circumstances, the first and second candidates in each subject receive each a Gold Medal of the value of five pounds.

Second M.B. Examination.*—No candidate is admitted to this examination within two academic years of the time of his passing the first examination, nor without certificates:—1. Of having passed the first M.B. examination. 2. Of having subsequently attended a course of lectures on each of two of the subjects for which he had not presented certificates at the first examination. 3. Of having conducted at least twenty labours.† 4 and 5. Of having attended the Surgical and the Medical Practice of a recognised Hospital or Hospitals during two years, with Clinical Instruction and Lectures on Clinical Surgery and Clinical Medicine.‡ 6. Of having, subsequently to the completion of his attendance on surgical and medical hospital practice, attended to Practical Medicine, Surgery, and Midwifery, with special charge of patients, in a hospital, Infirmary, Dispensary, or Parochial Union, during six months. 7. Of having acquired proficiency in vaccination.§ The candidate must also produce a certificate of moral character from a teacher in the last school or institution at which he has studied, as far as the teacher's opportunity of knowledge has extended. Candidates are examined in General Pathology, General Therapeutics, and Hygiene; Surgery; Medicine; Midwifery; Forensic Medicine. The examinations include questions in Surgical and Medical Anatomy, Pathological Anatomy, and Pathological Chemistry. The examinations are conducted by printed papers and *visd voce* interrogations; by practical examinations in obstetric preparations and apparatus; by examination, and report on cases, of medical patients in the wards of a hospital; demonstrations from specimens and preparation. Candidates are expected to write prescriptions in Latin, without abbreviations.

Bachelors of Medicine of the University of London have no right, as such, to assume the title of Doctor of Medicine.

Examination for Honours.—Any candidate who has been placed in the first division may be examined for Honours in (1) Medicine, (2) Obstetric Medicine, and (3) Forensic Medicine. If, in the opinion of the examiners, sufficient merit be evinced, the candidate who distinguishes himself the most in Medicine receives £50 *per annum* for the next two years, with the style of University Scholar in Medicine; and the candidates who distinguish themselves the most in Obstetric Medicine and in Forensic Medicine receive each £30 *per annum* for the next two years, with the style of University Scholar in Obstetric Medicine and in Forensic Medicine respectively. The first and second candidates in each of the preceding subjects each receive a Gold Medal, value £5.

BACHELOR OF SURGERY.

The candidates must produce certificates—1. Of having taken the degree of Bachelor of Medicine in this University. 2. Of having attended a course of instruction in Operative Surgery, and of having operated on the dead subject. The examinations are conducted by printed papers on surgical anatomy and surgical operations; by examination and report on cases of surgical patients; by performance of operations upon the dead subject; by application of surgical apparatus; and by *visd voce* interrogation.

Examination for Honours.—Any candidate who has been placed in the first division at the examination may be examined for Honours in Surgery. If, in the opinion of the examiners, sufficient merit be evinced, the candidate who distinguishes himself the most receives £50 *per annum* for the next two years, with the style of University Scholar in Surgery; and the first and second candidates each receive a Gold Medal of the value of five pounds.

MASTER IN SURGERY.

The candidate must produce certificates—1. Of having taken the

* Any candidate for the Second M.B. Examination who has passed the First M.B. Examination under the former regulations, is required to have also passed the Examination in Physiology at some previous First M.B. Examination carried on under the present regulations; at which examination he is not allowed to compete for honours.

† Certificates will be received from any legally qualified practitioner.
‡ The student's attendance on the Surgical and on the Medical Hospital Practice specified in Regulations 4 and 5, may commence at any date after his passing the Preliminary Scientific Examination, and may be comprised either within the same or within different years; provided that in every case his attendance on Hospital Practice be continued for at least eighteen months subsequently to his passing the First M.B. Examination. Attendance during three months in the wards of a Lunatic Asylum recognised by the University, with clinical instruction, may be substituted for a like period of attendance on medical hospital practice.

§ Certificates on this subject will be received only from the authorised vaccinators appointed by the Privy Council.

degree of Bachelor of Surgery* in this University. 2. Of having attended subsequently—(a) to Clinical or Practical Surgery during two years in a hospital or medical institution recognised by this University; (b) or to Clinical or Practical Surgery during one year in a recognised hospital or medical institution, and of having been engaged during three years in the practice of his profession; (c) or of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Surgery in this University.† 3. Of moral character, signed by two persons of respectability. The examination is conducted by means of printed papers and *visd voce* interrogation; and the candidates are examined in Logic and Moral Philosophy,‡ and in Surgery. If, in the opinion of the examiners, sufficient merit be evinced, the candidate who distinguishes himself the most at this examination receives a Gold Medal of the value of twenty pounds.

DOCTOR OF MEDICINE.

The candidate must produce certificates analogous to those required for candidates for the degree of Master in Surgery, but having special relation to Medicine. The examination is conducted by printed papers and *visd voce* interrogations; and candidates are examined in Logic and Moral Philosophy, and in Medicine. If, in the opinion of the examiners, sufficient merit be evinced, the candidate who distinguishes himself the most at this examination receives a Gold Medal of the value of twenty pounds.

UNIVERSITY OF DURHAM.

EVERY student in medicine must have been registered; and no one shall be registered unless he have passed the Registration Examination or such other examination as the Warden and Senate shall deem equivalent. The Registration Examination is directed to the rudiments of Religion, Literature, and Science; and is conducted by two or more examiners nominated by the Warden. The Registration Examinations will begin on September 14th, 1875, and April 18th and September 19th, 1876.§ The following Examinations are also accepted as qualifications for registration: Durham Senior Examination of persons not members of the University of Durham; || Durham Examination for Students of Arts in their first year. The Examinations for Licenses and Degrees in Medicine and Surgery are conducted in Newcastle. The first examination is held in April; the final examination in June.

LICENSE IN MEDICINE.

The candidate must be of the age of 21 years, and must, since his registration, have spent four years in medical study at one or more of the schools recognised by the Licensing Bodies named in Schedule (A) of the Medical Act. One at least of the four years must be spent at the College of Medicine at Newcastle-on-Tyne. There are two public examinations: the first, in Anatomy, Physiology, and Chemistry, after two years at least of medical study; the second after four years at least of medical study. Candidates must produce satisfactory testimonials of conduct, and such certificates of attendance on lectures and hospital practice as the Warden and Senate shall require.

BACHELOR OF MEDICINE.

The candidate must be of the standing of three terms at least as a Licentiate of Medicine, and of eighteen terms (six years) at least from

* Candidates who have obtained the degree of Bachelor of Medicine previously to 1866, will be admitted to the examination for the degree of Master in Surgery without having taken the degree of Bachelor of Surgery; and in the case of such candidates, the attendance on surgical practice required by regulation 2, may commence from the date of the M.B. Degree.

† One year of attendance on Clinical or Practical Surgery, or two years of practice, will be dispensed with in the case of those candidates who at the B.S. Examination have been placed in the first division.

‡ Any candidate who has taken the degree either of B.A., B.Sc., or M.D. in this University, is exempted from this part of the examination; and any candidate who has passed the Second M.B. Examination, may at any subsequent M.S. Examination present himself for Logic and Moral Philosophy alone, if he so prefer; thereby gaining exemption, if he should pass, from examination in that subject when he presents himself to be examined for the degree of Master in Surgery.—An analogous exemption is allowed in the case of candidates for the degree of M.D.

§ The following are the subjects for examination. The History contained in the Acts of the Apostles.—English Grammar and Composition.—Arithmetic, including Vulgar and Decimal Fractions; Algebra, including Simple Equations.—Euclid, Books I and II.—Latin Grammar, with—In April, Casar, *De Bello Gallico*, Lib. I and II.—In September, Virgil, *Æneid*, Lib. I and II.—Also one at least of the following: Greek Grammar, with Xenophon's *Memorabilia*.—French Grammar, with Voltaire's *Charles VII.*—German Grammar, with Goethe's *Dichtung und Wahrheit*, Book I.—Elementary Questions in Mechanics, Hydrostatics, and Pneumatics. Candidates must specify on which of the optional subjects they intend to be examined, one month before the examination.

The subjects of examination are:—Latin; Algebra (including Simple Equations); Euclid (Books I and II); and one of the following subjects—Greek; French; German; and Mechanics, Hydrostatics, and Pneumatics.

the date of registration or matriculation. He must have obtained a Degree in Arts of the University of Durham, or have passed the final examination for the Degree of Bachelor of Arts, or an equivalent to it; and must have passed the examination for the Degree of Bachelor of Medicine. The candidate must write an Essay on some medical subject, selected by himself and approved by the Professor of Medicine, and pass an examination thereon, including the collateral medical branches involved in the subject of the Essay.

DOCTOR OF MEDICINE.

The candidate must be of the standing of three terms at least as a Bachelor of Medicine in the University, and of the standing of twenty-one terms (seven years) from his registration or matriculation; and must have passed the examination for the Degree of Doctor of Medicine, which is similar to that for the Degree of Bachelor.

LICENSE IN SURGERY.

The regulations are similar to those for the License in Medicine; but the second examination is directed more particularly to Surgery, and may be passed at the same time with the final examination for a License in Medicine.

MASTER IN SURGERY.

The candidate must be a Licentiate in Surgery and in Medicine, and of the standing of eighteen terms (six years) at least from the date of his registration or matriculation, and of three terms at least from the date of his admission to the License in Surgery.—[In other respects, the regulations for this degree are analogous to those for that of Bachelor of Medicine.] The examination for this degree is directed chiefly to the Practice of Surgery.

Candidates for the Degrees of Master in Surgery, Bachelor of Medicine, and Doctor of Medicine, must reside and pursue the Arts course for three terms, either in Durham or at Newcastle, in addition to the four years of medical study.

Fees for Examinations and Degrees.—Senior Middle-Class Examination, £1; Examination at the end of First Year, £1; Registration Examination, £1; Extraordinary Registration Examination, £2; Registration, 5s.; each Public Examination in Medicine and in Surgery, £1; License in Medicine or in Surgery, £3; Degree of Master in Surgery, Bachelor in Medicine, or Doctor in Medicine, each £6.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

REGULATIONS FOR THE LICENSE.

No one can obtain the License of the College under the age of 21 years. Every applicant must produce satisfactory evidence of having been engaged in the study of Medicine during at least four years subsequently to registration as a student, and of having attended the following courses at an University, or at a medical school recognised by the College:—Anatomy, Practical Anatomy, Chemistry, Practice of Medicine, Clinical Medicine, and Principles and Practice of Surgery, each a six months' course; Practical Chemistry, Materia Medica and Pharmacy, Physiology or Institutes of Medicine, Clinical Surgery, Midwifery, Medical Jurisprudence, General Pathology, or Pathological Anatomy, and Practical Pharmacy, each a three months' course. He must have attended the practice of a Public Hospital (containing not fewer than eighty beds) during not less than twenty-four months, twelve of which must have been spent in attendance on the medical wards. He must also have attended for six months the practice of a public dispensary, or have acted for six months as clinical clerk or dresser in a hospital; or have been engaged during six months as visiting assistant to a registered practitioner. He must also have attended at least six cases of labour under the superintendence of a qualified medical practitioner, and have studied vaccination under a competent and recognised teacher. He must have passed the Preliminary Examination in Literature and Science,* and had his name inscribed in the General Medical Council's Register of Medical Students, previously to the commencement of his Medical Studies. Masters and Bachelors of Arts of any British or Foreign University, whose course of study may be approved of by the College, will be exempted from the preliminary examination; also those who have passed the examination of the national educational bodies, or any of the licensing boards recognised by the Medical Act.

The Professional Examination will be divided into two parts: (1) Anatomy, Physiology, Chemistry; (2) Materia Medica and Pharmacy, Pathology and Pathological Anatomy, Practice of Medicine, Midwifery, Medical Jurisprudence, Clinical Medicine. No candidate will be admitted to the first examination until he has completed two, or to the second until he has completed four, years of professional study. The

preliminary examinations are held in April, July, and October; the professional examinations in January, April, July, and October.

Candidates who already possess a qualification from a recognised Licensing Body, or who have passed the first professional examination before a qualifying body (provided it be as extensive as that required by this College), will be at once admitted to the second examination.

No candidate is admissible to examination who has been rejected by any other licensing board within the previous three months.

The Fee payable by a Licentiate is Ten Guineas. If a candidate be unsuccessful, Two Guineas will be retained to pay expenses.

Candidates may be admitted to special examination on bringing forward satisfactory reasons and paying an extra fee.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

REGULATIONS FOR CANDIDATES FOR THE DIPLOMA.

THE regulations regarding schools of medicine, preliminary examination, and professional study and examination, are similar to those for the double qualification (see below), except that the third course of Medicine and the course of Pathological Anatomy are not required. The first professional examinations will be held on October 26th, 1875; January 25th, April 4th and 25th, and July 25th, 1876. The second examination takes place immediately after the conclusion of the first.

At the second examination, the student, in furnishing the statement of his professional study, must, if he have been an apprentice, insert the name of his master, the date of his indenture, and the length of time for which he was bound. If the candidate have been an apprentice to a Fellow of the College, he must also produce his discharged indenture.

Recent Dissections, Anatomical Specimens, and articles of the Materia Medica, are employed during the examinations; and all candidates are required to write out formulæ of prescriptions. They are also subjected to a practical clinical examination in the Surgical Hospital.

No candidate shall be admissible to examination who has been rejected by any other Licensing Board within three months preceding his application to be examined.

The Fees are: for the first examination, £4; for the second, £6; from candidates who have elsewhere passed the first professional examination, £10. In each case, £2 is retained if the candidature be unsuccessful.

Candidates desirous of special examinations on other days than those fixed by the regulations, must prepare a case to be submitted to the consideration of the authorities of the College, with evidence to show why it was and is impossible for them to avail themselves of the ordinary examinations, past or future. They must at the same time produce certificates of the whole of the prescribed course of study, and of having passed the preliminary examination, and must state the earliest and the latest days within which they can present themselves. It is very desirable that all such candidates, and especially those who are a distance from Edinburgh, should present their applications as long beforehand as possible. The fees for special examinations, which must be lodged by 10 A.M. of the day preceding the examination-day, are as follows; viz.—£20 for first and second examinations, of which £12 will be returned to candidates remitted on the first examination; but no part of the money will be repaid to candidates who, having passed the first, are unsuccessful in the second examination; £17 for second examination. Of this, no part will be returned to candidate if unsuccessful.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH.

DOUBLE QUALIFICATION IN MEDICINE AND IN SURGERY.

THE Royal College of Physicians of Edinburgh and the Royal College of Surgeons of Edinburgh, while they still give their Diplomas separately, have made arrangements by which, after one series of examinations, the student may obtain the Diplomas of both Colleges. This joint examination is conducted by a Board, in which each body is represented for examination in the branches common to both Medicine and Surgery; but the College of Physicians takes exclusive charge of the examination in Medicine, and the College of Surgeons of the examination in Surgery. Students passing that examination are enabled to register two qualifications—Licentiate of the Royal College of Physicians of Edinburgh, and Licentiate of the Royal College of Surgeons of Edinburgh.

Every candidate must have followed his course of study in an University, or in an established School of Medicine, or in a Provincial

* For the subjects, see note to regulations for double qualification.

School specially recognised by the College of Physicians and Surgeons of that division of the United Kingdom in which it is situate. Under the title of *Established School of Medicine* are comprehended the medical schools of those cities of Great Britain and Ireland in which Diplomas in Medicine or Surgery are granted, and such Colonial and Foreign Schools as are similarly circumstanced in the countries in which they exist.

Professional Education.—1. Candidates must have been engaged, during four years after the examination in general education, in not less than four winter sessions*, or three winter and two summer sessions†, attendance at a recognised medical school.* 2. The candidate must have attended the following courses of lectures: Anatomy, two courses† of six months each, and Practical Anatomy, twelve months; or Anatomy, one course of six months, and Practical Anatomy, eighteen months; Physiology, not less than fifty lectures; Chemistry, Practice of Medicine, Clinical Medicine,‡ Medicine (a third course, either Practice or Clinical, at option),‡ Principles and Practice of Surgery, Clinical Surgery,‡ Surgery (a third course, either Principles and Practice or Clinical Surgery, at option),‡ each six months; Practical or Analytical Chemistry, Materia Medica, Midwifery, and Diseases of Women and Children, Medical Jurisprudence, and Pathological Anatomy,§ each three months.¶ 3. He must also produce certificates:—*a.* Of having attended at least six cases of labour under the superintendance of a registered medical practitioner. *b.* Of having attended, for three months, instruction in Practical Pharmacy. The teacher signing the certificate must be a Member of the Pharmaceutical Society of Great Britain, or a chemist and druggist recognised by either College on special application, or the superintendent of the laboratory of a Public Hospital or Dispensary, or a registered practitioner who dispenses medicine to his own patients. *c.* Of having attended, for twenty-four months, a public General Hospital containing, on an average, at least eighty patients. *d.* Of having attended, for six months, the practice of a public Dispensary specially recognised by either College; or of having been engaged for six months as assistant to a registered practitioner. *e.* Of having been instructed in vaccination; the certificate to be signed by the teacher, who must be a registered practitioner.

It is strongly recommended to students to avail themselves of opportunities of attending lectures on Ophthalmic and Mental Diseases, also on Natural History and Comparative Anatomy; and of obtaining practical instruction in the use of the Microscope.

Preliminary Examination in General Education.—All candidates for the Diplomas of the Colleges must have passed the examination in General Education,¶ and have had their names inscribed in the General Medical Council's Register of Medical Students at the commencement of their Medical studies. Certificates of having passed the examinations in General Education, conducted by other bodies (viz., those recognised by the General Medical Council), will be accepted as equivalent. Students who intend to undergo the preliminary examination, must give in their names, addresses, and places of birth to the officer of either College, not later than three days before the day of examination; and must pay a fee of Ten Shillings, not to be returned in case of rejection; but they will be admissible to re-examination at a future period without paying another fee.**

Professional Examination.—1. Candidates for the double qualification are subjected to two professional examinations. 2. Opportunities for both examinations will be presented six times in each year. On each occasion, the candidates write answers to the questions proposed; and are examined orally on the days immediately succeeding. 3. Unsuccessful

* Candidates commencing study prior to September 1866, will be admitted to examination after four winter sessions*, or three winter and two summer sessions†, attendance on classes at a regular Medical School.

† The two courses must not be attended in the same session.

‡ Two courses of Clinical Medicine or of Clinical Surgery of three months each, if not simultaneous, will be held equivalent to one course of six months. They must be attended during the attendance at the Hospital where they are delivered.

§ A certificate of attendance at the *Post Mortem* Examinations at a General Hospital will be accepted in lieu of this course.

¶ The six months' courses delivered in Scotland must consist of not fewer than one hundred lectures, with the exception of Clinical Medicine and Clinical Surgery. The three months' courses must consist of not fewer than fifty lectures.

¶ The examination will embrace the following subjects:—1. English language, including Grammar and Composition. 2. Arithmetic, including Vulgar and Decimal Fractions. Algebra, including Simple Equations. 3. Geometry: First Two Books of Euclid. 4. Latin: Cæsar, *De Bello Gallico*, Book IV; Virgil, *Æneid*, Book VIII; also a passage from an unprescribed author. 5. One of the following subjects at the option of the candidate:—(1) Greek: Herodotus, *History*, Book I; and Homer, *Iliad*, Book II. (2) French: Molière, *Le Malade Imaginaire*. (3) German: Schiller's *Wilhelm Tell*. (4) Natural Philosophy, including Mechanics, Hydrostatics, and Pneumatics. In Latin, Greek, French, and German, parsing of words from the passages given to be translated will be required; also, translation of short sentences from English into the respective languages.

** Candidates who commenced their professional studies before September 17th, 1866, may pass this examination at any period of their professional studies previously to the first professional examination. The fee is £1.

candidates are remitted to their studies for not less than three months. 4. The first examination embraces Anatomy, Physiology, and Chemistry; and takes place not sooner than the end of the second winter season. 5. Candidates must apply to the Inspector of Certificates on or before the Saturday preceding the day of examination; and must produce certificates of attendance on those courses of lectures which have reference to the subjects of the examination, and evidence of having passed the preliminary examination. 6. The sum of £6 must be paid to the Inspector of Certificates for this examination not later than 10 A.M. of the day preceding it. This sum will be considered as paid to account for the entire Fee of £16 payable for the two Diplomas. 7. In the case of a candidate being unsuccessful at this examination, £4 will be returned to him. 8. The second examination embraces Medicine, Surgery, and Surgical Anatomy, Midwifery, Pathological Anatomy, Materia Medica and Pharmacy, and Medical Jurisprudence; and takes place after the termination of the winter session of the last year of study, four years after the examination in general education. 9. Application for examination must be made to the Inspector of Certificates not later than the Monday previous to the day of examination. 10. Every candidate must produce—*a.* Satisfactory evidence of having attained the age of twenty-one years; *b.* A certificate of having passed the preliminary examination, unless this certificate have been already seen by the Inspector; *c.* A certificate of registration in the books of the General Medical Council; *d.* A certificate of having passed the first professional examination; *e.* The certificates of his classes, etc.; *f.* A tabular statement (for which a printed form will be furnished), exhibiting the whole of his professional education, and distinguishing the classes, hospitals, dispensaries, and schools, attended during each session. 11. The fee for this examination is £10, which must be lodged with the Inspector not later than 10 A.M. of the day preceding the examination day. 12. On the production of the above documents, and after receiving the fees, the Inspector gives the candidate a letter authorising the examiners to take him on trial. 13. In case of a candidate being unsuccessful at this examination, £8 will be returned to him. 14. Candidates who have passed the first professional examination in Anatomy, Physiology, and Chemistry, at any of the Licensing Boards recognised by the Medical Act, will be admissible to the second professional examination on producing certificates of the whole course of study prescribed, of having passed their preliminary and first professional examinations, and of having been registered as students. If any of the three subjects of the first examination have been omitted, the candidate will have to undergo an examination on the omitted subjects; and none of the subjects set down in § 3 will be omitted at the second examination. The fee payable by such candidates is £16, and unsuccessful candidates will receive back £14. 15. In addition to the written and oral examinations, all candidates are subjected to practical Clinical Examinations in Medicine and Surgery. 16. No candidate is admissible to examination who has been rejected by any other Licensing Board within the three preceding months.

Communications from candidates to be addressed to Dr. GAIRDNER, 45, Northumberland Street, Edinburgh.

The following will be the periods of examinations for the Double Qualification of the Royal Colleges of Physicians and Surgeons of Edinburgh, for the year 1875-76. *Preliminary Examination in General Education*, October 19th and 20th, 1875; April 18th and 19th, and July 22nd and 24th, 1876. *First Professional Examinations*.—Tuesdays, November 2nd, 1875; February 1st, April 11th, May 2nd, July 18th, and August 1st, 1876. *Second Professional Examinations*.—These will take place immediately after the conclusion of the first professional examinations. In no case will they be begun on an earlier day than the Thursday of any period.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

REGULATIONS FOR THE DIPLOMA.

THE Regulations respecting the Curriculum of Professional Study, and the Fees, are similar to those of the Royal College of Surgeons of Edinburgh.

Preliminary Examinations in General Literature will be held on October 8th and 20th, 1875; and April 21st, July 21st, September 15th, and October 20th, 1876.† The Fee is Ten Shillings. Candi-

* Candidates at a distance are requested to send their certificates much earlier, so as to give sufficient time for the exchange of one or two explanatory letters; as much disappointment has been occasioned by the discovery of defects in their course of study when it was too late to rectify them by the production of documents.

† The examination will embrace the following subjects:—1. English Language, including writing to dictation, Grammar, and Composition. 2. Latin: 1875, Translation from one of the two following Books, at the option of the candidate: Cæsar,

dates are requested to give in their names to the Secretary at least two days before the examination, and to give intimation of the optional subject they select.

The *First Professional Examinations* take place on the second Tuesday of every month except August. The *Second Professional Examinations* take place, the written part on the second Tuesday of every month except August, and the clinical and oral parts on the succeeding day.

The examinations are conducted partly in writing and partly orally. Recent Dissections, Anatomical Specimens, Chemical Tests, Articles of the *Materia Medica*, the Microscope, Surgical Apparatus, and Pathological Specimens are employed. Candidates are also subjected, at the second examination, to a practical Clinical Examination at the Hospital.

Candidates for the Diploma of the Faculty, who possess a qualification to practise, or who have passed the examination in Anatomy, Physiology, and Chemistry, before any of the Licensing Bodies enumerated in Schedule (A) of the Medical Act, on complying with the regulations in other respects, will be admitted to the second professional examination. In such cases, the full fee is exigible. In the case of unsuccessful candidates, £2 of the fee is retained.

A candidate, on showing a sufficient reason, may be admitted to examination on a day specially arranged, on paying an extra fee of £3.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH,
AND FACULTY OF PHYSICIANS AND SURGEONS
OF GLASGOW.

DOUBLE QUALIFICATION IN MEDICINE AND IN SURGERY.

THE Faculty of Physicians and Surgeons of Glasgow, and the Royal College of Physicians of Edinburgh, conjointly grant their Diplomas after one series of examinations before a Board of Examiners in which each body is represented. The regulations as to the curriculum of study, and the fees, are the same as those for the conjoined examinations of the Royal Colleges of Physicians and Surgeons of Edinburgh. The first examinations will be held on October 7th, 1875; January 12th, April 1st, May 4th, July 6th and 27th, and October 5th, 1876.

UNIVERSITIES OF EDINBURGH, GLASGOW, ABERDEEN,
AND ST. ANDREW'S.

REGULATIONS RESPECTING DEGREES IN MEDICINE.

[THE Regulations of these Universities are nearly similar. We, therefore, give but one statement, noticing points of difference when necessary.]

Three Medical Degrees are conferred by each University; viz., Bachelor of Medicine (M.B.), Master in Surgery (C.M.), and Doctor of Medicine (M.D.). The Degree of C.M. is not conferred on any person who does not also at the same time obtain the Degree of Bachelor of Medicine.

Preliminary Education.—The preliminary branches of extraprofessional education are English, Latin, Arithmetic, the Elements of Mathematics, and the Elements of Mechanics; and candidates must also pass a satisfactory examination in at least two of the following subjects:—Greek, French, German, Higher Mathematics, Natural Philosophy, Logic, Moral Philosophy.* The examinations on both classes of subjects take place before the candidate has entered on his medical curriculum. †

De Bello Gallico, Book I; and *Æneid*, Book II; 1876, Cæsar, *De Bello Gallico*, Books III and IV; an Exercise in rendering English correctly into Latin, the Latin words being supplied. 3. Arithmetic, to Vulgar and Decimal Fractions inclusive; Algebra, including Simple Equations. 4. Geometry: First two Books of Euclid (questions will be given on the third Book of Euclid, but the answering of them will be optional). 5. One of the following subjects at the option of the candidate. a. Natural Philosophy: Mechanics, Hydrostatics, and Pneumatics. b. Greek: 1875, Xenophon's *Anabasis*, Book III; or Homer's *Iliad*, Book III; 1876, Xenophon's *Anabasis*, Book II. c. French: 1875, Voltaire's *Histoire de Charles XII.*; 1876, Molière, *Le Médecin malgré lui*. d. German: Schiller's *Geschichte des dreissigjährigen Kriegs*, first two books. In the English, Latin, Greek, French, and German papers, special stress will be laid on accurate answering of the grammatical questions.

* The Universities of Glasgow, Aberdeen, and St. Andrew's, include Natural History.

† As far as possible.—*Aberdeen.*—At Glasgow, the examination in the second class must take place previously to the first professional examination.

‡ In Edinburgh, examinations on these subjects will be held on 12th and 13th October, 1875, and March 14th and 15th, 1876. 1. *English*—Writing a passage from dictation; composition, with correction of sentences of bad English; Grammar, with analysis of sentences and derivation and definition of some common English words; History and Geography. 2. *Latin*—Livy, Book xxvii; an easy passage (Latin) from a Prose Author, and a single passage of English (translated from a Latin Author) to

A Degree in Arts (not honorary) in any one of the Universities of England, Scotland, or Ireland, or in any Colonial or Foreign University specially recognised by the University Courts, exempts from all preliminary education. The Universities also recognise examination in Arts by any corporate body, whose examination has been recognised by the General Medical Council, and also approved by the University Court, so far as regards the preliminary examination in Arts on all subjects comprised in the examination of the said corporate body.

DEGREE OF BACHELOR IN MEDICINE AND MASTER IN SURGERY.

Candidates for the Degree of Bachelor in Medicine or Master in Surgery must have been engaged in medical and surgical study for four years—each *Annus Medicus* being constituted by at least two courses of not less than 100 lectures each, or by one such course, and two courses

be re-translated into Latin, the more difficult Latin words being given. 3. *Arithmetic*—The Common Rules, including Vulgar and Decimal Fractions. 4. *Elements of Mathematics*—Euclid, Books I, II, and III; and the Rudiments of Algebra, including Simple Equations. A knowledge of Euclid alone will not be sufficient. 5. *Elements of Mechanics*—Elementary Mechanics and Hydrostatics. (See Goodwin or Todhunter.)—At least two of the following subjects. 1. *Greek*—Xenophon, *Anabasis*, Book IV. 2. *French*—Molière, *Les Femmes Savantes*. 3. *German*—Schiller, *Wilhelm Tell*. 4. *Higher Mathematics*—Euclid, Books I to VI; Algebra, Trigonometry, and Conic Sections. 5. *Natural Philosophy*—Balfour Stewart's *Elementary Physics*. 6. *Logic*—Jevons' *Elementary Lessons in Logic*, or Fraser's *Selections from Berkeley*. 7. *Moral Philosophy*—Calderswood's *Handbook*, or (when the candidate is a Bachelor of Medicine) Laycock's *Mind and Brain*. In Latin, Greek, French, and German, questions in Grammar will be set, and passages to be translated from English.

In Glasgow, examinations will take place as follows. *First or Elementary Part; English*—Writing correctly a passage to dictation; Composition of a short Essay on a given theme; Questions in Grammar. *Latin*—Virgil, *Æneid*, Book IV; Sallust, *De Bello Jugurthino*, chap. 1-1. Translations of passages from authors not prescribed, and of English passages into Latin, the principal Latin words being supplied; Questions in Grammar and Construction. *Arithmetic*—The Common Rules, including Vulgar and Decimal Fractions. *Elements of Mathematics*—Euclid, Books I, II, and III; Algebra, as far as Simple Equations. *Elements of Mechanics*—Questions, for which such works as Tomlinson's *Rudimentary Mechanics* may serve as text-books. *Second Part, Exercises* in two of the subjects of which, to be selected by the candidate, are required. *Greek*—*Cyropædia* of Xenophon, Book II, and the Gospel according to St. John; Translations of passages from Greek authors not prescribed, and of English passages into Greek—the principal Greek words supplied; Questions in Grammar. *French*—Cornéille's *Le Cid*; Translations and exercises as in Latin and Greek. *German*—Lessing's *Laocoon*; Translations and exercises as in the other languages. *Mathematics*—Euclid, Books I to VI; Algebra, including Quadratic Equations, and the Rudiments of Trigonometry. *Natural Philosophy*—Such a knowledge of the principles as may be obtained from the Text-books of Golding Bird and Brooke, and Ganot.—*Natural History*—Geology or Zoology. Text-books—Jukes, Lyell, Dana, R. Jones, Nicholson. *Logic*—Whately's *Logic*, Books II and III. *Moral Philosophy*—The General Principles, as stated in Dugald Stewart on the Active Powers, or Dr. Fleming's Manual.

At Aberdeen, Examinations will be held on October 25th and 26th, 1875, and in April 1876. *First Part of Examination: English*—Composition, Grammar, and Writing to Dictation. *Latin*—Cæsar, *De Bello Gallico*, Book I; Virgil, *Æneid*, Book III; Grammatical Questions. *Arithmetic*—The Common Rules, Vulgar and Decimal Fractions, and Proportion. *Elements of Mathematics*—The First and Second Books of Euclid. *Algebra*—Simple Equations. *Elements of Mechanics*—Newth's *First Book of Natural Philosophy*, Chapters I, II, III. *Additional Subjects*—on two of which, at the option of candidates, a further examination has to be undergone, before admission to the First Professional Examination. *Greek*—Xenophon, *Anabasis*, Book II; Grammatical Questions. *French*—Voltaire's *Histoire de Pierre le Grand*. *German*—Schiller's *Wilhelm Tell*. *Higher Mathematics*—Plane Trigonometry, Solution of Triangles, Quadratic Equations, Binomial Theorem, Logarithms. *Natural Philosophy*—Light, Heat, Electricity (Golding Bird's *Elements of Natural Philosophy* recommended). *Natural History*—General Classification of the Animal Kingdom; Characters and Subdivisions of the Vertebrata (Nicholson's *Text-Book of Zoology* recommended). *Logic*—(Morrell's *Handbook of Logic* recommended). *Moral Philosophy*—(Reid's *Active Powers*, or Wayland's *Elements of Moral Science* recommended).

At St. Andrew's, every Student in Medicine must be registered; but no one can be registered unless he has passed the Registration Examination, or an equivalent examination. The Registration Examination takes place during the first week of the session. The following are the subjects: *English*—The qualifications of candidates will be tested by the style and general character of their written translations and answers, and by their knowledge of the derivations of words employed in Medicine. *Latin*—Cicero, *De Officiis*, Book I; Virgil, *Æneid*, Book II. *Mathematics*—Elementary Rules of Arithmetic, including Vulgar and Decimal Fractions; Euclid, Books I and II; Algebra as far as Simple Equations and Proportion. *Elements of Mechanics*—Composition and Resolution of Forces; the Lever, the Wheel and Axle, the Pulley, and the Inclined Plane; and the Centre of Gravity. Candidates will find the necessary information in Snowball's *Cambridge Elementary Course of Natural Philosophy*, or in Newth's *First Book of Natural Philosophy*. *Greek*—Xenophon, *Anabasis*, Books I and II; or any one book of Herodotus, or two books of Homer. *French*—Voltaire, *Charles XII.* *German*—Schiller's *Thirty Years War*, or any one of his dramas. *Higher Mathematics*—Euclid, Books I, II, III, IV, and V. *Algebra*, Plane Trigonometry, and the Elementary Propositions on the Straight Line, Circle, and Conic Sections, treated analytically. The Examiners recommend Potts's *Elements of Euclid*; Wood's or Todhunter's *Algebra*; Snowball's, Todhunter's, or Beasley's *Trigonometry*; and Todhunter's *Plane Co-ordinate Geometry*, with the omission of chapters iv, vii, xiv, xv, xvi. *Natural Philosophy*—Elementary Mechanics, Hydrostatics, and Optics. (A thorough knowledge of the manuals on these subjects by Galbraith and Haughton will enable candidates to pass this portion of the examination.) *Natural History*—Milne Edwards's *Éléments de Zoologie*. (A translation of this work has been published by Dr. Knox.) *Logic*—Whately's *Logic*, or his *Easy Lessons on Reasoning*. *Moral Philosophy*—Paley's *Moral Philosophy*, or Macintosh's *Dissertation on the Progress of Ethical Philosophy*.

of not less than 50 lectures each; with the exception of the clinical courses, in which lectures are to be given at least twice a week.

Every candidate for the degree of M.B. and C.M. must give sufficient evidence by certificates—1. That he has studied Anatomy, Chemistry, *Materia Medica*, Institutes of Medicine or Physiology, Practice of Medicine and of Surgery, Midwifery and the Diseases of Women and Children,* General Pathology,† during courses including not less than 100 Lectures; Practical Anatomy, a course of the same duration as the preceding; Practical Chemistry, three months; Practical Midwifery, three months at a Midwifery Hospital, or attendance on six cases under a registered medical practitioner; Clinical Medicine and Clinical Surgery, each course of not less than 100 lectures, or two courses of three months; Medical Jurisprudence, Botany, Natural History, including Zoology, courses of not less than 50 lectures. 2. That he has attended for at least two years the Medical and Surgical Practice of a General Hospital with not fewer than eighty patients. 3. That he has been engaged for at least three months in compounding and dispensing drugs at the Laboratory of a Hospital or Dispensary, of a Member of a Surgical College or Faculty, Licentiate of the London or Dublin Society of Apothecaries, or a Member of the Pharmaceutical Society of Great Britain.‡ 4. That he has attended, for at least six months, the out-practice of a hospital or the practice of a dispensary, or of a registered practitioner. Evidence of a practical knowledge of vaccination is also required.

One of the four years of medical and surgical study must be in the University granting the degree sought. Another year must be either in the same University, or in some other University entitled to give the Degree of Doctor of Medicine.§ [At St. Andrew's, no one can be received as a candidate for the Degree of Bachelor of Medicine or Master in Surgery unless two years at least of his four years of medical and surgical study shall have been in one or more of the following Universities and Colleges; viz., the Universities of St. Andrew's, Glasgow, Aberdeen, Edinburgh, Oxford, or Cambridge; Trinity College, Dublin; and Queen's College, Belfast, Cork, or Galway.] Attendance during at least six winter months on the medical or surgical practice of a General Hospital which accommodates at least eighty patients, and, during the same period, on a course of Practical Anatomy; and one year's attendance, to the extent of four of the departments of medical study required, on the lectures of teachers of Medicine in the hospital schools of London, or in the school of the College of Surgeons in Dublin, or of such teachers of Medicine in Edinburgh or elsewhere as shall from time to time be recognised by the Edinburgh University Court, may be reckoned as one of the four years.¶ All candidates not students of the University of Edinburgh attending the lectures of Extra-Academical Teachers in Edinburgh, must, at the commencement of each year of attendance, enrol their names in a book to be kept by the University for that purpose, paying a fee of the same amount as the Matriculation Fee.

Every candidate must deliver, at such time of the year as may be fixed by the *Senatus Academicus*—1. A declaration, in his own handwriting, that he is 21 years of age, or that he will be so on or before the day of graduation; and that he will not be, on the day of graduation, under articles of apprenticeship. 2. A statement of his studies, general and professional, accompanied with proper certificates.¶

In the University of Edinburgh, there are four professional examinations. Candidates are examined in writing and *visà voce*—1, on Chemistry, Botany, and Natural History; 2, on Anatomy, Institutes of Medicine, *Materia Medica* (including Practical Pharmacy), and Pathology; 3, on Surgery, Practice of Medicine, Midwifery, and Medical Jurisprudence; 4, Clinically on Medicine and on Surgery in a hospital. The examinations on Anatomy, Chemistry, Institutes of Medicine, Botany, Natural History, *Materia Medica*, and Pathology, are conducted, as far as possible, by demonstrations of objects. Students may be admitted to examination on the first division of these subjects at the end of their second year, and on the second division at the end of their third year. The examination on the third and fourth divisions

* Two courses of Midwifery, of three months each, are reckoned equivalent to a six months' course, provided different departments of Obstetric Medicine be taught in each of the courses.

† Or a three months' course of lectures on Morbid Anatomy, together with a supplemental course of Practice of Medicine or Clinical Medicine.

‡ In the Laboratory of an Hospital or Dispensary, of a Registered Medical Practitioner, or of a Member of the Pharmaceutical Society of Great Britain.—*Glasgow*.

§ Entitled to grant Degrees in Medicine.—*Glasgow*.

¶ The other two years may be constituted by attendance upon courses in the great Hospital Medical Schools of London or Dublin; and, in default of such attendance, one of the four years may be constituted by attendance on any general Hospital containing not less than eighty beds, provided attendance has been given at the same time on a course of Practical Anatomy.—*Glasgow*.

¶ The Universities of Aberdeen and St. Andrew's require an Inaugural Dissertation to be presented previously to the final examination for M.B. In Edinburgh and Glasgow, no Thesis is required until the candidate seeks the Degree of M.D.

cannot take place until the candidate has completed his fourth *Annus Medicus*. Candidates may be admitted to examination on the first two of these divisions at the end of their third year, or to the four examinations at the end of the fourth year. If any candidate be found unqualified, he cannot be again admitted to examination unless he has studied during another year two of the prescribed subjects, either in the University or in some other school of medicine.

In the other three Universities, every candidate for the Degree of Bachelor of Medicine and Master in Surgery must undergo three professional examinations, conducted in writing and *visà voce*. The first examination (not to be taken before the end of the second year of study) includes Chemistry, Elementary Anatomy, Botany, and *Materia Medica*.* The second examination (not to be taken before the end of the third year) includes advanced Anatomy, Physiology, Zoology with Comparative Anatomy, and Surgery.† The third examination (not to be taken before the end of the fourth year) includes General Pathology, Surgery, Practice of Medicine, Midwifery, Medical Jurisprudence, Clinical Medicine, and Clinical Surgery.‡ The examinations in Anatomy, Chemistry, Physiology, Botany, Zoology, and *Materia Medica* are conducted, as far as possible, by demonstrations of objects; and those on Medicine and Surgery, in part, by clinical demonstrations. Candidates may be admitted to examination on the first two at the end of the third year, or to the three examinations at the end of the fourth year. If any candidate be found unqualified, he is not again admitted to examination unless he shall have completed another year of medical study, or such portion of another year as may be prescribed by the examiners.

DEGREE OF DOCTOR OF MEDICINE.

The Degree of Doctor of Medicine may be conferred on any candidate who has obtained the Degree of Bachelor of Medicine, and is of the age of 24 years, and has been engaged, subsequently to having received the Degree of Bachelor of Medicine, for at least two years in attendance on a Hospital, or in the Military or Naval Medical Service, or in Medical and Surgical Practice. The candidate must be a Graduate in Arts, or must, before or at the time of his obtaining the degree of Bachelor of Medicine, or within three years thereafter, have passed a satisfactory examination in Greek and in Logic, or Moral Philosophy, and in one at least of the following subjects; viz., French, German, Higher Mathematics, and Natural Philosophy.§ He must submit to the Medical Faculty a Thesis composed by himself, and which shall be approved by the Faculty, on any branch of knowledge comprised in the professional examinations for the Degree of Bachelor of Medicine, which he may have made a subject of study after having received that degree.||

Candidates who commenced their medical studies in Edinburgh before February 4th, 1861, and in Aberdeen before November 1861, are entitled to be examined for the degree of Doctor of Medicine, under the regulations then in force in each University respectively. At Edinburgh, candidates, settled for a period of years in foreign parts, who have complied with all the regulations for the degree of M.D. (under the new statutes), but who cannot appear personally to receive the degree, may, on satisfying the *Senatus* to that effect, by production of sufficient official testimonials, have the degree conferred on them in absence.

The Degree of Doctor of Medicine may be conferred by the University of St. Andrew's on any Registered Medical Practitioner above the age of 40 years, whose professional position and experience are such as, in the estimation of the University, to entitle him to that Degree, and who shall, on examination, satisfy the Medical Examiner of the sufficiency of his professional knowledge, provided always that such degrees shall not be conferred on more than ten in any one year.

The *Graduation Fees* in each of the Universities are—for the Degree of M.B., three examinations, each £5 5s. £15 15s.; for the Degree of C.M., £5 5s. additional; for the Degree of M.D., £5 5s. additional to that for M.B., together with Government Stamp Duty (£10).

The fee for graduating under the old Regulations in Edinburgh is £25; at St. Andrew's, the fee for the Degree of M.D. under the section relative to Registered Medical Practitioners is 50 Guineas. Stamp Duty is included in both cases.

* *Materia Medica* in third examination at Glasgow.

† Surgery is deferred to the third examination at Glasgow.

‡ *Materia Medica* and Surgery.—*Glasgow*.

§ In Greek and in Logic or Moral Philosophy, and in any one of the other optional subjects in the examination in General Education.—*Glasgow*. Natural History added in optional subjects.—*Aberdeen and St. Andrew's*.

|| No thesis will be approved by the Medical Faculty which does not contain either the results of original observations in practical medicine, surgery, midwifery, or some of the sciences embraced in the curriculum for the Bachelor's degree; or else a full digest and critical exposition of the opinions and researches of others on the subject selected by the candidate, accompanied by precise references to the publications quoted, so that due verification may be facilitated.—*Edinburgh*.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

REGULATIONS RELATIVE TO THE LICENSE OF MEDICINE.

EXAMINATIONS for the License are held on the second Tuesday and following day in each month (except August and September).

A candidate who has not previously obtained any medical or surgical qualification recognised by the College must produce certificates—1. Of having been engaged in the study of Medicine for four years. 2. Of having passed the preliminary examination of one of the recognised Licensing Corporations before the termination of the second year of medical study. 3. Of having studied at a school or schools recognised by the College the following subjects: Practical Anatomy; Anatomy and Physiology, or Institutes of Medicine; Botany; Chemistry; Practical Chemistry; Materia Medica; Practice of Medicine and Pathology; Surgery; Midwifery; Medical Jurisprudence. 4. Of having attended a Medico-Chirurgical Hospital in which regular courses of Clinical Lectures are delivered, together with clinical instruction, for twenty-seven months, or such hospital for eighteen months, with nine months at a medical hospital. 5. Of having attended Practical Midwifery for six months at a recognised Lying-in Hospital, or evidence satisfactory to the College of having attended Practical Midwifery. 6. Of character, from two registered physicians or surgeons. A candidate who has already obtained a recognised medical or surgical qualification must fill up a schedule which will be supplied on application, and produce his diploma or certificate of registration, and the certificate of Practical Midwifery, and testimonials as to character.

The examination is conducted by printed questions and *visà voce*, and consists of two parts:—1. Anatomy; Physiology; Botany; Chemistry. 2. Materia Medica; Practice of Medicine; Medical Jurisprudence; Midwifery. Candidates will also be examined at the bedside.

Candidates who have already obtained a qualification from an University or other licensing body, or who have passed the first examination after a complete curriculum, are required to undergo the *second part* of the professional examination only. Physicians or surgeons of five years' standing are exempted from the written portion of the final examination. Fee for License in Medicine, £15 15s., of which £3 3s. are retained if the candidate be unsuccessful.

LICENSE IN MIDWIFERY.

Examinations for a diploma in Midwifery are held monthly. A Candidate who is already a Licentiate of the College may present himself at any of the examinations, on giving a week's notice. Candidates not Licentiates of the College must have a degree or license in Medicine or Surgery from any University or College in the United Kingdom, and must have attended Lectures in Midwifery for six months, and also Practical Midwifery. They must also produce certificates of character. The fee is £3 3s.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

LETTERS TESTIMONIAL.

EVERY person requiring to be registered as a pupil on the College books shall, if the Council think fit, be so registered on the payment of five guineas. Registered pupils are admitted to the Preliminary Examination of the College without further fee, and are permitted to study each week day in the Museum, to read in the Library; also to attend the Lectures on Comparative Anatomy, and to obtain a certificate for such attendance, without payment of any fee. These privileges are open to the students of any school recognised by the Council, who may have enrolled themselves as registered pupils. No student can be admitted as a candidate to any of the stated examinations, or to the special examinations for the Letters Testimonial, until he has been enrolled as a registered pupil, and also passed a preliminary examination.

Registered pupils may present themselves, without payment of any further fee, for the Preliminary Examination at any period previous to their first professional examination; but are expected to do so previously to the commencement of their professional studies. Students who are not registered pupils are admitted to the Preliminary Examination upon payment of ten shillings.*

* The following are the subjects upon which each candidate for the Preliminary Examination will be examined. The English language, including Grammar and Composition; Arithmetic, including Vulgar and Decimal Fractions; Algebra, including Simple Equations; Geometry, first two Books of Euclid; Greek and Latin, including Translation and Grammar. Greek—The Gospel of St. John, or the First Book of Xenophon's *Anabasis*, or the Dialogue of Lucian, entitled *Menippus* or the *Necromancy*. Latin—The First and Second Books of the *Aeneid* of Virgil, or the *Yugurthine War* of Sallust, or the Third Book of Livy. These examinations are held quarterly; viz., on the third Wednesday in January, April, July, and October in each year.

Students who have passed any of the Preliminary Examination Boards recognised by the General Medical Council, into the curriculum of which the Greek language enters as a compulsory subject, are exempt from any further preliminary examination, and are entitled to become registered pupils of the College.

Candidates for Letters Testimonial may present themselves either at a special or at a stated examination.

Special Examinations.—Every registered pupil shall be admitted, upon payment of a special fee of £5 5s. in addition to the ordinary fee of £21, to a special examination for Letters Testimonial, as producing evidence that he has passed a Preliminary Examination; that he has been engaged in the study of his profession for not less than four years; that he has attended during three years on a recognised Hospital where Clinical Instruction is given; that he has attended three courses each of Lectures on Anatomy and Physiology, and on the Theory and Practice of Surgery and of Dissections, accompanied by demonstrations; two courses of Lectures on Chemistry, or one course of Lectures on General and one on Practical Chemistry; one course each of Lectures on Materia Medica, Practice of Medicine, Midwifery, Medical Jurisprudence, and Botany.

The subjects for examination are the same as those hereinafter laid down for the Stated Examinations. A rejected candidate will only be entitled to receive back £15 15s.

Stated Examinations are held in April, July, and November. Candidates must be registered pupils, and are divided into two classes—Junior and Senior.

The Junior Class must produce certificates of having passed a Preliminary Examination, and of having attended three courses each of Lectures on Anatomy and Physiology, and on Practical Anatomy with Dissections; two courses of Lectures on Chemistry; one course each of Lectures on Materia Medica, Botany, and Forensic Medicine. This class is examined in Anatomy, Histology, Physiology, Materia Medica, and Chemistry.

The fee for this examination is £5 5s., in addition to the registration fee; not to be returned in case of rejection, but to be allowed the candidate in case he presents himself a second time for examination.

The Senior Class must produce certificates of having attended three courses of Lectures on the Theory and Practice of Surgery, one course each of Lectures on the Practice of Medicine, and on Midwifery; also of attendance on a recognised Hospital for three Winter and three Summer Sessions. This class is examined in Surgery, Operative Surgery and Surgical Appliances, Practice of Medicine, Medical Jurisprudence and Prescriptions.

The fee for the Senior Class Examination is £15 15s., returnable to the candidate in case of rejection.

The examinations are partly written and partly oral.

In addition to the foregoing fees, a fee of £1 1s. is to be paid to the Registrar. Every candidate rejected at a Stated Examination, on applying for re-examination, must pay £2 2s., in addition to the regular fees.

FELLOWSHIP.

Every registered pupil or licentiate may be admitted to examination for the Fellowship on producing a certificate that he is 25 years of age, and that he is a Bachelor of Arts, or has been examined with a view to ascertain that he has obtained a liberal preliminary education; also a certificate, signed by two or more Fellows of the College, of general good conduct. He must have been engaged in the acquisition of professional knowledge not less than six years (five years being required in the case of Bachelor of Arts), during three of which he must have studied in one or more of the schools and hospitals recognised by the Council. The other three years may have been passed in any approved school. He must also have acted as House-Surgeon or Dresser in a recognised hospital; and must have attended the lectures required of candidates for Letters Testimonial, together with one course of lectures on Comparative Anatomy, and one on Natural Philosophy. He must present a thesis on some medical subject, or clinical reports, with observations of six or more medical or surgical cases taken by himself.

Licentiates of the College, who cannot show that they have followed the course of study specified in the regulations, may, at the expiration of ten years from the date of their diploma, be admitted to the examination for the Fellowship, on producing satisfactory evidence that they have conducted themselves honourably in the practice of their profession.

Each candidate for the Fellowship is examined on two days. The subjects of the first examination are Anatomy and Physiology (Human and Comparative); those of the second—Pathology, Therapeutics, the Theory and Practice of Medicine and Surgery, and such other branch of medical science as the Council may direct. The examinations are

both oral and written. The candidates must perform Dissections and Operations on the dead bodies. Rejected candidates cannot present themselves a second time until after one year from the first examination.

