SIR,—I cannot remember having ever seen or heard of a case of complete absence of the uvula in the usual position in the middle of the soft palate. Perhaps such a malformation may be common, but I have never seen it; and I should like to know, through the medium of our JOURNAL, if such is the case. The subject of the malformation I now speak of was born some weeks ago; and lately the mother asked me to see if there was anything wrong with its throat, as it frequently appeared as if suffocating. On examination, I was surprised to observe complete absence of the usual uvula, and, in its place, an unusually tense and oval cartilaginous soft palate, but no vestige of uvula. However, on further inspection of the pharynx, I discovered that the deficiency there was atoned for, as the child had undoubtedly a perfect uvula on each side, but hanging from between the arches of the palate, close to the base of the tongue, and unusually long for an infant. These uvulae were, no doubt, the cause of the frequent suffocating fits. They were not, as some will say, only enlarged or odd-looking tonsils, as I am quite satisfied, from frequent examination, that they were misplaced, but perfect, uvulae, and nothing else. I have also looked in vain for the epiglottis; and, if present, it must be very rudimentary.—Yours faithfully,

W. ARNOLD THOMSON, F.R.C.S. Ireland.

Southall, Middlesex, September 4th.

MR. MADDEN.—The celebrated Radcliffe bequeathed to St. Bartholomew's Hospital for ever the yearly sum of £500 towards mending the diet of patients, and the further yearly sum of £100 for buying them linen.

A. A. D.—Copies of the temperature charts, drawn up by the late Dr. Franklin Gould, for daily use in the clinical wards of hospitals, may be obtained of Messrs. Widderspoon and Shaw, of Serle Street, Lincoln's Inn Fields.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, no later than Thursday, twelve o'clock.

AN ILL-CONSIDERED VERDICT.

The *Bridlington Free Press* of last week contains a report of an inquest held on a farm-servant who had been suffering from heart-disease for some time, had been ill for a week without medical attendance, and died. His master, during the night of his death, sent a groom to two medical men in succession, to request their attendance. One was, however, attending a labourer; and the other was worn out with fatigue, and indisposed, and therefore unable to attend. In the absence of the medical men in question, and upon *ex parte* statements which were in various respects incorrect, the jury appended to their verdict a resolution of censure for "inhumanity". It appears to us, however, that this censure rests rather on those who allowed the poor fellow to remain without medical attendance during the week, and only sent for the doctor in the middle of the night, when the man was dying. In any case, the medical men, whose reasons for non-attendance appear to be perfectly valid, have reason to complain that the inquest was not adjourned to give them the opportunity of explanation. The resolution of the jury appears to be entirely unfounded and extremely unjust.

CAPSICUM IN DELIRIUM ET POTU.

SIR,—In answer to Dr. Hadley concerning the treatment of delirium tremens by capsicum, after giving it a fair trial in three cases, I came to the conclusion that the drug in question proved itself of very doubtful value. Its administration, however, in several cases of semi-habitual drunkenness, was attended by remarkably beneficial results. The prescription that I have always ordered was, to take the common red capsicum, mixed with Marsala wine sufficient to cover the drug, the whole being placed in a bottle; the patient, when feeling the depression and craving for stimulants, merely having to shake from the bottle, through a quill, a few drops of the wine into a tumbler of water; the effect being temporary stimulation, with a genial feeling of warmth at the epigastrium so self-satisfying as to temporarily remove the abject craving for alcoholic stimulation. So pleasant has been the effect, that one of the patients in question would drink as many as a dozen glasses during the day. A suggestion that I would make is, that an opiate should invariably be given at night to procure sleep.—I am, sir, yours truly,

CHARLES CHITTENDEN, Surgeon R.N.

Constantinople, August 1875.

DEGREES OF EDINBURGH AND ERLANGEN.

SIR,—If your correspondent William Hitchman, M.D., will again look over the regulations for the Edinburgh M.D. degree, he will see that the provision for the bestowal of the degree *in absentia* refers only to candidates who have taken out the M.B. degree of the University, which, as he doubtless is aware, is neither an honorary degree nor one bestowed without residence.—I am, etc.,

Liverpool, September 6th, 1875.

M. D. EDIN.

SIR,—A correspondent in the JOURNAL of the September 4th, under the above heading, makes statements which, unless corrected, are calculated grossly to mislead. There is no analogy between the M.D. of Edinburgh and that of Erlangen. Your correspondent forgets to tell us that an aspirant to the M.D. Edin. has previously to get the degree of M.B. This last is awarded, after an Arts' examination much more extended than that required for the diplomas of the Colleges as I know to my cost, on finding that my London College of Surgeons' preliminary examination only qualified in Edinburgh University for English, Latin, and arithmetic, and then four professional examinations must be passed at stated periods, during and after a curriculum extending over four entire years. I say nothing here about residence. The M.D. cannot afterwards be obtained until the M.B. has been practising his profession for at least two years, evidence of which must be produced, until he has passed further in Greek, and in logic or moral philosophy, with one extra subject selected from a list (see University Calendar), and has also produced an approved written thesis on some subject in the curriculum for the M.B. This thesis is always rejected if not up to a standard required by the Faculty. Every candidate for the M.D. Edin. must necessarily appear in person for all the examinations previous to the thesis; and the latter part of Clause xvii (17) of the regulations is obviously to accommodate those who have, after passing all the examinations above specified, settled abroad, where, if the necessary ability be possessed, they can as well write a thesis (the remaining test) as in this country. The official testimonials the medical Faculty require from them are the proper evidences that they have been in practice the necessary length of time after taking the M.B. The M.D. Erlangen of your correspondent, on the contrary, he obtained, on his own admission, as I understand him, without going to the place at all for any examination, by merely sending some professional (or official, as he styles them) testimonials, and by the exhibition of some published octavo volumes pertaining to physic or physical science. If his letter prove anything, it is an argument against the registration of foreign M.D. degrees, and shows that the Medical Council are so far acting wisely in the matter. I think we shall find that, instead of too few, we have already one registerable M.D. too many, and that of British origin, if we refer to the reports of the visitors of examinations of the General Medical Council with respect to what they term "an institution of much antiquity and interest" in the north (as quoted in the JOURNAL for June 26th, 1875, p. 851). It is the Universities—especially the teaching ones—of Great Britain that we must look to, to oppose the registration of foreign medical qualifications, such as your correspondent refers to, and others, and so to protect their own interests, and, what are of equal importance, those of their graduates. If the General Medical Council do agree to register foreign medical diplomas on any conditions, thus putting them on a par with our British ones, they will surely discontinue what will then clearly be only an useless formality—the visitation of British medical examinations.—I am, etc.,

September 6th, 1875.

M. D. EDIN.

ABSTRACT OF LECTURES ON SYPHILIS;

AND

ON SOME LOCAL DISEASES AFFECTING PRINCIPALLY
THE ORGANS OF GENERATION.*Delivered at the Royal College of Surgeons of England, 1875.*

BY HENRY LEE, F.R.C.S.,

Professor of Surgery and Pathology to the College.

LECTURE VI.—*The Local Suppurating Venereal Sore.*

THE local suppurating venereal sore has never been known, so far as I am aware from personal observation, to infect a patient's constitution so as to produce secondary symptoms. It commences as a pustule, and runs a definite course. When artificially inoculated, the inoculated point becomes red within the first twenty-four hours. From the second to the third day it becomes slightly raised, and is surrounded by a red areola. Between the third and the fourth day, it contains a fluid more or less turbid. From the fourth to the fifth day, the pustule becomes fully formed, and from this time to the termination of the disease the secretion consists of well-formed pus. Sooner or later the cuticle covering the pustule is detached, and in some instances it may be removed, at the time of the inoculation, whether artificial or natural. This alters the appearance of the affection, but in no wise interferes with its essential characters. As soon as suppuration commences, there is a loss of substance in the part, and an ulcer forms, which has peculiar characters. When not interfered with by any accidental causes, it increases equally in every direction, so as to form a more or less perfect circle. The edges of the ulcer are cleanly cut, and present a sharp outline. The appearance presented is often that of a piece of skin having been removed by a punch. The edges of the ulcer are frequently slightly undermined and everted. The surface of the ulcer is irregular, sometimes presenting granulations, at other times presenting the appearance of having been worm-eaten. Often the bottom of the ulcer is covered by an adherent, greyish, tough matter, which probably is a part of the natural texture, which has undergone a kind of molecular necrosis, and is in process of being separated from the subjacent living parts.

Suppuration in itself does not necessarily involve a loss of substance, but these suppurating sores nevertheless often leave permanent and depressed scars. This evidence of loss of substance is probably in exact proportion to the degree in which the form of molecular necrosis before alluded to has been present in any individual case. The suppurating syphilitic sore gradually increases during a certain period, then remains stationary, and finally heals. This latter process is indicated by the base of the sore becoming clean and covered by red granulations, by the red areola which surrounded it becoming fainter, and by the edges of the wound gradually losing their prominence.

Such is a description of the typical form of chancre; but this may be modified by various accidental causes, of which the following are some of the most important.

1. If the specific pustule be destroyed by the application of caustic within the first five days of its existence, a simple ulcer alone will remain. This will then have none of the characters of the specific disease.

2. When a chancre during its progress meets with tissues of different natures, or when folds of the same texture are involved, its shape and appearance may be thereby modified.

3. Should the specific inflammation extend to the areolar tissue, a certain amount of inflammatory exudation will take place. This will produce an induration at the base of the chancre, which will sometimes very much resemble the induration which generally accompanies the infecting chancre. The induration which surrounds the suppurating form of the disease is generally characterised by gradually fading towards the circumference to the consistency of the surrounding parts. When this inflammatory exudation, however, in its progress meets with a different kind of tissue, it may terminate quite abruptly, and then it may be impossible to distinguish by the touch alone this kind of induration from that of the chancre which infects a patient's constitution. The character of the secretion of the sore, its inoculability on the same

patient, the history of the case, and the condition of the inguinal glands, must then be relied upon to distinguish the disease.

This description of the suppurating sore, derived from the experiments of Ricord and his followers, was for many years supposed to apply to syphilitic sores in general, but it does not apply to the form of disease which infects a patient's constitution. The infecting form of syphilis begins, as we have seen, in uncomplicated cases, with some adhesive form of inflammation, such as a papule, a tubercle, or an abrasion with a thickened base. This disease, characterised by the specific adhesive inflammation, cannot be reinoculated upon the patient so as to produce the same kind of action. It has a prolonged period of incubation. It cannot be destroyed by caustic, is very certainly followed by constitutional disease, and when it heals leaves no loss of substance. The suppurating sore, on the contrary, always commences with a pustule. It can always be inoculated upon the patient, so as to reproduce the same action. It may be completely destroyed by caustic so as to leave an ordinary sore only. It is not followed by any constitutional disease, and it leaves a depressed cicatrix.

In depressed states of the constitution, a local venereal sore may become extremely troublesome, assuming different forms of phagedenic, serpiginous, and other unhealthy kinds of inflammation. Such instances generally occur in patients whose systems have been undermined by intemperance or by previous syphilitic disease.

The treatment of the local venereal suppurating sore, in its uncomplicated form, is sufficiently simple. The venereal poison requires a living nidus for its development, and, even in the suppurate form of the disease, some time must elapse before its specific action is established.

If, within the first five days of the application of the poison, the part to which it has been applied be destroyed by caustic, the death of that part will determine the cessation of the morbid action. This cauterisation, to be effective, must, however, extend to all the tissues implicated. It can, therefore, only be practised with success within a very few days of the appearance of the chancre. If a longer time be allowed to elapse, the tissues will have so imbibed the poison that it will be in vain to attempt to destroy all the parts that have been affected.

Suppurating sores generally make their appearance soon after upon the application of the virus, and to these, therefore, alone the method of treatment by cauterisation is adapted. For the purpose of securing the intended result, strong caustics should be used; and, as these may sometimes extend further than is intended, it is always advisable, before applying the caustic, to have an antidote at hand, so as to limit its action when desirable. When the caustic has produced its requisite action, the antidote may be applied; this will have the effect of preventing the further extension of the caustic, and also relieve the pain to which it gives rise. Thus, if a strong acid be used, a solution of carbonate of potash or chalk will form a good antidote. If an alkaline caustic be employed, some vinegar may very conveniently be used to limit its action. When nitrate of silver is applied, the common olive-oil is the best subsequent application.

The caustics most used for the purpose of destroying the suppurating venereal sores are the mineral acids, or a combination of potash and lime. The nitrate of silver will seldom extend sufficiently deep to destroy the poison.

The strong nitric acid has often been employed, and acts extremely well, but it gives very considerable pain when applied to the surface of the body.

Another preparation, which has been much used, is a combination of sulphuric acid and powdered vegetable charcoal. When this preparation, in the form of a paste, is applied to a chancre, it dries quickly, and forms a kind of black crust, which remains adherent to the tissues, combines with them, and is not detached for several days. The wound sometimes will then be found to have lost its specific qualities, and to be in a healing condition. The application of this caustic causes very severe pain, which lasts for a considerable time. The pain, however, is said to be less than that produced by the nitric acid, but then it does not admit of being relieved in the same way by the application of an antidote.

Perhaps the most convenient form of caustic is the potassa cum calce, as prepared in the shape of little rods for the purpose. The lime combines with the moisture of the parts, and prevents this from extending itself over the neighbouring surface. The extent to which this caustic acts may, therefore, be regulated in the most accurate manner; and after it has done its duty the application of some dilute acid will relieve the pain which it has caused.

The actual cautery is a remedy which has often been successfully used for the phagedenic form of ulceration. The object with this, as with the other kinds of caustic, is to destroy the whole of the infected tissue, and completely to kill every part to which the cauterising action extends. For this purpose, the cautery should be heated to a white heat,

and allowed to remain on the diseased part sufficiently long to destroy the tissues to the requisite depth. Phagedænic sores, treated in this way, have been known subsequently to present a healthy surface, and to heal without further trouble.

Serpiginous sores are often too extensive to be conveniently treated in this way. A modification of the plan may then be adopted. The outer edge of the sore may be alone destroyed, so that the diseased part may be completely surrounded by an artificial line of demarcation. This will sometimes prevent the extension of the affection. It will often happen that the edges of serpiginous sores are undermined, and if the cautery be then applied to the edges alone of the skin, it may not reach to the circumference of the disease. It is safe, under such circumstances, to destroy the skin deeply two or three lines from its detached margin.

The ordinary suppurating venereal sore, if not in its origin destroyed by caustic, will generally run its course of five or six weeks' duration, and heal of its own accord, without leaving any injurious effects either in the lymphatic or in the patient's general system.

It may be well, however, to use various means to accelerate the healing of a suppurating sore, and such means are sometimes necessary.

So long as the sore has the specific characters of ulcerating deeply, with clearly defined vertical edges, it is well to continue the use of some mild caustic, such as a solution of nitrate of silver. When granulations spring up and the base appears healthy, it matters little what applications be used, provided the part be kept scrupulously clean.

The ulcer may assume the characters and appearances of ordinary lesions elsewhere situated; e.g., it may be indolent, irritable, or inflamed, or, by granulating too redundantly, impede the cicatrisation. Such symptoms are to be met by the same measures as would ordinarily be used.

If a chancre threaten to slough, it is best to dry the parts and apply nitric acid, afterwards using a lotion of potassio-tartrate of iron. With a solution of that salt applied to the sore, and the administration of the same drug internally, the phagedænic action will almost always alter its character.

Sometimes a large amount of inflammation, with great pain, attends the local progress of the disease. In such cases, the administration of opium is of great advantage.

EXCISION OF THE THYROID GLAND.*

By PATRICK HERON WATSON, M.D., F.R.C.S. Edin.,
Senior Surgeon to the Royal Infirmary, Edinburgh.

EXCISION of the thyroid gland appears to date back to the time of Albucahis. While it enjoyed a temporary reputation as an operation in the end of the last century, and in the beginning of the present, among some surgeons of repute upon the Continent, it appears to have been received with much less confidence in our own country.

In fact, on turning to one of the most recent, as it is one of the most representative, works upon modern surgery emanating from the southern metropolis, we find the learned author introducing his notice of this procedure in the following terms:—"Few surgeons believe that the entire thyroid gland has ever been successfully extirpated, although cases are so related (*sic*) by Desault, Roux, Gooch, Vogel, Theden, Hedenus, and others."

The late Mr. Liston, in his *Elements of Surgery* (page 469), speaks scarcely more encouragingly of such proceedings. "Extirpation of such growths", he says, "has been repeatedly attempted; but the patients, almost without exception, have perished from hæmorrhage under the hands of the knives. The immense supply of blood afforded to the gland in the healthy state must be kept in mind, as also the enlargement of the vessels proportioned to the increase of the part. . . . In short, the operation is attended with such risks, with so absolute a certainty almost of a fatal result, as not to be warranted under any circumstances, far less for removal of deformity only."

The late Mr. Syme, in the last edition of his *Principles of Surgery*, seems equally opposed to this operation (page 302), when he writes:—"The deep situation, muscular coverings, firm connections, and the large blood-vessels of bronchocele, forbid excision; and the attempts which have been made with this view afford a sufficient warning against their repetition by the fatal issue which almost invariably, and often immediately, followed them."

Boyer speaks even more decidedly (vol. vii, page 82): "A last measure, an extreme one, proposed for the cure of goitre, is its extirpation. This operation, recommended by Celsus and various others since his

time, has been undertaken, and has succeeded in some very exceptional cases where the tumour has been small and confined to one part only of the thyroid gland; but where the extirpation of a voluminous goitre, including the whole gland, has been attempted, the patients have died of hæmorrhage; or, should the operator have been successful in controlling the bleeding during the operation, the patients have died within two days from the disturbance of system occasioned by a tedious and very painful operation. Thus extirpation of the thyroid gland is one of those operations forbidden by prudence, reason, and experience." But, while these views, so decidedly condemnatory of operative interference, were held, we find that, from time to time, exceptional cases occurred in which the features of the tumour or the circumstances of the case were sufficient to lead to a transgression of such prudential judgments. Mr. Liston operated in this way more than once. In his *Practical Surgery*, he figures the external appearance of a case in which he operated after preliminary strangulation of the entire deep attachments of the mass. Mr. Syme, in speaking of this operation of Mr. Liston's, says (page 303): "I once adopted this method."

In assisting others, I twice witnessed very alarming hæmorrhage where partial extirpation of the organ was adopted. In one case, where the late Mr. Syme was the operator, the case was one of hæmatocele of the thyroid, in which tapping the sac, and injecting it with iodine, had been practised previously. The sac almost immediately thereafter refilled and pulsated strongly, and, on the ensuing day, while the pressure threatened to interfere seriously with respiration, copious bleeding occurred again and again from the gaping puncture made by the trocar. In these circumstances, Mr. Syme laid open the sac, and, failing to arrest the bleeding which poured out from the edges and interior of the opened sac, he attempted to cut away as much of the tissue of the enlarged gland as he could detach from the surrounding parts. But, as this failed to afford any relief to the continued rapid loss of blood, the cavity was stuffed with sponges, and the edges of the incision stitched together to maintain them in position. These measures failed to restrain the bleeding, and the patient died in our hands. In the second case, Professor Spence successfully extirpated a tumour of the isthmus of the thyroid, but with great freedom of active hæmorrhage attending upon the division of the vascular connections of the tumour.

The hæmorrhage which attended upon these two operations was certainly such as might be regarded as quite confirmatory of the unfavourable opinions expressed in most quarters in regard to the operation of extirpation of the thyroid gland, and assuredly fitted to deter one from any attempt at its repetition.

The first case which came under my own care, in which it seemed desirable to effect extirpation of a portion of the thyroid, occurred in my practice in May 1871. The case was one of a young lady, who for many years had been affected with a tumour of the neck. It was centrally situated, prominent, of the size of a China orange, moving with the trachea corresponding to its upper part, of a solid and elastic consistence. It was very disfiguring, and steadily increasing in size, and especially so within a recent period antecedent to her coming under my care. Recognising its thyroidal nature, I advised its removal by operation. I hoped, in operating, to find it easily enucleated, as it had made its way through the interval between the sterno-hyoid and thyroid muscles, and had no lateral extension over the carotid sheaths. The early steps of the operation were easily and rapidly completed. They consisted of a linear incision in the mesial line over the centre of the tumour, which, after division of the fascia, afforded a ready access to the tumour; and, by a few touches of the knife aided by the fingers, the whole prominent part of the tumour was exposed. But no sooner were the lateral attachments of the tumour severed upon the one side, than the blood gushed in a copious stream both from beneath the sterno-thyroid muscles and also from the margin of the tumour itself. The vascular connections, which had retracted, were after some trouble secured with a ligature of silk passed beneath the central mass of the tumour, and tied so as to occasion constriction of the mass, and staunch all further flow. To escape from further trouble from bleeding before dividing the lateral attachments of the tumour upon the opposite side, I passed preliminary ligatures beneath the superior and inferior thyroid vessels, and, having tied these ligatures, I completed the operation without further loss of blood. The patient, in spite of the loss of blood, made a rapid recovery. The effects of this method of controlling the circulation in connection with the thyroid gland led to my conceiving the idea of mediate deligation of the thyroids as a preliminary step in the operation of extirpation of a bronchocele.

I had not long to wait for an opportunity of putting my plan to the test of actual practice; for, in the course of the same month (May 1871), a patient was admitted to my care in the Royal Infirmary affected with a multilocular cystic goitre. She had previously been under treatment, when a single cyst, of which the tumour then seemed

* Read before the Surgical Section at the Annual Meeting of the British Medical Association in Edinburgh, August 1875.

to consist, had been tapped and injected with iodine. This plan of treatment had apparently checked the progress of the disease, but again it had enlarged, and, at the time of her admission, the swelling was of the size of two fists. The patient had further become anæmic, and affected with exophthalmos to a slight degree.

In operating in this case, I followed the same method as in the first instance just narrated, so far as opening the fascia between the muscles in the middle line. But, instead of opening the fascial sheath of the tumour, I pushed the parts aside, so as to carry my forefinger and thumb over the margin of the tumour at its upper and right corner, and felt for the situation where the superior thyroid passed upon the tumour. Recognising these vascular connections, I introduced an aneurism needle beneath them. In this manner, I was able to withdraw a ligature beneath the right superior vascular connections of the goitre. The needle was similarly carried beneath the posterior surface of the right inferior corner of the gland, so as to include all the right inferior thyroidal connections, and a ligature similarly withdrawn beneath them. The same process was repeated upon the left side, a ligature being carried beneath the left superior and inferior thyroidal connections. These four ligatures included not only the arteries and their corresponding veins, but the delicate fascial sheath which surrounds them, and, passing along them, forms the fascial investment or fascial capsule of the tumour. The ligatures were then tied separately, so as to secure the vessels as far from the tumour as possible. The fascial sheath of the tumour having been now divided in the mesial line, the attachments were cut through with scissors, and the tumour turned out of its bed by stripping away the fascial capsule with the fingers. After the tumour had thus been enucleated entire, one of the ligatures partially slipped, owing to its having been unduly strained as a means of keeping the soft parts separate. A gush of blood took place into the cavity; but this was at once checked by the pressure of a sponge until another ligature was carried round the vascular connections of the tumour corresponding to the bleeding part; when this was tied, all further bleeding ceased. The wound was closed by sutures, except at the lower angle, where a large drainage tube was inserted to secure the evacuation of all blood, serum, or other discharge, during the healing of the wound. The dressings were retained in position by means of a cravat composed of a muslin handkerchief folded upon a piece of buckram, after the manner of an old-fashioned stock. The skin, which at first hung loose and flaccid, had in two days so adapted itself to the parts beneath as to show no signs of redundancy. The wound, with the exception of the point where a ligature hung out, was healed in a fortnight.

The second case, one of multiple cystic goitre, was operated on in the Chalmers' Hospital in the autumn of 1871. It presented no peculiarities in contrast with the case just narrated. In it, catgut ligatures were used instead of silk, and were cut short after the removal of the tumour was completed. Here the healing process was completed in three weeks, and the patient, who had been sent to my charge by Dr. Howden of Montrose, returned to her duties as an asylum attendant. In this case, the anæmia and exophthalmos, which were present on admission, markedly diminished after the operation.

The third case was that of an Irishwoman, also affected with multiple cystic goitre. She was admitted to Chalmers' Hospital in the early part of 1872. The operation was performed in exactly the same manner as in the last mentioned cases, and was followed by equally favourable results.

The fourth case, a patient from Leith, was admitted to the Royal Infirmary in February 1872. This was also a case of multiple cystic goitre. It had grown steadily for twenty-three years, having commenced at the period of puberty. It was of the size of a large fist; it pulsed distinctly, and was accompanied by anæmia and exophthalmos. The operation was performed on March 1st, 1872, in precisely the same manner as already detailed. An anomalous aneurismal condition presented itself after the healing process was complete, in the situation of the right superior thyroid. When first remarked, six weeks after the operation, it was about the size of a hazel-nut; but it gradually increased until it became as large as a small walnut. It then presented all the characters of an aneurism with a venous communication, manifesting the peculiar rattling thrill and the *bruit de diable*. After continuing for about three weeks, it then disappeared gradually, no treatment beyond rest in bed having been employed.

In addition to these, I have operated successfully upon two other cases, and with a fatal result in one case. In this fatal case, the tumour, of very large size, was adherent to the trachea. After the preliminary application of ligatures and the division of the vascular attachments upon the right and left sides had been effected, on turning the tumour to one side, a large vein, lying posteriorly in the groove between the trachea and the œsophagus, was unfortunately wounded.

The pressure of the sponge applied to arrest its bleeding, together with the drag upon the trachea when the tumour was turned to one side, interrupting the respiration, led me to attempt to separate the attachments of the tumour from the trachea rapidly by means of the knife in a deep wound, from which bleeding was still going on. The thin and soft posterior wall of the trachea thus turned outwards was unfortunately wounded; and, before relief could be afforded by opening the trachea and introducing a tracheotomy-tube below the level of the tumour, so much blood had been sucked into the air-passages as to determine a fatal result in the course of the evening.

So far as I am aware, this method of extirpating the bronchocele is an original one. Mediate ligation of the thyroid arteries has, I am aware, been proposed and employed by Moreau, Desault, Bruyng-hausen, Mayor, Walker, Coates, Earle, Green, Blizard, Cooper, Brodie, and others, as a means of curing, or at least arresting, the growth of the tumour, though its practical employment was not found to be attended by such results as to lead to general adoption; but the combination of preliminary ligation of the thyroid with extirpation of a goitre is, so far as I have been able to discover, an operation which had not been practised previously to 1871.

In operating for excision of a goitre according to this method, I should recommend attention to the following particulars.

1. The external incision should be very free, extending from the larynx to the notch of the sternum, if the tumour be large and spread widely in a lateral direction.

2. The vessels, arterial and venous, in the early steps of the operation, should be secured as they are divided, to avoid any obscuration of the parts through oozing going on.

3. The fascia should be as freely opened as the skin; and, if the tumour be a large one, more space may be gained by a transverse division of the soft parts as far as the margins of the sterno-mastoid muscles on each side.

4. The delicate investing fascial sheath of the thyroid should be left undivided until the mediate ligation of the vessels included in their fine cellular sheath has been effected. This sheathing fascia or cellular capsule of the thyroid gland is only a prolongation of the sheath of the thyroidal vessels. If the capsule be opened, then, in pushing aside the soft parts to disclose the outline of the tumour, this delicate sheath is apt to glide off the surface of the gland; and, should this occur, the gland may readily be detached from the vessels even with comparatively gentle handling, and thus copious hæmorrhage difficult of restraint may be occasioned.

5. After the mediate ligation of the thyroidal vessels in their sheathing cellular envelope, the cellular capsule of the thyroid gland should now be opened by scratching through its tissue in the middle line, and the attachments which still retain the goitre in its position carefully divided by means of blunt-pointed scissors curved on the flat. There should be no tearing away of the gland, no pushing parts aside with any roughness of manipulation.

6. Should bleeding occur from any of the vascular attachments of the tumour after its separation, it must be remembered that it must occur from within the cellular sheath of the vessels, and find its way thence into the cavity consisting of the investing fascial capsule; and, therefore, if the vessels are to be tied, they should be secured *en masse* along with their cellular sheath. Without this sheath, furthermore, these enlarged thyroidal vessels will be found so fragile as to risk being cut by the ligature, while any attempt to reach the bleeding mouths within the fascial capsule will be balked by the infiltration of this cellular envelope of the vessels by a coagulum.

In connection with this operation, it is of exceeding interest to read Mr. Allan Burns's remarks in his work upon the *Surgical Anatomy of the Head and Neck*, written in the beginning of the present century, upon the anatomy of these parts as deduced from an examination of the body of a subject who suffered from goitre (page 199-201). "It is proper to know that every tumour is originally contained in a capsule of fascia, provided the swelling arise from enlargement of any glandular organ, and also that the adhesion of the one to the other is in indolent tumours for a considerable length of time slight. . . . Indeed, the union between the capsule and the gland was so slight, that I found no difficulty whatever in insinuating my fingers between the cyst and the gland, and detaching the one from the other till I reached the thyroid artery, round which I could most easily have passed a ligature. With the gentlest effort with the finger, I separated the tumour all round, and, in succession, touched the four arteries, and brought into view the trachea and gullet. When in this way I had ascertained the practicability of extirpating this tumour, I made an incision into its substance, and found that it presented precisely the appearances belonging to a bronchocele.

"It has been proved, from the inspection of the connections of the en-

larged thyroid gland in this body, that it might with a possible advantage have been removed by operation. Although this would have been practicable in this instance, still in others the tumour may be so situated, and may have formed such adhesions, as to preclude any attempt at extirpation. The respiration and swallowing may be both much impaired, and every remedy may have been tried and failed. Under such circumstances, is it necessary to leave the patient to die a miserable and lingering death? or is there any expedient which may reasonably be employed to protract life, and to render existence more comfortable? Such an expedient is within our reach. The dissection of this case proves its practicability. There it has been mentioned that the upper thyroid artery was greatly enlarged; that it was even nearly equal in size to the carotid; and also that it lay very near to the surface. Its coverings were few and thin; the pulsations of the artery were strong and distinct. Placed as that vessel almost always is, no one would have experienced difficulty in reaching it. The pulsation itself would be a guide, which would conduct us easily and safely to the vessel. No nerve of any importance would come in the way; no muscle would require to be displaced; no depth of substance to be divided; no intricate dissection to be performed. A small incision would expose that vessel on which the tumour in great measure depended for its support. It would be easy to carry a ligature round it to intercept the flow of blood to the gland; and, till the other vessels enlarged, the tumour would have more slowly increased in size; not only so, but it will sometimes be actually reduced and life protracted. A surgeon who would decline extirpating a large bronchocele would have little dread in tying the thyroid artery. Not a thyroid artery as in health, small, indistinct in its pulsation, and requiring, consequently, a more intricate dissection to expose it, but an artery too large to be missed. I would not, however, rest the question regarding the propriety of this procedure on conjecture, nor would I appeal to the healthy or morbid connections of the vessel alone to prove that it may be safely tied, when the operation has actually been performed on the living subject, and, in so far as concerns the tumour, with a favourable result, though we must regret that the patient died. . . . The patient died; yet this does not militate against the repetition of the experiment; the same might have happened from merely opening a vein, and, in the confined air of an unhealthy hospital, has actually happened. A tumour which, before its nutrient arteries were tied, was so large that it would have been folly to have attempted its excision, may, by depriving it of the circulation along the two upper thyroid arteries, be so reduced as to allow the operation to be performed, provided its connections do not prohibit us from interfering. It is not, therefore, the immediate effect on the disease which we are to look to in tying the arteries; we are to anticipate the command which it may ultimately give us over the tumour; and consequently, when the swelling, although very large, has not formed adhesion to the large cervical vessels and nerves, we are to urge the expediency of tying its nutrient arteries as a prelude to other proceedings. We shall not, however, in bronchocele, have occasion often to extirpate the thyroid gland, neither shall we require in many cases to tie the thyroid arteries.*

Again, a little further on, Mr. Allan Burns remarks: "In extirpating this gland, an incision of an elliptical shape, if the tumour be large, or if the integuments be diseased, is to be made over it with the long diameter directed from above to below. The surface of the swelling is next to be uncovered by dissecting back the integuments on both sides. The finger is to be insinuated between the skin and the muscles, pushing it upwards and backwards till it comes in contact with the thyroid artery, round which a ligature is to be passed with a blunt needle. In a similar manner, the other superior thyroid artery and the two inferior vessels are to be secured when the whole gland is to be removed. By these ligatures, we cut off the circulation into the tumour, and consequently are left at liberty to finish the operation by cutting the vessels nearer to the morbid parts than when the threads have been applied, and by dividing the sterno-hyoid and thyroid muscles above and below the tumour, which is afterwards to be detached from the trachea and gullet by cautious working with the fingers. In this way, we may remove one or both lobes of the thyroid gland; but the operation is difficult, tedious, and not without danger. . . . To those who are accustomed to do everything with the knife, the extirpation of the thyroid gland must appear a formidable operation; but, to one who knows when to use the scalpel, and when to substitute the fingers, the removal of the thyroid gland, although hazardous, does not appear impracticable. * Wilmer (*Cases in Surgery*, page 243), in his essay on *Bronchocele*, says: "When we reflect upon the situation of the thyroid gland, and consider its numerous arteries, which increase in diameter in proportion to the enlargement of the part, we shall not be surprised at the difficulties that must attend its extirpation in a diseased state, and the danger there ever must be of incurring a fatal hæmorrhage." These are

the notions entertained by all who reprobate this operation; but they are founded upon a mistake in anatomy. A diseased thyroid gland really derives all its blood from four arteries; if, therefore, the surgeon push at once to these and secure them, he will, in detaching the morbid parts, have nothing further to dread from bleeding arteries. By venous hæmorrhage, he may still be incommoded; but it will easily be checked. When, however, he employs the knife and trusts to tying the arteries after he has divided them, he will unquestionably experience all the difficulty, and the patient will run all the hazard that Gooch's did. The life of the patient will be saved only by having a succession of persons to keep a constant pressure upon the bleeding vessels day and night for near a week with their fingers upon proper compresses, after the operator has been repeatedly disappointed in the use of the needle and ligature" (page 232).

THE SANITATION OF HOUSES, ESPECIALLY IN THE MATTER OF DRAINAGE.*

By W. EASSIE, C.E.

THE evils induced by improper systems of drainage, etc., will be best observed by instancing the cases of houses which have from time to time been added to, until they have passed from the chrysalis or cottage condition to that of the winged mansion. When such cases occur, it will be found that the residences will have passed through all the applied gradations of sanitary knowledge. One will be able to trace there the first rude awakening up of the inmates, when something has been found wrong with the patrimonial cesspool in the kitchen, when perhaps it has filled up, choked the tributary drains, and even raised the paving-stones out of their places. When this happened in a village or hamlet, all that the united talent of the place could apparently suggest was merely a more or less partial emptying of the offensive receptacle, and the cleaning out of the drains leading from sink and closet. And, when this had occurred several times, or when the sides caved in, and the contents of the cesspool began to interfere with the economy of the sink or the working of the closet, the fiat would be issued for the excavation of a new dumb-well close by, and for the diversion of the drains to its mouth. The old cesspool was then duly covered with a stone, without being emptied. Very rarely, indeed, were these places cleaned out; the reason, doubtless, being that a disturbance of the deposits would render the absence of the family a matter of absolute necessity, owing to the overwhelming stench. Handy disinfectants for the use of soilmen were then unknown. It was, no doubt, also found cheaper to provide a paving-stone, and cover up the effete matter out of sight. And it is just the same in towns and cities. Only last week, I laid bare in the basement of a house in the West End of London three cesspools, which had been dug in most brotherly proximity, and abandoned in rotation as they filled up with ordure and filth. More than four cart-loads of night-soil were removed, and the bulk of it could not have been disturbed, I am sure, for half a century. Nor would this valuable kitchen-garden stuff, we will call it, have seen daylight now, and been carted to some spoil-bank, where will perhaps stand a future row of houses, had not the rats formed runs in the vicinity of the pits, and allowed horrible smells to invade the house by way of a long forgotten brick drain.