The fee payable is £21 if the candidate be a Licentiate, or £36 15s. if he be a registered pupil; provided in either case he intends to reside beyond ten miles from Dublin. Should the candidate intend to reside in Dublin, or within ten miles thereof, he pays, if a Licentiate, £31 10s.; if a registered pupil, £47 5s. Fellows entering on the country list, who may subsequently settle as practitioners in Dublin, or within ten miles thereof, must pay £10 10s. to the College.

DIPLOMA IN MIDWIFERY.

Midwifery Examination.—An examination for a Diploma in Midwifery is held from time to time. Any Fellow or Licentiate of the College is admissible to the examination on producing certificates of having attended a course of Lectures on Midwifery, the Practice (for six months) of a Lying-in Hospital, or of a Dispensary for Women and Children, and that he has attended at least thirty labours. The candidate shall, if passed, receive the Midwifery Diploma.

Candidates are examined on the Organisation of the Female; the Growth and Peculiarities of the Fœtus; the Practice of Midwifery, and the Diseases of Women and Children; and, if approved of, receive a license or diploma.

A rejected candidate is not again admitted to examination within three months, nor unless he produces satisfactory evidence of having been engaged in the study of Midwifery subsequently to his rejection.

The fee is £1 6s. if the Midwifery Diploma be taken out within one month from the date of the Letters Testimonial; afterwards it is £2 2s.

APOTHECARIES' HALL OF IRELAND.

REGULATIONS REGARDING THE LICENSE TO PRACTISE.

EVERY candidate for the License to practise is required to undergo a Preliminary and a Professional Education and Examination.* The Arts Examination will be held on the third Thursday in January, April, July, and October, at 12 noon. Answers in writing must be given to printed questions. Unsuccessful candidates will be remitted to their studies for six months.

Professional Education and Examination.—Every candidate for the License must produce certificates: 1. Of having passed an examination in Arts previously to entering on professional study. 2. Of being at least 21 years of age, and of good moral character. 3. Of apprenticeship to a qualified apothecary, or of having been engaged at practical pharmacy with an apothecary for three years subsequently to having passed the examination in Arts. 4. Of having spent four years in professional study. 5. Of having attended the following courses; viz.: Chemistry, Principles and Practice of Medicine and Surgery, each during one winter session; Anatomy and Physiology, Demonstrations and Dissections, each during two winter sessions; Botany and Natural History, and Forensic Medicine, each during one summer session; Practical Chemistry (in a recognised Laboratory) and Materia Medica, each during three months; Midwifery and Diseases of Women and Children, during six months; Practical Midwifery at a recognised Hospital (twenty cases); instruction in Vaccination. 6. Of having attended, at a recognised Hospital or Hospitals, the Practice of Medicine and Clinical Lectures on Medicine during two winter and two summer sessions; also the Practice of Surgery and Clinical Lectures on Surgery, during one winter and one summer session. 7. Of having performed vaccination successfully under a recognised vaccinator.

The examination for the License to practise is divided into parts. The first part comprehends Chemistry, Botany, Anatomy, Physiology, Materia Medica, and Pharmacy. The second—Medicine, Surgery, Pathology, Therapeutics, Midwifery, Forensic Medicine, and Hygiene. The first part may be undergone at the close of the second winter session; and the second at the termination of the fourth winter session.

The examinations will be held on the first and second Mondays in January, April, July, and October.

* The following are the subjects of Preliminary Examination:—*Compulsory.* 1. *English:* Grammar, Composition, writing from Dictation, and History. 2. *Arithmetic and Algebra:* Arithmetic, including Vulgar and Decimal Fractions; Algebra, including Simple Equations. 3. *Geometry:* First Two Books of Euclid. 4. *Latin:* The Twenty-first Book of Livy, or the First Three Books of the *Æneid* of Virgil, and Latin Prose Composition. 5. *Greek:* The First Two Books of the *Anabasis* of Xenophon, or the Ninth Book of the *Iliad* of Homer. 6. *French:* *Charles XII, Histoire de Vie, of Voltaire, or Voyage en Orient* of Lamartine. 7. *German:* *Wilhelm Tell* of Schiller.—Candidates will be examined in either French or German, as they may select.—*Optional.* 1. *Natural Philosophy:* Mechanics, Hydrostatics, and Pneumatics. 2. *Natural History:* The Classification, Elementary Structure, and General Physiology of Vegetables and Animals.

Candidates who fail to pass the first part of the professional examination will be remitted to their studies for three months. Unsuccessful candidates at the pass examination will not be readmitted until after six months.

Doctors of Medicine of any of the Universities of the United Kingdom, and Licentiates of a Royal College of Physicians, or Surgeons of any of the Royal Colleges of Surgeons, whose qualifications as such appear in the *Medical Register*, and who, having first passed an Examination in Arts, have also served an apprenticeship, or the required term at *practical* Pharmacy to a qualified Apothecary, may obtain the License of the Hall by undergoing an examination—the former in Pharmacy,* and the latter in Medicine and Pharmacy. Licentiates of the London Society of Apothecaries are admitted *ad eundem*, on presenting the certificate of their registration.

Candidates for the Professional Examinations must lodge their testimonials and enrol their names and addresses with the Clerk at the Hall, in Dublin, a clear week prior to the day of examination.

An *Honour* Examination for Apprentices is held at the Hall in the first week in May annually, upon some subject of Medical or Pharmaceutical Chemistry, which is announced by the Council of the Hall at the commencement of the previous Winter Session, and a Prize of Five Guineas is awarded to the successful competitor.

UNIVERSITY OF DUBLIN.

THE degrees in Medicine and Surgery granted by the University are: 1. Bachelor of Medicine; 2. Doctor of Medicine; 3. Bachelor in Surgery; 4. Master in Surgery. It also grants Licenses in Medicine and Surgery.

BACHELOR IN MEDICINE.

A candidate for the Degree of Bachelor in Medicine must be a Graduate in Arts, and may obtain the Degree of Bachelor in Medicine at the same commencement as that at which he receives his Degree of B.A., or at any subsequent commencement, provided the requisite medical education shall have been completed. The medical education is of four years' duration, and comprises attendance on a course of each of the following lectures: *Winter*—Anatomy; Practical Anatomy; Theoretical and Operative Surgery; Chemistry; Practical Course of Institutes of Medicine; Practice of Medicine; Midwifery. *Summer*—Botany; Institutes of Medicine; Comparative Anatomy; Materia Medica and Pharmacy; Medical Jurisprudence. *Term Courses*—Heat (Michaelmas); Electricity and Magnetism (Hilary). Six months' dissection, and three months' laboratory instruction in Chemistry. Three courses of nine months' attendance on the clinical lectures of Sir Patrick Dun's or other metropolitan hospital recognised by the Board.† A certificate of personal attendance on fever cases, with names and dates of cases. Six months' instruction in Practical Midwifery,‡ including clinical lectures. Any of the winter or summer courses may be attended at any medical school in Dublin recognised by the Provost and Senior Fellows.§ Students who shall have diligently attended the Practice of a recognised county infirmary for two years previous to the commencement of their metropolitan medical studies, are allowed to count those two years as equivalent to one year spent in a recognised metropolitan hospital.

Candidates for the Degree of M.B. must pass two examinations; the Previous Medical Examination, and the Bachelor of Medicine examination.

The *Previous Examination* comprises Descriptive Anatomy; Botany; Materia Medica and Pharmacy; Chemistry; and Physics. The Examination in Descriptive Anatomy includes Examination on the dead subject.

It is not necessary that the Student should pass in all these subjects at the same Examination; he is allowed to present himself for Examination in as many, or as few of them, as he pleases.

There are three Previous Medical Examinations held each year,

* The examination in Pharmacy will include Practical Pharmacy, Pharmaceutical Chemistry, Toxicology, Medical Botany, and the *British Pharmacopœia*.

† The following Hospitals are recognised:—1. Sir Patrick Dun's Hospital; 2. Meath Hospital; 3. House of Industry Hospital; 4. Dr. Steevens' Hospital; 5. Jervis Street Infirmary; 6. City of Dublin Hospital; 7. Mercer's Hospital; 8. St. Vincent's Hospital; 9. Adelaide Hospital; 10. Mater Misericordiarum Hospital.

‡ Certificates of practical Midwifery are received from—1. The Romondo Hospital; 2. The Coombe Hospital; 3. Sir P. Dun's Hospital Maternity; 4. Dr. Steevens' Hospital Maternity.

§ The following schools, in addition to the School of Physic of Trinity College, are recognised:—1. The School of the Royal College of Surgeons in Ireland; 2. The Carmichael Scho 1. 3. The School of Dr. Steevens' Hospital; 4. The St. Peter Street School; 5. The School of the Catholic University. The recognition is conditional on the students being furnished with *bona fide* certificates of regular attendance equivalent to that required by the University; i.e., three-fourths of the entire Lectures in each course.

immediately before each M.B. Examination, together with a Supplemental Examination in Botany, Chemistry, and Materia Medica, at the close of the Summer Session.

Bachelor of Medicine Examination.—The Candidate for the M.B. Examination must have previously passed the Previous Medical Examination in all the subjects; and have lodged with the Medical Registrar, on a certain day to be duly advertised, Certificates of Attendance upon all the Courses of Study above prescribed.

Candidates must pass a final Examination in the following subjects: Physiological Anatomy; Practice of Medicine; Surgery; Midwifery; Medical Jurisprudence; Institutes of Medicine. The Fee for the *Licent ad Examinandum* is £5; for the Degree of M.B., £11.

Members of the Royal Colleges of Physicians or Surgeons of Dublin, London, or Edinburgh, who are Graduates in Arts of Oxford, Cambridge, or Dublin, are admissible to the Examination for M.B.

DOCTOR IN MEDICINE.

A Doctor in Medicine must be a Bachelor in Medicine of three years' standing, or have been qualified to take the Degree of Bachelor in Medicine for three years. He must also read two Theses publicly before the Regius Professor of Physic, or must undergo an Examination before the Regius Professor of Physic, according to Regulations to be approved by the Provost and Senior Fellows. The total amount of Fees for this Degree is £13.

BACHELOR IN SURGERY.

A Bachelor in Surgery must be a Bachelor in Arts, and have spent four years in the study of Surgery and Anatomy. He must also pass a public Examination, having previously completed the prescribed Curriculum of study.* The Curriculum comprises the following, in addition to the complete Course for the Degree of Bachelor in Medicine: Theoretical and Operative Surgery and Ophthalmic Surgery, each one course; Dissections, two courses. Candidates are required to perform surgical operations on the dead subject. Candidates for the Degree of Bachelor in Surgery, who have already passed the Examination for the Degree of Bachelor in Medicine, will be examined in Anatomy and Surgery only. Fee for the *Licent ad Examinandum*, £5; for the Degree Bachelor in Surgery, £1.

MASTERY IN SURGERY.†

A Master in Surgery must be a Bachelor in Surgery of three years' standing, or have been qualified to take the Degree of Bachelor in Surgery for three years; and must read two Theses publicly before the Regius Professor of Surgery, or undergo an Examination before the Regius Professor, according to Regulations to be approved by the Provost and Senior Fellows. Fee for the Degree of Master in Surgery, £11.

UNIVERSITY LICENSES.

Candidates for the Licenses in Medicine or Surgery must be matriculated in Medicine, and must have completed two years in Arts, and four years in Medical Studies.

Licentiate in Medicine.—The Medical Course and Examination necessary for the License in Medicine are the same as for the Degree of M.B. A Licentiate in Medicine, on completing his Course in Arts, and proceeding to the Degree of B.A., may become a Bachelor in Medicine, on paying the Degree fees, without further Examination in Medicine.

Licentiate in Surgery.—The Surgical Course and Examination necessary for the License in Surgery is the same as for the Degree of Bachelor in Surgery.

Fee in each case for the *Licent ad Examinandum*, £5; for the License, £5.

QUEEN'S UNIVERSITY IN IRELAND.

DEGREES IN MEDICINE AND SURGERY.

THIS University grants the Degrees of Doctor in Medicine and Master in Surgery, and a Diploma in Midwifery. It includes three Colleges—the Queen's Colleges of Belfast, Cork, and Galway—each of which possesses a Faculty of Medicine. The curriculum of medical study extends over a period of four years, and is divided into two periods of two years each. The first period comprises attendance on Chemistry, Botany, Anatomy and Physiology, Practical Anatomy, Materia Medica and Pharmacy. The second period comprises attendance on Anatomy and Physiology, Practical Anatomy, Theory and Practice of Surgery, Midwifery, Theory and Practice of Medicine, Medical Jurisprudence.

* Students in the School of Physic who matriculated before 2nd June, 1872, may obtain the Degree of Master in Surgery, according to the regulations in force previous to the creation of the Degree of Bachelor in Surgery.

† After 1875, Masters in Surgery must be of the standing of Masters in Arts.

At least two of the above courses of lectures must be attended in some one of the Queen's Colleges; the remainder may be taken, at the option of the candidate, in any University, College, or School, recognised by the Senate of the Queen's University. Candidates are required, before graduating, to have also attended, in one of the Colleges of the Queen's University, Lectures on Experimental Physics and one Modern Continental Language, and to have passed the Matriculation Examination. They are further required to attend, during the first period, Practical Chemistry in a recognised Laboratory, and the practice during six months of a recognised Medico-Chirurgical Hospital containing at least sixty beds, together with clinical lectures delivered therein; and, during the second period, a recognised Midwifery Hospital, with clinical lectures therein delivered, for three months; or a Midwifery Dispensary for the same period; or ten cases of labour, under the superintendence of the medical officer of any hospital or dispensary where cases of labour are treated; and eighteen months' practice of a recognised Medico-Chirurgical Hospital containing at least sixty beds, with clinical instruction.

Candidates must pass three Examinations—the First University Examination, the Second University Examination, and the Degree Examination.

The First University Examination may be passed either in June or September. It comprises the following subjects: a Modern Language, Experimental Physics, Zoology, and Botany. Students may present themselves for examination in this group of subjects at any time after the close of the first Winter Session. Before being admitted to examination, each candidate must produce satisfactory evidence of having completed the prescribed course of study in the subjects of examination.

The Second University Examination may be passed either in June or September. It comprises Anatomy, Physiology, Materia Medica, and Chemistry; to which will be added Zoology and Botany in the examination of candidates who have not previously passed the First University Examination. Candidates who are in this position will be allowed either to undergo their examination in Modern Languages and Experimental Physics as a part of the Second University Examination, or may present themselves for examination in these subjects at any time between the Second University Examination and the Degree Examination. Students may present themselves for the Second University Examination at the termination of the first period of the curriculum, or at any subsequent period; but no student will be allowed to postpone his Second University Examination until he presents himself for his Degree Examination, unless the Senate shall have passed a grace permitting him to do so. Before being admitted to examination, each candidate must produce satisfactory evidence of having completed the course recommended for study during the first period.

Examinations for the Degree of M.D., M.Ch., and the Diploma in Midwifery, will be held in June and September. The Fee for each Degree is Five Pounds, and the Fee for the Diploma in Midwifery is Two Pounds. Each Fee must be lodged with the Secretary before the corresponding examination begins.

Degrees in Surgery and Diplomas in Midwifery will only be conferred on candidates who hold the Degree of Doctor in Medicine of the University. The Examination for the Degree of M.D. comprises the subjects recommended for study during the second period of medical education. The Examination for the Degree of M.Ch. comprises an examination in the Theory and Practice of Surgery, including Operative and Clinical Surgery.* The Examination for the Diploma in Midwifery comprises an examination in the Theory and Practice of Midwifery and the use of obstetrical instruments and appliances.†

Candidates who graduated with honours will be arranged in two classes. Candidates who take a First Class will receive a Medal and Prize; candidates who take a Second Class will receive a Prize. Both Honour and Pass Examinations are held in September. The Examination held in June is a Pass Examination.

Two Exhibitions, one consisting of two instalments of £20 each, and the other of two instalments of £15 each, will be awarded annually at the First University Examination in Medicine. The regulations concerning these Exhibitions, and all other information, will be found in the *Queen's University Calendar*, or may be obtained by application to the Secretary, Queen's University, Dublin Castle.

* Candidates for the Degree of Master in Surgery, who obtained the Degree of M.D. in this University before the 1st of January, 1865, will be exempted from the examination in Surgery. Candidates for the Degree in Surgery, who graduated in Medicine at a later period, will be required to undergo a paper and oral examination in the Theory and Practice of Surgery, and an examination in Operative and Clinical Surgery.

† Candidates for the Diploma in Midwifery who obtained the Degree of M.D. in the University before the 1st of January, 1872, will be exempted from this further examination.

MISCELLANEOUS.

ST. BARTHOLOMEW'S HOSPITAL.—House-Physicianships and House-Surgeons, £26 5s. Dresserships: 3 months, £12 12s.; 6 months, £18 18s.; 12 months, £26 5s. Demonstrations on Histology, £2 2s.

CHARING CROSS HOSPITAL.—Hospital Practice after third year, £5 5s. for each additional winter, and £3 3s. for each summer. Matriculated Students receive a deduction of 8 per cent., making the total aggregate (including matriculation fee of £2 2s.), £80 7s., which may be paid in four instalments. Non-matriculated Students pay £4 4s. for Comparative Anatomy. The Lectures on Psychology, and on Normal Histology and Operative Surgery, are free to matriculated students; non-matriculated students pay £1 1s. for the former, and £2 2s. for each of the two latter. Morbid Histology: matriculated, £1 1s.; non-matriculated, £2 2s. Private class of Operative Surgery, whole body, £6 6s.; half body, £4 4s. Electro-therapeutics, £1 1s.

ST. GEORGE'S HOSPITAL.—Perpetual Fee, £105; or pupils paying aggregate fee by instalments may become perpetual at any time by making up the payments to £115 10s.

GUY'S HOSPITAL.—Perpetual fee, £105 in one sum at entrance, or in two moieties at commencement of first winter and of following summer session. Natural Philosophy, £4 4s.

KING'S COLLEGE.—Perpetual Fee to Hospital Practice and all classes, £120 on

entrance; or £60 on entrance, £40 at second winter, and £30 at third winter. Non-matriculated students pay £42 for the three years' course of hospital practice, and £52 10s. for perpetual admission. Medical Tutor, £3 3s.; for preparation for Preliminary Scientific Examination of University of London, £5 5s. Practical Physiology in summer, s. £2 2s.; p. £3 3s. Students of Practical Physiology pay £1 1s. for use of microscope, unless possessing one. Practical Zoology, s. £4 4s.; p. £6 6s. Analytical and Experimental Chemistry (exclusive of materials, 1 month, £1 1s.; 3 months, £10 10s.; 6 months, £15 15s.).

LONDON HOSPITAL.—The fees for surgical hospital practice include dresserships for 3, 6, 18, and 12 months, and 2 years. Perpetual Fee for Lectures and Hospital Practice and two years' Practical Anatomy, £105; for lectures or hospital practice alone, £52 10s. Composition fee for students entering at or before second winter, £73 10s.; or in two equal instalments. Practical Chemistry, for apparatus and materials, to students of school, £2 2s.; to others, £3 3s. Practical Pharmacy, £4 4s. Use of microscope in Practical Physiology (unless possessing one), 10s. 6d. Diseases of Throat, s. £2 2s.; p. £3 3s.

ST. MARY'S HOSPITAL.—Unlimited attendance, £105 in instalments, or £99 15s. in one sum. Use of microscope (unless possessing one), £1 1s. Fee for subjects for dissection, £1 15s., at beginning of first and second winters. Inorganic Practical Chemistry (£3 3s.) included in General Fee; Organic ditto (£3 3s.) not included. Practical Pharmacy, 3 months, £3 3s.; 6 months, £6 6s.; 13 months, £10 10s. Instruction in Vaccination, £1 1s.

MIDDLESEX HOSPITAL.—Hospital Practice and Lectures each year after third, £10. Occasional students entering to the Hospital Practice pay a registration fee of £1 6s. Anatomy, including dissection, s., £10 10s.; p., £14 11s. Practical Surgery in summer, £4 4s. Instruction in Pharmacy without dispensing, 3 months, £4 4s.; with dispensing, 6 months, £5 5s.; 12 months, £8 8s.

ST. THOMAS'S HOSPITAL.—Perpetual fee, £105. A modified scale of fees is arranged for students entering in the second, third, or any subsequent year. Practical Physiology and Practical Chemistry, each £1 11s. 6d. for use of materials. Practical Pharmacy, £5 5s.

UNIVERSITY COLLEGE.—Physiological Laboratory fees (exclusive of materials), 1st month, £2 2s.; each succeeding month, £1 1s. Organic Chemistry alone, £2 2s.; Chemistry Exercise class, £2 2s. Practical Anatomy after 3 years, £1 1s. each winter; during summer, without lectures, £3 3s. Elementary Biology (summer), £3 3s. Laboratory instruction in Chemistry (exclusive of materials), £12 12s. Practical Pharmacy, 3 months, £3 3s.

WESTMINSTER HOSPITAL.—Perpetual Fee (if in one sum), £80. Students paying by instalments may become perpetual by paying £45 (in place of £40) at second winter session, or £18 18s. (in place of £13 13s.) at second summer session. Practical Pharmacy, 3 months, £3 3s.; 6 months, £5 5s. Instruction in Vaccination, £1 1s. Dissections only, 3 months, £2 2s.; summer, £3 3s.; 6 months, £3 3s.; each subsequent session, £2 2s. Diseases of Skin, s., £1 1s. Natural Philosophy, £1 1s.

QUEEN'S COLLEGE, BIRMINGHAM.—In addition to the fees, each student must deposit £2 as "caution money" which is returned on leaving the College, less deductions for breakages, etc. Midwifery and Diseases of Women, at Hospital (optional), £2 2s.; dental fee (optional), £1 1s.

BRISTOL MEDICAL SCHOOL.—The aggregate fee does not include Comparative Anatomy. *Royal Infirmary:* Entrance fee, £5 5s.; extra fee for dresser, one year, £12 12s.; two years, £21; 3 years, £26 5s.; apprenticeship to house-surgeon, including four years' residence and attendance on hospital practice (except dresser's fees), £315. House-pupils, £52 10s. per annum, and £52 10s. to the house-surgeon. *General Hospital:* Extra fee for clerk or dresser, £5 5s. for six months. Resident pupils, £100 for the first year, £60 for each subsequent year; or 5 years, with apprenticeship, £260.

LEEDS SCHOOL OF MEDICINE.—Instruction in Vaccination, £1 1s. LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.—Summer course of Practical Anatomy, £2 2s. The aggregate fee of £80 17s. for lectures and hospital practice is exclusive of Practical Chemistry, Ophthalmology, Dissections, and Practical Anatomy in summer. Vaccination, £1 1s.

OWENS COLLEGE (MANCHESTER ROYAL) SCHOOL OF MEDICINE. Extra charges beyond composition Fee; Medical Tutor, £2 2s. per annum; Practical Anatomy after two sessions, 3 months, £2 2s.; 6 months, £3 3s.; Demonstrations in Comparative Anatomy, and in Botany, each £1 1s.; Practical Chemistry, for chemicals, £1 1s.

NOTES CONCERNING THE HOSPITALS AND MEDICAL SCHOOLS IN LONDON.

In addition to the Tables of the Classes, hours of attendance, and fees, given at pages 336-339, we subjoin extracts from the Programmes issued by the several Medical Schools. We have extracted those points of information which are of most interest to the student, in addition to those given in the tables.

ST. BARTHOLOMEW'S HOSPITAL.—*The Clinical Practice of the Hospital* now comprises a service of 710 beds: of these 227 are allotted to the medical cases, 322 to the surgical cases, 26 to diseases of the eye, 23 to the diseases of women, and 81 to syphilitic cases; while 34 are at the Convalescent Hospital at Highgate. Children are admitted into both the medical and surgical wards; those under five years of age being received into the female wards.

Museums, etc.—The Anatomical Museum, and the Museum of Materia Medica and of Botany, are open to students daily from 10 A.M. to 4 P.M. The Reading Room is open every day; during winter from 10 to 5; summer, 9 to 5; vacations, 10 to 2.30.

College.—Students are admitted to residence on the recommendation of a medical officer of the hospital, which may be obtained on adducing satisfactory evidence of good moral character. The entrance-fee is £2 2s. Information regarding the College may be obtained on application to the Warden, Dr. Norman Moore.

Examinations.—Students preparing for their examinations are arranged in classes, and examined by the lecturers and demonstrators. An examination of all students of the first year is held at the close of the first winter and first summer sessions.

Appointments.—Four House-Physicians and four House-Surgeons (who must be qualified to practise) are appointed annually. Fee, £26 5s. Each of these officers receives a salary of £25. Two Midwifery Assistants are appointed every six months. An Ophthalmic House-Surgeon is appointed for six months. (The preceding are provided with rooms.) The Clinical Clerks to the medical in-patients, and the Clerks to the Physician-Accoucheurs, are chosen from the most diligent students. Sixteen dressers to the surgical in-patients and the surgical casualty department are selected each year from the students of the second year. Other in-patient dresserships may be obtained by payment of the usual fees. There are also Clerks and Dressers to the Assistant-Physicians and the Assistant-Surgeons in the special departments.

Exhibitions, Scholarships, and Prizes.—Open Scholarship in Science, value £100 for one year, to be competed for on September 27th, by candidates under twenty-five years of age, who have not entered to the medical or surgical practice of any metropolitan medical school. The subjects are Physics, Chemistry, Botany, and Zoology. *First Year.*—Jeaffreson's Exhibition: £20 yearly, tenable for two years. Confined to students of less than six months' standing. Examination on October 18th. Subjects, those of Preliminary Education appointed by the General Medical Council. Preliminary Scientific Exhibition, on October 28th; subjects, Physics, Chemistry, Botany, and Zoology; value £50, for one year; confined to students of less than six months' standing. The holder of the Open Scholarship is not eligible. Three Junior Scholarships, of the value of £50, £30, and £20, after the general examinations in first year's subjects at the end of the winter and summer sessions. Treasurer's Prize for Practical Anatomy, Junior. *Second Year.*—Foster Prize for Practical Anatomy, senior. *Second or Third Year.*—Senior Scholarship, value £50, in Anatomy, Physiology, and Chemistry. Wix Prize: subject, "The mutual influence of General Literature and Medical Science, as illustrated by the writers of the seventeenth century." Hichens Prize: subject of examination, Bishop Butler's *Analogy*. *Third or Fourth Year.*—Lawrence Scholarship and Gold Medal, value, £47 5s.: subjects, Anatomy and Physiology, Medicine and Surgery in all their Branches. Two Brackenbury Scholarships in Medicine and Surgery. Candidates for the Lawrence and Brackenbury Scholarships may not compete before the end of the third winter session, nor later than the beginning of the fifth winter session in the hospital. Bentley Prize, for the best report of not less than twelve surgical cases occurring in the wards of the hospital during the previous year. The Kirkes Gold Medal for Clinical Medicine. The conditions under which the exhibitions, scholarships, and prizes are awarded, will be found in the prospectus of the College.

The Abernethian Society, composed of the teachers and students of the hospital, meets in the library on every Thursday evening at 8 P.M. during the winter session, for the reading and discussion of papers on subjects of medical science or practice, and for the exhibition of pathological specimens.

Communications regarding the Hospital and Medical College must be addressed to the Warden of the College, St. Bartholomew's Hospital.

CHARING CROSS HOSPITAL.—Besides the Clinical Instruction in the Hospital, matriculated students are admitted to the practice of the Royal Westminster Ophthalmic Hospital (36 beds).

Appointments.—A Medical Registrar and a Surgical Registrar, each with a salary of £40 a year, are appointed. Resident Medical, Surgical, and Obstetrical Officers, Assistant Medical and Surgical Officers, Clinical Clerks, Surgeons' Dressers, and a Pathological Assistant, are appointed from among the matriculated students, without additional fee.

Scholarships, Medals, and Prizes.—Two Entrance Scholarships, value £30 and £20, tenable for one year, awarded after examination in English, Latin, French or German, and Mathematics, with (optional) either Chemistry, Mechanics, German, or French.—The Llewellyn Scholarship of £25, open to all matriculated students who have just completed their second year. Examination at the end of the second summer session, in Descriptive and Surgical Anatomy, Physiology, Materia Medica, Medicine, Surgery, Midwifery.—The Golding Scholarship, £15 a year, open to all matriculated students who have just completed their first year. Examination at the end of the first summer session, in Descriptive Anatomy, Physiology, Materia Medica, and Chemistry.—The Governors' Clinical Gold Medal, Silver and Bronze Class Medals and Certificates of Honour in all the classes.

Further information may be had of the Librarian, who attends at the office of the School, Chandos Street, Charing Cross, between the hours of 10 and 4; or of the Dean, Mr. Francis Hird.

ST. GEORGE'S HOSPITAL.—The Aggregate and Perpetual Fees do not include Practical Chemistry.* Gentlemen who have commenced their professional studies at an English University will be admitted as Perpetual Pupils on payment of a reduced fee.

The Hospital contains 353 beds, of which 205 are devoted to surgical, and 148 to medical, cases. Wards are especially set apart for the reception of cases of diseases of the eye, and diseases of women. In the women's wards, cribs are placed for the reception of children.

The *Library and Reading Room* and the *Museum* are open daily.

Clinical Instruction.—The pupils of the hospital are divided into classes under the superintendence of the physicians and surgeons in rotation, and are placed in charge of cases as Clerks and Dressers.

Hospital Appointments.—House-Physicians, House-Surgeons, an Assistant House-Physician, and an Assistant House-Surgeon, half-yearly, from among the perpetual pupils. The House-Physicians and House-Surgeons hold office for twelve months, and reside and board in the hospital free of expense. They must each deposit 50 guineas with the Treasurer of the hospital which will be returned to them on the expiration of their term of office, if they have satisfactorily performed their respective duties.—An Obstetric Assistant is appointed annually. He resides and boards in the hospital, and receives a yearly salary of £100.—A Curator of the Pathological Museum, a Medical and a Surgical Registrar, and a Demonstrator of Anatomy, are appointed annually from among the senior pupils, each with a salary of £50. Every student is required to assist the Curator for one month in performing *post mortem* examinations.—Two Assistant Medical Registrars are appointed every six months by competition. This office must be held before competing for that of House-Physician.—An Assistant-Surgical Registrar is also appointed; this office must be held, alternately with that of Ophthalmic Assistant, before competing for the office of Assistant House-Surgeon.

Exhibitions and Prizes.—The William Brown Exhibitions: 1. £100 *per annum* for two years to a perpetual pupil of the hospital under the age of 25, who has become entitled to be registered as a medical practitioner within two years previously; examination in July. 2. £40 *per annum* for three years to students of the third and fourth winter sessions.—Brackenbury Prizes in Medicine and in Surgery, each interest of £1,000 three per cent. consols, open to all pupils who have not completed the fourth year; examinations in May.—Sir Charles Clarke's Prize, interest of £200 annually, for good conduct; awarded at end of summer session.—The Thompson Silver Medal, and the Treasurer's Prize, at close of winter session, for proficiency in clinical examinations

* Perpetual Pupils are entitled to admission to the practice of the Physicians and Surgeons, to all the Lectures (except Practical Chemistry), to compete for all Prizes and Exhibitions, to hold the appointments of House-Physician, House-Surgeon, and Assistant House-Surgeon, and to become Clinical Clerks for two periods of three months each, and Dressers for two similar periods. This payment must in all cases be made at the time of entry.

in three Medical and three Surgical cases.—Sir Benjamin Brodie's Clinical Prize in Surgery, for the best report (with notes) of not more than twelve surgical cases in the hospital during the preceding twelve months.—Dr. Acland's Clinical Prize in Medicine, for the best record of not more than twelve cases of disease treated in the preceding twelve months. (The Clinical Prizes are open to fourth year's students. Reports must be sent in on or before May 1).—The Henry Charles Johnson Memorial Prize, for Practical Anatomy.—General Proficiency Prizes, £10 10s., for students of each year: subjects for first year, Anatomy, Physiology, Chemistry, and Botany; for second year, Anatomy, Physiology, Chemistry, and Materia Medica; for third year, Medicine, Surgery, Pathology, and Midwifery.

The Medical Society meets once a week at the hospital during the winter session. All former and present pupils of St. George's Hospital are eligible as members.

Further information may be obtained from Dr. Barclay, the Treasurer of the School; from Dr. Wadham, the Dean of the School; and from the Resident Medical Officer of the Hospital.

GUY'S HOSPITAL.—The hospital contains 690 beds. Of these, 220 are for medical cases, 260 for surgical cases, 26 for diseases of women, 48 for syphilitic, and 50 for ophthalmic cases; there are also 30 children's cots, and 60 reserve beds, with 8 in private rooms.

Museums, etc.—The Museums of Human Anatomy, Comparative Anatomy, Pathological Anatomy, and Materia Medica are open to the students. The Library contains upwards of 5,000 volumes, and is open to the students daily from 10 A.M. to 4 P.M.

Clinical Instruction.—Two wards, containing together forty beds, are especially devoted to clinical teaching in Medicine. The Surgeons lecture upon selected cases during the winter, and the Assistant-Surgeons in the summer. The Obstetric Physicians, and the Ophthalmic, Dental, and Aural Surgeons, also give clinical and practical instruction. Special demonstrations and instructions are also given in Cutaneous Diseases.

The Registrars and the Demonstrators of Anatomy and Chemistry assist the pupils in their studies.

Pupils attending the practical courses are charged for the materials used.

Pupils' Appointments.—All these appointments are given according to the respective merits of the candidates, and without payment. Six House-Physicians are appointed in each year, and hold office for six months each—two months as junior, four as senior. Six House-Surgeons and twelve Obstetric Residents are appointed every year: the former hold office each for four months, the latter for two months. The Senior House-Physician, House-Surgeon, Obstetric Resident, and the Dressers on special duty, reside in the hospital, and are boarded free of expense.—Clinical Assistants are selected from those students who have been medical ward-clerks.—Dressers are selected from those who have been surgical ward-clerks. They hold office for six months each.—The Assistant-Surgeons' Dressers and Dressers in the Surgery are appointed for three months; and all students who have not otherwise obtained certificates must hold each of these appointments. The Dressers in the Eye-Wards hold office for four months each.—Dressers are appointed to the Dental and to the Aural Surgeon for two months.—The Post Mortem Clerks are selected from students who have completed their second year, and hold office for two months each.—Extern Obstetric Attendants are appointed monthly.—Reporters or Ward-Clerks, and Clerks to the Assistant-Physicians and Assistant-Surgeons, are also appointed.—Two Clerks are appointed to attend in the Electricity Room.—A special honorary certificate is given to every gentleman who has diligently performed the duties of the various offices.

Prizes.—Voluntary examinations are held as follows: 1. At entrance, in Classics, Mathematics, Modern Languages, Chemistry, Physics, and Botany.* The first two of the successful candidates receive £60 and £30. Examination on October 7th, 8th, and 9th. 2. At end of first summer session, in the subjects of the year. Three prizes of £50, £25, and £10 10s. 3. At end of second summer session, in Anatomy, Physiology, and Practical Physiology. Two prizes of £25 and £10. 4. At end of third summer session, in Medicine, Surgery, Midwifery and Diseases of Women, and Medical Jurisprudence. Two prizes of £35 and £20. Honorary certificates are given to those candidates who pass creditable

* Mathematics includes Arithmetic; Algebra to Quadratic Equations; Euclid. Books 1, 11, 111, and 1V; and Plane Trigonometry. The classical subjects are, for 1875: Greek, Euripides, Hecuba; Herodotus, Book 111; Latin, Ovid, Epistles v, vii; Sallust, *Catiline's Conspiracy*. German: Schiller's *Wilhelm Tell*; French: Voltaire, *Charles XII*. For 1876: Greek: Homer, *Iliad*, Book 111; Xenophon, *Memorabilia*, Books 1 and 11; Latin: Virgil, *Æneid*, Book 1; Cæsar, *De Bello Gallico*, Books 1 and 11; German, Goethe, *Hermann und Dorothea*; French: Molière, *Le Misanthrope*. Candidates may substitute French and German for Greek.

examinations. Special certificates are given to gentlemen who have attended 100 cases of Midwifery.—Two Gold Medals given annually by the Treasurer to students who have completed the third, and not exceeded the fourth year, for proficiency in Clinical Medicine and Clinical Surgery.

The Pupils' Physical Society meets on alternate Saturdays, at 7.30 P.M. A prize of £5 from the funds of the Society is given at the end of the session to the member who sends in the best essay and report of cases. Two other prizes of £5 and £10 are given to the members who are judged to have read the best essays before the Society. A fourth prize of £5 is given to the member who has most distinguished himself in the debates.

Further information may be obtained from the Dean, Dr. F. Taylor; or from Mr. Stocker, Secretary to the School.

KING'S COLLEGE AND HOSPITAL.—Matriculated students are those who (with certain exceptions named in the *Calendar*) receive their entire medical education at King's College. They have the privilege of filling the offices of clinical clerks, dressers, dentists' assistant, physician's assistant, physician accoucheur's assistant, assistant house-accoucheur, assistant house-physician, house-surgeon, and assistant house-surgeon, to the hospital; of becoming candidates for the Daniel, Inglis, Warnford, and Medical Scholarships, for the Sambrooke Registrarships, and for the Warnford, Leathes, Todd, Tanner, Jelf, and other endowed prizes. They are also admitted to the practice of the hospital at a reduced fee.

Attendance on the Medical Tutor is compulsory on residents during their first year. The Principal requests each student, on entering his second term, to contribute £1 1s. towards the expenses of the restoration of the College Chapel.

The Hospital contains 170 beds in use.

The Museums of Anatomy, Materia Medica, Natural History, etc., are open daily from 10 till 4. The Medical Library is open daily.

Clinical Instruction is given in the wards and by lectures in the medical and surgical departments; also in the Diseases of Women and Children, in Dental Surgery, in Diseases of the Eye, in Throat-Diseases, and in Skin-Diseases.—Demonstration and practical instruction in Morbid Anatomy are given in the *Post Mortem* Theatre.—Special Instruction is given in Medical Chemistry and the Microscope by the Physicians.

The Medical Tutor assists, by instruction and examination, all students in the subjects of the first winter and summer sessions, as well as those preparing for the Preliminary Scientific Examination of the University of London.

Resident Medical Officers, Clinical Clerks and Dressers, are chosen by examination from matriculated students who are pupils at the Hospital.

Scholarships and Prizes.—Two Warnford Scholarships, £25 per annum for three years, for the encouragement of previous education;* and one Warnford Scholarship of £25 per annum, for two years, for resident medical students.—College Scholarships given yearly to matriculated students—one of £40 for two years, open to students of the third and fourth year; one of £30 for one year, open to students of the second and third year; three for £20 for one year, open to students of the first year.—The Daniell Scholarship, open to students who have worked in the laboratory six months, £20 per annum for two years.—Sambrooke Registrarships.—Science Exhibitions given by the Clothworkers' Company—one, annually, of £25 per annum for two years, for

* Two Scholarships, of the value of £25 per annum each, to be held for three years, will be given in October 1875. Candidates must be matriculated students of the Medical Department, and also perpetual pupils of the Hospital. Their first Winter Session must commence in October 1875. The examination will be in the following subjects: 1. Divinity: The First and Second Books of Samuel, and the Book of Psalms; The Gospel according to St. Luke, and the Acts of the Apostles; The Prayer Book, its general history and structure; (Proctor on the Book of Common Prayer recommended). 2. English Language and Literature: Shakespeare, *Macbeth*; English History—History of England during the Reign of Elizabeth. 3. Latin: Sallust, *The Conspiracy of Catiline*. 4. Mathematics: Arithmetic; the ordinary rules, with vulgar and decimal fractions; Algebra, as far as and including Quadratic Equations; Euclid, Book I, Book II except props. 8, 9, 10, Book III. 5. Greek: Homer, *Odyssey*, Book XVI. 6. French, *De la Grandeur et de la Décadence des Romains*, par Montesquieu. 7. German: Lessing's *Minna von Barnhelm* (Clarendon Press Series). 8. Chemistry: Miller's *Inorganic Chemistry* in Longman's Series of Text Books on Science). 9. Natural Philosophy: Descartes's *Natural Philosophy*, translated by Professor Everett, Part I and Part IV. 10. Botany: Bentley's *Manual of Botany*, 3rd edition, to page 203, together with chapters on the General Principles of Classification, and Diagnosis of the following natural orders: Ranunculaceæ, Rosaceæ, Compositæ, Labiate, Scrofulariaceæ, and Liliaceæ. Subjects 1, 2, 3, 4, are compulsory; candidates will also be allowed to select one subject out of 5, 6, and 7, and another either out of 5, 6, 7, or out of 8, 9, 10.—The days of examination for 1875 are fixed as follows: Wednesday, September 29th, Divinity; Thursday, September 30th, Mathematics and Latin; Friday, October 1st, History and English Literature. The other subjects will be arranged as most convenient.

proficiency in four of the following subjects: Mathematics, Mechanics, Physics, Chemistry, Botany, and Zoology.—Leathes' Prizes: Interest of £300, applied in purchase of a Bible and Prayer-Book, as annual prizes to two matriculated students.—Warneford Prizes: £40 in medals and books, to two matriculated students.—Class Prizes: Books of the value of £3, and certificates of honour, are awarded annually for proficiency in each of the several subjects taught in the classes.—Two Medical Clinical Prizes, one of £3 for the winter session, and the other of £2 for the summer session; and two Surgical Clinical Prizes of the same value.—Todd Medical Clinical Prize: Bronze Medal and Books to the value of £4 4s.—Jelf Medal, to the candidate at the senior scholarship examination who is second in order of merit.—Tanner Prize, value £10, for proficiency in Diseases of Women and Children, and in Obstetrics.

Associates of King's College.—At the end of each winter session, the professors recommend to the Council the names of medical students to be elected associates.

Residence.—Rooms are provided within the College for a limited number of matriculated students. The cost of the academical year varies from £50 to £60. Some of the professors, etc., receive pupils into their houses. There is a dining-hall in the College.

The Medical Society meets on Thursdays, at 8.30 P.M.

The Dean of the Medical Department or the Subdean attends daily, Saturday excepted, at King's College, from 11 A.M. to 1 P.M., for the purpose of seeing students and their friends. Any letter addressed to the Dean on the subject of this department will receive early attention.

LONDON HOSPITAL.—Students in Arts of Universities where residence is required, who may have attended Lectures in Anatomy, Physiology, Chemistry, Botany, or Comparative Anatomy, and have obtained signatures for such attendance, fulfilling the requirements of the Examining Boards, may become pupils of the London Hospital, eligible for Hospital Prizes and Appointments, on payment of £52 10s. for Practice (perpetual) at the Hospital. Entrance can be made to separate Courses of Lectures. Graduates of Canadian or American Universities or Medical Colleges are admitted, on showing their diplomas, to six months' dressership and perpetual hospital practice for £10 10s. Courses of lectures must be paid for if certificates are required.

The Hospital contains about 600 beds, thus allotted: Accidents and surgical cases, 324; medical cases, 179; diseases of women, 13; children under seven years of age, 36; ophthalmic cases, 12; out-door wards, 36. The completion of the new wing will raise the number of beds to 800.

Museums, &c.—The Anatomical and Pathological Museum, the Materia Medica Museum, and the Library, are open daily.

Clinical Instruction.—Two medical wards, containing together thirty beds, have been set apart for clinical teaching. The Clinical Professor will meet his class twice a week. Bedside instruction will also be given by the physicians not on special clinical duty. Students requiring signatures for medical practice must attend the Clinical Professor. In the out-patient department, the Physicians and Assistant-Physicians impart instruction at each visit. The surgeons make clinical observations on their cases, and a clinical lecture is given once a week.

Special Departments.—There are departments for instruction in Obstetric Medicine and Surgery, Vaccination, Diseases of the Eye and the Use of the Ophthalmoscope, Diseases of the Ear, Diseases of the Skin and of the Throat, Syphilis and Local Contagious Diseases, Mental Diseases, Dentistry, and Practical Pharmacy. Students desirous of obtaining a practical knowledge of Mental Diseases can attend, without additional fee, the practice of Dr. Millar, at the Bethnal House Asylum, every Wednesday, from 10 to 12. Dr. Huggings Jackson intends to give a short course of lectures on Mental Diseases.

Appointments.—A Resident Medical Officer, qualified to practise Medicine, who receives £75, is appointed for twelve months. He is eligible for re-election, and then receives £100. Two Junior Resident Medical Officers are appointed every six months. Eight Medical Assistants, two for each Physician, are appointed every three or six months. Every student is expected to act as Clinical Clerk for six weeks in the Medical, and as Dresser for three months in the Surgical out-patient department. A Resident Accoucheur is appointed for six months. All students who have attended a course of instruction in Midwifery can place their names on the list of Maternity Pupils, and have cases. Four House-Surgeons are elected, usually for six months. Any student may enter his name on the list as a Dresser. Two Dressers reside and board in the hospital every week. Two Clinical Assistants are appointed every three months for the medical, and two for the surgical out-patients and special departments. They are eligible for re-election. Each receives £40 *per annum*. A Medical Registrar and a

Surgical Registrar are appointed annually; the former receives £100, the latter £100. A Dental Assistant, *Post Mortem* Clerks, and two Prosectors of Anatomy are also appointed. Full pupils, and those who, having commenced elsewhere, pay the general fee to the hospital and college, are eligible for all scholarships, prizes, and appointments. Students who have commenced elsewhere, but who, at or before the beginning of the second winter session, become pupils of the hospital and college by paying the composition fee, will be eligible for the Dresserships, for three months as House-Surgeon, and for the offices of Ward Clerk, *Post Mortem* Clerk, Maternity Pupil, Clinical Assistant, and Registrar. All the appointments are open to students without fee. The holders of resident appointments are provided with rooms and board.

Scholarships and Prizes.—Nine scholarships will be offered for competition. 1 and 2. Two Entrance scholarships, value £60 and £40; examination on September 27th, 28th, and 29th; subjects the same as those of the Preliminary Scientific Examination of the University of London. 3 and 4. Two Buxton scholarships, value £30 and £20, in October, after examination in the subjects of preliminary education.* These scholarships are open to full students of less than three months' standing. 5. A scholarship at the end of the winter session, value £20, to a first year's student: subject, Human Anatomy. 6. A scholarship, value £25, to a first or second year's student, at the end of the winter session: subjects, Anatomy, Physiology, and Chemistry. 7, 8, 9. Hospital scholarships, value each £20, for proficiency and zeal in Clinical Medicine, Surgery, and Obstetrics; also a second prize, value £5, with certificate, for attendance on the largest number of Obstetric cases.—The Duckworth Nelson Prize, value £10, at the end of the winter session, 1875-76, open to all students who have not completed their education: subjects, Practical Medicine and Surgery.—Money prizes to the value of £60 *per annum* to the most meritorious of the dressers in the out-patient rooms. Special certificates to those gentlemen who have faithfully performed their duties in the hospital, and to those who have distinguished themselves at the examinations.

The Medical Society meets for the reading and discussion of papers at 7.30 P.M. on alternate Wednesdays during the winter session.

Information may be obtained from Mr. Warren Tay, Vice-Dean; from any Member of the Hospital Staff; or from the Lecturers at the College.

ST. MARY'S HOSPITAL.—Students who have kept the two years' course of medical study at the University of Cambridge are admitted as perpetual pupils on payment of a composition fee of £57 15s.; and students who have kept a portion of the course there or elsewhere, at a proportionate reduction.

The Hospital contains 170 beds—68 medical and 102 surgical. Two wards are appropriated to Diseases of Children and one to those of Women; there are also beds for ophthalmic cases.

The Reading Room and Library are open daily. *The Museum* is open daily to students. It contains about 3,000 specimens of healthy and morbid anatomy. There are also a Materia Medica Department, and a collection of specimens illustrative of Comparative Anatomy.

Clinical Lectures twice a week by the Physicians and Surgeons. Special courses are given on Ophthalmic, Aurial, and Dental Surgery; also clinical demonstrations on Diseases of the Skin and of the Throat. The students are carefully trained to the use of the Microscope. A Histological Room is open daily.

The Medical Tutor assists the students daily in the wards of the hospital, and gives elementary practical instruction on medical and surgical cases. He also examines practically students who are preparing for their final examinations. He receives a certain number of students to board and lodge in his house.

Hospital Appointments are open to the pupils without additional fee. Three Resident Medical Officers are appointed for twelve months, and an Obstetric Officer for six months; all live free of expense in the hospital.—A Demonstrator of Anatomy, a Medical Tutor, and a Resident Registrar, with salaries of £100, are appointed annually, and may be re-elected.—All students must act as clinical clerks and dressers for six months after passing the Primary Examination. Students of the third year are appointed to assist the Physicians and Surgeons in charge of the out-patients for three months each.

Scholarships and Prizes.—Three Scholarships in Natural Science,

* The subjects are:—1. The English Language, including Grammar and Composition. 2. Arithmetic, including Vulgar and Decimal Fractions. 3. Algebra, including Simple Equation. 4. Geometry—first Two Books of Euclid. 5. Latin—Caesar, *De Bello Gallico*, Book II. 6. One of the following subjects at the discretion of the candidate: (a) Greek—Xenophon's *Anabasis*, Book I; (b) French—X. B. Saintine's *Picciola*; (c) German—Schiller's *Wilhelm Tell*; (d) Natural Philosophy, including Mechanics, Hydrostatics, Pneumatics.

tenable for three years; value £60 the first year, £40 the second year, and £20 the third year, are awarded by competitive examination at commencement of winter session every year. An exhibition of £20 for one year to the second candidate in order of merit. A Scholarship in Natural Science, tenable for three years; value £60 the first year, £25 the second year, and £15 the third year; restricted to students educated at Epsom College. An open Scholarship in Classics and Mathematics, value £35 for one year.* The successful candidates for Scholarships and Exhibitions must enter as perpetual pupils of the Hospital.—A prize of £4 4s. in Anatomy and Histology, and three of £2 2s. each in Chemistry, Practical (inorganic) Chemistry, and *Materia Medica* and Botany, to first year's students.—A Scholarship in Anatomy, value £20, for one year, after competitive examination in Anatomy, Physiology, and Histology; a prize of £4 4s. for Anatomy and General Physiology; and prizes of £2 2s. each for Midwifery and Medical Jurisprudence; to students of the second year.—A Scholarship in Pathological Anatomy, value £20, after competitive examination in Morbid Anatomy, Dissection, and Microscopic Anatomy, tenable for one year, and prizes of £3 3s. each in Medicine and in Surgery, and two of £2 2s. each in Pathology and Comparative Anatomy, for third year's students; £3 3s. each to the Clinical Clerk and to the In-patient Dresser who shall have discharged their duties in the most satisfactory manner.—Two Prosectors are appointed annually, who each receive a certificate and £5.

The *Medical Society* meets an alternate Wednesday evenings during the Winter Session, at 8 P.M.

Further information may be obtained from Dr. Shepherd, Dean of the School; from any of the Lecturers, or from the Resident Registrar, at the Hospital.

MIDDLESEX HOSPITAL.—The aggregate fee admits to the Library, to one course of Practical Chemistry and two courses of Dissections, to all the lectures, and to the instruction of the tutor; it includes also all charges for Clinical Clerkships and Dresserships. Members of English Universities who have completed one year of medical study in University are admitted to all lectures and hospital practice required (except Practical Chemistry) for £55; this may be paid in instalments of £35 and £20; but in the latter case, £10 must be paid for each additional year.

The *Hospital* contains upwards of 300 beds, of which 185 are devoted to surgical and 120 to medical cases. There are 33 beds for cases of cancer; also wards for cases of uterine disease and of syphilis, and beds for cases of diseases of the eye.

The *Museum* is open to students daily from 9 to 5. It contains above 5,000 specimens.—The *Library and Reading Room* are open to all general students.

Clinical Lectures are delivered regularly by the Physicians and Surgeons, and by the Physician-Accoucheur and the Ophthalmic Surgeon.—Special instruction in Diseases of the Skin, and of the Larynx and Ear is given.

The *College Tutors* assist all general students of the hospital, especially those who are preparing for examination.

Appointments, etc.—Two House-Surgeons are appointed for six months, after competitive examination, in April and October. Candidates must be 21 years of age, and must have obtained certificates of proficiency as in-patient dressers. The Junior House-Surgeon succeeds to the office of Senior House-Surgeon only if he have performed his duties satisfactorily. Each House-Surgeon pays a fee of £21; if he have not been a surgical pupil of the hospital, he pays £31 10s. Three Resident Physicians' Assistants are appointed from time to time for six months, after competitive examination. They must have a legal qualification. Each Resident Physician's Assistant pays £10 10s. on appointment; and, if he have been a medical pupil of the hospital for a limited time, a sum sufficient to make him a perpetual student of the medical practice; if he have been neither a general nor an occasional pupil of the hospital, he pays a fee of £21. A Resident Obstetric Assistant is appointed for six months. He pays £10 10s. Clinical Clerks and Dressers are appointed for six months. The appointments are so arranged that every student may take both a clerkship and a dressership at some period. Each student must be an out-patient clerk and out-patient dresser for six months respectively before being eligible to an in-patient clerkship or dressership.

Scholarships and Prizes.—Two Broderip Scholarships, value £30 and £20, tenable for two years, to students who have completed the third year, for reports or comments on selected medical and surgical cases.—Two Entrance Scholarships, value £25 and £20, tenable for

two years,* open to all gentlemen commencing their medical studies at the hospital in October, 1875.—The John Murray Scholarship and Gold Medal, founded in connection with the University of Aberdeen, will be awarded every third year to a student of the Middlesex Hospital.—The Governors' Prize, value £21, to the student who, at the end of the third winter session, shall have been most diligent in the wards, and have attained the highest proficiency in the periodical examinations.—A Clinical Prize of £10 10s. to the candidate who stands third in the competition for the Broderip Scholarships.—Class Prizes are given in each subject.

The *Students' Medical Society* meets in the Board Room of the Hospital once a fortnight during the winter session.

Information may be obtained from Dr. Robert King, the Dean; from Dr. Greenhow, Treasurer of the College; from any of the Lecturers; or from the Resident Medical Officer at the Hospital.

ST. THOMAS'S HOSPITAL.—The *Hospital* contains 569 beds, distributed as follows: Medical, 180; Surgical, 230; Ophthalmic, 20; Diseases of Women, 20; Venereal (women), 30; Infectious Diseases, 59; Children under six years of age, 30.

Clinical Instruction in the wards and Clinical Lectures are given by the Physicians, Obstetric Physician, Surgeons, and Ophthalmic Surgeon. There are special departments for the diseases of women and children; diseases of the eye, with ophthalmoscopic demonstrations; diseases of the skin; diseases of the teeth; and for vaccination. A course of practical and manipulative Surgery is given in accordance with the regulations of the Royal College of Surgeons, and of the Army, Navy, and India Boards. A course on Mental Diseases is given by Dr. Wm. Rhys Williams, Resident Physician at Bethlem Royal Hospital.

Museum, etc.—Students have access to the Library and to the Museums of Human Anatomy, of Comparative Anatomy, of *Materia Medica*, and of Chemistry and Mineralogy, and to the Laboratories of Practical Physiology and Practical Chemistry.

Scholarships and Prizes.—Two Entrance Scholarships in Natural Science, value £60 and £40, in first week in October; subjects, Physics, Chemistry, Botany, and Zoology.—The William Tite Scholarship, £30, to the student highest on the first class list at the examination at the end of the winter session.—The Musgrove Scholarship, value £42 per annum, biennially to the student highest in the first class list at the end of the second winter session.—A College Scholarship of same value, alternately with the Musgrove Scholarship.—College Prizes for each year's students, of £20, £15, and £10 each winter, and £15, £10, and £5 each summer.—The Cheselden Medal, annually, for Surgery, and Surgical Anatomy.—The Mead Medal, annually, to a third year's student for the practical examination in Medicine.—The Treasurer's Gold Medal, annually, to a third year's student, for general proficiency and good conduct.—The Grainger Testimonial Prize, value £20, biennially, to third or fourth year's students, for a Physiological Essay. The Solly Medal, with a Prize of £10 10s., every two years, for Reports of Surgical Cases.

Appointments.—All students have the opportunity afforded them of being engaged in the performance of practical duties in connection with the Medical, Surgical, Obstetrical, Ophthalmic, and Pathological Departments of the Hospital. Obstetric Clerks are from time to time appointed. Each holds office for a fortnight, and Certificates of Honour are awarded to those gentlemen who have satisfactorily attended fifty Maternity cases. Two or more gentlemen are selected from students who have completed their second winter session, to act as Assistants in the Dissecting Room. Two House-Physicians, two House-Surgeons, and a Resident-Accoucheur, are selected according to merit from gentlemen who have obtained their diplomas, and are provided with rooms and commons. Two Hospital Registrars each year, preference being given to gentlemen who have completed their studies in the school. Each Registrar, on completing his Annual Report to the satisfaction of the Physicians or Surgeons, receives £40.

Further information may be obtained from Mr. R. G. Whitfield, the Medical Secretary, at the Hospital.

* The Examination will take place on September 28th and following days. The following are the subjects for Examination. *Latin.*—Passages for translation into English, short passages for translation from English into Latin, and questions in Grammar and Ancient Geography.—*Greek.*—Easy passages for translation into English; questions in Grammar and Ancient Geography.—*French or German.*—Passages for translation into English, short passages for translation from English into French or German, and questions in Grammar.—*Mathematics.*—Arithmetic, Algebra up to and including Quadratic Equations, and Euclid, books i, ii, iii.—*Natural Philosophy.—Chemistry.—Botany.—Zoology.*—Huxley's Classification of the Animal Kingdom; Rudiments of Animal Physiology. Candidates will be examined in any three, and not more, of the above subjects which they may select; but only one Modern Language and two out of the last three subjects are permitted.

* Subjects: Sallust, *Conspiracy of Catiline*; Homer, *Odyssey*, Book XVII; First Four Books of Euclid, with Algebra as far as Quadratic Equations.

UNIVERSITY COLLEGE AND HOSPITAL.—The General and Medical Libraries, the Museums of Anatomy and Pathology, of Comparative Anatomy, of Materia Medica and Chemistry, of Geology, and of Natural Philosophy, are open daily. There are also a Chemical and a Physiological Laboratory, where instruction is given under the superintendence of the Professors of Chemistry and of Physiology.

Clinical Instruction is given by the physicians and surgeons in the wards and in the out-patient department, and by lectures and examinations. Dr. Wilson Fox, the Holme Professor of Clinical Medicine, delivers Clinical Lectures, and trains the pupils in the practical study of disease. Dr. Roberts, Assistant-Teacher of Clinical Medicine, gives special instruction in Physical Diagnosis and Clinical Observation. Lectures are given once a week by Mr. Christopher Heath, the Holme Professor of Clinical Surgery; once a fortnight or oftener by Mr. Marshall, Mr. Berkeley Hill, and occasionally by Mr. Erichsen. Sir Henry Thompson, Emeritus Professor of Clinical Surgery, will deliver a short course during the session. In the summer, the Assistant-Surgeons will instruct first year's students in the observation of patients. Clinical Lectures on Midwifery and the Diseases of Women are delivered once a fortnight; also on Ophthalmic Surgery, and on Diseases of the Skin. Arrangements are made for practical instruction in Vaccination.

Private Instruction.—Gentlemen may obtain assistance in their studies within the College, on application to the respective Professors.

Offices.—Physicians' Assistants, House-Surgeons, Midwifery Assistants, Physicians' Clerks, Surgeons' Dressers, Ophthalmic Surgeons' Assistants, and Ward-Clerks, are selected from among the pupils without additional fees. The Physicians' Assistants, the Obstetric Assistant, and the House-Surgeons reside in the hospital, paying for their board.

Scholarships, etc.—Three Entrance Exhibitions, value £30, £20, and £10 *per annum*, tenable for two years, to gentlemen who are about to commence their first winter's attendance.*—The Atkinson-Morley Surgical Scholarship, £45, tenable for three years, for proficiency in Surgery.—The Sharpey Physiological Scholarship, annual value about £70.—The Filbiter Exhibition of £30, annually in July, for proficiency in Pathological Anatomy.—Dr. Fellowes's Clinical Medals, one Gold and one Silver, with Certificates of Honour, at the end of each winter and each summer session.—The Liston Gold Medal, with Certificates of Honour, at the end of the session, for reports and observations on the Surgical Cases in the Hospital.—The Alexander Bruce Gold Medal, for proficiency in Pathology and Surgery.—The Cluff Memorial Prize, every second year, to the most proficient in Anatomy, Physiology, and Chemistry: next award in 1877.—Gold and Silver Medals or other Prizes, as well as Certificates of Honour, after competitive examinations in the classes.—Prizes to the value of £10 in the class of Hygiene.

The Medical Society meets to read and discuss papers on alternate Wednesdays throughout the session, at 7 P.M.

Residence of Students.—Several gentlemen connected with the College receive students to reside with them; and in the office of the College there is kept a register of persons who receive boarders.

Information respecting the College may be obtained from the Dean, Dr. Bastian; the Vice-Dean, Mr. Marshall; or the Secretary, Mr. J. Robson.

WESTMINSTER HOSPITAL.—The aggregate and perpetual fees include only one course of Practical Chemistry and Practical Physiology.† Gentlemen who do not enter as perpetual students before the end of their second year will be charged a fee of £4 4s. for every session after the completion of their third year, in addition to any special fees which may be payable. Members of the Universities of Oxford or Cambridge, who have completed one year of medical study at the University, will be admitted to the Hospital Practice and Lectures (except Practical Chemistry and Comparative Anatomy) required by those Universities, and by the Colleges of Physicians and Surgeons, on payment of £52 10s. in one sum.

The Hospital contains 191 beds.

Museums, etc.—The Anatomical Museum is constantly open to the

* The subjects of examination are the following. Latin and Greek—Translation into English of passages from Caesar and Xenophon; Translation of short English sentences into Latin. French or German—Translation into English of passages from Bossuet's *Discours sur l'Histoire Universelle*, or of passages from Schiller's *Geschichte des dreissigjährigen Krieges*. Mathematics and Natural Philosophy—the subjects required for the Matriculation Examination of the University of London, with the addition of Acoustics Nature of Sound. The next examination will take place at the College on September 28th and 29th, 1875.

† The following additional classes are free to general students. Psychological Medicine (in connection with the Forensic Medicine course). Ophthalmic Surgery, Minor Surgery and Bandaging, Diseases of the Skin, Aural Surgery, Dental Surgery, Natural Philosophy, and Comparative Anatomy. The fees for these courses must, however, be paid, should a special certificate be required.

Students. There are also a Pathological Museum and a Materia Medica Museum.—The Reading Room is open daily.

Instruction.—There are separate departments for Diseases of the Eye, Ear, Skin, and Teeth, and for Diseases of Women.

Appointments.—All these are made without fee.—A Medical and a Surgical Registrar are appointed annually, each with a salary of £40.—A House-Physician, a House-Surgeon, and a Resident Obstetric Assistant are appointed by competition, and are provided with rooms and commons.—An Assistant House-Surgeon is appointed from among the senior students. He is provided with commons at the hospital table.—A Physician's Assistant, Surgeon's Assistant, and Ophthalmic Assistant are appointed from students of the fourth year.—Clinical Clerks and Dressers for in-patients are appointed for six months from general students of the hospital who have passed their first Examination.—Out-patients' Clerkships and Dresserships are conferred on all students in rotation for three months.

Scholarships and Prizes.—Four Entrance Scholarships, two of the value of £20 and two of £10, tenable for two years.*—Exhibition in Anatomy and Physiology, value £10 10s., tenable for one year for first year's men.—A prize of £2 2s. by Mr. Davy, to the first year's student who is most regular and diligent in the Dissecting Room.—Scholarship in Anatomy and Physiology, value £21, to student of second year (to be styled Assistant Demonstrator).—Prize by Dr. Allchin, in class of Histology; by Dr. Potter, in class of Midwifery.—At the end of third year, prizes of £5 each (or books or instruments, in Clinical Medicine and Pathology, and in Clinical Surgery and Pathology.—Frederic Bird Medal and Prize, to perpetual students who have completed their fourth year; subjects of examination: Medicine, Midwifery, Diseases of Women and Children, and Pathology.—Chadwick Prize for General Proficiency, £21 to the most meritorious student or students of any year not exceeding the fifth.—Certificates of Honour in each Class. Insufficient attendance on lectures and hospital practice disqualifies from receiving any prize.

Communications respecting the Medical School should be addressed to Mr. Cowell, the Dean of the School, from whom all particulars may be obtained. Information may also be obtained from any of the Lecturers, or from the Secretary at the Hospital.

NOTES CONCERNING THE PROVINCIAL AND SCOTCH HOSPITALS AND MEDICAL SCHOOLS.

UNIVERSITY OF OXFORD.—The instruction in Natural Science is carried on at the Museum, where there is practical instruction in Physics, Chemistry, and Anatomy and Physiology, together with courses of lectures by the several professors; viz.—Regius Professor of Medicine and Professor of Clinical Medicine—H. W. Acland, M.D., D.C.L., F.R.S.; Geometry—H. J. S. Smith, M.A., F.R.S.; Natural Philosophy—Rev. B. Price, M.A., F.R.S.; Experimental Philosophy, R. B. Clifton, M.A., F.R.S.; Chemistry—W. Odling, M.B., F.R.S.; Physiology—G. Rolleston, M.D., F.R.S.; Zoology—J. O. Westwood, M.A., F.L.S.; Botany—M. A. Lawson, M.A.; Mineralogy—M. H. N. Story-Maskelyne, M.A., F.R.S.; Lee's Reader in Anatomy—J. B. Thompson, B.A.

Large collections illustrate the several subjects; there is a pathological series, including the collection of Schroeder Van der Kolk, in the medical department, and a medical laboratory. The Radcliffe Library, containing nearly 20,000 scientific volumes, is open to all students daily from ten to four, and on certain evenings during term. There are also lectures and practical instruction in Botany at the Botanical Gardens; and clinical instruction at the Infirmary.

UNIVERSITY OF CAMBRIDGE.—The following Courses of Lectures will be delivered during the ensuing Academic Year. *Michaelmas Term*, 1875.—Physics: Heat and Elasticity, by Professor Maxwell, Tu., Th., S., 12.15; General Physics and Sound, by Mr. Trotter (at Trinity College), M., W., F., 10 A.M. Chemistry, General Course, by Professor Liveing, M., W., F., 12; Spectroscopic Analysis, by Profes-

* The next Examination will be held at the Hospital on October 5th and 6th. The following are the subjects:—Latin—Sallust, *Conspiracy of Cataline*. Book VI. The paper will contain passages for translation, questions in Grammar, and easy English sentences for translation into Latin. French, German, or Greek—Homer, *Odyssey*, Book XVII. *Arithmetic*—including Vulgar and Decimal Fractions, and extraction of Square Root. *Algebra*—Addition, Subtraction, Multiplication, and Division of Algebraical Quantities; Proportion, Arithmetical and Geometrical Progression, Simple Equations. *Geometry*—First four Books of Euclid, or the subjects thereof. Notice of intention to compete, with a statement of the second language in which the Candidate wishes to be examined, and a certificate of moral character, must be sent to the Dean not later than September 27th.

sor Liveing, M., W., F., 1: Qualitative Analysis, by Professor Liveing and the Demonstrator, daily: Dissociation and Thermal Chemistry, by Mr. Dewar (Jacksonian Professor), Tu., Th., 12: Principles of Qualitative Analysis, by Mr. Main (at St. John's College), Tu., Th., S., 12: Volumetric Analysis, by Mr. Apjohn (at Caius Laboratory), M., W., F., 10. Anatomy and Physiology: Zoology and Comparative Anatomy, by Professor Newton, M., W., F., 1: Practical Course of Comparative Anatomy, by the Demonstrator of Comparative Anatomy, daily, Sundays excepted: Elementary Course of Practical Morphology, by Mr. Balfour and Mr. Marshall (at the New Museum), M., W., 9 A.M., Anatomy and Physiology, by Professor Humphry, Tu., Th., S., 1: Practical Anatomy, by Professor Humphry and Demonstrator, daily, 9 A.M.: Practical Physiology and Histology, by Dr. M. Foster (Trinity Prælector), Elementary, Tu., S., 10; Advanced, Th., 10, and such other times as may be found convenient; Physiology, by Dr. Bradbury (at Downing College), M., W., and F., 9 A.M. Botany: Vegetable Morphology, by Mr. Hicks (at Sidney College), Tu., Th., S., 11. Materia Medica and General Therapeutics, by Dr. Latham (Downing Professor of Medicine), Tu., Th., S., 9 A.M. Pathology, by Dr. Bradbury (Linacre Lecturer), Tu., 10 A.M. Clinical Medicine, by Dr. Paget (Regius Professor), M., W., Th., and F., 10 A.M. Clinical Surgery, by Mr. Lestougeon, Tu., Th., 11.

Lent Term, 1876.—Physics: Electricity and Magnetism, by Professor Maxwell, Tu., Th., S., 12.15: Sound and Light, by Mr. Trotter (at Trinity College), M., W., F., 9: Electricity and Magnetism (Elementary Course), by Mr. Trotter (at Trinity College), M., W., F., 11. Chemistry: General Course, continued, by Professor Liveing, M., W., F., 12: Analysis, by the Professor or Demonstrator of Chemistry, daily: Organic Chemistry, by Mr. Dewar (Jacksonian Professor), Th., S., 12: Elementary Course, by Mr. Main (at St. John's Laboratory), Tu., Th., S., 12: Non-metallic Elements, by Mr. Apjohn (at Caius Laboratory), M., W., F., 10. Botany: Vegetable Histology and Physiology, by Mr. Hicks (at Sidney College), Tu., Th., S., 11. Anatomy and Physiology: Zoology and Comparative Anatomy, by Professor Newton, M., W., F., 1: Practical Comparative Anatomy, by the Demonstrator, daily: Elementary Practical Course of Morphology, by Dr. Balfour and Mr. Marshall (at the New Museum), M., W., 9 A.M.: Anatomy and Physiology, by Professor Humphry, Tu., Th., S., 1: Practical Anatomy, by Professor Humphry and the Demonstrator, 9 A.M., daily until Jan. 30, afterwards Tu., Th., and S.: Practical Physiology and Histology, by Dr. M. Foster (Trinity Prælector), continued, Tu., Th., S., 10 A.M.: Anatomy and Physiology, by Dr. Bradbury (at Caius College), Tu., Th., S., 12: Physiology, by Dr. Bradbury (at Downing College), M., W., F., 9 A.M. Principles and Practice of Medicine, by Dr. Paget (Regius Professor), M., F., 9 A.M. Pathological Anatomy, by Dr. Bradbury (Linacre Lecturer), Tu., 10 A.M. Clinical Medicine, by Dr. Latham (Downing Professor), M., W., Th., F., 10 A.M. Clinical Surgery, by Mr. Carver, Tu., Th., F., S., 11.

Easter Term, 1876.—Physics: Electro-magnetism, by Professor Maxwell, Tu., Th., S., 12: Heat (Advanced), by Mr. Trotter (at Trinity College), M., W., F., 9: Heat (Elementary), by Mr. Trotter (at Trinity College), M., W., F., 10. Chemistry: History of Chemistry, by Professor Liveing, M., W., F., 12: Analysis, by Professor Liveing or the Demonstrator, daily: Laboratory Instruction in Chemical research, by Mr. Dewar (Jacksonian Professor): Elementary Organic Chemistry, by the Demonstrator, Tu., Th., S., 12: Elementary Course (concluded), by Mr. Main, Tu., Th., S., 12: Organic Analysis and Elementary Organic Chemistry by Mr. Apjohn (at Caius Laboratory), Tu., F., 12. Anatomy and Physiology: Practical Comparative Anatomy, by the Demonstrator of Comparative Anatomy, daily, Sundays excepted; Anatomy and Physiology, for preparation for the second examination for M.B., by Professor Humphry, twice a week, 10 A.M.: Practical Elementary Biology, by Dr. M. Foster (Trinity Prælector), Tu., Th., S., 10 A.M.: Anatomy and Physiology, by Dr. Bradbury (at Caius College), Tu., Th., S., 12. Botany, by Professor Babington, M., Tu., Th., F., 1. Materia Medica and General Therapeutics, by Dr. Latham (Downing Professor), Tu., Th., S., 9 A.M. Principles and Practice of Medicine, by Dr. Paget (Regius Professor), M., W., F., 9 A.M. Clinical Medicine, by Dr. Bradbury, M., W., Th., F., 10 A.M. Clinical Surgery, by Dr. Humphry, Tu., Th., F., S., 11.

Long Vacation.—Practical Chemistry in the University Laboratory: Course of Instruction in Practical Anatomy; Course of Practical Histology; Clinical Instruction at the Hospital. The Chemical Laboratory of the University will be open daily for the use of the students. The Demonstrator attends daily to give instruction alternately morning and afternoon. The Dissecting Rooms and Museums of Anatomy are open daily during the vacations as well as in the terms, and the Professor and Demonstrator of Anatomy are in attendance to assist and

direct the students. The Museum of Materia Medica at Downing College is open daily to all Medical Students.

Opportunities for Clinical Instruction in mental diseases will be afforded at the County Asylum, Fulbourn, by Dr. Bacon, during the Michaelmas and Lent Terms. Notice will be given of the days and hours.

Commencing Students of Medicine must be registered according to the Regulations of the General Council of Medical Education and Registration. Forms for registration, abstracts of regulations, schedules, and other papers may be obtained from the attendant at the Anatomical Schools, Pembroke Street.

Attendance on the Lectures on Chemistry, Botany, Materia Medica, Anatomy, Physiology, Dissections, and Medicine, is recognised by the Royal College of Surgeons, England. Hence all the Courses required for admission to the first Professional Examination at that College may be attended in Cambridge.

BIRMINGHAM—QUEEN'S COLLEGE.—Clinical Lectures and Lectures in special departments are given in the General Hospital and the Queen's Hospital, which have a total of upwards of 400 beds. Special instruction is given in the use of the microscope, laryngoscope, and ophthalmoscope, also in case-taking and bandaging, with minor surgery and prescribing. Students must attend for six months alternately at each hospital, except those who enter for six months only.

Appointments.—*General Hospital:* Resident Medical and Resident Surgical Assistant, two Resident Dressers, tenable six months after examination, and with board and lodging. *Queen's Hospital:* Resident Obstetric Assistant, tenable six months; Resident Dresser, tenable three months.

Prizes.—The Sands Cox Prize, value £20 annually, to students who have completed their curriculum, after examination in Medicine, Surgery, and Midwifery.—Warden's Prize, £5 5s to the most proficient student of the first year.—The Percy Prize, books of the value of £5 5s., for the best examination in German.—Medals and Certificates of Honour, annually, in each class after examination.

Clinical Prizes.—Two Senior Medical and two Senior Surgical Prizes (third and fourth years), value in each department £5 5s. and £3 3s.; two Junior Medical and two Junior Surgical Prizes (second year), values £3 3s. and £2 2s.; Midwifery Prize, £4 4s.

Further particulars may be obtained by application to the Rev. the Warden, at the College; to Dr. Jolly, S3, Newhall Street; to Mr. Thomas, Bradford Street; or to Dr. Hinds, 10, Easy Row.

BRISTOL MEDICAL SCHOOL.—Clinical Lectures are delivered at the Royal Infirmary and the General Hospital. The Royal Infirmary contains 242 beds, of which 112 are medical, and 126 surgical. The General Hospital contains 154 beds. The Infirmary and the Hospital each contain a Library and a Museum.

Appointments.—*Royal Infirmary.* Each physician can appoint a Clinical Clerk from among the most diligent of his pupils. Dressers reside in the house in weekly rotation when qualified. A Pathological Clerk is appointed every three months, and receives £3 3s. if his duties have been performed satisfactorily.—*General Hospital.* Clinical Clerks and Dressers are appointed. The dressers reside in the hospital in rotation, free of expense.

Prizes.—Prizes and Certificates of Honour will be distributed at the end of the winter session, after examination in all the subjects of each year.—Prizes and Certificates of Honour for Practical Anatomy.—*Royal Infirmary.* Suple's Medical Prize, and Suple's Surgical Prize, each a gold medal value £5 5s. and about £7 7s. in money, awarded after examinations in Medicine and in Surgery respectively. Clark's prize (interest of £500) to the prizeman of the third year in the Medical School, if he have attended the Royal Infirmary.—*General Hospital.* Lady Habberfield's Prize (interest of £1,000) for general proficiency. Guthrie Medical Scholarship and Clarke Surgical Scholarship, each £15, annually. Sanders Scholarship (interest of £500) for Proficiency in Medicine and Surgery.

Further particulars respecting the infirmary may be known on application to the House-Surgeon of the infirmary; respecting the hospital, on application to Dr. Skerritt, at the hospital. Information regarding the Medical School will be afforded by the Honorary Secretary, Dr. G. F. Burder.

LEEDS SCHOOL OF MEDICINE.—There are Anatomical, Pathological, Chemical, Botanical, and Materia Medica Museums. The course of Chemistry is conducted at the Yorkshire College of Science.

Clinical Instruction, &c.—Clinical Lectures are delivered by the Physicians and Surgeons of the Infirmary, which contains 310 beds.—Courses of Practical Physiology and Practical Surgery are given.—

Demonstrations of Cutaneous and Aural Diseases, and Ophthalmoscopic Demonstrations, are given.—The West Riding Lunatic Asylum at Wakefield is open for the study of Mental Diseases, and a course of lectures will be given during the summer.—Students can also attend the practice of the Leeds Public Dispensary and the Fever Hospital. There are several Resident Appointments at these Institutions.

Hospital Appointments.—Every student in turn must hold the offices of Clinical Clerk and Dresser. Four Assistants are elected to work under the direction of the Senior Resident Officers. They are selected from the senior students who have shown industry and skill as Dressers and Clinical Clerks.

Prizes.—At the close of each Session, Silver and Bronze Medals, Books, and Certificates of Honour, are awarded according to merit.—The Hardwick Clinical Prize, value £10, is given annually for the best reports of medical cases, and the Surgeon's Clinical Prizes of £8, £5, and £3, for the best reports of surgical cases, during the winter session.—The Thorp Scholarship in Forensic Medicine (£10) at the close of each summer session.

LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.—There are a Museum containing specimens of Morbid and Comparative Anatomy; a collection of Wax Models; and a collection of *Materia Medica*; a Library, and a Reading Room.

Clinical Instruction, etc.—Clinical Lectures are given weekly at the Royal Infirmary, which contains nearly 300 beds; the Lock Hospital adjoining contains 80 beds. The Northern Hospital contains 146 beds. For the study of Mental Diseases, a class will be formed to attend the practice of the Rainhill Asylum, where instruction will be given by Dr. Rogers once a week during the summer.

Appointments: Royal Infirmary.—Two House-Physicians and Three House-Surgeons are appointed for six months after (if there be more applicants than vacancies) competitive examination. Candidates must have a legal qualification.—Three Dressers for each Surgeon and three Clinical Clerks for each Physician are elected quarterly.—Two *Post mortem* Clerks are appointed for six weeks. All students must perform this duty before the final certificate is signed.

Exhibitions and Prizes.—The sum of £2,000 has been left by the late Mr. Roger Lyon Jones for the purpose of founding a scholarship; but the bequest is not yet actually possessed by the school.—Gold Medal for Anatomy and Physiology, presented by Mr. Torr, M.P., for second year's students; and one, also, for Anatomy and Physiology, presented by Dr. J. Bligh, for students of first year.—Medals and Certificates of Honour for groups of "junior" and "senior" subjects.—Clinical Prize to be awarded by the Surgeons of the Infirmary in May, 1876, value £5, for the best report of twelve surgical cases in the Infirmary.

Communications should be addressed to the Registrar, Mr. W. Mitchell Banks.

LIVERPOOL ROYAL SOUTHERN HOSPITAL.—Physicians: Dr. Cameron, Dr. Carter. Surgeons: Dr. Nottingham, Mr. Hamilton, Dr. Wollaston. The hospital contains 200 beds. Clinical Lectures are given by the Physicians and Surgeons during the winter and summer sessions. Clinical Clerkships and Dresserships are open to all students. There is a special ward for diseases and accidents of children. Fees for Hospital Practice and Clinical Lectures, perpetual, £26 5s.; one year, £10 10s.; six months, £7 7s.; three months, £4 4s. The practice of the hospital is recognised by all the examining bodies. For further particulars, application must be made to the House-Surgeon.

OWENS COLLEGE (MANCHESTER ROYAL) SCHOOL OF MEDICINE.—Museums of Human and Comparative Anatomy and of *Materia Medica*, and Physiological and Chemical Laboratories, are connected with the College.

The *Royal Infirmary* contains 100 medical and 170 surgical beds. In addition to the practice of the infirmary, the Mossil Fever Hospital (130 beds) and the Barnes Convalescent Home (140 beds) will be open, under certain regulations, for the purposes of instruction. The Royal Lunatic Asylum at Cheadle is also connected with the infirmary, and accommodates 150 patients.

Clinical Instruction, etc.—Medical Demonstrations will be given by Dr. Leech and Dr. Dreschfeld, and Surgical Demonstrations by Mr. Bradley and Mr. Whitehead. These classes must be attended for three months before a clerkship or dressership can be taken, or the clinical classes attended.—Pathological Demonstrations are given by Dr. Dreschfeld.—Medical Clinical Classes are held, in the winter by Dr. Roberts, and in the summer by Dr. Simpson; and Surgical Clinical Classes by Mr. Southam and Mr. Lund in the winter, and Mr. Heath, and Mr. Bowring in the summer. Ward-classes are also

held by the other Physicians and Surgeons.—Dr. Simpson will give instruction in the use of the Laryngoscope; Dr. Wilkinson, clinical instruction in Fever and Contagious Diseases; Dr. Thorburn, clinical instruction in Diseases of Women; and Mr. Mould, demonstrations of Mental Diseases.

Appointments.—Dressers and Clinical Clerks in the Royal Infirmary are appointed for periods of three months. A senior House-Surgeon, two junior House-Surgeons, a House-Physician, and four Physicians' Assistants, are appointed annually. The senior House-Surgeon and House-Physician are appointed for twelve months, the others for six months; they all receive board, residence, and salary.

Prizes.—Turner Scholarship of £25 for third years' students, one of £15 for second years' students, and one of £10 for first year's students—all for perpetual students; also £15 and £10 prizes for General Proficiency.—Two Platt Physiological Scholarships, value £50 each, tenable for two years, to students who have attended Physiology in the College Laboratory during one session, for best original investigation and the result of a written examination.—Dumville Surgical prize, value £20, at end of winter session, to students of two years, who have attended four courses, including at least one in Surgery.—A Gilchrist Scholarship of £50 *per annum*, tenable for three years in the College, to the candidate standing highest in the Matriculation Examination of the University of London in June, if in the Honours Division; or two of £25 each to the first two candidates in the First Division.—Medical and Surgical Clinical Prizes are given for reports of cases.

Prospectuses may be obtained from the Registrar, Mr. J. H. Nicholson.

SHEFFIELD MEDICAL SCHOOL.—The General Infirmary contains 200 beds. Opportunities for clinical study may be obtained at the Sheffield Hospital and Dispensary (99 beds), and at the Sheffield Hospital for Diseases of Women.

The Infirmary contains a Museum of Pathology, a Library, and a *Post Mortem* Theatre, with Microscopes and all the appliances for clinical research.—The Library of the Medical School is open to students.

Prizes and Certificates of Honour are given annually.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-ON-TYNE.—Chemistry and Practical Physiology are excepted from the courses which may be attended in perpetuity by composition students.

A course of Practical Physiology will be given during the summer by the Professor of Physiology and Biology. Fee for use of microscopes, 10s. 6d. Separate courses of *Materia Medica* and Pharmaceutical Chemistry, and of Therapeutics, are delivered; the former by Dr. W. C. Arnison, and the latter by Dr. T. Humble.

The Laboratories, Libraries, and Museums of Anatomy, Pathology, and *Materia Medica* are open daily.

The Newcastle Infirmary contains 230 beds. Four Resident Dressers are elected half-yearly. They are provided with board and apartments on payment of £10 10s. for the six months. Midwifery can be attended at the Newcastle Lying-in Hospital, and Diseases of the Eye at the Eye Infirmary.

Prizes.—Four Medical Scholarships, annual value £25 each, tenable for four years, by students residing in Durham or Newcastle. One will be awarded in October.—The Dickinson Memorial Scholarship, value £15 annually, for general proficiency.—A Silver Medal and Certificates of Honour in each class.

Further information may be obtained from the Secretary, Dr. Byrom Bramwell, Newcastle-on-Tyne.

UNIVERSITY OF ABERDEEN.—Fee to each class, £3 3s., except Anatomical Demonstrations, £2 2s. Matriculation fee, both sessions, £1; summer session alone, 10s. A three months' course of Practical Ophthalmology is given in summer.

ROYAL INFIRMARY, ABERDEEN.—Perpetual fee, £6; or first year, £3 10s.; second year, £3. Clinical Medicine and Clinical Surgery, each £3 3s.—The General Dispensary and the Lying-in and Vaccine Institutions are open daily, and the Eye Institution three days in the week.—Clinical Instruction is given in the Royal Lunatic Asylum for three months in the year.

UNIVERSITY OF EDINBURGH.—Minimum expenses for Lectures and Hospital Practice (including also £21 for degrees of M.B. and C.M.), £104 18s.; Annual Fee for each subject required in the ordinary curriculum (including Clinical Medicine and Clinical Surgery), £4 4s.; except Anatomical Demonstrations; Dispensary (third winter) and Instruction in Vaccination, each £1 1s.; Practical Midwifery, £1 4s.;

TABLE OF THE MEDICAL OFFICERS, PROFESSORS, AND LECTURERS IN
MEDICAL SCHOOLS OF SCOTLAND.

For further particulars regarding each Hospital and Medical School, see pp. 347-49. The letters (W.) and (S.) in this Table denote respectively Winter and Summer Courses.

LECTURES, ETC.	ABERDEEN UNIVERSITY.	EDINBURGH UNIVERSITY. (d.)	SCHOOL OF MEDICINE, EDINBURGH. (g.)	GLASGOW UNIVERSITY. (l.)	GLASGOW, ANDERSON'S UNIVERSITY. (r.)
ANATOMY	Dr. Struthers, 11 (W.)	Mr. Turner, 1 (W.)	Dr. Handyside, 1 (W.)	Dr. Allen Thomson and Demonstrator, jun. 11; sen. 2 (W.); Embryol. and Dem., 11 (S.); Elem. Anat. M. W. F., 1 (S.)	Dr. A. M. Buchanan, jun., 10; sen., 3 (W.); Surgical Anatomy, 12; Osteology, daily (S.)
ANATOMICAL DEMONSTRATIONS...	Dr. Struthers, and Demonstrator, 9 (W.); 2 (S.)	Mr. Turner, 4	Dr. Handyside, 4 (W.) 11 (S.)		Dr. A. Buchanan, 4 (W.)
DISSECTIONS	9 to 4 (W. and S.)	Daily (W. and S.)	9 to 4 (W. and S.)	9 to 4 (W.); 7 to 2 (S.)	Daily (W. and S.)

a. Zoology with Comparative Anatomy.

b. With Medical Logic.

c. ABERDEEN ROYAL INFIRMARY: Physicians—Dr. J. W. F. Smith-Shand, Dr. Beveridge, Dr. A. Fraser; Surgeons—Dr. Pirrie, Dr. D. Kerr, Dr. A. Ogston; Junior Surgeon—Dr. Will; Ophthalmic Surgeon—Dr. Davidson; Dental Surgeon—Mr. Williamson.

d. Medical Psychology and Mental Diseases, Dr. Laycock (S.)

e. Vaccination, six weeks' courses in Winter and Summer, Dr. Husband. Diseases of Children, Dr. Stephenson (S.), Tu. and F., 3. Diseases of the Eye, Dr. A. Robertson (S.), Tu. and F., 3. Insanity, Dr. Batty Tuke (S.), M. and Th., 3. State Medicine and Hygiene, Dr. A. Smart, W. and S., 4 P.M.

f. Operative Surgery and Surgical Appliances, Dr. J. Bell (S.), 4; Operative Surgery and Surgical Anatomy, Dr. Chiene (S.), 4; Practical Surgery, Dr. J. Duncan (S.), 4.

g. EDINBURGH ROYAL INFIRMARY: Physicians—Dr. Laycock, Dr. MacLagan, Dr. Sanders, Dr. R. Haldane, Dr. G. W. Balfour, Dr. T. Grainger Stewart, Dr. J. M. Duncan, and Dr. A. R. Simpson; Assistant Physicians—Dr. C. Muirhead and Dr. D. J. Brakenridge; Consulting Surgeons—Dr. J. Dunsinore and Dr. J. D. Gillespie; Surgeons—Mr. J. Spence, Dr. P. H. Watson, Mr. J. Lister, Mr. Annandale, and Dr. J. Bell; Ophthalmic Surgeons—Mr. Walker and Dr. D. A. Robertson

Surgeon for Ovarian Diseases—Dr. T. Keith; Assistant Surgeons—Dr. John Duncan and Mr. J. Chiene; Dental Surgeon—Dr. J. Smith; Pathologist—Dr. J. B. Pettigrew.

h. Dr. M. Duncan gives Clinical Lectures on Diseases of Women.

i. Operative Surgery, Dr. Macleod, M. W. F., 1 (S.); Lectures on Eye, Dr. T. Reid, Tu. Th., 1 (S.); Practical Pharmacy, Dr. Tennent, M. W. Th., 12 (S.)

m. Chemical Laboratory from 10 A.M. to 4 P.M. (W. and S.)

n. Demonstrations in the Botanical Garden, 6.30 P.M.

o. Dr. Gairdner lectures in the Summer at 12 noon on Tuesdays and Fridays, on Diseases of the Heart, etc.

p. GLASGOW ROYAL INFIRMARY: Physicians—Dr. Scott Orr, Dr. Perry, Dr. MacLaren, Dr. Wood Smith, and Dr. Charteris. Surgeons—Dr. E. Watson, Dr. Dewar, Dr. Dunlop, Dr. Cameron, and Dr. Morton.

q. GLASGOW WESTERN INFIRMARY: Physicians—Dr. Gairdner, Dr. McCall Anderson, Dr. Finlayson; Surgeons—Dr. Macleod, Dr. G. Buchanan, Dr. A. Patterson; Dispensary Physicians—Dr. Tennant, Dr. Coats, and Mr. McVail; Dispensary Surgeons—Dr. J. G. Lyon, Mr. Fleming, and Mr. Knox; Pathologist—Dr. Coats.

r. Ophthalmic Medicine and Surgery, Dr. Wolfe, daily, 1 (W. and S.)

s. Practical Medical Chemistry—Mr. Dittmar, 1 (S.)

Practical Pharmacy and Dispensary (third summer), each £2 2s.; Practical Anatomy and Practical Chemistry, each £3 3s.—Every Student, before entering with any Professor, must produce a matriculation ticket for the ensuing session, for which a fee of £1 is paid at the beginning of each winter session. Students first entering in the summer session pay a matriculation fee of 10s. for that session.—The Library is open every lawful day during the winter session, from 10 A.M. till 4 P.M.; on Saturdays, till 1 o'clock.

Fellowships, etc.—Falconer Memorial Fellowship, for the encouragement of the study of Paleontology and Geology, value £100, tenable for two years, open to graduates in Science or Medicine of the University of not more than three years' standing. The next appointment may be made in October 1876. Syme Surgical Fellowship, value about £100, tenable for two years, open to Bachelors of Medicine of not more than three years' standing, who shall present the best Thesis on a Surgical subject, giving evidence of original research. Sibbald Scholarship, value about £40, tenable for four years. Abercromby Bursary of £20, for four years, to students who have been brought up in Heriot's Hospital. Sibbald Bursaries, £30 each, tenable for four years, open to the sons of duly registered medical men practising, or who may have practised in Scotland, and to the sons of parents who are or may have been householders in Edinburgh. Grierson Bursary, £20 per annum for three years, open to students who have completed one winter session: Subjects of Examination—Chemistry, Botany, and Natural History. Tyndall-Bruce Bursary, £25 for one year, to students who have completed the third winter session: Subjects—Materia Medica and Pathology. (The above three bursaries are to be awarded in November. Competitors must have studied the subject of examination at the University of Edinburgh.) Ettles Medical Prize, value about £40, to the most distinguished Graduate in Medicine of the year. Hope Chemistry Prize, value £100, open to all students of the University not more than twenty-five years of age, who have worked for eight months, or for two summer sessions, in the chemical laboratory. Neil Arnott Prize, about £40, to the candidate who, having been a medical student of the University during either a summer or a winter session, shall pass with the greatest distinction the ordinary examination in Natural Philosophy for the degree of M.A. The successful candidate must continue to prosecute his medical studies in the winter session succeeding the award. The Ellis Prize for the best Essay on the Respiration of Plants as distinguished from their Nutrition, open to students or graduates of five years' standing. Value, proceeds of sum of £500 accumulated for three years. Essays to be given in by November 2nd. Goodsir Memorial Prize, to be founded in commemoration of the late Professor Goodsir.—Gold Medals are given on graduation to Doctors of Medicine whose theses are deemed worthy.

EDINBURGH ROYAL INFIRMARY.—Fees: 6 months, £3 3s.; 1 year, £5 5s.; perpetual, £10 10s. Clinical Medicine and Clinical Surgery, each £4 4s. for the course.—No fees for any medical or surgical appointment. Four Resident Physicians and four Resident Surgeons are appointed; they live in the house for six months free of charge. Candidates must be registered as legally qualified practitioners. Non-resident Clinical Clerks are appointed. Each surgeon appoints from four to nine Dressers for six months. Assistants in the Pathological Department are appointed by the Pathologist.—Instruction is given in special departments.

SCHOOL OF MEDICINE, EDINBURGH.—The courses qualify for examination for various diplomas and licenses, and for degrees in those years in which University residence is not required.

Fees.—For the first of each Course of Lectures, £3 5s.; second, £2 4s.; perpetual, £5 5s. To those who have already attended a first course in Edinburgh, the perpetual fee is £2 4s. Second Course of Midwifery, £1 3s. Practical Chemistry and Practical Anatomy (six months), each £3 3s. Anatomical Demonstrations, £2 2s.; with Practical Anatomy, £1 1s.; perpetual, £4 4s. Analytical Chemistry, £2 a month, £5 for three months, or £10 for six months. Vaccination, £1 1s.; State Medicine and Hygiene, £2 2s. Summer Courses of Clinical Surgery and Clinical Medicine, each £2 4s.; Practical Anatomy, including demonstrations, Operative Surgery, Diseases of the Eye, and Insanity, each £2 2s.—The minimum education costs in this school for the double qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh, including the examination fee, is £90 4s., payable by yearly instalments; for the single diploma of either Physician or Surgeon, including the examination fee, £80.

Practical instruction in various subjects may also be obtained on payment of moderate fees at the Sick Children's Hospital, Royal

Public Dispensary and New Town Dispensary, Royal Maternity Hospital, and the Edinburgh Eye Infirmary.

UNIVERSITY OF GLASGOW.—Fees, each course, £3 3s.; except Lectures on the Eye, £1 1s.

GLASGOW ROYAL INFIRMARY.—Fees, 1st and 2nd years, each £3 3s.; 3rd year, and perpetual, £1 1s.; 6 months, £2 2s.; 3 months, £1 11s. 6d. Vaccination, £1 1s.; Practical Pharmacy (6 months), £3 3s. Clinical Lectures in Medicine or Surgery, as for the courses of lectures in the University.

GLASGOW WESTERN INFIRMARY.—Fees, 1st and 2nd years, each £3 3s.; 3rd year, £1 1s. The fees for clinical lectures are the same as for the courses in the University.

GLASGOW EYE INFIRMARY.—Fee, 6 months, £2 2s.; to students who are attending or have attended the Lectures on the Eye in the University, £1 1s.

Instruction may also be obtained at the Glasgow University Lying-in Hospital and Dispensary for Diseases of Women and Children; and at the Dispensaries for Diseases of the Skin and Ear; and the Royal Lunatic Asylum, Gartnavel, is open to students on payment of a small fee.

GLASGOW.—ANDERSON'S UNIVERSITY.—Fees for all the Lectures required for the Diplomas of Physician and Surgeon, £50. Class Fees for each course of Lectures: First session, £2 2s.; 2nd session, £1 1s.; afterwards free. Anatomy Class Fees, for Lectures and Demonstrations: 1st session, £4 4s.; 2nd session, £4 4s.; summer session, with dissection, £1 1s. The Dissecting-room is free for two sessions to those who attend both courses of Anatomy; after the second year, £1 1s. per session. There is a Matriculation Fee of £1 1s. at the beginning of each winter session.

BRITISH MEDICAL JOURNAL.

SATURDAY, SEPTEMBER 11TH, 1875.

THE CHOICE OF TEXT-BOOKS.

MEDICAL students are often much puzzled in the choice of their text-books by hearing very conflicting accounts of the value of different books. We shall not attempt to remove all these difficulties by any dogmatic selection. The lecturers and tutors at the respective Medical Colleges generally make this a part of their business. We may, however, advise students not to encumber themselves at the outset with too many books, but to wait till their own experience develops and enables them, each to decide for himself, what sort of book suits his own quality of mind and power of learning. To this we add the advice to buy only the best text-books, and to lean as little as possible on "outlines", "sketches", "handy books", "epitomes", and "memoranda".

The first year's student's first care is to get a good handbook of "the bones"; and, strange to say, there is not one really good monograph in print on the subject. There are a good many competitors for favour, but none that at all equals that most excellent and complete little book of Ward. A student can scarcely be said to "know his bones" thoroughly until he has studied Ward; and Ward is out of print. Copies, however, may be had occasionally; and fortunate the student who gets one, and thoroughly masters it. Next to Ward in merit are Gray and Holden. Holden is, we believe, out of print. The descriptions of bones in Quain, Wilson, Norton, and the rest, are somewhat wanting in accuracy, completeness, and method. Gray's *Anatomy* generally is an excellent handbook, and so are Ellis's and Heath's dissectors. In Chemistry, there is a long list; but we know of nothing which has superseded Fownes in popular favour, except, perhaps, the larger and more costly treatise of Miller, which is a general favourite for the University of London and other higher examinations. Of manuals of Surgery there is a good choice in Druitt and Bryant, to which, we see, will this session be added one by Holmes, the accomplished editor of Gray and of the great *System of Surgery*, from whom much will, of course, be expected. By common consent, no manual of Midwifery yet published has come up to the useful character of Tyler Smith's.

Leishman's book is probably the most successful; it remains to be seen what Dr. Playfair's promised manual yields. Of students' books of Medicine there have been some excellent ones of late years. Roberts and Aitken are the most recent. Tanner is an old favourite, although it has always seemed to us not of so high a character as a modern text-book should be. Watson's great book is at once instructive and delightful. Dr. Fagge and Dr. Bristowe are both engaged on new manuals of medicine; and, as both are careful, thorough, and highly accomplished physicians and writers, their books are sure to be good. In text-books of Physiology there is an acknowledged want. There is nothing except the great laboratory manual of Sanderson which represents the present status of physiology—physiology as it exists, as it is taught in some schools, and ought to be in all. Kirkes's *Physiology* hardly continues to deserve the popularity which in earlier years justly belonged to it. It belongs in a measure to a pre-scientific period in physiology. Carpenter's book is scientifically out of date. A little manual by Küss, just translated for Messrs. Baillière, Tindall, and Co., is very handy; and Professor Gamgee, of Owens College, Manchester, announces an edition of Hermann's *Handbook of Physiology* with notes. This is reported to be the best students' handbook of physiology extant: it is a great favourite in German medical schools, and Dr. Gamgee's edition of it is looked for by many physiological teachers as likely to be very useful in their classes. Huxley's small manual is most admirable, but is not specially designed for medical students. Of large books, Dalton's *Physiology* is the most readable and useful. In Histology, the works of Stricker and Frey are of unexceptionable excellence; but they are very ponderous. The section of histology in Quain's *Anatomy* is very accurate and well done. In Pathology, we have two most excellent manuals by Payne (the new edition, rewritten by him, of Sieveking and Jones's manual) and by Dr. T. H. Green; the latter singularly clear and good, but of course much less copious than the former. The second and greatly improved edition of Green is just out. Wilks and Moxon's monograph is more suited for highly advanced students or practitioners.

For the medical ward, we should recommend to younger students of medicine Sturges's *Clinical Introduction*, or Barclay on *Diagnosis*; or, for more advanced students, Da Costa's admirable treatise on *Medical Diagnosis*. For the surgical student, a more complete guide to the study of surgery in the wards is wanting. Heath's and Berkeley Hill's little books are excellent for dressers. For surgical operations, Bell and Maunder have written two very good little handbooks. Erichsen, Gross, Fergusson, Spence, and Pirrie, among the greater books, will prove profitable reading at all times during the student's career. He can hardly do without one or other of them.

In *Materia Medica* and Therapeutics there is an *embarras des richesses*. Ringer is excellent reading, thoughtful, and liberal, but unsystematic, and so incomplete and unsystematical as to be bewildering. Scoresby Jackson is concise and sound, but old-fashioned. Bentley and Redwood's Pereira is particularly suited for pharmaceutical students, but wants therapeutic value for medical students. Garrod's last edition is very good, and would be the best extant if an American physician, Dr. Wood, had not lately written one which is decidedly better, so far as it takes the scientific view of therapeutic action, and is from the basis upwards written in the modern spirit. Garrod's excellent book begins to show patchwork too much. Dr. Lauder Brunton, Lecturer on Therapeutics at St. Bartholomew's, is announced to be writing a handbook, which, we suppose, is intended to be the handbook of the day in respect to scientific therapeutical investigation; he being our principal expert at present in the physiological investigation of the action of medicines. But it is still in embryo. We hear also of a forthcoming work on the same subject by Dr. Fothergill, an accomplished and indefatigable worker in the field of therapeutics. Squire's classic *Companion to the Pharmacopœia* is extremely useful. Dr. Walter Smith's *Handbook of the Pharmacopœia* is intended to supersede it for medical students; and, as it has had the benefit of revision by Dr. Aquilla Smith, the Professor

of *Materia Medica* in the University of Dublin, who was and is one of the *Pharmacopœia* Committee, it should be a good book. We have had no experience of its use, but hear it favourably spoken of as a text-book for examinations and for practice. For special subjects, there are a great many handbooks, of which students will be able to estimate the relative usefulness as they pass on in their studies. In books of Practical Chemistry, so much depends on the particular line taken by the teacher, that they must be guided almost entirely by that consideration. In Toxicology and Medical Jurisprudence, Taylor's standard books are scarcely to be excelled.

Physiological Chemistry still needs a *vates sacer* in this country. We have few physiological chemists, and no good handbook of the subject. Ralfe and Moore have written little outlines not without merit, but said to be meagre and full of faults. Of Medical Physics, we have no book at all, such as the French have in Gavarret. In Surgical Anatomy, we are wanting a good monograph. The translation of Roser by Galton, published by Renshaw, is, however, a very handy little book, and good as far as it goes. Blandford's little *Manual of Insanity* is a good one on that subject. Winslow's handbook relates to the practical management of lunatics, and is for practitioners, and not for students. The valuable works by Bucknill and Tuke, and by Maudsley, are standards for advanced study.