The reason why these ancient nuisances are found inside houses in towns and cities is not necessarily because the residences were built in rows or terraces, with but little external accommodation; for the same practice held good in country houses, where space was no object. It was rather owing to the absence of a proper flushing supply, and the improbability that the slops from the kitchen would suffice to carry away the more solid wastes outside the walls of the house. Indeed, they would be certain to be insufficient; for, at the time when these cesspools were excavated, only brick-built drains were used, generally laid with uneven bed, and through the open or perished joints of which, too, most of the fluids percolated.

The plan (Fig. 1) gives the earliest appearance of the basement of a house with which I have lately had to do, and I propose to follow its history up to the present time. At first, it must have been drained in some such manner as indicated by the dotted black lines, and I have drawn the cesspools in the kitchen, &c. That cesspools are somewhere there I strongly diagnose. In a similar manner, the stables and coach-house, s, were once drained into the cesspool shown by the black spot between the stalls, because I have already discovered that one. Fortunately, the soil was of an impervious nature, or the whole basement would have been sodden throughout, and the well at w poisoned.

* Read before the Public Medicine Section at the Annual Meeting of the British Medical Association in Edinburgh, August 1875. 1

Here we have a very fair representation of a house built fifty or sixty years ago; the sinks and, by-and-bye, a closet upstairs drained into the intramural cesspools. Successive ones were dug, because there was no overflow provided; nor would an overflow have been of service, since the floating matters would never have run off, but only clogged up the pipe. The stable-cesspool acted as a catch-pit for the urine, and the dung was removed to the pit beside the boundary-wall. An old-fashioned, and consequently filthy and unwholesome, privy was also in use by the family or the servants.

Fig. 1.

We will now pass to the second stage of progress, still regarding the same diagram, and this was reached when the water-closet was introduced, and glazed earthenware pipes. The black lines, which indicate this state of things, will show that the sink and upstairs closet drained down into the garden, picking up the conservatory floor-drain and the drain from the stables, and so on to the first cesspool. When this ran full, the overflow was into another, lower down; and both, which were built with brick, were, of course, sealed down in an air-tight fashion. There could have been no ventilation, except through the trapping-water of the syphons at the foot of the sink-waste, soil-pipe, or rain-water stack. The privy arrangement had been continued probably from a paucity of water.

And here I might interpolate a line or two, to say that it does not follow that the drainage of such a house into a cesspool is necessarily a dangerous proceeding. Provided only that the waste-pipe of the sink be made to deliver on the outside of the house over a suitable trap; provided, too, that the soil-pipe be carried up through the roof, and the highest point of the drain, near the stable at R, ventilated by a shaft up to the eaves, the residence might be deemed a safe one. It would, nevertheless, be wise to ventilate the (outdoor) cesspool by an upright pipe, or the insertion in the cover of a ventilating trap, the charcoal of which could not be saturated by rainfall. Similar or even open ventilators could even be inserted in the march of the drain, and an earth or ash-closet would improve the surroundings in the stable-yard.

The plan (Fig. 2) exhibits the same house under different auspices. The stable buildings at S have been converted into servants' offices and butler's pantry, and the loft over raised to the dignity of sleeping-rooms. A new wing has also been added at A; and, fresh land having been purchased on the stable side, new stables and coach-houses have been erected at B. The laying down of a parish sewer in the main road—the first enhancing agency in the price of land—without doubt led to these improvements; for improvements they certainly were. We will now see how matters were managed from a sanitary point of view.

First of all, then, owing to the introduction of an upstairs closet at D, it became necessary to lay the drain to that point, and also to a servants' closet which was added at E; the latter with a closet situated immediately above it in the hall. The builder began to lead a drain from the sink at F round the garden front of the house to the old privy, which he raised to the dignity of a water-closet, and then continued the drain-pipes to the front of the house, between the old and new stable on to the sewer, draining, of course, the stables in passing, and taking up also some surface-drains. All this was proper enough; but he fell into his first error when he led the surface-drain, M, downstairs, and laid pipes on to meet the sink-drain at N. No sewage from the three closets could possibly have passed the rectangular

junction at N. Nor was this his only blunder; for, thinking to exclude any sewer-gas from entering the house from the sewer, he interposed in the line of drain a common deep syphon at U.

Fig. 2.

Another mistake of his was to continue the use of the garden cesspools, and the leading of the rain-water cistern overflow at R, the waste of the butler's sink at Y, and the floor-drain of the conservatory C in the old drains down to the cesspools. I have since ascertained that he did this to please his client, who objected to the deep digging between M and the sewer in the road. The consequence, however, was, that the gases forced the conservatory floor-trap, and found their way into the drawing-room, invaded the butler's sanctum by way of the sink at Y, and regularly stormed the servants' sleeping-rooms through the cistern overflow at R. He, moreover, forgot to dig up the old stable cesspool at S, and, as a consequence of this, that portion of the domicile smelt very offensively to those whose pituitary membranes were at all sensitive. The non-placement of any ventilating-pipe in the new drains was also a great oversight.

The sins of omission and commission of sanitary law came speedily upon the inmates. First of all, the syphon at U became stopped up, owing to the sluggish flow of the faecal matter from the closet at X,

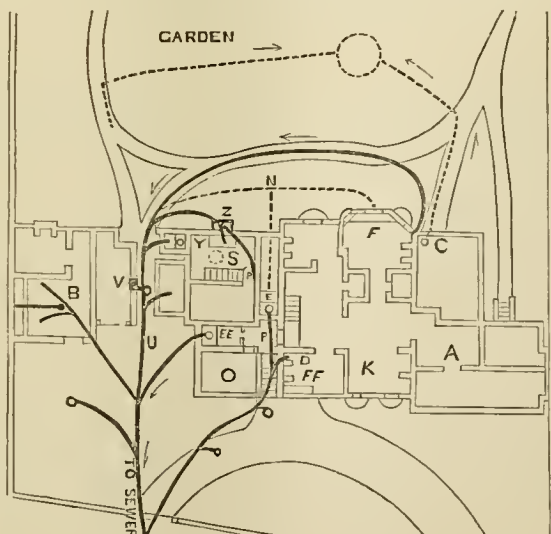

Fig. 3.

and the paltriness of the flushing water. The closets at D and E also filled up their portion of the drain. On taking up the drain below the syphon U, I found that during the whole of the time not one particle of sewage had ever reached the main sewer. Some of the drains had

also been laid in with a *backward* fall; and, in fact, it became necessary to dismiss the builder and send for the engineer.

After discovering the stoppage and its cause, and after removing some cart-loads of ordure out of the extra large-sized pipes, I began to re-arrange the whole, as shown upon plan (Fig. 3). I dug out the drain-pipes on the dotted line between the points E and N, and transferred the servants' closet from the middle of the house to E E, in the corner of a new coal-cellar, which I built at O. I also carried the drain from the foot of the upstairs water-closets, through the open area P on to the sewer in the road, and moved the scullery-sink from F to the site F F, which was more convenient to the servants. I next dug up the old stable-cesspool at S, and led the wastes of the cistern and butler's pantry to an open disconnecting chamber seen at Z, and on to the main-drain, easing the bends as I went on. I also laid in a new drain round the garden-path from the rain-water stack-pipe in the conservatory C, and so made sure of an occasional good flushing for the new drain. Ventilation for the drain I provided by erecting a shaft at V up the high gable of the new stable building B, and upon the top of it I fixed a foul air withdrawing cowl. Very little remains to be done, except to ventilate the soil-pipes and relay the basement-floor; first searching for the cesspools, and concreting the surface over. An open area round the building would also prove a blessing.

An example of a large-sized mansion, which was partly drained into cesspools and partly otherwise, is given on the plan (Fig. 4). The

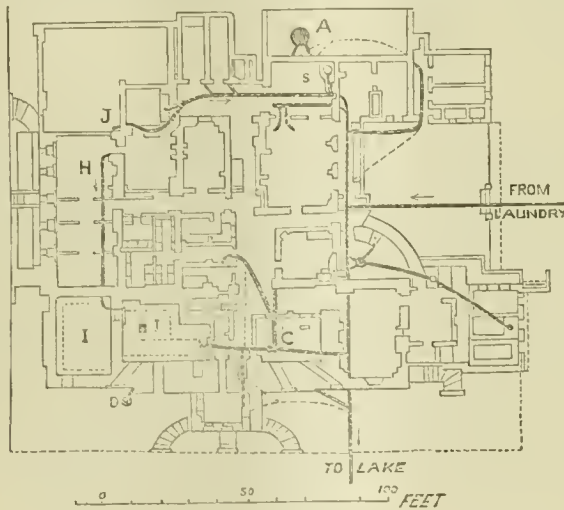

Fig. 4.

drainage was at first collected, as shown by the black lines, and ran down to a lake where the drain was trapped, the sewage falling through a valved grating into the water. The outlet being thus hydraulically sealed, and there being no ventilation in the march of the drain, the gas generated in the drains (which, by the way, were all brick-barrel ones) found its way into nearly every room of the house.

The collection from one side of the house commenced with an old rotten brick drain under the housekeeper's room at H, and the state in which it was found sufficiently accounted for certain smells prevalent thereabouts, for dampness, and for the presence of slugs. The rain-water flowing down this drain led to the beer-cellars I I, and then ran in an open channel (see faint dotted line) as far as the passage, when it entered the store-room, and here, at C, was put a catch-trap, which was relied upon to shut out the air of the drains from the house. It then ran on to the main-drain. The smells in this part of the basement were intensified, owing to the beer-droppings in the open channelling. The collection from the other side of the house led on from J through the scullery S, a separate pipe being led on from the sink. The water-closets throughout the establishment were eighteen in number, and of these ten drained direct into the drain, and so on to the lake; five into a cesspool in the quadrant-shaped yard, and only the overflow into the drain, and the other three drained into deep cesspools at A and D, excavated in the chalk. And I might here note, as a curious thing, that, upon opening a cesspool cut in the chalk, it will be found that the soil disappears there with an unaccountable rapidity. But, when once the cesspool is emptied, and the porosity of the sides interfered with, it holds water like a common brick cesspool, and becomes a receptacle where disease-germs multiply.

Whatever gas was generated in the main-drain or tributaries, or in the large cesspool in the quadrant yard, had, therefore, no escape, save into the house. The cure, therefore, lay in the abolition of this cesspool, the diversion of the drain which led into the catch-pit C outside the house altogether, the ventilating to the roof of the heretofore unventilated soil-pipes, the disconnection of the house-sinks from the drains, and the taking up of the retardative brick drains, and substitution of earthenware pipes. The large cesspool A was also filled up after having been emptied, and the closets which formerly discharged there were drained by way of the dotted line into the main sewer.

The plan (Fig. 5) illustrates the ground-floor of a large house of

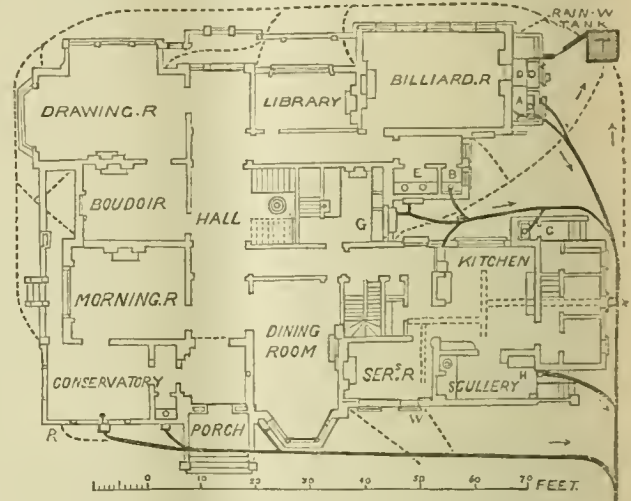

Fig. 5.

which I was both architect and engineer; and I exhibit it merely to demonstrate how easy it is to arrange so as to have the whole of the wastes delivered immediately outside the house. The water-closets A, B, and C, and others above these, the lavatories D and E, and the sinks G and H, have only the exterior wall between them and the drain. Hence none of these drains which convey the soil and other effete matters pass under the house. When it was found advisable to drain the basement—and here I found it so along the dotted double lines—I disconnected it from the main drain by interposing over the junction a ventilating shaft at X. The sinks and lavatories also deliver in the open air. To assist in flushing, some rain-water pipes, for instance, R and W, might, under certain circumstances, be led into the soil-drains. But, as a rule, it will be found wise to collect the rain-water as I did, by the dotted single line of drain-pipes to the tank T, for use in the laundry and green-houses. The main walls of the house were also built hollow, and protected from rising damp by a damp-proof course.

TWO CASES OF PUNCTURED FRACTURE OF THE FRONTAL BONE TREATED BY TREPHINING;

AND RESULTING ONE IN TOTAL THE OTHER IN PARTIAL LOSS OF VISION.

By KELBURNE KING, M.D., F.R.C.S.,
Surgeon to the General Infirmary, Hull.

THE following cases seem to me to possess sufficient interest, both in a surgical and a physiological point of view, to warrant me in bringing them before the notice of this section. Though differing greatly in the extent of injury, they have this in common: that in each the most formidable symptoms depended upon extensive fracture and displacement of the internal osseous plate of the skull, of which but little evidence was procured by means of external examination; and in both the ultimate result of the accident was loss of vision: of both eyes in the first, of one eye in the second; although in both the seat of the accident was far removed from the origin or course of the optic nerves.

CASE I.—G. A., aged 17, was kicked by a horse on the left side of

* Read before the Surgical Section at the Annual Meeting of the British Medical Association in Edinburgh, August 1875.

his forehead, on January 3rd, 1874. Though considerably injured—for he had two front teeth knocked out, and lost a good deal of blood from the wound—he rode a distance of two miles to the residence of Mr. Morley, of Barton, who dressed the wound, and observed that the lad was perfectly self-possessed, and showed no symptom of disturbance in the functions of the brain or the organs of sense. He was cautioned to keep quiet; but, two days after, again rode over to have the wound dressed. After this, the forehead and nose became swollen; sickness, slowness of pulse, headache, and supuration of the wound supervened. On January 12th, the sickness and headache had subsided. There was much less supuration, but rough bone was felt at the bottom of the sinus. The pulse was 44. His memory was not impaired, nor were his faculties affected; except that he was sluggish, disinclined to exertion, and uninterested in what was going on around him. I saw him on February 5th, about a month after the receipt of the accident. He was then confined to bed; had lately suffered much from sickness and headache, though these symptoms were again relieved. His pulse was 40, and full. He answered questions slowly and hesitatingly. His pupils responded to light but slowly; his vision was not affected. His mental condition was clouded; his faculties were not effaced, but they acted slowly. He had a general feeling of distress and depression, and was quite anxious to have anything done for his relief.

On examining the forehead, there was found a fistulous opening just above, and a little external to, the left supraciliary ridge. A probe led to bare bone, and then could be passed on indefinitely. On examining with the finger, a punctured depression was felt in the bone, not larger than a split pea. Pressure in this situation caused him to wince. From these conditions, Mr. Morley and myself concluded that the injury to the internal plate of the skull was much greater than that to the external. The wound was enlarged, and a circular piece of bone removed with the trephine. On raising it up, the internal plate was found divided into three parts, and driven inwards, forming a kind of cone, the apex of which was opposite the small punctured depression of the external plate. Here the dura mater was ulcerated and sloughing.

A fortnight after, on the 19th February, Mr. Morley informed me that the lad was steadily progressing towards recovery; there was no hernia cerebri. Mr. Morley added: "The only bad symptom he has is diplopia; and he tells me that he sees double, even when I close his right eye." After this, however, protrusion took place; and an abscess formed, which burst on March 13th. On the 17th March, Mr. Morley sent me the following report. "He has not been sick for a week. Pus is still flowing, the bulging is gradually diminishing, and cicatrisation advancing. Pulse 70. He does not see double with the left eye, as before; but he does with the right, the left being closed." The purulent discharge continued to the beginning of May; his general condition improved so much, that, with this exception, he might be considered as well. In the early part of May, the discharge ceased, and the wound cicatrised. He then noticed a failure of vision: first, in the left; afterwards, also in the right eye. The blindness increased; and he came under my care in the Hull Infirmary on the 26th of May. He could then distinguish light from darkness, and but little more. Both eyes were equally affected. There was a pulsating tumour, about the size of a walnut, over the seat of the operation, which could be reduced by pressure, without pain or inconvenience, but immediately returned. The pupils were dilated and sluggish, but responded distinctly to the stimulus of light. There was no paralysis, except of the optic nerve. As blindness supervened on the cessation of purulent discharge, I thought it possible that there might be deep-seated matter, and passed a fine trocar deep into the substance of the brain. No pus was discharged, and no effect was produced. He eventually left the hospital perfectly well in health, but practically quite blind. The ophthalmoscope showed white atrophy of the retina; and his condition is, I suppose, incurable.

In this case, there are two points to which I would call special attention.

Firstly, we had abscess of the left anterior lobe of the brain producing blindness of the left, then also of the right, eye. Secondly, we had the extraordinary symptoms noted by Mr. Morley, of double vision: first of the left eye, when the right was closed; then of the right eye, the left being closed.

CASE II.—The next case was that of J. F., aged 25, a sailor, who, on the 14th October, 1874, fell from the yard-arm of a ship into the empty hold—a height of upwards of thirty feet—was taken up insensible, and conveyed to the Hull Infirmary. On admission, his whole head and face were very much swollen, so that it was impossible to examine his pupils. There was a slight abrasion of the skin over the right eyebrow; and above the left supraciliary ridge, an indentation of the bone was perceptible, sharp and deep, but not wider than a split-pea. Pressure here caused him to shrink, though he was otherwise

unconscious, incapable of being roused, all voluntary action being suspended, and only the reflex functions being carried on. In this state, he continued till the 19th—five days—when consciousness began to return, though the excretions were still passed involuntarily, and the swollen condition of the head and face prevented examination of the pupils. On the 27th, the oedema had so far subsided, that this examination could be made; when the left pupil was found to be natural, but the right was dilated and insensible to light. There was ptosis of the right eyelid; and the right eye, though capable of distinguishing light from darkness, could not discern objects with any distinctness. After this, the pulse became rapid and hard; and he suffered from severe headache, with hot skin, restlessness, and general fever. The pain was especially severe over the left supraciliary ridge, where the depression was felt, and pressure there greatly increased the pain. It was evident that inflammatory fever was being set up as the symptoms of concussion subsided; and was probably occasioned by displacement of the inner table of the skull at this point. Accordingly, on the 4th November, the trephine was applied over the punctured bone. A portion of the outer table being thus removed, the internal was found broken up extensively, and forced inwards upon the brain. One jagged spicula, an inch and a half in length, and half an inch in breadth, was forced through the membranes right into the substance of the anterior lobe. On removing it, broken down portions of brain came away through the ulcerated aperture. At first, he seemed relieved after the operation; but, three days after, on the 7th, the part became swollen and painful; and, though pus and broken down brain-structure came away freely from the wound, he again became feverish, with great restlessness, so that he could only with difficulty be kept in bed. On the 10th, erysipelas set in in the face and scalp, affecting principally the right side; the feverish symptoms increased, and he became quite delirious. In the course of a week, the erysipelas disappeared, and the fever diminished. He became more tractable, but was very weak, and had very little muscular control. The right eye was quite blind, and the power of moving the eyeball was lost. His speech was very indistinct; the left ear was almost incapable of hearing; and the left side of the body was partially paralysed, especially the left arm. A new feature now began to present itself (November 17th). He complained of great pain in the back, legs, and feet, increased by pressure, and he dreaded even the weight of the bedclothes. In the latter part of November, and during the whole of December, his condition seemed to be desperate. There was almost complete loss of power in both legs and in the left arm, the right arm being the only limb over which he had any control. His legs were bent and drawn up, and in such a state of hyperæsthesia that the slightest touch elicited cries of pain. He was quite blind in both eyes; could hear only very loud sounds with the right ear, the left being quite deaf. His speech was not quite lost, but consisted of little more than inarticulate ejaculations. The excretions were passed involuntarily. Nevertheless, about the beginning of January, he began to improve. The oedema of the head had so far subsided that a fissured fracture—the inferior lip of which was slightly depressed—was perceived extending from the trephined part to near the left parietal protuberance. On January 13th, I made the following entry: "His general condition is much improved. Hyperæsthesia is much diminished, but still present in the legs. Muscular power is returning in the left arm, and also, though more slowly, in the legs. He has more power of moving the right eyeball, but there is still complete loss of vision in both eyes. The ophthalmoscope shows extravasation of blood in the retina of both eyes; but, on the right side, the optic nerve is becoming cupped and atrophied." From this time, his symptoms gradually improved. On April 7th, he had quite recovered control over the sphincters. The vision of the left eye was restored, but the right was quite blind. The ophthalmoscope showed that the blood patches on both retinae were absorbed, but the atrophy of the right optic disc increased. Hearing had returned: first on the right, afterwards also on the left, side. There was occasional stammering; but the power of speech was greatly improved. The paralysis and hyperæsthesia of the limbs had disappeared. His memory, though imperfect, was daily increasing in strength. There remained some numbness of the right side of the face. When he laughed or whistled, the right side was still slightly paralysed. The movements of the right eyeball were imperfect, but he could completely close the eyelids. He had gained greatly in flesh, and his general health was good.

On the 14th of April, 1875, he left the Infirmary, cured, with the exception of complete blindness of the right eye.

The nervous system in this case are difficult to explain. The optic and motor nerves of the right eyeball and portio dura suffered most, while the left auditory nerve and the left side of the body generally were more affected than the right. In a case of such severe in-

jury, it would not be right to attribute all the results to the injury caused by the splinter of bone driven through the membranes into the brain, and removed by the operation of trephining. But, in the first case related, the injury was clearly restricted to that caused by the punctured fracture; and, as it resulted in atrophy of both optic nerves, it affords proof that injury and irritation of the anterior lobe of the brain may result in loss of vision of either or both eyes.

The practical deduction is that, in cases of punctured fracture, the greatest care and caution ought to be observed; and, on the appearance of head-symptoms, the trephine ought to be applied without delay, so as to remove all offending spicule of bone from the membranes and substance of the brain.

Percival Pott declared that "perforation is absolutely necessary in seven cases out of ten of simple undepressed fracture of the skull", a doctrine which subsequent experience has disproved; but it is not impossible that, in punctured fracture, some such proportion of cases may demand the operation; and in all such it must be of vital importance that its performance should be as early as possible, and before serious changes have been set up in the substance of the brain.

A CASE OF POISONING BY THE INHALATION OF COAL-GAS.*

By STEWART LOCKIE, M.D.,
Physician to the Cumberland Infirmary.

I FEEL justified in drawing attention to the details of the following case, as accounts of the symptoms and *post mortem* appearances in cases of poisoning by the inhalation of coal-gas are of comparative rarity; and yet it might happen to any one of us practising in towns to be summoned to a similar case.

I was called between eight and nine o'clock in the morning of 26th April to see W. J. B., aged about 18, "assistant boots" at one of the hotels in this city, who was stated to have been found in bed in an unconscious condition, and incapable of being roused. He slept in a cupboard bed in the smoking-room of the hotel. There was no fireplace in the room. He had retired to rest about half-past twelve. At twenty minutes past eight, the "boots" knocked at his door, but, receiving no reply, entered the apartment. There was a strong smell of gas in the room, so strong that the "boots" could not at first remain; the sliding gaselier was drawn down as far as possible, and one of the two jets was burning with the cock turned full. The "boots" tried to arouse him; but, failing to do so, came for me.

I arrived at 8.50 A.M. I found him lying on the right side in the semiprone position. There was a little staining of the pillow with a brownish coloured fluid near the position of the mouth. He was completely comatose, breathing irregularly, now rapidly, now more slowly, moaning much. The face was livid; the pupils were equal, neither abnormally contracted nor dilated, and sensible to light.

I had him immediately removed to a larger room, laid him on a mattress on the floor, and established a current of fresh air through the apartment. Then it was further observed that the pulse was feeble and excessively rapid (150), and that the temperature in the axilla was 102.8 deg. The eyeballs were observed to roll about in a peculiar fashion. The eyes were turned slowly to the extreme left, as if the patient were looking to his left, they then slowly returned to the median line, then back to the left, and so on. The motion was almost rhythmical, and nearly constant. It took place whether the eyelids were opened or closed. The breath smelt of coal-gas.

Dr. Maclaren was kind enough to render me his assistance and advice in the treatment of the case, as also did subsequently Dr. Coldstream and Mr. George Murphy. The subsequent notes were made by one or other of us—by whomever it was that happened to be present.

10.55 A.M. Temperature 102.2 deg. Respirations 52. Pulse 160. The conjunctivæ and corneæ were quite insensible to touch.

11.40 A.M. There was slight reflex action of the lids on touching the conjunctivæ.

It had been determined to try the effects of the administration of oxygen gas; and at 12 noon, an apparatus having been obtained, this was commenced in a modified form by setting free oxygen and conducting it by means of a tube near the mouth of the patient. This was continued with a few short intervals until 1.45 P.M., when it was discontinued. No perceptible improvement occurred during the administration.

1.45 P.M. A catheter was passed, and about a pint of clear pale

amber urine was withdrawn. A considerable portion of this had to be pressed out of the bladder with the hand, showing some degree of paralysis of the organ. Shortly afterwards, an involuntary fecal evacuation occurred. One ounce of brandy and six ounces of beef-tea were administered as an enema.

During the afternoon, our efforts were directed to obtaining a larger supply of oxygen, with a view to its administration in a pure state. An apparatus for the production of the gas was obtained, and, through the kind courtesy of Mr. Hele, a bag capable of containing twenty-six gallons with tube and mouthpiece for its administration. After considerable delay, we succeeded in obtaining the bag full of gas; and, at 6.30 P.M., commenced its administration. The whole twenty-six gallons were inhaled with two short intervals. Except that respiration was increased in frequency and the distress aggravated, no effect was observed.

By 10 P.M., we had obtained another bagful of oxygen. It was agreed to try a different method of administration, viz., to give three or four inhalations every five minutes. This was continued for an hour and a half, during which the whole twenty-six gallons were again inhaled. As before, it only seemed temporarily to increase the distressing symptoms.

At 11 P.M., the temperature had risen to 105 deg. Four ounces of urine had been withdrawn; an enema of beef-tea and gin was administered. At 11.30 P.M., the practice of cold affusion to the head was commenced. This seemed, at first, to have a good effect, the respiration becoming deeper and easier, and the temperature lower. At 12 midnight, the thermometer in the axilla registered 102.6 deg. (a fall of 2.4 deg.) Respirations 48. Pulse 150. The cold affusions were continued at short intervals until 1 A.M. (April 27th), always with apparent though temporary relief to the symptoms. After this, they were practised at longer intervals.

At 5 A.M., it was noted: "There is passive rigidity constantly present in both upper and lower limbs, and about every half minute the muscles become more rigid for a few seconds, and the patient moans. Pupils dilated, and nearly insensible to light; conjunctivæ much injected; about four ounces of urine removed. Pulse 148. Respirations 52. Temperature 103.6 deg." At 5.20 A.M., cold affusion to head; two chamber ewers full. At 5.30 A.M., temperature 102.4 deg.; pupils sensible to light; cold affusion again for eight minutes. At 5.45 A.M., temperature 102.5 deg.; no fall, but rather the reverse after this affusion. It was again practised for eight minutes. At 5.55 A.M., the temperature was 102.8 deg.

At 8.5 A.M., cold affusion was commenced again for ten minutes; before affusion, pulse 144, respirations 48, temperature 103.2 deg.; after affusion, pulse 140, respirations 48, temperature 103.4 deg. 9.5 A.M. Cold affusion had been continued, at intervals, for thirty minutes; before affusion, respirations 57, pulse 140; afterwards, respirations 42, pulse 144, temperature 103 deg.; the conjunctivæ were less injected; the pupils were sensible to light; there was spasmodic rigidity of arms now nearly constant. 10.15 A.M. Cold affusion was applied for ten minutes. The temperature had been gradually rising, and was now 104 deg. 10.45 A.M. Cold affusion was applied for fifteen minutes. Temperature 103.8 deg. Three ounces of urine were withdrawn. 11.40 A.M. Temperature 104.6 deg., pulse 140, respirations 51. 12 noon. Cold affusion was applied. The temperature afterwards was 102.8 deg. Betwixt noon and 3.40 P.M., affusion was practised four times, but it seemed to have lost the effect of reducing the temperature, and was, therefore, abandoned at this time. The nutritive enemata had been given about every four hours. During the afternoon, it was observed that the rolling of the eyeballs had ceased. 7 P.M. Pulse 160. Respirations 65. Temperature 105.4 deg. 8.45 P.M. About six ounces of urine were withdrawn. A trace of albumen was found in this specimen. At 11.30 P.M., we commenced to feed the patient by means of the stomach-pump. One of the enemata had not been retained, and we indulged the hope that, as the struggle was so protracted, if the patient were adequately supported, he might possibly rally. Upwards of a pint of a mixture of coffee and milk, with two ounces of gin, was administered. Soon afterwards, the pulse was observed rather stronger.

April 28th, 3.30 A.M. He was in profuse perspiration. Respirations 66. Pulse decidedly stronger, but 180 at least. Temperature 105.8 degs. He was again fed by the stomach-pump with a similar mixture. Six ounces of urine were withdrawn. 8 A.M. Pulse 180 at least, more feeble. Respirations 64. Temperature 105 degs. There was no spasmodic rigidity. 8.15 A.M. Upwards of a pint of a mixture of beef-tea, milk, and gin was administered. 12 noon. Pulse very feeble, could not be counted. Respirations 62. Temperature 105.5 degs. Eight ounces of urine were withdrawn. He was fed again by the means of the pump. At this point of the case, it was agreed to try

* Read at the Spring Meeting of the Border Counties Branch, held at Carlisle.

ence will dispute. What, then, are the characteristics of such a climate? Lind, an old but very good authority, thus vividly describes them: "The first proof of an unhealthy country is a sudden and great change in the air at sunset, from intolerable heat to chilling cold. This is perceived as soon as the sun is set, and for the most part is accompanied with a very heavy dew. It shows an unhealthy swampy soil, the nature of which is such, that no sooner the sunbeams are withdrawn than the vapours emitted from it render the air *raw*, *damp*, and *chilling* in the most sultry climates; so that, even under the equator, in some unhealthy places, the night air is cold to an European constitution."

Dr. Maclean will, no doubt, admit that this is an accurate description of the climate of the Gold Coast. Here, then, we have the predisposing cause of climatic fevers, viz., intense heat by day, followed by the damp chill atmosphere at night, exposure to which is generally the exciting cause of these diseases. An officer, who held a very important position in the late expedition, says: "What kills people on the Gold Coast is cold"; and adds: "We always find that some distinct act of imprudence producing chilliness has preceded fever in this country." This is not the testimony of a person whose views are biased in favour of the "chill-theory". On the contrary, this officer, who was himself attacked by fever on taking a cold bath after a walk, thinks that the nauseous penetrating smell, which proceeded from the decay of the marshy vegetation, and by which his clothes, etc., were pervaded, must have been associated with some malarial poison. So difficult is it to escape from the influence of impressions once formed.

If so-called "malarious" fevers occurred only in swamps, and only where the odour of decomposing vegetation existed, there would be good reason for connecting the foul smell with the fevers, as cause and effect. There is, however, no disputing the fact, that these diseases prevail not only where there is no smell, but also where vegetable decomposition is impossible. One condition only is always present, and that is chill!

I need scarcely point out, that no poison or other agent, which does not exist *whenever* and *wherever* these diseases prevail, can possibly be the exciting cause of "malarious" fevers; unless, indeed, the causes be many.

In my work on this subject, many instances are quoted, and I could mention many more, in which these fevers have occurred in the absence of vegetation, living or dead; where the soil is utterly sterile, and the ground undisturbed; where the drinking-water is faultless; and even on board ships far out at sea. Moreover, I have demonstrated, that the disorders referred to do not prevail in the presence of any of the conditions, hitherto supposed to produce them, unless these are associated with some influence capable of abstracting heat from the body. Still further, I have shown that the severity of these fevers is in proportion to the previous exposure to a continued high temperature; and that, owing to this, in cool climates they are mild, and in hot climates severe. I think, therefore, it cannot with justice be said that I have failed to explain the nature and origin of the fevers which prevailed in the force on the Gold Coast.

In conclusion, I fully agree with Dr. Maclean as to the very severe form which climatic fevers often assume, and as to the great mortality caused by them. The gravity of the subject, however, should serve to stimulate inquiry. How else is the truth to be established?

I fail to see that anything but advantage can ensue from the exposure of the untenable nature of a theory which utterly fails to account for the origin of these diseases; and which, by diverting attention from the real cause (as at Hong-Kong), tends to prevent the adoption of rational measures for their prevention.

ON A RARE FORM OF INFANTILE PARALYSIS (?).

By J. MEREDITH, M.D. Edin., Wellington, Somerset.

TOWARDS the end of the year 1873, when I was civil medical officer of the town and district of Pooree, Bengal, a case which I have designated as above, was brought to me at the public dispensary of the town as an out-patient. The history was briefly as follows.

A boy named Muria, aged about five years, son of a washerman residing in the town of Pooree, was stated to have been well and healthy until he was nearly four years of age. He could talk, play, sleep, use his hands, etc., like any other child of his age. At this period, he had attacks of the endemic fever of the country, enlargement of the spleen followed, then convulsions, and he was for some days unconscious; during these days, his upper extremities became paralysed, and had remained so. His lower limbs were not affected. When the fever and unconsciousness passed away, the boy was left a

mute, having lost all power of articulate speech; although able to cry and to make various noises.

The boy when brought to me appeared healthy and strong, with well formed limbs and in good condition. His head might be taken as being a little larger than usual in children of the same age belonging to his race, particularly in the transverse occipito-parietal diameter. On each temple he had a large scar where he had been cauterised, according to the native fashion, by a cow's tooth heated in the fire; these marks, however, surmounted a merry laughing face. The boy could put out his tongue straight, and without any tremor or apparent want of control. His sight and hearing were perfect, as was also the sense of touch in every part of his body. The curious thing about him was, that he could not endure the sound of coughing. Whenever any one coughed near him, he would generally fall down and become unconscious for some seconds of time; I say generally, because after undergoing an attack, he could endure the sound for a certain time without again being paralysed by it.

While I was looking at the boy, some one coughed near him, and at once he fell in a sitting posture on the floor as if shot, with his head bent forward, his eyes glazed and fixed, his mouth a little open, and saliva trickling out of it. Both arms were rigidly thrown out before him; the hands and fingers a little bent; all, however, quite rigid. There were no convulsive jerkings in any part. He was evidently completely unconscious, and remained so for some seconds; then he recovered himself, looked round at the bystanders, smiled, got up and began playing about the ward as he had done before. The boy was not, however, affected by the sound of his own cough, and he coughed strong and hard at times. Some one stated one day that other noises besides coughing would throw him into a fit, but could not say what kind of noise. To test this, I had him taken through the native bazaar where, I fancy, well high every variety of sound is heard. The piping shrieks of elephants, barking of dogs, beating of drums, shouts, and cries; but none of them affected the little patient further than amusing him for the time. In short, after trying him with every form of sound I could discover, I found that nothing affected him except a cough. A make-belief cough was hardly successful either, while a real catarrhal one seldom failed to paralyse him.