We have spoken here only of English and American text-books. We advise, however, those who can read French or German moderately well to provide themselves with one or two in those languages: first, because there are a few of great excellence not yet translated; and, secondly, because it will greatly aid their acquisition of familiarity with the foreign technical terms in the medical sciences to study a French or German alongside with an English text-book. We shall on a future occasion discuss the merits of some of the principal French and German text-books.

CHANGES IN THE HOSPITALS AND MEDICAL SCHOOLS.

THE following changes have taken place during the past year.

At St. Bartholomew's Hospital, Dr. Harris has retired from the office of Physician. Dr. Church has been promoted to be Physician; and Dr. Lauder Brunton has been appointed Assistant-Physician. A new office—that of Assistant Physician-Accoucheur—has been created, to which Dr. Clement Godson has been appointed. Dr. Norman Moore lectures on Comparative Anatomy in place of Dr. Church; and Mr. Marrant Baker gives instruction in Diseases of the Skin in place of Dr. Duckworth.

At the Charing Cross Hospital, Dr. Poore has retired from the offices of Assistant-Physician and Lecturer on Medical Jurisprudence, in consequence of his appointment to University College Hospital. Dr. Irvine succeeds Dr. Dowson as Lecturer on Botany; he also gives instruction in Auscultation in place of Dr. Green, and in Diseases of Children in place of Dr. Bruce. Mr. J. F. Blake has succeeded Mr. A. H. Garrod as Lecturer on Comparative Anatomy.

At St. George's Hospital, Dr. Barnes has been appointed Obstetric Physician and Lecturer on Midwifery in the room of Dr. John Clarke. Dr. R. J. Lee has retired from the office of Assistant Obstetric Physician, and gives demonstrations in Morbid Anatomy. Mr. Prescott Hewett having resigned the office of Surgeon, Mr. Rouse has become full Surgeon, and Mr. Warrington Howard has been appointed Assistant-Surgeon. Mr. Howard also teaches Practical Surgery, and takes charge of the Orthopædic Department, in place of Mr. Pick, who retires from the lectureship on Surgery, and succeeds Mr. Rouse as Lecturer on Anatomy. Dr. Brailey succeeds Dr. Cavafy as Lecturer on Comparative Anatomy. Dr. Ralfe succeeds the late Mr. S. W. Moore as teacher of Physiological Chemistry.

At Guy's Hospital, Mr. Birkett has retired from the office of Surgeon. Mr. Howse has been promoted to a Surgeonship; and Mr. R. C. Lucas and Mr. Golding Bird have been appointed Assistant-Sur-

geons. Mr. Davies-Colley succeeds Mr. Durham as Mr. Howse's colleague in the Lectureship on Anatomy. The lectures on Surgery will be delivered by Mr. Bryant and Mr. Durham, in place of Mr. Birkett and Mr. Cooper Forster. Mr. Jacobson lectures on Comparative Anatomy instead of Dr. Pye-Smith.

At King's College, the vacancy in the Professorship of Physiology, caused by the appointment of Dr. Rutherford to the Chair in the University of Edinburgh, has been filled by the appointment of Dr. Gerald F. Yeo, Lecturer on Physiology in the Carmichael School of Medicine, Dublin. Dr. Buchanan Baxter and Dr. Curnow have been appointed Assistant-Physicians. Dr. I. B. Yeo gives demonstrations with the Laryngoscope, in place of Dr. George Johnson.

At the London Hospital, the course of Lectures in Medicine is given by Dr. Davies and Dr. Fenwick, Dr. Ramskill and Dr. Down having ceased to lecture on this subject. Dr. Palfrey has succeeded Dr. Head as Obstetric Physician and Lecturer on Midwifery. Mr. E. B. Aveling has been appointed Lecturer on Comparative Anatomy.

At St. Mary's Hospital, Dr. Wiltshire lectures on Midwifery conjointly with Dr. Meadows.

At the Middlesex Hospital, Mr. Hulke becomes Mr. Campbell De Morgan's colleague in the Lectureship on Surgery.

At St. Thomas's Hospital, Dr. Clapton has retired from the office of Physician, and Dr. Stone has become full Physician. Dr. Gervis succeeds Dr. Barnes (appointed to St. George's) as Obstetric Physician and Lecturer on Midwifery; and Dr. Cory has been appointed Assistant Obstetric Physician in the vacancy caused by the promotion of Dr. Gervis. Dr. Gervis retires from the Lectureship on Forensic Medicine, which is now held by Dr. Stone alone. Dr. Greenfield teaches Pathological Anatomy jointly with Mr. Arnott, and Mr. McKellar joins Mr. Croft in giving instruction in Practical Surgery.

At University College, Mr. E. Ray Lankester has been appointed Professor of Comparative Anatomy in the room of the late Dr. Grant. Dr. G. V. Poore has been appointed an Assistant-Physician to the Hospital. Sir Henry Thompson has retired from the office of Surgeon to the Hospital; and Mr. A. E. J. Barker, late Surgeon to the City of Dublin Hospital, has been appointed Assistant-Surgeon. Mr. Christopher Heath has succeeded Mr. Erichsen as Holme Professor of Clinical Surgery.

At the Westminster Hospital, the vacancy in the office of Physician caused last year by the death of Dr. Anstie was filled by the promotion of Sir D. Gibb, who has himself lately retired. Dr. A. S. Donkin has been appointed Assistant-Physician. Dr. Anstie's post as Lecturer on Medicine has been filled by the appointment of Dr. Fincham and Dr. Sturges as joint Lecturers; and Dr. C. D. F. Phillips succeeds Dr. Sturges as Lecturer on Materia Medica.

In the Queen's College, Birmingham, Dr. Rickards joins Dr. Norris and Mr. Bartleet as Professor of Physiology, and Dr. Jolly becomes Mr. Thomas's colleague in the Professorship of Anatomy. Dr. Sawyer gives Pathological Demonstrations in place of Dr. Rickards.

At the Bristol General Hospital, Dr. Skerritt has been appointed Physician; Mr. Coe has retired from the office of Surgeon, and Mr. Keall has been appointed; and Dr. Swayne is succeeded by Dr. Lawrence as Physician-Accoucheur, but continues to lecture on Midwifery in the Medical School.

At the Leeds School of Medicine, the lectures on Chemistry and the instruction in Practical Chemistry are given by Dr. Thorpe, in place of Mr. Fairley. Mr. Wheelhouse has retired from his share of the Lectureship on Surgery; this subject is now taught by Mr. Teale, Mr. Jessop, and Mr. Atkinson. Mr. Price and Dr. J. Braithwaite lecture on Midwifery in place of Mr. W. Hall. The Lectureship on Botany, lately held by Mr. Atkinson, is vacant.

At the University of Durham College of Medicine at Newcastle, Dr. Reoch has been appointed Lecturer on Physiology, in the place of Dr. H. A. Nicholson, who has gone to St. Andrews' University as Professor of Natural History. Dr. Nesham has retired from the Lectureship on Anatomy, and lectures on Midwifery in conjunction with Dr. Gibson.

Mr. McBean has become Mr. H. E. Armstrong's colleague in the Lectureship on Botany. Dr. F. Page lectures on Forensic Medicine, in place of Dr. Bramwell, who has been appointed a Physician to the Infirmary, and teaches Pathology in conjunction with Dr. Gibb.

In the University of Aberdeen, Dr. Smith-Shand has been appointed Professor of Medicine in the room of Dr. Macrobin, resigned; and the vacancy in the Professorship of Midwifery, caused by the death of Dr. Inglis, has been filled by the appointment of Dr. Stephenson.

In the University of Edinburgh, the vacancy in the Professorship of Institutes of Medicine, caused by the resignation of Dr. Hughes Bennett, has been filled by the appointment of Dr. W. Rutherford, lately Professor of Physiology in King's College, London.

In the Edinburgh Extra-Academical School of Medicine, several additions have been made. Mr. J. Falconer King teaches Practical Chemistry; Dr. Underhill lectures in the summer on Midwifery and Diseases of Women and Children; and Dr. J. G. S. Coghill teaches General Pathology and Pathological Anatomy.

In the University of Glasgow, Practical Physiology is taught by Dr. A. Buchanan and Mr. Fleming in the summer session. The Western Infirmary is announced as open for Clinical Instruction.

In Anderson's University, Glasgow, Dr. Eben Watson is announced as teaching Practical Physiology in the summer session. Mr. Dittmar teaches Chemistry and Practical Chemistry in place of Dr. Thorpe.

OPENING OF THE MEDICAL SCHOOLS.

THE subjoined is a list of the Medical Schools in England and Scotland, with the date of their opening, and the names of the gentlemen appointed to deliver introductory addresses. Where no name is inserted, there is no special introductory lecture.

- St. Bartholomew's Hospital—October 1st.
- Charing Cross Hospital—Mr. Fairlie Clarke—October 1st, 4 P.M.
- St. George's Hospital—Dr. Barnes—October 1st, 4 P.M.
- Guy's Hospital—Dr. Stevenson—October 1st, 2 P.M.
- King's College—Dr. Curnow—October 1st, 4 P.M.
- London Hospital—Dr. W. B. Woodman—October 1st, 3 P.M.
- St. Mary's Hospital—Dr. Randall—October 1st, 8 P.M.
- Middlesex Hospital—Mr. B. T. Lowne—October 1st, 3 P.M.
- St. Thomas's Hospital—Dr. Payne—October 1st, 3 P.M.
- University College—Dr. Corfield—October 4th, 3 P.M.
- Westminster Hospital—Mr. R. Davy—October 4th, 3 P.M.
- Bristol Medical School—October 1st.
- Birmingham (Queen's College)—The Warden (Rev. W. H. Poulton)—October 1st, 3 P.M.
- Birmingham (General and Queen's Hospital)—Introductory Clinical Address at the General Hospital—Mr. A. Baker—Oct. 8th, 3.30 P.M.
- Bristol Medical School—October 1st.
- Leeds School of Medicine—Mr. Jessop—October 1st, 4 P.M.
- Liverpool Royal Infirmary School of Medicine—Dr. Dickinson—October 2nd, 3 P.M.
- Owens College (Manchester Royal) School of Medicine—Mr. Lund—October 4th, 4 P.M.
- Newcastle College of Medicine—Mr. H. E. Armstrong—October 1st, 2 P.M.
- Sheffield School of Medicine—Dr. J. Young—October 1st, 4 P.M.
- Aberdeen University—October 27th.
- Edinburgh University—The Principal—November 3rd, 2 P.M.
- Edinburgh School of Medicine—Mr. Chiene—November 1st, 11 A.M.
- Glasgow University—Dr. G. Buchanan—October 26th, 12 noon.
- Glasgow, Anderson's University—October 26th.

It is announced that very extensive alterations and sanitary improvements are being carried out at a great outlay at St. Mary's Hospital, London. It is right that the teachings of sanitary science should be rigorously applied to hospitals, and that patients introduced into wards for the purpose of cure, should be freed from all extraneous causes of disease and mortality. Many other hospitals may take a lesson from St. Mary's, where several thousand pounds are now being expended on the wholesome work of sanitation.

A WOMAN is reported to have died on August 8th at Dekan near Rakontsky, in Bohemia, at the age of 115 years.

SURGEON-GENERAL BALFOUR, M.D., has left for Gibraltar to resume medical charge at the station from leave of absence.

M. DEMARQUAY has left direction in his will that any of his old pupils who desire it shall have *souvenirs* of their master, in the form of books or instruments.

THE CHOLERA IN SYRIA.

OUR correspondent at Constantinople writes:—The latest advices received from Syria concerning the present outbreak of cholera are on the whole reassuring; though, I am sorry to say, that some cases with fatal results have occurred in the Lebanon. It seems on the decline in all the Syrian towns with the exception of Aleppo; where, during the week ending August 15th, there were 341 cases and 253 deaths. At Damascus, from the 9th to the 11th, there were only nine new cases. A large amount of intermittent fever, frequently of the form "perniciosa", prevails throughout the entire country, more especially along the shores of the Narmora and Black Sea, which may be accounted for by the fact of the continued wet; the presence of hot sun and heavy rainfalls invariably increasing the amount of malaria.

TEACHING OF STATE MEDICINE.

THE extension of the functions and sphere of duty of State Medicine, and the multiplication of medical "health appointments", has given rise to a call for additional special instruction. This is very necessary to enable candidates for such appointments to fulfil their duties satisfactorily; it is probably indispensable to most of those who may wish to arm themselves with diplomas in State Medicine of either of the Universities or examining bodies who propose to grant them. Separate courses of lectures on Hygiene are now delivered in several of the London and provincial medical schools; while in others the subject is taught as a part of Forensic Medicine. We observe that the authorities of University College have made special provision for the purpose of teaching this subject under the guidance of Professor Corfield and Professor Williamson. A complete laboratory course has been arranged, in addition to systematic lectures on hygiene and public health. In Owens College, Manchester, it is announced that, in addition to a comprehensive course of lectures on Hygiene by Dr. Arthur Ransome, practical instruction in the analysis of food, etc., will be given by Professor Roscoe. So far as we know, the organisation at University College for the teaching of State Medicine is the most complete that has yet been added to a medical school; but the hint will no doubt be taken elsewhere. Preventive medicine is now an essential element in the education of almost every medical student.

HOSPITAL SATURDAY.

HOSPITAL Saturday, we learn, is still going on, that is to say, subscriptions are yet coming in, and will be received by the committee until the end of the present month, when the accounts for the year will be made up and published. The sum already collected is £4,700, and further sums of £200 or £300 from one local committee, of between £100 and £200 from another such committee, of sums unknown from several other committees, from the south-eastern district post-office, and from about five hundred firms from which intimations have been received, and of about £100 from the South-Western Railway are still expected to swell the amount. The expenses this year have been only about £900, against £1,800 last year; and the accounts will be duly audited. But we fear that the amount for distribution will not be so large as that of 1874, when the sum collected exceeded £6,463.

THE HEALTH OF LONDON.

DURING last week, London had the lowest death-rate of the eighteen largest English towns. The metropolitan rate of mortality was 21.6; and in the other towns the rate ranged upwards to 36 in Salford and in Nottingham. In London the deaths were 1,429, and were 6 below

the average. There were 2 deaths from small-pox, 22 from measles, 99 from scarlet fever, 9 from diphtheria, 60 from whooping-cough, 29 from different forms of fever, and 188 from diarrhoea: or 409 deaths (equal to an annual rate of 6.1 per 1,000 persons living) from the seven principal zymotic diseases. Both the deaths classed to small-pox were, however, cases of chicken-pox. In outer London, the total death-rate and the zymotic death-rate were 19.9 and 4.7 per 1,000 respectively, against 21.6 and 6.1 in inner London. The mean temperature of the air at Greenwich during the week was 60 deg. or 0.5 deg. above the average. The wind was variable in direction. Rain fell on Sunday and Friday to the extent of .23 of an inch.

REGISTRATION AND COMPULSORY EDUCATION FOR DENTISTS.

A MEETING was held at Manchester on the 1st instant, with a view to promoting the compulsory education and registration of dentists. Mr. C. J. Fox took the chair, and the principal resolution was moved by Mr. Dennant of Brighton, and seconded by Mr. Wormald of Bury. It is a question whether any government would be prepared to pass an Act rendering dental education compulsory, since the practice of dentistry in many of its branches involves no personal risk to the patient from the ignorance of the practitioner. It is different with dental surgery proper. Here we find an undoubted necessity for higher education of a compulsory character, but it must be quite separated from mechanical dentistry, and hence arises a complication. The promoters of the present movement evidently overlook the point that we raised some two weeks back, that dentistry is still half a profession and half a business. We should have thought that an attempt to obtain registration would have had the best chance of success if it had been commenced in London, since in the metropolis we have the largest proportion of dentists possessing a purely surgical degree; we shall, however, watch the movement with interest, to see how far the profession is prepared for the great change that the movement, if successful, involves.

ASSOCIATION INTELLIGENCE.

SOUTH WALES AND MONMOUTHSHIRE BRANCH.

THE autumnal meeting of this Branch will be held at Tenby, on Thursday, September 30th.

Nomination-papers must be sent to one of the undersigned by the 9th instant.

ANDREW DAVIES, Swansea. } Hon. Secs.
ALFRED SHEEN, M.D., Cardiff. }

September 2nd, 1875.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT.

THE next meeting of the above Branch will be held at the Pavilion Hotel, Folkestone, on Thursday, September 16th, 1875, at 3 o'clock; Dr. HENRY LEWIS of Folkestone in the Chair.

Dinner at 5 o'clock precisely. Charge, 6s. 6d., exclusive of wine.

Gentlemen who wish to make communications to the meeting are requested to inform me at once, in order that a notice thereof may be included in the circular convening the meeting.

EDWARD WHITFIELD THURSTON, *Honorary Secretary*.
Ashford, August 29th, 1875.

READING BRANCH.

THE annual meeting of the above Branch will be held in the Library of the Athenæum, Friar Street, Reading, on Wednesday, Sept. 15th.

Mr. MAY, the President, will take the Chair about 4.30, and deliver an address.

The election of a President and other Officers of the Branch for the year 1875-76 will then take place.

The meeting will then adjourn to the Queen's Hotel, where dinner will be provided at Six o'clock. Tickets, 16s. each (comprehending the entire charge), should be obtained of Mrs. George, at the Queen's Hotel, on or before Saturday, September 11th, to allow the necessary arrangements to be made.

RICHARD C. SHETLEF, M.D., *Honorary Secretary*.
Reading, September 2nd, 1875.

NORTHERN COUNTIES (SCOTLAND) BRANCH.

THE annual meeting will be held in Gray's Hospital, Elgin, on Saturday, September 18th, at 12.30 P.M.; Dr. VASS, of Tain, President-elect.

The following papers have been promised.

1. Address by the President-elect.
 2. Cases of Monstrosities. By Dr. Duff.
 3. The Sanitary Condition of our Villages and Rural Districts. By Dr. R. S. Turner.
- Luncheon in Gordon's Arms Hotel, at 2.30.
J. W. NORRIS MACKAY, M.D., *Hon. Sec. and Treasurer.*
Elgin, September 8th, 1875.

SOUTH MIDLAND BRANCH.

THE autumnal meeting of the above Branch will be held in the Council Chamber of the Guildhall, Northampton, on Wednesday, September 22nd, at 2 P.M.; HENRY TERRY, Esq., President-elect.

Gentlemen intending to read papers are requested to forward their titles forthwith to Dr. Bryan.

J. M. BRYAN, M.D. } *Honorary Secretaries.*
W. MOXON, Esq. }

Northampton, September 1st, 1875.

SOUTH EASTERN BRANCH: EAST SUSSEX DISTRICT.

THE next meeting for the above District will be held on Wednesday, September 22nd, at the Burlington Hotel, Eastbourne, at 3.30 P.M.; T. F. SANGER, Esq., of Alfriston, in the Chair.

Dinner at 5.30 P.M. Charge, 5s., exclusive of wine.

Notice of intended communications is requested by Tuesday, the 14th instant, in order that they may be inserted in the circular convening the meeting.

THOMAS TROLLOPE, M.D. Cantab., *Hon. District Secretary.*
35, Marina, St. Leonards-on-Sea.

SHROPSHIRE SCIENTIFIC BRANCH.

THE annual meeting of the above Branch will be held in the Museum, Shrewsbury, on Wednesday, September 22nd, at 2 o'clock; WILLIAM MATHEWS, Esq., President-elect.

Dinner at the George Hotel at 5 o'clock, exact time.

Gentlemen intending to read papers are requested to communicate with the Honorary Secretary.

SAMUEL WOOD, *Honorary Secretary.*
Shrewsbury, September 8th, 1875.

MIDLAND BRANCH.

A MEETING of the above Branch will be held at Matlock Bath, on Thursday, September 23rd. Several papers have been promised. Further information in next week's JOURNAL.

F. W. WRIGHT, *Honorary Secretary.*

Derby, September 1st, 1875.

NORTH OF ENGLAND BRANCH.

THE autumnal meeting of this Branch will be held at the Queen's Hotel, Sunderland, on Thursday, September 23rd, at 3 P.M.; S. E. PIPER, F.R.C.S., President.

The following papers have been promised.

1. Dr. J. W. Eastwood. The Prevalent Practice of Advertising Medical Works in the Non-Medical Press.
2. Dr. C. Gibson. Certain Forms of Blood-Diseases.
3. Dr. G. Y. Heath. Some of the less noticed complications of Prostatic Disease.
4. C. S. Jeaffreson, Esq. Remarks on some of the recent Advances in Surgical Pathology and Therapeutics.
5. Edward Jepson, jun., Esq. The Mechanical Treatment of Intestinal Obstruction.
6. Edward Jepson, jun., Esq. Case of Tumour of the Neck.
7. Dr. Byrom Bramwell. Report of a Case of Hydatid Disease of the Liver.

Gentlemen who are desirous of reading papers will oblige by communicating with the Secretary.

Dinner at the Queen's Hotel, at 4.45 P.M. Tickets, exclusive of wine, seven shillings and sixpence.

G. H. PHILIPSON, M.D., *Honorary Secretary.*
Newcastle-upon-Tyne, September 1st, 1875.

CORRESPONDENCE.

ETHER AS AN ANÆSTHETIC.

SIR,—In reply to the question put to me in your leading article on July 31st, I beg to say that the kind of ether which I make use of is what is called washed ether—*i.e.*, pure sulphuric ether, containing as much water as it will take up when agitated with water, and of specific gravity .735; but I find it desirable to keep its temperature at about 65 deg., by means of a vessel holding water.

I presume the difficulty of supplying ether-vapour of sufficient strength during the latter part of a prolonged operation by means of washed ether, given from a sponge or towel is the reason why anhydrous ether is often preferred.—I am, sir, yours faithfully,

J. T. CLOVER.

Cavendish Place, Cavendish Square, W., August 1875.

MEDICAL NEWS.

MEDICAL VACANCIES.

THE following vacancies are announced:—

- BLACKBURN and EAST LANCASHIRE INFIRMARY—House-Surgeon. Salary, £100 per annum, with board, lodging, and washing. Applications on or before the 14th instant.
- BOURNEMOUTH GENERAL DISPENSARY—Resident Medical Officer and Secretary. Salary, £120 per annum, with furnished apartments, coals, gas, and attendance.
- BRISTOL LUNATIC ASYLUM—Assistant Medical Superintendent. Salary, £100 per annum, with furnished apartments, board, and washing. Applications on or before the 16th instant.
- CAISTOR UNION—Medical Officer and Public Vaccinator for the Tealy District. Salary, £30 per annum, and fees. Applications on or before Oct. 1st.
- COLCHESTER UNION—Medical Officer for the Second District. Salary, £75 per annum.
- DISPENSARY FOR SICK CHILDREN, Manchester—Assistant Medical Officer. Salary, £180 per annum. Applications on or before September 15th.
- DOVER HOSPITAL and DISPENSARY—Resident Medical Officer. Salary, £100 per annum, with furnished apartments, coals, and lights. Applications on or before the 14th instant.
- DUNDEE ROYAL INFIRMARY—Resident Medical Assistant. Salary, £70 per annum, with board, lodging, and washing. Applications on or before the 15th instant.
- ESSEX and COLCHESTER HOSPITAL—House-Surgeon and Apothecary. Applications on or before October 7th.
- GATESHEAD UNION—Medical Officer for the Township of Winklaton. Salary, £25 per annum.
- HENLEY UNION—Medical Officer for the Nettlebed District. Salary, £80 per annum.
- HOSPITAL FOR SICK CHILDREN, Manchester—Assistant Physician. Salary, £300 per annum. Applications on or before September 15th.
- INVERNESS DISTRICT ASYLUM—Assistant Medical Officer. Salary, £70 per annum, with bed, board, and washing. Applications on or before the 11th prox.
- NORWICH DISPENSARY—Salary, £120 per annum, with unfurnished residence and apartments.
- OSWESTRY INCORPORATION—Medical Officer for the Llansilin District. Salary, £35 per annum.
- PEMBROKE UNION—Medical Officer for the First District.
- QUEEN'S HOSPITAL, Birmingham—House-Physician. Salary, £50 per annum, with board, lodging, and washing. Applications on or before the 23rd instant.
- ROYAL UNITED HOSPITAL, Bath—House Surgeon. Salary, £60 per annum, with board and residence. Applications on or before the 22nd instant.
- ST. GILES-IN-THE-FIELDS and ST. GEORGE, BLOOMSBURY, Parishes—Medical Officer. Salary, £250 per annum.
- SHEPTON MALLETT UNION—Medical Officer for the Fourth District. Salary, £32 per annum.
- SOLIHULL UNION—Medical Officer for the Yardley District. Salary, £17 per annum, and fees.
- STAINES UNION—Medical Officer for the Shepperton District.
- STROUD GENERAL HOSPITAL—House-Surgeon.
- SWAFFHAM UNION—Medical Officer for the Seaham Toney District. Applications on or before the 13th instant.
- WARWICK COUNTY LUNATIC ASYLUM—Second Assistant Medical Officer. Salary, £100 per annum, with board, lodging, and washing.
- WIMBORNE and CRANBORNE UNION—Medical Officer for No. 1 and 2 District and Workhouse. Salary, £85 per annum for No. 1, and £75 for No. 2, with £20 additional for the Workhouse. Applications on or before the 23rd instant.
- WORCESTER GENERAL INFIRMARY—Physician. Applications on or before the 25th instant.
- YORK DISPENSARY—Resident Medical Officer. Salary, £130 per annum, with furnished apartments, coal, and gas. Applications on or before the 16th inst.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTH.

UNDERHILL.—On September 7th, at Great Bridge, ton, the wife of *A. S. Underhill, M.B., of a daughter.

OPERATION DAYS AT THE HOSPITALS.

MONDAY	Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.
TUESDAY	Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.
WEDNESDAY	..	St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.
THURSDAY	St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.
FRIDAY	Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.
SATURDAY	St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with Duplicate Copies.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

MR. J. V. SOLOMON (Birmingham).—1. Next week. 2. Already arranged.

MEDICAL ETIQUETTE.

A CORRESPONDENT in SUSSEX states the following case, and asks our opinion:

Dr. A. is in attendance on Mrs. B. The mother, authorised by Mrs. B.'s husband, calls on Mr. C., requesting him to attend Mrs. B. C. declines, on hearing that Dr. A. is in attendance, but suggests meeting Dr. A. in consultation. The mother states they will not have any more of Dr. A.'s attendance; they are determined to have fresh aid. She goes to the house of Dr. A., and specifically declines further attendance on the part of Dr. A. The mother then returns to Mr. C., and informs him that, if he will not attend, she, the mother, must seek medical attendance elsewhere.

Does not Mr. C. act professionally in undertaking the case under these conditions?

* * * In the circumstances stated, Mr. C. is perfectly justified in attending; it is, of course, understood that he has neither directly nor indirectly undermined confidence in Dr. A., nor procured his dismissal.

DR. GARDNER (Pognor).—1. The letter has been handed to the General Secretary, to whom all directions as to change of address and business communications should be sent. 2. We shall be happy to hear from our correspondent on the subjects mentioned, and wish him success.

THE WORCESTER INFIRMARY.

We mentioned last week that the Executive Committee of the Worcester Infirmary had declined to recognise the necessity of making any alteration in their rules in respect to the manner in which the members of the honorary staff were to supply substitutes in the case of their unavoidable absence. We intimated, also, that the medical staff, not being contented to let matters remain on the present uncertain footing, had signified their intention of bringing the questions in dispute before the general body of governors. We have since received a full report of the meeting at which the Executive Committee came to the above-mentioned determination. From this, we learn that a letter from the honorary medical staff was submitted to the Committee, in which they expressed their regret that the alterations which they had suggested had not met with a favourable reception, and intimated their intention of shortly calling a general meeting of the governors, in order to obtain their opinion on the matter. The rules proposed by the medical men were the following:

"58. The physicians and surgeons shall visit their in-patients at least twice every week, and whenever they shall receive any notice from the House-Surgeon of any emergency. They shall also attend at the Infirmary every Wednesday and Saturday, between the hours of eleven and twelve, for the purpose of receiving governors' letters and prescribing for the out-patients."

"59. In the event of the unavoidable absence of any one of the Honorary Medical Staff from the Infirmary at the time appointed for his attendance, he shall, if possible, secure the services of a colleague to act for him; but in the event of his being unable to do this in proper time the House-Surgeon shall, at twelve o'clock, attend to such of the out-patients as may be waiting to see the absent physician or surgeon. But on every such occasion, the particulars of such absence, and the reason for failing to comply with the rules, shall be laid before the House-Committee at every meeting.

Surely these are reasonable enough. But the medical men were even willing to

make a further concession, and stated that they would be satisfied if the governors insisted only upon an authoritative declaration that the existing rules should always be construed with fairness and liberality, and with a due regard to the exigencies of private practice. The temperate and conciliatory character of these proposals is worthy of all praise, more particularly when we consider the manner in which Dr. Inglis has been treated. We quite agree with the *Worcestershire Chronicle* that "it was a great mistake on the part of the Executive Committee not to have settled the thing on the easy terms held out." "Had the Subcommittee but recommended, and the Executive Committee but sanctioned, the trivial alteration in the rules called for by the medical staff, the difference would have come to an end, and all would have been set right again." As it is, it is well that the matter is in train for reference to the governors; and we sincerely trust that, in one shape or the other, the requirements of the medical men will obtain their assent.

NIL DESPERANDEUM.—It is stated that Dr. Cheyne weighed, in 1755, more than thirty stone; but afterwards, by changing his habits, and living on milk and vegetables, reduced himself to less than half that weight.

IMPROVED HYPODERMIC SYRINGE.

SIR,—I see, in the last number of the BRITISH MEDICAL JOURNAL, a notice of a new hypodermic syringe, supposed to be invented by Messrs. L. Blaise and Co., St. James's Street. With respect to this instrument, I beg to state that I exhibited precisely the same make syringe at the Norwich Meeting of the British Medical Association in 1874, and also exhibited it at the Edinburgh meeting this year. 3, St. Thomas's Street, Borough. I am, sir, yours, etc., J. MILLIKEN.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, no later than Thursday, twelve o'clock.

DR. CAMPBELL.—See Taylor's *Medical Jurisprudence*. You will also find cases in Morgagni. In the letters of the first Earl of Malmesbury, published by Bentley 1870, it is stated at page 199, that "General Armiger, aged 65, was married at eight o'clock last Saturday evening (March 20th, 1770) to a lady between thirty and forty years, went to bed, and was dead by one o'clock."

LX.—The late Lord St. Leonard's, when Lord Chancellor of Ireland, founded the Sugden Prize. It is awarded by the Irish College of Surgeons.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Bristol Daily Post; The Bristol Daily Times and Mirror; The Derby and Chesterfield Reporter; The Lincolnshire Herald; The Glasgow Herald; The Sunderland Daily Echo; The Carnarvon and Denbigh Herald; The Manchester Guardian; The European Review; The Hackney and Kingsland Gazette; The Worcestershire Chronicle; The Birmingham Daily Post; The Brighton Daily News; The Sussex Daily News; The Glasgow Herald; The Cork Examiner; The Scotsman; The Cork Daily Herald; The Southampton Times and Hampshire Express; The Hampshire Advertiser; The Birmingham Morning News; The Chester Courant; The Metropolitan; The Live-Stock Journal; The Shield; The Grocer; The Shipping and Mercantile Gazette; The Advertiser; The Islington Gazette; The Penrith Observer; The Hastings and St. Leonards Gazette; The Ilkley Free Press; The Leicester Daily Post; The York Herald; etc.

COMMUNICATIONS, LETTERS, ETC., have been received from:—

Dr. Corfield, London; Mr. C. Rawson, London; Dr. F. Ogston, jun., Aberdeen; Dr. T. W. Blackshaw, Stockport; Dr. Norris, Birmingham; Dr. W. M. Campbell, Liverpool; Dr. Needham, Gloucester; Dr. E. T. Wilson, Cheltenham; Mr. T. Law Webb, Ironbridge; Our Birmingham Correspondent; M.R.C.S.; Dr. McKendrick, Edinburgh; Dr. Wolfe, Glasgow; Mr. Thurston, Ashford; Mr. E. R. Morgan, Neath; Dr. Myrtle, Harrogate; Dr. Jolly, Birmingham; Mr. Sharman Wood, Boston; The Secretary of the Accident Assurance Company; Dr. Cameron, Glasgow; Dr. Inglis, Worcester; Dr. Dowse, Highgate; Dr. Hardie, Manchester; The Secretary of Apothecaries' Hall; The Registrar-General of Ireland; Mr. T. M. Stone, London; The Registrar-General of England; Dr. G. M. Humphry, Cambridge; Dr. Taaffe, Brighton; Mr. W. A. Thomson, Southall; Dr. R. Shettle, Reading; the Secretary of the Glasgow Medico-Chirurgical Society; Mr. W. R. Smith, Winchester; Mr. S. M. Bradley, Manchester; Dr. James Gardner, Bognor; Dr. Johnson, Canterbury; Mr. J. V. A LECTURE ON THE RELATION BETWEEN CROUP AND DIPHThERIA.

By GEORGE JOHNSON, M.D., F.R.S.,

Physician to King's College Hospital; Professor of Medicine in King's College.

GENTLEMEN,—Some of you probably will remember that, at the beginning of the year 1870, the relation between croup and diphtheria formed the subject of discussion in the BRITISH MEDICAL JOURNAL—a discussion which had its origin in a paper which I there published on the Morbid Anatomy of Croup and Diphtheria. In that paper, I expressed my belief that, while most English writers on croup had confounded together two essentially distinct diseases—namely, simple catarrhal laryngitis and the specific diphtheritic membranous laryngitis—the true doctrine is that of the French pathologists, who teach that membranous croup is always diphtheritic, and that laryngitis from exposure to cold never results in the formation of false membrane.

At the commencement of the present year, the *Lancet* published simultaneously a lecture by Sir William Jenner on Croup and the Diseases that resemble it, and a paper of mine on Certain Points relating to the Etiology, Pathology, and Treatment of Diphtheria. In this paper, I reiterated my former statement that membranous croup is no other than laryngeal diphtheria; and Sir William Jenner stated that his opinion had undergone some modification. He said: "I am inclined now to the belief that there is no such disease as idiopathic simple membranous inflammation of the larynx. I say I am inclined to that belief. I am not sure that it is true; but, as I formerly thought that the weight of evidence was in favour of their non-identity, I now incline, from my further experience, to think that the two diseases are really identical; that the so-called croup" (that is, membranous croup) "is really diphtheria". The simultaneous statement of this pathological doctrine by Sir William Jenner and myself appears to have excited considerable interest, and has given rise to a prolonged discussion in the columns of the *Lancet*. Latterly, too, several communications on the same interesting subject have appeared in the BRITISH MEDICAL JOURNAL. I propose now to set forth briefly the main facts relating to this subject, which appear to me to be established almost beyond controversy.

In the first place, then, it is an unquestionable fact, that, although the name *diphtheria* is a modern invention of Bretonnean, the disease which we now recognise by that appropriate designation has existed for centuries. Bretonneau, in his first memoir on *Diphtheria*, translated by the New Sydenham Society, gives an interesting historical account of the disease, and shows that Aretæus describes it, and speaks of it as being so common in Egypt and Syria, that it had received the name of the Egyptian or Syriac ulcer. Two or three centuries later, the same disease is described by Aëtius; but, to come nearer to our own time, ever since the end of the sixteenth century, the disease now recognised as diphtheria has shown itself frequently in Spain, Italy, France, England, Sweden, and in America. Dr. John Starr, in the *Philosophical Transactions* (1749-50), describes under the name of *morbus strangulatorius* a disease which he says "has within a few years reigned in several parts of Cornwall with great severity". In his description we recognise the unmistakable features of diphtheria. He speaks of a "white body seen on the palate and tonsils", and gives a woodcut illustration of a membranous cast of the larynx, trachea, and primary bronchi, which was expectorated by one of his patients. He also describes the formation of a white membrane on blistered cutaneous surfaces.

Huxham, in his *Dissertation on the Malignant Ulcerous Sore-throat* (3rd ed., 1759), evidently confounds together the two diseases scarlet fever and diphtheria. We recognise diphtheria in his description of ash-coloured spots on the tonsils, uvula, palate, and pharynx, in the noisy breathing resulting from the extension of the disease to the air-passages, and in the expectoration of portions of membrane from the windpipe. He speaks of the discharge from the nostrils as being so acrid that it excoriated the lips and hands of the patients, and the

fingers and arms of the nurses. He believes that the "rheum" from the throat and nostrils, being swallowed, caused griping pains, diarrhoea, and excoriations of the anus and buttocks. While passing into the air-passages, "the windpipe itself was sometimes much corroded by it, and pieces of its internal membrane were spit up".

In the first volume of the *American Philosophical Transactions*, originally published in 1771, Dr. Samuel Bard gives an admirable description of diphtheria, under the name of *angina suffocativa, or sore-throat distemper*, as it appeared at New York. He describes the membrane on the tonsils as being frequently, but not invariably, present. He speaks of the membrane in the air-passages as being "preternaturally thickened mucus", without much inflammation; and he contrasts this with a case in which, death having resulted from "a very violent inflammation of the internal membrane of the trachea, there was no such mucous lining to be discovered upon it". He describes the formation of membranes on the abraded skin; and he recognises the infectiousness of the disease, but rather, as he says, "from the breath of the infected persons", than from "any generally prevailing disposition of the air". And this, he says, explains the fact that a whole family may suffer from the disease while the next-door neighbours escape. He speaks of one family in which seven cases occurred, three of which were fatal.

In the year 1765, Dr. Home published his treatise on the *Nature, Cause, and Cure of Croup*. The word "croup" had long been in popular use in Scotland to designate a disease, or a group of diseases, attended with the symptom of noisy breathing. Dr. Home was the first to describe a membrane lining the air-passages as the essential anatomical character of croup. A careful study of his cases clearly shows that under the name of croup he included two diseases essentially different; namely, simple laryngitis from cold, and the specific disease diphtheria. Most of the cases that recovered belonged to the former class, while the fatal cases were diphtheritic. His two first fatal cases of croup with false membrane occurred in a brother and a sister aged respectively seven and five years, who died within a few days of each other. The fact of two fatal cases occurring thus in quick succession would alone excite a suspicion that the disease was diphtheria. In the second case, there was "purulent" expectoration; "the amygdalæ were a little swelled and covered with mucus"; and after death, besides the false membrane in the trachea, the back of the tongue was covered with mucus, and "all about the glottis was covered with tough viscid mucus". It can scarcely be doubted that these cases of so-called croup were really diphtheritic. Cullen, in his *First Lines of the Practice of Physic*, 4th ed., 1784, in describing *cynanche trachealis*, refers to Home as "the first who has given any distinct account of it"; and, after describing the purulent and sometimes membranous expectoration, says that, "when the internal fauces are viewed, they are sometimes without any appearance of inflammation, but frequently a redness and even swelling appear; and sometimes in the fauces there is an appearance of matter like to that rejected by coughing". Under the head of *cynanche maligna*, Cullen evidently includes scarlatina anginosa and diphtheria. The latter cases are indicated by the appearance of white or ash-coloured spots on the fauces, and by the fact that "the larynx and trachea are often affected in the same manner as in the *cynanche trachealis*"; as a consequence of which, "the *cynanche maligna* often proves fatal by such a sudden suffocation as happens in the proper *cynanche trachealis*". But he adds: "There is reason to suspect that dissectors have not always properly distinguished between the two diseases."

Mr. Henry Rumsey, in "An Account of the Croup as it appeared in the Town and Neighbourhood of Chesham, in Buckinghamshire, in the years 1793 and 1794" (*Med. Chir. Trans.*, vol. ii), says that "frequently large films of a white substance were formed on the tonsils", evidently what we now call a diphtheritic exudation; and he describes "a film or membranous substance lining the cavity of the trachea". Mr. Rumsey, after referring to the opinion of Drs. Home and Cullen, that croup is an inflammatory disease, makes the following remarkable comment. "It appears to me that the croup is an inflammation of its own kind. If it consisted in common inflammation, we might expect to find the same appearances (that is, the same kind of concretion on the surface of the trachea) every day, as its mucous membrane is so frequently the subject of inflammation attended with an increased secretion. The matter, however, of which this substance is formed, possesses different properties from those of the mucus which is thrown out upon the membrane of the nose or of the trachea in common catarrhal affections." In these remarks of Mr. Rumsey, we have the earliest intimation of the specific character of that inflammation of the larynx and trachea which results in the formation of false membrane, and of the essential difference between that and what he calls common inflammation.

Dr. Cheyne's treatise on the *Pathology of the Membrane of the Larynx and Bronchi* was published in 1809. In describing croup, he says: "I have seen children so affected that I at first imagined they were suffering under the second stage of croup; but, upon examination, I discovered sloughs on the tonsils and uvula. The cough, voice, and breathing were those of the second stage of croup." Dr. Cheyne doubts whether these were cases of "true croup"; but it can scarcely be doubted that they were cases of diphtheritic croup. Dr. Cheyne mentions two cases in which croup occurred as a complication of scarlet fever. In a child, there was croupy cough and breathing, and "the fauces were sloughy". In this case, no examination was made after death; but, in the case of a soldier who died, "the trachea was found lined by a membrane as in croup". Unquestionably, these were cases of diphtheria associated with scarlet fever.

I have shown you that our English writers on croup, from Hume and Cullen downwards, unquestionably met with cases of membranous exudation on the fauces and air-passages which could have been no other than the disease which we now recognise as diphtheria; but until the publication of Bretonneau's memoirs on *Diphtheria*, if we except the brief statement which I just now quoted from Rumsey, no one had pointed out the essential distinction between the specific diphtheritic inflammation of the throat and air-passages, with its resulting membranous exudation, and simple catarrhal inflammation of the same structures.

Most writers on croup before the time of Bretonneau, and many writers since, have confounded two essentially distinct diseases; namely, a specific diphtheritic laryngo-tracheitis, and simple catarrhal inflammation of the air-passages. Bretonneau, Trousseau, Guersant, and all the leading French pathologists, agree in defining true croup to be that form of the disease which is attended with a membranous exudation. They also agree that this is a specific product of the diphtheritic poison; while "false croup", or, as they call it, "stridulous laryngitis", is a catarrhal inflammation excited by cold, and not resulting in the formation of a coherent membrane. I believe this pathology to be correct; but it is unfortunate that the term croup should have been diverted from its original significance of a croaking or crowing noise, to express an anatomical condition. It is unquestionable, that this attempt to restrict the application of the term croup has been a source of confusion, especially to English practitioners, who, having been accustomed to think of croup as an inflammatory disease the result of exposure to cold, often fail to distinguish between this simple inflammatory croup and the "true croup" of the French.

It is evident that most cases of membranous croup have been and are diphtheritic, and the only question that remains for consideration is this: Is there a form of membranous croup which is not diphtheritic? It is possible that there may be more than one form or modification of morbid poison which may excite a membranous exudation in the air-passages. Of this, however, we have no proof; but the evidence is very weighty against the opinion entertained by some that exposure to cold alone may excite a membranous inflammation. Our experience of catarrhal inflammation of the mucous membrane of the air-passages is very great. We see it constantly under the forms of laryngo-tracheitis and bronchitis; and the product of this inflammation, at every period of life from infancy to old age, is the same—a muco-purulent secretion, and not a coherent false membrane.

On the other hand, we meet with numerous cases of diphtheritic inflammation affecting the nares, fauces, and air-passages, with the formation of a more or less coherent membranous exudation; this product being, as Mr. Rumsey said eighty years ago, entirely different from that of ordinary catarrhal inflammation.

It is, then, unquestionable that, in the vast majority of cases, a membranous exudation in the air-passages is the specific product of diphtheria. It is equally certain that, as a rule, catarrhal inflammation the result of cold, although intense enough to destroy life, as it does in very numerous instances, is attended with no such membranous exudation. The arguments which are sometimes put forth in support of the proposition that there is a form of membranous croup which is not diphtheritic, are quite inconclusive. It is admitted by the best authorities that the morbid anatomy of membranous croup is identical with that of diphtheria. The infiltration of the mucous membrane, by some supposed to be characteristic of diphtheria, may exist in the fauces and larynx, while in the trachea and bronchi of the same subject there is an unadherent so-called croupous exudation on the surface. It is certain that the absence of exudation on the fauces will not prove the croup to be non-diphtheritic; for the diphtheritic process may begin in the larynx, or, what is more common, the exudation which first occurred on the fauces may become detached, while the disease is extending downwards into the air-passages. In some cases, the posterior surface of the soft palate is covered by exudation, while none is visible on the

anterior surface. I saw two sisters, aged respectively nine and six years, who were taken ill simultaneously. The younger child had a diphtheritic patch on one tonsil, which went no further, and she was soon well; the other had a croupy cough and breathing, but no visible exudation on the fauces, and she quickly died from obstructed breathing. There was no *post mortem* examination; but there could be no question that the case was one of laryngeal diphtheria without exudation on the fauces. Mr. Lattey of Southam mentions a case (*BRIT. MED. JOUR.*, May 29th, 1875) in which a pellicle appeared on the tonsils on the second day, and separated on the third, when, a day or two afterwards, croupy symptoms occurred; so that, if this case had been first seen at that period, it would have been taken for a case of croup without exudation on the fauces.

It is sometimes said that, whereas membranous croup is a sthenic disease, diphtheria is asthenic; but it is notorious that, in many cases of undoubted diphtheria, there is a remarkable absence of constitutional symptoms until the larynx is invaded. Then, although diphtheria belongs to the class of epidemic and contagious diseases, it often occurs sporadically, and shows no disposition to spread from the sick to the healthy.

It has been urged, as an argument against the identity of membranous croup with laryngeal diphtheria, that the older writers on croup make no mention of the paralytic sequelæ which occur in some diphtheritic cases. In reply to this argument, I would remark first, that, since laryngeal diphtheria is usually fatal, it rarely happens that the sufferers from this form of disease live long enough to develop the paralytic sequelæ; and, secondly, it is remarkable that in none of Bretonneau's elaborate memoirs on diphtheria is there any reference to these paralytic symptoms, which had escaped the notice of that acute observer. We see only what we have been educated to observe. To deny the identity of laryngeal diphtheria with membranous croup because no reference in past times was made to paralytic sequelæ, would be as unreasonable as to doubt their identity because the frequent coexistence of albuminuria was never mentioned until Dr. Wade pointed out the fact, and so taught us to look for it.

One remarkable fact in the history of diphtheria is, that it often occurs as a complication of other diseases. Thus it may coexist with scarlet fever, or with measles; and it is probable that a common catarrh may act as a concurring cause of the specific diphtheritic process. As an abraded skin may become inoculated by the diphtheritic poison, so may the throat when abraded by a simple catarrhal inflammation. Now, with reference to cases of this kind, I wish to impress upon you a point of great practical importance. Whenever you meet with a case of membranous croup which has been supposed to be a result of mere exposure to cold, make careful inquiry for any possible source of infection from a similar case; and, failing this, make a rigid search for insanitary conditions in the house where the disease originated. You must not be content with simply asking whether the drains and the water-supply are such as they should be; but you must search for insanitary conditions with the certain conviction that they exist; and, unless your experience is different from mine, you will find that the cases of supposed membranous croup from exposure to cold resolve themselves into cases of diphtheria the result of poisoning by foul air or contaminated water; for diphtheria in all its forms and varieties is as certainly as typhoid fever a disease of filth-origin. If ever it should be found that membranous laryngitis occurs from simple exposure to cold, without evidence of infection or of septic poisoning, I shall abandon the belief, which at present I hold firmly, that membranous croup and laryngeal diphtheria are one and the same disease.

In future, if we would avoid confusion in the use of the word croup, we must associate it with a distinctive prefix. There are three distinct diseases to which the term croup has been applied generically.

1. Spasmodic croup; syn., laryngismus stridulus, crowing inspiration, child-crowing, thymic asthma. This is a pure neurosis, and is often associated with infantile convulsions. It is the "false croup" of some English writers.

2. Inflammatory croup; syn., catarrhal laryngitis, the "stridulous laryngitis" or "false croup" of French writers. This disease is a catarrhal inflammation of the larynx and trachea, excited by exposure to cold, often complicated with laryngeal spasm, usually recurring again and again in the same subject in successive cold seasons, rarely fatal, and never associated with the formation of a coherent false membrane in the air-passages.

3. Diphtheritic croup; syn., laryngeal diphtheria, membranous laryngitis, membranous croup, the "true croup" of French pathologists; a specific contagious disease, which may be either sporadic or epidemic, and which may exist alone or as a complication of other diseases, as, for example, measles and scarlet fever. This form of disease is one of the most fatal complications of diphtheria.

ON ACCIDENTAL DEATHS IN THE NAVY AND ARMY.*

By W. R. E. SMART, M.D., C.B., K.L.H.,
Inspector-General of Hospitals and Fleets.

IN dealing with the subject of deaths by accident or by negligence occurring in the navy and army, it is fortunate to have a reliable standard from civil life through an equally long period in the Registrar-General's Reports, Annual Summary, 1874, Table 9, giving the causes of deaths registered in London in each of the thirteen years 1862-1874.

The mean population is approximated by the half of the sum of the censuses of 1861 and 1871, yielding 3,030,000 souls, which is here adopted as the divisor of the total of deaths under the various headings, after their division by 13, the number of years of the entire period.

The data for the services are abstracted from the Sanitary Returns published annually by authority; and, in dealing with these, the same rule has been observed as with the Report of the Registrar-General, the period of thirteen years being 1860-1872. In the Navy Returns for 1870 there is an exceptional calamity that augments the ratios of death by drowning—the foundering of H.M.S. *Captain* with 418 picked officers and men; but, in comparing the risks to life in the sister services, I have preferred to present this apart from ordinary risks.

It is to be regretted that the sanitary returns are not drawn up with uniformity of, at least, the "total results", as that would render comparisons less difficult than they now are. The specialities of the services would be treated apart, as at present; and with respect to these, I consider each service would derive advantage by copying some of the forms used by the other.

The gross totals, and the annual means of deaths from all causes, accidental or by negligence, drawn from these various sources, together with the relative ratios, are :

	Average Population.	ACCIDENTAL DEATHS.				
		Total in 13 yrs.	Annual mean.	Annual ratio.	Including the Captain. 13 yrs.	Mean. Ratio.
Metropolitans, of all ages	3,030,000	27,868	2143	.707	—	—
Army, 17 to 45 yrs. .	176,100	2200	176	1.	—	—
Navy, " ..	52,700	2098	161	3.05	2576	198 3.75

A cursory examination of this table elicits a very great inequality in the risks incurred in the navy above those of the army in generally peaceful periods, when the latter do not exceed those of the metropolis more than 30 per cent. This percentage would be reduced if data were at hand for the classification of the metropolitan deaths by violence according to ages, since we are only able to show the gross statistics, including all ages, from the overlaid infant to the octogenarian run over by a careless driver—extremes of age in which deaths by violence are at their minimum—which reduces the ratios of working age, when they are at their maximum, in the statistics thus presented in gross; so that it may be assumed that, by classification of age-periods, the same ages in civil life would offer as high a ratio as those of the army. It is seen also that the ratio of violent deaths in the navy exceeds that of the army in the proportion of 1 to 3 per 1,000 men; so that, whatever may be found to be the ratios of deaths from climatic causes and from ordinary diseases, it is clear that, apart from them, the special dangers arising from calling are higher in naval than in military life. Although the naval ratios on this head are high comparatively with those of life ashore in a great city and in barracks and camps, yet there are grounds for the belief that they are still lower than those of the mercantile navy, concerning which full and reliable statistics are still wanting.

The second stage in this inquiry will be the estimating of the various elements of danger which, combined, render the sea-service so much more destructive by accidents than the land-service; to obtain which satisfactorily, the relative conditions of health, sickness, and mortality of the two services must be ascertained. Then we must proceed to examine the ratios of deaths by accidents of every description; and, finally, we may discriminate the same under the headings: in battle, or in face of an enemy; by drowning, without proof of suicidal intention; from all other kinds of accidental violence: the first being the speciality of the fighting services, the second being appropriate to sea-

life, and the last being the ground on which the sister services might be expected to stand somewhat on an equality.

The yearly averages relative to diseases and injury are, in round numbers, as follows.

Averages of 13 Years.	Navy.	Deaths.	Army.	Deaths.
Mean strength	52,700	—	176,100	—
Admissions, total	70,050	—	201,390	—
Deaths, total	—	615*	—	2949
Admissions for sickness .. .	54,500	—	184,900	—
Deaths by sickness	—	445	—	2698
Admission for injuries .. .	15,550	—	16,470	—
Deaths by injuries	—	161	—	176

By examining the ratios per 1,000 of these several elements, a fair estimate may be formed of the comparative sanitary conditions and the causes of mortality existing in the fighting services of the country.

Group I.		Navy.		Army.	
		1329	1143	1034	1050
Group I.	Admissions, total, to mean strength .. .	11.6	16.6	8.4	15.3
	" sick, " .. .	3.05	1.	8.16	14.7
	" hurt, " .. .	10.35	10.68	371.	65.02
Group II.	Deaths, total, to mean strength .. .	721.	902.	262.	59.
	" diseases, " .. .	36	137	1.72	4.6
	" injuries, " .. .	1.16	4.5	—	—
	" diseases, to admissions sick .. .	—	—	—	—
	" injuries, to admissions hurt .. .	—	—	—	—
	" injuries, to deaths by disease .. .	—	—	—	—
	" diseases, to total deaths .. .	—	—	—	—
Group II.	" injuries, to total deaths .. .	—	—	—	—
	" in battle, to mean strength .. .	—	—	—	—
	" by drowning, " .. .	—	—	—	—
	" all other injuries, " .. .	—	—	—	—

The first group of these ratios per 1,000 proves that more men are taken under treatment in the navy than in the army; that the admissions for diseases are nearly alike in both services, while the admissions for injuries are more than thrice as numerous in the navy than in the army. Equality of disease and inequality of "hurts" are the prominent characteristics; and it remains to be shown whether these indicate similar relations in the mortality under these general heads—i. e., whether the death-rates by diseases are equal where the admissions for treatment of disease are equal; and whether the increased ratio of admissions for hurts in the navy carries a correspondingly high death-rate.

The second group affords the reply to these questions, where it is shown, on the very threshold, that the average total mortality in the army is about 50 per cent. higher than that in the navy, consisting in a much higher death-rate by disease in the former than in the latter service, which much more than counterbalances the higher death-rate by accidents in the latter; the deaths by diseases alone being 15.3 per 1000 in the army, against 11.45 in the navy by diseases and accidents combined, or as 31 to 23. This is a very strongly marked inequality, that indicates the greater salubrity of the conditions prevailing in ships over those of garrisons and camps in every part of the world, which may be assigned to the diminished force of climatic causes afloat, and to the decreased liability to zymotic and epidemic diseases which seamen enjoy relatively to soldiers.

Collating the data concerning disease and its mortality, we find :

	Mean Strength.	Admitted.	Ratios per 1000.	DEATH RATIOS PER 1000.		
				Dead.	To Mean Strength.	To Admitted.
Navy.....	52,700	54,500	1034	445	8.4	8.16
Army.....	176,100	184,900	1050	2698	15.3	14.7

The reading of which is this, that in the navy there are 8.4 deaths to each 10,000 men, and 81 deaths in every 10,000 treated for diseases medical and surgical; and that in the army there are 15.3 and 14.7 deaths respectively in the same conditions. It follows that the navy is, so far as the Sanitary Reports instruct us, a far healthier service than the army; but these reports afford no data beyond the proximate mortality resulting from diseases contracted in the services, as they do not trace out the history of the *invalids* who are discharged on account of disability from diseases attributable to or contracted in the services, without which, through at least three years after their discharge, there cannot be any accurate estimate of the mortality by disease dependent on calling, as applied to seamen and soldiers.

Naval returns prove that in the period of thirteen years, with which this inquiry interests itself, the annual average of invalids amounted to

* The difference between the "total deaths" and the sum of the "deaths by sickness" and "deaths by injuries" represents "deaths by suicide", etc., which are not classed with "accidents".

* Read before the Public Medicine Section at the Annual Meeting of the British Medical Association in Edinburgh, August 1875.

35 per 1,000, concerning whom there are no published data to show how many have returned to the service with restored health, how many have died after their discharge from the diseases with which they were invalided, nor how many have been permanently broken down in health so as to become pensioners. Such data are essentially necessary to any just conclusions as to the pathological results of the seaman's calling, relatively to other callings, which becomes the more evident in consideration of the fact that a large proportion of the total invalids are on account of such diseases as phthisis, diseases of the heart and aneurisms, Bright's disease, and climatic diseases of the liver, dysentery, and the sequelæ of fevers. So far as is known, similar conditions surround the question of results among invalids from the army.

Thus the statistics of mortality in the services are to be accepted as the exponent of the direct results of disease, attacking previously healthy individuals and terminating fatally between the time of attack and that of arrival in England of such as were invalided, of whom a certain proportion may have succumbed soon after their return home; and, this return being effected more quickly by seamen than by soldiers, it follows that more invalided soldiers than sailors die on foreign stations, thus increasing the death-rate by disease of the army disproportionately to that of the navy while away from England.

Passing on to the consideration of deaths from accidental causes, we find that, as the duty of soldiers exposes them to higher ratios of death by disease, so that of sailors involves greater risks of destruction by violence, which is the special danger of their calling; and it is found that deaths by accidents are very rare among troops taking passage in H.M. transports, falling in much larger proportion among the outward bound than among others—for it is the sailor's work that kills.

There is in all minds an intuitive conception of this fact, in reflection on the characteristics of the seaman's vocation; performing duties that demand rapidity of motion on an unstable standing-place, where he is constantly dealing with unusually heavy bodies, or aloft, where he must devote his attention and his prehensile power to his personal safety in a degree always diminishing with the increasingly less favourable conditions of weather that of themselves render his position less safe. The terrible nature of the accidents that befall him is well displayed in the quotation of some of the injuries, prognosed as fatal on first inspection, if he have escaped annihilation by the stroke; among them are enumerated:

Multiple injuries by crushing, etc.	59
Fractures of vertebrae and pelvis	74
Fractures of skull, often complicated with other injuries equally fatal	429
Injuries of brain, cord, and viscera	49

Presenting a total of 609 in 52,000 seamen, against 474 for the army distributed among a body of men counting 176,000 of average strength, whose analogous cases of fatal injuries are thus classed:

Multiple injuries	32
Fractures and luxations	269
Contusions	48
Injuries of brain, cord, and viscera	125

These facts alone show the accumulated dangers by accidents, to which seamen are so much more subject than soldiers, that they may be regarded as special risks of the naval service.

With this light thrown in advance on the question, the force of the tabulated ratios may be the more readily understood; viz., that deaths by accidental violence are as 3 in the navy to 1 in the army, which may seem to depend on the greater number of accidents that occur in the former than in the latter service, standing as 295 to 93 of admissions for hurts: so that, with thrice as many admissions, there are thrice as many deaths: although, from difference of relative position and other reasons too numerous to mention here, it is credible that the admissions for minor hurts are relatively far more numerous than in the army. On the same ground, it must be inferred that, were the injuries admitted in the navy for treatment reducible to a parallel severity with those admitted in the army, the ratio of mortality to each 1,000 admitted would not be so low as 10.35 in 295 among sailors, against 10.68 in 93 among soldiers. For, deduct the excess of slight injuries from the navy admissions, and a higher ratio of deaths to the reduced number admitted, will at once appear.

Collating the data concerning accidental deaths, we find:

	Mean Strength.	Admitted.	Ratios per 1000.	DEATH-RATIOS PER 1000.		
				Dead.	To Mean Strength.	To Admitted.
Navy.....	52,700	15,550	295	161	3.05	10.35
Army.....	176,100	16,470	93	176	1.00	10.68

The reading of this is, that in the navy there are by casualties 3 deaths, and in the army 1 death, to every 1,000 men; and that the proportion of deaths to each 1,000 of accidents admitted are nearly alike, being as 10.35 in the navy to 10.68 in the army. At first sight this approximation might seem fallacious, and the opinion would receive support from other data in Group II, that out of every 1,000 deaths there succumb by casualties 262 in the navy to 59 in the army; but it is a complexity that clears away on a correct appreciation of the internal modifications proper to the service in their immediate and prospective conditions.

In whatever light it may be viewed, it will be admitted that a contrast so strong must originate in differentiating causes, influencing the principles of action of such large bodies of men. Every allowance being made for the impulse to run to the surgeon at once on the receipt of any injury, which declines with the shock and is therefore more frequently obeyed where the surgeon is always at hand, as on shipboard, than in barracks or camps where he may not be equally accessible; and also for the desire on the part of the surgeon to obviate inflammatory aggravation of slight wounds, which was formerly a common consequence, there remains a large margin for further consideration. Perhaps there may have been with soldiers a diffidence to being admitted to hospital, which, until 1874, incurred stoppage of pay: this feeling has had no weight with naval seamen, always free from such stoppage. Experience also teaches the seaman that the final consideration he may claim for disabilities arising from injuries may in no small degree depend on the early date of the record of the same made by the medical officer, which may influence the amount, if it do not deprive him, of a Greenwich Hospital pension. Besides this, the more provident of them become, while in health, beneficiary members of lodges and clubs ashore, and not unfrequently in ships, for the relief of those who are discharged on account of injuries: this has been a guiding principle of their community since the days of Elizabeth, when they voluntarily submitted to a deduction from their pay to institute the "Chest of Chatham", to which alone they could look for aid under such circumstances. In these respects, notwithstanding a general reputation for improvidence, the seamen of our day have not degenerated from their predecessors, as is clearly shown in the present agitation among them to create a fund, to be placed under control of the Government, for the benefit of their widows and orphans or fatherless children. It is to these principles of action we may look, I think, for an explanation of the reasons why the sick-list of the navy presents so marked a feature in contrast with that of the army as its excess in the actual number of admissions for hurts, as well as the disproportion between the numbers admitted for treatment and the proportion of fatal cases recorded, which, under the opposite conditions, might become far closer, as it is in the army. There is no other inference, in face of the great preponderance shown in the relative numbers of the directly fatal injuries on the side of the navy; because from that there must be a gradually descending scale of severity, and not a sudden descent from those of the utmost gravity to those of minor importance, free from every danger of a fatal result. But, with every just allowance on these grounds, even to the extent of one-half the admissions for hurts, there remains so wide a difference as to leave the inference that, from this habitual prudence of seamen in seeking treatment for every injury, however trivial, and from the extreme caution of their medical officers, the death-rate by injury is diminished in the naval statistics, not only in favour of the sufferers, but beneficially to the service itself.

The next and final point I have proposed for examination is that of the ratios of disease under the headings of "Battle, Drowning, and other Violence". With regard to these, we discover that under the first the loss of life is truly insignificant under ordinary service, free from great wars with civilised nations, although not without such hostile events as wars in China, New Zealand, and Abyssinia, in all of which the army prestige has sometimes stood as if alone worthy of national consideration, the services of the navy being subordinated to it in general estimation. Even with this drawback, it is found, statistically, that the actual loss of life in face of an enemy stands at a higher point in the navy than in the army. On each of those occasions sailors have formed an integral portion of the force employed; for, if the enemy have been unable to contest with them on their own element, they have been ever ready to co-operate with the army on shore to gain the object of the campaign, to which the history of our Naval Brigades brings ample testimony. In addition to this, boats' crews are sometimes, when employed on barbarous coasts, brought into conflict with the natives, thus undergoing considerable losses in battle, without the formal declarations necessary to our ideas of "war", although not the less so in its realities.

With reference to the ratios of "drowned"—1.72 per 1,000 in the navy, against .426 in the army—it may be said that, considering the

intrinsic natures of the services, it may well be a source of marvel and admiration that there should be only four deaths in the navy against one in the army; but out of this the question arises, why the army ratio should stand so high as it does relatively to that where lives are passed on the sea. But, if the appalling calamity that fell on 478 persons on board the *Captain* were superadded, the naval ratio would be raised from 1.72 to 2.46 per 1,000. For the reasons already given, the *Captain* has been excluded from the ordinary ratios.

Lastly, the deaths by accident from "all other causes combined" are as 1.16 to .435 per 1,000, or nearly as 11 to 4. This ratio, together with that of drowning, are the criteria which establish beyond question the greater risks of deaths from accidental causes to which seamen are exposed beyond the men of the army; and the reasons for its comparative excess are to be found in the lists of primarily fatal injuries given prefatory to the estimation of the ratios in both services.

Notwithstanding this proved inequality of the navy on the ground of the greater mortality by accidental violence, it is an irrefutable fact, that the causes of disease to which the army is exposed beyond the navy render service in it more inimical to life, or more subject to death-causes, than service in the navy, in the proportion of 17 to 12. Having in view the main features of this disparity, it may be hoped that, by increasing our efforts to mitigate in the respective services the causes of increased mortality peculiar to each, very much may still be done to render the lives of seamen and soldiers more secure than they are at present. Enforced attention to sanitary measures in the army and navy has already produced very marked improvement in their health-conditions, and a decrease of the mortality in both services, as shown by comparison of the later annual statistics with the average ratios of the past, affording us the highest encouragement to rely on statistics, and to persevere in the direction they point out. Greater care than ever before is devoted to the ventilation of ships, and to the diet and regimen of their crews, which is quite equalled in the army by improvements in barracks and in the selection of healthy sites for camps, to which we owe the decrease of death-by-disease rates which marks our era, in which it is deeply felt by all authorities that where by careful treatment we may, as practitioners, save hundreds, the enforced laws of hygiene will protect thousands from destructive diseases; and we are not forbidden to hope that, with reference to the casualties which present so large a summary of deaths by violence, there is a margin within the inevitable in which the lives of men might, by equal precautions adapted to that end, be rendered safe. Seamanship, like railway travelling, will ever exact an indefinite amount of sacrifice of life; and so imbued is the public mind with a sense of that necessity, that nothing short of a great wreck or a railway disaster creates any emotion. It must, however, have fallen to the lot of most dwellers on the depths of the ocean to see life needlessly sacrificed, where there is no coroner's law to investigate the circumstances and to assign blame where due. Where obedience is the fundamental principle, guiding men implicitly by the orders of their officers, it behoves those who command to dwell on these facts, so that their rule of action shall bear always the impress of foresight to prevent accidents, so far as may be, in a service where unusual risks are inevitable, but at the same time mitigable, as is proved by their greater frequency in some ships than in others. In the streets of cities, the rarity of fatal accidents depends much on the vigilance of police; and likewise it is not beyond probability that their frequency might be reduced in the navy, if special tabulated returns, not less minute in details than the returns of punishments, were required from every ship in commission.

Hygiene is the science of saving life by obviating the causes of death. As applied to diseases, the public services afford ample proof of its efficacy, and there seems to be no reason why the prevention of accidents should not be deemed worthy of being included within its legitimate bounds; nor why the combatant officers of both services should not be instructed in this science in their schools and colleges; for it is one which, from the earliest records of the military art, was deemed essential to the perfection of a great commander.

Concerning it, we read an interesting discussion of its merits and necessity in the first book of the *Institution of Cyrus*, as held between that mighty king, when a prince, and his uncle, to this effect. Cyrus speaks thus: "With respect to health, having heard and observed that cities wanting in health get physicians, and that generals, for the sake of their men, take physicians with them, so, when I was placed in command, I at once had regard to this point; and I believe that I have in my army men who are very skilful in that art." To this Cyaxares replied, "But these men are only like the patchers of worn garments, for it is only when men are sick that physicians are had recourse to; but your care of the health of your troops should be of a nobler nature—to prevent your army from becoming sickly, is what you, as a commander, ought to attend to." Then follow sanitary maxims, the

root of all army hygiene, imparted by the veteran to the younger soldier.

Thus we recognise that, from the earliest epochs of military history, hygiene has been regarded by the most enlightened conquerors as a study demanding their personal attention.

We may trace further back, by the aid of sacred history, the same principle of action in the Book of Leviticus, which contains precepts that have stood the test of three thousand years, embodying the experience of forty years of camp life, and there the execution was placed under the ægis of religion by an inspired leader and lawgiver.

In the modern history of civilised states, this important duty has become relegated from the limits of strategy and religion to those of medicine, with great advantage to mankind.

Whilst we accept the change as one adapted to the law of the fitness of social affairs, and may glory in this, that the practitioners of medicine, who were once looked at as like to the menders of ragged uniforms, have become the proper administrators of that which has been regarded as a very noble and divine office and function, we can yet safely admit that our own efficiency in it is proportioned to the enlightenment in the same path of those under whom we are called to serve, and therefore we may hail with satisfaction any course of instruction to them which would aid and support us in our endeavours to lessen still further the mortality amongst seamen and soldiers.

A CASE OF TRIPLETS, COMPLICATED WITH DOUBLE UTERUS.

By ALEXANDER G. DUNCAN, M.B., Crimond, N.B.

On the 25th December, 1873, I was asked to see a woman, who, on my arrival, informed me that she was pregnant for the fifth time. She was about eight and a half months advanced in her pregnancy, and anticipated her confinement to take place in about a fortnight; but, as she was different in shape and size from what she had ever been previous to her other confinements, she wished to consult me.

She had, as I have already mentioned, borne four children previously to her present pregnancy, all of whom are strong and healthy.

Upon examination, she had a somewhat strange appearance. The abdomen seemed much larger than usual, and also to fall too far forward; and, at the same time, the width was greater than in most cases, with a well marked depression from above downwards, and a little to the left side. Upon further examination, I found that this depression was a distinct division between two tumours; the one upon the left side being the larger of the two, and reaching further up in the abdomen, also overlapping the tumour to the left side. At the same time, I could insert my hand between the two, separating them down to the pubes. I could also move the one tumour distinctly without in any way moving the other. Upon applying the stethoscope, I could detect fetal heart-sounds in both tumours. At this stage, I was firmly convinced that I had to do with a case of double uterus, each division containing a fœtus.

My patient was a very intelligent person of her class, anxious about her condition, and wished distinctly to know what was wrong with her, for that there was something unusual she was firmly convinced. The case seemed so uncommon, that I declined to say anything concerning it until I had consulted with some of my neighbouring medical friends. Unfortunately, I never had any opportunity of doing so, owing to her labour coming on rather suddenly two days after my visit, and before I had an opportunity of consulting with any of my brethren.

I was called again on the 27th December, at 7 P.M., found the os fully dilated, the head presenting in the first position; and in a very short period she was delivered of a healthy female infant, which weighed a little over six pounds. The pains continued, and a breech presented, and in time we had another female child, this time weighing rather less than six pounds; in ten minutes, with a little assistance, the double placenta came away, and the newly emptied cavity contracted well.

There was now the well contracted womb in the lower part of the abdomen, to the right side; but there still remained the other tumour, which lay to the left, and rather behind the lately emptied cavity. It gradually assumed a middle position in the abdomen, and inclined to fall forward and overlap the contracted womb; however, I applied a binder in the usual way, and, with the exception of an occasional after-pain, she felt very comfortable.

After waiting about four hours, and there being no appearance of any action in the remaining tumour, I left, after giving the nurse instructions as to her duty if there should be any symptoms of labour in my absence.

In two hours after I left her, and six hours after the removal of the placenta, she again complained of pains, and I was again sent for. On my arrival, I found the head of the third child at the perinæum. This was also a female, but a much stronger child than any of its predecessors, weighing over seven pounds; the combined weight of all the three being over twenty pounds.

After the separation of the placenta, the tumours were now about equal in size, and quite distinct the one from the other, neither of the two occupying a middle position, but each taking its own side.

I examined my patient lately, and I found that the external os was single, the opening very much elongated from side to side; but, upon tilting it forward, the dividing septum was distinctly seen. I also introduced an uterine sound into each cavity. The septum could also be felt by the introduction of the finger.

This case may only be interesting in an anatomical point of view, as there was little skill or dexterity in manipulation required during the confinement; but, as such cases are rare, I concluded that the case would not be altogether void of interest to the members of the Association.

SYMPATHETIC OPTHALMIA: A HISTORICAL CORRECTION.

By J. VOSE SOLOMON, F.R.C.S., Birmingham.

MR. CARTER, in his recently published work on *Eye-Diseases*, in treating of the channel through which sympathetic irritation is conveyed, makes the following statement in reference to myself.

"Mr. Vose Solomon accuses the optic nerve, but only on the ground that, in a single instance, sympathetic ophthalmia followed enucleation of the eye in a patient of his own, whose optic nerve, on account of some imperfection in the scissors employed, was bruised at the place of division, instead of being cut."

My reply to these statements is, that not only such case has never occurred in my own practice, but, so far from its being considered by me that the optic nerve is the channel through which irritation is primarily conveyed, I contributed in February 1863 to the *Dublin Quarterly Journal*, page 58, a short article and illustrative case to prove that such hypothesis was untenable. (*Idem* also Braithwaite's *Retrospect*, vol. ii, 1864, p. 275.) The following is an epitome of the case with remarks: the latter are unabridged.

A man, aged 36, lost his left eye from a burn. In two months, sympathetic irritation affected the right. The left was excised, with great relief to the symptoms in the best eye. A bridle having formed between the lid and conjunctiva of the empty orbit, a glass mask was inserted, with the effect of reproducing the same train of symptoms as existed in the right before excision was performed. A retrocession of the sympathetic disturbance followed the removal of the mask, but, on its reinsertion, the symptoms returned with the addition of *photopsys*.

"English authors on ophthalmology have hitherto attributed the occurrence of sympathetic traumatic ophthalmia to the (existence of the) commissural arrangement of the optic nerve-fibres. The phenomena presented by the preceding case do not appear to afford a *locus standi* for such theory, inasmuch as the optic nerve on the side of irritation had been severed; but they may be satisfactorily explained, on the supposition that the irritation from the eyelid orbit was conveyed by the ophthalmic division of the fifth pair to the centre, and thence reflected to the opposite side. This view derives support from examples of reflex traumatic disorder, wherein the symptoms are those purely of hyperæsthesia of the fifth, and which yield almost *instantaneously* on removal of the original source of irritation; of this class of cases, some account is given in a paper of mine in the *BRITISH MEDICAL JOURNAL* for June 13th, 1857.

"Careful observation of a large number of instances of reflex ophthalmia has led me to the following, among other conclusions: that the primary traumatic irritation is conveyed to the sound eye through (sensory) branches of the fifth nerve; that soon afterwards, and sometimes simultaneously, the vaso-motor nerves (trophic) take on disordered action, and, as a consequence, intraocular congestions and their results occur; that if the disease be not arrested, the optic nerve-fibres become inflamed, or affected with such changes as induce atrophy, and which lead to similar degeneration of the opposite nerve. In this stage of the complaint, the commissural arrangement of the optic nerve-fibres is probably the channel through which the disorder is conveyed. Where there is an advanced amaurosis (of the eye affected sympathetically), the usual signs of atrophy of the optic nerve are revealed."

Since writing the above, my attention has been drawn to a valuable and carefully written article on this subject in the *British and Foreign Medical Review* for January 1868, in which my case and physiological views are adduced, as supporting the opinion that the vaso-motor nerves are the channel of communication; and if reference be made to the dates of publication of the author's works, which the reviewer has ably analysed, it will be found that my views, which were formed quite independently, possess priority of publication.

A NEW METHOD OF PERFORMING PLASTIC OPERATIONS.

By J. R. WOLFE, M.D., F.R.C.S. Ed.,

Surgeon to the Glasgow Ophthalmic Institution; Lecturer on Ophthalmic Surgery in Anderson's University.

IT is now nearly three hundred years since Tagliacozzi published his great work on *Plastic Operations*; and, notwithstanding the admiration which the work of the Bologna professor had elicited, it is remarkable how comparatively little has since been done for the cultivation of plastic surgery. The reasons are obvious. The fact is that, in operations on the nose, eyelids, and face—the most interesting regions for improving deformities—Tagliacozzi's method of taking flaps from the arm has been generally abandoned, on account of the extreme discomfort which it involves; and the practice of taking flaps from the forehead or face having been the only one in vogue, the procedure came to be considered more serious. In addition, when we take into account the elements of failure, from shrinking of the flap, from crupiselas or gangrene, it is not to be wondered at that surgeons are generally chary of resorting to the expedient, except in great emergencies. It amounts to this: we are to cut skin off the face to repair the face; and, in doing so, we run great risk of failure. To render plastic operations on the face more acceptable, and to bring them within a wider scope of utility, the following conditions must be fulfilled. 1. We must take a flap from the arm, or from any other part but the face. 2. We must seek to eliminate the elements of failure. I propose, in this short communication, to indicate the means of fulfilling both these conditions.

First, Tagliacozzi laid down the rule, which has ever since been considered as the primary law, and *sine quâ non* to the success of the operation, that the flap must retain its connection to the adjacent living structure by a pedicle which is to be severed only after complete union and cicatrization of the raw surfaces. This pedicle has, in my opinion, been a source of great embarrassment to surgeons, and tended rather to retard the progress of plastic surgery. From my observations on transplantation of structures from the lower animals and on skin-grafting, as well as on plastic operations, I have long held it demonstrated, that in most cases the pedicle is not essential, if indeed it do contribute anything, to the vitality of flap. This being once established, we are henceforward free to choose our bit of skin from any part of the body we may find suitable.

My next endeavour has been to eliminate the elements of failure. The principal cause of failure I find to be in the subcutaneous structures. If we wish a skin-flap to adhere to a new surface by first intention or agglutination, we must be sure that it is cleared of all areolar tissue, and properly fixed in its new place. The following case will illustrate the points referred to.

Formation of the Lower Eyelid with Skin from the Forearm.—P. C., aged 25, a quarrier, was admitted into the Glasgow Ophthalmic Institution, with his face, eyes, and eyelids injured by an explosion of powder. I showed the man recently to the Edinburgh meeting of the Association, as an instance of conjunctival transplantation from the rabbit.* The right upper eyelid, which was strongly everted, I partially succeeded in correcting by skin-grafting. The lower right eyelid being completely everted, its integument totally destroyed, and the skin of the face consisting of discoloured cicatrices not by any means suitable for plastic operations, I formed a new lower eyelid in the following manner. The edges of the upper and lower eyelids having been vivified, I introduced three ligatures into the border of the lower eyelid, which I entrusted to my assistant. By means of these ligatures, he used traction, whilst I dissected the whole of the cicatricial tissue, and thus liberated the subjacent structure. The ligatures were then introduced into the upper eyelid, and the edges of the upper and lower eyelids were thus united. I then elevated the edges of the wound, preparing them to receive the

* This patient had to undergo several operations before his eyes were rendered serviceable and his face presentable. Left eye: 1. Artificial pupil; 2. Conjunctival transplantation from rabbit. Right eye: 1. Paracentesis for onyx and hypopyon; 2. Skin-grafting on upper eyelid; 3. Plastic operation on lower eyelid. All these operations were done without chloroform.

new flap like a watch-glass. The skin required for the formation of this eyelid was two inches in length and one inch in breadth, which I took from the forearm. To test the principles above indicated, I divided my flap into three portions. The first I removed, along with the cellular tissue, as close to the dermis as compatible with the integrity of the flap. The other two portions, after removing them from the forearm, I turned up; and with a cataract-knife I sliced off the areolar tissue, leaving a white surface, which I applied to the eyelid. The difference between these flaps was very remarkable. The two flaps, which were previously prepared, healed by agglutination, without exhibiting even the slightest tendency to desquamation of the cuticle. Twenty-four hours after the operation, the surfaces looked pale; but the next day the temperature was normal, and appearance healthy; whilst that part which was applied without previous preparation looked rather livid the first day, improved the next two days; the fourth day, it began slightly to suppurate; and, after a hard struggle for life, a portion of it only remained, while the rest shrank. This, however, will not compromise the result of the operation, which may be considered satisfactory.

The dressing consisted of gutta-percha tissue applied next to the skin, a graduated lint-compress, and a bandage to maintain immobility of both eyes. The union was so rapid and so perfect, that I separated the upper from the lower eyelid on the fourth day.

This figure was taken eight days after the operation, when union was complete. The thicker upper dotted line represents the elevated dissected edge, and the thinner lower dotted line shows the point of insertion of the new skin. The vertical lines mark the division of the flap. The two outer and larger portions have been prepared before application; while the smaller, placed at the inner canthus, has been applied without previous preparation.

In conclusion, I would recommend this method to the profession, from its simplicity and safety, for trial, not only in similar cases, but also for the cure of congenital blotches on the skin of the face, which are not amenable to any other treatment.

CASE OF MENINGEAL APOPLEXY.*

By GEORGE F. HODGSON, M.R.C.S.Eng., Brighton.

ON the 19th of last March, about mid-day, I was asked to see a widow, aged 42, a cook in a private family, who had then been suffering for about two hours with severe pain in the back of her head and neck, which she declared "must drive her mad if it could not be relieved soon". This was considered by her mistress and myself an exaggerated expression, as the woman was known to be of a very irritable temper, and also of a highly nervous temperament, especially since the death of her husband, which took place suddenly (twenty years previously) whilst in bed by her side. In the condition of her tongue, pulse, etc., no departure from health was present to offer a clue to the nature of the severe pain; but as it transpired that she had, twice in her life, been laid up with rheumatic fever, and that on the day previously she had been out for two hours in the piercing north-east wind, the attack was apprehended to be rheumatic; and accordingly I prescribed a potash saline draught every four hours, together with five grains of chlorhydrate, and seven grains of bromide of ammonium.

Next day (March 20th), I was informed that, within two hours of my having seen her yesterday, and before the first dose of the medicine, she had become "stupid", and had been more or less so ever since. The word "stupid" was not altogether inapplicable, although evidently her state was one for which she was not responsible, unless she had been "drinking"; but there was no history of such a habit. She still complained of the pain; answered questions, and put out her tongue reluctantly. She had taken her medicine; had had some sleep; and had taken both milk and gruel, though not without much persuasion. In

other respects, she was much as on the previous day. She was ordered to go on with the medicine.

On the 21st, she was rather worse. She was sick once last evening. The bowels had been moved each day. The urine was clear, and not albuminous. Pulse 80, firm and full. The heart's impulse was rather strong; an aortic *bruit* was heard with the systole. The tongue was becoming furred and dry. Temperature 101 deg. She was still in a semi-stupid state; but complained of the pain in the back of her head. She could put out her tongue, but seemed obstinate and intractable about taking her food and medicines. The catamenia occurred a fortnight ago. An empty bottle was found in one of her drawers, labelled and smelling of "paregoric". Her medicine was stopped. On the 22nd, she seemed more ill; pulse 90, bounding. Temperature, 104 deg.; tongue white. She passed urine, and her bowels were moved. She complained less of the pain; and the stupidity was not so great, although she was still very "queer". On her mistress pressing me for an opinion, I replied that I could only guess that she was suffering from rheumatism of the membranes of the brain, or possibly from typhoid fever; and from this vagueness on my part, especially as to the issue of the case, her mistress decided on moving her into the Sussex County Hospital. On one of the other maids asking her where she kept her clean night-gowns, she replied she would get one herself, and therewith got out of bed, went to her drawers, and took one out.

On March 23rd (at the Hospital), she became violent, and was restrained by a strait waistcoat. Her physician did not venture on a diagnosis; and prescribed simple saline draughts. Subsequently, hemiplegia (left) occurred of the arm and leg; the cranial nerves were not involved; and, on the 27th, death ensued.

A necropsy was made the next day, of which the following notes are all that I have been able to obtain, viz.: "Brain remarkably congested throughout. The subarachnoid space round the medulla oblongata (especially on the right side) filled with recent clot of bright coloured blood, probably about an ounce and a half in bulk. Arteries extensively atheromatous. Heart much hypertrophied; valves healthy; commencement of the aorta much dilated and roughened by atheroma."

I presume that the hæmorrhage occurred on the first seizure of the illness on the 19th; but the case, both at its onset and in its subsequent course, illustrates the excessive difficulty there is sometimes in diagnosing apoplexy. This has been my chief object in recording the case.

CASES OF PALPITATION OF THE HEART DUE TO EPILEPSY, WITH REMARKS.

By WM. L. LANE, M.B., etc., Crossgates, Dunfermline.

THE following cases, which I shall describe in a summary manner, are somewhat interesting in showing how palpitation of the heart may be due to a cause hitherto unobserved, viz., epilepsy.

CASE I. Michael B., aged 42, a strong healthy man in appearance, has been complaining for the last three years of a constant pain at the cardiac region, which is not increased by pressure, and is accompanied by a strong impulse of the heart. This pain and beating, which are never entirely absent, get more severe upon any excitement or exertion. The pulse is 78 a minute, and strong. The heart has no valvular lesion nor any hypertrophy, although its impulse is stronger than normal. Lately, that is, within the last eighteen months, he has had some attacks of epileptic vertigo and two or three severe fits of epilepsy (*grand mal*). He describes the attacks of epileptic vertigo, or, as he terms them, attacks of "giddiness", thus: the beating of the heart and the pain over it, which are worse than usual for a day or two before the attack of giddiness, suddenly, a few seconds before the attack, become much worse; he then fixes his eyes upon a spot from which he cannot move, loses his senses, staggers, or falls down, and then immediately recovers consciousness (the attack altogether does not last longer than a quarter or half a minute), feeling his head sore and his memory confused. The beating and the pain, which I stated as being more troublesome some time previously to the attack, continue so for some hours after it.

CASE II. Wm. B., aged 31, is a healthy strong man; his aunt was epileptic at one time; her son (his cousin) is a great epileptic. Wm. B.'s father was insane at one time. Wm. B. has never had any fits. He complains of an uneasy pain in the cardiac region and a strong beating of his heart. He feels very anxious about his condition. I examined his heart with the utmost care, and found it healthy in every respect. There is no tenderness upon pressure over the cardiac region, but the cardiac impulse is stronger than normal. The pulse is strong, and 72 a minute. Respiration is normal. His appetite is good. His

* Read at the East Sussex District Meeting at Lewes,

bowels are open regularly. The pain and cardiac beating are worse at times, and are aggravated by mental excitement or bodily exertion.

CASE III. Mrs. D., aged 50, who has a strong and healthy appearance, has been suffering from a beating of the heart and a pain at the cardiac region for the last twelve months. The heart's sounds and size are normal, but its impulse is stronger than normal. A few days ago, while she was at the railway station here, apparently in excellent health, she had a fit and fell upon the ground. Her face was severely hurt by her fall. She states that lately she has a few attacks of dizziness (most probably epileptic vertigo), which pass away very quickly. Her appetite is excellent; her bowels are regular. She has ceased menstruating since she was forty-seven years old.

REMARKS.—The predominant symptoms in these cases are the cardiac pain and the strong cardiac impulse, and the feelings of anxiety which these symptoms cause the patients. I may say that they have consulted various medical men in this district and Edinburgh for their palpitation without any benefit. Cases of this kind, which are by no means uncommon, differ from cases of palpitation which we usually meet in many respects. 1. The heart's action is not accelerated, nor is it irregular. 2. The causes which produce palpitation, such as anemia, indigestion, excessive smoking, alcoholic or tea drinking, could not be discovered in these. 3. The cases occur in individuals strongly predisposed to or suffering from epilepsy. I have often thought that the name "mild angina pectoris" would be a very appropriate one for cases like these, on account of the symptoms somewhat resembling angina pectoris, but being a great deal less severe. I may say that cases of this kind are generally unbenefited by any of the remedies, such as bromide of potassium, belladonna, etc., that I have used or seen others use.

OBSTETRIC MEMORANDA.

NOTE ON PUERPERAL FEVER.

PUERPERAL peritonitis does not often come under my observation, but in the year 1873 two cases occurred in my practice. I made notes of them at the time; and, as bearing on the question of contagion, the cases seem worthy of a brief record.

I was requested to see, in consultation with her medical attendant, Mrs. F., on the day week of her delivery of her sixth child. Four days previous to our visit, she had a shivering fit, which was quickly followed by the usual symptoms of peritonitis. She died on the day following our visit. Fifteen days after the death of this patient, I was requested to visit Mrs. B. She had been confined three days before of her second child, and went on well until the day before I saw her, when she had an attack of shivering. The patient, when seen, was suffering great agony from abdominal pain. She died on the day following. Both these women were patients of the gentleman referred to. The one who died first was delivered by him; but, although he visited the other, no examination was made by him, and the woman was delivered by his assistant.

It might be supposed that the precautions taken were sufficient to prevent the action of contagion in the second of these unfortunate cases; yet it is impossible to avoid the conclusion that both deaths were in some way due to the same cause—namely, contagion conveyed by the medical attendant or his assistant. Whether these gentlemen had any recent experience of puerperal fever previously to the occurrence of the first case, I am not aware.

ARTHUR LEARED, M.D., F.R.C.P.

CASE OF PUERPERAL FEVER CAUSED BY EXPOSURE TO THE CONTAGION OF ERYSIPELAS.

THE numbers of the JOURNAL containing a report of the Obstetrical Society's interesting debate on puerperal fever have just reached me. In connection with that discussion, the following case, which occurred in my practice only a few weeks ago, may perhaps appear worthy of publication.

During the last two months there have been three cases of erysipelas in this generally healthy village. In two of these cases, the head and face were attacked; in the third, it commenced round a fistulous opening in the abdominal wall. One of these patients, who had a rather severe attack of erysipelas of the head, followed by abscesses below each eye, and a large one in the right forearm, was attended throughout her illness by her daughter, a Mrs. V., the wife of a farmer living about twelve miles from this village. On June 22nd, Mrs. V. returned home, having stayed with her mother, now convalescent, exactly a

month. Mrs. V. was at this time four months pregnant; she was about thirty years of age, had been married seven years, had one child, and thought she had a miscarriage at the second month about a year ago. On June 25th, without any apparent cause, she had a miscarriage, and remained in bed. On the evening of the 26th, she had rigors and complained of great pain and tenderness at the hypogastrium. Next day, she was much worse; I was sent for, and found all the symptoms of peritonitis. I carefully examined the uterus for any pieces of membrane or clots, but found nothing. I was again summoned on the 29th, and found her sinking fast; she died on the morning of the 30th. Mr. V.'s sheep-farm is healthily situated in one of the healthiest districts in this colony. There had been no sickness on the farm previously, and I have heard of no case of puerperal fever occurring within a hundred miles of this for months. When I saw Mrs. V. on the 27th, I noticed lying in the room some of the clothes she had worn while nursing her mother.

The connection between the erysipelas and the puerperal fever in this case can, I think, scarcely be doubted.

E. KNOX DAVIES, M.R.C.S.Eng.,
Hanover, District of Colesberg, Cape Colony.

ABDOMINAL PRESENTATION.

On May 11th, 1875, at 7.45 A.M., Mrs. W., who had had several children, sent for me to attend her with all expedition; she had been in labour for some hours. The medical man whom she had previously engaged had been sent for at 6 A.M., and, not feeling satisfied with the presentation and progress of the case, was anxious for a second opinion. Upon my arrival, he decided to leave the case in my hands, which responsibility I at once accepted. On vaginal examination, I found what I felt assured was an abdominal presentation. The presentation was considerably low down and perfectly immovable, pressure being exerted in various directions without any success; considerable efforts at dislodgement were made until 11 A.M., the patient's strength in the meanwhile remaining little, if at all, impaired. About this time it was just possible to feel the knees, and the hand could be passed sufficiently high up to seize one leg; the other quickly followed, and the child was delivered as in an ordinary case of turning. Unfortunately, the child was born dead from asphyxia, from pressure upon the cord, but the patient made a rapid recovery, and up to the present has suffered from no ill effects.

Valetta, Malta.

PUERPERAL ECLAMPSIA.

I WAS called in at 6.30 on December 26th to see Mrs. P., a primipara, who had been in labour eight hours. I was told she had had three fits of a very severe character, which quite alarmed her friends. A few minutes after my arrival, she had a convulsion, her face becoming suddenly livid and distorted, directed first to the left shoulder, afterwards to the right; the fit ended in opisthotonos, lasting quite five minutes, followed by a comatose condition. After the fit, I made a vaginal examination, and found the head presenting at the brim normally, and the os well dilated. Without unnecessary haste, I delivered with the long forceps, and forcibly removed the placenta, which was adherent. She still continued to have convulsions of a severe character, and I ordered full doses of bromide of potassium and cannabis Indica, combined with diuretics, as, on inquiry, I elicited that no urine had been passed to the knowledge of anyone present. This fact led me to examine the bladder, but I found it empty. I saw her at 11 A.M.: pulse, 100; temperature, 104. At 4 P.M., I saw her again: pulse, 110. She had some more convulsions, and stronger, remaining longer comatose; the pupils were more dilated. I emptied the bladder of five ounces of highly albuminous urine, specific gravity, 1.028. I ordered ten grains of chloral every two hours. At 5 o'clock, I saw her in conjunction with Mr. Knight. Pulse, 120; temperature, 109. I had the bowels emptied by injections and croton-oil internally. I ordered sinapisms to be applied to the calves of the legs and neck, and the chloral to be continued throughout the night. At 10 P.M., she had had no more convulsions since the first dose of chloral. She was still perfectly unconscious under the influence of the drug, as well as comatose. On the 27th, she was much calmer, but not yet conscious; she passed feces and urine in bed. I saw her several times during the day. The pulse was coming down; temperature lower. There was slight consciousness as the effects of the chloral passed off in the evening. She took beef-tea and milk. Temperature, 100. She recognised her husband and myself for the first time since the convulsions commenced. On the 28th, the pulse was 90; temperature, 98. She was improving rapidly, and had no more

convulsions. The immediate effects of the bromide and cannabis Indica were *nil*. Chloral was a success. This was a very severe attack, with every probability of a fatal issue, judging from the increment of danger in the pulse, coma, and temperature, the latter probably of some interest as being very high. The sinapisms were perhaps of little use; and, as Dr. Robert Barnes has remarked, in his Lumleian lectures on the Treatment of Puerperal Convulsions, it is "a sin against physiology" to cause peripheral irritation when the whole surface is in a state of hyperaesthesia. The improvement in this case was coincident with the restoration of the natural function of the kidneys, and the abatement of the uræmic poisoning.

HARRY D'O. FOOTE, M.D.,
Surgeon to the Rotherham Hospital and Dispensary.

SURGICAL MEMORANDA.

CHANCRE WITHIN THE NOSTRIL, FOLLOWED BY CONSTITUTIONAL SYPHILIS.

MRS. G., aged about 28, was sent to me at the South London Ophthalmic Hospital by Dr. Baxter on April 3rd, 1875, for a lacrymal abscess consequent on some obstruction in the left nostril. She was eight months pregnant. Besides the left lacrymal abscess, there was considerable dusky inflammatory swelling of the skin on the corresponding side of the nose and cheek: the left nostril was completely blocked, and as much of the mucous membrane as was visible presented an unhealthy-looking ulcerated surface, which ended below by an abrupt edge at the junction of the nasal mucous membrane with the skin of the prolabium. She complained of much pain in the nose. The appearance of the ulcer was suggestive of a syphilitic origin, but I did not feel able to decide without more evidence whether, if syphilitic, it was a chancre or a tertiary ulcer. A considerable mass of indolent enlarged lymphatic glands was present in front of the corresponding ear and behind the lower jaw, and they were stated to have appeared since the obstruction in the nose began; as, however, there was some degree of similar enlargement, of several years' standing, on the other side, the diagnostic value of the former mass was diminished. The woman said, that the earliest symptoms had begun shortly before Christmas 1874 with a swelling of the left side of the nose below the position of the abscess, accompanied by obstruction of the nostril, and soon followed by the symptoms of acute lacrymal abscess. No other facts corroborative of the suspicion as to syphilis were obtained at this visit. Iodide of potassium and black wash were prescribed. My questions had, however, roused her suspicion, and the next time I saw her she said that she had some sore places on the genitals, which had been present about six weeks; she would not, however, allow an examination. At this date (7th) Mr. Hutchinson saw her, and considered the sore in the nose to be probably syphilitic, but from the evidence then forthcoming, was unable to decide whether it was primary or not. He advised free cauterisation with nitric acid, as he thought that the sore threatened to become phagedænic. I applied this on the 8th, when she also submitted to an examination of the genitals, and I found on the labia several well-marked condylomata, but no ulceration and no inguinal bubo. There was no rash elsewhere on the skin, and no sore-throat. She was quite clear in her statement that she had noticed nothing amiss with the genitals until six weeks previously, *i. e.*, until about two months after the symptoms began in the nose. The acid acted well, and, on the 10th, the sore in the nose was much healthier; mercury was now begun internally, black wash ordered to the nostril, and calomel to the condylomata; the iodide was discontinued. On the 14th, she was confined, and did not attend again until May 5th, when I learnt that the child (a boy) was healthy-looking at birth, but withered away rapidly and died at nineteen days old, the medical attendant giving her to understand that he considered it to be syphilitic. The sore in the patient's nostril had improved, but she now showed a few papular, shiny, dullish-red spots on the back of her neck. Mercury, which had been discontinued since April 14th, was now resumed. On May 8th, there were numerous similar spots on the fronts of the forearms, insides of the thighs, and on the abdomen, while those on the neck had enlarged; the rash was quite characteristic of secondary syphilis. Under the continued use of the mercurial, the rash rapidly diminished, and had almost entirely disappeared on May 19th. She has continued the mercury, with a few short intermissions, to the present time. She is now quite free from secondary symptoms, the ulcer in the nostril has been quite healed for some weeks, and her health has improved very markedly. The opposite sides of the nostril have adhered together, probably owing to the free use of the nitric acid, its channel is, therefore, still quite blocked, and the lacry-

mal fistula continues to discharge muco-purulent matter; there is, however, no inflammation of the nostril whatever, and she experiences so little inconvenience from the condition of things, that she is not very anxious to undergo any operative treatment. With regard to the probable source of her chancre I could learn nothing of any value. Her husband would not admit to her that he had ever had venereal disease, and the woman herself did not know of any accidental source of contagion.

EDWARD NETTLESHIP, F.R.C.S.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

WESTMINSTER HOSPITAL.

CASE OF PYO-PNEUMOTHORAX.

(Under the care of Dr. FINCHAM.)

[Reported by Dr. DE HAVILLAND HALL, Medical Registrar.]

THE following case of pyo-pneumothorax is interesting, as occurring as a sequel to abscesses following pneumonia. It is also worthy of notice that the invasion symptoms were hardly marked at all, the existence of the pneumothorax being first demonstrated by percussion and auscultation, none of the subjective symptoms of the patient having suggested the idea, and it was not till two days later that he made any great complaint, and then he suffered very much from dyspnoea; but there was an entire absence of the sudden, sharp, agonising pain so often met with in these cases. Great relief followed paracentesis thoracis; but it was only temporary, as, two days later, the dyspnoea was as bad as ever.

James C., aged 24, a carman, was admitted on March 12th, 1875. The patient was a well built powerful man. He had always been a great drinker, but lately he had been drinking more than usual. He was at work on March 7th, and felt tolerably well. After he went to bed, he began to retch and felt feverish. He tried to go to work on the morning of the 8th, but was unable to do so. During the course of the day, he had rigors, frontal headache, short hacking cough, and a pain in the right side.

On the afternoon of his admission, the following note was taken. Temperature, 102.4 deg. (Fahr.); face flushed; pulse, 132, very weak and feeble; heart-sounds clear; respirations, 52. The right side was dull posteriorly to the spine of the scapula, anteriorly to the nipple-line. No breathing-sounds were heard, except a little crepitation at the base. The left lung was normal. He was slightly delirious, talking about his horses. Evening temperature, 103 deg. (Fahr.)—March 13th, 10.30 A.M. He was violently delirious all night, so much so that he had to be tied down. He had two fifteen-grain doses of chloral-hydrate during the night, but without any effect. He was calling out for his horse, and was perspiring freely. His face was flushed, and somewhat livid. He put out his tongue when told to do so. There was not much cough; the sputa were scanty, not rusty. Respirations, 60, panting. The physical signs were as on the previous day. Pulse, 120, of fair volume; temperature, 104.6 deg. (Fahr.) The bowels were relaxed. He was ordered to have thirty grains of chloral-hydrate immediately, and a draught of five grains of carbonate of ammonia in infusion of cinchona every three hours; also wine. At 1 P.M., twenty grains of chloral-hydrate were given; and, at 3 P.M., ten grains. Evening temperature, 101.2 deg. (Fahr.)—March 14th. Temperature, 103 deg. (Fahr.); respirations, 36; pulse, 112, feeble. He was very violent up till 4 P.M. on the 13th. He was quiet, and slept for some hours after that time, and awoke at 3 A.M. rational; he afterwards dosed again. He was ordered four ounces of brandy, four eggs, two pints of milk, the same quantity of beef-tea, and the medicine to be taken every four hours. Evening temperature, 103 deg. (Fahr.)—March 15th. Pulse, 108, of better volume; respirations, 36; temperature, 102.3 deg. (Fahr.) Resonance was somewhat improved in the interscapular region, where there was bronchial breathing, with slight rhonchus. The sputa were scanty, viscid, and slightly rusty. Evening temperature, 102.8 deg. (Fahr.)—March 17th. Pulse, 112, dicrotous; respirations, 40; temperature, 102 deg. (Fahr.) He had a troublesome cough; the sputa were somewhat rusty, viscid; the right chest was resonant down to the angle of the scapula; scanty rales were heard all over the chest. Evening temperature, 102.6 deg. (Fahr.)—March 19th. Pulse, 120, very feeble; respirations, 36. Breathing-sounds were heard all over the lung. In the right infra-axillary region, on coughing, a sound like the twanging of a harp-string was to be

heard.—March 22nd. Pulse, 120; respirations, 36. He had a very urgent attack of dyspnoea during the night. There was good resonance over the right front, and very feeble breathing. Sibilus was heard all over the left front. Morning temperature, 101 deg. (Fahr.); evening temperature, 101.4 deg. (Fahr.)—March 23rd, 11 A.M. Pulse, 116, very feeble; respirations, 44, panting. He had troublesome cough, with mucopurulent expectoration. The right front was more prominent than the left, and moved less. Very distinct metallic tinkling could be heard all over the right front, especially just outside the nipple. Sonoro-sibilant *râles* were heard all over the left front. The heart's impulse was an inch to the outer side of the nipple-line. He was perspiring freely.—1.30 P.M. He was much distressed. There was a metallic splash on succussion. Pulse, 124. The aspirator was used, and ninety ounces of sweet pus were evacuated, together with a considerable amount of air. After aspiration, the pulse was 112, the face improved, and the breathing was easier.—March 24th. Pulse, 116, of better volume; respirations, 48. He had a restless night, being delirious and trying to get out of bed. He said he felt more comfortable this morning. There was resonance over all the right chest, most marked metallic tinkling, and also loud metallic splash on succussion. No air entered. In the left chest, the mucous *râles* were much less marked than on the previous day. The heart's impulse was in the nipple-line. Evening temperature, 99.3 deg. (Fahr.)—March 25th. He had great dyspnoea all night, and was almost moribund at times. Pulse, 112, irregular and very feeble; respirations, 36; temperature, 98.6 deg. (Fahr.) There was great lividity of the face. He was perspiring freely. He lay propped up in bed dosing. He was sensible when spoken to. The hands were cold; there were *râles* in the throat. *Râles* were heard all over the left chest.