He came to me in the beginning of November 1873, and was given five grains of bromide of potassium thrice daily. On the 29th of the month his condition was as follows. "He cannot now be made to fall by a cough; he only stops suddenly if he be moving, and puts out his arms straight from the shoulders, the palms turned upwards. Yesterday and the day before, his friends say that he did not fall once when coughed near, either intentionally or accidentally; he only stopped with a start, and put out his arms as if to ward off danger. His face became grave and serious for a second or two; after that, all was right again."

He had never used his hands to feed himself since his illness, and various means were tried to induce him to do so, but to no purpose; he seized his food directly by his lips or teeth. He could put his hands up to his face as he rubbed his eyes when he cried, but he was incapable of deliberate co-ordinate action in this respect.

The next note taken of his case was on December 4th, when he appeared as lively and cheerful as ever. He had had no falls since last entry; was only staggered as above mentioned. While examining him on this day, the hospital assistant happened to cough just behind him. At once the little patient's attitude became fixed, his eyes assumed a glazed appearance, his face looked grave, his left arm was jerked out to full extension, with the palm turned upwards; the right flexed at the elbow with the fist resting near the axilla. He stood thus for some seconds; then recovered, looked round rather confused, not knowing whether to cry or laugh; but the latter inclination prevailed, and he was soon running about the ward in his usual manner.

December 28th. The boy on this date was said to be worse again. He had not been regular in his attendance, nor taken his medicine of late. He had had several falls, besides being staggered frequently. On December 31st, I had an opportunity of showing the case to Deputy Surgeon-General Buckle, C.B., of Calcutta, and some non-professional friends. Three attacks were induced in the usual way by coughing in his presence; and that within a very short space of time. The boy happened to sneeze at the time; and by this he was staggered, and reeled nearly to falling. I lost sight of the case early in January 1874, as he ceased to attend at the hospital.

The boy's father was a blind old man, and had a troublesome cough, due to chronic bronchitis, and as he and his boy were much together, the little one's peculiar sensitiveness was often put to sore test. Even at night during sleep he was thrown into attacks nearly as bad as when awake and running about in the daytime. His attacks during sleep were nearly always due to his poor old father's chronic cough.

During one of these, he was thrown into a tense condition of the whole body, but more especially of the upper part, and remained so about his usual length of time, then passed into his natural sleep again without once awaking.

There is but little to add by way of comment on the case. It is like nothing that I have either seen or read of before, as far as my memory serves; and I refrain from offering an opinion as to the nature and situation of the lesion causing so peculiar a disorder.*

The case seemed certainly to improve under the administration of bromide of potassium, and I had some hopes of its ultimately much improving, if not recovering, if the boy could be separated from the irritation which was so embarrassing to him, and be persuaded to persevere with his medicine.

THERAPEUTIC MEMORANDA.

TREATMENT OF WHOOPING-COUGH WITH CARBOLIC ACID VAPOUR.

In No. 764 of the BRITISH MEDICAL JOURNAL, page 229, I find a report of a paper read by Dr. Robert J. Lee on Whooping-cough and its Treatment with Carbolic Acid Vapour. I beg you will compare this report with the enclosed paper, from which you will find that I used, in the summer of 1873, the steam of a solution of carbolic acid in water (1½ to 2 parts of acid in 100 parts of water) for inhalations three times a day, with perfect and speedy success, in the treatment of whooping-cough. The same inhalations may also be used with great advantage in other affections of the respiratory organs.

I am fully persuaded that Dr. Lee arrived at his almost identical treatment by original research, and I am glad to hear that he confirms the statements which I have made. Not so much for the purpose of claiming priority, but for the mutual confirmation of our observations, and for the sake of effecting a more general introduction of a treatment alike simple and effective, and which may save many lives, I wish that my paper may be noticed in your JOURNAL.

DR. BURCHARDT, Oberstabsarzt and Lecturer at the University of Berlin.

ESERINE DISCS IN TIC.

In the JOURNAL of October 31st, 1874, I published some cases of tic treated by Calabar bean, and then expressed a wish that I could obtain gelatine squares containing physostigmine (or eserine). Through the kindness of Sir J. R. Cormack of Paris, I got a number of discs for trial, and have since obtained a supply from the Messrs. Squire of Oxford Street (to whom I am much indebted). Discs containing one twenty-fifth of a kilogramme (.0006 grain) do for the purpose, one half being sufficient as a rule to remove tic which has no persistent cause, in from five to fifteen minutes. The discs are made by H. Duquesnel (late Vée), 42, Faubourg St. Denis, Paris. I may mention that, since October, I have used extract of Calabar bean with advantage as a sudorific in cases of incipient bronchitis, congestion of the liver, phthisis with dry hot skin, etc., being always able to bring down the temperature two or three degrees, when sufficient doses were used; such dose being for an ordinary adult, one-fifth, or at least one-sixth of a grain, as a minimum, which can be safely repeated every four to six hours till the desired effect is produced, so long as the patient is carefully watched. I may remark that the exceedingly small doses required to act in tic of the eserine (1-3200th of a grain) are a striking fulfilment of the prophecy, so to speak, written by Sir R. Christison exactly twenty years ago (*Edinburgh Medical and Surgical Journal*, July 1855), that Calabar bean would yet be found to contain a poison more powerful than any yet known.

W. MUNRO, M.D., C.M.
Cupar-Fife.

BISMUTH AND CREASOTE IN INFANTILE VOMITING.

The present epidemic of diarrhoea has furnished us at the Birmingham Children's Hospital with a large number of cases, in which vomiting has seemed a more than usually frequent and troublesome symptom.

Purgatives or ordinary astringents being either premised or contra-indicated, a valuable remedy is known in quarter or half drop doses of dilute hydrocyanic acid, with a grain or two of soda in camphor or dill water. But in severe cases with much depression, and in many cases as an alternative treatment, bismuth and creasote together will be found

* The name by which I have designated this case is open to one great objection—namely, that in paralysis there is observed wasting of the limbs, whereas there was none here.

extremely good. They may be well combined by dropping a minim of the liquid first upon a small quantity of magnesia, rubbing up with eight grains of subnitrate of bismuth, and dividing into four powders; for elder children, into two. They should be freshly prepared for use, and to infants given gently on a moistened finger-tip every three, four, or six hours. In the intervals, my cases generally get a little saccharated lime-water with milk. This plan I have proved now for several years with much success. It is not more infallible, perhaps, than others, nor will it supply for the carelessness or bad hygiene of poor mothers, but, over some approved remedies, it has this vast advantage, that it can do no harm.

EDWARD MACKAY, M.D., M.R.C.P., Birmingham.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

GUY'S HOSPITAL.

PULSATING SARCOMA OF LOWER JAW TWICE UNSUCCESSFULLY REMOVED: EXCISION OF BODY OF JAW: RECOVERY.

(Under the care of Mr. HOWSE.)

[Reported by Messrs. WRIGHT, PARKE, and JAYNES.]

J. P., AGED 76, a brazier and tinman, residing at Bexley, was admitted into Guy's Hospital on July 17th, 1875. He first noticed a good deal of pain on the right side of his lower jaw about nine months ago. Thinking it was toothache, he had the first bicuspid tooth on that side extracted. Speedily afterwards a small lump began to form on the inner side of the jaw, which increased in bulk until it attained the size of a walnut. He was then admitted into Lazarus Ward, under the care of Mr. Birkett. There was then a large irregular fungating mass growing from the gum, and projecting backwards into the cavity of the mouth. It extended from the canine tooth of the right side, which still remained, as far back as the point where the last molar tooth had been implanted; but all the teeth on that side, from the first bicuspid to the last molar inclusive, were wanting. It appeared to be tolerably movable with the gum upon the bone below.

On January 5th, Mr. Birkett removed the tumour (without chloroform) by snipping it through at its base with cutting forceps. A portion of the gum was then cut away with scissors. The growth was attached at one spot to the alveolar process of the maxilla, which was absorbed to a considerable extent. On section, the tumour was fairly resistant, was of a purple-reddish colour, and only exuded serum on scraping. Microscopically examined, it proved to be made up of roundish cells with clear nuclei and much vascular tissue; but no myeloid cells were detected.

Recurrence took place very quickly; and on the 14th portions of new growth along the alveolus were removed by scissors. This was repeated three times in the course of the following month, but still a piece remained. At the end of this time, the patient became very ill, suffering from diarrhoea, etc. On March 4th, he had a kind of epileptiform seizure; and on the 8th, thinking that he should be better in the country, he left of his own accord.

On April 5th, he was readmitted with a growth about three-quarters of an inch in diameter, attached to the alveolus at the same point as at first. It did not cause him any inconvenience in eating, nor was it ulcerated on the surface; but it was adherent to the cheek; and pulsation, not arrested by pressure on the facial artery, was distinctly noticed in the growth. On April 14th, chloroform was administered, and Mr. Birkett made an incision along the margin of the jaw from the anterior edge of the masseter to the symphysis. By raising the soft parts, the tumour was exposed without opening the cavity of the mouth; but the mental branch of the inferior dental nerve was exposed at its emergence from the mental foramen; and, in hooking it out of the way, some of the branches crossing the tumour were divided. The growth was then removed from the jaw with a chisel, some of the surrounding bone being also cut away. The facial artery was not interfered with during the whole operation; but, in the removal of the tumour, the cavity of mouth was laid open into the wound; it was, however, closed in the ordinary manner with sutures.

Primary union took place along the greater part of the skin-incision; and the gap in the jaw granulated, the pus mostly discharging into the mouth. There was numbness over the right side of the lower lip, owing to the division of the filaments of the mental nerve; but this

REGULATIONS TO BE OBSERVED BY CANDIDATES FOR ADMISSION INTO THE ARMY AND INDIAN MEDICAL SERVICES.

THE ARMY MEDICAL SERVICE.

The following are the present regulations affecting candidates for commissions in the Army Medical Service. 1. Every candidate desirous of presenting himself for admission to the Army Medical Service must be not under 21 nor over 28 years of age. He must produce a certificate from the district registrar, in which the date of birth is stated; or if this cannot be obtained, an affidavit from one of the parents or other near relative who can attest the date of birth, will be accepted. He must also produce a certificate of moral character from the parochial minister, if possible. 2. The candidate must make a declaration that his parents are of unmixed European blood, and that he labours under no mental or constitutional disease, nor any imperfection or disability that can interfere with the most efficient discharge of the duties of a medical officer in any climate. His physical fitness will be determined by a board of medical officers, who are required to certify that the candidate's vision is sufficiently good to enable him to perform any surgical operation without the aid of glasses. A moderate degree of myopia would not be considered a disqualification, provided it did not necessitate the use of glasses during the performance of operations, and that no organic disease of the eyes existed. The board must also certify that he is free from organic or other disease, and from constitutional weakness or other disability likely to unfit him for military service in any climate. 3. The candidate must possess two diplomas or licenses—one to practise medicine, and the other surgery in Great Britain and Ireland, and must be registered under the Medical Act in force at the time of his appointment. 4. Certificates of registration, character, and age must accompany the declaration when filled up and returned. 5. Candidates will be examined by the Examining Board in the following compulsory subjects, and the highest number of marks attainable will be distributed as follows: *a.* Anatomy and physiology, 1,000 marks; *b.* Surgery, 1,000 marks; *c.* Medicine, including therapeutics, the diseases of women and children, 1,000 marks; *d.* Chemistry and pharmacy, and a practical knowledge of drugs, 100 marks.—N.B. The examination in medicine and surgery will be in part practical, and will include operations on the dead body, the application of surgical apparatus, and the examination of medical and surgical patients at the bedside. The eligibility of each candidate for the Army Medical Service will be determined by the result of the examinations in these subjects only. Examinations will also be held in the following voluntary subjects, for which the maximum number of marks will be: French and German (150 each), 300 marks; Natural Sciences, 300 marks. The knowledge of modern languages being considered of great importance, all intending competitors are urged to qualify in French and German. The Natural Sciences will include Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany, with special reference to *Materia Medica*. The number of marks gained in both the voluntary subjects will be added to the total number of marks obtained by those who shall have been found qualified for admission, and whose position on the list of successful competitors will thus be improved in proportion to their knowledge of modern languages and natural sciences. 6. After passing this examination, every candidate will be required to attend one entire course of practical instruction at the Army Medical School on (1) Hygiene; (2) Clinical and Military Medicine; (3) Clinical and Military Surgery; (4) Pathology of Diseases and Injuries incident to Military Service. 7. At its conclusion, the candidate will be required to pass an examination on the subjects taught in the school. If he give satisfactory evidence of being qualified for the practical duties of an army medical officer, he will be eligible for a commission as surgeon. 8. During the period of his residence at the Army Medical School, each candidate will receive an allowance of 5s. *per diem* with quarters, or 7s. *per diem* without quarters, to cover all cost of maintenance; and he will be required to provide himself with uniform; viz., the regulation undress uniform of a surgeon, but without the sword. 9. All candidates will be required to conform to such rules of discipline as the Senate may, from time to time, enact.

INDIAN MEDICAL SERVICE.

1. All natural born subjects of Her Majesty between twenty-two and twenty-eight years of age at the date of the examination, and of sound bodily health, may be candidates. They may be married or unmarried. They must possess a Diploma in Surgery, or a license to practise it, as well as a Degree in Medicine, or a license to practise it in Great Britain or Ireland. 2. They must subscribe and send in to the Military Secre-

tary, India Office, Westminster, so as to reach that address at least a fortnight before the date fixed for the examination, a declaration according to a form. 3. This declaration must be accompanied by the following documents: *a.* Proof of age, either by extract from the register of the parish in which the candidate was born, or by his own declaration, form of which can be obtained at the India Office, such extract and declaration respectively bearing the stamps required by law; *b.* A certificate of moral character from a magistrate, or a minister of the religious denomination to which the candidate belongs, who has personally known him for at least two preceding years; *c.* A certificate of registration, in accordance with the Medical Act of 1858, of the degrees, diplomas, and licenses possessed by the candidate. 4. The physical fitness of candidates will be determined previous to examination by a Board of Medical Officers, who are required to certify that the candidate's vision is sufficiently good to enable him to perform any surgical operation without the aid of glasses. A moderate degree of myopia would not be considered a disqualification, provided it did not necessitate the use of glasses during the performance of operations, and that no organic disease of the eyes existed. Every candidate must also be free from organic diseases of other organs, and from constitutional weakness, or other disability likely to unfit him for military service in India. 5. On producing the foregoing qualifications, the candidate will be examined by the Examining Board in the following compulsory subjects, and the highest number of marks attainable will be distributed as follows: *a.* Anatomy and Physiology, 1,000; *b.* Surgery, 1,000; *c.* Medicine, including Therapeutics, the Diseases of Women and Children, 1,000; *d.* Chemistry and Pharmacy, and a practical knowledge of drugs, 100. (The examination in Medicine and Surgery will be in part practical, and will include operations on the dead body, the application of surgical apparatus, and the examination of medical and surgical patients at the bedside). 6. The eligibility of each candidate for the Indian Medical Service will be determined by the result of the examinations in these subjects only. 7. Candidates, who desire it, will be examined in French, German, and Hindustani, Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany, with special reference to *Materia Medica*. 8. The number of marks gained in these subjects will be added to the total number of marks obtained in the obligatory part of the examination by candidates who shall have been found qualified for admission, and whose position on the list of successful competitors will thus be improved in proportion to their knowledge of modern languages and natural sciences. 9. The maximum number of marks allotted to the voluntary subjects will be as follows: French, German, and Hindustani (150 each), 450; Natural Science, 300. 10. The subjects for this part of the examination will be taken from the following books: *Animal Kingdom*, by W. S. Dallas, F.L.S.; *Outlines of the Structure and Functions of the Animal Kingdom*, by Rymer Jones, or *Cours Élémentaire d'Histoire Naturelle*, par Milne-Edwards; *Lindley's School Botany*, *Lindley's Medical and Economic Botany*, *Henfrey's Elementary Course of Botany*; *Elements of Natural Philosophy*, by Golding Bird and C. Brooke; *Physical Geography*, by Mrs. Somerville. 11. The Examiners in London will prepare a list in order of merit, with the marks affixed in the different subjects, to be transmitted to the Director-General and communicated to the Professors of the Army Medical School. If any candidate is found to be deficient in any particular subject, this shall be stated, in order that he may receive special instruction on the point at Netley. 12. After passing his preliminary examination, candidates will be required to attend one entire course of practical instruction at the Army Medical School, before being admitted to examination for a commission—(1.) Hygiene; (2.) Clinical and Military Medicine; (3.) Clinical and Military Surgery; (4.) Pathology of Diseases and Injuries incident to Military Service. These courses are to be of not less than four months duration; but candidates who have already gone through a course at Netley as candidates for the Army or Navy Medical Service may, if thought desirable, be exempted from attending the School a second time. 13. During the period of his residence at the Army Medical School, each candidate will receive an allowance of 5s. *per diem*, with quarters, or 7s. *per diem* without quarters, to cover all costs of maintenance; and he will be required to provide himself with uniform (viz., the regulation undress uniform of a Surgeon of the British Service, but without the sword). 14. All candidates will be required to conform to such rules of discipline as the Senate may, from time to time, enact. 15. At the conclusion of the course, candidates will be required to pass an examination on the subjects taught in the School. The examination will be conducted by the Professors of the School. The Director-General, or any medical officer deputed by him, may be present and take part in the examination. If the candidate give satisfactory evidence of being qualified for the practical duties of an Army Medical Officer, he will be eligible for a commission as surgeon. 16. The position of the candidates on the list of Surgeons

will be determined by the combined results of the preliminary and of the final examinations, and, so far as the requirements of the service will permit, they will have the choice of Presidency in India, according to their position in that list. *M.B.*—The examinations for admission to the Indian Medical Service will usually take place twice a year, viz., in February and in August.

MEDICAL SCHOOLS AND HOSPITALS IN IRELAND.

UNIVERSITY OF DUBLIN SCHOOL OF PHYSIC.—Regius Professor of Physic, Dr. W. Stokes, D.C.L., F.R.S.; Regius Professor of Surgery, Dr. W. Colles; University Professor of Anatomy and Surgery, Dr. B. G. M'Dowel; University Professor of Chemistry, Dr. Reynolds; University Professor of Botany, Dr. E. P. Wright; Professor of Surgery in Trinity College, Dr. E. H. Bennett; University Anatomist, Dr. T. Evelyn Little; Professor of Comparative Anatomy and Zoology, Dr. Macalister; Erasmus Smith's Professor of Natural Philosophy, Rev. John Leslie, M.A.; University Lecturer in Operative Surgery, Dr. R. G. Butcher; King's Professor of Institutes of Medicine, Dr. J. M. Purser; King's Professor of Practice of Medicine, Dr. W. Moore; King's Professor of *Materia Medica* and Pharmacy, Dr. Aquilla Smith; King's Professor of Midwifery, Dr. E. B. Sinclair; Professor of Medical Jurisprudence, Dr. R. Travers.

The Winter Session commences on the 1st October, and terminates on the 31st March. Lectures will commence on the 1st November. The Dissecting Room will be opened on the 1st October. The Winter Courses consist of fifty-six Lectures each. Attendance on at least forty-two Lectures in each Course is required. Two Medical Scholars are elected annually by the Board of Trinity College, at an Examination held at the end of June. Each Scholarship is worth £20 *per annum*, and is tenable for two years. The Professors of the School of Physic give three Exhibitions annually, amounting altogether in value to £40. No student can attend any of the Lectures delivered in the School of Physic, or Dissections, who has not complied with the provisions of the School of Physic Act as to Matriculation.

CARMICHAEL SCHOOL OF MEDICINE.—The following are the courses of lectures.—Winter Session, commencing Monday, November 1st. Surgery, Mr. Anthony H. Corley, Tu., Th., and S., 12; Practice of Medicine, Dr. Samuel Gordon and Dr. J. W. Moore, M., W., and F., 12; Anatomy, Mr. Foy, Tu., Th., and S., 1; Physiology, Dr. Reuben J. Harvey, M., W., and F., 1; Midwifery, Dr. W. B. Jennings, M., Tu., and F., 2; Chemistry, Dr. C. R. C. Tichborne, Tu., Th., and S., 2; Ophthalmic Surgery, Mr. C. E. Fitzgerald, W., 11. Summer Session, commencing Monday, April 6th, 1876.—Institute of Medicine, Dr. R. J. Harvey, Tu., W., Th., and F., 11; *Materia Medica*, Dr. Auchinleck, M., W., and F., 12; Botany, Mr. E. B. Blakeley, Tu., Th., and S., 12; Practical Chemistry, Dr. C. R. C. Tichborne, Tu., Th., and S., 1; Forensic Medicine, Dr. Woodhouse, M., W., and F., 1. The Carmichael (formerly Richmond Hospital) School of Medicine, in which all the courses of lectures required for the different Colleges are delivered, is in the immediate vicinity of the Richmond, Whitworth, and Hardwicke Hospitals, and is connected with these institutions by its teachers. Certificates of attendance on the lectures in this school are recognised by all the licensing bodies in the United Kingdom.—Class premiums, to the value of £60, on the foundation of the late Richard Carmichael, Esq.; and the Mayne Scholarship, value £15, are awarded at the termination of the session.—Fees, for each course of lectures, £3 3s.; for all the courses of lectures required in order to obtain the diploma of the Dublin College of Surgeons, £66 3s.; a discount, amounting to £9 19s. 6d., is allowed in the case of perpetual pupils. Perpetual Pupils, paying £56 3s. 6d. (either on entrance, or half at the commencement of the first, and the remainder at the commencement of the second session), can attend all Lectures necessary to obtain the license of the Dublin College of Surgeons. For all the lectures required by the Royal College of Surgeons of England, London, £51 9s.; for all the lectures required by the College of Surgeons, Edinburgh, £45 3s. The dissections are superintended by the lecturers and demonstrators who attend at the following hours, daily from 11 to 4, to assist the students in the study of Practical Anatomy. During the session, the lecturer on Surgery will give special courses of demonstrations and illustrations in Operative Surgery. Special Classes will be formed for practical instruction in Histology and Physiological Chemistry, and will be conducted by the lecturer on Physiology. The Museum of the School comprises a valuable collection of Anatomical and Pathological preparations. There is also an extensive Museum of *Materia Medica*. For further information

respecting the School, apply to Dr. Harvey, 7, Upper Merrion Street, or any of the lecturers.

DR. STEEVENS' HOSPITAL AND MEDICAL COLLEGE.—The Hospital contains 250 beds, and is provided with special wards for the treatment of fever, syphilis, and diseases of females. Visiting Physicians, Dr. W. M. Burke; Visiting Surgeons, Mr. S. G. Wilmot and Mr. C. Fleming; Physicians, Dr. H. Freke, Dr. T. W. Grimshaw; Physician-Accoucheur, Dr. J. Isdell; Surgeons, Mr. W. Colles, Dr. E. Hamilton, Dr. R. M'Donnell. The hospital is visited at 8.30 P.M.; and clinical instruction is given as follows: Mr. Wilmot (on Saturdays at 10); Dr. Freke, Monday; Mr. M'Donnell, Tuesday; Mr. Hamilton, Wednesday; Mr. Colles, Thursday; Dr. Grimshaw, Friday; Dr. Isdell, Saturday—each at 9 A.M. Operations are performed on Saturdays at 10. Pathological Demonstrations are given by the Lecturers as opportunity offers. The following lectures are given in the Medical School. Anatomy, Physiology, and Morbid Anatomy, Mr. Hamilton, daily, exc. Sat., 10; Practice of Medicine, Dr. Freke, M., W., F., 11; Surgery, Mr. Colles, Tu., Th., S., 11; Midwifery and Diseases of Women and Children, Dr. Isdell, M., W., F., 12; Chemistry, Dr. Bell, Tu., Th., S., 12; Descriptive Anatomy, Mr. Swan, daily, except Sat., 1; Dissections superintended by the Lecturers on Anatomy and the Demonstrators, 7 A.M. to 8 P.M. Practical Anatomy and Hospital Attendance commence on the first Monday in October. The Sessional Lectures commence on the first Monday in November. Lectures are also given on *Materia Medica* by Dr. Grimshaw; on Medical Jurisprudence by Dr. Tweedy; and on Botany by Mr. Warren. The Reading Room and Museum are open daily. There is also a Lending Library. Fees: Hospital Practice, 9 months, £9 9s.; 6 months, £7 7s. Practical Anatomy, £5 5s. Lectures, each course, £3 3s. Resident Dresser (6 months), Winter, £21; Summer, £15 15s. A perpetual fee of 78 guineas, which may be paid in two instalments, entitles the student to attend all the lectures and hospital practice required by the Colleges of Surgeons, Halls, and the public service.

General Examinations will be held at the close of the Session, at which Students are expected to answer, in order to entitle them to Certificates of Attendance. Students who reach a certain standard will be recommended for honours, and will receive Special Certificates. The following prizes are offered: Medical and Surgical Clinical Prizes; and Cusack Medals and Exhibitions.

Further particulars may be learned from any of the Professors; from the Resident Surgeon at the Hospital; or from Dr. E. Hamilton, 120, Stephen's Green West.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.—Physicians: Dr. A. W. Foot, Dr. J. W. Moore. Surgeons: Dr. G. H. Porter, Mr. J. H. Wharton, Mr. P. C. Smyly, Mr. R. Macnamara, Mr. R. P. White, Mr. L. H. Ormsby. Four Clinical Lectures are given weekly, on alternate days. The Physicians and Surgeons visit the Hospital at 9 A.M. Fees: 9 winter months, £9 9s.; 6 winter months, £7 7s.; 3 winter months, £3 13s. 6d.; 3 summer months, £3 3s. The Hospital contains 120 beds; it has a Dispensary, Lending Library, and Physiological Laboratory attached, and is within a few minutes' walk of the University, the College of Surgeons, and the Ledwich School of Medicine. It contains a ward for Diseases of Children. Prizes are given at the end of the Winter course. The office of Resident Pupil is open to pupils as well as to apprentices. Further information may be obtained of Mr. L. H. Ormsby, 12, Lower Fitzwilliam Street.

MERCER'S HOSPITAL, DUBLIN.—Physician: Dr. Thomas P. Mason. Surgeons: Mr. Edward Ledwich, Mr. E. S. O'Grady, Dr. John Morgan, and Dr. Benjamin F. McDowell. The Hospital is visited daily at 9 A.M. There are wards for Fever and Contagious Diseases. Dressers are selected from the most attentive of the students. The Dispensary affords ample opportunities for acquiring dexterity in minor Surgery, and a practical knowledge of the Diseases of Women and Children. Systematic Clinical Lectures and catechetical instruction will be given daily. The appointment of Resident Students is open to all perpetual Pupils of the Hospital, through Competitive Examination. The Hospital is in the immediate vicinity of two of the principal Medical Schools. Fees: 6 months, £6 6s.; 9 months, £8 8s.; perpetual, £21. Further information can be obtained from any of the Physicians or Surgeons of the Hospital, or from the Registrar, Mr. James Shaw.

SIR PATRICK DUN'S HOSPITAL.—Consulting-Physician: Dr. W. Stokes, D.C.L., F.R.S. Consulting-Surgeon: Dr. R. Adams. Clinical Physicians: Dr. J. M. Purser, Dr. W. Moore, Dr. Aquilla Smith. Midwifery Physician: Dr. E. B. Sinclair. Clinical Surgeons: Dr. B.

gradually diminished. Recurrence of the growth again took place very speedily; and on April 27th it was noted that "a small, soft, elastic swelling could be felt on the anterior part of the opening into the mouth". This rapidly increased in size, and on May 6th was found to be very distinctly pulsating. Discouraged at the want of success attending these operative proceedings, the man left the hospital on May 12th, thinking he would try to manage at home without treatment.

On July 17th, however, he was readmitted into Naaman Ward, under Mr. Howse, with a pulsating tumour in the same situation, about an inch and a half in diameter. It was adherent to the lip, was ulcerated on the surface, and—the symptom which had alarmed him principally—had bled profusely on several occasions. There was still partial anaesthesia, both inside and out, over the right half of the lower lip. A small sinus, from which a slight purulent discharge issued, still existed externally in the site of the old operation.

On July 20th, chloroform having been administered, an incision was made along the lower margin of the inferior maxilla from the angle to the symphysis, which traversed the cicatrix and the sinus remaining from the former operation. The facial artery, with one or two smaller vessels, were secured with gut ligatures. The jaw was then divided behind the position of the last molar tooth, obliquely backwards to the angle, with a finger-saw. The same process was repeated at the symphysis; but at this point it was deemed advisable to take away a second slice, as it was found, on making a section of the growth, that it had encroached very far on the bone in this direction. In this way, the whole of the symphysis was removed. The bleeding vessels having been twisted or ligatured, the edges of the skin-incision were brought together in the usual way with sutures.

No single bad symptom followed the operation. On the next day, the body temperature was normal, and the patient managed to swallow much milk through the mouth without recourse to the nasal tube. On the two following days, his temperature rose to 99.8 deg., but fell again to normal. On the 28th, two of the sutures were taken out, and on the 30th the remaining sutures were removed, complete primary union having taken place. On August 25th, he left the hospital, having then been quite well and about the ward for some time. Since that date, he has returned on two occasions to report progress, and have a large useless tooth in the upper jaw on the right side removed, as it pressed on the cicatrix and was otherwise inconvenient. A very large amount of dense gristly substance had formed in the site of the removed jaw, and he was well able to use the jaw in the mastication of soft food. There was no sign of recurrence of the disease.

On making a section of the growth, it was seen to spring deeply from the centre of the jaw itself, and to run forwards as far as the symphysis, backwards as far as the last molar tooth. Hence no operative measure short of the one adopted would have been of the slightest avail. In only one place did the tumour approach at all near the line of incision, and that was towards the lip, which was adherent to the growth, so that the dissection had to be carried out rather finely at this point. Microscopically examined, the growth was similar to that first described; viz., sarcomatous cells with much vascular tissue (angio-sarcoma).

The result so far must be considered very satisfactory, considering the age of the patient (76), and the very speedy recurrence of the disease after the previous operations. It should be added that the patient was a little, lithe, wiry man, who looked as if he had yet twenty years to live, if the natural period of his life were not interrupted by accidents.

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

CASE OF CHOREA GRADUALLY BECOMING WORSE UNDER TREATMENT BY ARSENIC. RAPID IMPROVEMENT UNDER INFLUENCE OF CHLORAL, PORT WINE, AND IRON.

(Under the care of Dr. BRADBURY.)

M. N., AGED 15, a domestic servant, was admitted into the hospital May 25th, 1875, with well-marked symptoms of chorea. She had a similar attack two years ago, in which both sides of the body were affected. This attack lasted eight weeks, and the existing cause of it was frigid.

Her present illness began eight weeks ago, and she could assign no cause for it. Her health had been quite good for some time past. On admission, there were distressing choreic movements, the left side of the body being more affected than the right. She appeared in a very excited condition. Walking was attended with difficulty, and her articulation was interfered with, so that her sentences were interrupted. Bowels regular. Tongue clean. The catamenia had not yet appeared. At the heart's apex, a systolic *bruit* was heard. There was no history of rheumatism in the family, nor of any nervous disorder, so far as could

be ascertained. About the time when the present attack came on, she had been doing an excessive amount of work, and, from lack of sufficient time for her meals, she used "to bolt" her food. The choreic movements came on gradually, beginning in her right hand.

She was placed on full diet. Two days after her admission, she was ordered five minims of liquor arsenicalis three times a day, the dose being increased to six minims on May 31st, on the evening of which day the following note was made. "The choreic movements are considerably worse than on admission. From the time she came into the hospital to the present, she has been getting worse, and particularly so since she began to take the arsenic."

On June 1st, she was so bad that the arsenic was discontinued. Mastication was almost impossible, and for the last day or two she had had to be fed. She was ordered ten grains of bromide of potassium with tincture of henbane three times a day. On the morning of the 2nd, she was a little quieter; but in the evening she was again very wild and excited.

June 3rd. She was very bad all through the night. The wrist was red and swollen, and there was redness about the arms and shoulders, and even slight abrasions over the sacrum due to the incessant movements. Pulse 120. The temperature taken for the first time this evening was 102.4 deg. Fahr. She was quite unable to take solid food, from the difficulty of mastication and deglutition. She was very thirsty. She was ordered to be fed frequently with milk and beef-tea.

R. Chloral-hydrat. gr. xv; syrapi aurantii ℥xx; aquam ad ℥j.

Misce. Fiat haustus, hæc nocte sumendus.

R. Misturæ ferri comp. ℥vj; decoct. aloes co. ℥ij. M. Fiat haustus, quater in die sumendus.

June 4th. She had a much better night, sleeping for three or four hours. Morning temperature, 100.8 deg.; evening temperature, 101.6 deg. The chloral draught was repeated.

June 5th. She seemed to have improved considerably, though she appeared much exhausted. The chloral was repeated, and two ounces of port wine ordered. In consequence of a bed-sore over the sacrum, she was placed on an air-bed. She could now eat a little bread, although the mouth and lips were very sore. Morning temperature, 100 deg.; evening temperature, 101 deg.

June 6th. She ate a little fish. Temperature diminishing.

She continued to make rapid improvement, being able to dispense with the chloral on the 9th, and on the 10th she begged for meat again. The evening temperature kept a little above the normal till the 14th, but since then there has been no elevation.

On July 8th, she appeared quite well. A systolic *bruit* still, however, remained at the heart's apex; and the catamenia had not appeared.

REMARKS.—This case is of interest in connection with the comments of Drs. Eustace Smith and John K. Spender, and of Messrs. Jones and Gaskoin, in the JOURNALS for May 1st, May 15th, and June 5th, on the treatment of chorea by arsenic in large doses. Having read the observations of these gentlemen just previously to the above case coming under his care, Dr. Bradbury resolved to give arsenic in large doses a fair trial. Finding, however, that even medium doses (five and six minims) thrice daily did harm rather than good, Dr. Bradbury did not resort to the large doses recommended by Dr. Smith, and he cannot but think that it is a mistake to treat all cases of chorea by any single remedy. Each case must be treated upon its own merits, the predisposing and exciting causes of the disease being especially inquired into; indeed, the more Dr. Bradbury saw of the practice of medicine, the more he felt the great importance of finding out the *fons et origo mali*. During the past Easter Term, when he had charge of the wards, several cases of chorea came under his care. One got well without any medicine: good food and the discipline of the hospital being all that were required. Another, with amenorrhœa, was cured with Griffith's mixture and compound decoction of aloes given in combination. A third, a woman seven months advanced in pregnancy, who had had two previous attacks of chorea, the first after acute rheumatism, was benefited by cod-liver oil and bromide of potassium; but the disease will probably not completely subside till she has been confined.* Among his out-patients, Dr. Bradbury has had great success with arsenic in chorea, and of all single remedies he considers it the most frequently successful. In the case recorded above, however, it signally failed to be of any service, and this not from any want of tolerance of the drug by the patient. The amendment following the administration of the chloral was very marked, but how much of the improvement was due to the iron it is difficult to estimate. It ought to be remarked that this case of chorea passed from an apparently non-febrile to a febrile state whilst under treatment by arsenic.

* This woman has since been delivered, and the chorea has completely left her.

REVIEWS AND NOTICES.

LUNATIC ASYLUM REPORTS, 1875.