He died on March 26th, at noon. The *post mortem* examination was made by the house-physician, Mr. Basham, twenty hours after death. On opening the thorax, a quantity of air escaped with a rush (no disagreeable smell) from the right side. The right lung was completely collapsed, and pushed up to the upper and anterior part of the thorax. There were considerable adhesions to the upper four ribs and their cartilages. The cavity contained two pints and a half of a thin cream-coloured fluid. The lung sank in water. On the posterior and upper part of the lung was a small aperture about the size of a crow-quill, which on section was found to communicate with an abscess in the substance of the lung about the size of a walnut. Four or five other abscesses were also discovered lined with a thin pyogenic membrane, varying in size from a walnut to a pea. On microscopic examination, no hooklets could be discovered. The left lung was emphysematous; there were no adhesions; it was crepitant throughout, and congested, especially posteriorly. There was a large quantity of frothy mucus in the bronchial tubes. The pericardium was fully distended with gas; it contained the normal amount of fluid. All the cavities of the heart were filled with *post mortem* clots and blood. The valves and substance of the heart were healthy. There was nothing particularly noticeable in the other viscera, except that the liver was much depressed and pushed over towards the left side.

ROYAL INFIRMARY, EDINBURGH.

CASE OF RHEUMATIC FEVER, FOLLOWED BY PNEUMONIA, AND TERMINATING IN ULCERATIVE ENDOCARDITIS, MYOCARDITIS, AND PERICARDITIS, WITH EFFUSION.

(Under the care of Dr. GRAINGER STEWART.)

FOR the following notes we are indebted to Dr. A. M. Cash, Resident-Physician.

J. S., aged 25, ironmonger, was admitted into Ward 7, Medical Royal Infirmary, Edinburgh, under the care of Dr. Grainger Stewart, on March 22nd, complaining of dyspnoea, with swelling of the legs and abdomen. He gave the following history. About the middle of December last, he was in the infirmary for a crushed finger, and, before leaving, he got an attack of rheumatic fever, which obliged him to remain under treatment for about two months. He did not seem to have made a good recovery from this; for, three weeks ago, when his present illness began, he was still suffering from its effects. At that time, he said, he got a severe cold, and shortly had a rigor, pain in the left side, cough, and shortness of breath, with a slight dark-coloured expectoration. Soon afterwards, his feet and abdomen began to swell, and the difficulty of breathing increased so that he could not lie down, but had to be propped up in bed. He was readmitted into the infirmary. On admission, the patient was a powerful, well-made young man. His expression was anxious; his face pale, dusky, and covered with a clammy perspiration. He had orthopnoea. The temperature in the axilla was 100.7 deg. (Fahr.) About the mouth were traces of a slight herpetic eruption. Palpation and percussion of the abdomen

revealed considerable ascites. He suffered from pain and uneasiness in the region of the heart. Distinct, though slight, bulging was visible over the præcordia. No apex-beat could be seen or felt. There was an area of absolute dullness over the heart, somewhat square in form, extending downwards from the third rib on the left side for a distance of five inches, and having a transverse diameter in the intermaxillary line of seven inches. Auscultation simply showed the cardiac sounds to be muffled and indistinct. No murmur could be detected. The pulse was full, strong in its impulse, but suddenly collapsing under the finger. It was irregular and somewhat compressible, and about 120 per minute. There was distinct evidence of the pneumonic condition of the base of the left lung. He had frequent paroxysms of a hard dry cough, which gave him great pain and distress. The urine passed was somewhat reduced below the normal daily average amount. It contained a very large amount of amorphous urates, but no albumen. The chlorides were not diminished.

He was treated in the usual way by expectorants, diuretics, stimulants, and counterirritation to the chest by means of mustard and fly-blisters, with the result of slight improvement in his general condition, though the physical signs remained the same. The possibility of paracentesis of the pericardium becoming necessary was kept in view, and I had instructions from Dr. Stewart to resort to this should the dyspnoea become greatly increased.

On the morning of the 26th (the fourth day after admission), after sleeping quietly for a short time, he suddenly awoke in extreme distress from his breathing. The dyspnoea became rapidly worse; he fell back, and, death being imminent, I introduced the finest needle of a Mathieu's aspirator through the fourth left intercostal space close to the sternum, and drew off fourteen ounces of serum containing large flakes of lymph, a little blood, and a considerable quantity of pus. He was much relieved for the time, and was able to sit up and speak. There was now comparative resonance over a good part of the area which was absolutely dull before. The dyspnoea, however, which had never entirely been got rid of, gradually increased, and he sank a few hours later.

NECROPSY (twenty-four hours after death).—The body was well nourished. There were some purpuric spots scattered over the surface, chiefly on the abdomen. On opening the thorax, the pericardium was found to be thickened and very vascular. Its surface was covered with lymph, and in its cavity were contained a few ounces of fluid. The surface of the heart was in a similar condition. Its walls were thin, soft, and friable, and the microscope revealed numerous fine fatty granules amongst the striae of its muscular fibres. The cusps of the mitral valve were thickened. The aortic valve bore evidence of severe suppurative endocarditis. The corpora Arantii were thickened. The segments of the valve were eroded, torn, and ulcerated, and at the base of one of them the septum ventriculorum was expanded into an aneurismal pouch of irregular shape, into which a probe could be passed for the distance of an inch. The valves were utterly incompetent; the lungs were congested, and the left, at the base, was consolidated and hepatised; the liver was "hob-nailed", and weighed 6½ lbs; the kidneys and spleen were congested and enlarged.

REMARKS.—It would seem that the attack of rheumatic fever from which this man had suffered developed certain cardiac lesions, and these, being followed by a pneumonia, brought him into the extremely reduced state he was in on admission. How long he had laboured under effusion into the pericardium we have no means of knowing, as he was away from notice at the time when it probably came on. Its presence, dulling and muffling the heart's sounds, made it impossible to distinguish whether these were pure, or if any murmurs were present. That some endocardial lesion of a serious nature existed was inferred—1. From the fact that the dyspnoea and distress were out of proportion to the amount of effusion, which was not nearly as great as is often seen in cases where the embarrassment to breathing is far less; and 2. From the character and condition of the pulse. This had the peculiar feel met with in a pulse of aortic incompetence and regurgitation. The diseased valves and weak fatty muscular walls fully accounted for the comparatively slightly relieved state of the patient after the tapping; for, though the mechanical impediment of pressure on the heart by the fluid from without (which must have been very great) was removed, still the exhausted organ could not stand longer exertion, and its function quickly failed. I may remark, in conclusion, that this case exhibited strongly the great value of the aspirator when paracentesis of the pericardium is necessary. The shreds of lymph were of great size, and could be spread out to cover a shilling or a florin, and yet they all came away through a capillary tube of the finest calibre. This could only be accomplished by very powerful suction, and the instrument made by Mathieu of Paris is all that can be desired in this respect.

THE GENERAL HOSPITAL, BIRMINGHAM.

A CASE OF CEREBRO-SPINAL MENINGITIS.

(Under the care of Dr. RICKARDS.)

[Reported by Mr. R. H. NORRIS, Clinical Clerk.]

GEORGE BLUNT, aged 14, glass-cutter, was admitted into the hospital, May 20th, 1875. He was much emaciated and could not stand. When placed on his legs, his body and head were arched backwards; when lying down, he could move his legs and arms freely. There was no evidence of mischief in the chest or abdomen; no paralysis of face or tongue, or of the muscles of the eye. He was intelligent, though he sometimes made curious observations. His eyes were bright; the pupils not quite equal; he could distinguish the number of fingers, though he could not read even large type. There was hyperæmia of both optic discs, with numerous patches of exudation. He complained of severe and constant pain in the forehead and back of the neck, and also of pain in the back. He said he had been subject to fits during his illness. From his mother's account, one day, at the end of April last, he felt cold and ill, and vomited several times. In consequence, he went to bed. The following day, pain in the forehead came on, and light affected his eyes. The vomiting continued. On the third day of his illness, he had pain in the back of his neck and in his back, and an eruption appeared in the right leg; the latter fading in a few days. He had two epileptiform fits, each of which lasted about ten minutes. His head became drawn backward, as was his whole body, though in a less degree. The pain in the forehead, back of the neck and back, the vomiting, photophobia, fits, emaciation, retraction of the head and arched condition of the body, continued. The vomiting, which was unaccompanied by any feeling of nausea, and at first constant after taking food, subsequently occurred three or four times in the course of the week, and now came on after every meal. The pain in the head and neck, and the spasm in the muscles of the neck, had been constant. The fits, which at first numbered three or four in the week, were now of almost daily occurrence, sometimes four or five in the day. In them he became livid in the face, swore, and would tear up his shirt. His body was stiff, and arched backwards. He could sometimes answer questions during the fits, but when they were over he did not know what had occurred. They lasted from ten to thirty minutes. Throughout the illness, there had been occasional involuntary micturition. Six months ago he had a blow on his forehead, which caused him to leave off work for three days, and left a scar which seemed non-adherent to the skull.

June 3rd. All the previous symptoms continued, and emaciation increased. He had occasional twitching of the right side of the face, and there was slight loss of expression on the left side. The tongue deviated a little to the left side, and he grasped more firmly with his right than his left hand. The vomiting was constant after food, which he took greedily. It was acid, and contained no sarcinae. He had six fits yesterday. He had slept well till last night. The temperature varied daily from 97 to 99 degs. Fahr. Pulse 80 to 100. Respiration about 22. Urine scanty, acid, non-albuminous, without sugar, of specific gravity from 1025 to 1030; it contained oxalates and phosphates of lime.

June 8th. The threatening paralysis of the left side had disappeared. The twitching of the right cheek remained. He sometimes passed the day without vomiting. He had fish daily, and generally kept it down. The other symptoms were worse. He was becoming weaker.

June 12th. He had frequent vomiting. His mind was clear, but his remarks were peculiar; he was noisy at night. In the fits there was usually opisthotonos, and to day slight trismus.

June 14th. He gradually sank and died.

Mr. F. F. Hopkins of Birmingham, who saw the case on the third day of his illness, states that, in addition to the symptoms described, there was pyrexia with a tendency to delirium, but no jactitation; that for the first ten days the patient seemed in some respects to improve, but subsequently, until his removal to the hospital, he suffered much pain in the course of the cerebro-spinal centre.

Treatment.—Iodide of potassium and bichloride of mercury were given, and seemed to allay the vomiting, but not to improve the head symptoms. Chloral and bromide of potassium were given with good effect to prevent restless nights.

POST MORTEM EXAMINATION twenty-four hours after death.—On removing the skull, no fluid escaped. The convolutions of the brain were very much flattened; the vessels of its surface were very full of blood. There was distinct fluctuation over the ventricles. The brain-substance was of ordinary consistency, but very anæmic. All the ventricles were much dilated, and contained over seven measured ounces of colourless, almost transparent fluid. The septum, fornix, and

surface of the ventricles were softer than usual, had lost their brilliancy, and the lining membrane appeared to have undergone a gelatinous degeneration. This change was most noticeable in the fourth ventricle, where the distension by the fluid was great. There was fluctuation over the spinal sheath, which, when opened, was found to contain over three ounces of fluid similar to that found in the ventricles. The surface of the cord was hyperæmic, its substance anæmic. The ophthalmic veins and veins of Galen were all pervious; the venous sinuses were also pervious and quite empty. The optic tracts seemed much flattened. The viscera of the chest and abdomen were healthy. The right side of the heart was full of fluid blood, the left side empty. The abdominal viscera were also full of blood. The fluid found in the ventricles, and in the subarachnoid space of the brain and cord, contained one third albumen; no sugar. The sediment from it contained granule-globules and granular matter. There was no effused lymph, purulent infiltration, or inflammatory thickening in any part of the brain or cord.

REMARKS.—Dr. Rickards remarked that, while pain in the head, vomiting, epileptiform attacks, disease of the optic discs, emaciation, eruptions, involuntary micturition were symptoms found in many head-affections, the sudden onset of symptoms, pain in the back of the neck, the stiffness of the muscle of the neck, and retraction of the head, were sufficient to separate cerebro-spinal meningitis from hydrocephalus acquisitus, basilar meningitis, and tumour of the brain, diseases to which in its symptoms it was nearly allied. While the disease often rapidly terminated fatally, its chronicity and the absence of jactitation were probably due to the character of the fluid effused, and the absence of purulent infiltration. Microscopical examination of the hardened brain-substance did not reveal any morbid change.

BRADFORD INFIRMARY.

CONTRACTED KIDNEYS: HYPERTROPHY OF LEFT VENTRICLE: CEREBRAL HÆMORRHAGE.

(Under the care of Dr. ALEXANDER.)

MARTHA L., aged 33, married, drawer, was admitted at 11 A.M. on the 26th of January, 1875, with the statement that, whilst at work about an hour before admission, she had suddenly fallen down insensible. On admission, she was a somewhat spare woman, with face more furrowed than was compatible with her years. She was profoundly unconscious; both pupils were strongly contracted and insensible to light; the left pupil, however, was slightly less contracted than the right; the conjunctivæ were injected, and insensible to the touch. The breathing was not stertorous. The pulse was irregular, now above, now below, the normal frequency. There was no response on pinching the arms strongly; and, when raised, they fell heavily; but, on raising the legs, some resistance was met with. Every few minutes, there were slight convulsive movements of the body and limbs. Flipping the breast with the wet corner of a towel was followed, in a minute or two, by restlessness and moaning cries, and gradual dilatation of the left pupil, the right remaining contracted. She made several attempts to vomit before she ejected two or three drachms of brownish "slimy" matter. The cardiac sounds could not be clearly heard, on account of the noisy respiration. At 1 P.M., both pupils were widely dilated and insensible to light, and there was no response on touching the corneæ. The right angle of the mouth opened on expiration, and the right cheek flapped slightly, the left remaining motionless. There was complete loss of sensation and motion in the arms, but she lay with her legs somewhat drawn up, and on pinching her feet the legs were drawn away. She moaned frequently. Pulse 102, regular, and of moderate volume and firmness. There was incontinence of urine, which was very pale, barely acid, and contained about three-eighths of albumen. She was not seen again by the resident medical officer before her death, at 4 P.M., five hours after admission.

The following particulars were obtained after death:

Family History.—Her father was living, aged 60; he had been a "hard drinker", and suffered from "rheumatism" in his legs and feet. Her mother died at the age of forty-eight; the cause of death was unknown. One brother, a soldier, who had been a "heavy drinker", died of apoplexy. "All the family are heavy drinkers."

Personal History.—She had been married fourteen years, and had had six children. She had enjoyed moderate health up to about seven months ago, when she sought medical advice for the first time. She had not drunk more than a daily average of one or two glasses of whiskey. For the last two or three years her appetite had been variable, with occasional vomiting and attacks of frontal headache. There had been occasional nocturnal micturition, and she remarked frequently that she passed a good deal of urine. Latterly, she had slight occasional

attacks of lumbar pain. These symptoms, which were regarded as trivial, and which did not prevent her from following her occupation of spinning, were only elicited on close inquiry. More than seven months ago, when nearly seven months advanced in pregnancy, she had an attack of hemiplegia. The left arm and leg were partially paralysed, the mouth "was drawn to the left side", and her speech was thick and indistinct. She recovered but slowly, till her confinement prematurely five weeks afterwards, when her recovery became much more rapid. The child died anasarctous, aged fourteen weeks, four days after vaccination. For the last nine or ten weeks, her sight had been becoming weaker. She was in good spirits the evening before her death, and ate a very hearty supper of somewhat indigestible materials. She went to work feeling quite well early the following morning; but, between nine and ten o'clock, complained of sickness, and vomited; and with the exclamation, "Oh dear, I'm going to die!", she fell back insensible. She was removed to the infirmary in about an hour.

The diagnosis was hæmorrhage into the pons Varolii. The necropsy was made twenty-two hours after death. On examining the base of the brain, a large black clot of gelatinous consistence was seen entangled among the arteries and nerves about the circle of Willis. The pons Varolii had a flattened appearance, and was soft and boggy to the touch; on removing a thin slice from its inferior surface, the whole of the interior was found to be occupied by a large, soft, black clot, mixed with shreds of cerebral substance; the clot extended into and ploughed up the crura cerebri, and also reached slightly into the fourth ventricle. On making a vertical section of the right corpus striatum, a cyst of the size of a filbert was discovered near its outer surface, containing a dirty yellowish fluid; the substance of the corpus immediately surrounding the cyst had a more granular and less compact appearance than the rest of the corpus striatum. No clot nor any abnormal appearance was discovered in any other part of the brain. The heart seemed larger than normal. There were a few pieces of decolorised clot in the right auricle. The right ventricle was of normal size, and empty. The left ventricle was large, hard, and contracted, and, on section, presented walls about an inch in thickness; it was quite empty; the muscoli papillares were very thick, and the chordæ tendinæ strong. There was no valvular disease. The heart weighed 14½ ounces. The kidneys were small; the surface rough and irregular; the capsules thickened and adherent, removing the kidney-substance when stripped. The cortical substance was much diminished, of greyish colour, and very hard, requiring great pressure before the finger nail could penetrate it. There was a cyst the size of a pea on the surface of the right kidney. The weight of the right kidney was 3¾ ozs., the left 4¼ ozs. The liver was a little enlarged; its surface was smooth, its substance soft and very friable.

REMARKS.—The symptoms suggesting the diagnosis of hæmorrhage into pons Varolii were: 1. The extremely contracted pupils; 2. The profound unconsciousness. The succeeding dilatation appears to have corresponded with the extension of the lesion into the crura cerebri and the implication of the third nerves. It is worthy of notice, that the long-standing kidney-disease had affected the general health so little as to permit her continuing her work up to the day of her death.

REVIEWS AND NOTICES.

I. PAU, THE PYRENEAN WINTER-STATION: HYGIENIC APPRECIATION OF ITS CLIMATE. By the COMMISSION SYNDICATE OF PAU. Translated into English. Pp. 114. 1874.—2. ANSWER TO DR. CHARLES TH. WILLIAMS, F.R.C.P., Physician at Brompton Hospital, London. By Dr. E. CAZENAVE DE LA ROCHE, Physician at Pau and Eaux-Bonnes. Pp. 12. 1875.

PAU has long been a favourite winter resort for invalids, but its advantages lie not so much in the warmth of its climate, as in the still mildness of its air, and in the absence of high winds and sudden changes of temperature, which are often very trying on the shores of the Mediterranean. If to these advantages we add the attractions of the beautiful scenery of the Pyrenees, the excellent roads, and the agreeable society of Pau, there is little chance of its charms being overlooked. Of the pamphlets above named, the first compiled by an association in the town, the second by a resident physician, both seem to be issued with a view to diminish this chance; and their translation into English (which, by the way, is more in words than in idiom) indicates the anxiety of the writers to attract English visitors.

The first pamphlet is chiefly composed of the materials common to all

guide-books; laudatory descriptions of the place, surrounding scenery, and historical associations. The "hygienic appreciations" are contained in a dozen pages, and consist chiefly of quotations from the late Dr. Louis, Dr. Cazenave de la Roche, and Sir A. Taylor. M. Louis passed a few months at Pau on the sad occasion of bringing thither his only son in the last stage of consumption. The melancholy issue of his visit in this case did not prevent him from estimating the benefit to be derived from the still air and soft climate of Pau in cases less advanced, and in those of pulmonary catarrh. M. Cazenave de la Roche and Sir A. Taylor, in more laudatory terms, dwell on the complete exemption of Pau from the mistral, tramontana, and sirocco winds, which are the scourges of the Riviera and of the Italian places of resort; and, although the latter may be more favoured in temperature and sunshine, these writers maintain that Pau is safer and more salutary for invalids. On the other hand, if the doctors of Hyères, Cannes, Nice, Mentone, Rome, etc., were appealed to, they would give a still more favourable verdict on behalf of their respective localities.

From such competing authorities it does seem desirable to look out for an impartial judge, with facts rather than opinions to guide him; and the paper by Dr. Theodore Williams, On the Effects of Warm Climates in Pulmonary Consumption, in the fifty-fifth volume of the *Medico-Chirurgical Transactions*, did appear to be a contribution to this end. Out of 1,000 cases occurring in his father's and his own practice, selected for statistical comparison, he found that 251 had, in addition to other treatment, spent one or more winters at one of the places in question; and, by a numerical comparison of the resulting condition of the patients, whether improved, stationary, or worse, he formed some estimate of the amount of benefit to be derived from a winter's residence in these places respectively. Thus, of 152 patients who wintered in the South of Europe on the borders of the Mediterranean, 62.50 per cent. were improved; 29.39 stationary; and 31.91 worse. Of 70 sent to Madeira, 53.81 per cent. were improved; 14.28 stationary; and 17.10 worse. Of 44 at Pau, 50 per cent. were improved; 4.55 stationary; and 45.45 worse. In other words, half improved, a few remained stationary, and the remainder became worse. This cannot be called a very unfavourable result, although inferior to that of the Mediterranean. The paper of Dr. T. Williams has been translated into French by Dr. Duranty of Marseilles, and seems to have excited much interest in France. It has now drawn forth a reply from Dr. Cazenave de la Roche, which has been widely circulated, and now appears in English in the second pamphlet at the head of this notice. But, instead of opposing Dr. Williams's conclusions by facts and figures, he begins by denouncing altogether the use of the numerical method in medicine. "In my opinion, which is now-a-days the opinion of nearly every one, the application of figures in the practice of medicine, is a method subject to serious mistakes, and which ought to be rejected as anything but philosophical" (p. 4). He then charges Dr. Williams with the grave error of omitting all mention of the form of tuberculosis in his cases; and, assuming that the unfavourable results were due to the disease being of the torpid kind, and therefore not suited to the climate of Pau, he repudiates the accuracy of the conclusions.

Dr. Cazenave's summary condemnation of the use of numbers in medicine will not carry much weight, and is not consistent with the deference which he professes for his eminent countryman Louis, the great champion of the numerical method; who, even in the letters quoted in the first pamphlet as eulogistic of Pau, says, "the only *thérapeutique* which has a right to persuade us, is that derived from well observed and numerous facts".

If Dr. Cazenave's charge were just, that Dr. Williams "does not mention in the least the morbid form which characterises the 251 cases", his objection to the conclusions would be reasonable; but, on referring to Dr. Williams's paper in the *Medico-Chirurgical Transactions*, we find not only the form specified in each case (inflammatory, catarrhal, scrofulous, etc.), but there are separate paragraphs and tables in which the several forms and stages of the disease, and the influence of the different climates on them, are expressly discussed. And when M. Cazenave ascribes the less favourable results at Pau to the wrong cases being sent there, he should bear in mind that the sedative qualities of its climate have long been made known by the writings of Sir James Clark and Sir A. Taylor; and it is not likely that the Drs. Williams, father and son, who have so long made climates for invalids a special study, would have failed to exercise a due discretion in selecting the fittest cases for each locality.

If, instead, Dr. Cazenave de la Roche would bring forward statistical facts from his own experience on the influence of the climate of Pau in consumptive cases, he would furnish the proper materials for a reply to Dr. Williams's numerical conclusions. At present, they remain unanswered; but they only amount to this, that, although many patients do well at Pau, a still larger proportion do well in some other places.

FERNERE MITTHEILUNGEN ÜBER DAS ENDRESULTÄT DER RESEKTIONEN IM KRIEGE 1864 IN DER DÄNISCHEN ARMEE. Von Professor Dr. ADOLPH HANNOVER. Copenhagen: 1875.

IN the first volume of the BRITISH MEDICAL JOURNAL for 1870, at page 61, there appeared a review of some published remarks by Professor HANNOVER of Copenhagen on the final results of the resections of joints which had been performed on Danish soldiers during the war of 1864. These results Dr. Hannover showed to be so unfavourable, that the general conclusion was to condemn resection of joints for gunshot injury in military practice altogether, and to recommend the practice of amputation instead. The strictures of Professor Hannover were shortly afterwards answered in Germany, where they attracted considerable attention, by Surgeon-General Dr. Loeffler, Professor of Military Surgery at Berlin, and the author of the *Medical History of the Danish War of 1864*, and also by Professor von Langenbeck. Dr. Loeffler's reply to Dr. Hannover was noticed at page 551 of the volume of the BRITISH MEDICAL JOURNAL above mentioned. But the dispute did not end with these replies. At the congress of the German Society of Surgery held in Berlin the year before last, Professor von Langenbeck read a paper on the Final Results of Resections of Joints in War, and again disputed the correctness of the statements and conclusions of Dr. Hannover; while Professor Esmarch, at the same congress, stated that the Danish military surgeons had exhibited a decided opposition to the practice of resection during the first Schleswig-Holstein war as well as in later campaigns, and that apparently this prejudice against the operation, and a certain amount of political antipathy, had influenced Dr. Hannover in publishing the strictures which he had done against the resections performed by the German surgeons on the Danes wounded in the war of 1864.

These remarks by Professors von Langenbeck and Esmarch have called forth another reply from Dr. Hannover, which we have now before us, and the title of which is placed at the head of these remarks. Dr. Hannover meets the charges made against him very fully, and we must allow, after reading his pamphlet, that he refutes them most thoroughly. Not long after the discussion at the congress of the German Society of Surgery in 1873, Dr. Hannover mentions, he received a request from Professor Gurlt of Berlin to procure for him copies of the invaliding certificates respecting the Danish soldiers who had been disabled for service, and pensioned, on account of gunshot wounds of joints in which resection had been performed. He asked for these statements, as he was engaged in composing an extensive work on the final results of resections of joints. Dr. Hannover at once, in order to obtain the latest news of the condition of the men for Dr. Gurlt, requested various medical practitioners to furnish him with precise detailed statements of the condition of the limbs of the pensioners who had been subjected to resection, and who were living in their respective neighbourhoods. These were after a time all furnished, and are now printed in the pamphlet before us. The detailed reports thus obtained show the condition of the resected Danish officers and soldiers after a lapse of more than ten years, and include fifteen cases of resection of the shoulder-joint, fifteen of the elbow-joint, one of the knee, and three of the ankle-joint. Certainly these reports, communicated as they are in most instances by civil surgeons living in various parts of Denmark, cannot be regarded as having been furnished otherwise than in good faith and with professional accuracy; and it is impossible to read them without coming to the conclusion that the results of the practice of resection in these instances, to whatever cause it may be attributed, whether to the operation having been performed in unsuitable cases, or to defective after-treatment, have been most unfavourable and unfortunate. Dr. Hannover denies that any prejudice against resection has existed in the minds of Danish surgeons beyond what has naturally followed observation of its results in these cases; and, as to the accusation of political feeling influencing the remarks by himself or other Danish surgeons on the operation, he treats it as an absurdity. He frankly admits that, both in 1848 and in 1864, a natural and strong antipathy prevailed against Germany, but denies that this ever intruded itself into matters of professional practice.

Dr. Hannover accuses Professor Langenbeck of doing him injustice by asserting that he had condemned resection, and had instead advocated conservative treatment, or treatment by amputation, in all cases of gunshot wounds of joints. We must, however, say that the impression made on our own mind, on reading Dr. Hannover's two previous pamphlets on the subject, was the same as appears to have been made on the mind of Baron Langenbeck in this respect; and we could not help feeling at the time that the sweeping condemnation of resection by Professor Hannover was an unwarrantable one, however unfavourable the results of the operation might have been in the instances of the wounded Danes which had come under his notice. We have

now Dr. Hannover's statement that it was not his intention to condemn resection of joints in general, but to limit himself to the assertion that the experience of this operation furnished by the Danish soldiers in whom it had been performed was condemnatory of it. So far, we cannot help agreeing with him.

ERYSIPELAS AND CHILD-BED FEVER. By THOMAS MINOR, M.D. Cincinnati: 1874.

THERE are few subjects of greater interest in medicine than puerperal fever; any addition to our knowledge on this obscure subject will be gladly received by all inquirers into this disease. Dr. Braxton Hicks did good service by taking the investigation of this disease out of the old beaten tract of *type*, and replacing *cause* as the basis of classification; this method has done much to further inquiry. If advance is to be made in our knowledge of this affection, it will be perhaps sooner obtained by carefully investigating its etiology, much of which is at present enwrapped in mystery. A thoughtful study from this point of view we feel convinced will rapidly dissipate any preconceived idea of puerperal fever being a fever *sui generis*. Amongst the many now well known causes, the poisons of erysipelas, scarlatina, and typhus, the aggregation of parturient women, coupled with defective ventilation and drainage, stands chief and foremost. A connection between this disease and erysipelas would seem to have been observed by our "father of medicine" Hippocrates, who, when speaking of an epidemic of puerperal fever, relates that erysipelas of a more or less malignant type existed at the same time. Peauteau revived the idea in 1755, which was further insisted upon by Clarke of London, and still later by Gordon of Scotland (1795). Since then, many authors have endeavoured to show that puerperal fever *par excellence* is erysipelas. Chief amongst the advocates of this theory stands Professor Virchow. It is the form of puerperal fever, or rather the puerperal fever engendered from this virus, that has been so often mistaken for a puerperal fever *sui generis*. That puerperal fever and erysipelas are frequently rife at the same time has been repeatedly shown, as also that the most malignant epidemics of the latter have been accompanied with the most severe of the former. The Report of the Registrar-General for Scotland for the year 1860, called particular attention to the great increase in the number of deaths from erysipelas and from puerperal fever in that year. Partial surveys of this connection between puerperal fever and erysipelas have been from time to time abstracted from the Registrar-General's Reports, but Dr. MINOR's work is the first with which we are acquainted that has given a really comprehensive view of the subject, as the two diseases have sporadically prevailed over a vast area of territory. The idea of making such a vast research arose, he states, from the variance of opinion that seemed to prevail in Cincinnati upon the propriety or non-propriety of attending labours whilst visiting cases of erysipelas. It was undertaken for the purpose of satisfying his own mind upon this moot point. All scientific inquirers must feel that they owe him a debt of gratitude for the amount of valuable information he has obtained; and this essay will come, we feel certain, to be regarded as the standard work on this subject. We strongly recommend its perusal to all those who still hold to puerperal fever *sui generis*, or ignore the contagiousness of erysipelas. For the purpose of carrying out his inquiry, he divided the whole of the United States into four sections: New England States, Middle, Southern, and Western States; carefully noting the climatology, the character of the country, sectional topography, etc., of each individual State that composed these four larger subdivisions.

After a most careful analysis of the whole subject, he comes to the following conclusion: That erysipelas is confined to no particular geographical section, nor subject to any particular climatic influences. The disease is more prevalent amongst men than women: the reverse being the generally received notion. In an admirable table, the mortality from erysipelas and puerperal fever in the different States and Territories, is shown for each month of the year 1870.

In the New England States, the season of greatest mortality was found to be spring, and the month April; of puerperal fever, the same season, but the month May. There were about 3½ millions of inhabitants in this division, and the total number of deaths from erysipelas were 306 and 86 from puerperal fever.

In the Middle States, with a population of nearly 9 millions, the mortality from erysipelas was 811, against 353 from puerperal fever. The season of the greatest mortality was spring in each case, and the month in the former disease April, and in the latter March. The Southern States, containing 8½ millions of people, lost 499 from erysipelas and 450 from puerperal fever. The seasons of greatest mortality was spring in both cases, and the month May in the former, and April in the latter. The Western States, having a population of about

17 millions, had 1,520 deaths from erysipelas and 923 from puerperal fever. In both instances, the season of greatest mortality was spring, and in the former affection March, and in the latter February. There was a grand total of 3,162 fatal cases of erysipelas, and 1,828 of child-bed fever. No general epidemic of either disease prevailed; the bulk of the cases seemed to be sporadic. The month of greatest mortality among men was March, among women April; of puerperal fever March; the latter month had the most deaths from erysipelas. The latitude and longitude of each State are given, with a geographical sketch, a monthly record of temperature, and a quarterly report of the rainfall from two or more points of observation, together with a brief history of the inhabitants. There is also, as it is called, a study of the table, in which the sex and the race of those who died from both these diseases, are given; and, lastly, we have reflections where any facts of particular note are recorded, and the sporadic, endemic, epidemic type of the disease, is discussed. But, to revert back to the general deductions: it is found that the coloured population have a remarkable immunity from erysipelas, only 1 in 39,000 dying from that disease, whereas we have 1 in 10,500 among the native white population. From puerperal fever there is rather an excess of deaths among the coloured women, the proportion being 1 in 12,000 against 1 in 11,500 in native born white women.

The mortality from both affections is very large amongst the Irish and Germans, particularly the latter, from puerperal fever; from which fact Dr. Minor concludes that these races bring with them an hereditary predisposition for the disease, as not only is the mortality great among immigrants, but even among their descendants.

The immunity of the blacks from erysipelas he attempts to explain on a similar hypothesis, and believes that a mean average of temperature of 70 degs. and upwards acquires a diathesis inimical to erysipelas.

The effects of altitude on the two diseases is carefully considered, and the author concludes, 1. That it rather favours the development of any erysipelatos tendency that may exist; and, 2. That it tends to diminish the tendency towards puerperal fever. A high altitude seems very favourable to scarlet fever; in one State, with an altitude of 4,500 feet, one quarter of the deaths were from that disease.

Both diseases prevail whether the season be wet or dry. Again, the ages of those dying from erysipelas are given, showing that persons at the extremes of age are the most liable to be victims of the disease. The maximum mortality from puerperal fever occurs at the age twenty to twenty-five.

In conclusion, he gives an inquiry into the connection between puerperal fever and erysipelas, as viewed from an epidemic that lately attacked Cincinnati.

He comes to the following conclusions, from a thoughtful study of the whole subject. 1. Erysipelas and puerperal fever seem to prevail together throughout all the States. 2. Any marked increase in one locality of one disease seems to be accompanied by a corresponding increase of the other. 3. Where histories of great epidemics of either disease are obtainable from any of the States, the seeming connection of the two diseases was noticed by the physicians at the time of the epidemics. 4. For these reasons, we are justified in concluding that an intimate connection exists between the two diseases; and, in fact, in any place where erysipelas is found, there will be found puerperal fever.

We are sorry we cannot make longer abstracts of the work; but the whole is so worthy of thoughtful and careful study, that to make a really faithful abridgment is impossible. Those interested in the subject will find ample material for reflection, and its perusal will repay them the trouble. The superior claims of erysipelas in connection with epidemic puerperal fever are ably, and we think conclusively, argued. At this particular period, when there seem to be some doubts about the infectiousness of erysipelas, the perusal of that portion treating of the epidemics of puerperal fever in Cincinnati can be strongly commended to the notice of doubters or disbelievers. Although not agreeing with all the views enunciated in this thesis, we can candidly say few works on the subject have given us greater pleasure in reading, or display more honest conscientious work. *Facta non verba* would appear to have been the author's principle, and he has ably carried it out.

A DESCRIPTION OF THE HUMAN BODY; ITS STRUCTURE AND FUNCTIONS. Illustrated by 11 Physiological Diagrams, containing 240 Coloured Figures. By JOHN MARSHALL, F.R.S., F.R.C.S. Third edition, enlarged. London: Smith, Elder and Co. 1875.

THE above work is a reduction of the author's well-known life-sized diagrams of the human figure, which were originally prepared at the request of the Department of Science and Art. For the convenience

of pupils and teachers, and the public generally, for all whom the work is well adapted, a smaller edition was prepared; and the success of this reduced copy is apparent in the fact that the third edition is now before us. The diagrams in the new edition are all carefully coloured, and drawn minutely to scale, and the volume is a portable and convenient one for study and reference. The plates have all been redrawn, and the illustrations are in accordance with the latest scientific discoveries. They have also the rare merit of combining strict scientific accuracy of detail with artistic beauty. The combination forms an excellent, clear, and complete presentment of human anatomy, valuable alike both to the artist, the medical student, and the teacher; whilst the price is such as will bring the work within reach of a large class.

NOTES ON THE TREATMENT OF SKIN-DISEASES. By ROBERT LIVEING, A.M. and M.D. Cantab., F.R.C.P. Lond., Physician to the Middlesex Hospital in charge of the Cutaneous Department. Pp. 116. London: Longmans, Green and Co., 1875.

THE third edition of this handy little volume will be welcome to many, dealing as it does specially with the practical treatment of skin-diseases. It has been thoroughly revised and somewhat enlarged, the character of the book remaining unchanged.

The chapter on eczema is especially worthy of notice, as giving a full and clear account of the treatment of that disease in all its forms and phases.

Speaking of *tinea decalvans*, the writer points out that it is an error to believe in the existence of a disease "*tinea decalvans* as distinct, on the one hand, from alopecia areata, and, on the other, from *tinea tonsurans*". He further remarks, that the mistake has probably arisen from the fact that *tinea tonsurans* sometimes produces perfectly smooth patches, exactly like alopecia areata; and, further, that common ring-worm and area occasionally occur together.

The chapter on the morbid anatomy of the skin, and the accounts of xanthoma, lichen planus, pityriasis rubra, and epithelioma, have been introduced into this edition for the first time.

The fact of the work having so soon reached a third edition is sufficient guarantee of its merit. We can safely recommend it as a most instructive pocket companion for senior students and junior practitioners. It supplies a want that is often experienced. The *formule* at the end will prove of much service to every one who is called upon to prescribe for skin-diseases.

SELECTIONS FROM JOURNALS.

THERAPEUTICS.

TREATMENT OF HYSTERIA BY CHLORIDE OF GOLD AND SODIUM.—Dr. Martini, in the *Pabellon Medico*, vaunts the efficacy of this drug in the hysteria symptomatic of functional changes in the uterus and its appendages. He says that it is indicated in congestions and obstructions of the neck or of the body of the uterus, in doses of from one-fifth to nine-tenths of a grain. In five cases of congenital atrophy of the neck of the uterus, causing sterility, the use of chloride of gold and sodium produced excellent effects; the neck of the uterus acquired size as well as consistence; and in three cases the treatment was followed by pregnancy. According to Dr. Martini, chloride of gold and sodium has an elective action on the nutrition of the uterus; and it may be employed with advantage for the prevention of abortion and premature delivery, when these accidents are dependent on weakness alone of the womb. This drug should be given in pills only, on account of its disagreeable flavour. Dr. Martini gives a formula for pills, in which it is associated with the extract of dulcamara, in the proportion of one *gramme* of the extract to one *centigramme* of salt.

GELSEMINUM SEMPERVIRENS AS AN ANTINEURALGIC.—In the *Centralblatt für die Medicinischen Wissenschaften* for July 10th, Dr. A. Jurasz of Heidelberg has a contribution on the therapeutic action of gelseminum sempervirens. After some introductory remarks on the drug and its preparations, he gives a brief record of five cases of neuralgia in which he used it with success. In the first case, a strong man aged 30 had suffered for some weeks from neuralgia of the first division of the fifth nerve, which was only temporarily relieved by the internal use of quinine and the external use of veratria ointment. All other treatment being omitted, tincture of gelseminum was given in five-drop doses three times a day; and the patient was quite cured in three days.

In a second case, a sempstress aged 30 had had partial neuralgia for more than a year and a half. It had been treated by spirituous applications, also by liniments, and by iodide of potassium internally, with only transient benefit. The patient was cured in six days by the tincture of gelseminum, given in four-drop doses three times a day. In a third case, the patient was a man aged 64, who had for some days had severe neuralgia of the left supraorbital nerve. A cure was produced in four days by the use of ten drops of the tincture three times daily. The fourth patient was a healthy woman aged 38, with neuralgia of the first and second divisions of the fifth nerve on both sides. The affection had lasted eight weeks, and was becoming more intense. Perfect recovery followed the use of five drops of the tincture daily for two days. In the fifth case, a strong man aged 60 was confined to bed by severe sciatica on the right side. On the eighth day, various remedies having been tried in vain, all other treatment was omitted, and the tincture of gelseminum was given in doses of eight drops three times a day. In fifteen days, the pain had nearly left him, and he was able to walk with a stick. Recovery was quickened by the use of the constant electric current and warm baths. Dr. Jurasz has also given gelseminum without result in a case of hemicrania of long duration, and in two cases of muscular rheumatism. He has not been able to observe any special effect to be produced on the organism by the gelseminum.

THERAPEUTIC USES OF SALICYLIC ACID.—The *Wiener Medizinische Wochenschrift* for April 10th gives a summary of the observations made on the physiological and therapeutic properties of salicylic acid, including those of Professors Kolbe and Thiersch, which were noticed at page 25 of this JOURNAL for February 20th. Professor Wunderlich gives salicylic acid in an almond emulsion with syrup of almonds and orange-flower water, by which its taste is completely concealed. After ten minutes' immersion in a bath of about 69 gallons of water at 102.75, in which nearly 9 ounces of salicylic acid had been dissolved, Kolbe could find no trace of the acid in the urine. W. Wagner has used salicylic acid externally in cases of contused wound and recent burns, by strewing a thin layer over the surface, and covering it with cotton-wadding. The healing process appeared to be accelerated. He has found an ointment (salicylic acid 1.5 parts, dissolved in 3 parts of spirit of wine, and rubbed with 15 parts of hog's lard) very useful in atonic ulcers of the foot, and especially in obstinate eczema of the face and head. He also praises a salicylic acid mouth-wash and gargle in cases of ulcerated gum, in sore-throat with abscess, in various forms of stomatitis, and in diphtheria. In the last named disease, Wagner treats children who cannot gargle with a solution of 0.15 to 0.3 gramme of salicylic acid in water every two hours; for other children, he uses a gargle of salicylic acid 1.5, spirit of wine 15, distilled water 150. If small crystals fall down, the solution must be warmed before being used. Wagner has treated fifteen cases of diphtheria with salicylic acid, with very encouraging results even when the trachea was affected. None of the cases died. He also used salicylic acid internally with benefit in a case of cancer of the pylorus attended with frequent vomiting of masses of readily fermenting matter—the acid having in this case more effect than creasote; and in a case of chronic gastric catarrh with foetid eructation and in two cases of violent diarrhoea with much decomposition of the contents of the intestines. Wagner has observed that the medicine is well borne, and that a portion is passed unchanged with the stools; also that it soon passes into the urine, in which it can be found at the end of two hours (giving a dark violet colour with solution of salts of iron). Dr. Langfeldt relates a severe case of diphtheria of the larynx in a girl aged two years, in which the obstruction of the larynx, which threatened life, was overcome by salicylic acid. The child, however, died of suffocation in consequence of obstruction of the larynx by the membranes that were coughed up from the bronchial tubes. Dr. Forthelm (*Memorabilien*, vol. xix) has treated thirty-one cases of diphtheria with salicylic acid, without one death. The duration of treatment in the most severe cases was eight days; in the slighter cases, two to four days. None of the cases were attended with diphtheritic nephritis (albuminuria); in one, there was paralysis of the soft palate. In the severe cases, Dr. Forthelm applied to the diphtheritic membrane every three hours a sponge dipped in a solution of salicylic acid, giving at the same intervals a teaspoonful of the solution internally. The solution consisted of salicylic acid 2 parts, spirit of wine 9.1 parts, distilled water 200 parts.—E. Stephanides writes in the *Wiener Medizin. Presse* (No. 14, 1875) on the use of salicylic acid in dysentery and chronic diarrhoea. Dysentery has been very prevalent during the winter, as a result of overcrowding, in the Lower Austria Lunatic Asylum, of which Dr. Stephanides is one of the medical officers; it has caused four or five deaths each month. He appears to have given the acid in two cases, one of dysentery and the other of diarrhoea, both internally and in the form of enema, with marked good

effect—all other treatment having failed.—Dr. Paul Fürbringer, assistant in the medical clinic at Heidelberg, describes in the *Centralblatt für die Med. Wissensch.* (No. 18) the results of some experiments on the action of salicylic acid given internally and subcutaneously. In sixteen experiments (ten on rabbits, six on men), the administration of 0.1 gramme of salicylic acid to rabbits, and of 0.25 to 0.5 gramme to men, did not produce any change of the variations of temperature that had been carefully noted for some days. In nine experiments in which septic fever was artificially induced, salicylic acid produced a distinct lowering of the temperature and a rapid reduction of the fever. The dose of salicylic acid used in these experiments (on rabbits) varied from 0.05 to 0.2 gramme; it was given in three cases in starch-enema; in two, by the stomach, dissolved in water; in three, by subcutaneous injection (dissolved in alcohol or in warm water); and in one, by both subcutaneous injection and enema. Dr. Fürbringer is making further researches in Professor Friedreich's wards on the use of salicylic acid in febrile affections.—Dr. Butt of St. Gall reports briefly in the same number of the *Centralblatt* that he has found salicylic acid to be a valuable antipyretic remedy in cases of enteric fever, erysipelas, acute articular rheumatism, etc. He promises further details on the subject.—Professor Thiersch of Leipzig has published an elaborate article in Volkmann's *Sammlung Klinischer Vorträge* (Nos. 84 and 85, 1875) on Lister's treatment of wounds and on the substitution of salicylic acid for carbolic acid. He speaks highly of the salicylic acid dressing, especially when used with jute, as being both less irritant and cheaper than Lister's carbolic acid dressing. Dr. Hanow (*Berliner Klinische Wochenschrift*, No. 20) has for some months given salicylic acid in a number of cases of diphtheria, and strongly recommends its use in this disease. He uses a solution of 1 part of the acid and 1 of phosphate of soda in 300 of water, giving a tablespoonful to adults and a teaspoonful to children every hour. The medicine is to be swallowed slowly.

PROPHYLAXIS OF PUERPERAL FEVER.—Dr. J. H. Miller Moberly (*New York Medical Record*) formulates the chief points for practice as follows. 1. The most scrupulous cleanliness must be observed by all concerned. 2. Unremitting vigilance on the part of the physician. 3. The antiseptic treatment by carbolated oil and by salicylic acid and by thymol. 4. The early condensation of the uterine walls by means of ergot. 5. The thrice daily employment of the thermometer. 6. Large doses of quinine in the incipency of the disease.—*Brit. Med. Jour.*

A PROPHYLACTIC FOR SORE NIPPLES.—Dr. Julius Fehr writes (*New York Medical Record*, August 21st):—The curative, as well as the palliative, treatment of sore or cracked nipples being well known to be futile, my aim for a long time was directed to the finding of a reliable prophylactic. After trying a good many formulas of others, and combinations of myself, I came at last to the use of tannate of lead, the "cataplasma ad decubitus" of the *Pharmacopœia Germanica*, with the addition of a little glycerine to modify, in some degree, the excessive drying properties of that preparation. This "plumbum tannicum pulvisforme" I had applied, for about one month before parturition, two or three times a day, directly to the nipples. This, I found, "tanned" the nipples in so thorough a manner that they were perfectly able to withstand all suckling and all pulling on the part of the infant successfully. At the same time, I use a piece of cotton felt, about one inch and a half in diameter, and half an inch in thickness, with an aperture in the middle large enough to give free access to the nipple. This will not only prevent the pressure of the garments on the nipples, but will give, at the same time, to the nipples a chance to develop themselves better, which is often so much needed.—*Brit. Med. Jour.*

COLUMN FOR THE CURIOUS.

A "TOAD DOCTOR."—A correspondent of *Notes and Queries* says: "A lady informed me the other day that in the month of July, 1822, she was staying at Haselbury Brian, near Blandford, and that while she was there a man came in a gig, who was known as 'the toad doctor'. He brought with him a number of small bags, and the people flocked to him from far and near with toads. The 'doctor' cut off the hind legs of these toads, and put the severed portions into the bags, and hung them around the necks of his patients, the newly cut-off limbs quivering on their naked chests. This was held to be a certain remedy for the king's evil. An old woman, whom my informant knew, told her that 'it turned the blood wrong side up'. The bags had to be worn around the patient's neck until the legs inside were quite decayed away. The 'doctor' charged seven shillings each for those bags; and at that time, I believe, the farm-labourers in the neighbourhood were not receiving more than six or seven shillings per week."

BRITISH MEDICAL ASSOCIATION:
SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, SEPTEMBER 18TH, 1875.

THE MORTALITY AMONG EUROPEAN SOLDIERS' CHILDREN IN INDIA.

THIS subject is, we are glad to see, at length beginning to attract some share of public attention in India and in England, as is evidenced by a portion of the press of both countries, by a discussion which recently took place in the House of Lords between Lord Waveney and the Secretary of State for India, and by a speech delivered at this year's meeting of the British Association by Sir G. Campbell, M.P., late Lieutenant-Governor of Bengal. It occurs to us, therefore, that it may not be inopportune to lay before our readers a succinct account of the present aspect of affairs regarding this important topic.

A reference to the annual report of the Sanitary Commissioner with the Government of India for 1873, published last November, shows that out of a total of 59,839 European soldiers serving in that country on the 1st of May of that year, 6,736 were married and the fathers of 11,878 children of all ages up to sixteen years, all of them resident at the same stations as their parents. Out of this number, 714, or 60.11 per 1,000, died in the year, a mortality which, as the Sanitary Commissioner observes, is "much less than usual"; and when it is added that, in 1872, 99.08 per 1,000 children succumbed to disease—thus escaping decimation by a decimal point only—and that the average annual death-rate of the eight preceding years was over 94 per 1,000, Dr. Cunningham's observation will not be considered too forcible. Prior to the accession to office of the present Sanitary Commissioner, no detailed official record of the mortality among soldiers' children in India generally appears to have been published; but the subjoined figures, gleaned from different sources, may be accepted as authentic; and, dealing as they do with unselected groups of years extending back to 1851, will indicate that the sanitary improvements effected in Indian stations during late years, to which so large a share of the reduction in the mortality rates of our soldiers is generally attributed, have signally failed to make any favourable impression on the death-ratios of the children. Soldiers are, however, when their health breaks down, sent to England in large numbers (2,434 were, for instance, invalidated home in 1873), whereas children are never invalidated.

Average death-rate of children per 1,000 per annum. { 68.83, four years 1851-54, Dr. H. Macpherson.
94.41, six years 1864-69, Sanitary Commissioner.
94.58, five years 1868-72, Dr. Bryden.

These data refer to Bengal alone, more comprehensive statistics, dealing with comparatively lengthened periods, not being, so far as we are aware, available. But the deficiency is not of any real importance, because not only is the great majority of the European army of India stationed in Bengal, but the condition of things with which it is our purpose to deal is, there is every reason to believe, much the same in the three presidencies. The significance of these figures will, perhaps, be more readily appreciated if we take the mortality of one year, and compare it with that which prevailed among children of the same age, during the same year, in London, as calculated from the tables contained in the annual summary of the Registrar-General. We select 1872, the mortality at all ages for which approximates within 5 per 1,000 to the average of the eight preceding years, and may, therefore, be taken as fairly representative.

Death-rate per 1,000, 1872.

	Under 1 year.	1-5 years.	5-16 years.	5-20 years.
India	314	104	20	—
London	185	35	„	5

The residence in India, therefore, during 1872, of a certain number of infants under one year of age involved a sacrifice of 129 in every 1,000 lives, which would doubtless have been saved had these infants been located in London. At ages between 1 and 5 years, the death-rate is almost exactly three times as great in India as in London; and, although a divergence which occurs in the grouping of subsequent periods adopted by the Indian Sanitary Commissioner and the English Registrar-General precludes the institution of a precise comparison, it is probable that the Indian death-rate increases comparatively in proportion to increase of age. It is, at all events, quite certain that children in India between 5 and 16 years of age die with four times the rapidity which obtains among individuals ranging between the ages of 5 and 20 years in London. Having proved that the mortality among our soldiers' children in India is absolutely and relatively very excessive, and, moreover, that there appears to have been no permanent change for the better since 1851—the evidence, indeed, so far as it goes, seeming to point altogether the other way—we shall proceed to an examination of the practical questions, To what is this enormous mortality attributable? and, What measures should be taken to prevent, or even to mitigate, it?

As most people are aware, our Indian military stations are, from a health point of view, divisible into two classes, namely, those situated on the mountain ranges and those on the plains; the former being as conspicuous for their natural salubrity of climate and coolness as the latter are for the reverse. Of course, we are aware that the late advices from India have brought intelligence that serious outbreaks of cholera have this summer occurred at Simla and Mussourie, the most populous of our Himalayan stations; but the knowledge of this fact does not alter the high opinion we entertain as to the natural salubrity of these hill sanitarium, because the most favoured climates cannot expect immunity from cholera if their general sanitary condition—more especially their water-supply—is not in a very different state to that which obtains at Simla and Mussourie. Taking 1873 as a fair example of what the geographical distribution of our soldiers' children is, and has been during the last few years, we find that in that year in Bengal, 1,082 were located on the hills, and 5,671 on the plains, the death-rate among the former being 50 per 1,000, while among the latter it was 71. In 1872, the death-ratios on the hills and plains were respectively 93 and 117 per 1,000. The statistics of the four years previous to 1872, for which alone particulars have been published, show that about the same proportionate mortality existed in these years. Climate excepted, soldiers' children on the hills and plains are similarly circumstanced as regards their health, wherefore the inference is beyond all doubt that rather more than 20 per 1,000, or about 110 out of 5,671 children in Bengal, die annually, simply from exposure to the pernicious climate of the plains. We think it highly probable that another cause of ill-health and loss of life is the frequent inability experienced on the part of the parents to purchase a sufficient amount of appropriate nutriment for their children. There must be some cause for the very great increase which has taken place in the rates of mortality since the time referred to by Dr. Macpherson's statistics which we have quoted above, and we find it impossible to assign any other than the one just mentioned. The age and parentage of the children, as well as the climate in which they live, are the same as they were twenty years ago, while their abodes and general sanitary surroundings have been materially improved. But, on the other hand, the Government allowance of five shillings *per mensem* for each child is unaltered, the value of money has deteriorated in India quite as much as in England in late years, the allowance, if all expended on milk alone, would not now provide each child with one pint and a half daily, and the nature of the climate and other circumstances deter the parents from contributing by the earnings of manual labour to the support of their offspring, as is done at home. Statistics bearing

on this point are not procurable, but we think we are justified in arriving, by the method of exclusion we have adopted, at the conclusion that it is highly probable that the death-rate of the children is augmented by the poverty of the parents.

Residence in a pernicious climate and, very probably, a deficient supply of proper food being, then, to our minds the chief factors in the production of the excessive mortality prevalent among our soldiers' children in India, what preventive measures should be adopted? Three alternatives appear to present themselves, and these are: 1. The total abolition of matrimony amongst the rank and file in India; 2. Sending the mothers and children, without their fathers, to the hills during the hot season and rains, *i.e.*, for about seven months in each year; and 3. Locating permanently the whole of the married privates (who number 4,810 out of 6,736 men on the married strength of the Indian European army), together with their families, on carefully selected sites on the mountain ranges. The first alternative, which we have heard suggested by kind-hearted men driven almost to despair at witnessing the condition in which these poor little children now exist, may, we apprehend, be summarily dismissed with the observation that, pending the formation of a local European army for India—of which we see no immediate, if any, prospect—the abolition of matrimony in our regiments serving in that country, would necessarily involve the application of a similar measure to our army as a whole, a step which, if we are not much mistaken, no Government would, in our time, be prepared to take. The second proposal, which, by the way, is not without its advocates in the Indian press, strikes us as being morally and financially inadmissible; and, accordingly, we gladly endorse the language used with reference to it by the Marquis of Salisbury in the parliamentary debate already alluded to, when he remarked that "he could at once say that he did not think encouragement should be given by the Government of India to any proposal for separating the women from their husbands".

The third alternative seems to be so commendable and, withal, so feasible that we have no hesitation in recommending that it be carried into effect without delay. We are not, however, blind to the fact that certain objections are raised to the adoption of this plan, but we do not anticipate much difficulty in showing that they are, to say the least, superficial. We will endeavour to state, and briefly reply to, each objection. In the first place, it is asked, "Why should you give to a certain number of men the privilege of a residence on the hills because they happen to be married, and when, moreover, the absence of these married men from their regiments on the plains causes an additional amount of duty to devolve on their single comrades?" We answer that, putting motives of humanity aside, as, fortunately in the present case we can afford to do, marriage in the army is rightly regarded as one of the rewards for long service and good conduct; that the soldier who does not aspire to qualify at one time or other for matrimony is a rare exception; and to the single man the knowledge of the fact that, when his own turn for marriage comes, his progeny will also be placed in a good climate instead of a bad one, would be a powerful incentive not only to discharge a little extra duty cheerfully, but, by good conduct, to earn the privilege of being himself allowed to get married as soon as possible. Then, again, we are asked, "Why should privates only be sent to the hills, while married non-commissioned officers, equally, if not more, deserving men, are still to be retained on the plains?" Again we answer: Privates can be spared from their regiments, non-commissioned officers cannot. The married private, so long as he is in India, would, stationed on the hills, contribute quite as much towards the maintenance of our empire, as he would if quartered on the plains. According to our idea, he would form one of a reserve, and be liable to be directed to rejoin his regiment only in the event of its being about to leave the country, or go on active service, or in case he should be promoted to the rank of sergeant—an unusual contingency at the married private's time of life. Besides, the non-commissioned officer being, pecuniarily, tolerably well off, he can afford appropriate nourishment and many little necessary comforts for

his children, and thereby assist them in tiding over the baneful influences of the climate of the plains. Lastly, it is objected that even on the hills the death-rate of soldiers' children living with their parents, as contradistinguished from those in the Lawrence and other asylums is very high. We have shown that, in a series of years, the difference in the death-rate in favour of the hills is about 20 per 1,000 *per annum*; and this we submit is a great deal. But we are convinced that this by no means represents the saving of life which might be fairly anticipated if the system we propose were carried out, and we base our opinion on the following grounds: Children are now sent to the hills very often because they are in a delicate state of health. They go up suddenly from the heated plains, and arrive at their destination early in spring, when the weather is yet very cold. Their parents' resources, more than ever attenuated by the expenses incidental to a march of many days' duration, are inadequate to provide proper food and clothing to enable their children to cope to advantage with this sudden change of climate, and the result, as might be foreseen, is a large mortality. How different things are in the Lawrence asylums on the hills, where soldiers' orphans are permanently located and liberally fed and clothed. It is a notorious fact that the inmates of these institutions would, as regards health, compare favourably with those of our best English schools. If, therefore, instead of hurrying a limited number of married privates and their families to the hills when their health breaks down, and allowing them to remain there only for a few months as is now the system, we were to adopt the plan we advocate of permanent location on well-selected sites, a great change for the better would undoubtedly come about. Settled in a climate much the same as their own in England, with judicious management and distribution, the parents could, and doubtless would, profitably pursue agricultural and other industrial avocations, and thus be in a position to provide more liberally than they now can for the maintenance of their offspring. The latter would in time develop into hardy, healthy, intelligent youths, most of whom would probably be induced to become soldiers, and so contribute to lessen the drain to which the mother country is continually being subjected by India for recruits, as well as the great expense attendant upon transporting them thither. The small huts which would be admirably adapted for the housing of their families in the hills would cost very little indeed, and land fairly adapted for agriculture is not difficult to be found on the Himalayas and other mountain ranges. These soldier settlements, carefully fostered, might gradually become the nuclei of larger and more self-sustaining colonies which, especially in the Himalayas, could not fail to materially strengthen our hold upon our empire in the East. We commend this subject from this latter and more comprehensive point of view to the attention of Indian statesmen; but, in the meantime, we earnestly hope that needless delay of any kind may not occur in rescuing the 7,000, or so, children of privates among whom death is at present making such sad havoc on the plains, by locating them, together with their parents, permanently on the hills.

THE assessment of St. Thomas's Hospital has been reduced by the Lambeth Vestry Assessment Committee from £10,900 to £7,000.

SIR JAMES PAGET will preside at the distribution of prizes to the students of the Dental Hospital of the London Medical School on Monday, October 4th, at 4 P.M.

SURGEON-GENERAL C. A. GORDON, M.D., C.B., is said to be engaged on a work on Burma, he having recently visited the country in conjunction with Lieutenant-General Sir F. P. Haines, K.C.B., on whose staff he is serving at Madras.

It was stated at an inquest held this week in Clerkenwell on an old woman who had died in an epileptic fit that the body had been allowed to lie for three days and nights in a small room occupied by another old woman. The jury made a strong representation as to the want of proper provision for such cases in the parish.

THE President of the Metropolitan Counties Branch, Dr. Barnes, has issued cards for a *conversazione* at Willis's Rooms on Wednesday, the 6th October.

MR. RICHARD JONES, F.R.C.S. Eng., having resigned the post of surgeon to the Warneford, Leamington, and South Warwickshire Hospital, has been appointed consulting surgeon, and received a cordial vote of thanks for his "very valuable gratuitous services during a period of nearly half a century".

THE annual report of the Royal Westminster Ophthalmic Hospital just issued, states that, during the past year, 631 operations have been performed on in-patients, and 1,803 operations in the out-patients' department. The accommodation being inadequate to meet the demands made upon it, the surgeons have suggested the addition of another storey to the building.

THE Wrexham papers contain glowing accounts of an interesting public ceremonial on the occasion of the presentation of a portrait and address to Mr. T. T. Griffith of Wrexham. This venerable practitioner, "the father of the profession" in Wales, is held in the highest esteem by his townsmen as by his professional brethren. The presentation was made in eloquent terms by Sir Watkin Wynn; the portrait will be placed in the infirmary, of which Mr. Griffith was the founder. He was the first president of the North Wales Branch in 1849, and again president in 1872. He founded the ragged schools and the infirmary, to which he has presented nearly £1,000. Mr. Griffith has been fifty-seven years in practice, and has earned universal regard and esteem.

THE HOSPITAL SUNDAY FUND.

MANY fears have been expressed that the difficulties through which the Metropolitan Hospital Sunday Fund had passed would lessen its popularity, and cause a falling off in the amount collected. We regret to find that these predictions have been to some extent realised; but we trust that the unpopularity will be only transient, and that the judicious measures which have been adopted by the Council will speedily reinstate the movement in public opinion. The fund, including interest, now amounts in the aggregate to £26,703 7s., as against a total of £29,817 3s 9d. received last year. It will be divided within the next fortnight among 122 institutions—namely, 17 general hospitals, 4 chest hospitals, 8 children's hospitals, 4 lying-in hospitals, 5 hospitals for women, and 21 other special hospitals, including dental and homoeopathic hospitals, 7 convalescent hospitals, 1 fever hospital, 3 cottage hospitals, 48 dispensaries, and 4 infirmaries and sanatoria. The arithmetical bases of distribution have been provisionally settled by the committee, but these may probably be affected by the verbal statements which the managers of the special hospitals may make in explanation of their accounts and position. Deputations from 20 of such institutions have been received, and the delay in distributing the Fund has arisen through the difficulty in getting people together in the holiday season.

DR. F. W. HEADLAND.

THE announcement this week of the death of Dr. F. W. Headland in his forty-sixth year, will be received by many with great regret. Dr. Headland had very early given promise of uncommon distinction. His university career was brilliant, and his Fothergillian prize essay on the action of medicines in the system was far above the average of such productions. It quickly took rank among the standard works of the day, and evinced a power of original research and clinical skill, which marked its author as a man capable of taking a high place as an investigator and a practitioner. Dr. Headland early became connected with Charing Cross Hospital, and his promotion there was sufficiently rapid. His tastes, however, led him rather into literary than into medical pursuits; and, after a time, he gave his chief energy to political writing for the conservative papers of the day. The

scientific instincts and the love of research faded before the interest of his new pursuits, and for many years Dr. Headland had been at least as much a political journalist as a practising physician. For the subjects which specially relate to the advancement of public health and social welfare he did not show any peculiar proclivity, and he connected himself but little with medical interests or societies. He was, however, always desirous to aid social reforms; and, although the form of usefulness and activity which he chose was one in which the individual is effaced and only his work is seen, it is a kind of work which exercises now a vast and potent influence. Political journalism is a huge power in this day, and men of culture, precise knowledge, and high principle, such as Headland, are those by whom the power has been chiefly created, and to whom it may most safely be trusted.

AN INTERESTING DISCOVERY.

AN interesting discovery has been made at Greenwich. Owing to some excavations which had been made for building purposes in the grounds of the Royal Naval School, it became necessary to remove several coffins which had been committed to the earth for upwards of thirty years. In one part of the grounds several coffins were found intact, the brass nails and the coffins themselves looking as bright and fresh as on the day they were made. On opening these coffins, the bodies were found to be in an equally good state of preservation. The embroidery on one of the dresses was as unruined and complete as if it had only just left the hands of the dressmaker; even in the minutest particulars, the bodies and their surroundings were as perfect and undisturbed as they had ever been. To use the words of an eye-witness, the infants were as perfect as if they had just been born. The reasons for this antiseptic action of the earth are worthy of investigation by Mr. Seymour Haden.

TYPHOID MILK.

A SEVERE outbreak of typhoid fever, a counterpart of the Marylebone epidemic, has occurred at Jarrow. It has been discovered by Mr. John Spear, medical officer of health, to have arisen from an infected dairy, his suspicions of this farm having arisen from the fact that fourteen of the infected families received their milk from that source. On visiting the farm, Mr. Spear found that six of the farmer's family, including himself, were laid up with typhoid. The water used in the dairy was derived from a well eighteen yards distant from a privy and cesspit, a hole in the ground unprotected by any brickwork. An analysis of the water revealed the fact that it was contaminated with sewage to a very great extent; the analysis showing—

Total solids	106.3	grains per gallon
Chloride of sodium	12.6	" "
Free and saline ammonia031	" "
Organic ammonia053	" "

An analysis of the milk, while it showed a poor quality, did not prove any adulteration by water. The washing of the cans with water from a contaminated source is quite sufficient to render it infectious. The peculiar system also by which each customer has his own tin bottle containing his daily supply, each bottle having, in addition to the usual cork, a piece of rag wrapped round it for the purpose of making it fit tightly, the piece of rag being passed from hand to hand must increase the danger of infection immensely. Besides the water-pollution of this particular place, the whole arrangements were of a most disgusting kind. There was direct communication between the dairy and the rooms in which some of the fever patients were lying, whilst the dairy itself did double duty as a washhouse, and clothes from the fever patients had actually been washed there. The girl who milked the cows, a daughter, was in constant attendance on her sick relatives. The first patient was the boy who delivered the milk, and his case rapidly gave rise to others. Of twenty-seven families who received their milk-supply from this one source, eleven suffered. The aggregate number of cases amounted to twenty-five. To the prompt and efficient action taken by Mr. Spear and his staff of sanitary

inspectors is due the fact that the fever was stayed. The polluted milk-supply was at once cut off, and disinfectants were freely used. Mr. Spear also ascribes the rapidity with which in some instances the disease extended, to the unwholesomeness of the houses, and the abominable state of some of the privies and ashpits attached to them. One of the chief conclusions which Mr. Spear draws from this outbreak, is the necessity which exists for some radical alteration in the mode in which the milk trade is carried on, and in this we cordially agree with him. In some of the best London dairies, a rigid sanitary inspection of all the farms which supply them with milk, and an analysis of the well-water in which the utensils are cleansed, are insisted on; and had some such inspection been made in the case of this particular farmhouse, we may safely assume that this epidemic would have been prevented.

INTERNATIONAL BULLETINS.

THE Signal Service Bureau of the American War Department have issued the first number of a bulletin containing an international exchange of weather reports. There could be no more significant illustration of the recent rapid advances in meteorological science than this record of observations taken simultaneously at numerous stations throughout the great northern hemisphere. Algeria, Austria, Belgium, Sweden, Switzerland, Turkey, Great Britain, France, Germany, Italy, Canada, and the United States, here contribute a uniform system of weather records, comprising data of barometric pressure, temperature, humidity, wind-movements, clouds, and rainfall. These observations will in future permit the study of atmospheric changes the world over, enabling storms and other disturbances to be traced from their origin throughout their course, until they disappear. The *Boston Medical Journal* observes, it is a source of national pride that their own government observers, of whom General Myer is the chief officer, have put the work into practical operation, and established the form which we have before us. It indulges the sanguine hope that the system of meteorological observations above described may presently point the way to a similar scheme applied to the record of epidemic movements and prevalent diseases. It is not too much to expect that sometime we may have an international bulletin setting forth officially the movements of "waves" of epidemic disease from their initiation to their decline, medical "signal officers" becoming the counterpart of the weather observers. The practical advantages of such a general system in its relation to the public health are obvious; while the obstacles in the way of its accomplishment are not more insurmountable than were those that seemed a few years ago to stand in the way of the present admirably managed signal service at Washington.

CRIMINAL RESPONSIBILITY.

THE extent to which medical knowledge can contribute to the determination of criminal responsibility was discussed in an interesting paper by Dr. John Sibbald, Deputy Commissioner in Lunacy, at the recent Edinburgh meeting of the British Medical Association. Dr. Sibbald first pointed out that the question of criminal responsibility is a strictly legal question, and that it is neither necessary nor desirable to introduce into it abstract ethical theories. As it involves the question of the sanity of the individual, it has been found necessary to resort to the aid of the medical practitioner in investigating certain cases. But the present position of this branch of the subject is very unsatisfactory. The definition of irresponsible insanity given by the fifteen judges, and still looked on as the most authoritative legal statement on the subject, is disapproved of both by legal and by medical writers. Dr. Sibbald considered that the attempt which has been made by the latter to suggest theories of responsibility has failed, and that the best solution of the difficulties involved in the subject would be to leave the legal side of the investigation entirely to the lawyer, and to keep the medical side entirely to the physician; that is, to let the one deal with responsibility, and the other with insanity. He proposed that attempts to define legal insanity should be given up, and that it should be laid down as the legal

doctrine that responsibility does not attach to any act which can be shown to be the result of disease. The medical witness would have to show whether the accused was affected by any disease of which the act in question was the natural outcome. The question whether persons labouring under such a disease are to be looked on as either wholly or partially responsible, would be removed from his consideration.

ISOLATION OF INFECTIOUS CASES.

IN the *Gentleman's Magazine* for the present month, Mr. McCullagh Torrens, M.P. for Finsbury, discusses the question whether it is better that members of the labouring and poorer classes of society who happen to be suffering from any of the infectious diseases should, for their own good as well as the general welfare of the community, be treated in their own homes, or removed to the large hospitals which are established for these maladies. Mr. Torrens decides for the former plan of treatment, which he would combine with small local hospitals and dispensaries. Members of the medical profession who are interested in this question will do well to examine Mr. Torrens' paper.

THE WORCESTER INFIRMARY.

DR. INGLIS writes to us in reference to the subjects at issue as follows:

"I observed in the *BRITISH MEDICAL JOURNAL* of August 28th, a letter headed 'The Worcester Infirmary', and signed 'One of the Executive Committee'. I trust you will allow me to answer a few of the remarks made in that letter.

"The Committee feel that they have got themselves into a difficulty; but what is more to be deplored, they have placed the infirmary in a critical position, and, as drowning men will clutch at a straw, so they are anxious to lay hold of anything for their justification, and have seized upon the one of *urgency*, and blame me, because I omitted to state in my letter of explanation, that the case I went to was urgent. Every member of the Committee knew that I had been called to see a patient twelve miles from Worcester. It is not usual for people to send a special messenger so far for a physician unless the case is urgent, or at any rate those sending suppose it to be so. I think there are very few who will accept this miserable plea put forward by the Committee, as any justification for the vote of censure they passed upon me.

"I infer that the author of the letter considers that the Committee ought to have some statement of exceptional circumstances, or some plea of justification, on every occasion when the exigencies of private practice prevent an honorary officer from attending to his hospital duties. In my opinion, such ought to be the exception, and not the rule; and that it is only where there is continued infringement that should require the Committee to put an honorary officer on his defence. If matters are ever to go smoothly, the medical men ought to be able to feel that they can rely upon the Committee for support instead of censure, and without that feeling their duties cease to be a labour of love, and become irksome and harassing. In my case, the Committee had the letter I addressed to the house-surgeon before them, which was an ample reply to the Rev. Martin Amphlett's grievance.

"We are all aware that there are a certain number of people so constituted mentally, that grievances are necessary for their existence. A county hospital is at all times a fruitful source whence to obtain them. The Committee are every now and again obliged to investigate into these complaints, but in nine cases out of ten they are of a frivolous character, and a satisfactory explanation can be given by the Committee without troubling the medical staff. The Committee ought to make it part of their duty to curb rather than foster the zeal of grievance-mongers.

"It appears like mockery for one of the Executive Committee to talk of rules being *prudently* and *wisely* understood, and that they do not impose upon the honorary medical staff any *rigid* or *inflexible* yoke. It is just that want of prudence and wisdom, combined with the rigid and inflexible manner in which the laws have been construed, that the medical staff have had to complain of. At the meeting on the 21st of June, when I sent in a letter of remonstrance, the Rev. John Pearson is reported to have spoken as follows. 'He could not allow a letter like that to pass altogether unnoticed, because he could not at all agree with Dr. Inglis. He could not agree that they had taken a narrow view of the rule. Nothing could be more plain and distinct than it was. Where was there anything in it which said that he could get the house-surgeon to perform his duty? It was not hinted at. He (Mr. Pearson) could not understand what was meant by a liberal view. He

could not see that the letter or the spirit of the rule could allow of it.' To these remarks none of the members present offered any opposition. The Committee seem afraid to face the governors, and in order to avoid that, at a special meeting held on August 30th, they passed the following resolution as a sop to the medical staff. 'That the Executive Committee, in acknowledging the letter of the honorary medical staff, are glad to find that the difference of opinion between them is so much reduced, and they are persuaded that fairness and liberality of construction of the circumstances which may occasion an infringement of the rules, will always be extended to the honorary medical staff, if the Committee are treated with the confidence to which they are justly entitled.' *Tempora mutantur et nos mutamur in illis.* But two months seem much too rapid for such a change in principles to appear genuine, and, as the fairness and liberality is only conditional on the honorary medical staff confiding in the Committee, it leaves then a wide loophole; so the would-be tempting bait has been respectfully declined.

'A meeting of governors will be summoned as early as possible to take into consideration an amendment of rule 59. It is to be hoped that all subscribers who wish well to the Worcester Infirmary will attend the meeting, and assist in rendering the rule equitable, and so put it beyond the power of this or any future Committee, to again construe it as they have done. A line of practice such as the Executive Committee have carried out for the last six months, if persisted in, would effectually put an end to gratuitous medical services, so far as Worcester is concerned.'

THE INTERNATIONAL MEDICAL CONGRESS AT BRUSSELS.

THE past experience of these "international" congresses appears to have been sufficiently satisfactory to prolong their existence till this the fourth session, which is about to be opened on September 19th at Brussels, under the presidency of M. Vlemminckx. The conditions of admission are very light, and they are practically within reach of all comers. The general secretary of this meeting is M. Warlomont, Avenue de la Toison d'Or, 74, and all information and assistance are given to strangers by Dr. Delecosse, Rue de l'Hôpital, 14. Hitherto, however, these congresses have been in effect rather national than international in their character. They are managed on a system in many respects different from that which prevails at our British medical meeting. A number of sections are arranged; a "bureau" of affairs is appointed, and a series of questions for discussion are determined in each section. Each of these questions is some months before a meeting referred to a committee for report, and the "reporter" appointed prepares an elaborate document, setting forth what he conceives to be the actual state of knowledge on the subject, and ending by a series of "conclusions"; the said report becomes the order of the day each day in the section. The "provisional conclusions" of all the reporters are printed in a "programme", which is issued to the members for preliminary study; the report is discussed, and the "provisional conclusions" are submitted to the sections for adoption, and on them the debate turns. Such discussions are often formal, and the whole proceeding has a cut and dried official character very repressive of originality. But when, as is often the case, the reports are able, and the conclusions are sharply contested or cleverly supported by members who have obtained the programme before hand, and prepared themselves for the debate, the discussion assumes an interesting shape. The whole of the "bureau" and of the reporters are Belgian this time. The subjects treated, however, are very interesting, and the conclusions seem to us well calculated to provoke valuable discussions. They include—prophylaxis of cholera; alcohol in therapeutics; the inoculability of tubercle; surgical anaesthesia; the dressing of wounds after operations; maternities; the vaso-motor nerves and their modes of action; the value of experiments, founded on artificial (schematic) circulatory apparatus; the sanitation of workshops in which phosphorus is used; the organisation of the service of public hygiene; the manufacture of beer; defects of vision from the point of view of military service; the means of registering hearing power, and registering it in an uniform manner in all countries; defects of hearing from a military point of view; the moral and legal position, and the disposal of criminal and dangerous lunatics; should the medical use of chemically defined immediate principles be

extended, and the preparations of them be multiplied in pharmacopœias? the establishment of an universal pharmacopœia. Here is material for all tastes and food for all appetites. We are assured that any English physician or surgeon proposing to attend this congress will have a courteous welcome.

THE ANTIVIVISECTIONISTS AND THE LATE DR. JOHN REID.

A STATEMENT has lately been industriously circulated by the "Society for the Abolition of Vivisection", that the late Dr. John Reid, Professor of Medicine at St. Andrew's, during the painful illness (cancer of the tongue) from which he died, stated on several occasions that the pain which he suffered was "a judgment on him for the sufferings which he inflicted on animals", in his researches on the eighth pair of nerves. The words referred to are attributed to Dr. Reid in his biography by Dr. George Wilson. In the *Edinburgh Medical Journal* for the present month, Sir John Rose Cormack, one of Dr. Reid's most intimate friends, publishes a letter in refutation of the statement made by the antivivisectionists. He says that, during the recent meeting of the Association, in Edinburgh, he was several times asked by professional friends who knew his close and intimate friendship with Dr. Reid, and who remembered that they had worked together in physiological research, whether he believed that Dr. Reid used the expression attributed to him. He says: "I do not believe that my dear departed friend ever said in seriousness, or even thought, that the pain he experienced from cancerous disease of the tongue and pharynx was a judgment for the sufferings he had inflicted on animals. John Reid was, I firmly believe, a sincere Christian, but also a man of robust common sense." Sir John Cormack refers also to a visit of four days' duration which Dr. John Reid paid him in 1848, after he had undergone removal of the greater part of his tongue. He was then completing his volume of collected works; and, although the subject of physiological experiments was several times discussed, "neither then", says Sir J. R. Cormack, "nor at any other time, did Reid speak to me regretfully of his experiments on animals. . . . John Reid was too conscientious a man, and too frank and true in his friendship to me, to have stopped short on that occasion in disclosing his altered views as to experiments on animals had there been any alteration to communicate." Sir John Cormack states also that, during his recent visit to Edinburgh, he discussed this and other subjects relating to Dr. John Reid with Professor Spence, who was also one of Reid's closest friends, and one of his assistants in his experiments; and that Mr. Spence agrees with him in not believing that Dr. Reid ever entertained or expressed the opinion attributed to him. There is, then, the strongest reason for believing that Dr. Reid never held the idea attributed to him by his amiable but injudicious biographer, unless, perhaps, as Sir J. Cormack remarks, when he was "in a condition of delirious mental enfeeblement engendered by pain and morphia". Possibly, Sir John Cormack suggests, the statement may have originated in the fact that, during Dr. Reid's life, a sermon was delivered before the Edinburgh Society for the Suppression of Cruelty to Animals, in which the preacher had the bad taste and impiety to inform his audience that a great physiologist was then suffering agonising pain in the very same nerves on which he had experimented in dogs; and that this was a special judgment for his horrid cruelties!

RECENT URBAN MORTALITY.

DURING last week, 5,547 births and 3,723 deaths, equal to an annual rate of mortality of 25 per 1,000 persons living, were registered in London and twenty other large towns of the United Kingdom. The annual death-rate in each town was as follows: Portsmouth, 20; Glasgow, 22; London and Edinburgh, 23; Dublin, Sheffield, Sunderland, Oldham, and Birmingham, 24; Norwich and Nottingham, 25; Wolverhampton, 26; Bristol, 27; Leeds and Leicester, 29; Manchester and Newcastle-on-Tyne, 30; Bradford, 32; Liverpool, 33; Salford, 36; and Hull, 39. Scarlet fever prevails in Bristol and Bradford; and diarrhoea in Birmingham and Norwich. In London the

births were 88, and the deaths 77, above the average for the week. The deaths referred to the principal zymotic diseases were 388, and included 2 from small-pox, 25 from measles, 71 from scarlet fever, 5 from diphtheria, 69 (30 above the average) from whooping-cough, 26 from different forms of fever, and 190 (25 above the average) from diarrhoea. A child, aged twelve years, died in St. Bartholomew's Hospital, from "hydrophobia from the bite of a cat, about seven weeks". In outer London, the general and zymotic death-rates were 19.0 and 4.7 per 1,000 respectively, against 22.6 and 5.9 in inner London. At Greenwich, the mean reading of the barometer during the week was 29.91 inches; the average temperature of the air was 60.8 degs., or 2.5 degs. above the average of the week. No rain fell during the week.

THE LATE DR. DEMPSEY.

WE regret to announce the death of Dr. J. M. Dempsey of Charterhouse Square. The deceased gentleman was probably best known as a microscopist; and his collection of microscopic objects was very large and valuable. It contained numerous preparations of injected tissues; of which those of the brain formed a large proportion. For the past eighteen months, Dr. Dempsey's health had been failing; and about six weeks ago, under medical advice, he went to Carlsbad. After his return on Wednesday, the 8th instant, he took to his bed, and died of hepatic disease on Tuesday last, aged 53. He was in general practice, and has left two sons and a daughter. His eldest son succeeds to the practice. Dr. Dempsey was a genial, unobtrusive, hardworking member of the profession, who will be deeply regretted by all who had the privilege of his acquaintance.

ETHER AND CHLOROFORM.

THE *Boston Medical Journal*, referring to the recent discussion opened by Mr. Pollock's letter, observes that it hopes that the comments of the medical press "indicate that our more conservative British colleagues are beginning to realise the position in which they have placed themselves. Should prejudice still blind them, however, we have strong hopes from the revivalists represented by such men as Mr. Pollock and many other prominent English surgeons who have received valuable support from the BRITISH MEDICAL JOURNAL. In conclusion, we would simply caution our friends against the use of an impure article. Avoid everything but pure ether, such as is obtained in this country from Squibb, or Powers and Weightman; follow the simple directions laid down by Dr. H. J. Bigelow in an article in the *Journal* of November 20th, 1873, which appeared shortly afterwards in the BRITISH MEDICAL JOURNAL, and such cases as have appeared in late numbers of the English journals will cease to be reported. Give ether simply a fair chance, and the most stubborn and ignorant of its opponents will surely be obliged to acknowledge its superiority."

SCOTLAND.

THE Royal Commission appointed to inquire into the operation of the Factory Acts met this week at Glasgow, under the presidency of Sir James Ferguson. A deputation from the Drapers' early closing Association waited upon the Commissioners and urged the necessity of legislative enactments to meet the evils of late hours and improper sanitary arrangements, especially in reference to the health of women and children.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

THE first meeting of the session was held on the 3rd instant. The following office-bearers were elected. *President*: Dr. James Morton. *Vice-Presidents*: Dr. D. Richmond (Paisley), Dr. Robert Perry. *Council*: Dr. R. Stewart (Coatbridge), Dr. James Scanlan, Dr. Alex. Patterson, Dr. James Dunlop, Dr. D. Taylor (Paisley), Mr. A. Macfarlan, Dr. T. Reid, Dr. T. McCall Anderson. *Secretaries*: Dr. J. Coats, Dr. Gavin P. Tennant. *Treasurer*: Dr. Hugh Thomson. At

the conclusion of the private business, Dr. Fergus gave a discourse on "Sanitary Hints on Domestic Drainage". He referred to the defects of cesspools and traps, in respect chiefly to the absence of any proper system of ventilation, and suggested a variety of devices for their improvement. It is well known that Dr. Fergus objects altogether to the water-closet system, and only suggested these as palliatives of what seems at present to be a necessary evil. A somewhat prolonged discussion followed the remarks of Dr. Fergus.

THE NEW MEDICAL SCHOOL IN GLASGOW.

A LETTER has appeared in one of the Glasgow daily papers, which purports to give a correct view of the history of the proposal to found a new school of medicine in Glasgow in connection with the Royal Infirmary. The writer is an Andersonian student apparently, and has naturally a great regard for his own school, while he strongly resents the determination of the Glasgow University not to recognise its classes. It appears to him, that the University is afraid of the Andersonian becoming a formidable rival, and has devised this scheme of a Royal Infirmary school in order to check the growing popularity of the Andersonian; and that this has been done by means of the University professors, two of whom have a seat on the board of directors. We have taken care to inform ourselves of the facts of the case, and can state, that one of these professors strongly opposed the proposal for the formation of such a school; and the other stated publicly, that he had not been present at the meetings at which it had been discussed. This theory of the Andersonian student is, therefore, quite devoid of foundation, and is only worthy of notice because it may possibly be held by a number of other students who cannot be expected to be informed of the facts. There is nothing more certain than that the Glasgow University has had nothing whatever to do with the origination of this scheme, which, if properly carried out would, we think, confer a great benefit on the whole of the medical profession of Glasgow, by raising its tone and giving an open field for any young man who had an ambition to become a teacher of medicine.

IRELAND.

AT a late meeting of the Thurles Board of Guardians, the salary of Dr. Russell, dispensary medical officer, was increased by £20 *per annum*.

SIR JOHN ARNOTT, proprietor of the *Irish Times*, has executed a deed of gift vesting the large sum of £20,000 in trustees for such charitable institutions in Cork as he shall afterwards designate. The sum so vested consists of shares in the City of Cork Steampacket Company, and the dividends will be applied to the purpose intended.

Dr. J. J. CHARLES of Belfast, whose accomplishments as an anatomist are well known, is a candidate, we hear, for the professorship of Anatomy in the Queen's College, Cork. Mr. Charles has been for six years demonstrator in the Queen's College at Belfast. His contributions to science, of which some have been published in these pages, afford satisfactory evidence of fitness for the office which he now seeks.

Dr. H. MACNAUGHTEN JONES, Cork, is, we learn, a candidate for the chair of *Materia Medica*, in the Queen's College, Cork. Dr. Jones has given evidence of great industry and varied ability, and has all the qualifications for such a post. As the honorary secretary of the South of Ireland Branch of the British Medical Association, he has rendered valuable professional services to his brethren, and we trust he may receive the appointment.

MATER MISERICORDIÆ HOSPITAL, DUBLIN.

Dr. FARRELL has been appointed by the Superiress and Sisters of Mercy of Baggot Street, Assistant-Physician to this institution, in the place of Dr. Browne, who has left for New South Wales.

HEALTH OF IRELAND: QUARTERLY REPORT.

DURING the quarter ending June 30th, there were registered 37,393 births, a number equal to an annual birth-rate of 28.2 in every 1,000; and 25,375 deaths, representing an annual mortality of 19.1 per 1,000. These returns show that the birth-rate is again under, and the death-rate over, the average for the corresponding quarter for the previous five years. The deaths from small-pox numbered 225, and abundant evidence is forthcoming that the disease has been widely spread by the baneful practice of inoculation. Measles produced 202 deaths, being a considerable increase as regards the corresponding quarter of last year. Scarlatina caused 913 deaths, a decrease of 194 from the previous quarter; but, in some districts, it was of a most malignant character. The deaths from diphtheria amounted to 111, and from whooping-cough 305, whilst fever proved fatal in 756 instances, and 397 deaths were ascribed to diarrhoea. Several registrars speak with approval of the effects of the Sanitary Act, whilst others consider that but trifling results so far have followed; all are agreed, however, that in too many districts there is room for improvement, and much to tax the energies of sanitarians.

DANIEL TOLER THOMAS MAUNSELL, M.B.

IT was with much regret that we lately announced the death of Dr. Maunsell, the able and well known Secretary of the Irish Poor-law Medical Officers' Association. Dr. Maunsell was the son of the late Rev. Thomas Maunsell, of the County Tyrone, a clergyman of the Irish Church. Having obtained an extensive and careful preliminary education, he entered Trinity College, Dublin, of which College he was a distinguished student. In 1859, he graduated A.B. and M.B. at Dublin University. While a student, Dr. Maunsell devoted special attention to the scientific subjects ancillary to medicine, and was a distinguished member of the anatomical, botanical, and chemical classes of Trinity College; in the latter subject, he obtained high honours. Dr. Maunsell was also a Licentiate in Surgery and Midwifery of the Royal College of Surgeons in Ireland. Early in his career, Dr. Maunsell was appointed Demonstrator of Anatomy in the Ledwich School of Medicine. Subsequently, he was appointed to the chair of *Materia Medica*, and at the time of his death held the chair of Botany in the same school. Dr. Maunsell was Physician to the High Street Division of the South City Dispensary District of Dublin. His occupation of dispensary physician soon directed his attention to the organisation of the important public service in which he was employed, and to a great extent determined his future career in medical politics and literature. From henceforth Dr. Maunsell became the most prominent writer in Ireland upon subjects connected with the Poor-law Medical Service, the relations between sickness, pauperism, and disease; and latterly devoted his pen almost entirely to sanitary reform, especially in its relation to the Poor-law and the Poor-law Medical Service. Dr. Maunsell was the author of the various pamphlets and articles well known as written by "Dispensarius". His *Sketch of the History of the Poor-Law*, and his pamphlet on the *Irish Dispensary Medical Officer, his Work and his Pay*, at once made him the leader of the Poor-law medical officers, and ultimately contributed to the foundation of the Irish Poor-law Medical Officers' Association, of which Dr. Maunsell was the unanimously elected Secretary. The various annual and other reports and circulars issued from time to time by the Secretary to the members of the Irish Medical Officers' Association form a complete record of the different phases of the discussions on Public Medicine in Ireland during the past ten years. Many of these reports involved an immense amount of work, especially of a statistical character. One of these reports, entitled "An Analysis of the Population, Acreage, and Expenditure, under the Sanitary and Medical Charities Acts in Ireland," published in 1873, involved an amount of labour, in compilation and arrangement of statistics, seldom undertaken outside a Government-office. We have seen this paper quoted over and over again in parliamentary discussion, and we believe few who employed the figures ever believed that the work was the result of the

almost unaided efforts of a single unpaid officer. It will be remembered by those who attended the Public Health Section of this Association at its London meeting in August 1873, that a paper entitled "Observations on State Medicine and Public Health in Ireland", by Drs. Grimshaw and Maunsell, was brought forward at that meeting; and that Dr. Grimshaw, in reading the paper, had to apologise for the absence of Dr. Maunsell, owing to his having met with a serious accident. That accident was serious injury to the knee, caused by the upsetting of a carriage. The effects of this accident for a long time disabled Dr. Maunsell from active work, and so seriously impaired his health, that we believe it tended much to lay the foundation of his last fatal illness. While still suffering from the effects of this accident, Dr. Maunsell worked hard at his portion of the paper on State Medicine and Public Health. The suggestions in this paper, and the energy with which they were afterwards urged upon the Government, tended much to the production of the Irish Public Health Act of 1874. Our space will not permit us to point out the many ways in which Dr. Maunsell has left his mark on medical politics and legislation. We believe he has done more than any one ever did gratuitously to improve the Public Medical Service of Ireland, not only for the benefit of his own profession, but for the welfare of the public. The genial and happy manner of "Tom Maunsell", as he was called by his familiar friends, of whom he had many, will long be remembered. His life was not unchequered by the troubles and annoyances usually encountered by reformers; and we much fear that these troubles, combined with the effects of the accident previously referred to, tended not a little to the fatal result, which occurred rather unexpectedly on August 18th, at his residence in South Richmond Street, Dublin.

AN IRISH SPA.

LISDOONVARNA Spas are coming into notice. These mineral waters are situated in the County Clare, and recent analysis of the waters has been made in the laboratory of the Royal College of Science at Dublin. One of the waters examined contained, like Harrogate and Aix-la-Chapelle, sulphur in the form of sulphuretted hydrogen; whilst another possessed iron and a small quantity of manganese. The Lisdoonvarna water also contains a small proportion of lithia, and less common salt than the other varieties. The visitors at the Spas have this year been exceedingly numerous, and the hotels and boarding-houses, as a necessary result, have been inconveniently crowded. Dr. Mapother of Dublin has written a pamphlet descriptive of these mineral waters, and speaks highly of their efficacy in various diseased conditions.

DEATHS IN IRELAND.

ON March 14th, 1874, we noticed the volume on the Status of Disease published by the Irish Census Commission. That volume was dated October 31st, 1873. We have now before us the second volume, dated March 31st, 1875, containing the statistics of deaths in Ireland collected by the Irish Census Commissioners of 1871. When are we to have the rest of those statistics? we hope some time before the issue of the next Census Commission in 1881.

A first glance at this volume almost inclined us to lay it aside and merely announce its appearance. It is too late to be of much value, and is extremely imperfect, and not certainly drawn up in accordance with the spirit of the times. We should remind our readers that death-registration in Ireland commenced in the year 1864, that is, less than three years after the short period of taking of the census of 1861. The want of registered information with regard to deaths for the thirty-three months out of the decade of 1861-1871, is made one reason by the Irish Census Commission for resorting to the clumsy and old-fashioned system of collecting death-statistics through queries on the census forms. Why should the Irish Census Commission not have availed themselves of the registered deaths for the time during which death-registration existed, and merely collected the records for the odd thirty-three months by hearsay? We might then have had a fairly accurate return, but, as it is, the census-returns differ so much from the Registrar-General's returns, that the inaccuracy of the former is but too manifest. The Commissioners, referring to previous reports, state, "In these several

reports, extending over the decade ending in 1841, and concluding with that ending on April 7th, 1861, the Commissioners adopted, with some modifications, a nosological arrangement of diseases originally published in accordance with the most distinguished scientific authorities on such subjects in Great Britain, the Continent of Europe, and America". And again, "Since the taking of the census of 1851, several changes in the matter of nosological arrangement have been made in the tables of deaths annually presented by the Registrar-General of England. Believing, however, that the plan now presented for the fourth time is based upon scientific principles, and has been approved of by many distinguished medical statisticians; and because we think it more adapted to Ireland than that published by the English Registrar-General; and, likewise, because it affords a means of comparing one decade with another, with what has already been presented by us on previous occasions, we have, with some additions and modifications, continued the arrangement formerly pursued". The italics are ours.

Upon what grounds do Commissioners Donnelly, Abraham, and Wilde (or rather the latter, whose name stands at the head of the table), believe that their system of nosology is more suited to Ireland than the system adopted by the English Registrar-General? We have yet to learn that Irish and English diseases so differ that they will not fall into the same classification. We are at present unaware of any disease which is not common to both countries, and to all divisions of the United Kingdom; moreover, Mr. Donnelly, who is the Irish Registrar-General, uses for registration purposes the same classification as his English confrère. When the Irish Census Commissioners write of comparison with "what has been previously presented", do they forget that a more important comparison is to be instituted with what is yet to come, and that, in judging of the comparative health of places and towns in the United Kingdom, an uniform classification is essential? We pointed out in our notice of the first volume, that Government had not utilised Dr. Burke, the Medical Superintendent of Statistics at the Irish Registration Office, and pointed out how Dr. Burke's supervision would have added much to the accuracy of the census returns of the status of disease. In the present instance, the want of Dr. Burke's direction is more than ever visible—in fact, such a mass of badly arranged figures would not have been allowed if Dr. Burke had been a Census Commissioner. A table of equivalents is indeed given at the beginning of the report, by which anyone who chooses to spend hours over the work, can partially convert the Irish census nosology into modern nosological equivalents. Having thus cautioned our readers against being over credulous in accepting the figures given in the report under consideration, we shall proceed to put before them some of the more reliable of the results.

It is stated that the annual rate of mortality per 1,000 for the decade was only 13.8 against 14.8, 17.5, and 13.7, for the decades ending 1841, 1851, and 1861 respectively. We need scarcely say, that all these figures are much under the real rates. We know that the registered death-rate for Ireland is, for the last ten years, 17 per 1,000 *per annum*, and this is somewhat under the mark. We believe, however, that the relation between the number for the several decades is correct.

There has been a remarkable increase in the number of inquests held, being 27,291, or 1 in 28.1 of all the deaths registered; against 1 in 58.4, 1 in 46.5, and 1 in 30.8 in the former decades. This is attributed to the increase in sudden deaths from apoplectic and cardiac affections; but we think it may, with greater truth, be ascribed to increased vigilance on the part of coroners and police-officers. Medical evidence was given in only 70.2 per cent. of the inquest cases. This, however, is an increase on former decades, showing a farther tendency to increased exactness in the management of inquests. The number of inquests held on "unknown infants" has considerably decreased, proving a decrease in the crimes of concealment of birth, desertion, and infanticide. There has been a steady decrease in the number of deaths from "homicide"; but, we are sorry to say, a rise in murders. There has been a steady increase in the number of suicides during the past decade. Accidental deaths have also increased in frequency, from 1 in 1,013 of the population for 1841, to 1 in 521 for the last decade. Deaths from the "immoderate use of ardent spirits" have, according to the Census Commissioners, diminished to a very great extent, being 1 in 11,443 of the population in the last, against 1 in 6,508 in the preceding decade. The increase in the proportion of deaths among females from this cause is not encouraging.

With regard to hospitals, it is pleasant to learn that a great increase has taken place in the amount of "general hospital accommodation in Ireland". In the decade 1841-51, there were 105,040 admissions to "general" hospitals; in 1851-61, there were 128,370; in 1861-71 there were 155,954, showing an increase of one half in the accommoda-

tion for the sick poor during the past thirty years. This increase is in addition to the extra accommodation provided for the sick in the workhouse infirmaries. By the increased provision for the sick in the workhouse hospitals, the general hospitals have been much relieved of the burden of incurable cases, and have thus had their usefulness considerably augmented.

In the portion of the report which refers to the general mortality of Ireland, a table is given, which shows the relation between the number of deaths registered and the number returned upon the census-papers for the seven years during which registration had continued. The registered deaths were 639,068, the number returned on the census-papers 579,734, being 59,334 less, or an error of 9.3 per cent. This seems to satisfy the Commissioners, as they say the "comparison will be found to give very favourable results as to the accuracy of the census returns". We cannot think that, when there is an error of 9 per cent., the results are favourable, especially as in some years the error is more than double this amount. We regret that for all these seven years the detailed tables are compiled from the less accurate returns and not from the registration returns, so that all the deaths are underestimated to the average extent of 9 per cent. at least; and, allowing for the probable deficiencies in registration, we cannot estimate the error at less than 10 per cent.

The grouping of diseases in the tables is of such a confused character that we shall not attempt to lay any conclusions derived from the totals of each group before our readers, but confine ourselves to some of the more important diseases individually.

The mortality from *small-pox* has steadily decreased in the last four decades, the deaths returned having been for that ending 1841, 58,006; for 1851, 38,275; for 1861, 12,727; and for 1871, only 4,113; being respectively 1 in 20, 1 in 36, 1 in 64, and 1 in 187 of the deaths from all causes. In the year 1870, there were only 163 deaths from small-pox returned. The greatest prevalence of small-pox was in the years 1863, 1864, and 1865; especially in 1864. The disease has been much more prevalent in Connaught than in any other of the four provinces. Thus the death-rate from small-pox for the decade was in Connaught, 10.7; Munster, 8.1; Ulster, 7.0; and in Leinster, 5.1 per 10,000 of annual average population. In other words, vaccination has been less common and possibly inoculation more frequent, just in proportion as we recede from the great centres of active life and education.

The mortality from measles is stated to have decreased, while that from scarlatina has as steadily increased. Although the Commissioners seem to think that the symptoms of measles are popularly so well known that but few mistakes could have occurred, yet we rather incline to the opinion, that the apparent decrease in measles and increase in scarlatina is, in a great degree, owing to a more accurate recognition of the difference between the diseases by the non-medical public, from whom the census-returns are collected. It is pretty clear, however, that there is a very considerable increase in the mortality from scarlatina, and this, the report states, is "almost exclusively in civic districts". The mortality from whooping-cough has diminished. Dysentery and diarrhoea have decreased.

Only one cholera epidemic is recorded in the decade, and that the slight one of 1866, causing together, with "sporadic" cases, 2,923 deaths during the decade; of which, 2,062 occurred in Leinster, 486 in Munster, 311 in Ulster, and only 64 in Connaught.

The class fever, comprising all forms of continued fever "returned on the census-forms", shows a marked diminution. To show in what an extraordinary way classification has been carried out, we find gastric fever (which most nosologists know *generally* means *enteric* fever), included among the diseases of the digestive organs. Such being the case, we need scarcely say the figures in the fever class are even more incorrect than the others contained in this volume. We think it scarcely necessary to consider in detail the other forms of disease mentioned in the returns, as very little reliance can be placed on their accuracy, and as they throw but little light upon the state of the general health of the Irish people.

An elaborate report on the sanitary condition of Dublin is included in the report. As this report on Dublin is much inferior to that to be found in Thom's *Directory* for the present year, page 1,408, *et seq.*, we think it unnecessary to make further remarks thereon. We heartily endorse the concluding remark of the Commissioners, that they conceive "that, in future census compilations, it will not be necessary to publish so many tables of deaths and to report thereon", in consequence of the general registration of deaths in Ireland under the Act of 1864. If the Commissioners had availed themselves of the registration-returns which already exist, they might have, even in 1871, found that it was not "necessary to publish so many tables of death and to report thereon", and might have furnished a much more accurate and valuable report than they have done.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

The Sewage of Paris.—Increased Duration of Life in France.—Prize of the Academy of Sciences.

To render a city salubrious and to maintain it so, is a problem that has tried the wits of many a sanitarian and engineer, particularly when that city is densely populated, as are London and Paris, Vienna, St. Petersburg, etc. M. Dubourg, a civil engineer, lately submitted to the municipal council of Paris a plan, according to which the contents of the sewers and latrines may by means of canals be emptied into the sea. But this has not been received with much favour, owing to the enormous expense it would involve, and the great objection that would certainly be made against it by the inhabitants of the tracts through which the offensive matters would pass. M. Charbonneau, another civil engineer, proposes to suppress all cesspools and to have the refuse matter carried away out of the walls of the city. This system already exists in Paris; but the advantage that M. Charbonneau's plan has over it consists in the refuse matter being removed in a dry state, to which it is reduced by a peculiar apparatus invented by this gentleman, as well as by the action of chemical agents. This matter would thus lose none of its properties as manure, and would realise an annual revenue of nine or ten millions of francs; but the enterprise itself would cost at least fifty millions of francs, which the financial state of the country cannot at present afford. Moreover, I do not see in what respect it is an improvement on the present system, which, to say the least, is one of the most objectionable ever conceived by man, and the only wonder to me is that, in spite of these repositories of human dejections, Paris can, in a sanitary point of view, bear comparison with any other city in the world. There is, moreover, another serious objection to M. Charbonneau's plan; it deals simply with the solid portion of the dejections, but he does not state how the liquid portion is to be disposed of. From what I can gather from his report, he would have the liquid dejections emptied into the sewers, but he forgets that these may contain elements even more deadly than the solid parts, and that they may thus disseminate their dire influence as they pass along the sewers. To obviate this, the use of disinfectants has been proposed by others interested in the matter, but these have been found utterly useless and too expensive. It is, however, high time that something should be done in this direction, for the present system of removing the dejections is not only most offensive to the olfactory nerves, but cannot be free from danger to the public health. For the information of those who have not resided any time in Paris, I may here state, that the contents of the privies are emptied into cesspools, with which the former communicate directly by means of pipes. The cesspools are generally sunk in the courtyard, but, in the older houses, they are under the building itself. These cesspools are of good masonry and perfectly waterproof; and, as soon as they are full, the filth is pumped up into huge casks and carted away outside the walls of the city. Here the matter is made to dry, and, after having been reduced to powder, is sold as manure under the name of "poudrette". The operation of carting off the contents of the cesspools is always performed about midnight, so as to render it as little offensive as possible; but, notwithstanding this, I consider the whole system defective, and not to be compared with the system of sewage in London. The sewers in Paris are perfect models of their kind, but the difficulty is, how to dispose of their contents so as to render them not only innocuous but of some utility.