THE annual report of the Somerset County Asylum has been just issued. The chief point of interest in it is the experience of the Superintendent, Dr. Madden-Medlicott, with regard to the influence on the admissions of the subsidy recently granted by the Exchequer of four shillings a week to the unions for each patient. Though not saying directly that the grant has been taken advantage of for the purpose of removing the imbeciles and the chronic insane to the asylum, instead of keeping them in the workhouses, still such a conclusion is to be drawn from the hints thrown out. From Dr. Medlicott's remarks on this subject, we have no hesitation in differing. He says that "the detention of this latter class (imbecile and chronic insane) in workhouses, as long as they remain cleanly, quiet, and harmless, is proper enough; and their removal to the county asylum inflicts an unjust tax on the ratepayers". But is not this rather begging the question in supposing that workhouses do afford the means for the treatment of patients in such a way that they shall remain clean and harmless? The Committee of the Somerset Asylum, indeed (p. 16), did make the attempt of utilising workhouses as lunatic asylums by transferring "forty-seven selected harmless cases"; but "of these nineteen were returned, the majority greatly deteriorated in mental, and particularly so in bodily condition." Even when more stringent regulations were enforced on the workhouse authorities as to diet and exercise, it was found that, after a period of only five months, one out of the patients had to be returned. It must be allowed that preference should always be given to the admission of acute cases, and that, *faute de mieux*, the imbecile and chronic insane had better be kept in the workhouses under some sort of supervision, than in their own homes under none; but the experience of the new metropolitan asylums, and in this we are borne out by the Lunacy Commissioners, is directly in favour of the immense benefits conferred on the chronic insane, regarding alike their bodily condition, mental quietude, and useful occupation, by removal from the workhouse to a thoroughly carried-out system of asylum treatment. It seems hardly fair to complain of want of room for these patients, since (though the report under notice does not mention it) the asylum contains private patients, paying sums varying from three to five shillings per head more than those from the county of Somerset itself. Some of these patients are chargeable (or were in October 1873) to Shoreditch, and some to Bethnal Green. It would be interesting to have a return made of the mental condition of these inmates, so that, if suitable, they might be transferred to one of the metropolitan asylums, in which vacancies exist, at a saving to the ratepayers of seven shillings per head per week. Relieved of these "boarded out" cases for which the metropolis is both able and willing to provide, and of a certain number of "criminal lunatics", which ought to be maintained elsewhere (the wrong to other inmates of keeping "criminal lunatics" in county asylums we have often urged, and are constant hearing complaints about), there will be room provided for the treatment of the chronic insane, for whom an asylum is as much a "hospital for the insane" as it is for acute cases.

Beyond this matter, there is nothing in the Report calling for notice except the remarks of the chaplain. This gentleman makes a refined distinction between "moral" and "physical" melancholia, expecting to meet with success in his ministrations to the former, but not to the latter. Whatever the exciting cause may be, the proximate one is always physical, and the absurdity of relaxing our efforts because melancholia depends on such a cause as hemorrhoids, and redoubling them when it is supposed to depend upon such a transcendental hypothesis as a depressed psychic force, is manifest to all who have any real knowledge of the subject. Clergymen had better leave the vexed question of classification of disease in the insane untouched. In the table of "causes of death", we find the word "Plura", which scarcely looks like a printer's error; and in the table of "Forms of Disorder", a distinction made between "Dementia" and "Fatuity", which seems an useless refinement, if, indeed, allowable.

The Report from the Devon County Asylum, of which Dr. Symes Saunders is the Superintendent, deals with the same question as that of the Somerset Asylum, viz., the influence of the Government grant on the increase of admissions of chronic lunatics. Dr. Saunders does not like this class of patients, though he admits that they entail an additional amount of care and responsibility to the workhouse. The cases adduced as "typical" will scarcely bear criticism. One was an idiot girl, a deaf-mute, "who required no special treatment". We should

have thought that, if one case had been more fitted than another for reception into an asylum, this was the one; and for, under skilled treatment, her habits might have been improved, her faculties developed, and her condition of life rendered more comfortable. The experience and attention required to effect these ends could not be had in a workhouse; and it is simply outrageous to expect a special staff to be kept in a workhouse to deal with cases for which the asylum was purposely built. Another case, "M. A. P.", was violent when in the workhouse, and "her superfluous energy found vent by striking those who annoyed her; though in the asylum she is docile, harmless, well conducted, and employs herself in domestic work". A curious instance, this, to give of the absurdity of removing a person, deaf-mute, from the workhouse to an asylum! It is doubtless more interesting for a superintendent to have a number of acute cases under his hands, since his proportion of cures will be greater, and his death-rate less, than if the chronic insane, many of them, perhaps, in the last stages of dementia, are brought in; but it has been proved, over and over again, that the insane are not, and cannot be, properly treated in workhouses, and it is only a retrograde philanthropy that proposes to keep them there. The law on the subject is so simple and clear, that no apprehensions need be felt as to the improper incarceration of persons in consequence of the Government grant. If a person become insane, the proper place for him, whether his insanity be acute or chronic, is the asylum; and the fact of the ratepayers being relieved to the extent of four shillings per head per week, can make no difference as to the propriety or not of sending him to a place where he can be placed under the best possible conditions for his comfort and recovery (and the experience of Leazesden and Caterham has shown amply that "chronic" lunatics may recover). If, on the other hand, persons who are simply troublesome in the workhouse, but not insane, are sent to the asylum, the remedy is easy—viz., discharge them, and, if necessary, prosecute those who tried to incarcerate them improperly. The general management of the asylum appears to be satisfactory; but we notice that the death in one instance was "impaction of food in the larynx", and that no inquest was held. Without doubt, the circumstance was reported to the coroner at the time; but it would have been more satisfactory if an inquest had been held, as there is nothing so salutary as a temporary check in public institutions for making the subordinate officers more careful. Dr. Saunders concludes by suggesting that the Government grant should be applied for the building and repairs of asylums, and for salaries and superannuations. If we mistake not, the same proposal was made in a letter to the *Times* by Dr. Robertson when the grant was first made.

The want of appreciation of the Government grant which we have shown to exist in the Reports of the Somerset and Devon Asylums is confirmed by what the Committee of the Chester County Asylum and Dr. Davidson have to say. These hope that, in consequence of it, "patients will be brought sooner for asylum treatment, and thus afford a more favourable prospect of recovery"; and "though the effect will probably be an increase in the number of admissions, the increase will not be permanent." Such enlightened views deserve imitation. It is mere prejudice on the part of superintendents to object to chronic cases; for it is now an absolute fact that many so-called "chronic" cases recover under good auspices; or, if they do not recover, they are, by removal from the workhouse to the asylum, placed under the advantageous conditions to which, both by law and by common consent, they are entitled. A remark recently made by a commissioner in one of his visits to one of the metropolitan asylums, is worth quoting. It was to this effect: "Well, if occasionally improper cases are sent down, these asylums have clearly demonstrated that chronic insanity is not always an incurable disease, and have formed a new era which no superintendent should forget." After all, what is "chronic disease"? It cannot be measured by time. There is no definition in the whole bounds of medicine more difficult; and, in the present state of uncertainty, it is best to give all the benefit of the doubt.

ANNUAL REPORT OF THE FEVER HOSPITAL AND HOUSE OF RECOVERY, CORK STREET, DUBLIN, for the Year ending March 31st, 1875.

THIS report consists chiefly of a series of tables showing the number of admissions of the principal diseases and their mortality during the year, and comparing them with those admitted during the same periods of previous years. Other tables give an analysis of the ages of the patients; while the remainder of the report is devoted to a short account of the localities whence the patients came, and some observations on the connection between a large number of cases of pneumonia and the meteorological conditions at the time. In Dr. Grimshaw's table, there does not appear to be any relation between the rainfall and the number of admissions of pneumonia cases. In August,

when the rainfall was most heavy, but four cases were admitted; in another month, when the rainfall was nearly as heavy, the cases were numerous. The same observation may be made with regard to the temperature. It is interesting, however, to learn that Dr. Grimshaw concludes that he has distinctly traced the cause of the pneumonia to a miasmatic source.

SELECTIONS FROM JOURNALS.

MEDICINE.

GIOVANNI ON CONTRACTED PUPIL IN HEART-DISEASE.—Professor Giovanni (*Annali Universali di Medicina*) has studied with care three cases of advanced organic heart-disease accompanied with bilateral myosis, from which he draws some interesting conclusions. All three were accompanied by severe dyspnoea, continuous or recurrent. One was a case of mitral narrowing and insufficiency; the second, a case of aortic narrowing, with valvular insufficiency; the third, aortic narrowing, with mitral insufficiency. In all three, there was constant bilateral myosis; in two, this symptom was more marked when the dyspnoea was more urgent. Since Pourfour, Du Petit, Bernard, and Biffi demonstrated the influence of the sympathetic on the pupil, the action of aortic aneurisms and of other tumours on the pupil has been studied. Eulenbergh, Gultmann, and others, have shown that all affections which produce compression of the sympathetic in the neck are followed by pupillary stenosis. The author has not found this symptom mentioned in isolated cardiac affections. In order to determine the clinical value of myosis of cardiac origin, its origin and mechanism must be studied. It is a paralytic myosis. It may arise from three sorts of lesion: 1, lesions of the cervical cord; 2, lesions of the superior cervical ganglia; 3, of the terminal filaments of the sympathetic which go to the radial fibres of the iris. We must here dwell on the lesion of the superior cervical ganglion. The author has examined with the microscope the sympathetic and many sections of the cervical spinal cord of the patients in question. He has found great hyperæmia of the ganglia of the sympathetic, with more or less intense infiltration of the lymphoid elements. At the same time, the tissue of the ganglia was softer and more infiltrated with fluid than in the normal state. The upper part of the cord presented no similar condition; nor was there any reason to admit an isolated lesion of the terminal sympathetic nerves of the iris. These different lesions are the consequence of the stasis of the blood produced by the state of the heart. They exist, probably, in all patients of this class, but are not always manifest. The disorders which have their source in the sympathetic are comparable to those which proceed from the encephalon or from the spinal marrow. In certain patients with cardiac disease, cerebral excitement is found; in others, somnolence. Myosis has a very distinct significance; it does not only indicate stasis of the blood, but a profound lesion of the ganglionic cells, thenceforth paralysed. The ganglionic lesion affects equally the heart and the lung, to the innervation of which the ganglionic cells contribute. The cardiac activity and pulmonary circulation are therefore more seriously affected than in other cases, when myosis exists. The author draws from these facts the following conclusion from the point of view of prognosis. Myosis in affections of the heart is a symptom of very grave prognostic value. It announces the presence of a lesion of the ganglia of the sympathetic, which tells upon the heart itself and the lungs.

MILK-DIET.—Milk-diet, as a means of treatment in dropsical disease, is specially advocated by Dr. Serre d'Alais (*Journal de Connaissances Médicales*). He associates it with a diet of onions, raw or cooked. He prescribes three *soupes au lait* every day, onions, and a dry diet. He lays down, as his method of treatment, first to relieve the urinary gland by abstinence from drinks generally; to excite it gently with onion; to nourish the body with milk, its primitive nutriment, without irritating it. M. Serre terminates by saying that, if this régime be not successful, the régime is bad. M. Desnos, at the Pitié, employs milk a good deal when it is desirable to provoke diuresis, and that in very different cases. But he is not a partisan of the exclusively milk diet, which is often not well tolerated, and is not sufficiently nourishing. The patient eats meat, drinks wine, but adds to his diet two pints of milk every day. The milk is drunk cold, and salted with two *grammes* of kitchen-salt to the pint. M. Desnos recommends milk especially in acute catarrhal nephritis. In chronic nephritis, it is only palliative. In dropsies complicating the diseases of the heart, M. Desnos employs also milk, which provokes abundant diuresis, and unloads the vascular system; but if, after two or three days, diuresis be

not established, he stops the milk-treatment, for then the circulatory system would become loaded rather than relieved. Milk is advantageous also in simple pleurisy; but there must be an absence of fever, and the milk must only be employed when we wish to avoid puncture. It is especially employed when the effusion has resisted blistering and natural diuretics. It has also succeeded sometimes in chronic pleurisy.

MIDWIFERY AND DISEASES OF WOMEN.

OBSTRUCTIVE DYSMENORRŒA.—Dr. Thomas Addis Emmet, in the *New York Medical Journal*, August, 1875, divides cases of obstructive dysmenorrhœa into two classes: 1. Obstruction at or below the vaginal junction; 2. Obstruction in the body of the uterus. The first class he considers congenital, and due to the more rapid growth of the cervix, causing it to turn against the posterior vaginal wall, and producing a flexure at the junction of the body and neck. Predisposing causes: laxity of uterine tissues and elongation of cervix. In this class, the pain passes off as the flow becomes established; congestion causing thickening and shortening, with consequent straightening of the cervix. For these cases, he advocates dividing the cervix posteriorly. This cuts the circular fibres; and the longitudinal ones gradually contract and retract, and the canals become straight. The advantages of posterior division are, less risk of hæmorrhage, and the prevention of gaping by the lateral pressure of the vaginal walls. The operation should be performed by slitting the cervix back to the vaginal fold with scissors. If this be made the guide, there is no danger of wounding the circular artery. A tampon should be applied, in case bleeding comes on after the operation; and the wound kept open by drawing a sound through its angle, with daily dressings. The patient must be kept in bed till the parts have healed. The second class are due to flexions in the body of the uterus from chronic metritis or fibroid tumour. In these, increase of congestion increases the flexure. When of old standing, the fibres at the point of flexure degenerate fatty, and are absorbed; hence the deformity becomes permanent. In these cases, the pain is worse as the flow goes on. The cure is very tedious. No operative measures should be undertaken until all tenderness at and around the uterus has been removed by appropriate treatment. Hot-water vaginal injections; iodine or the impure carbolic acid to the interior of the uterus. When all disease is remedied, divide the cervix posteriorly, as in the other cases; and then carry up an uterotome, and incise the uterus at the point of stricture, so as to leave a permanent channel.

COMPLICATED OVARIOTOMY.—A case of ovariectomy complicated with pregnancy and Cæsarean operation is recorded by Mr. Thomas Hillas, M.R.C.S. Eng., in the *Australian Medical Journal*, February, 1875. M. McC., aged 24, single, was admitted into the Ballarat District Hospital on June 4th, 1872, having previously been in another hospital for supposed pregnancy, and been discharged after a seven months' residence as suffering from ovarian tumour. After admission at the Ballarat District Hospital, she was examined by the staff, and a consultation held, when ovariectomy was decided on. On June 13th, Mr. Hillas commenced the operation, and, in entering the peritoneal cavity, cut into a gravid uterus. The abdominal incision being enlarged, an ovarian tumour was removed, and the clamp applied to the pedicle; the uterus all this time lying on the thighs, with a wound probably into the placenta. The general advice was to sew up the wound in the uterus, and let nature take its course; but Mr. Hillas, thinking labour must soon come on, and fearing rupture of the uterus at the wounded point, decided to perform Cæsarean section. The uterus was incised to five inches; and the placenta, with a living and well developed fœtus at about the eighth month, extracted. Nine or ten silver sutures were then put into the uterus, the cut ends being carefully tucked down into the incision. The uterus immediately firmly contracted. The abdominal wound was then closed with deep and superficial stitches, the clamp at the lower angle of the wound having a good deal of drag on it. The patient vomited for forty-eight hours after the operation. In four days, all unfavourable symptoms ceased, and she was discharged cured at the end of six weeks. On July 3rd, a month after the operation, she menstruated moderately for four days; and again on August 28th. She has since been seen several times in good health. [The success attending ovariectomy during pregnancy, without interfering with the uterus, is well established by many successful cases. The above case seems to show that we need not be in despair if such a very unfortunate accident as wound of the uterus occur. It would be very interesting to have the farther history of the silver sutures, especially should the woman again become pregnant.]

BRITISH MEDICAL ASSOCIATION:
SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st, Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, SEPTEMBER 25TH, 1875.

PSYCHOLOGY AND THE NERVOUS SYSTEM.

I.

SOME of those who are sceptical as to there being representation of movements in the cerebral hemispheres seem to us altogether overlook several kinds of evidence in favour of it. This evidence has recently been presented in a pamphlet, of which this article is in great part a summary. The lower nervous centres represent movements; and thus it would be a marvellous breach of the principle of continuity, of which so much use is made, if the highest nervous centres—the cerebral hemispheres—did not. So long as thirty-five years ago, Laycock was led to the conclusion that the cerebral hemispheres are functionally like the lower nervous centres, except for differences of degree and complication. The following is a remarkable statement, considering that it was made so long ago.

“Four years have elapsed since I published my opinion, supported by such arguments as I could then state, that the *brain*, although the organ of consciousness, *is subject to the laws of reflex action; and that, in this respect, it does not differ from the other ganglia of the nervous system.* I was led to this conclusion by the general principle that the ganglia within the cranium, being a continuation of the spinal cord, *must necessarily be regulated, as to their reaction on external agencies, by laws identical with those governing the spinal ganglia, and their analogues in the lower animals.*” (Laycock, *British and Foreign Medical Review*, vol. xix, January 1845, p. 298.)

If the lower centres represent impressions and movements, why should not the highest nervous centres represent them? The reader must bear in mind that this question was asked before the recent brilliant experiments of Hitzig and Ferrier were made. As we wish to show that there is, independently of these experiments, strong although indirect evidence of another kind that the cerebral hemispheres do represent movements, we are anxious that the following arguments should not be considered as mere after-thoughts. Five years ago it was asked, “*Of what ‘substance’ can the organ of mind be composed, unless of processes representing movements and impressions; and how can the convolutions differ from the inferior centres, except as parts representing more intricate co-ordinations of impressions and movements in time and space than they do?*” Are we to believe that the hemisphere is built on a plan fundamentally different from that of the motor tract?”

To questions like these, one reply often is, that the highest nervous centres, being the organ of Mind, have a different “function” from that of lower centres. The implication of this objection evidently is that, in asking such questions, we confound Mental states with Physiological states. The objection cannot be sustained; in fact, the assertion is an irrelevant one. That the highest centres are concerned in mental operations, no educated person denies now-a-days; but, in regarding the function of the highest nerve-centres as being the co-ordination of impressions and movements, we do not ignore that other so-called function, Mind. Our supposed objector speaks of Mind being a “function” of brain; he speaks, indeed, quite easily, as if there were no sort of difficulty as to the nature of the connection betwixt mind and brain. It is very easy to say the highest nervous centres are for mental operations; the lower for physical functions. We wish to urge, however, that nothing whatever is known as to the nature of

the connection betwixt nervous states and mental states. We can only assume a parallelism. The word “function” should be limited to physical operations. Consciousness is, at any rate, not a function of brain in the same sense that secretion of bile is a function of the liver. We repeat our belief that the function of the brain with which we as medical men are directly concerned is the co-ordination of impressions and movements. There is no *more* difficulty as to the connection between physical states and mental states, if the physical states be, as we affirm, nervous arrangements for the co-ordination of movements and impressions; because the problem is an insoluble one, whatever the physical states may be. Indeed, so far are we from confounding mental states with physical states, that we make the widest possible, because an absolute, distinction betwixt the two. We are not trying to explain mental states in physiological terms. For example, in showing that the anatomical substratum of a visual idea is a nervous arrangement representing certain retinal impressions and particular ocular movements, we do not pretend to have done anything whatever towards solving the problem as to the nature of the connection betwixt any mental state and any nervous state. Before we can give reasons for the belief that the unit of composition of the organ of mind is, like that of the lower centres, a *sensori-motor* process, we must speak more explicitly on the differences betwixt psychology and the physiology of the nervous system, or, as we think it should be put, betwixt psychology on the one hand and the anatomy and physiology of the nervous system on the other. The best reasons for the belief that the convolutions represent movements are the facts of the experiments of disease—for example, partial convulsive seizures from disease in the cerebrum—and more especially the experiments, properly so called, of Hitzig and Ferrier. Whatever interpretation may be put on the experiments of these distinguished physicians, it cannot be denied that the facts they have established are of inestimable value. It is not, then, because we underrate them, that we bring forward other evidence. The argument in the following is, we think, entirely in harmony with the conclusion Hitzig and Ferrier draw from their experiments, that convolutions are centres for movements. But, as their facts are not considered by very many to be conclusive, we shall advance a different kind of evidence.

What we wish to insist on is that, whilst assuming a parallelism betwixt mental states and nervous action, we have nothing to do with the *nature* of the connection betwixt the two; that is, of course, in our character of anatomists and physiologists. The term psychology is often used as if it were applicable to what we may call the finest part of the anatomy and physiology of the nervous system. A common popular doctrine is this. Up to the corpus striatum, we have to do with anatomy and physiology; we have to do with the co-ordination of impressions and movements. When we come to the convolutions, we have to do with psychology. We believe this, which seems so clear, is only the clearness of shallowness. Such schemes lead to confusion. Psychology, dealing with mental states, is one thing. The anatomy and physiology of the nervous system are quite other things; they have to do with certain complex questions in *physics*—that is, with nervous states and dynamics. The nature of the connection betwixt physical and mental states is not a problem either in psychology or in anatomy and physiology; it is a metaphysical problem. In saying, then, that the constitution of the cerebral hemisphere is fundamentally like that of the lower nervous centres, we are not to be understood as even remotely and indirectly comparing mental states and physical states of the nervous system. We beg the reader to bear in mind that the comparison is betwixt the *physical* functions of the cerebral hemisphere *which in some unknown way are associated with mental states*, and the physical functions of lower centres which (that is, as is commonly supposed) have no mental states in association with them. We say as commonly supposed; for Lewes believes that there is attending active states of even the lowest nervous centres a “sensitivity” homologous with that sensibility which we call consciousness attending active states of the highest nervous centres. Then, whilst we believe that the

highest centres are, like the lower, made up of nervous arrangements for the co-ordination of impressions and movements, we of course believe that they are unlike them, in that the co-ordinations they effect differ greatly in degree of complexity. These differences of degree of complexity on the physical side would, we suppose, according to Lewes, have on the psychical side corresponding differences in degrees of Sensibility, from consciousness ordinarily so called attending active states of the very highest centres, to the under-consciousness or Sensibility attending active states of the lowest: a ganglion of the sympathetic, for example.

The absolute distinction we have made betwixt mental states and physical states is the one made by Sir William Hamilton, Mill, Spencer, Huxley, Tyndall, Clifford, etc. We do not mean that the view as to the particular constitution we attribute to the physical states—that they represent impressions and movements—is the one accepted. Clifford puts the distinction very well. "It is not a right thing to say, for example, that the mind is a force, because, if the mind were a force, we should be able to perceive it.....But I may very well say that among the physical facts which go along at the same time with mental facts, there are forces at work. That is perfectly true; but the two things are on two utterly different platforms: the physical facts go along by themselves, and the mental facts go along by themselves. There is a parallelism between them, but there is no interference of one with the other." (*Fortnightly Review*, December 1874.) G. H. Lewes, however, differs; and his opinion on such a matter deserves the most respectful consideration. Lewes thinks (*Problems of Life and Mind*, vol. ii, p. 459) that "the neural process and the feeling are one and the same process viewed under different aspects. Viewed from the physical or objective side, it is a neural process; viewed from the psychological or subjective side, it is a sentient process." This is not, as Lewes states, the opinion usually accepted. He quotes the well known remarks by Tyndall, part of which is, "the passage from the physics of the brain to the corresponding facts of consciousness is unthinkable". Lewes adds: "To the same effect, Mill, *Logic*, ii, 436; Du Bois Reymond, *über die Grenzen des Naturerkennens*, 1872, p. 17; Griesinger, *Maladies Mentales*, 1865, p. 7; Donders, in the *Archiv. für Anat. u. Physiol.*, 1868, p. 658; Lotze, *Mikrokosmos*, 1861, i, 161. We reproduce these references, in order to show that there is a powerful array of authorities in favour of the absolute distinction between mental states and physical states, in spite of their assumed parallelism.

Whether this distinction be accepted or not does not make very much difference for our further exposition. We had, however, to defend ourselves against the inference sure to be drawn by a certain section, that, because we attempt an explanation of the physical *substrata* of mind, we are trying to explain mind in terms of matter. What we wish to insist on most is, that to give a materialistic explanation of mind—even assuming that a materialistic explanation can be given—is not to give an anatomical and physiological one. Suppose mind is a force, as some say, we should still have to seek lines on which it manifests its effects in particular mental operations. But the strange thing is, that some of those who take materialistic views practically ignore anatomy and physiology. Let us clear the ground before we consider this statement. To hold any one of the following views as to the relation betwixt states of the nervous system and states of mind does not warrant us in ignoring the anatomy and physiology of the nervous system. We may believe (1) that nervous states are parallel with mental states, the nature of the connection being unknown; (2) that mental states and certain nervous states are one and the same thing under two names; (3) that there is a soul acting through a mere mechanism.

Taking, then, for consideration the material basis, we have, whichever of the above views we hold, to give an account of its anatomy and physiology. We can now draw attention to the error of some of those who consider their method to be physiological. It is, that they give a merely morphological account of the material basis, in place of giving an anatomical account. This is a common error. In this way work is

really done on the old method by so-called materialists and by some of those who consider they are doing physiological work. We assert that to speak of centres for "volition", for "ideation", for "memory of words", without regard to the anatomy and physiology of these centres, is to work essentially on the old method. The difference is, that the mind is supposed to be a solid one, made up of nerve-cells and fibres. Instead of having "ideas", "emotions", etc., unassociated with physical substrata, we have "ideational cells", etc. Let us quote authority on this matter.

Mr. G. H. Lewes, in his *Problems of Life and Mind*, vol. i, p. 126, remarks on the "disposition to translate psychological observations into physiological language, and to accept this as biological illumination; which not unjustifiably provokes the scorn of the pure psychologist. One example of this may be given here. Some anatomists having conceived the infelicitous idea of distinguishing nerve-cells into sensory, motor, and sympathetic, this nomenclature, so misleading even where it is not profoundly unphysiological, is adopted by several writers, who first establish the illusory distinctions of sensational cells, ideational cells, and emotional cells, and then proceed to explain the mental mechanism by these imaginary cells."

Let us take a particular class of ideas. We choose visual ideas. These are the most important of all ideas; in them most of our mental operations are carried on; they form the most developed part of perceptive mind (Spencer). Moreover, we can, by aid of certain experiments of disease, trace their relations to tactual ideas.

A visual idea has a material basis; this basis is morphologically made up of nerve-cells and fibres. These are truisms needing no comment. The questions we try to answer are: 1. What is the anatomical constitution of this substratum of cells and fibres? and 2. What is its physiology? We must define these two words. Anatomy of the nervous system, or nervous statics, is not to be confounded with morphology. Anatomy is concerned with showing what peripheral parts of the body particular nervous centres represent. The reader must not lose sight of this definition. Thus we shall try to show that the anatomical substratum of a visual idea represents or re-represents a retinal impression and an ocular movement. More generally, the anatomical unit of composition of the nervous system is not a cell and fibre; that is the morphological unit. The anatomical unit is a sensori-motor process. We may thus illustrate. A grouping of cells and fibres no more forms the unit of the nervous system than a grouping of words forms the unit of speech. The unit of composition of the nervous system is of cells and fibres arranged so as to form a sensori-motor process; the unit of composition of speech is of words arranged so as to form a proposition. Next we give our definition of physiology. Physiology of the nervous system, or nervous dynamics, is concerned with varying conditions of the anatomical substrata; with nerve-currents and nervous discharges. The variation is great. Thus most of our ideas are latent. This is a psychological expression; the corresponding physiological expression is, that their anatomical substrata are unexcited, or not strongly excited. And of ideas actual there are two degrees. Thus we see an object before us; at that time, the substratum is excited or discharged strongly and widely. After actually seeing that object, we can see it ideally; then the same substratum is excited or discharged slightly and to a limited extent.

THE late Mr. Richard Winter Mount, of Wingham House, Wingham, and who for many years was a solicitor in extensive practice at Canterbury, has left a legacy of £10,000 to the Kent County Ophthalmic Hospital, at Maidstone. After making other minor bequests, he leaves the residue of his property to the Royal South London Ophthalmic Hospital.

IN addition to the large bequest to ophthalmic hospitals by Mr. Mount, other important benefactions are announced this week; prominent among them is the bequest of a reversion of £10,000 stock to the Medical Benevolent College at Epsom for the creation of pen-

sioners to receive annuities without residence. This generous benefaction is the act of Mr. T. B. Pugh, and we hail it with great gratification. Mr. Pugh leaves also, to the Royal Sea-Bathing Infirmary, Margate, £3,000; to the Hastings and St. Leonard's Home for Invalid Gentlewomen, the London Fever Hospital, and the Samaritan Society of St. Thomas's Hospital, £300 each.

THE Rev. Henry Morgan of Oakfield, Berks, has bequeathed to the Royal Berkshire Hospital, the North London Consumption Hospital, the North London (University College) Hospital, the Middlesex Hospital, the London Hospital (Whitechapel), St. Mary's Hospital (Paddington), St. George's Hospital, Queen Charlotte's Lying-in Hospital, the Lock Hospital, Westminster Hospital, King's College Hospital, the Royal London Ophthalmic Hospital, the Asylum for Idiots (Earlswood), the Hereford Infirmary, the Society for the Relief of Widows and Orphans of Medical Men, and the Ross Dispensary, £1,000 each.

WE are pleased to have to announce that Sir W. Jenner has forwarded to Dr. Joseph Rogers a cheque for £5 5s, in aid of the fund he is raising for the benefit of the widow and children of the late Dr. Maunsell of Dublin, who have, by his premature death, been left in straitened circumstances.

THE amount of property left by Sir C. Locock has been sworn under £100,000. The most noticeable provisions of his will are, that his remains should be buried in Kensal Green in an unostentatious manner, and that, in the event of his death occurring from any obscure or doubtful disease, his remains should be subjected to *post mortem* examination.

A NEW Hospital for Women has been established at 45, Castle Gate, Nottingham, and Dr. B. R. Morris appointed physician, and Mr. George Elder surgeon, to the institution.

DR. J. B. BRADBURY of Downing College, Cambridge, Linacre Lecturer of Physic at St. John's College, has been appointed Medical Lecturer at Gonville and Caius College, in the place of Dr. Drosier, resigned.

AN "Association of Medical Officers of Health for Yorkshire" has been formed, and the following officers appointed, viz., *President*: Samuel William North, M.R.C.S.Eng. *Secretary and Treasurer*: John Sebastian Wesley, M.B.Lond. *Committeemen*: William Swift Wade, L.R.C.P.Edin.; Geo. Goldie, L.R.C.P.Edin.; Titus Deville, M.D.; T. Britton, M.D.St.And.; E. Buller Hicks, L.R.C.P.Lond.; and Henry Franklin Parsons, M.D.Lond. The next meeting is to be held at Wakefield on October 27th.

WE publish in another column a letter from Dr. James Macaulay, the editor of the *Leisure Hour*, on the alleged evils of the over education of girls. We are rather inclined to the precisely opposite view of Dr. Wilks and others, that the health of girls suffers chiefly from idleness and insufficient education; but the subject is one which only large experience can finally decide, and on which we should be glad to encourage the freest discussion on the basis of observed fact.

MR. HENLEY has been addressing his constituents. Mr. Henley is a good representative of old-fashioned good sense mixed with current prejudices. He is apt at manufacturing catch-words; among other things, he is reported to have said: "Then the whole sanitary law was consolidated, which was no trifling work. He thought that would stop many evils that were around them, if only the law was administered with moderation and discretion. This country had up to the present refused to be priest-ridden, and he did not believe they would consent to be doctor-ridden." The consolidation of the sanitary law is no doubt useful, but mainly so as a stepping-stone to its amendment; and of this it is difficult to be hopeful, when the prominent men of the party in power adopt as their watch-word simply obstructive fallacies.

OUR readers will be gratified to learn that the health of Mr. George Southam, the respected late President of Council of the Association, is somewhat improved; but they will regret to learn that he still remains weak, and is unable to do any work.

THE decoration of the Legion of Honour has been conferred upon Dr. Bormemaison, Physician-in-Chief of the Hôtel-Dieu of Toulouse; Helsen Batu, Surgeon-in-Chief of the hospitals of Toulouse; and Dr. Th. Desclaux, the Mayor of Tonniens, for their actions during the recent inundation.

STATE MEDICINE EXAMINATIONS.

THE Senatus of the University of Cambridge have fixed the date of their first examination in State Medicine for October 5th.

MORTUARIES FOR THE METROPOLIS.

AT a meeting of the Strand Board of Works on Wednesday, September 22nd, the following notice of motion by Dr. Joseph Rogers was carried unanimously.

"That, with a view to the more effectually and economically securing the establishment of mortuaries in the metropolis, this Board do memorialise the Metropolitan Board of Works to apply, in the next session of Parliament, for powers authorising that body to undertake their erection in such parts of the metropolis as may be considered necessary."

It was also resolved that a copy of the resolutions should be forwarded to the several Boards of Works in the metropolis, and that they should be requested to co-operate with the Strand Board in pressing the question on the attention of the Metropolitan Board. Dr. Joseph Rogers, Mr. Betts, Mr. Phillips (the representative of the Board on the Metropolitan Board), and Mr. Jenkins (the clerk), were appointed to draw up the form of memorial to be forwarded to the Metropolitan Board.

A MEDICAL STRIKE.

AT a recent meeting of the Caermarthenshire Board of Guardians, a round robin was sent in by the six medical officers of the union asking for an increase in the amount of their salaries, and intimating at the same time their intention to resign unless the request was complied with. The board adjourned the matter for further consideration.

MEDICAL CONGRESS AT BRUSSELS.

THE International Congress at Brussels was opened by the King of the Belgians, with great ceremony, on September 18th. His Majesty was warmly cheered by the assembly. Dr. Vleminckx was elected President and Dr. Warlemont Secretary-General, both being Belgians. Out of compliment, however, to the different foreign medical celebrities present, several honorary Presidents were also elected—viz., Drs. Bouilland, Jaccoud, Larrey, and Verneuil (France); Mr. Bowman (England), Drs. Semmola and Palasciano (Italy), Drs. Langenbeck and Graefe (Germany), and Drs. Signund and Hebra (Austria). We shall publish an abstract of the most interesting portions of the proceedings. The attendance is stated to be under three hundred, mainly Belgian physicians; but the programme promises an interesting meeting. The subjects to be discussed are important and well digested.

THE HUNTERIAN SOCIETY.

THE Honorary Secretary of this excellent and old-established Society writes to us, at the desire of the Council, to ask us to bring under the notice of the local profession some facts connected with this Society showing its advantages and uses. They are briefly as follows.

1. The London Institution, Finsbury Circus, in which its meetings are held, now forms the central point on which no less than nine suburban railways converge, at only three minutes' walking distance from each. 2. It possesses the most complete accommodation for small as well as very large meetings. 3. Its permanent medical library consists of nearly four thousand volumes; and it has established a circulating one by subscription to Lewis's, by which each member can

obtain all the latest works by application to the librarian between the hours of 10 A.M. and 4 P.M. 4. It is a Society originally established (fifty-seven years ago) for the purpose of encouraging kindly feeling, friendly discussion, and integrity of purpose, amongst its members. These objects it has steadily fulfilled during its course, and has always maintained a sound financial position. One reason for its being less known than other medical societies is a rule, made *in limine*, that publication should be avoided, lest it should restrict freedom of discussion; another, the migration to the West of the men who were, at the period of its formation, the leading members of the profession; and the third, the difficulty of access to its former place of meeting. This is now changed, and the Council desire to bring the fact as prominently forward as they legitimately can before the profession."

It is probably the limitation of publicity mentioned which has injured the growth of the Society. The theory of publicity restricting freedom of discussion is calculated to provoke a smile, and its nominal operation has no doubt stunted the growth of the Society. Practically, the authors of good papers read before this Society have generally taken care to secure publicity for them; and they would have acted unwisely, and in a manner contrary to the interests of science and of the Society, if they had not done so. The Society, indeed, mainly owes such prosperity as it enjoys to the infraction of the rule which it puts forward.

ROYAL COLLEGE OF SURGEONS.

NOTICE has been given that the Council of the College will, at a special meeting, to be held on the 13th proximo, proceed to the election of three Fellows of the College as members of the Court of Examiners. With the exception of Mr. Hancock, we believe that the retiring members will offer themselves for re-election. Fellows desirous of being considered candidates for the office are invited to send in their names on or before October 12th.

THE LATE WILLIAM CLIFT.

MANY years ago, in fact, soon after the death of Clift, an accomplished member of the College, Dr. Hugh Diamond of Twickenham, quietly and unostentatiously walked into the hall of that institution and deposited on one of the then vacant pedestals, an excellent and life-like bust of Mr. Clift, by the late Mr. Archer, saying to an old official he happened to encounter, "There, I have done what I consider a duty, to preserve the memory of that dear good and faithful servant of the College and of the profession, and hope your great guns will have it executed in marble". There it remained until, at the last meeting of the trustees of the Hunterian collection, Sir James Paget, Bart., suggested its removal to the museum, where over the principal entrance it is to be placed, on a bracket, with the simple inscription, "William Clift, F.R.S., the first Conservator of this Museum". It is to be hoped that the wish of Dr. Diamond may yet be carried out, especially as an eminent sculptor, Mr. Henry Weekes, R.A., many of whose works adorn the College, happily survives, who, from his long and intimate acquaintance with Mr. Clift, would no doubt do full justice to the subject.

POISONING OF FIFTY-EIGHT BOYS BY THE ROOTS OF LABURNUM.

ON the morning of the 3rd of August, between 6 and 7 A.M., before breakfast, 58 boys in the Forest Gate Industrial School chewed varying quantities of the roots of an old laburnum tree, which had been cut across the preceding afternoon, they either mistaking it for, or thinking it very much like, stick liquorice, which it certainly resembles in smell; in a very short time, these boys were affected with symptoms of narcotic poisoning, varying in severity from simple sleepiness to complete stupor; none of them complained of any pain, or burning of mouth, throat, or stomach, nor was there any sickness until emetics were given. They were taken into the Infirmary, looking pale and cold, and staggering about; their pupils were somewhat dilated. Dr. Vallance of Stratford, the medical officer of the school, states that the boys were treated immediately by emetic doses of mustard and water; and, in the worst cases, by sulphate of zinc and ipecacuan. It was remarkable to see the boys, whilst in the act of

vomiting, going to sleep, some with the basins in their hands, others standing at the sink. Two boys were much worse than the rest; they, after freely vomiting, were insensible, and showed very strange waving motions of the arms to and fro, whilst now and then their legs, first one and then the other, were convulsively drawn up; there was also in one of the two slight frothing of the mouth, and the pupils of each were *unequally dilated*. This latter symptom was noticed several times. These two boys were strong and robust, and thirteen years old. Ten hours after taking the poison, they went to sleep, whilst being walked about the yard, after having had cold douches, strong coffee, &c. Upon careful inquiry, it was found that these boys could not have chewed more than half an ounce of the laburnum root. All the cases speedily recovered, and, on the next day, showed hardly any traces of injury. Dr. Vallance thinks there are indications of great therapeutical value in the laburnum root, although he has failed to find any description of its effects in the books he has consulted. The seeds are summarily put down as narcotic acrid poisons, and they may be so; but certainly, in these fifty-eight cases, the root, whilst showing plenty of narcotic effects, exhibited none that could be called acrid.

SCARLET-FEVER AT FELSTEAD SCHOOL.

MOST people have read the excellent letter in which Mr. Hardcastle describes the result of Mr. Grignon's protest against the opening of the drains at Felstead Grammar School, and the subsequent "isolation" of the boys sick with scarlet-fever in the wardrobe room. Seeing that clothing will retain the seeds of scarlet-fever, and subsequently disseminate them, unless disinfected, during a long series of years, we can but hope that every article of this school-wardrobe either has been, or will be, disinfected by dry-heat or destroyed. It is needless to say that Mr. Grignon seems to us to have done his duty in the matter manfully, and that his censure and removal for such causes is scarcely credible. Mr. Hardcastle's narrative can scarcely fail to arouse the utmost possible indignation, and we trust that full reparation will be made.

MEDICAL EDUCATION OF WOMEN.

OUR Birmingham correspondent writes, under date September 20th:—About two years ago, application was made to the authorities of Queen's College, Birmingham, to admit several lady medical students. After much consideration, this was declined, though not unanimously. The liberal tendency of public opinion in the town was, however, strongly in favour of providing a medical education for women, and an Association was formed to promote that object. Last week, the Mayor (Mr. Chamberlain), accompanied by an influential deputation which included many well-known professional men and merchants, attended a meeting of the College Council, in order to urge the desirability of their providing the necessary facilities. In the course of his speech, Mr. Chamberlain said that they felt justified in appealing again on this subject by the fact that it had assumed a different aspect since the reply to the Government of the highest medical authority in London—the General Medical Council—in favour of the medical education of women. The deputation were agreed that it was an unfair and improper thing, when there were competent women who desired to enter the medical profession, that they should be refused the opportunity of gaining a satisfactory education. They believed such a thing was unjust in itself, and constituted a grievance which was certainly discreditable to all concerned as long as it remained, and should as soon as possible be removed. They had not attended to argue the matter, but to confer, and to ask the Council, in the interests of the College, to take such steps as would secure the medical education of women in connection with it; and they were prepared to seek with the Council, if they granted the principle, a means of remedying any pecuniary or other difficulties which might arise. Dr. Heslop observed that many members of the Medical Council were of opinion that the profession was not a fit one for women; but still, as a number had chosen it, and shown themselves capable of passing examinations, it appeared needful to take steps to give them an education and place them on the

Register. The obtaining of an education, especially at Zurich, had been easy; but this did not always end in obtaining a degree, and it was very desirable they should not be exposed to the embarrassments of foreign residence. The public and the women being now agreed upon this matter, it came to this: Should the College undertake the work, or should some other institution be founded for it? No doubt there was a difficulty as to hospital practice; but that could be surmounted. The Queen's Hospital was bound by its charter to accept such students as the College admitted; and, if female students were received there, they would probably be so also at the General Hospital—at first, doubtless, in separate classes. But, if the existing hospitals opposed great difficulties, he believed that the materials for a new clinical hospital existed in Birmingham. The general tone of the conversation which followed was evidently favourable to the cause in question. The Warden mentioned an important point when he said the College finances might be affected by the objection of parents to sending their sons to the same classes as ladies; for this, and objection upon the part of the students themselves, were threatened when the subject was mooted last time. It was agreed, however, that these and other difficulties were not insuperable; and the Mayor, in thanking the Council, summed up by saying that he understood *they made no objection on the score of principle*, and would, therefore, concur with the deputation, conditionally upon the assent of the hospital authorities, and conditionally also upon their being prepared to guarantee to them a sufficient amount to cover the fees in those cases in which the professors declined to lecture to double classes.

THE DIGESTIVE PRINCIPLES OF PLANTS.

DR. CHANCE, Sydenham Hill, writes to us: "Immediately I heard of Mr. Darwin's experiments with insectivorous plants, it occurred to me that the principle or principles, in virtue of which these plants dissolve albuminous substances, might possibly be found useful, as pepsine is, in assisting the digestive powers of the human stomach. This idea must have occurred to many others as well as to myself; but have any steps yet been taken with the view of ascertaining whether it can be turned to any practical account?"

EARLY MENTION OF JABORANDI.

In the works of the Hon. Robert Boyle, London, 1772, vol. iii, p. 155, Dr. Piso's *Travels in South America* are quoted from. The latter says: "I saw divers, as it were in an instant redeemed from death, who had been poisoned by the eating of venomous mushrooms and other unwholesome things, only by drinking a recent infusion of the root of *jaborandi*, whilst myself and others of Galen's disciples blushed to see the ineffectual endeavours of all our alexipharmacy, treacles, and other antidotes: so that I afterwards suffered myself to be joined in consultation with these barbarous colleagues, not so much to be arbiters of the condition of our men by their pulse, as to gain their assistance and counsel in the above-mentioned way, viz., the prescribing of proper medicines."

A NOVEL BUT EFFECTUAL SCREEN.

RECENTLY, one of the most eminent naval surgeons was stationed off the West Coast of Africa. At the station, the chief surgeon on shore, who had a very large practice amongst all classes of the community, native and English, was sorely harassed by the large number of deaths which occurred in a short time amongst his patients. At his wits' end to obviate the discredit which he feared might ensue to himself should he not be able to stop, or at any rate to remove from his own shoulders the responsibility of these numerous fatal cases, he hit upon the expedient, when he found his patient to be *in extremis*, of sending to the naval surgeon to meet him in consultation. This he did in six consecutive cases, with the result that some twenty-four hours after the consultation, the patient died. When he sent the seventh time to the naval surgeon, the latter politely declined the consultation, on the ground that, unless his medical colleague on shore could arrange to

meet him before things became desperate, he felt that even a large fee must not tempt him to laboriously earn the reputation of his visits, being the invariable harbinger of death. Surely many physicians might complain with equal cause, that their aid is too often sought by their medical brethren when their experience and skill can be of no possible avail. We commend this incident to the thoughtful consideration of general practitioners throughout the United Kingdom.

THE CENTRAL LONDON EAR AND THROAT HOSPITAL.

LAST week, Madame Adelina Patti (Marquise de Caux) laid the foundation stone of the new building, which the Committee of this hospital are about to erect in the Gray's Inn Road. It is worthy of record, as showing the dearth of news which the daily newspapers experience at this season of the year, that the *Times* devoted a whole column to a description of the ceremony and to an account of the objects and progress of this new and insignificant charity; and that all the other morning and evening papers, without exception, pursued a similar course. Whatever may be said against special hospitals, and we have often in these columns shown that the necessity for them as distinct institutions does not now exist, owing to the excellent special departments which are attached to the principal London hospitals, it cannot be denied that the specialists show much commendable energy and ability in promoting the success of their institutions. Many of our larger hospitals might well take a hint from the specialists in this respect, and we feel sure, that if half the energy they display in promoting the success of their cause were manifested by the managers of not a few of the less wealthy general hospitals in London, they would soon cease to complain of the lack of support they receive from the general public.

SCOTLAND.

THE annual meeting of the members of the Scottish Midland and Western Medical Association will be held on Thursday, the 30th inst., at the Imperial Hotel, George Street, Glasgow. The chair will be taken at 2 o'clock by Dr. Moffatt of Falkirk, Senior Vice-President of the Association. Dr. Wm. Dean Fairlies of Kirklands, Bothwell, is the General Secretary of this Branch.

IRELAND.

At the Queen's University in Ireland the following examiners have been appointed: Benjamin M'Dowel, M.D., Examiner in Medicine; Anthony H. Corley, M.D., Examiner in Surgery; William Roe, M.D., Examiner in Midwifery; Charles F. Moore, M.D., Examiner in Materia Medica; Matthias O'Keefe, M.A., M.D., Examiner in Medical Jurisprudence.

LIMERICK LUNATIC ASYLUM.

A MEETING of the Board of Governors of this institution was held last week, when it was stated that a tender for the execution of the enlargement of the asylum at a cost of £11,800 had been accepted. It is expected that the work will be completed in about eighteen months. Increased room is much required, a considerable amount of overcrowding having taken place for a long time. Dr. Courtenay, the resident medical superintendent, at the same meeting, drew attention to the fact that, under a recent Act of Parliament, the Governors were empowered to sue relatives in the same way as Poor-law Guardians did, and compel them when able to contribute to the support of their friends. A list of the parties liable has been drawn up, and the necessary steps taken relative to the matter.

MR. H. A. CÆSAR, Public Vaccinator, Western District of Mile End, has received a grant of £36:19 from the Local Government Board for efficient Vaccination.

R. C. Thomas, equal; W. J. W. Proffitt, Edward Fardon, Thomas Crook, and James. *Forensic Medicine*—T. F. Pearce, W. J. W. Proffitt, and A. R. Davis. *Materia Medica*—A. J. Newman, H. B. Mason, and A. S. M'Cauley. *Botany*—C. G. Betts, A. S. M'Cauley, and Thomas Jackson. *Comparative Anatomy*—F. Bellaby and S. F. Pearce, equal. *Psychological Medicine*—A. K. Davis.

ST. THOMAS'S HOSPITAL.—*Summer Session, 1874*.—*Second Year's Student*, J. F. Nicholson, College Prize, £15, and Certificate. *First Year's Students*. College Prizes and Certificates—G. B. Longstaff, £15; C. E. Sheppard, £10; F. H. Weekes, £5. *Winter Session, 1874-75*.—*Third Year's Student*, J. F. Nicholson, College Prize, £20, and Certificate. *Second Year's Students*. College Prizes and Certificates—C. E. Sheppard, £20; F. H. Weekes, £15; W. H. Bault, £10. *First Year's Students*. College Prizes and Certificates—J. Shaw, £20; H. Castle, £15. *Physical Society's Prizes*—G. F. Poynder, Third Year's Prize and Certificate; T. J. Sharkey, Second Year's Prize and Certificate; G. B. Longstaff, First Year's Prize and Certificate. *Prosectors*—F. R. Barker and C. K. Morris, Prizes and Certificates. *Resident Accoucheurs*—H. S. Bonnet and C. M. Taylor, Certificates. *Graviner Testimonial Prize*—H. P. Potter, £20, and Certificate. *Surgery and Surgical Anatomy*—J. F. Nicholson, Cheselden Medal; T. Fisher, Prize and Certificate. *Practical Medicine*—J. F. Nicholson, Mead Medal. *House-Physicians*—A. S. L. Newington, J. W. Charkon, W. S. Mavor, and A. Lingard, Certificates. *House-Surgeons*—J. Crossman, C. M. Taylor, G. F. Rossiter, and J. W. Clarkson, Certificates. *General Proficiency and Good Conduct*—Treasurer's Gold Medal and Certificate, J. F. Nicholson.

UNIVERSITY COLLEGE.—*Winter Session, 1874-75*: *Atkinson Norley Surgical Scholarship*, E. Markham Skeritt. *Filliter Exhibition in Pathological Anatomy*, A. J. Pepper. *Liston Gold Medal for Clinical Surgery*, C. J. Manning. *Bruce Medal for Proficiency in Surgery and Pathology*, A. J. Pepper. *Cluff Memorial Prize for Proficiency in Anatomy, Physiology, and Chemistry*, G. C. Henderson. *Surgery*—Gold Medal, A. J. Pepper; 1st Silver, J. Arthur Kempe; 2nd Silver, L. S. Jameson; Certificates—4. Alfred Aplin; 5. John Gardiner; 6. R. W. Greenish; 7. G. H. B. Fisk; 8. J. Sydney Pearce; 9. H. Lawrence Crocker; 10. G. S. Bayly; 11. Henry R. Dale. *Physiology*—Gold Medal, F. Lucas Benham; Silver, J. Stanley N. Boyd; Certificates—3. James Hudson; 4. James W. Bond; 5. D. J. Williams; 6. R. S. Miller. *Anatomy (Senior Class)*—Gold Medal, Howard Cane; 1st Silver, Judson S. Bury; 2nd Silver, Richard S. Miller; Certificates—4. Edw. n Hughes; 5. F. Lucas Benham; 6. George C. Henderson; 7. Alfred James; 8. David Jones; 9. Chas. E. Beevor; 10. Boyd B. Joll; 11. J. W. Bond; 12. E. J. Thompson; 13. A. E. Broster; 14. James Hudson; 15. W. M. Hope; 16. Frank S. Goulder. *(Junior Class)*—Silver Medal, William Banks; Certificates—2. Bilton Pollard; 3. W. S. Tuke; 4. N. S. Whitney; 5. W. H. Copley; 6. Kenneth R. Smith; 7. Chas. M. Maxwell; 8. C. B. Hill; 9. Jas. O'Connor; 10. H. Ewbank; 11. D. F. Dymott; 12. W. W. Colborne; 13. W. E. Good; 14. S. E. Duncan; 15. Michael Oppenheim; 16. Christopher Briggs. *Chemistry*—Gold Medal, W. K. Parker; 1st Silver, Ernest Westlake; 2nd Silver, L. C. Ponsford; Certificates—4. Francis M. Webb; 5. W. G. Chuckerbutty; 6. equal, F. L. Teed, R. S. Miller; 7. R. H. Wright; 8. H. A. H. Fenton; 9. equal, J. H. Oldroyd, J. R. Salter; 10. equal, H. P. Miller, J. A. Voelcker, J. W. Evans; 11. equal, John Marshall, L. C. Parkes; 12. equal, Bilton Pollard, W. C. Adams, F. S. Arnold, V. A. H. Horsley; 13. equal, K. Jameson, C. G. Stein, T. Buxton, A. J. Harries; 14. equal, J. E. Squire, A. M. Palmer, N. Jean-Louis, S. H. Heaty; 15. equal, J. E. Hine, D. E. Anderson; 16. equal, J. S. Tew, Mark F. Sayer; 17. equal, Angel Money, David Gamble, C. E. Cassall, Y. J. Cruz; 18. equal, O. F. Combe, J. A. Broun, A. H. Cooke, F. W. Motr, Julian Stephens, W. Francis. *Medicine*—Gold Medal, George H. Voelcker; 1st Silver, A. J. Pepp r; 2nd Silver, L. S. Jameson; Certificate—4. James Ryley. *Practical Physiology*—1st Silver Medal, D. J. Williams; 2nd Silver, W. Gristock; Certificates—3. Alfred James; 4. Boyd B. Joll; 5. J. W. Bond. *Clinical Medicine: Fellowes Medals*—Gold, T. K. Rogers; Silver, equal, A. J. Pepper, G. H. Voelcker; Certificates—4. J. F. Trafford; 5. L. J. Hobson; 6. P. M. Chapman; 7. J. Moore. *Junior Class: Fellowes Medals*—1st Silver, J. G. Langley; 2nd Silver, J. Todd; Certificates—3. P. Ballard; 4. equal, S. H. Burton, A. W. Kempe; 6. J. Ryley; 7. equal, L. M. Buckell, W. James Pickup; 9. J. S. Pearce; 10. H. L. Crocker; 11. F. F. Perry; 12. W. M. Lory. *Dental Surgery*—Silver Medal, E. J. M. Phillips. *Summer Session: Pathological Anatomy: Filliter Exhibition of £30*—F. J. Davies; Silver Medal, James Ryley; 3rd Certificate, S. H. Burton. *Practical Chemistry (Senior Class)*—Gold Medal, K. R. Smith; 1st Silver Medal, D. J. Williams; 2nd Silver Medal, Herbert Robson. Certificates—4. H. R. H. Bigg; 5. equal, J. Stanley N. Boyd, R. S. Miller; 6. equal, Boyd B. Joll, J. S. Bury, J. R. Salter, W. R. Nicholson; 7. equal, W. Gristock, F. L. Benham; 8. equal, F. W. S. Culhane, S. P. Phillips, Harry Duncan, Bilton Pollard; 9. David Lloyd. *Junior Class*—Gold Medal, Wm. Banks; 1st Silver Medal, L. de Montille; 2nd Silver Medal, S. R. Corder; Certificates—4. equal, A. London, V. Ito, A. M. Palmer, W. S. Tuke; 5. equal, W. R. Parker, T. Buxton 6. equal, F. W. Mott, A. Hemsted; 7. equal, W. Pasteur, H. P. Miller, A. J. Harries, M. Oppenheim, P. S. Kendall; 8. equal, P. N. Bose, W. C. Adams; 9. equal, D. Duncan, Theophilus Hoskin, J. I. Paddle, H. E. Spencer, H. F. Stokes, J. A. Broun; 10. equal, J. E. Hine, G. N. Stathers, E. H. Fenwick; 11. equal, Archibald Blair, V. A. Horsley, J. E. Squire, P. E. Shearman, A. E. Wigg; 12. equal, S. E. Duncan, D. T. Ho-kyn, Nemours Jean-Louis, C. M. Maxwell; 13. equal, Reuter Roth, C. J. Watkins, D. E. Anderson, E. J. Brook Smith, J. S. Buck, E. Eardley-Wilmot; 14. H. Atley Phillips; 15. David Gamble. *Materia Medica and Therapeutics*—Gold Medal, W. Banks; 1st Silver Medal, N. S. Whitney; 2nd Silver Medal, H. E. Spencer; Certificates—4. R. S. Miller, A. Hemsted; 6. L. E. Williams; 7. Boyd B. Joll; 8. equal, Arch bald Blair, J. R. Salter, W. S. Tuke. *Midwifery (Senior Class)*—Gold Medal, H. F. Bailey; Silver Medal, A. Hullard; Certificates—3. equal, Ernest G. Francis, Howard Cane; 5. J. F. Trafford; 6. T. E. Foster MacGeagh; 7. S. H. Burton; 8. A. W. Galloway. *Junior Class*—Silver Medal, D. J. Williams; Certificates—2. J. Stanley N. Boyd; 3. H. F. Hann; 4. J. E. Bullock; 5. H. R. Dale; 6. Brian Rigden. *Medical Jurisprudence*—Gold Medal, A. Hullard; Silver Medal, Arthur Whitelegge; Certificates—3. D. R. Jones; 4. equal, H. R. Dale, J. E. Bullock; 6. A. J. Smith; 7. A. W. Kempe; 8. Brian Rigden. *Botany*—1st Silver Medal, W. Rushton Parker; 2nd Silver Medal, W. Carey Trafford; Certificate—3. Walter Pearce. *Hygiene and Public Health*—Silver Medal and 1st Prize, Alfred Aplin; 2nd Prize, H. K. R. Kirriker; Certificates—3. A. Hemsted; 4. R. B. Wilkins. *Mental Diseases*—Prize and Silver Medal, K. R. Kirriker. *Ophthalmic Medicine and Surgery*—Silver Medal, A. Hullard. *Zoology*—Silver Medal, Angel Money; Certificate—2. J. Stanley N. Boyd. *Comparative Anatomy and Zoology*—Gold Medal, H. R. Heather Bigg; Silver Medal, V. A. Horsley; Certificates—3. J. E. Hine; 4. E. H. Fenwick. *Clinical Medicine*—1st Prize, equal, J. S. Pearce, B. M. S. Roth; 3rd Prize, J. A. Kempe.

WESTMINSTER HOSPITAL.—*Entrance Scholarships*—1. George Shaw; 2. T. H. May. *Mr. Davy's Prize for Practical Anatomy*—T. H. May and T. G. Munyard, equal. *Exhibition in Anatomy and Physiology*—Thomas G. Munyard. *Dr. Alchian's Prize for Practical Histology*—George Eliot. *Scholarship in Anatomy and Physiology*—George S. Robertson. *Chadwick Prize*—No award. *Class Certificates: Junior Anatomy*—Horace Elliott and Thomas G. Munyard, equal. *Junior Physiology*—1. George Shaw; 2. Thomas G. Munyard. *Chemistry*—1. Thos. G. Munyard; 2. George Shaw. *Senior Anatomy*—1. George S. Robertson; 2. Geo. Eliot. *Senior Physiology*—1. George S. Robertson; 2. George Eliot. *Histology*—1. Geo. S. Robertson; 2. George Eliot. *Junior Medicine*—2. Thomas Gaddes. *Junior Surgery*—2. Wm. J. Foster. *Senior Medicine*—1. Wm. J. Quicke. *Senior Surgery*—2. Richard Clarke.

BRISTOL MEDICAL SCHOOL.—*First Year's Prize*, not awarded; *Second Year's Prize*, Mr. F. Taylor; *Third Year's Prize*, Mr. J. R. Guy; *Prize for Practical Anatomy*, Mr. C. C. Cripps. *ROYAL INFIRMARY*.—*Supple Medical Prize and Gold Medal*, Mr. C. Newman; *Supple Surgical Prize and Gold Medal*, Mr. F. C. Palmer; *Clark Prize*, Mr. J. R. Guy. *GENERAL HOSPITAL*.—*Guthrie Scholarship*, Mr. C. Jones; *Clarke Scholarship*, Mr. T. C. Norton; *Sanders Scholarship*, Mr. J. Taylor.

LEEDS SCHOOL OF MEDICINE.—*Hardwick Prize* (Clinical Medicine), value £10, J. B. Hellier. *The Surgeons' Prize* (Clinical Surgery), 1, value £10, Caudley Dawson; 2nd, value £5, E. B. Holwell. *Medicine*—Medal, Cantley Dawson. *Surgery*—Medal, Cautrey Dawson; Certificate, G. H. Higgins. *Anatomy (Senior)*—Medal, J. H. Thorp; Certificate, R. N. Hartley. *Anatomy (Junior)*—Medal, R. B. Morley; Certificate, F. W. Storry. *Anatomy (Lecturers' Book Prizes)*—Senior, W. S. Porter; Junior, F. W. Storry. *Physiology*—Medal, J. H. Thorp; Certificate, C. C. Lepage. *Chemistry*—Medal, R. Haggard; Certificate, F. Robinson. *Thorp Scholarship (Forensic Medicine)*, value £10, A. K. Scattergood. *Forensic Medicine*—Medal, A. K. Scattergood. *Midwifery*—Certificate, G. F. Bates. *Materia Medica*—Medal, J. D. F. Reckitt; Certificate, R. Haggard. *Botany*—Medal, R. B. Morley; Certificates, J. W. Oglesby and R. Haggard. *Practical Chemistry*—Medal, R. Haggard; Certificates, R. B. Morley and E. P. Pickersgill.

LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.—*Winter Session*.—*Exhibitioners*: Mr. H. Gorst, Mr. S. F. Bigger, Mr. G. H. Jackson, and Mr. W. G. Miskelly. *Third Year Subjects* (Medicine, Surgery, and Pathology): Mr. John Twincem, Silver Medal; Mr. W. H. Wright, Bronze Medal. *Second Year Subjects* (Advanced Anatomy and Physiology): Mr. J. Wigglesworth, Torr Gold Medal; Mr. W. Gillibrand, Bronze Medal; Mr. R. H. Jones, 1st Honorary Certificate; Mr. D. Harrison, 2nd Honorary Certificate. *First Year Subjects* (Elementary Anatomy and Physiology and Chemistry): Mr. T. W. O. Pugh, Bligh Gold Medal; Mr. T. M. Porter, Bronze Medal; Mr. C. E. Steele, 1st Honorary Certificate; Mr. T. O. Beckitt, 2nd Honorary Certificate. *Summer Session: Second Year Subjects* (Obstetric Medicine, Medical Jurisprudence, and Toxicology): Mr. W. B. Hadden, Honorary Certificate. *First Year Subjects* (Botany, Materia Medica, and Practical Chemistry): Mr. R. Bredin, Silver Medal; Mr. Charles E. Steele, Bronze Medal. *Comparative Anatomy and Zoology*: Mr. R. Bredin, Prize; Mr. T. W. O. Pugh, Mr. A. Meeson, and Mr. A. C. Rich, Honorary Certificates. *Students' Debating Society's Prize*: Mr. W. B. Hadden.

OWENS COLLEGE (MANCHESTER ROYAL) SCHOOL OF MEDICINE.—Third year: Turner Scholarship, £20, H. Tomkins; first prize, £5 ss., Stanford Harris, John Chadwick; 2nd prize, £3 ss., not awarded; third prize, £2 ss., Arthur Richardson. *Second Year*: Scholarship, £15, Charles Frederick Dingle; first prize, £5 ss., Arthur Thomas Wilkinson; second prize, £4 ss., not awarded; third prize, £3 ss., not awarded. *First year*: Scholarship, £10, not awarded; first prize, £5 ss., Walter Muir; second prize, £4 ss., John Hodgson; third prize, £3 ss., Hector Leak. *Platt Physiological Scholarship*, £50 per annum, tenable for two years, John Priestley. *Dumville Surgical Prize*, £20, Arthur Richardson.

SHEFFIELD MEDICAL SCHOOL.—*First Year's Prize*—1. Mr. Beard; 2. Mr. Collier. *Second Year's Prize*—Not awarded.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-ON-TYNE.—*Winter Session, 1874-75*.—*Physiology*: Medal and First Certificate, Mark Malvin; Second Certificate, Marshall Taylor; Third Certificate, Charles James Sutherland. *Chemistry*: Medal and First Certificate, Charles James Sutherland; Second Certificate, Charles M'Ivor Goyder; Third Certificate, Septimus Lowes. *Anatomy*: Medal and First Certificate, Thomas G. Ainsley; Second Certificate, James B. Noble; Third Certificate, Charles Green. *Medicine*: Medal and First Certificate, George Newton; Second Certificate, G. O. M'Kane. *Dickinson Memorial Scholarship*, George Newton. *Summer Session, 1875*.—*Practical Physiology*: Medal and First Certificate, William J. Sweet; Second Certificate, James B. Noble. *Practical Chemistry*: Medal and First Certificate, Charles M'Ivor Goyder; Second Certificate, William J. Sweet. *Botany*: Medal and First Certificate, William J. Smith; Second Certificate, James T. T. Reed. *Medical Jurisprudence*: Medal and First Certificate, Mark Malvin. *Midwifery*: Medal and First Certificate, Mark Malvin. *Materia Medica*: Medal and First Certificate, A. Snowdon.

NEW REMEDIES IN 1875.

MR. GROVES, the President of the Pharmaceutical Conference recently held at Bristol, discusses this subject at some length, and with good judgment. We make the following extracts from it, passing over the notice of jaborandi, of which the literature has been fully given in these pages:—

The Brazilian drugs recently presented to the Pharmaceutical Society by Messrs. Cyriax and Farries, and reported on by Mr. Holmes, contain among them several that seem to call for further inquiry and examination on the part of pharmacists. It seems, indeed, that South America, to which we are indebted for some of the most destructive diseases, is endeavouring to balance the account by providing the means of effecting their cure.

The statement respecting butea, "that it contains a basic substance which, combined with sulphuric acid, is white almost like that of cinchona, and is exported to Europe in great quantities to adulterate quinine", deserves to be taken note of, though one part of it seems highly improbable.

Erva de Rato, a cinchonaceous plant used in Brazil for killing rats and mice, exerts, it is said, on the heart an action similar to that of digitalis. This statement certainly deserves careful examination; should the action not be identical, probably it is only similar, it might furnish another means of alleviating a class of disease of a peculiarly painful and hitherto intractable character.

To Dr. Fayer of Calcutta is mainly due the introduction to European medical practice of Goa powder, called also Bahia powder, and Araroba powder, a potent remedy in certain skin-diseases—herpes circinatus, chloasma, etc. This, too, has a Brazilian origin, and seems to have been an article of export from Bahia to Goa, when both were Portuguese colonies. Its origin long remained a profound secret, and its employment was confined to those irregular practitioners of medicine whose untrammelled intellects have so often opened a path for the more staid and methodical practitioners of the schools. Dr. J. F. da Silva Lima has traced the substance from its place of production to its place of sale, and made evident the fact that the Goa, Bahia, and Araroba powders are one and the same, and the produce of a leguminous plant growing in Bahia, where several species of it are to be found, all, with characteristic Brazilian indifference, called by the same name "araroba", or tawny-coloured. Some plants of araroba are now, thanks to Dr. da Silva Lima, growing in the Royal Botanical Gardens of Edinburgh, so that it will not be long before botanists will be able probably to give a complete account of the true source of this interesting remedy. Professor Atfield, in a paper read before a meeting of the North British Branch of the Pharmaceutical Society of Great Britain, described fully the chemical characters of the pure powder sent to him by Mr. David Kemp of Bombay, by whom it had been christened, with the view to doing away with troublesome synonyms, chrysarobin. The one remarkable fact connected with a most patient and able analysis is this, that chrysarobin contains from 80 to 84 per cent. of pure chrysophanic acid. This acid, long known as a constituent of rhubarb roots, *Parmelia parietina*, and perhaps also senna leaves, had never been suspected of possessing powers such as now it must be credited with. Should the price of chrysarobin ever become disproportionately high, it will always be possible to revert to its active principle derived from well known and native sources, but that contingency seems remote, as, according to Dr. da Silva Lima, it is obtainable in Brazil in any reasonable quantity. Possibly its wonderful properties as a dyeing material may eventually be made use of. It is a singular fact, referred to by Mr. Holmes in his paper on the identity of Goa and Araroba powders, that dock-root, a well known but poor source of chrysophanic acid, was used in the time of Gerrard for the treatment of certain skin-diseases, and Professor Bentley affirms that it is still used in Sweden for scurvy, and in many cutaneous disorders.

Gurgun balsam, a fluid of oleoresin, attained by incisions of the bark of *Dipterocarpus laccis*, has, until recently, been regarded solely as an object of suspicion and a possible adulterant of copaiba. It now is in a fair way of being recognised as a most valuable agent in the treatment of skin-diseases, and especially of that most horrible one, leprosy. Dr. Dougall, a medical officer of the Indian Government, first conceived the idea of so employing it, and, having observed decided mitigation of the worst symptoms of the cases first experimented upon, carried out on an extensive scale a series of trials of the remedy at the Haddo Leprous Hospital, Andaman Islands. In his report to Government, he gives details of the remarkable results of the treatment, leaving no doubt that the doctor has hit upon a most valuable agent which renders tractable a most loathsome disease, that hitherto has defied human efforts at removal, and it may almost be said of alleviation. The balsam emulsed with lime-water is given to the extent of twelve drachms daily, and at the same time the whole body is anointed with a similar emulsion night and morning. The Indian Government attaches so much importance to the discovery, that it has instructed the keeper of medical stores at Calcutta to collect a large supply of the balsam, for distribution wherever competent persons can be found to administer and report upon it. The issue of these reports will be awaited with interest, more especially since the balsam has been found by so trustworthy an observer as Erasmus Wilson to exercise a beneficial influence in the treatment of a disease of equally painful character affecting Her Majesty's European subjects, viz., cancer.

More than fifteen years ago, Kolbe and Lautermann demonstrated the possibility of preparing from carbolic acid the then little esteemed salicylic acid. The process adopted was one suggested by Wanklyn, who in the same year discovered that when carbonic acid was passed

into sodic alcohol, propionate of soda was formed, and similarly when methylic alcohol was used instead of ethylic, acetic acid was the result. More recently the reaction has been carefully studied by Kolbe with the view of procuring the acid at a cheap rate for the economical uses which Professor Kolbe was the first to recognise in it. He imagined that, seeing their easy convertibility, the two acids carbolic and salicylic might probably be endowed with similar physiological properties, and that idea he has since fully demonstrated the truth of by experiment. As an antiseptic, salicylic acid is a formidable rival to carbolic acid, preventing and destroying with equal certainty the action of both organised and inorganised ferments. Thus, it destroys the activity of the alcoholic ferment in saccharine fluids, and the ammoniacal ferment in solutions of urea, whilst it equally prevents the decomposing action of emulsion on amygdalin, and of synaptase on myronic acid. Its power as an antiseptic, when used instead of carbolic acid for the dressing of wounds, is considered by Mr. Lister to be scarcely equal to that of the latter substance. This inferiority possibly depends on its less volatility, which, whilst offering the advantage of absence of disagreeable smell, entails the disadvantage of limiting seriously its action on the atmosphere surrounding the diseased surface. On this account, we may expect that, as a general disinfectant, carbolic acid will continue to hold its ground, and that notwithstanding its extremely poisonous character, a fact of which we are now and then reminded painfully by the occurrence of loss of life through its accidental administration.