Flourens, the celebrated French physiologist, and others, have expressed the opinion that, constituted as man is, his tenure of life in this world is more than a hundred years. Although Flourens himself did not live much beyond three score years and ten, it would seem he had some grounds to justify such an assertion, from the number of centenarians we hear of on all sides. We are not prepared to say that human longevity has been really increased; but one thing is certain, that, within the last fifty years at least, the average duration of human life has been considerably on the increase; for, according to a statistical report recently published, the mean average in France, which in 1817 was 31 years and 3 months, has attained the respectable standard of 39 years and 8 months for each individual inhabitant. Indeed, for the last five or six centuries the average duration of human life has been slowly but steadily increasing; and this may be attributed to a combination of circumstances: 1. The intelligent extension and application of the principles of the healing art, including vaccination; 2. The general extension of wealth and comfort; 3. A better understanding of

the principles and advantages of public and private hygiene; 4. The dissemination of elementary instruction.

The Academy of Sciences has awarded to M. Paul Bert, Professor at the College of France, the biennial prize of 10,000 francs (£400) for his researches in physics and mathematics.

BIRMINGHAM.

[FROM OUR OWN CORRESPONDENT.]

Epidemics.—The Medical Staff of the Workhouse.—Out-patient Reform.—Children's Hospital.—Medical Education of Women Question.—Cases of Tetanus.—The Institute.

DIARRHŒA may be said to be always prevalent here. Last year, it caused almost as many deaths as small-pox—more than 600—but, for the last two or three weeks, it has been epidemic, especially amongst children. It has been usual to blame the water-supply, and this became a strong point, and rightly enough, against surface-wells in the recent Parliamentary proceedings which have given to our corporation the control of the waterworks; but, in our experience, the open "middens", which are still numerous, are a much more direct source of mischief, especially under present climatic conditions. The small-pox epidemic is reduced at length to small proportions. Only two new cases were returned last week, and seventeen remain in our wards. The total mortality in the last four years is given as 1,300 out of 8,000 cases.

In the Birmingham Workhouse there are nearly 2,000 persons. The average weekly number of sick, including bed-ridden, is over 600. There are, in addition, 200 lunatics; there are three or four births weekly, and about ten deaths. There are about 100 admissions per week, each one to be examined and classed; and a proportionate number of discharges to be certified. Will it be believed that, for all the work and responsibility represented by these figures, there is only one medical officer? A few advanced thinkers are beginning to inquire how much longer such an injustice may continue. We believe it is not generally known that the Local Government Board pay half the medical salary, and undertake to pay half of that of any fresh medical officer required.

In a recent number of the JOURNAL (August 21st) is an account of the efforts of the managers of the Great Northern Hospital in London towards the reform of their out-patient department. The somewhat similar action desired by the authorities of the Queen's Hospital, and referred to in my last letter, was hindered at the public meeting called to consider the question by the action of a "working men party", who objected to give up the ticket system, and were indignant at the idea of an inquiry and the payment of a "registration fee". There can be little doubt, however, that the public opinion of the large majority of subscribers is in favour of a free system with inquiry; but, in order to conciliate, the decision of the points at issue was adjourned until November. It has been remarked that, if this important reform be really frustrated by the votes of working men who object to an independent inquiry into the circumstances of applicants, the result to the subscription list will be disastrous. The public like to be assured that they are not imposed upon, though they will seldom take the trouble to assure themselves, and to forbid inquiry has an ugly look. We think, moreover, that the profession has equal, if not greater, right and interest than the public to insist upon inquiry whether certain patients are real objects of charity or no. A case in point may be found in the *Medical Times and Gazette* for August 28th. The income of the patient's mother was over £1,000 a year, and the patient's own £300. The Birmingham Ear and Throat Infirmary has held its annual meeting, and reported financially that its subscription list was diminishing. It was said by one of the speakers that the "criterion of the usefulness of a charity was an increasing subscription list", and his proposition was to make this institution also free and abolish privileges; but the question was reserved for consideration.

At the Children's Hospital, extensive improvements have been set on foot. The out-patient hall is to be enlarged, a separate room is to be built, and a separate officer to be appointed to see new cases and separate infectious ones. At the in-patient department, land has been bought for new and separate fever, croup and diphtheria, and quarantine wards, which, to judge from plans before us, will really be models of hospital construction in every sense. An appeal for £6,000 has been addressed to the public, and a large portion of this sum received, including a donation of £1,000 *in memoriam*, so popular is a well managed charity.

An influential deputation, including the mayor and several councillors and clergymen, have requested an interview with the Council

of the Queen's College on the subject of possible facilities for the medical education of women.

Amongst interesting cases recently observed at the Queen's Hospital are two of traumatic tetanus treated by hydrate of chloral and diaphoresis. The first followed a compound fracture of the hand, the second of the elbow, with exposure of the ulnar nerve. The former recovered, but the latter proved fatal in twelve days. Both cases were in Mr. Jordan's practice. At the same hospital, Mr. Priestley Smith has been unanimously appointed as ophthalmic surgeon, after having conducted an Eye Department for some time past on a temporary basis, which has proved a valuable acquisition to the hospital resources.

I understand that the programme of the Medical Institute is being well developed. A very good nucleus of a library has been formed, and will, it is hoped, be made available in rented rooms before very long, and without waiting for a permanent location.

ASSOCIATION INTELLIGENCE.

NORTHERN COUNTIES (SCOTLAND) BRANCH.

THE annual meeting will be held in Gray's Hospital, Elgin, on Saturday, September 18th, at 12.30 P.M.; Dr. VASS, of Tain, President-elect.

The following papers have been promised.

1. Address by the President-elect.
2. Cases of Monstrosities. By Dr. Duff.
3. The Sanitary Condition of our Villages and Rural Districts. By Dr. R. S. Turner.

Luncheon in Gordon's Arms Hotel, at 2.30.

J. W. NORRIS MACKAY, M.D., *Hon. Sec. and Treasurer.*
Elgin, September 8th, 1875.

SOUTH MIDLAND BRANCH.

THE autumnal meeting of the above Branch will be held in the Council Chamber of the Guildhall, Northampton, on Wednesday, September 22nd, at 2 P.M.; HENRY TERRY, Esq., President-elect.

Gentlemen intending to read papers are requested to forward their titles forthwith to Dr. Bryan.

J. M. BRYAN, M.D. } *Honorary Secretaries.*
W. MOXON, Esq. }

Northampton, September 1st, 1875.

SOUTH EASTERN BRANCH: EAST SUSSEX DISTRICT.

THE next meeting for the above District will be held on Wednesday, September 22nd, at the Burlington Hotel, Eastbourne, at 3.30 P.M.; T. F. SANGER, Esq., of Alfriston, in the Chair.

Dinner at 5.30 P.M. Charge, 5s., exclusive of wine.

Notice of intended communications is requested by Tuesday, the 14th instant, in order that they may be inserted in the circular convening the meeting.

THOMAS TROLLOPE, M.D. Cantab., *Hon. District Secretary.*
35, Marina, St. Leonards-on-Sea.

SHROPSHIRE SCIENTIFIC BRANCH.

THE annual meeting of the above Branch will be held in the Museum, Shrewsbury, on Wednesday, September 22nd, at 2 o'clock; WILLIAM MATHEWS, Esq., President-elect.

Dinner at the George Hotel at 5 o'clock, exact time.

Gentlemen intending to read papers are requested to communicate with the Honorary Secretary.

SAMUEL WOOD, *Honorary Secretary.*
Shrewsbury, September 8th, 1875.

NORTH OF ENGLAND BRANCH.

THE autumnal meeting of this Branch will be held at the Queen's Hotel, Sunderland, on Thursday, September 23rd, at 3 P.M.; S. E. PIPER, F.R.C.S., President.

The following papers have been promised.

1. Dr. J. W. Eastwood. The Prevalent Practice of Advertising Medical Works in the Non-Medical Press.
2. Dr. C. Gibson. Certain Forms of Blood-Diseases.
3. Dr. G. Y. Heath. Some of the less noticed complications of Prostatic Disease.

4. C. S. Jeaffreson, Esq. Remarks on some of the recent Advances in Surgical Pathology and Therapeutics.

5. Edward Jepson, jun., Esq. The Mechanical Treatment of Intestinal Obstruction.

6. Edward Jepson, jun., Esq. Case of Tumour of the Neck.

7. Dr. Byrom Bramwell. Report of a Case of Hydatid Disease of the Liver.

8. Dr. Ayre Smith. Report of a Case of Femoral Aneurism; also, exhibition of patient.

9. G. B. Morgan, Esq. Case of Removal of Cystic Tumour (Hydrocele?) of Neck, treated Antiseptically.

10. E. A. Maling, Esq. Report of a Case of Femoral Aneurism, treated by Pressure.

Gentlemen who are desirous of reading papers will oblige by communicating with the Secretary.

Dinner at the Queen's Hotel, at 4.45 P.M. Tickets, exclusive of wine, seven shillings and sixpence.

G. H. PHILIPSON, M.D., *Honorary Secretary.*
Newcastle-upon-Tyne, September 14th, 1875.

MIDLAND BRANCH.

A MEETING of the above Branch will be held at Matlock Bath, on Thursday, September 23rd. Several papers have been promised. Further information in next week's JOURNAL.

F. W. WRIGHT, *Honorary Secretary.*
Derby, September 1st, 1875.

SOUTH WALES AND MONMOUTHSHIRE BRANCH.

THE autumnal meeting of this Branch will be held at Tenby, on Thursday, September 30th.

Nomination-papers must be sent to one of the undersigned by the 9th instant.

ANDREW DAVIES, Swansea. } *Hon. Secs.*
ALFRED SHEEN, M.D., Cardiff. }

September 2nd, 1875.

YORKSHIRE, AND EAST YORK AND NORTH LINCOLN BRANCHES.

It having been decided by the respective Councils of the above Branches that the autumnal meeting shall be held conjointly at the York Museum on October 13th, 1875, members of these Branches intending to read papers or cases are requested to forward the title to either of the Secretaries on or before the 27th instant, so that a notice thereof may be included in the circular convening the meeting.

Dinner at the Station Hotel at 5 o'clock. Tickets (exclusive of wine) 7s. 6d. each.

W. PROCTER, M.D., York, } *Hon.*
R. H. NICHOLSON, Hull, } *Secs.*

York, September 18th, 1875.

WEST SOMERSET BRANCH.

THE autumnal meeting of this Branch will be held at the Railway Hotel, Taunton, on Thursday, October 14th, at 5 o'clock.

The following question has been settled by the Council as the one on which members should be invited to express their opinion at the said meeting after dinner:—"Is the disuse of Bloodletting in the Treatment of Disease in accordance with the principles of Pathology?"

Dr. Cordwint proposes to read a paper "On Tissue-Change in Fevers".

Dinner (on the table at 5 o'clock), 4s. a head, exclusive of wine.

W. M. KELLY, M.D., *Honorary Secretary.*
Taunton, September 16th, 1875.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT MEETING.

A SPECIAL meeting, to consider the adjourned discussion as to the foundation of an Ethical Committee for the District, was held in the Library of the County Hospital, Canterbury, on September 2nd; Mr. WACHER in the chair.

The following resolutions were introduced by Mr. REID, and carried.

1. That subjects intended for the consideration and report of the Committee shall have relation only to the general interests of the profession in the district; and all subjects in any wise having a mere personal or individual character shall be excluded.

II. That any subject to be considered shall be proposed, seconded, and approved of by a majority of a general meeting, to which notice of it has been given beforehand. When thus approved, the Committee shall, as soon as may be convenient, consider it and report to another general meeting, which shall deal with it as the majority agree.

III. When such report of Committee has been confirmed by a general meeting, it shall be considered as a general recommendation for the members of the district.

IV. The Committee shall be composed of seven members, selected, as far as possible, from the several places at which the meetings of the district are ordinarily held, and shall be elected annually (after its first appointment), at the meeting when the arrangements for the ensuing year are made.

V. That the Committee be now formed, and that the following gentlemen be requested to act upon it: Dr. Wilks (Ashford), Mr. Reid (Canterbury), Mr. Rigden (Canterbury), Dr. Parsons (Dover), Dr. Bowles (Folkestone), Mr. Thornton (Margate), and Mr. Hicks (Ramsgate).

It was then resolved that these resolutions be forwarded to the Executive Council of the Branch for their approval.

Mr. REID proposed, and Mr. OSBORN seconded, that the Committee take into consideration—

1. The formation of a Medico-Chirurgical Tariff, to be recommended to the District.

II. To consider and report on the usages and customs of attending funerals.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

GREAT confusion having been caused at various times from the existence of two Sedgley Local Boards, Upper and Lower, the name of the latter has been altered to Coseley.

The salary of Dr. John F. W. Tatham, Medical Officer of Health for the Salford Urban Sanitary District, has been increased from £400 to £500 *per annum*.

SUPERANNUATIONS.—Mr. William P. Cullen, late medical officer for the St. Luke District, Holborn Union, has been granted £70 *per annum*, and Mr. William Stedman, late medical officer for the Bedhampton and Hayling Districts, Havant Union, £40 *per annum*.

PAYMENT FOR SICKNESS RETURNS.

SIR,—I have received a letter from the Local Government Board, dated September 13th, 1875, acknowledging my report, in which the following statement occurs, which will, I think, be received with satisfaction, both by district medical officers and medical officers of health, as it points out the wish of the Local Government Board to interpret the new Public Health Act in a just and liberal spirit.

“Adverting to your remark on page 28 of the Report, that there seems to be no means in the present law of giving a district medical officer remuneration for information respecting sickness in his district, which he may furnish to the medical officer of health, I am directed to state that the Board consider that it is competent for urban sanitary authorities, if they think proper to do so, to enter into an arrangement to pay district medical officers reasonable remuneration for supplying the medical officer of health with information which he requires for the efficient discharge of his duties.”

The portion of my report which has elicited this decision is as follows.

Prevalent Diseases.—“I can only speak on this subject from the small amount of personal observation I have had since May, and from the Registrars' and Union Returns, the medical men in this town refusing to give me any information. This is from no want of courtesy to myself, but they say that, from a matter of principle, they ought not to give any assistance or do any work beyond their contract as district medical officers without increased pay, and argue that, as the district subregistrars are allowed payment for information of death to the medical officers of health, so ought they to be remunerated as district medical officers. I regret there seems to be no means in the present law of giving these district medical officers any extra remuneration. The 1875 Act, sec. 6, provides that the Local Government Board may appoint district medical officers to assist the medical officer of a

constituent district, and that he should receive remuneration for so doing, but I fear this will only apply to large conjoint districts.”

Feeling that the refusal of the district medical officers, both in the urban and rural sanitary districts, was purely a matter of principle, in which I myself sympathised, I thought it right to mention the matter in my report, and it gives me much pleasure to find that it has elicited so important a decision.—Yours faithfully,

HORACE SWETE, Medical Officer of Health,
Droitwich Rural and Urban Sanitary Districts.
5, Newbold Terrace, Leamington, September 14th, 1875.

THE IRISH POOR-LAW MEDICAL OFFICERS AND THE PUBLIC HEALTH ACT OF 1874.

THE great demand upon our space at this time of the year has up to the present prevented us from referring to the very important question of the position and pay at present allotted to the Irish Poor-law medical officers under the Public Health Act of 1874. Great things were expected from the working of the Irish Public Health Act of 1874. All the advocates of sanitary reform in Ireland, who at the same time held the interests of the Poor-law Medical Service and the public in view—for both these interests are identical—advocated the utilisation of the well-organised Poor-law Medical Service as the leading feature in any sanitary organisation which might be adopted for Ireland. The Government adopted the view that Poor-law and Public Health services should be the same; and the medical officers of the service, with few exceptions, cheerfully accepted the position advocated by men whom they knew to be their best friends, and compulsorily imposed upon them by Parliament. While the dispensary medical officers of Ireland accepted these duties without a murmur, they did so believing the Government would honestly and sufficiently remunerate them for their work. What, therefore, are the surprise and disappointment of the medical officers to find that Government, having obtained their services and power to remunerate them for those services, deliberately fixes salaries which, for the most part, are merely nominal, when compared with the duties to be performed! Many complaints and protests were made to Sir M. Hicks-Beach, the *nominal* President of the Irish Local Government Board, but all in vain. The Board pursued the extraordinary course of issuing an order that the maximum salaries of the officers should be *one-fourth* of their present salaries for their duties as dispensary medical officers. This means that the average salary would be about £25 *per annum* as a maximum. Now, what can be expected from a Public Health Service where the salaries are paid at such a nominal rate? Our answer is distinctly, “Nothing”. The Poor-law officers have been for many years underpaid for their attendance on the sick poor. Their payments as registrars of births and deaths have been merely nominal—namely, *one shilling* for each registration; whereas in England the registrar is entitled to half-a-crown for each twenty births and deaths in every quarter, which, if carried into effect in Ireland, would amount to £12 a year additional salary. In vaccination, the same policy has been followed, and but *one shilling* is allowed for each vaccination.

The Irish Public Medical Service, having conducted itself in an exemplary and patient manner, and having shown a good and at the same time humble public spirit in the carrying out of registration and vaccination for the Queen's shilling, and having taken care of dangerous lunatics “without fee or reward” for a considerable number of years, is rewarded for its long-suffering by being paid at the same rate for its sanitary services. How has this payment been fixed? It is well that a Blue-book—namely, the Report of the Irish Local Government Board for 1874-75—has furnished us with the information; otherwise we might never have found out. It seems that on October 14th, 1874, the Irish Local Government Board, having been tormented by various questions from local authorities, medical officers, Irish medical corporations, and others, discovered suddenly that it must ask the Treasury for money to pay salaries to the officers of the new Public Health Service. Accordingly, a letter was written from the Local Government Board in Dublin to the Treasury in London, asking for the sanction of the Treasury for the nominal salaries proposed, and for a grant of some £20,000 as the Treasury contribution to the expenses of the working of the Irish Public Health Act. The result was, that the Treasury *took no notice* of the communication. Then came an extraordinary roundabout pulling of red tape and writing of letters, and pounding of the political buffer known as the Irish Government, the smooth front of which is situated in Dublin Castle, and the more intricate portions of its machinery in the Irish Office in London. The result of all this work was, that on November 23rd, 1874, the Secretary of the Treasury declared that the proposed

increase of salaries "does not strike my lords as exorbitant"; and, after more redtape and more action of the Irish Government buffer, on February 5th, 1875, months after the Act had come into force and the appointments had been made, the Lords of the Treasury "confirmed their assent, which they understood to be already given". Now, we submit that the approving of salaries because "not exorbitant", and the ignorance of the Treasury as to whether those salaries had or had not been already sanctioned, show an amount of carelessness of the public welfare which is quite inexcusable, and well calculated to promote the discontent which has arisen in consequence of the maladministration of the Irish Public Health Act.

Dr. O'Leary, the member for Drogheda, brought the matter under the notice of Parliament, and, we must say, met with but an evasive answer from the Solicitor-General for Ireland, who, we presume, was instructed by the office of the Dublin Board. The Solicitor-General said that the Act had only been in operation for two months. We at first thought there was an error in reporting; but, on inquiry, we find this really was the statement of Mr. Plunket; and of course he believed his statement to be correct. The fact was, the Act had been in operation for nearly a year. Mr. Plunket also tried to cast the blame of the small salaries upon the local, not the central authority; and, as a proof thereof, stated that the Local Government Board had increased some salaries which had been fixed too low by the local authorities. Yes, so the Board did; but the Board also *reduced* some salaries which, in our opinion, were low enough before. This the Solicitor-General probably did not know, as he has no connexion whatever with the Local Government Board, which he was defending. Unless the Government immediately take measures to remove the grievances of the Irish Public Health and Poor-law Medical Service, that service, which has long been the most efficient civil medical service in the world, will gradually dwindle away, and become a reproach instead of a pride to the British Government.

MR. J. A. WOLSELEY.—In the metropolis, the medical officers of health are appointed by the district boards and vestries, and are removable at their pleasure under the 132nd section of the Metropolis Local Management Act. In the provinces, under the Public Health Act (1872), the medical officer of health in urban sanitary districts is appointed by the local authority, which may be either the town council of a borough, a body of improvement commissioners, or the local board of a local government district; in rural sanitary districts, he is appointed by the boards of guardians. There are certain exceptions and qualifications, which do not affect the answers to your questions. The medical officer of health must be a legally qualified medical practitioner, and he is appointed for a period not exceeding five years. A medical officer of an union may be appointed medical officer of health, and the medical officer of health may hold two or more districts. The Local Government Board can exercise authority where a portion of the salary is paid out of moneys voted by Parliament.

MR. HAILEY AND THE NEWPORT PAGNELL UNION.

SIR,—Being compelled on one occasion to put a question to a poor fellow, an applicant for a charity, "Have you ever been in a workhouse, or taken parish relief?" the answer being in the affirmative, and the candidate disqualified, I was struck with his reply: "It is a hard thing, sir, not to be able to take relief from your richer neighbour, when sick, without being degraded as a pauper. The man who has been in prison for a crime is not so treated."

I think the few remarks I am about to record would convince my poor friend that he is not the only person maltreated by this degrading system; but that the man who, for a trifle, undertakes to relieve the sufferings of his fellow creature, is treated much worse. For some years (more than a quarter of a century), I held the office of medical officer to the Newport Pagnell Workhouse, and two districts. The former office I resigned in 1874, owing to some disagreement between the Local Government Board and myself respecting the keeping of the medical relief book. On February 24th, 1875, being board day, and Mr. Henley present, a relieving officer sent a paper to the Board to the effect "that he had on several occasions met the public vaccinator, and he had promised to forward him a certain duplicate certificate or certificate, but he had not done so; and he could summon him, and obtain a fine of twenty shillings." The Board (it is stated, at the advice of Mr. Henley) directed him to summon the public vaccinator; and, on the 25th, I received a letter from the clerk to that effect. I immediately called upon that gentleman, and explained the case; and he assured me, if I sent the lost certificate by that evening's post, he would write and tell the officer, as he now had all he required, and that he should not get the summons signed until after the Board met again, and the public vaccinator would explain the matter to the satisfaction of the Board. On the 26th, the officer received the certificate and the clerk's letter. Late on the 27th, he went to a magistrate, a friend of mine, and got the summons signed. On March 1st, at 10 A.M., a policeman served the summons upon me. I then called upon the clerk, and stated that I could not get my solicitor in so short a period, viz., between 11 A.M. on the 1st, and 11 A.M. on the 3rd, when the magistrates met. He, therefore, wrote to the officer again, and told him he was not to come with his witnesses on the 3rd; the case would be postponed to the next bench day, to enable the public vaccinator to obtain advice. I heard, just as I was leaving town on the morning of March 3rd, that the officer was at the bench with his witnesses; and rather an insolent letter addressed by him to the clerk to the board of guardians was placed in my hands. The result was that, in my absence, he got his case heard, and I was fined £2. This case was not a solitary one of the kind; and it was the common conversation among persons conversant with union matters in this locality, that the relieving officer was placed be-

fore the medical officer. After this officer insulting me, and actually treating the clerk to the board in the same manner, I resigned all my offices so far as he was concerned; and, on March 24th, wrote a letter to the board of guardians, based upon documents in my possession, complaining of these and other insults, and politely telling the board that I considered these the *fons et origo mali*. The truth was too apparent; for, after a few minutes' consultation, they came to the conclusion that the Local Government Board should have one copy, and the relieving officer another, of my letter. On April 10th, I received the following letter from the Local Government Board, which I will give *verbatim*.

The Board observe with regret the spirit of hostility you have displayed towards the guardians, your employers, in impeaching their conduct as a public body; and, having regard to the highly improper tone of your letter to the chairman, the Board cannot avoid the conclusion that the amicable arrangements that should subsist between the guardians and each of their officers cannot, in your case, be maintained, and therefore request you to place the resignation of your office in the hands of the guardians.

This letter, observed a critic, is amusing from the fact that a public body send down one of their staff to direct an inferior to insult a superior officer; and, when the latter kicks, they tell him to resign on account of a want of brotherly feeling. Upon the receipt of this letter, it was my intention to resign; but, at the same time, I received an answer to a letter sent by me to the Chairman of the Board of Guardians, who said: "I gladly accept your disclaimer that you intended nothing offensive to me personally in your letter of the 24th of March." Under these circumstances, my solicitor advised me (as many of the guardians were my friends) to write a letter of explanation to the Local Government Board. This I did; and although they at first refused to change their decision, when I positively refused to resign on the ground that I had not violated the consolidated order, they sent, on June 6th, my letter to the Newport Board of Guardians for their consideration. I deputised a gentleman to inform the Board it was not my intention to hold the office, but to resign as soon as the subject was satisfactorily settled. The Board met on June 16th, no notice of the meeting having been given, and only sixteen or seventeen guardians being present (out of sixty). The subject was put to the vote, when fourteen voted, six being for a recommendation in favour of my letter, and eight against it, or for not interfering. On June 17th, I received a letter from the clerk of the board saying that "he was instructed by the guardians to write to the Local Government Board to inform them that the board declined to make any recommendation on my correspondence." On the 20th, I wrote to the Local Government Board, stating what took place at the board on the 16th, and asking them "to allow a full meeting of the guardians to consider my reply, and that due notice be given of such meeting to each guardian; and that I made this application at the request of a great number of the said guardians." On the 22nd, I heard from them no mention of my letter of the 20th being made; that, "as the Newport Board of Guardians had declined to make any recommendation on my letter, they had directed an order for my removal to be issued under seal." On the 26th, I heard again that they had received my letter of the 20th, "but declined to reopen the case to which it referred"; and, on the 27th, the order for my removal came by post.

Dr. Lush, M.P., at the advice of Dr. Joseph Rogers, presented a petition to Parliament based on the foregoing remarks, and asking for further inquiry; and, on July 26th, Mr. Sclater-Booth stated in the House of Commons that "Mr. Hailey was not removed solely for writing the letter complained of; but his conduct had been the subject of complaint for years past." Now, with regard to this excuse, on the part of the local inspectors, after being told I must resign on account of the "improper tone of my letter to the chairman," I can most positively assert that, in the office I was called upon to resign, I never received a single complaint of my conduct, professional or otherwise, from the board of guardians or Local Government Board during the whole twenty-seven years I held office; and, in the office I resigned in 1872, nothing but the dispute respecting the keeping of the medical relief book, recorded in the early part of this letter. My conduct during the time I held office can be summed up in a few words. 1. I suggested and obtained a new fever-ward for the workhouse, which now is the only part of the building capable of accommodating the sick. 2. When I found, after twenty years of service, that I was worse paid than any of my neighbours, after twelve months' labour I succeeded in obtaining an increase of salary, which I hope my successors will enjoy. 3. I strongly opposed a proposed scheme of redistribution of the medical districts, because I knew it was not done to benefit the poor or the profession, but simply to place the union (or the principal part of it) in the hands of one officer. This event has since taken place; and the poor, in the place of having a medical man within reach, have to go five or six miles for one, and a journey of ten miles to obtain their medicine. 4. I wrote a letter, based upon facts, to prove that the medical officer was not treated as a gentleman; that letter my opponents have strongly opposed my defending. In conclusion, I beg to assure my late union medical brethren that until they write and obtain a Court of Appeal in cases of unjust or oppressive conduct on the part of boards of guardians and the Local Government Board, their situations are no better and less secure than those of their domestic servants, the Local Government Board having the discretionary power given them by Parliament to remove any paid officer whom they may deem unfit; and law has decided that there is no appeal against their decision.—I am, sir, yours truly,

Tickford, Newport Pagnell, August 16th, 1875.

HAMMETT HAILEY.

POOR-LAW MEDICAL APPOINTMENTS.

- LATTEY, Arthur, M.R.C.S. Eng., appointed Medical Officer and Public Vaccinator for the Southminster District of the Maldon Union, *vice* T. C. Wigg, M.R.C.S. Eng., resigned.
- LEACROFT, John William, M.B., appointed a Public Vaccinator for the Alcester Union, *vice* J. H. Hiron, M.R.C.S. Eng., resigned.
- PALMER, T. S., M.R.C.S., appointed Medical Officer for the Mortlake District of the Richmond (Surrey) Union, *vice* A. Crichton, L.R.C.P. Ed., deceased.
- SMITH, F. A., M.D., appointed Medical Officer to the Workhouse of the Mere Union, *vice* Wilton Provis, L.R.C.P. Ed., deceased.
- STAFFORD, John Francis, L.R.C.P. Ed., appointed Medical Officer and Public Vaccinator for No. 4 or Widdleham District of the Chertsey Union, Surrey, *vice* E. Kough, M.B., resigned.
- STEDMAN, Frederick, M.R.C.S. Eng., appointed Medical Officer for the Castleton District of the Chapel-en-le-Frith Union, *vice* A. O. Haslewood, M.R.C.S., resigned.
- STONE, Valention, F.R.C.S. Eng., appointed Medical Officer and Public Vaccinator for the Parish of Fettercairn, *vice* W. Stephen, M.D., resigned.

OBITUARY.

J. M. GILLESPIE, M.D.

At Accrington, on the 7th instant, died John Morris Gillespie, a gentleman very much respected in the town. He was born in Glasgow in 1826, took his M.D. degree in 1850, and L.R.C.S. in Edinburgh the same year. He had been established in practice in Accrington since 1860, and at the time of his death was union medical officer, police doctor, and medical officer of health. The members of the Local Board, Poor-law guardians, medical profession, police, etc., paid their last tribute of respect by attending his funeral on the 9th instant, his remains being interred in the Accrington cemetery. The cause of death was congestion of the brain.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, September 2nd, 1875.

Angove, William Thomas, Mount Pleasant, Cambourne
Grimwood, Harry Charles, Stowmarket, Suffolk
Lenden, Edwin Harding, Maidstone, Kent
Whitmore, William Tickle, West London Hospital
Wickham, Henry, Tetbury, Gloucestershire

The following gentlemen also on the same day passed their primary professional examination.

Boodle, George Adolphus, St. Bartholomew's Hospital
Boswell, Alexander, St. Bartholomew's Hospital
Nundy, Edward, University College
Paul, Reginald, Middlesex Hospital
Webster, John, University College

The following gentlemen passed their examination in the science and practice of medicine and received certificates to practise, on Thursday, September 9th, 1875.

Dowding, Alexander William Woodman, Leighton Buzzard
Duke, Herbert, 321, Clapham Road
Mapei, Luigi Vincenzo, Golborne, Lancashire

The following gentlemen also on the same day passed their primary professional examination.

Baker, Thomas, St. Bartholomew's Hospital
Tweedale, James Taylor, Owens College, Manchester

MEDICAL VACANCIES.

The following vacancies are announced:—

- BRISTOL GENERAL HOSPITAL**—House-Surgeon. Salary, £100 per annum, with board, lodging, and washing. Applications on or before the 23rd instant.
- BRISTOL HOSPITAL FOR SICK CHILDREN**—House-Surgeon. Salary, £100 per annum, with furnished rooms, coal, gas, and attendance. Applications on or before October 7th.
- CAISTON UNION**—Medical Officer and Public Vaccinator for the Tealby District. Salary, £50 per annum, and fees. Applications on or before Oct. 1st.
- COLCHESTER UNION**—Medical Officer for the Second District. Salary, £75 per annum.
- ESSEX and COLCHESTER HOSPITAL**—House-Surgeon and Apothecary. Salary, £80 per annum, with board and lodging. Applications on or before October 7th.
- GATESHEAD UNION**—Medical Officer for the Township of Winlaton. Salary, £25 per annum.
- HENLEY UNION**—Medical Officer for the Nettlebed District. Salary, £80 per annum.
- INVERNESS DISTRICT ASYLUM**—Assistant Medical Officer. Salary, £70 per annum, with bed, board, and washing. Applications on or before the 11th prox.
- LIVERPOOL DISPENSARIES**—Assistant Resident House-Surgeon. Salary, £108 per annum, with furnished apartments, coals, gas, and attendance. Applications on or before the 27th instant.
- LONDON HOSPITAL**—Assistant Obstetric Physician. Applications on or before the 27th instant.
- MEDICAL AID SOCIETY, Macclesfield**—Medical Officer.
- NORWICH DISPENSARY**—Salary, £120 per annum, with unfurnished residence and apartments.
- OSWESTRY INCORPORATION**—Medical Officer for the Llansilin District. Salary, £35 per annum.
- OWENS COLLEGE MEDICAL SCHOOL**—Sub-Curator of the Anatomical Museum. Applications on or before the 27th instant.
- PAISLEY INFIRMARY**—House-Surgeon. Salary, £80 per annum, with board. Applications on or before October 1st.
- PEMBROKE UNION**—Medical Officer for the First District.
- QUEEN'S HOSPITAL, Birmingham**—House-Physician. Salary, £50 per annum, with board, lodging, and washing. Applications on or before the 23rd instant.
- QUEEN'S UNIVERSITY, Ireland**—Professorship of Materia Medica. Applications on or before the 20th instant.
- ROYAL UNITED HOSPITAL, Bath**—House Surgeon. Salary, £60 per annum, with board and residence. Applications on or before the 22nd instant.
- ST. GILES-IN-THE-FIELDS and ST. GEORGE, BLOOMSBURY, Parishes**—Medical Officer. Salary, £250 per annum.

- ST. MARY'S HOSPITAL AND DISPENSARY FOR WOMEN AND CHILDREN, Manchester**—Medical Officer. Salary, £80 per annum, with board and residence. Applications on or before October 1st.
- SCARBOROUGH DISPENSARY and ACCIDENT HOSPITAL**—House Surgeon. Salary, £120 per annum, with apartments, coals, gas, and attendance. Applications on or before the 21st instant.
- SHEPTON MALLETT UNION**—Medical Officer for the Fourth District. Salary, £32 per annum.
- SOLIHULL UNION**—Medical Officer for the Yardley District. Salary, £17 per annum, and fees.
- SOUTHPORT INFIRMARY**—House-Surgeon. Salary, £100 per annum, with board, lodging, etc. Applications on or before the 23rd instant.
- STAINES UNION**—Medical Officer for the Shepperton District.
- STROUD GENERAL HOSPITAL**—House-Surgeon.
- TEWKESBURY RURAL HOSPITAL**—Assistant-Surgeon.
- WARWICK COUNTY LUNATIC ASYLUM**—Second Assistant Medical Officer. Salary, £100 per annum, with board, lodging, and washing.
- WESTMINSTER HOSPITAL**—Physician and Assistant-Physician. Applications on or before the 28th instant.
- WIMBORNE and CRANBORNE UNION**—Medical Officer for No. 1 and District and Workhouse. Salary, £85 per annum for No. 1, and £75 for No. 2, with £20 additional for the Workhouse. Applications on or before the 23rd instant.
- WORCESTER GENERAL INFIRMARY**—Physician. Applications on or before the 25th instant.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

PARKER, Adams, L.D.S.R.C.S., to be one of the Consulting Surgeon-Dentists to the Birmingham Dental Hospital.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTH.

BIRD.—On September 14th, at St. Leonard's Place, York, the wife of William Bird, M.D., of a daughter.

MARRIAGE.

HOLLINGSHEAD—MUCKLOW.—On Sept. 9th, at Holy Trinity Church, Coventry, by the Rev. F. Beaumont, M.A., Vicar, Francis Hollingshead, M.R.C.S. Eng. L.S.A. Lond., of Selly Oak, Birmingham, to Amy, second daughter of the late Thomas Mucklow, of Birmingham.

DEATH.

GILLESPIE, John Morris, M.D., L.R.C.S. Glasgow & Edinburgh, in his 50th year at Accrington, Lancashire, on the 7th instant, deeply regretted.

TESTIMONIAL.—Dr. John M. Atkin of Virginia, co. Cavan, has been presented with an address and a gold watch and chain upon his retirement, after practising for half a century.

The deaths of two centenarians are reported, one an inmate of the Yeovil Workhouse, John Chaffery, Bradley, Dorchester, who is said to have attained his 104th year, and the other a man named Egan belonging to Urna, on the banks of the Shannon, who is stated to have been 102 years of age.

COMMUNICATIONS, LETTERS, ETC., have been received from:—

Dr. John Whitmore, London; Dr. W. M. Kelly, Taunton; Mr. G. H. Darwin, Manchester; Dr. Church, London; Dr. Percy Boulton, London; Mr. T. Ralph, London; Mr. Thomas J. Denton, Bridlington; Mr. R. Eaton Power, Dartmoor; Mr. J. Sutherland, Berwick; Dr. James Ellis, California; Mr. John M. McDiarmid, Murtle; Dr. Joseph Coats, Glasgow; Dr. W. H. Jalland, York; Mr. Edward Bellamy, London; Dr. E. West Squires, Skipton; Dr. W. M. Dobie, St. Andrew's; Dr. J. Ashburton Thompson, London; Dr. S. W. Smith, Pershore; Dr. Goldie, Leeds; Mr. Hammett Bailey, Tickford; Mr. J. Vose Solomon, Birmingham; Mr. J. J. Charles, Belfast; Dr. W. Farr, London; Mr. Edward W. Thurston, Ashford; Dr. George Barkley, Prizington; Mr. H. C. Burdett, Greenwich; Dr. Horace Swete, Leamington; Mr. Adams Parker, Birmingham; Mrs. Carlil, London; The Medical Secretary of St. Thomas's Hospital; Mr. John Ingpen, London; Mr. J. O. Snowdon, Haltwhistle; The President of the Metropolitan Counties Branch; Mr. Thomas R. Fraser, Knutsford; Mr. A. D. Kettle, Aboyn; Mr. H. A. Allbut, Leeds; Mr. E. Honslet, Leicester; Dr. W. Procter, York; Mr. W. J. Haram Wood, Boston; Dr. R. J. Wolfe, Glasgow; The Registrar-General of Ireland; Dr. Cornelius B. Fox, Chelmsford; The Secretary of Apothecaries' Hall; Dr. H. Macnaughton Jones, Cork; The Registrar-General of England; Mr. Eastes, London; Dr. T. W. Grimshaw, Dublin; Dr. Bradbury, Cambridge; Dr. J. Milner Fothergill, London; Dr. Edis, London; Dr. T. Clay Shaw, Leaveness; Mr. A. Bender, London; Mr. T. H. Smith, Alcester; Dr. John M. Kendrick, Edinburgh; Mr. E. A. D. Akerman, Cheltenham; Mr. Sydney Chater, Boulogne; Dr. John Haddon, Manchester; Dr. De Havilland Hall, London; Dr. Patrick Heron Watson, Edinburgh; Our Dublin Correspondent; Dr. J. Crichton Browne, Wakefield; Dr. G. H. Philipson, Newcastle-upon-Tyne; Dr. Thomas Skinner, Liverpool; Dr. Septimus Gibbon, London; Mr. Thomas Jones Dyke, Merthyr Tydvil; A Correspondent; Mr. W. Fairlie Clarke, London; Mr. H. G. Howse, London; etc.

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.
 TUESDAY.....Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.
 WEDNESDAY..St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.
 THURSDAY....St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 3 P.M.
 FRIDAY.....Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.
 SATURDAY...St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M. and 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

FRIDAY.—Quekett Microscopical Club (University College), 8 P.M. Mr. James Fullagar, "On the Development of *Actinophrys Sol.*"

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.
 PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with Duplicate Copies.
 AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queena Street, W.C.
 CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.
 WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.
 COMMUNICATIONS respecting editorial matters, should be addressed to the Editor; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queena Street, W.C.

MR. SNOWDON (Haltwhistle, Carlisle).—We have not seen the pamphlet mentioned, and can therefore give no opinion on it.

MEDICAL CERTIFICATES.

SIR.—Will you kindly, in Answers to Correspondents, inform me on a point of law in reference to registration of deaths. 1. Is the district registrar entitled to give a burial order without a certificate? 2. Must not a certificate of death proceed from either a medical man or the coroner? 3. If it is contrary to law to give a burial order without medical or coroner's order, ought not such practice to be submitted to the notice of the Registrar-General? 4. On whom falls the disagreeable duty of reporting to the Registrar-General?—I am, sir, yours faithfully, X. E. G.
 * * * According to the Births and Deaths Registration Act (1874), one of three documents should invariably be produced to the officiating minister at each burial. A "certificate" from the local registrar, to the effect that the death of the deceased person has been duly registered; a "notification", also supplied by the local registrar, stating that he has received due notice of the death, and that it will be registered within fourteen days of the death; and, thirdly, an order from the coroner. A registrar is required to obtain a medical certificate of the cause of death in every case of death in which a registered medical practitioner has been in attendance during the last illness of the deceased; but in cases where there has been no medical practitioner in attendance, the registrar cannot refuse to register the death, unless he have reason to believe it to be a case which should be referred to the coroner. In cases where no medical certificate of the cause of death can be obtained, and in which an inquest appears to be, or is pronounced by the coroner to be, unnecessary, the particulars to be inserted in the "Cause of Death" column of the Death-Register are supplied by the ordinary informant of the death; the words "certified by", etc., are, however, then omitted. A "notification", which allows burial to take place previously to registration, can only be issued by the registrar if he have received a medical certificate of the cause of death, signed by a registered medical practitioner, although a certificate of registration can be issued even if registration have been completed without the production of a medical certificate. In many parts of Wales, and in some sparsely populated districts of England, a considerable proportion of deaths occur without any medical attendance; and the law, as it stands at present, directs that all such deaths must be registered, notwithstanding this fact, without the intervention of medical expert or coroner. It is much to be regretted that recent legislation on this subject should have left matters in so unsatisfactory a condition, as the cause of every death not certified by a registered practitioner should be inquired into by the coroner, or by some medical expert with analogous powers.

STUDENT.—Mr. Edward Bellamy's *Text-Book of Surgical Anatomy* is, we think, a very good one.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Powke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

OFFENSIVE DISCHARGE FROM CANCER.

SIR,—In reply to a query by "Triceps" in the JOURNAL of August 28th, as to the best deodorant in cases of cancer, I would strongly recommend the use of "terebene", which not only deodorises effectually, but substitutes a smell of pine-wood, which is at once pleasant and refreshing. The terebene may be used as a wash, or as a covering to other dressings. I have found it the greatest comfort in many cases of infectious disease, and believe it to be a very valuable disinfecting agent. I am, yours faithfully, EDWARD T. WILSON, M.B. Oxon., F.R.C.P. Westal, Cheltenham, September 2nd, 1875.

SIR,—In the JOURNAL of August 28th, your correspondent "Triceps" asks for a good disinfectant for a case of cancerous breast. Allow me to inform him that I have lately used in such a case Dr. Bond's "terebene", and have found it to answer perfectly. The odour of "terebene" is very agreeable, and in marked contrast to the stinking carbolic acid lotion generally used in such cases.

In one case under my care, there was considerable hemorrhage from the ulcerated surface; and I found the "terebene" acted so well as a styptic, that I required no other application. As a disinfectant lotion, I used one fluid-ounce of terebene to four ounces of water. As a styptic, I applied it undiluted to the bleeding surface. I have used the terebene for a number of other purposes, and found it answered admirably as a deodorant and disinfectant, the only drawback being that it mixes badly with water.—I am, sir, yours faithfully, WM. H. PAINE, M.D., Physician to the Stroud General Hospital. Stroud, September 2nd, 1875.

SIR,—In answer to "Triceps", in your JOURNAL of August 28th, as to the best disinfectant for cancerous discharges, I would recommend him to use a solution of hydrate of chloral (Sivj to 3xv), which in my practice has proved efficacious, both as an anodyne and disinfectant. The parts must be thoroughly cleansed with a weak solution of chloride of zinc, and then three or four folds of lint or plugs of cotton wool saturated with the chloral lotion applied. It must then be covered with oiled silk. The dressings to be changed two or three times in the twenty-four hours.—I am, etc., T. S. DOWSE, Upper Holloway, N., September 3rd, 1875.

M.D.—In the present state of the law, it is not an offence for a chemist to act as a bone-setter; nor does a bone-setter require a diploma. It is only illegal for him to pretend to be "legally qualified"; that is, to have a qualifying diploma, if he have not one.

ARREST OF SPEECH AND HEARING AFTER ACCIDENTS OR CONVULSIONS.

SIR,—I have not met with a case exactly corresponding to the interesting one reported by Mr. Glissan in the JOURNAL of September 4th, where he describes the case of a child eighteen months old, who, after a blow on the left temporal region, lost all ability and inclination to speak; but I have now under my care a child, four years old, who, after convulsions six months ago, became dumb, whom on examination I found to be also absolutely deaf. Not improbably, Mr. Glissan's little patient is also deaf; and, if so, the prognosis must be considered very unfavourable. It is very common to find that after concussion, there ensues entire deafness, or, if the blow on the head be localised, the deafness frequently exists on one side only; in the latter case, it will generally be found that the deafness in the ear implicated is complete, and that the patient cannot hear a watch or tuning fork, either on contact with the cranium or close to the ear. In many of these cases, the membrane appears entirely healthy, and without a trace of rupture, though in some cases there is a history of blood having issued from the ear. If no improvement take place in these cases within two months of the injury, I believe them to be very hopeless. Occasionally, severe tinnitus ensues, which renders the case still more distressing. It is difficult to determine, with any degree of accuracy, whether the injury produces paralysis of the auditory nerve, or actual rupture of its structure, or of the cochlea or labyrinth, or separation of the ossicula. In those cases which recover, they were probably owing to paralysis from concussion. Most practitioners must have met with cases of absolute deafness following various fevers, especially typhus, without any injury to the membranes, ulceration or otorrhoea. The only treatment which appears to offer any hopes of success, is the application of galvanism, which would certainly do good if the affection were only functional.—Yours truly, LLEWELYN THOMAS, M.D., Surgeon to the Central London Throat and Ear Hospital. 44, Weymouth Street, W., September 4th, 1875.

DR. SMITH (Pershore).—We will await further communication.

SPINA BIFIDA.

SIR,—In the JOURNAL of April 17th, 1875, is a letter from Dr. Henry P. Drummond on the above affection. He relates the case of a patient who "attained the age of twenty-five years", and says, "I have never met with any record of such longevity". The following seven cases, taken at random from articles on the subject, will, I trust, be sufficient to prove to him that his case is by no means unique. Camper relates a case that lived to the age of twenty-eight years; and Swagerman mentions an individual thus affected who lived fifty years (Churchill's *Diseases of Children*). In Druitt's *Surgeon's Vade Mecum* is given the case of a woman aged twenty-seven years. A case is recorded by Behrend as having reached the age of fifty-one years; another died at forty-three of stone in the bladder, after having recovered from a previous operation. A case of Mr. Haynes Walton's lived twenty-nine years. . . . Moulinie of Bordeaux met with a man aged thirty-seven years (Cooper's *Surgical Dictionary*).—I remain, sir, yours faithfully, St. Vincent, W. I., August 9th, 1875. OTHO GALGLEY, L.R.C.S.I., etc.

A YOUNG MEMBER.—Under the circumstances stated, we think it would not be necessary to insist on a consultation. But, of course, in particular cases it might be; and the newly summoned medical man would always reserve his right to make that a condition of his attending the case. In many instances it would be painful to all parties.

MR. E. A. D. AKERMAN (Cheltenham) will find in any "charities' list" the names of several hospitals for diseases of the lungs—prominent among them, the Brompton Hospital, the Victoria Park Hospital, and the Hospital for Diseases of the Chest in the City Road. Fortunately, there is not yet any special hospital for "diseases of the liver".

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

THE CONTAGIOUS DISEASES ACTS.

SIR,—It is refreshing to find so earnest a supporter of the Contagious Diseases Acts as Mr. P. H. Holland acknowledging that a "compulsory examination, not for the benefit of the woman examined, cannot be justified unless a very important public benefit be not otherwise attainable"; and also to read his confession "that many doubt if it would be justifiable even then". His suggestion, however, that surgeons should be "relieved from such disgusting duty" by the preliminary substitution of women examiners, is already carried out. Many of your readers are doubtless unaware that, by a special clause in the Acts, young girls who are menstruating are first examined by a woman, who generally suggests that, "if not so very bad, they had better undergo the ordeal, even in that condition, rather than submit to imprisonment".

The editor of the *Medical Times and Gazette* remarks "That nothing would tend more to deprive medicine of the rank of a respectable calling than the fact that practitioners could be found willing to lend themselves to the dirty work of examining prostitutes, in order to enable them to carry on their trade"; and adds, "If the heads of colleges wish to protect their members from degradation, here is an opportunity". This feeling is evidently shared to some extent by Mr. Holland; and I must say that I sympathise with his desire that the burden and disgrace should be shifted on to other shoulders than those of members of our noble profession. The class of women who would undertake such a duty would be, doubtless, old brothel keepers, who, when suffering from age and infirmity, could be thus conveniently pensioned by the Government to which, we are told, they now render essential service by maintaining an *entente cordiale* with the police, by supplying information, and denouncing such females as may in any way offend them. I fear, however, that, in his zeal against women, Mr. Holland overlooks the great difficulty of detecting disease. Mr. Henry Lee, in his *Lectures on the Contagious Diseases Act of 1873*, remarks, "That if the exact nature of a discharge in man is difficult of diagnosis, the difficulty in woman is increased tenfold"; and he adds a remark which I commend to Mr. Holland's notice: "There is here matter for the serious consideration of any medical man who undertakes to advise Her Majesty's ministers with respect to the working of the Contagious Diseases Acts." Dr. Aitken, in his *Science and Practice of Medicine*, remarks that the true syphilitic sore can rarely be detected in the female; and that it is readily overlooked, even when searched for with great care, aided by a vaginal examination with a speculum. Mr. Simon also declares that "the various local states which most habitually spread the infection of true syphilis are often overlooked in examinations made expressly for their discovery." M. Le Fort has declared that the laws against syphilis in Paris amount to nothing, because the examinations of the *filles publiques* do not answer their end.

Mr. Holland further argues that diminishing the fear of disease does not increase profligacy; that the fear of punishment does not check vice; and that if disease were stamped out by the Contagious Diseases Acts, men would have more dread of disease than they have now. He says that, if as many people died of hydrophobia as die of fever, we should not dread it any more. He might as well say that people fear to take prussic acid much more than alcohol; yet alcohol kills far more people than prussic acid; therefore, if accidental deaths from prussic acid were as frequent as those occasioned by alcohol, we should have as little dread of prussic acid as we now have of brandy and water. There is no fear, however, of people coming to dread disease because it has been stamped out by the Contagious Diseases Acts; on the contrary, true syphilis, as shown by the army returns last published, has increased, and gonorrhoea has considerably increased; while venereal sores, which fell off very considerably without the Acts, have only decreased very slightly with them. The opponents of the Acts do not, as Mr. Holland states, object to treat disease; they do not object to voluntary hospitals; but they do consider it wrong to tempt men into sin, misery, and disease, by providing securities (however false) beforehand for the safe commission of vice. The women, driven to the examining house by the police, are not proved to be prostitutes; they have committed no crime, and are not suspected of any legal offence whatever; they are, with rare exceptions, not suffering from disease; and not above four in one thousand ever see a magistrate. The women thus treated and outraged by periodical violation with the speculum, have their rights at common law just as Mr. Holland has; those rights are deliberately trampled under foot; and yet he asserts that the fact that humane men should oppose such laws is to him "most wonderful".—Your obedient servant,

Peachey Terrace, Nottingham.

THOMAS WORTH, M.R.C.S.L.