Salicylic acid, on the contrary, is comparatively innocuous, and being a solid does not invite the attention of drinkers and others too apt to conclude that a carefully hidden bottle must conceal something nice. The antiseptic action of salicylic acid is not shared with its salts, so that when the saturation of the acid accidentally occurs through the evolution of ammonia generated by putrefaction, its utility ceases, or at least is suspended until the addition of an acid sets it free again. Nothing could more forcibly illustrate the non-poisonous nature of salicylic acid, than the fact that it has been recommended to be added in minute quantities to the water in which leeches are preserved. It is said that their mortality is in that way very much lessened. The future of salicylic acid seems to point rather in the direction of internal than external applications. It has been suggested as likely to be a potent remedy in diseases of a zymotic character; perhaps its exhibition in conjunction with sulphurous acid would be more beneficial than when given alone, as the sulphurous acid would not only directly assist it, but by preventing its neutralisation, conduce to the permanence of its action. Mr. John Williams, at a recent meeting of the Pharmaceutical Society, exhibited oil of wintergreen (salicylate of methyl) prepared from the artificial acid, and possessing perfectly the taste and odour of the oil yielded by the plant on distillation. The methylic element was probably obtained in the usual way from wood spirit, but it would not have been difficult to prepare this from purely inorganic sources, as Berthelot pointed out some years ago.

Salicylic acid is now quoted in the price lists at 5s. per oz. for the natural product: 2s. per oz. for the artificial.

In October 1871, Dr. Broughton of Ootacamund, presented to the museum of the Pharmaceutical Society, a very pure and interesting specimen of carbolic acid derived indirectly from the essential oil of *Andromeda Leschenaultii*, a plant that grows in inexhaustible profusion on the Neigherrie Hills. This oil is nearly identical with that of wintergreen, and consists almost wholly of salicylate of methyl. The production of carbolic acid is effected by first saponifying the oil with potash, then adding a mineral acid which precipitates the salicylic acid in a state of purity, and finally distilling the dry acid with lime and sand. The result is pure carbolic acid, which crystallises at once on reaching the receiver. Dr. Broughton calculates that by pursuing this method, pure carbolic acid could be produced at from five to seven shillings per pound. It is obvious that, by dispensing with the last operation, and stopping at salicylic acid, that acid could be rendered at a price considerably less than the figures I have quoted—possibly at four shillings per pound. Here, then, is a hopeful source of a cheap and pure supply of this valuable drug. I have written to Dr. Broughton with reference to it, and hope to have in time for this Conference a note from him respecting it. Dr. de Vrij has also pointed out a new source of oil of wintergreen—*Gouhieria punctata*, a plant growing in great abundance in Java, and yielding on distillation as much as 1.15 per cent. of crude oil. This might possibly be similarly utilised.

M. Natuelle, who discovered, in 1872, a method of preparing from the leaves of *Digitalis purpurea* a crystalline substance possessing the physiological properties of the plant, and which he named digitalin, has had a hard time of it lately in the defence of his position. In the April number of the *J. de Ph. et de Ch.*, he repels the attack of M. Kosmann, who had reasserted his belief that the true active principle of foxglove is an amorphous body, and affirmed that M. Natuelle's

digitalin was a product of change, such as might take place, such is the instability of the true digitalin, either inside or outside the plant. To attempt to give an outline, even of the results described by Nativelle, Kossmann, Homolle, Walz, and Schmiedeberg, would occupy much longer time than I could devote to this subject. Probably, not less than a dozen definite principles, if one could believe their discoverers, would have to be examined. Certain it is, one could not find *digits* enough to count them upon; and, moreover, the greater number of them seem possessed of toxic properties. Schmiedeberg's last announcement, digitoxin, is so poisonous that he doubts whether it is fit for medicinal use. It moreover is completely insoluble in water, in that respect agreeing with the digitalin of Nativelle, which Schmiedeberg declares to be a mixture of digitoxin and paridigitogenin. Anyhow, Nativelle was the first to produce and exhibit a crystalline principle derived from foxglove, and representing with tolerable exactness its physiological action, and while such can be obtained of constant composition and definite form, that assuredly is the article that ought to be employed, and not an amorphous substance possessing no definite characters by which it might be recognised. Doubtless the more complex of the vegetable alkaloids are extremely prone to alteration, and until we know more of the true constitution of that class of bodies, it will be useless to attempt to decide as to which is the mother substance of such series as are met with in foxglove, aconite, cinchona. This Conference has already made a money vote towards the elucidation of the aconite mystery, and will probably be asked for a second grant; but it would, in my humble opinion, be more usefully devoted to the determination of the exact chemical position occupied by one or two of the more stable alkaloids. It doubtless is very interesting to ring the changes upon such a substance as morphia, but this might go on for ever, and I have failed to perceive that up to this time any consensus of opinion has been arrived at, on what may be termed the previous question—What is an alkaloid?

MEDICAL ADVERTISING.

THE following resolution was last week proposed by Dr. PARSONS, seconded by Dr. BOWLES, and carried unanimously, at a full meeting of the East Kent District Branch of the British Medical Association.

"That, in the opinion of this meeting, the practice of advertising medical books in the public papers is derogatory to the interest and dignity of the profession, and likely to occasion social inconvenience and annoyance, and should therefore be abandoned."

REPORTS OF SOCIETIES.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

WEDNESDAY, JULY 21ST, 1875.

G. W. BALFOUR, M.D., Vice-President, in the Chair.

Exhibition of Patients, Pathological Specimens, etc.—Dr. LITTLEJOHN showed (1) a skull-cap and membranes, including an osseous mass as large as an almond in the falx. The deceased, who was a notorious drunkard, and had suffered several times from delirium tremens, died very suddenly in the hands of the police. The diseased condition of the heart, liver, and kidneys, satisfactorily accounted for his death. (2) A part of the small intestine of a boy, who had died without medical attendance after urgent vomiting. The portion had passed through an opening in the mesentery, and had thus become occluded.—Dr. G. W. BALFOUR showed (1) Rosenthal's apparatus for washing out the stomach in cases of dilatation, which he had used with great advantage in various cases, especially in one in which the dilatation was due to pyloric constriction. For the principle of the method, the profession is indebted to Kussmaul. (2) A patient who, three months ago, had exhibited all the symptoms of locomotor ataxy. He then could not walk, nor stand with his eyes shut. Now, in all points, he was much improved. The treatment which had been successful in his case, as well as in many others in Dr. Balfour's hands, was that proposed by Wunderlich, *i.e.*, the use of half-grain doses of nitrate of silver night and morning, for six weeks continuously. It should then be broken off for a fortnight or three weeks, and resumed, if necessary. (3) He gave an account of three cases, all of which had been benefited by the use of large quantities of raw onions as a diuretic. All had been previously dropsical, and had been tapped, other diuretics having failed. Under the use of the onions, the urine steadily increased in quantity, and the dropsy disappeared.—Dr. P. H. WATSON showed (1) an oxalate of

lime calculus removed by the lateral operation; (2) a small one taken out of the eye of Clover's washing catheter; (3) and the detritus of another removed after five crushings; (4) a sarcomatous tumour of the lower third of the femur, for which he had amputated the thigh; (5) a cast of a deformed limb, on which he had lately operated. It was a fracture of the fibula, with rotation of the astragalus and ankylosis of the ankle-joint, which had been treated by an irregular practitioner. Dr. Watson cut out the astragalus after division of the fibula, with the best possible result. (6) The contents of an aneurismal sac, for which he had lately performed the old operation. It was in the axilla, and the result of a severe injury to the shoulder-joint, which the patient seemed to have at first made light of. Pulsation and *bruit* were absent, till the introduction of a trocar to assist diagnosis at once rendered the nature of the swelling evident, and, by the relief of tension, allowed the pulsation and *bruit* to be felt. Aided by Dr. John Duncan, who compressed the subclavian artery above the clavicle, Dr. Watson introduced his finger by a limited incision into the tumour; felt whence the warm gush of blood came from as pressure was relaxed; compressed the spot; then divided the pectoralis minor, extended the incision, and secured the divided ends of the ruptured artery. Very little blood was lost; but, unfortunately, gangrene of the arm showed itself next day, and the arm had to be amputated at the shoulder.—Dr. BATTY TUKE showed the right corpus striatum of a patient who had been the subject of constitutional syphilis, and, for three years, of chronic mania. He had suddenly become unconscious and paralysed, and died on the eighth day after the seizure.

Accidental Poisoning.—Dr. CUTHBERT read a case of accidental poisoning of a child two years and three months old, by two drachms of Bow's liniment. It was interesting, not only from the very large quantity of opium and ammonia in so young a child (it being estimated that fifteen grains of opium must have been swallowed), but from the fact that, owing to Dr. Cuthbert's prolonged and careful use of a galvanic battery during many hours, the child, though several times its case appeared absolutely hopeless, at length recovered completely.—Dr. ANGUS MACDONALD complimented Dr. Cuthbert on the successful termination of this most remarkable case. He could hardly have believed it possible for the child to survive, even with the very prompt and energetic means used. In his opinion, however, the danger of small doses of opium in childhood had been exaggerated, at least after they were two or three years old. He mentioned two cases; in one, a boy, aged 2 years, swallowed a grain of opium, and recovered, though he became deeply comatose; in the other, of a similar age, a teaspoonful of laudanum was given by mistake for a teaspoonful of syrup of senna. He recovered after about fourteen hours, though there had been time for the full absorption of the poison.

Malignant Pustule.—Mr. JOSEPH BELL read notes of a case of malignant pustule. A fine healthy ploughman had helped to skin and dress the carcase of an ox that had died of spleen-disease. On the next day, he felt itching and pain in the wrist. On the third and fourth days, he was ill, shivering and feverish; the mark on the wrist had proved to be a black pustule with a hard yellowish-red circumference. On the fifth day, he was comatose, with all the symptoms of extreme blood-poisoning; and, when he was seen by Mr. Bell in consultation, the limb was cold, dead to the elbow, and yellowish and putrescent to the shoulder. Free incision did not even draw blood; he was comatose and pulseless, and he died in three hours. Mr. Bell gave a detailed account of the latest views of the pathology, causation, and treatment of this malady, and described the micro-copic appearances of the blood, which became thickly loaded with bacteria of various shapes.—The PRESIDENT alluded to the interest and rarity of the case. This disease, in its essential pathology, was closely allied to the plague; it was not, therefore, a mere local affection, but a continued fever of a malignant type; and death was due, not to the carbuncle, but to the resultant blood-poisoning.—Dr. WATSON had only seen one case, in the person of a cow-keeper, who had a pustule on one finger, and, notwithstanding free incisions, died of it. He referred to the work of M. Bourgeois on the subject. Fortunately for the public, this disease did not seem to be easily or frequently communicated by eating the flesh of animals which died of it.

Excision of the Knee.—Mr. CHIENE read a note on the after-treatment of excision of the knee-joint, in which he advocated the use of the weight and pulley as a means of keeping up extension. The case which served as a text was in a young child. The chief reason for approving of it seemed to be the comparative facility by which, in this method of dressing, the antiseptic precautions could be carried out.—Dr. WATSON had never tried the method spoken of by Mr. Chiene; but, after a lengthened trial, he had no reason to wish to change the method he himself had introduced and continued to use. By it, if necessary, he could still keep up the strictest antiseptic dressings; still

he must not be supposed to think that antiseptic dressings had any miraculous results in such cases, as he had quite as good, and certainly much more speedy, cures before employing antiseptics than since. He was glad to hear that, even in the practice of a staunch supporter of antiseptics, suppuration did occasionally occur. A few days of serous discharge used to be all that was admitted as possible under antiseptic surgery. Time seemed to be modifying the views held by its supporters.—Mr. BELL wished to give his support to Dr. Watson's splint. Before this mode of dressing was introduced, the results of knee-excision in the Edinburgh Infirmary, so far as he had watched them, were not good; after it came into use, they were good. This method allowed the patient to move, while it kept his limb at perfect rest. In his own practice, he had never lost a case of excision of knee; and, in his last case, the result was almost immediate union without using antiseptics at all. He doubted if Mr. Chiene's plan would be possible in a patient over 20 years of age.—Mr. CHIENE briefly replied, saying that he was glad to elicit an expression of opinion. In his own case, he thought the weight steadied the limb, and even yet, if the weight were removed, the extensors contracted, and the patient's face assumed an anxious expression.

ASSOCIATION INTELLIGENCE.

COMMITTEE OF COUNCIL: NOTICE OF MEETING.

A MEETING of the Committee of Council will be held at the Office of the Association, 36, Great Queen Street, London, on Tuesday, the 12th day of October next, at Three o'clock in the afternoon.

FRANCIS FOWKE,
General Secretary.

36, Great Queen Street, London, W.C., September 23rd, 1875.

SOUTH WALES AND MONMOUTHSHIRE BRANCH.

THE autumnal meeting of this Branch will be held at Tenby, on Thursday, September 30th.

Nomination-papers must be sent to one of the undersigned by the 9th instant.

ANDREW DAVIES, Swansea. } *Hon. Secs.*
ALFRED SHEEN, M.D., Cardiff. }

September 2nd, 1875.

YORKSHIRE, AND EAST YORK AND NORTH LINCOLN BRANCHES.

IT having been decided by the respective Councils of the above Branches that the autumnal meeting shall be held conjointly at the York Museum on October 13th, 1875, members of these Branches intending to read papers or cases are requested to forward the title to either of the Secretaries on or before the 27th instant, so that a notice thereof may be included in the circular convening the meeting.

Dinner at the Station Hotel at 5 o'clock. Tickets (exclusive of wine) 7s. 6d. each.

W. PROCTER, M.D., York, } *Hon.*
R. H. NICHOLSON, Hull, } *Secs.*

York, September 18th, 1875.

SOUTHERN BRANCH: SOUTH-EAST HANTS DISTRICT.

THE next ordinary meeting of the above Branch will be held at the India Arms Hotel, Gosport, on Wednesday, October 13th, at 4.30 P.M.

Notice has been received of the following communications:—

1. Dr. W. Hoare: Venesection.
 2. Surgeon-General J. Monat, V.C., C.B.: Pyæmia.
 3. Dr. Ward Cousins: Case of large Cystic Tumour of Lower Jaw.
- Dinner will be provided at 6.15 P.M.; charge 6s., exclusive of wine. Members intending to be present are requested to communicate with Dr. Kealy, Gosport, on or before October 10th.

J. WARD COUSINS, *Honorary Secretary.*

Southsea, September 23rd, 1875.

BATH AND BRISTOL BRANCH.

THE first ordinary meeting of the Session will be held at the York House, Bath, on Thursday, October 28th, at 7.15 P.M.: W. M. CLARKE, Esq., President.

R. S. FOWLER, Bath. } *Honorary Secretaries.*
E. C. BOARD, Clifton. }

Bath, September 24th, 1875.

WEST SOMERSET BRANCH.

THE autumnal meeting of this Branch will be held at the Railway Hotel, Taunton, on Thursday, October 14th, at 5 o'clock.

The following question has been settled by the Council as the one on which members should be invited to express their opinion at the said meeting after dinner:—"Is the disuse of Bloodletting in the Treatment of Disease in accordance with the principles of Pathology?"

Dr. Cordwint proposes to read a paper "On Tissue-Change in Fevers".

Dinner (on the table at 5 o'clock), 4s. a head, exclusive of wine.

W. M. KELLY, M.D., *Honorary Secretary.*

Taunton, September 16th, 1875.

READING BRANCH: ANNUAL MEETING.

THE annual meeting of the above Branch was held at the Athenæum, on Wednesday, September 16th. There were fifteen members present.

Mr. Maurice, having resigned the chair in favour of Mr. May, President for the year 1875-76, the usual officers were elected.

Subsequently, the President delivered a very able address, for which he received the thanks of the meeting.

The members afterwards adjourned to the Queen's Hotel, where they dined and spent an agreeable evening.

PUBLIC HEALTH

AND

POOR-LAW MEDICAL SERVICES.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE MORTALITY-TABLES OF THE CITY OF GLASGOW FOR THE QUARTER ENDING MARCH 31ST, 1875.—Dr. Russell, the Medical Officer of Health for Glasgow, commences the explanatory statement or report accompanying his tables, with a comparison of the meteorological phenomena of the first quarter of 1875 with those of the corresponding quarters in the ten preceding years. It appears that the temperature last January was lower, and the rainfall larger, than the average; the temperature and rainfall in February were both lower than the average; whilst in March the atmospheric conditions were normal in character. We do not perceive, however, that the death-rate was much influenced by the meteorological states. During the first quarter of 1875, the death-rate was $35\frac{1}{2}$ per 1,000 living; the birth-rate, 39 per 1,000. The death-rate was obviously very unfavourable, and trenched close upon the birth-rate, which was itself high. The death-rate per 1,000 living under one year was 195; and from one and under five years, 80; from five years and upwards, 24. As compared with standard death-rates at the same ages, these ratios indicate a very high mortality. The total death-rate under five years was 108, which was more than 50 per cent. in excess of the mean rate at that period of life. The deaths under five years amounted to 42 per cent. of the total deaths, and the deaths under one year were 17 per cent. of the total births. Of the births, 8 per cent. were illegitimate, which is a very high number. We observe from these tables that there is a great defect in the registration system in Scotland; for Dr. Russell informs us that, "of the deaths under one year, in only 65 per cent. was the cause of death certified; of the deaths at one and under five years, in 78 per cent.; of the deaths above five years, in $88\frac{1}{2}$ per cent." Thirty-five children out of every hundred who died under one year in Glasgow in the first quarter of the year were buried, therefore, without any certain knowledge being obtained by the authorities of the cause of death. Associating this fact with the large number of illegitimate births, we draw the conclusion that it is high time for the sanitary authorities of Glasgow to look into this matter and improve the registration. It is not necessary to impute crime anywhere. The mere facts, as they are stated, point to a laxity which gives facilities to crime; and these facilities, in a well-regulated community, should be diminished. In an admirable tabular statement drawn up by Dr. Russell, we find these figures: Of 786 legitimate children dying under one year, 539 were certified, or about 68 per cent.; whilst of 112 illegitimate children dying under one year, only 47 were certified, or about 42 per cent. There are thus about 50 per cent. more deaths of infants certified among the legitimate than among the illegitimate. Among the classified causes of disease, there was a large proportion from phthisis and acute diseases of the lungs, as might be expected from the season, viz., 1,981; from scarlet fever, measles, whooping-cough, croup, and diphtheria, 667; from nervous diseases of children, atrophy and

debility of children, 535; from fevers, 74; diarrhoeal diseases, 57; from small-pox, 1. The total deaths were 4,756, and out of this number so many as 1,441 were uncertified. Dr. Russell gives two tables to show the proportion contributed by each class of disease to the total deaths in the earlier and adult periods of life, and he also tabulates the death-rate in the several subdivisions of the city. Kelvinhaugh and Sandyford show the lowest, $17\frac{1}{2}$; whilst Bridgegate and Wynds show 65; High Street and Closes (East), 58; High Street and Closes (West), 56; Gorbals, $50\frac{1}{2}$; St. Andrew's Square, $49\frac{1}{2}$; Cowcaddens, 49. The group in which the latter subdivisions are included contains 83,174 persons, and the density is 369 to the acre. "They are the worst districts in Glasgow," as Dr. Russell says, "both morally and physically." So we should judge from the terrible mortality. The operations of the Improvement Trust are carried on in this quarter, and the density is already diminished 14 per cent. There is plenty of room for bold work here. Such reports as this by Dr. Russell must do great good by demonstrating in an unmistakable manner the more crying evils, and by pointing out to the authorities the course of action to be taken for their removal. There can be no doubt that the authorities of Glasgow have already done much good service in behalf of their poorer fellow-citizens.

MILITARY AND NAVAL MEDICAL SERVICES.

DEPUTY SURGEON-GENERAL A. CROCKER is appointed to the Staff at Cork as Principal Medical Officer, on return from China, *vice* Deputy Surgeon-General M. W. Murphy, retired.

THE INDIAN MEDICAL DEPARTMENT.

THE *Pioneer Mail* of the 18th ultimo contains an article on a proposed reorganisation of the Indian Medical Department, in which article changes in the constitution of that body, of a somewhat fundamental and comprehensive character, are advocated. Our contemporary believes that the present plan of attaching an European medical officer to each native regiment is "not only injurious to the interests of the taxpayers, but intellectually injurious to the medical officers themselves".

Well-educated native practitioners, whose services would cost less than a fourth of the expenditure at present incurred, and who are "more conversant with the gastronomic indulgences of their brethren than any European can be", are now obtainable without stint of numbers, and might, with advantage, be placed in charge of native regiments. The European officers thus relieved would, it is alleged, be more profitably and congenially employed in the sanitary supervision of areas of two or three districts to be allotted to each, in immediate subordination to the sanitary commissioner of the province. Finally, dispensaries should be established in "tehsels", or sub-districts, under native doctors, who would be responsible for the proper performance of their duties to the European medical officers of district areas. In this way, our contemporary thinks, medical and sanitary relief would really be brought into contact with the masses of the people, at a total extra cost not exceeding "double the yearly revenue of a first-class London hospital"; moreover, the country would have, what is now so much needed, an organised and intelligent staff, capable of dealing promptly with the varied contingencies of epidemic outbreaks as they arise, and of deducing from them on the spot information which may lead to a solution of the mystery which envelopes the causes of cholera, Burdwan fever, leprosy, and the other diseases to which the vast population of our Eastern Empire is so peculiarly and fatally liable. As so many of our readers are more or less directly interested in Indian medical affairs, we have thought it as well to reproduce, for what they are worth, the salient points of the scheme proposed by the *Pioneer*, which paper, we believe we are correct in saying, is about the most influential and best informed organ of the Indian press.

CORRESPONDENCE.

THE FLEXIBLE CLINICAL STETHOSCOPE.

SIR,—This instrument, of which you gave a notice on September 4th, was in daily use in the Royal Infirmary of Glasgow eighteen years ago, and how long before that time I cannot say. It was made, I believe, by Mr. Hilliard of Glasgow for Dr. Tannahill, physician to the infirmary. The advertised advantages of the said form of stethoscope were long ago well appreciated, and are not by any means new.

Yours faithfully,

JOHN BRUNTON, M.D.

21, Euston Road, September 1875.

DEGREE OF M.D. IN THE UNIVERSITY OF EDINBURGH.

SIR,—Dr. William Hitchman of Liverpool, in his letter inserted in the number of the *BRITISH MEDICAL JOURNAL* for September 4th, in referring to the degree of M.D. of the University of Edinburgh, has not given the full particulars of that degree. I now supply the deficiency by sending a copy of the regulation concerning it.

"The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degree of Bachelor of Medicine in the University of Edinburgh, and is of the age of twenty-four years, and has produced a certificate of having been engaged, subsequently to his having received the degree of Bachelor of Medicine, for at least two years in attendance on an hospital, or in the military or naval medical services, or in medical and surgical practice, provided always that the degree of Doctor of Medicine shall not be conferred on any person, unless he be a graduate of arts in one of the Universities of England, Scotland, or Ireland, or of such other Universities as are above specified, or unless he shall, before or at the time of his obtaining the degree of Bachelor of Medicine, or thereafter, have passed a satisfactory examination in Greek, and in Logic or Moral Philosophy, and in one at least of the following subjects—namely, French, German, Higher Mathematics, and Natural Philosophy; and provided also that the candidate for the degree of Doctor of Medicine shall submit to the Medical Faculty a Thesis, certified by him to have been composed by himself, and which shall be approved by the Faculty, on any branch of knowledge comprised in the professional examinations for the degree of Bachelor of Medicine, which he may have made a subject of study after having received that degree. The candidate must lodge his thesis with the Dean on or before 30th April of the year in which he proposes to graduate. No thesis will be approved by the Medical Faculty which does not contain either the results of original observations in practical Medicine, Surgery, Midwifery, or some of the sciences embraced in the curriculum for the Bachelor's degree; or else a full digest and critical exposition of the opinions and researches of others on the subject selected by the candidate, accompanied by precise references to the publications quoted, so that due verification may be facilitated.

"Candidates, settled for a period of years in foreign parts, who have complied with all the above regulations for the degree of M.D., but who cannot appear personally to receive the degree, may, on satisfying the Senatus to that effect, by production of sufficient official testimonials, have the degree conferred on them in absence."

I am, sir, your obedient servant,

J. W. BALFOUR, M.D., F.R.S., Dean of the Medical Faculty.
Edinburgh, September 16th, 1875.

UNIVERSITY LOCAL EXAMINATIONS.

SIR,—I am surprised that no voice has been heard from anyone in the medical profession in regard to the University examinations as applied to girls. My attention has been specially directed to the matter by being asked to advise whether two young ladies, aged 14 and 13, ought to go in for the "Cambridge Locals". The book was put into my hands containing the examination papers for last year and the programme of studies for next year. Of this book, I need not occupy space by giving any detailed account, but only say that I do not believe one of our school inspectors could stand examination without a good deal of preparation, and I know I would require some months' "coaching" to make a creditable appearance. In quality, some things are objectionable; but I confine myself to quantity in the subjects prescribed. So large an amount of brain-work and straining of the memory and other faculties at this particular time of female life, when the nervous power is more needed for physical development, must be injurious. No girl can enter for the junior examination who is over 15. I have known cases of brain fever and of permanently injured health from excessive study for prizes and other competitions at this age in ordinary schools. The University examinations are giving new impetus and development to this system of "forcing" all over the country.

I say nothing at present of the examinations as applied to boys' schools. Mr. Fawcett, M.P., in a recent speech, met supposed objections, and said that, for one boy whose health was injured by excessive study, nine were injured by insufficient mental work. I will not dispute this, especially as the tendency is now rather towards "muscular training" in excess. But, in regard to girls at the same age, I would reverse Mr. Fawcett's proportion, and say that nine out of ten are likely to be injured by excessive study.

When in America some years ago, I found that this subject of mental "forcing", by competition both in the public schools and in private seminaries, was occupying much attention. Dr. Storer of Boston and other eminent medical men strongly opposed the system, and they

attributed to it, more than to climate, the nervous and unhealthy temperament of many of the educated women in the New England States, especially in large cities and towns, where the competition is greatest.

When the great Napoleon asked Madame de Staël what she thought was most needed for the welfare of France, the answer was, "Good mothers". The answer was excellent, if it included both moral and physical points of goodness, and is applicable to England as well as to France. But mere intellectual forcing, if pushed to excess, will be at the cost both of moral and physical good training. We used to laugh at the "accomplishments" which were taught in boarding-schools for girls; but they had this advantage: that they occupied pleasantly some of the time which is now all required for unnatural training of the mind and the memory.

It is very well for professional inspectors and college Fellows to prepare these schemes of study; but medical men are in a position to regulate their application in particular cases with a view to social benefit and public health. Let any father examine these books, and, if he would not allow his own daughters to be overworked, he may give the same advice to his friends and neighbours.

Let me not be misunderstood. The University local examinations are doing good service in diffusing sound principles of education and in directing the courses of study in schools. It is only one abuse of the system to which I am calling attention. Professor Maurice, some years ago, gave warning as to the evil results of overstudy and over-competition among boys. I am sure the warning is now doubly needed with regard to girls. I am, etc.,

JAMES MACAULAY, M.D., Editor of the *Leisure Hour*.

PLASTIC OPERATIONS.

SIR,—I observe the description of "a new method of performing plastic operations" by Dr. Wolfe (Glasgow) in the last number of your JOURNAL (September 18th, 1875), which, allow me to say, is a misnomer, inasmuch as the method which he has described is not new; and, in making the following remarks, I, for one, protest against the lofty stand which, in that article, he has assumed towards the profession. Anyone would think, in reading the communication referred to, that no progress had been made in plastic surgery for three hundred years previous to the advent of Dr. Wolfe.

But to the subject in hand. If I read Dr. Wolfe's article aright, he claims originality of thought on two points. First, the complete dissection of the flap of skin from the arm; and, second, the confining of it to the dermis and epidermis without the adherence of cellular tissue. With regard to the latter point, Mr. Lister, in describing skin-grafting on Reverdin's principle in the *Lancet* of May 1875, says:—"The skin of the inner side of the upper arm having been lightly washed with one to twenty of watery solution of carbolic acid, to purify its surface, a thin layer of the integument is shaved off with a very sharp knife, so as to take barely more than the epidermis, scarcely drawing blood or causing pain." Regarding the first condition, viz., complete severance of the flap and its insertion into the gap in the surface prepared for it, I have more than once seen it successfully performed, and that long before Dr. Wolfe appears to have practised it. Where, then, is the originality of this "new method of performing plastic operations"? the article describing which has been got up with such hot haste, that the author fails to give the date of the operation, and the wood-cut illustration of same was made only eight days afterwards.

Dr. Wolfe's communication is, therefore, worthless, as no one can say in eight days whether the flap will not by the lapse of time shrink to a nodule or even die. A month at least should have been allowed to elapse before the case was published, and then the profession would have some assurance that one of the elements of failure in such operations, namely, shrinkage of the flap (which this new method is intended to obviate) has not occurred in the very case which has been brought forward as proof.

One or two cautions, and I have done. I would recommend Dr. Wolfe to put a date to any new operation which he may lay before the profession in future, in order that, when years afterwards the history of his achievements is written, all priority of claim by others may be easily set aside. Again, for his own reputation during his lifetime, he might well be a little less hasty before communicating to the profession the results of his experiments. I am, sir, yours truly, FIDES.

STAFF-SURGEON ARCHIBALD LESLIE ARCHER, M.D., has been appointed Visiting Surgeon at Plymouth, Devonport, Dartmouth, Ivy Bridge, and Plympton, under the Contagious Diseases Acts of 1866-69, *vice* Dr. Patrick Digan, deceased. The appointment to date from August 10th, 1875.

MEDICAL NEWS.

MEDICAL VACANCIES.

The following vacancies are announced:—

- BATTLE UNION—Medical Officer for the Ashburnham District. Salary, £25 per annum.
- BODMIN UNION—Medical Officer for the Sixth District. Salary, £39.5 per annum.
- BRIDGNORTH INFIRMARY and DISPENSARY—House-Surgeon. Salary, £120 per annum, increasing £10 a year till it reaches £150, with coals, gas, and furnished apartments. Applications on or before the 28th instant.
- BRISTOL GENERAL HOSPITAL—House-Surgeon. Salary, £100 per annum, with board, lodging, and washing. Applications on or before the 29th instant.
- BRISTOL HOSPITAL FOR SICK CHILDREN—House-Surgeon. Salary, £100 per annum, with furnished rooms, coal, gas, and attendance. Applications on or before October 7th.
- CAISTON UNION—Medical Officer and Public Vaccinator for the Tealby District. Salary, £30 per annum, and fees. Applications on or before Oct. 1st.
- CHESTER GENERAL INFIRMARY—Visiting Surgeon. Salary to commence at £80 per annum, with board, lodging, and washing. Applications on or before the 27th instant.
- COLCHESTER UNION—Medical Officer for the Second District. Salary, £75 per annum.
- DONCASTER INFIRMARY—House-Surgeon. Salary, £100 per annum, with board and lodging. Applications to be made on or before October 18th.
- ESSEX and COLCHESTER HOSPITAL—House-Surgeon and Apothecary. Salary, £80 per annum, with board and lodging. Applications on or before October 7th.
- HASLINGDEN UNION—Medical Officer for the Accrington District. Salary, £90 per annum.
- HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST—Resident Clinical Assistant. Applications to be made on or before October 4th.
- INVERNESS DISTRICT ASYLUM—Assistant Medical Officer. Salary, £70 per annum, with bed, board, and washing. Applications on or before the 11th prox.
- LIVERPOOL DISPENSARIES—Assistant Resident House-Surgeon. Salary, £108 per annum, with furnished apartments, coals, gas, and attendance. Applications on or before the 27th instant.
- LONDON HOSPITAL—Assistant Obstetric Physician. Applications on or before the 27th instant.
- NORTH WALES COUNTIES LUNATIC ASYLUM, Denbigh—Assistant Medical Officer. Salary, £100 per annum, with board, lodging, and washing. A knowledge of Welsh indispensable. Applications to be made on or before October 13th.
- NORWICH DISPENSARY—Salary, £120 per annum, with unfurnished residence and apartments.
- ONGAR UNION—Medical Officer for the First District. Salary, £105 per annum.
- OWENS COLLEGE MEDICAL SCHOOL—Sub-Curator of the Anatomical Museum. Applications on or before the 27th instant.
- PAISLEY INFIRMARY—House-Surgeon. Salary, £80 per annum, with board. Applications on or before October 1st.
- PEMBROKE UNION—Medical Officer for the First District.
- ROYAL HANTS COUNTY HOSPITAL—House-Surgeon and Secretary. Salary, £100 per annum, with board and lodging. Applications on or before the 29th instant.
- ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road—House-Physician. Applications to be made on or before October 2nd.
- ST. MARY'S HOSPITAL and DISPENSARY FOR WOMEN AND CHILDREN, Manchester.—Medical Officer. Salary, £80 per annum, with board and residence. Applications on or before October 1st.
- STROUD GENERAL HOSPITAL—House-Surgeon.
- WESTMINSTER HOSPITAL—Physician and Assistant-Physician. Applications on or before the 28th instant.
- WEST NORFOLK and LYNN HOSPITAL—House-Surgeon and Secretary. Salary, £100 per annum, with board, lodging, and washing. Applications on or before October 2nd.
- WEST SUSSEX, EAST HANTS, and CHICHESTER GENERAL INFIRMARY and DISPENSARY—House-Surgeon. Salary, £80 per annum, and £20 per annum as Secretary, with board, lodging, and washing. Applications to be made on or before October 23rd.—Assistant House-Surgeon to dispense. Salary, £20 per annum, with board, lodging, and washing. Applications to be made immediately.
- WORKSOP DISPENSARY—Resident Surgeon. Salary, £100 per annum, with furnished apartments, coals, gas, and attendance. Applications on or before the 30th instant.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTHS.

- BARRIE.—On September 15th, at Elmbank, Dumfries, the wife of Andrew D. Barrie, M.B., C.M., of a son.
- NOAD.—On the 18th inst., at East Cowes Villa, Lower Norwood, the wife of H. Carden Noad, L.R.C.P. Lond., M.R.C.S. Eng., of a son.

MARRIAGES.

- BLYTHMAN.—Ellis.—On September 16th, at Thurnscoe, by the Rev. Arthur Blythman, brother of the bridegroom, assisted by the Rev. J. B. Ellis, brother of the bride, Clement S. Blythman, M.B., etc., of Swinton, to Annie, only daughter of J. D. Ellis, Esq., of Thurnscoe Hall, Yorkshire.—No cards.
- MCDOWALL—CAREY.—On the 21st instant, at the Parish Church, Ryton-on-Tyne, by the Rev. T. Finch, B.A., Dr. T. W. McDowall, Northumberland County Asylum, Morpeth, to Alice, eldest daughter of H. C. Carey, Esq., Elnore, Denmark.—No cards.
- MACLAREN—CAMPBELL.—On the 15th instant, at St. Paul's Church, Carlisle, by the Rev. F. Richardson, Roderick MacLaren, M.D., to Isabella Emma, youngest daughter of the late Rev. Duncan Campbell, North Knapdale.

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.
 PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with Duplicate Copies.
 AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Ricbards, 37, Great Queen Street, W.C.
 CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.
 WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.
 COMMUNICATIONS respecting editorial matters, should be addressed to the Editor; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

CAPSICUM IN DELIRIUM & POTU.

SIR,—In reference to the remarks of Mr. L'Heureux Blenkarne in the JOURNAL of May 8th, I beg to state that I have been in the habit of using capsicum in delirium tremens, with the best results. Many years ago, this treatment was recommended by Dr. Lyons of Dublin, who found it very beneficial; and, as I said before, I have frequently had recourse to it myself with success, after morphia, spirits of chloroform, chloral hydrate, hyoscyamus, and digitalis, had failed to induce sleep. Dr. Lyons generally prescribed the powdered capsicum in twenty-five grain doses, made into a bolus with a little honey. This dose, though excessively pungent to the palate, as may be imagined, was always taken readily, and without any unpleasant after-effects. So convinced am I of the usefulness of this mode of treatment, that I now usually adopt it in the first instance, in preference to any other. Capsicum, like most plants of the order Solanaceae, appears to act as a direct sedative when taken in large doses.—I am etc., OTHO GALVEY.
 St. Vincent, West Indies, August 1875.

SIR,—I am sorry that, through ill-health and other private affairs, I have not been able to answer a query in one of your JOURNALS; I think a fortnight ago. It was about the dose of tinct. capsici in cases of "potomania", on which subject I have written several letters to *Land and Water*, under the head of "Tippling in Private Life". In one of these, I advocated the use of capsicum, as suggested in your columns in 1871 by Dr. Ringer. I gave a patient of mine in Boulogne the following prescription.

R. Tinct. capsici ʒiiss; tr. aurant. ʒiv; syr. ejusdem ʒiv; aquam ad ʒvj. M. Fiat mist. A tablespoonful three or four times a day, as required.

I afterwards increased the dose of tinct. capsici to nearly double the strength of the original dose before my patient left for London, an altered man in every way; who, as I said in my letter to *Land and Water* of January 20th (same was copied into the columns of the BRITISH MEDICAL JOURNAL), "took to his bottle"—the capsicum one—whenever he felt inclined to indulge in the other sort of "tincture", and was quite well when last I heard of him.—I am, sir, yours faithfully, SONEY CHATER.
 76, Rue des Vieillards, Boulogne-sur-Mer, September 15th, 1875.

G. H. D. inquires whether a gentleman, having served three years to a medical man previous to the passing of the Act enforcing the preliminary examination, would be exempt from passing the preliminary on producing certificate of same.
 . No; certainly not.

"YE VAMPYRES."

SIR,—A "victim" wishes to warn medical gentlemen to be extremely cautious before they trust their hardly earned money in the hands of assurance or other companies, which require medical gentlemen to invest certain sums in order to obtain certain salaried appointments to the said companies. He can assure them that their investments sometimes end in more than disappointment. Trusting this will act as a warning to many, I am, sir,

A HATER OF ALL "VAMPYRES".

MR. A. BENDER (Dalston).—We do not recommend medical men. Mr. Bender had better consult any respectable practitioner in his neighbourhood, and avoid advertising quacks.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

THE USES OF TEREBENE.

SIR,—I observe that two of your correspondents have drawn attention to the use of terebene as a deodorant in cancer and other cases. It may not, perhaps, be out of place for me, as having been the first to introduce this body into medical use, to supplement the evidence given by Drs. Wilson and Paine in its favour by a few facts which may be of some interest in connection with the subject. Although, as Dr. Paine points out, terebene does not mix readily with water, it is easily miscible with olive oil, with which it may be diluted to any extent, the combination thus produced forming a very convenient way of applying it for external purposes. For internal use it may be given in gum emulsion, to which a few drops of acetic acid may be added.

Your correspondents have drawn attention to the value of terebene for deodorising or disinfecting purposes, and any one who is interested in these applications of it can readily satisfy himself that their recommendation of it is well founded; my object in this communication is, however, to invite attention to its use for internal purposes, and especially as a substitute for salicylic acid. The number of the JOURNAL in which the letters of Drs. Wilson and Paine occur, contains a very full summary of the experiments of Wunderlich, Wagoer, and others, on the therapeutic applications of salicylic acid, and it is curious how equally most of their statements would apply to terebene. Thus Wagner speaks of the effect of the former body in promoting the healing of atonic ulcers and wounds; terebene has been found to produce the same effect. He also praises the acid as a mouth-wash and gargle in offensive mouth-affections; a drop or two of terebene in a few ounces of water makes one of the most effective mouth-washes which can be desired. The effects of the two, when given internally, are apparently identical. Terebene, when given in doses of 5-10 minims, arrests more or less completely the putrefaction of the contents of the intestinal canal, the fæces becoming almost entirely odourless. Its power in this direction is especially marked, in offensive diarrhoea of some forms of peritonitis. In addition, it exercises somewhat of an antiseptic influence on the alimentary canal, which is in harmony with Dr. Paine's evidence as to its styptic powers. When given by the mouth, it passes off partly by the bowel, in an unchanged form; partly in an oxidised form, and with a characteristic odour, in the urine; and partly also, I think, by the pulmonary membrane—at least it seems slightly to promote bronchial secretion.

The above facts indicate that terebene, like salicylic acid, is specially applicable in cases of excessive intestinal secretion, accompanied with a tendency to rapid and offensive decomposition, such as that of dysentery and enteric fever, which the antiseptic properties of both of these bodies seem well adapted to check; though it is noteworthy that terebene, like salicylic acid, does not interfere with the fermentative process of digestion, which proceeds unchecked during its use.

I have not yet had an opportunity of getting terebene tried in diphtheria, but I feel satisfied that, from its analogies in other respects, it would be found to be equally effective with salicylic acid.

I may add, that I shall be happy to send a small sample of terebene to any of your readers who may wish to examine it.—I am, faithfully yours,
 Gloucester, September 1875. FRANCIS T. BOND, M.D.

DR. JOHN TATHAM.—Yes, report for 1874 received.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

THE TREATMENT OF CHLOROFORM-POISONING.

SIR,—I should content myself with thanking Dr. Skinner in a private letter for his suggestions in reference to my case of chloroform-poisoning, were it not that, in addition to criticising my treatment, he makes certain statements which seem to me both dangerous and erroneous; and I am therefore compelled to make some remarks, "in the hope", to quote his own words, "that humanity may profit by them."

His opinion that my patient was in an epileptic fit, and would have come to himself if left alone, is curious, but not, I think, correct. When attention was called to the lad's condition, the operation was nearly completed, the administration of chloroform was stopped; and, from the fact that the teeth were closed (not clenched), it is evident that the lad was not completely under the influence of the drug. The frothy mucus at the angles of the mouth was due to the temporary suspension of the act of swallowing. There was no convulsive action, and nothing whatever to justify the name of fit; indeed, he had struggled perhaps less than is common during the early stages of the administration, when the convulsive movements of a patient would often seem to partake somewhat of the nature of an epileptic attack.

Dr. Skinner says, in speaking of the treatment adopted, viz., that of inversion, that he should have preferred the horizontal position; but it is really not a question of objection or preference. As a matter of fact, no one would prefer to be hung up like a sheep by the heels; and both surgeon and patient would be sure to condemn such an obviously inconvenient method, unless it were superior to, in being safer than, any other plan. This is the very point to be determined, the point which both could and should be finally settled by experiments upon animals. All that we are able to say at present is that recoveries have taken place under the plan of inversion after a longer period of suspended animation than have taken place under any other method. Mr. Whitehead informs me that, since publishing the details of my case, he has had a very similar experience—circulation and respiration both abruptly (losing in a patient whilst recovering from chloroform, the plan of Silvester adopted without success, but respiration almost immediately following inversion of the patient, though in his case artificial respiration was not continued when the patient was turned upside down.

But it is to another point in Dr. Skinner's letter that I especially wish to draw attention. He states that, inasmuch as the lad was not completely under the influence of chloroform, therefore there was no danger. "In chloroform-poisoning, as a rule," he remarks, "whenever there is muscular contraction or rigidity, I should consider my patient's life safe." Now, I fear if this statement were generally accepted, it would lead to the loss of lives in disabusing our minds of the presence of danger when anaesthesia is incomplete. The details of fatal cases, on the contrary, prove, beyond all doubt, that danger and death attend each and every step of the process. There is, so to speak, no point on the line where a return ticket is always procurable. I find, for example, that, in the years 1871, 1872, 1873, and the first half of 1874, about forty-five deaths from chloroform reported in the BRITISH MEDICAL JOURNAL; and of these, twenty died when insensibility was incomplete, several of them whilst in the act of struggling. Some died after vomiting, others in making efforts to vomit. Many died before the operation was begun; some few when it was over, and after animation had been partially restored. Some died gradually; in others, death was instantaneous. Let us not, then, dwell in a fool's paradise of safety in thinking our patient safe because he is kicking; but let us be prepared to encounter danger, and resort to treatment at any stage of the administration of chloroform; and surely it is not expecting too much to look for some authoritative decision upon the exact treatment which should be adopted when alarming symptoms appear.—I am, etc.,

Manchester, September 7th, 1875. S. MESSENGER BRADLEY.

DR. CROFT.—The midwives' chair is in common use at Cairo, and is carried from house to house when wanted, and is probably similar to the stools mentioned in Exodus, chap. i, v. 16: "And he said when ye do the office of a midwife to the Hebrew women, and see them upon the stools, if it be a son then ye shall kill him, but if it be a daughter then she shall live." A similar stool is used at the present time by the Germans, and by them is called the Geburts-stuhl.

THE KING'S EVIL.

In his *History of Advertising*, Mr. Sampson publishes the following announcement from the *Public Intelligencer* of May 1664: "Whitehall.—His Sacred Majesty having declared it to be his royal will and purpose to continue the healing of his people for the evil during the month of May, and then to give over till Michaelmas next, I am commanded to give notice thereof, that the people may not come up to town in the interim and lose their labour." How passing strange that a people who had tried, condemned, and executed one king like any common man, should have put faith in such an announcement as the above.

DERMATOLOGIST.—A second edition of Professor Wilson's descriptive catalogue of the dermatological specimens contained in the museum of the College of Surgeons has just been published.

VERY AMAZING.

Two physicians in Quincy, Illinois, have been sued by a patient on whom they operated for hernia. The declaration states that the defendants conducted themselves in an ignorant manner, by unnecessarily, wantonly, improperly, and unskillfully performing a surgical operation on the body of the plaintiff, by cutting through the flesh of said plaintiff into the cavity and through the left lower region of the abdomen; and in an unskillful manner the defendants took and removed from the cavity of the abdomen of plaintiff twenty-five feet of bowels, by reason of which ignorance his recovery is greatly impeded.—*Med. and Surg. Rep.*

SIR,—The letter signed William Hitchman, M.D., in your issue of September 4th, is in my opinion likely to mislead. The statute he refers to with regard to M.D. Edin. only relates to the simple ceremony of conferring the degree; and at Edinburgh, at any rate, no one is admitted to M.D. until two years after obtaining M.B.; and to obtain M.B., one year at the very least must be passed at the Edinburgh University.—I am, etc.,

Skipton, September 9th, 1875. E. WEST SYMES, M.D. EDIN.

AN OLD MEMBER.—It was abolished a few years ago; prior to which the Presidents of the Colleges of Physicians and Surgeons of London received respectively, as members of the Vaccine Board, the annual honorarium of one hundred guineas.

A MEMBER will be pleased to receive, through the medium of the JOURNAL, any suggestions for the cure of an inveterate habit of biting finger-nails.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, no later than Thursday, twelve o'clock.

DR. CHEYNE.

See, in connection with the paragraph in your issue of 12th day reading to Dr. Cheyne, I venture to send you the following short passage of some between him and Dr. Winter, in the hope that it may serve as a diversion from the weightier matters of the profession. At the time that Dr. Cheyne and Dr. Winter were the two principal physicians at Bath, they adopted very opposite modes of practice; but the former gave some credence to his prescription of milk-diet by making it the principal article of his own sustenance. On this occasion, Winter wrote him the following stanzas.

"Tell me from whom, fat-headed Scot,
Thou didst thy system learn:
From Hippocrates thou hast it not,
Nor Celsus, nor Pitcairn.
Suppose we own that milk is good,
And say the same of grass—
The one for babes and calves is food,
The other for an ass.
Doctor, one new prescription try
(A friend's advice forgive),
Eat grass, reduce thyself, and die,
Thy patients theo may live."

Dr. Cheyne's answer:

"My system, Doctor, 's all my own,
No teacher I pretend;
My blunders hurt myself alone,
But yours your dearest friend.
Were you to milk and straw confined,
Thrice happy might you be;
Perhaps you might regain your mind,
And from your wit get free.
I can't your kind prescription try,
But heartily forgive:
'Tis natural you should bid me die
That you yourself may live."

I have taken this from an old volume, published more than fifty years ago, and it may be authentic.—I am, yours truly, A. D. KEITH.
Craigieigh, Aboyne, Sept. 14th, 1876.

REMARKS

ON

THE TREATMENT OF ACUTE RHEUMATISM BY
TINCTURE OF THE PERCHLORIDE
OF IRON.*By J. RUSSELL REYNOLDS, M.D., F.R.S.,
Professor of Medicine in University College, London.

IN the year 1869, at the meeting of this Association in Leeds, I had the honour to read a paper upon the Treatment of Acute Rheumatism by the Tincture of the Perchloride of Iron. The facts which I then recorded were such as to induce me to continue the mode of treatment which I then described, and I wish now to lay before you some further results of that mode of dealing with the disease in question.

You will allow me to remind you that the possibility of relieving acute rheumatism by the tincture of perchloride of iron was suggested to my mind by observing the rapid arrest of certain other "spreading" inflammations—such as erysipelas, diphtheroid and hepatic sore-throats—by the administration of this drug; and that I stated at the time, and wish now to repeat the statement, that, in my judgment, the cases that I could then bring before you, and those which I can now submit to your consideration, are not sufficiently numerous to establish a therapeutic position; but that they are, so far as I can see, sufficiently significant to warrant a further trial of a mode of treatment which is certainly better than that which Warren said was all that he knew of that was good for rheumatism, viz., six weeks.

In the front of this paper I wish to state, that very many cases that have been under my care, both in hospital and in private practice, but of which I have no sufficient notes, have left upon my mind the strong conviction that those which I am able to bring before you under-estimate rather than overrate the value of the mode of treatment that I have suggested. This I am convinced is the case especially with regard to the time of the relief afforded to spontaneous pain.

The treatment has been generally the administration of the tincture of perchloride of iron, in doses varying from 15 minims to a drachm every four hours, with or without 20 to 30 minims of glycerine and spirits of chloroform. No patient has complained of any discomfort of any kind, which could be referred to the medicine.

The facts which I have to submit to you have been gathered by my very able clinical assistant in University College Hospital, Mr. Voelcker, from the case-books of Sir William Jenner, Dr. Wilson Fox, and myself. The cases are sixty-five in number, all treated by iron, and the general results are as follows. Hyperpyrexia occurred in 3 cases; was fatal in 2, relieved in 1 on the seventeenth day. A normal temperature was observed throughout in 2 cases; 1 presenting friction sound and systolic apex murmur, probably old. No heart-affection was observed in 27 of 52 cases. The joint-affection was severe in 18, of medium intensity in 16, and but slight in 5. The severity of the disease, as judged of by the temperature before the commencement of the iron treatment, may be represented thus, generally, that in 37 of 52 cases it was at or above 102 degs. Fahr.

Analysing these cases more minutely, I find the following results.

1. With regard to the date on which the temperature became normal after the commencement of treatment, that in 20 of 57 cases the normal condition was reached on or before the fifth day; in 26, *i. e.*, in 45 per cent., before the end of the first week; in 15, between the fifth and tenth day, *i. e.*, in 35 cases, or 61 per cent. before the tenth day; in 15, between the tenth and twentieth days, *i. e.*, in 50 cases of 57, before the end of the third week. The most important point to notice here is, that in 36 per cent. the temperature was normal on or before the fifth day after the commencement of iron treatment.

2. The date of the disappearance of all pain may be shown thus: in 2 cases on the second day, in 3 on the third, in 6 on the fourth, and in 4 on the fifth, that is to say that in 15 of 57 cases (22 per cent.) all pain had gone by the fifth day; in 14 other cases, the pain had ceased after the sixth and before the tenth day. This gives 29 of 57 cases, more than 50 per cent., free from pain on or before the tenth day. And further, 22 cases found relief between the tenth and twentieth days; *i. e.*, 51 of 57 cases were relieved of all pain within twenty days. Here, again, the principal point of interest is the earliness of the date upon which pain disappeared in a considerable number of cases.

3. The relation between the severity of the disease, as judged of by temperature elevation, and its duration after the iron was administered, may be thus exhibited in 52 cases. Under 101 degs. Fahr. of 15 cases, the temperature became normal in 7 during the first week, in 5 during the second week; at 102 degs., and between 101 and 102 degs. of 19 cases, the temperature became normal in 11 during the first week, in 2 during the second week, and in 9 during the third and fourth weeks. In 14 cases when the temperature was 103 degs. at the commencement of treatment, 4 convalesced in the first week, 4 in the second, 5 in the third, and 1 in the fourth. Of 4 cases in which the temperature was 104 degs. when the iron was first given, 2 presented a normal heat in the second week, and 2 others in the third.

The result of this examination may be most correctly exhibited by dividing the cases into two groups, those in the first having a temperature ranging from 99 to 101 degs., those in the second group varying from above 101 to 104 degs. Of the first group, 15 in number, 46 per cent. convalesced during the first week; of the second group, 37 in number, 40 per cent. attained a normal temperature within the same period. It is obvious from these facts, that the duration of fever after the administration of iron was not determined, and but only slightly affected (6 per cent.) by the degree of fever which had been previously attained. In other words, it was in severe as well as in moderate and mild cases, that the beneficial effects of treatment might be observed.

4. The degree to which the condition of the heart affected the duration of fever in cases of acute rheumatism, may be shown in 52 cases; thus, in 21 cases the heart was healthy throughout, and of these, 10 convalesced within five days, and 6 between the fifth and tenth days; whereas, of 31 cases with endocarditis, pericarditis, or the two combined, but 9 reached a normal temperature on or before the fifth day, and 6 between the fifth and tenth days. Further, of those 21 cases in which the heart was healthy, five only presented an abnormal temperature beyond the second week; while of those 31 in whom heart-disease existed, 16 remained feverish beyond that period. Representing these facts by calculations per cent., they stand thus; that when there was no cardiac affection the temperature was normal before the tenth day in 76 per cent., and when there was heart disease only 22 per cent. convalesced during that period. It may be interesting further to know, that of these 52 cases, 16 presented endocarditis alone, 7 pericarditis alone, and 3 endopericarditis.

From this it is obvious, that the presence of cardiac affection protracted the duration of the fever, and, *pro tanto*, diminished the beneficial action of the drug.

5. The influence of the severity of the joint-affection upon the duration of the abnormal temperature may be exhibited in 39 cases. In 18 the severity was great, in 16 medium, and in 5 inconsiderable. Of the 18 severe cases the temperature became normal within the fifth day in 4, between the fifth and tenth days in 5, between the tenth and fifteenth in 4, and between the fifteenth and twentieth in another 4; and, in one case, it was not reduced to 98.4 until the thirtieth day. In 21 cases of medium or slight severity, the temperature was normal in 7 before the fifth day, in 8 between the fifth and tenth days, in 3 between the tenth and nineteenth days; in 2 medium cases it remained elevated until the twentieth day; and, in one mild case, the fever continued until the thirtieth day.

Representing these facts by percentage, they show that in severe cases the temperature became normal before the tenth day in 50 per cent.; and that it was normal in moderate and slight cases in 71 per cent. by the same date. Or, separating those of medium severity from those of but slight joint affection, we find the temperature normal before the tenth day in extreme cases in 50 per cent., in moderate cases in 68 per cent., in mild cases in 80 per cent. Remembering that, as a rule, endo- and pericarditis are more frequently found in cases of severe than of but slight joint affection, the facts that I have stated cannot, I think, be referred to the mere chapter of accidents. I do not remember to have seen under other modes of treatment one half of the cases of severe acute rheumatism, presenting a normal temperature within fifteen days from the commencement of treatment.

6. The length of the persistence of pyrexia after the commencement of treatment by iron in relation to the day from the attack at which such treatment was begun, is somewhat curious. No case was treated before the third day of the attack; and of those which were treated within the first week, 23 in number, 10 presented a normal temperature before the seventh day, 8 before the end of the second week, 1 in the third week, and 4 in the fourth. Of those, 15 whose treatment did not commence until the second week from the date of attack, 5 presented a normal temperature within seven days, whereas abnormal heat remained in 8 until eight and twelve days from the administration of the iron. It is interesting to note that in two cases, each of whom had suffered for

* Read in the Medical Section at the Annual Meeting of the British Medical Association in Edinburgh, August 1875.

longer than three weeks before the medicine was given, this temperature became normal in one on the second day, and in another on the third. Of 45 individuals, including extreme cases, the mean duration of fever after giving iron was eleven days; and this was so in each of two groups, one of 25 in whom the treatment was commenced before the seventh day, and in the other, of 20 cases who had undergone no treatment until after that date. The point of importance lies in the fact that although, when treated within the first week, 43 per cent. presented a normal temperature within seven days; and that when the treatment was not commenced until the second week, 33 per cent. lost their fever during the same period, it is not warrantable to conclude that the date at which the case was taken into hand alone determined the duration of the malady, for in two cases which had resisted other treatment for a period of three weeks, relief followed the administration of iron, and the temperature became normal within three days.

7. The relation between the number of attacks which the patients have suffered, and the duration of abnormal temperature may be thus shown in 55 cases: 29 were in their first attack, and, of these, 13 lost all fever within the first week; 9 within the first five days; 19 were in their second attack, and of these 7 were of normal heat within six days; 6 were in their third attack, and of these 3 presented a normal temperature within five days. Or, putting it another way, of those who were in their first attack, 44 per cent. were convalescent within the first week, while of those who suffered in their second, third, or fourth attack, 42 per cent. recovered within the same period.

It is obvious from these facts that so far as iron treatment is concerned, it is a matter of indifference whether the patient be suffering in a first, second, or third attack.

In several cases I have observed a remarkable diminution in the frequency of the pulse at and after the time at which the temperature has become normal; thus it has been as low as 40, 30, and even 28, but regular in rhythm and force, and the patients have made no complaint of pain or faintness.

I have purposely stated the facts already in my possession, in a bald manner, and have avoided all theory with regard to the treating, that at some future meeting of this Association I may be able so to increase their number as to be able positively to answer the question as to the utility of treating acute rheumatism in the manner I have described.

SACCUATION OF, AND STONE IN, THE BLADDER.*

By W. CADGE, F.R.C.S.,
Surgeon to the Norfolk and Norwich Hospital.

I DESIRE in this communication, as briefly as I can, to direct the attention of the meeting to the combination—I may say the unhappy combination—of stone in and sacculation of the bladder, chiefly with reference to operations for the removal of the stone, and especially to the risks of lithotripsy in such cases. I do not allude to ordinary cases of encysted stone—cases which may occur in the young as well as in the aged—in which probably there is a single cyst, which may, and very likely have, been caused by the presence of the stone itself. These cases are fully described in surgical works; they are happily rare in practice, and each one must be dealt with, or left alone, according to the judgment and skill of individual surgeons. I allude rather to those cases of sacculation of the bladder which occur chiefly in the aged, or in those who have experienced continued obstruction to the outflow of the urine, whether from stricture of the urethra, from enlargement of the prostate gland, or from other causes. The mode of formation of these sacculi is well understood and easily explained. The impediment to the escape of urine necessitates increased expelling power on the part of the bladder; this leads to hypertrophy of the muscular walls and interlacing columns; the equal pressure of the fluid in all directions forces the mucous membrane, which is capable of great distension, into the spaces between the interlacing muscular columns; and in this way sacculi of every size, shape, and character are accounted for, from the simple recess between the muscular columns to the perfect hernial protrusion through the entire muscular wall, in which there is no covering to the sac except the peritonium. Muscular hypertrophy of the bladder, as of the heart, may exist under two conditions, simple hypertrophy, or hypertrophy with dilatation. The former is seen most frequently in cases where the obstruction is due to stricture, where the patients are of middle age, and in the possession of fair vital power; the latter, in the aged, whose enlarged prostate is the

impediment, whose vital power is on the wane, and in whom the bladder is apt to exhibit atony or even paralysis. In simple hypertrophy, the result of stricture, sacculation is far less frequently met with than where there is a dilated bladder from prostatic obstruction. In the latter case, judging from my own observation in *post mortem* examinations and of specimens in museums, sacculation of the mucous membrane exists in the majority of cases.

Given, then, such a sacculated condition of bladder, let us inquire what may happen when a calculus passes into it from the kidney. From the impediment to the escape of urine which always exists in these cases, the stone is very likely to remain in the bladder and increase in size. It may pass at once into one of the sacs, remain and grow there, and cause the symptoms characteristic of encysted stone; or it may not, and I believe, as a rule, does not, at first enter a sac, but remains free in the bladder, and causes the usual symptoms of stone with which we are all familiar.

Then comes the question of operation. The patient either submits to lithotomy, in which case he would probably recover as if no sacculation existed; or to lithotripsy, in which case some of the small fragments or *débris* will be very likely to find entrance into one or more of the sacs, and lead either to immediate fatal inflammation extending to the peritoneal membrane, or to prolonged incurable cystitis, recurring stone, and ultimate death. These chronic and deplorable results, however, do not manifest themselves at once; the present and immediate effects of the operation are satisfactory. The mass of the stone, excepting only a few imprisoned pieces, being well removed, the bladder is for the time happy and comfortable; the symptoms almost disappear; only a slight irritability remains, which is attributed either to the enlarged prostate or to the effects of the frequent recent use of instruments; the patient goes home; and the case swells the lists of triumphant successes of lithotripsy which now and then appear in the medical journals. If you scrutinise these lists of successful cases, you will find a not inconsiderable number described somewhat in this way: "A gentleman, aged 70; six sittings; all the stone removed, but some irritability of the bladder remaining." Now, in many of these cases—these so-called "successful" cases—I believe that some fragment has entered one or more of the numerous sacculi, and keeps up the irritability; that by degrees it increases in size, and projects into the cavity of the bladder, and is again met with by the sound, and is probably reduced in size by the lithotrite, and the patient's condition is for a time improved. But the imprisoned stone can never be removed (or but very seldom) from the cyst; it soon sprouts up again into the cavity of the bladder, to be again attacked by the lithotrite; and so the process goes on, until the patient is worn out by continued suffering and repeated operations. No one, I apprehend, will deny the truth of this picture; but it is said that such cases are very rarely met with. Is it so? I have looked closely through my own cases, and, finding half a dozen at least in which this accident (if I may call it so) has occurred, the conviction is strong in my mind that it is of more frequent occurrence than writers on lithotripsy have been willing to allow. It is probable that provincial surgeons, who draw their cases mainly from their own neighbourhood, are better able to trace the subsequent history of their patients than those who practise in London; and to them, therefore, we must look for a note of warning, such as that which I am now attempting to give.

Permit me to illustrate these points by briefly narrating a few cases.

CASE 1.—In 1868, a Jewish gentleman, aged 64, from Varmouth, consulted me for stone in the bladder. For four or five years, he had had chronic prostatic retention, and passed all his urine by the catheter. For some months, he had experienced sharp symptoms of stone, in addition to those of enlarged prostate, with cystitis. I examined him with a lithotrite, and found that there was more than one stone, the largest of which measured seven lines. After four or five sittings, in which the stone was well broken, and the fragments removed partly by repeated introduction of the screw-scoop, and partly by Clover's exhausting syringe, all the stone appeared to be gone, and the symptoms were greatly improved. Very soon, however, the cystitis returned; small atoms of phosphatic stone began to escape through the large eye of a large catheter; and in a month or two I was enabled, after several vain explorations, to detect a stone, which then, and always afterwards, appeared to be fixed and encysted at the lower and right side of the bladder. At first, it was very difficult to find this stone, or rather the small point of it which projected through the mouth of the sac; but by degrees it grew up into the bladder, and was from time to time attacked by the lithotrite; that is to say, it was broken off level with the aperture leading into the sac, and the loose pieces removed. For nearly two years I did this for him at frequent intervals, and his condition was one of persistent cystitis. He is still living; and his surgeon, Mr. Meadows, I believe, carries on the same

* Read at the annual meeting of the East Anglian, Cambridge and Huntingdon, and South Midland Branches, at Cambridge.

treatment, though at longer intervals, and with less cystitis. The future of this patient must be one of recurring stone and persistent misery. Could I have told that his bladder was sacculated, and had subjected him to lithotomy, he would probably have recovered and remained well afterwards.

CASE II.—In August 1868, I admitted a man aged 63 into the Norfolk and Norwich Hospital, who had undergone five or six sittings of lithotripsy by a surgeon in the country; the last, six weeks before admission. He had voided a good deal of calculous debris; but he had still acute vesical pain and tenesmus, with foetid alkaline urine and mucopurulent deposit. I found, on examination, a very tender, hard, distended bladder, having a few small pieces of stone lying loose in it. I gently crushed these pieces once or twice, and ordered the bladder to be emptied by a flexible catheter occasionally; but his sufferings continued unabated, and he died worn out by pain in a month or so. *Post mortem* examination showed a thickened bladder, having numerous sacculi, one large enough to hold a walnut, in which were found two considerable pieces of stone. The mucous membrane was everywhere rather dark-coloured, and covered with pale tenacious mucus; but the inflammation was most acute, and the colour darkest, in and around this sac. There were several small fragments of stone still in the bladder; some of these appeared to be fixed, as it were, in little recesses or commencing sacs of the mucous membrane, and retained there partly by the hypertrophied muscular columns, and partly by the tenacious mucus, which seemed to glue them to the membrane. In this case, it is clear that, even had the cystitis not proved fatal, he would ever after have suffered from encysted stone; and it is equally clear that his best chance of recovery would have been from lithotomy.

One other similar case deserves mention.

CASE III.—Captain B., aged 70, came to Norwich in July 1868, from Brighton, for treatment, under the following circumstances. In August 1865, a lithic acid stone was crushed repeatedly by an eminent lithotripter in London. Recovery was nearly complete; he was supposed to be cured, and returned home to Brighton. In a month or two, however, the symptoms returned, and he consulted another distinguished lithotripter, who examined him, and could find no fragment. I mention this because, although these two distinguished surgeons could find no stone remaining, he not unfrequently passed pieces of lithic calculus then and for some time after, showing that, in all probability, these pieces occupied pouches or small sacs of the mucous membrane, and so eluded their practised touch; and yet, under favourable circumstances, they were occasionally discharged. After a time, cystitis came on, with severe suffering; the urine became foetid and alkaline; the bladder lost its tone; and the catheter became necessary three or four times a day. This was his condition when he came under my care. For months he had been treated by homœopaths, who attributed all his distress to enlarged prostate. I examined, and found a phosphatic stone of no great size, fixed and apparently embedded in the lower and right side of the bladder. It seemed very improbable that a permanent cure would result from a repetition of lithotripsy. It had already failed in very skilful hands, and when the bladder was fairly healthy. Now, when the bladder was unable to empty itself, and was chronically inflamed, there seemed less chance of a good result. Moreover, the patient was tired of the plan, and there was clearly either an embedded or an encysted stone. I therefore performed lithotomy. Owing to the large size of the prostate gland, the forefinger could barely reach the bladder. After some trouble, several portions of rough phosphatic stone were removed. I then became aware that there was still an encysted stone on the right side of the floor of the bladder, behind the prostate. I could just reach it with the finger-nail; but by no device could I dislodge it by a scoop, or seize it with forceps. By pushing a stick-sponge, well oiled, far into the rectum, and hooking the bladder forcibly towards the perinæum, I have once or twice been enabled to remove an encysted stone, but could not in this case. Sometimes the searcher would not touch it, and the bladder would feel empty; then again it became evident; but finally I was obliged to desist, as it was not prudent to do too much to his diseased bladder, and in his enfeebled state. He slowly recovered from the operation; and slowly too, but very surely, came back the symptoms of stone. This gentleman lived nearly four years after the operation I have just described; and these years were years of continual distress, of the constant sprouting up of stone from the encysted portion, and the frequent use of the lithotrite to break off and remove that which was removable. But at length he yielded, and died from exhaustion; and again the only remark I can offer is that, had his stone been fortunately removed at first by lithotomy, he would in all likelihood have been spared all his after-misery, and enjoyed a longer term of life and health.

I said at the outset of my remarks, that sometimes fragments of

stone passed into the sacculi, and produced rapid fatal peritonitis. Let me mention two cases in point.

CASE IV.—In October 1866, a feeble white-haired man of 76 was admitted into hospital with severe symptoms of stone. His prostate was large; he could retain water about two hours; the urine was alkaline, specific gravity 1008; no albumen; some mucus and phosphates. I measured the stone, and found it one and a quarter by three-quarters of an inch. This examination, short and gentle as it was, caused a rigor; which, however, passed off and did no harm. In a few days, I crushed the stone. The operation was simple enough, and did not occupy two minutes. Cystitis, however, followed in a day or two, with much pain and vesical tenesmus, and with the deposit of much pus in the urine. There were also abdominal pain and tenderness, but no tympanitic distension. His strength gradually failed, and he died fourteen days after the operation. After death, I found signs of general peritonitis, and a large effusion of lymph, particularly in the pelvis. The bladder was rather small, with thick muscular walls. The mucous membrane was deeply injected. A large sac existed at the lower and right side, larger than the bladder itself; the aperture of communication would just admit the tip of the forefinger; its walls consisted simply of mucous membrane and peritoneum, and were dark-coloured and almost sloughy. It was from this part that the fatal peritonitis commenced; some fragments of stone were found in it. An oval stone, partially broken, was lying free in the bladder. The prostate was enlarged to four times its usual size. The ureters were dilated and inflamed; and the kidneys were coarse in structure, and unhealthy.

CASE V.—The other case was very similar, and occurred almost at the same time. The patient was a feeble pale-faced man, aged 75, admitted November 1866, with symptoms of stone, increasing in severity. He voided water every hour or hour and a half, with much straining and pain. There were proofs of the presence of more than one stone; but they were small. The prostate gland was not much enlarged. I broke one of the stones. The bladder was quiet; and the operation was easy, and apparently satisfactory. Cystitis, however, ensued, and was followed by abdominal pain and fulness. He became gradually exhausted, and died fifteen days after the operation. Peritonitis was found, chiefly on the right side of the abdomen. The bladder held about half a pint. There was hypertrophy of its muscular wall, with prominent interlacing columns. The mucous membrane was much injected and inflamed. Sacculi were present everywhere; some large enough to hold a walnut; others, a horse-bean. In one or two of the larger ones, the mucous membrane was almost sloughy, and formed the starting-point of the peritonitis which caused death. Three small stones were found in the bladder, one of which was thoroughly broken, while some of the fragments had passed into the inflamed sacculi.

These two cases exhibit the disastrous results of lithotripsy where sacculi exist. Beyond question, these patients would have had a better chance of recovery if lithotomy had been performed; but, as I have said, they were feeble old men, not well fitted to undergo so serious an operation for the removal of stones which, so far as regards their size, were confessedly within the reach of lithotripsy.

I could easily report other similar cases, were it necessary, and did time permit; but when five such instances occur in the practice of one surgeon in the space of two years, it shows, I maintain, that such cases are not so rare as they have been supposed to be, and that the risks of lithotripsy from this cause in old men with prostatic obstruction are real and positive.

I hope it will not be thought that I am seeking to throw a stone at lithotripsy—an operation which I deem to be one of the most splendid contributions of modern surgery, and which I find myself adopting in practice more and more. By overstating the merits and advantages, and understating the drawbacks and risks, of any mode of practice, we retard rather than advance its progress, and tend to bring it into ultimate discredit.

It will naturally be asked, How can this state of sacculation of the bladder, with or without stone, be recognised during life? It must, I fear, be admitted that the indications are few and unreliable. By noting that a man, having an enlarged prostate, makes water slowly and with considerable exertion; that, when a catheter is used, and after the bladder is apparently emptied, there is still a further flow; and particularly if the appearance of the urine during this double flow vary considerably,—we may infer that cysts or sacculi do exist, although we cannot surely know it. What I desire is to show that sacculation does frequently occur; that it is a real danger and drawback to lithotripsy; and that, by remembering this, we may, in those doubtful cases in which a difficulty is felt which operation to select, feel inclined to give the preference to the old rather than to the new practice.

ON AUSCULTATION OF THE ŒSOPHAGUS.*

By T. CLIFFORD ALLBUTT, M.D.,
Physician to the General Infirmary, Leeds.

DI-EASES of the œsophagus often prove somewhat difficult of investigation, and it is not likely that we shall ever succeed in bringing this tube within the range of vision, as we have brought the larynx, the inner eye, and even the cavity of the bladder. Diseases of the œsophagus, moreover, even when benignant in character, have a peculiar terror in the peril of starvation which threatens the sufferer. Any help, then, which we can obtain either in our diagnosis or our treatment of disease in this part, should be carefully cherished; and for this reason I venture to bring before you a means of diagnosis which, in my opinion, has been unduly neglected. The only means used in cases of alleged disease of the œsophagus are the catechising of the patient and his friends, and the exploration of the tube with the sound; and not infrequently this latter cannot safely or judiciously be employed; in which case we are wholly dependent upon more general clinical observation and inquiry. The method of auscultation of the œsophagus which I have found to be useful is especially useful in cases of this kind, and will tell us much that we could not otherwise discover with any certainty. Nevertheless, I do not find that auscultation of the œsophagus is commonly practised. Nay, I cannot call to mind a single consultation in a case of this kind where the patient's medical attendant had used auscultation, or had even heard of it before I pointed it out to him. Nor, again, in the ordinary text-books on medicine do I find any allusion to auscultation of the œsophagus; nor is it described in special treatises on auscultation. So far as I know, the only systematic account of the method is to be found in the papers of Hamburger, which appeared in the *Oesterreichische Medicin. Jahrbucher* for 1867-8-9. My own initiation into the plan was through these papers; but whether Hamburger was the first to introduce it into practice, I know not, nor in this place does it much matter. During the six or seven years that I have tested Hamburger's statements, I have found that, although there is much exaggeration, inaccuracy and whim in his way of putting them, nevertheless, after all deductions, there remains a solid residue of valuable observation.

The method of auscultation of the œsophagus depends upon the audibility of the swallow both in the neck and thorax. It is best, of course, to educate the ear at first upon a healthy subject. The subject is requested to take a mouthful of water, and to swallow it at a signal. The operator then places the stethoscope (Sibson's stethoscope is the best for the purpose, I find, but any stethoscope will do) first upon the trachea anywhere between the hyoid bone and the supraclavicular fossa. The signal being given, the patient now swallows; and, as he does so, a very distinct resonant gurgle is heard at the place of the stethoscope. This sound, which is very loud at the hyoid bone, where the water is as it were slung through a tube into the observer's ear, becomes duller as the instrument is removed to deeper parts of the neck. Below the cricoid cartilage, the sound is more heavy or solid in character, and the morsel is as it were shoved downwards with a whiz. To examine the lower part of the œsophagus, the instrument must be removed to the spine, and must be carried down the left side of the spines of the first eight dorsal vertebrae. Here the sound is still more distant, though still very distinct, and is like a smooth body slipping through with a sort of cluck.

By repeated observations upon the healthy subject, the operator must make himself thoroughly familiar with the tone, with the apparent size of the morsel, with the energy of the œsophageal contraction, with the rapidity of it, and also with the direction of the morsel. The rapidity of the passage of the morsel is ascertained by putting the instrument over the cardiac orifice while a finger is placed upon the larynx. The moment of commencement of deglutition is known precisely by the rise of the larynx; the moment of its completion is recognised by the ear. The rate of the swallow varies a little in individuals, and is generally distinctly slower in weakly persons at all times, and in healthy persons after a prolonged meal. The direction of the swallow may be reversed, as in regurgitation. In this case, the gulped fluid eddies as it were in a funnel with a prolonged resonant gurgle; or the direction of the swallow may be diverted, as in one case under my notice, where the œsophagus was perforated, and the matters escaped into the pleural cavity. Hamburger had more than one case of the kind; and he prepared me to recognise this condition, which was quite easy when one was thus forewarned. The small quantity of diverted fluid passed through the chink in the œsophagus with a kind of sizzling murmur. Pyopneumo-

thorax of course was present as a consequence, and there was thereby a metallic quality added to the tone. Or, again, while the swallow still runs in the tube, it may be heard to cross the vertebral column, and to appear on the right side only for a greater or less distance. Hamburger relates a case of this kind, in which it was found, after death, that the œsophagus had been pushed over by an aneurism of the descending aorta. The swallow was in no way interfered with, so that it seems desirable to auscultate the œsophagus as a routine in cases of suspected aneurism of the descending aorta. The energy of the swallow must be considered apart from its rapidity. In cases of dilated œsophagus, the fluid may pass the tube quickly enough; but the absence of energy of contraction is known by the want of grasp. The fluid passes down the tube with a squirting or running sound, not as though slung in a piece. It must be remembered, however, that in obstruction at the cardiac orifice, the accumulation of mucus may, and often does, modify or prevent the usual sounds for some five or six inches above the seat of the disease. In tender places, as in ulcers of the œsophagus, Hamburger says that the morsel may seem to stick or recoil. My own experience does not enable me as yet to speak decidedly on this point. It sounds to me rather like an over-refinement. So, again, with the rubbing or friction-sounds in inflammation of the tube, which I certainly have never been able myself to detect. But the *tone* of the swallow, on the other hand, is changed in quality by the presence of rough ulcers and the like on the inner surface of the tube, so that it becomes deadened; though the more common and more easily known result is the prolongation of the morsel. It is, indeed, the prolongation of the morsel which, more than all other changes, has caught my own ear. Almost all changes in the inner surface of the tube may be regarded as diminutions of its calibre, and as checks to its peristalsis: so that, where disease exists, be it ulcer, be it contraction, be it tumour, we hear there a slackening of the rate at which the morsel is slung downwards, and a prolongation of the morsel itself. It tails off and slackens as it passes by. If the stricture be tighter, the morsel, when it reaches the spot, eddies through with a creak, or even with a squeak. If the stricture be tighter still, we hear the resonant regurgitation of which I have already spoken.

After thus describing the changes in the swallow readily to be heard in the various states of disease, I need not stay to point out how valuable these signs must prove in the consulting-room. My hearers will be astonished, when they put it to the test, how readily they will spot the exact site of an organic stricture, and how easily they may prove the nervous nature of a dysphagia which causes no stethoscopic disturbances in the swallow. Time will not allow me to read notes of the numerous cases in which I have found œsophageal auscultation of value; but among the best of them are many in which the absence of organic stricture was thus almost proved, to the infinite satisfaction of timid patients and their timid friends, who shrank in fear from the name of the sound; while in others the unmistakable signs of a local stricture have forbidden us to nurse any hopes of a spasm which might pass away. For spasmodic dysphagia is unknown to the stethoscope.

SYME'S OPERATION MODIFIED AND IMPROVED BY SAVING THE PERIOSTEUM OF THE OS CALCIS.

By JOSEPH BELL, F.R.C.S.Ed.,
Surgeon to the Edinburgh Royal Infirmary.

PIROGOFF's operation is by some preferred to Syme's, as it leaves, or is said to leave, a more useful stump, while at the same time it avoids the difficult and tedious dissection of the soft parts from the os calcis.

A plan I have used for some three or four years, and practised in ten cases, will, I believe, be found to give the advantages promised by Pirogoff's method, and yet to avoid the risk of recurrence of disease of bone in the portion of os calcis left in Pirogoff's operation.

It is a very simple and slight modification, and consists in leaving attached to the flap the periosteum of the posterior part of the os calcis, and instead of dissecting the soft parts alone off the bone, stripping along with them the whole periosteum. In the case of amputation for disease of tarsus in children, this is done with the most perfect ease. It adds to the chance of vitality of flaps, diminishes the risk of sloughing and number of vessels to tie, and gives the most excellent results. Especially if the patient be encouraged early to move his flap by means of the tendons which soon take on new adhesions, we find that a considerable power of moving the heel flap over the end of tibia is saved, and, in some cases, a deal of new bone is formed from the periosteum. So much so is this the case, that in

* Read before the Medical Section at the Annual Meeting of the British Medical Association in Edinburgh, August 1875.

one patient on whom I operated in 1874, it was hardly possible to persuade those who saw the stump, that it was not a portion of astragalus which had been left, with the integrity of the ankle-joint preserved. As all the cases in which I have practised this modification have survived and been successful, I have not found any objection to it, nor had the opportunity of making any *post mortem* examination.

One case had to be taken down about the fifth day for secondary hæmorrhage from the posterior tibial, yet I did not find that the presence of the periosteum implicated in any way the subsequent secondary union of granulations which healed the wound.

ON THE TREATMENT OF BROKEN-NOSE BY FORCIBLY STRAIGHTENING AND MECHANICAL RETENTIVE APPARATUS.*

BY WILLIAM ADAMS, F.R.C.S.,
Surgeon to the Great Northern Hospital, etc.

THE treatment of broken nose is a subject which does not appear to have sufficiently attracted the notice of the profession, although the importance of the accident to the patient in producing a permanent and conspicuous deformity, as well as in many cases interfering with the voice and breathing, is very great.

It has been too generally supposed that no permanent benefit can be derived from treatment; and in the cases which I propose to describe, nothing whatever had been done, although high surgical authorities had been consulted. It occurred to me, however, that, by the operation of forcibly straightening the nose under chloroform, and afterwards employing some retentive apparatus, varying according to the nature of the case, much good might be done, and in some instances the deformity entirely removed.

All cases of so-called broken nose may be divided into two classes: viz., 1. Those in which the injury is limited to the anterior or cartilaginous portion of the nose, and consists essentially of depression, with lateral bending of the cartilaginous septum; a partial displacement of this septum from its attachment to the vomer also occurring in many cases. 2. Those in which the nasal bones are fractured, in addition to depression and displacement of the cartilaginous septum from the vomer. Several examples of both these forms of injury have fallen under my observation in private practice, but all the cases, with one exception, in which I have been consulted, have been at periods varying from one to six months after the accident. In one case, however, that of a young lady eleven years of age, the accident occurred six years previously in a fall down a sloping bank, forty feet in height.

In all these cases, the principle of treatment which I have adopted has been, whilst the patient is under chloroform, to straighten the bent cartilaginous septum, and bring it into a direct line with the vomer, using for this purpose a pair of strong forceps, with flat parallel blades, represented in Fig. 1; and, when the nasal bones are depressed, to raise these also, by carrying the blades of the forceps directly upwards. In some cases the two blades, when closed, may be forced up each nostril, under the lower portion of the nasal bones, and lateral pressure may be made externally by the thumb, at the same time that the bones are raised from within. This was done in the second case reported—that of C. R., in which sufficient force was employed to refracture the left nasal bone.

After this operation of forcibly straightening the nose, I employ a retentive apparatus, consisting of the steel-screw compressor, represented in Fig. 2, which is applied so as to support the septum, one blade

(a) being introduced into each nostril, and the screw (b) tightened just sufficiently to hold it in position, and bring the blades into contact with the septum, but without making any pressure upon it. This apparatus can be worn for two or three days and nights without removal. After this, I introduce the ivory plugs represented in Fig. 3, which the pa-

Fig. 2.—Steel Screw Compressor.

Fig. 3.—Ivory Plugs.

tients can remove at pleasure, and reintroduce, so that both nostrils are kept moderately distended, and support given to the cartilaginous septum.

It would not be possible to support the nasal bone by any plug introduced in the upper part of the nasal cavity, from its small size, and the sensitive character of the lining membrane. When the nasal bones have been fractured, I have employed a retentive apparatus externally,

by means of a pad adjusted by cog-wheels, and attached to the front part of a steel band passing round the head, forming a kind of nose-truss, if it may be so termed. This apparatus is represented in Fig. 4, and was first used in the case of C. R., and found to answer extremely well. This truss can be worn day and night for two or three weeks, according to the extent of the injury, and in the case above referred to was worn for a still longer period.

The operation of forcibly straightening the nose does not require to be repeated, except in cases of great severity; but it may in some instances have to be repeated once or twice before the deformity can be rectified, the retentive apparatus being afterwards employed. When the nose has been straightened, I have not found that there has been any disposition to relapse of the deformity: the nasal bones and the cartilaginous septum retain their improved position and relations the more readily, as they are not subjected to any muscular influences tending to cause displacement.

Although I have not had the opportunity of applying the treatment above described at an earlier date than a month from the accident, there can be no doubt that its employment would be more easy and effectual in proportion to the early period at which it was adopted after the accident; but, should there be much swelling and ecchymosis, it would be advisable to wait until these had subsided, and in a week or ten days the treatment by forcible straightening and retentive apparatus could be employed with every probability of success. In recent cases, however, it may not always be necessary to employ any retentive apparatus.

Fig. 4.—Nose-Truss, with Screw-Pads.

* Read before the Medical Society of London.

The first case which came under my observation, and was submitted to treatment by forcible straightening, was one belonging to the series described in the first class.

CASE I. *Depressed and Bent Cartilaginous Septum of the Nose rectified by Forcible Straightening one Month after the Accident.*—L. L., aged 16, was brought to me on the 12th of July, 1861. He had received a blow on the nose a month previously from a cricket-ball at Eton, and two surgeons who had been consulted considered that nothing could be done. The external deformity was slight, consisting of a depression a little above the tip of the nose, at the junction of the cartilage with the bone, with some lateral inclination of the former; but since the accident the voice had become completely altered, and the breathing through the right nostril much interfered with.

On examination, I found the right nostril obstructed by the cartilaginous septum, which had been bent by the blow from the cricket-ball, and now projected into the cavity of the nostril, so that a probe could not be made to pass through it. The cavity of the left nostril was much enlarged, by the depression and bending of the cartilaginous septum into the right nostril. Considering all the circumstances of this case, I advised that some attempt should be made to straighten the septum, in the hope both of rectifying the deformity and restoring the voice, and in both these respects the result was successful.

On the following day, consent was given by the parents, and I gave instructions to Mr. Blaise of St. James' Street to prepare the forceps, screw-compressor, and ivory plugs, which are represented in figs. 1, 2, and 3.

On July 16th, the first attempt to straighten the septum was made, with only partial success, in consequence of the patient not being allowed by his father to take chloroform, and the pain and sneezing rendering it impossible to proceed. The steel screw-compressor was, however, worn for three days and nights, and afterwards the ivory plugs were used with as little intermission as possible. This did not cause much pain or inconvenience, and the improvement was very decided, although incomplete. Consent to the administration of chloroform was now obtained; and on July 30th I repeated the operation, the chloroform being administered by my friend Dr. Allan, the medical attendant of the family. I now completely straightened the septum, and the obstruction of the right nostril was at once removed, so that the forceps, with the blades closed, could readily be passed through it. The retentive apparatus was used as before, the ivory plugs being worn at night for several weeks. It was not necessary to repeat the operation; the external deformity was so far removed that a trace of it only could be said to remain, and the voice was completely restored.

CASE II. *Fracture of the Nasal Bones, with Depression and Bending of the Cartilaginous Septum, much improved by Forcible Straightening Six Months after the Accident.*—This was one of a much more severe character than the preceding. C. R., aged 22, an officer in the army, first consulted me on June 6th, 1871, having sustained a very severe injury to the nose by a fall in the previous December. This gentleman was wearing one of the new fashioned Ulster coats, and, having both hands in the pockets, fell down flat at a railway station, the nose coming into contact with an iron rail. The nasal bones had been fractured, and projected towards the left side; the cartilaginous septum was also much depressed and bent, projecting into the left nostril, whilst the tip of the nose was directed towards the right side, somewhat in the shape of a half-moon, giving to the face altogether a most unsightly appearance. In this case, also, more than one surgeon of eminence had been consulted, and the opinion given was, that no treatment could be adopted with any probability of success. I advised the same treatment as in the former case, and this was assented to.

On June 9th, I performed the operation, chloroform being administered by Mr. Braine. The cartilaginous septum was straightened, but very little improvement effected in the position of the nasal bones. The steel screw-compressor was used continuously for three days and nights, followed by the use of the ivory plugs. The improvement, so far as the front part of the nose and cartilaginous septum were concerned, was satisfactory; but the nasal bones being still depressed and displaced towards the left side, I directed Mr. Blaise to construct a kind of steel truss (represented in Fig. 4) to pass round the head, having a small oval pad connected with the front part, and capable of accurate adjustment, by means of two cog-wheels, so as to be applied to the left nasal bone, as a retentive apparatus, after the bone had been forcibly bent or rebroken.

On June 21st, chloroform was again given by Mr. Braine; I then rebroke the nose. In this operation, considerable force was employed in the attempt to bring the nasal bones into their natural position by a firm and long continued pressure on the left nasal bone. Very considerable improvement was effected, and the steel truss and pad were immediately applied as a retentive apparatus. I also more completely

straightened the cartilaginous septum; and the steel screw-compressor, followed by the ivory plugs, was used to support the septum, at the same time that the truss was applied to support the nasal bones externally.

After this operation, the progress was satisfactory, and the improvement very marked and well maintained; still, however, from the severity of the case and its duration, neither the depression, nor the lateral deviation of the nasal bones, was entirely removed.

On July 5th, 1871, I repeated the operation, chloroform being given by Mr. Braine. Still further improvement was gained, with very little force, and the retentive apparatus used as before for several weeks.

On November 27th, I saw him for the last time. I found the improvement had been well maintained, and the appearance of the nose so much improved that it would scarcely attract attention, and the result was considered to be very satisfactory.

CASE III. *Both Nasal Bones evenly Depressed between the Nasal Processes of the Superior Maxillary Bones, producing Flattening of the Upper Part of the Nose: Cartilaginous Septum also Depressed and Bent, projecting into the Right Nostril: the Tip of the Nose deviating towards the Left Side.*—Miss F., aged 11, was sent to me by my friend Mr. Walter Coulson, on the 9th June, 1874, and the nose then presented the general appearance indicated in the above description. The accident occurred six years previously, when she was only five years of age, by her falling down a sloping bank forty feet in height, the nose coming into contact, probably with a stone, when she first rolled off the embankment. In addition to the external deformity, the breathing was very much interfered with in this case; the voice was also much altered, and an offensive discharge constantly occurred from the nostrils, as in ordinary ozæna. No evidence of necrosis of bone could be obtained by examination with the probe, nor was this indicated by any tenderness to pressure externally. I therefore advised the operation of straightening as in the preceding cases.

On June 10th, 1874, chloroform being administered by Mr. Braine, I straightened the cartilaginous septum with the steel forceps, and to some extent succeeded in improving the position of the nasal bones. The steel screw-compressor and ivory plugs were worn without inconvenience.

On July 2nd, I endeavoured still further to raise the depressed nasal bones, with the assistance of Dr. Sliman of Hackney, who administered chloroform. The blades of the forceps were carried directly upwards in a direction to elevate the nasal bones, and a firm lateral pressure applied externally at the same time. A marked improvement in the shape of the nose was thus produced, and the same retentive apparatus employed, but it was difficult to maintain sufficient lateral pressure externally. The general improvement in the form and shape of the nose was considerable, and much of the depression removed. The offensive discharge from the nostrils entirely ceased, and both the breathing and voice were much improved.

Several other cases have fallen under my observation, in which the injury has been limited to depression and lateral bending of the cartilaginous septum, with partial displacement from the vomer, as in the first case, and in every instance the treatment has been perfectly successful.

A CASE OF PERFORATING ULCER OF THE DUODENUM, WITHOUT DIAGNOSTIC SYMPTOMS.

By EDMUND J. SPITTA, L.R.C.P. Lond.,

Late Demonstrator of Anatomy at the School of St. George's Hospital.

ULCERS of the duodenum are by no means rare, but in nearly all such cases symptoms occur which are diagnostic. In the one, however, which I am about to relate, no such symptoms were present, and perforation occurred most suddenly without a single warning.

X., aged 61, came to see me on Monday morning, June 21st, complaining of pain in the epigastrium. "He had always had good health, never knowing a day's illness." I prescribed some opium pills, of which he took a few, with much benefit. On the following morning, however (June 22nd), he again appeared, the pain, although much better the previous day, having now become worse. I told him he had better go to bed, apply warm poultices, and continue the pills. As he was leaving, he stopped and asked me "to call and see him some time when passing by." I did so in about two hours, and found him sitting up in bed (he said it was more comfortable than to lie down), and still in pain. His pulse was slightly irritable, but his skin cool. His appearance was natural, and his countenance wore no anxious expression; he was able to move in bed and to talk. His wife told me he enjoyed

good health, excepting for the last two years, when he had occasionally complained of wind in the stomach. This was always relieved by hot brandy and water, which caused him "to bring up a quantity of wind". I ordered a continuance of the treatment.

Two hours later, his wife came to ask whether there was anything else to be done, as he was still in great pain. I ordered hot poppy fomentations, and the pills every half hour until the pain abated.

I heard nothing more of the case that day, and, therefore, presumed he was better. But when I went the next morning, to my astonishment, I found the patient dead. On inquiry, I learnt that the deceased appeared so much better in the afternoon that his wife only gave the pills every hour; but that in the evening, after straining at stool, he felt faint, perspired profusely, and in a quarter of an hour died.

On hearing this account, I assured the friends that there must be something unusual to account for so sudden a death, and that perforation of the bowel had probably taken place. I therefore desired a *post mortem* examination, which I was permitted to conduct thirty-six hours after death. On examination, the peritoneal cavity was found much distended with foetid gas and fluid, the latter consisting of fluids swallowed, fluid feculent matters and bile. The peritoneum was healthy throughout. In the first portion of the duodenum, there was a large old ulcer, about the size of a sixpence, which had perforated the bowel and opened into the peritoneal cavity. Its edges were thickened, but the adjacent parts presented no signs of inflammation, neither was the peritoneum, even at that part, at all inflamed. The peritoneal aspect of the perforation showed that the ulcer had for some time entirely eaten away all the coats of the bowel excepting the peritoneal, for the flaps of that membrane were distinctly visible. The parts adjacent to the bowel were healthy.

Such is a condensed history of the case; but the fact to which I wish to draw attention is that the patient, who most likely had the ulcer for one or two years, never presented any specially diagnostic symptoms until the perforation occurred. He never had vomiting of blood nor pain after food; neither was there any history of bloody stools, with occasional attacks of faintness; and up to the very last there were no signs of peritonitis.

Of course, it is a matter of doubt whether the perforation took place before I saw him at his house or whilst straining at stool. I should think the latter, seeing that he appeared so much better in the afternoon, and that when I saw him in the morning there were certainly no symptoms of collapse. So lightly did he think of his pain when he called upon me in the morning, that he only asked me to see him "sometime when passing by"; and, indeed, the very fact of his walking home seemed enough to allay any suspicions of so rapid and fatal a result.

The only case I know precisely similar to this, is one which occurred in the practice of Dr. Barlow, many years since, of a brewer who died suddenly, without any marked symptoms, and in which a *post mortem* displayed an old ulcer of the duodenum, evidently similar to that of my own.

ETHER AS AN ANÆSTHETIC.

By THOMAS SKINNER, M.D., Liverpool.

So far back as July last, I had prepared the following remarks on Ether as an Anæsthetic. The letter in this week's JOURNAL from the pen of Mr. Clover has induced me to precipitate its publication; and all the more so, as Mr. Clover has arrived at the same conclusion as myself as to the best specific gravity of ether for anæsthetic purposes.

Everyone knows how much I prefer chloroform to ether or any other liquid as a general anæsthetic and in midwifery, whilst it is not a long time since I stated my belief in these pages that there are special occasions and operations where ether is much to be preferred to chloroform, namely, in all operations on the eye, head, and abdomen, such as cataract, iridectomy, hernia, and ovariectomy. This being so, it behoves us to ascertain the most convenient form of the drug and the readiest and simplest mode of administering it effectually.

After a number of experiments, I have ascertained that the specific gravity of the ether is of the greatest importance to be attended to. If accurately adjusted ether-inhalers are used, such as Snow's, Squire's, and the like, it matters little about the specific gravity, as the patient is pretty certain to get the entire of the vapour; all that is necessary is that the ether shall be chemically pure. Of course, the only substances affecting the specific gravity admissible are alcohol and water. In other respects, as I consider all mechanical inhalers as cumbersome, not unattended with danger to the patient, and the very reverse of the readiest, simplest, and most economical methods of inducing anæsthesia by means of any drug, I cannot advise their use.

When we come to the simpler and readier methods of inhaling ether, however, the tables are turned. Ether of a low specific gravity is a very great mistake. I have used it from .720 up to .735 (I am certain that it varies a good deal by keeping, especially if it be not kept in a very cool place), and I have no hesitation in declaring that I have given up using any other than that of the *British Pharmacopœia*, which has a specific gravity of .735, and which is spoken of so highly by Mr. Clover. With ether of this specific gravity, the patient gets far more of it with very much less loss; and less of it goes a much greater length. As to the comparative safety of ether according to specific gravity, if alcohol and water are the only foreign ingredients affecting it, it is *nil*, and need not enter into the calculation. I have not used ether made from methylated spirit as yet, but I believe it to be quite as safe as that made from the best rectified spirit; and I should not hesitate to use it, even though "methylated ether leaves an odour after it has evaporated" (*Squire's Companion to the British Pharmacopœia*, 1871).

Among the ready methods of administering sulphuric ether of specific gravity .735—which is the simplest and handiest? If any man have been at the trouble to devise a method, and come to the conclusion that he has succeeded, it is but natural that his own will, in his estimation, eclipse all others; but the world must be the judge, and not he. I am perfectly willing to be judged by such a tribunal in the present instance—as all who have seen my mode of administering ether of any specific gravity, and in particular of .735, are agreed that it is all that can be desired for simplicity, durability, portability, cleanliness, economy, and effectiveness.

Apparatus.—A good sound cork perforated with a glass or metal tube, the same as that of my chloroform bottle, only larger in the bore. The cork must fit an ordinary half-pint or pint bottle, and the tube must be sealed at the point to the diameter of the twelfth or sixteenth of an inch, sufficient to admit of a free and straight flow of the ether from the bottle when inverted. The tube must not be drawn out to a point which is certain to be broken off, but round, and the tube ought not to extend above three-quarters of an inch beyond the cork. A closely fitting cap of cork, or leather, or leather and cork (not India-rubber, as the ether destroys it) might be added with advantage, as it would prevent the escape of the ether in the interval or *en route*. If the tube be made of metal, a cap of the same material will be most suitable. I have generally placed my finger on the end of the tube, but this is not so necessary when the ether is of a higher and more manageable specific gravity, such as .735 of the *British Pharmacopœia*. The bottle, a half-pint or pint, should be of actinic glass, yellow being the best if obtainable, or it may be covered with leather or thick paper of any or no colour (yellow is the most actinic) for the purposes of excluding the light, lessening the chance of breakage and of protecting the ether from the heat of the hand. If covered with leather, a slit or tell-tale should be cut in it in order the more readily to ascertain the amount of fluid remaining in the bottle.

Inhaler.—It is composed of an interior of thick white felt, and an exterior of patent or black enamelled leather. It is altogether close, having no aperture except where it fits over the nose and mouth, which it closes very perfectly, if need be. The enamelled leather cover is reflected for the distance of an inch, inwardly, over the thick white felt, the internal and external surfaces of leather being temporarily stitched through the felt and the two plies of leather to keep all firm. After administration, the stitches are cut or undone, the felt is removed and washed, dried and returned, and restitched ready for another patient, or a second felt may be kept ready for use. I beg here to repeat a rule which I have previously laid down in these pages, namely, that cleanliness and decency demand that no two individuals should be made to breathe through the same inhaling apparatus without its being thoroughly cleansed—a step which is perfectly impossible with permanent mouth-pieces, tubes, and evaporating or air-chambers. The leather cover admits of washing the same as the felt, inside and out. The form of the inhaler is that of "Punch's" nose, seven inches in the longest diameter by five inches. It is a professional black, and folds perfectly flat, occupying the space of a flat and folded pocket-handkerchief.

The mode of using the inhaler is very simple. The ether-bottle being only three-fourths or two-thirds full, pour about half an ounce of ether (.735 *British Pharmacopœia*) into the inhaler, directing it especially on the sides of the felt; then insert the tubed-cork into the bottle of ether. Apply the inhaler over the nose and mouth of the patient, but not too close at first, although the sooner it can be closely applied, the sooner the patient will be anæsthetised. In renewing the ether, lose no time; invert the inhaler and quickly sprinkle the surface of the felt with a free allowance from the bottle; as quickly reapply the inhaler, never giving the patient time to rally from the previous inhalation. At one time, I had the leather cover perforated, so as to enable me to give additional

ether without the necessity of removing the inhaler; but I soon found my mistake, as more vapour escaped through the aperture than was introduced, and the patient took a much longer time to get under its influence. At times, it is advisable to remove the inhaler a little way from the mouth and nose; especially is this advisable after the patient is once fairly off—that is, when it is desirable simply to keep him under. A great deal is said about patients becoming dark in the visage while getting under the influence of ether. I have hitherto observed very little of this, and I cannot help thinking that its occurrence is greatly owing to the unnecessary exclusion of atmospheric air and too large a quantity of vapour being administered at a time. By the apparatus I now recommend, the passage of air is very little impeded, as anyone can learn by applying it closely over his air-passages and breathing. If the patient's countenance should become dark or livid, give more air by withdrawing the inhaler a little way, say an eighth of an inch or more, and increase the ether vapour by a fresh and free supply. It is a great mistake to suppose that a patient's respiration can be sustained on the vapour of ether alone; he must have air, and he gets it, whether the observer is aware of it or not. In administering ether, it is well to have no naked flame of any kind in the room. As with chloroform, so with ether, food ought not to be partaken of for at least four hours beforehand. I have no doubt that ether of a still lower specific gravity will do. I have not tried it, but that of .735 is so good that I could scarcely wish a better.

If anyone will try this inhaler and mode of feeding it with sulphuric ether of specific gravity .735 *British Pharmacopæia*, he will soon be satisfied that, for simplicity, durability, portability, cleanliness, economy, and effectiveness, it is not to be surpassed.

The inhaler and cork or bottle are to be obtained from Messrs. Maw, Son, and Thompson, of 11, Aldersgate Street, City; and from Mr. Wood, Church Street, Liverpool.

SOME REMARKS* ON THE CONDITION OF THE CEREBRAL CIRCULATION PRODUCED BY STIMULANTS AND HYPNOTICS.

By HERBERT L. SNOW, M.D. Lond., Bayswater.

It appears to me that the science of therapeutics is at present much impeded by the want of a rational system of classification; and also by the vagueness of the general terms in ordinary use; that when men speak, for example, of a stimulant or narcotic, their ideas of what constitutes a stimulant or narcotic, of the essential feature in the stimulating or narcotising process, are more or less hazy and empirical. Since Dr. George Johnson's discoveries have directed attention to the contractility of the arterioles, it has become obvious that nearly all our drugs (excluding those prescribed merely for their chemical affinities) produce their effects upon the body—of course, through the agency of the nervous system—by the alterations they induce in the calibre of these vessels. The fact is one which it is especially important to bear in mind, in the case of remedies which affect the functions of the brain or spinal cord; inasmuch as, by empirically administering such potent agents, we are sure occasionally to do harm; and, as it is of the highest importance to form definite ideas of the influences that are brought to bear upon parts of such extremely sensitive and marvellously complex organisation, I venture, in the present paper, to offer a few suggestions upon this topic, hoping that, if my views are erroneous, they may be speedily corrected by some one qualified to pronounce upon them authoritatively.

Premising that the arterioles are dilated by the vaso-motor nerves, which belong to the cerebro-spinal system, and contracted by the fibres of Remak (sympathetic), I will first notice the medicines, which are commonly called stimulants, and which agree in producing exhilaration of the mind, a genial feeling of warmth throughout the body, and increased force and frequency of the heart's contractions. The primary and essential feature of this process, I take to be dilatation of the arterioles (*teste* the flushed face), to which the increased energy of the heart is but secondary, following as a necessary sequence.

If the dilatation be slight, the vessels soon return to their normal condition; and the above is all that is necessary to the action of a pure stimulant. Tea, coffee, and guarana seem to be the purest we have; most of the others, as alcohol and opium, are only purely stimulant in small doses. After a larger dose, that is, after a greater dilatation of the arterioles, a train of other symptoms succeeds; and the former stimulant now becomes either a hypnotic or a narcotic. Either the dilatation gives place to contraction; when the previous excitement is followed by healthy sleep, in which the essential feature is a moderate and sustained contraction of the cerebral arterioles, lessening the supply of blood, and so of oxygen, to the nerve-tissue. Or, secondly, if the

dilatation be extreme or protracted, a state of abnormal sleep or *coma* supervenes; when, although the vessels are widely dilated, the blood moves sluggishly through them, its ordinary chemical properties being at the same time more or less modified.

To the last, when not fatal, succeeds another stage, indicated by the headache following a debauch. There is now pallor of the countenance; the vessels are slightly contracted, and their muscular walls have lost their tone. A repetition of the stimulant dose speedily relieves the prostration, but may aggravate the headache; this being apparently due to distension of the veins, which, dilated by the previously accelerated blood-current, do not readily recover their former calibre, when the *vis à tergo* is removed, supposing the latter to have been protracted. Alcohol and opium furnish us with the most familiar examples of this train of events.

Respecting the phenomena of sleep, I believe that much uncertainty of thought and of language prevails in medical works—at least, so far as regards artificially induced sleep. It was long since proved that, during healthy slumber, the brain is anæmic; in other words, that the arterioles are contracted. Yet, it seems to be generally thought that opium acts as a hypnotic by causing venous congestion. As sleep is dependent upon a diminution in the supply of oxygen to the brain-tissue, it is manifest that the veins cannot have any share, at least primarily, in its causation. The arterioles alone regulate the quantity of oxygenated blood which is supplied to the cerebral or to any other tissue, and are the sole agents to be regarded in examining these phenomena; although it is true that, in the case of a mechanical impediment to the circulation, the veins would exert a retrograde influence upon them. As a general rule, congestion of the cerebral veins would cause headache, but not sleep. Opium, therefore, acts as a hypnotic by contracting the arterioles; and it is worthy of note, that the face is at first pale in cases of poisoning by this drug. As has been already explained, however, after a very large dose, the arterioles may be dilated, with the current greatly slackened, and the blood chemically altered. *Post mortem* venous congestion is not constantly present, and only indicates the prolonged action of a stimulant.

So also in slumber brought on by chloral or by bromide of potassium, the same condition of the arterioles obtains; and these medicines have been found experimentally to contract the vessels in the frog's foot. They differ, however, from opium in the absence of a primary stage of stimulation; and hence their use is less frequently followed by headache. They, besides, do not check secretion, and so do not interfere with the purification of the blood by the excretory organs. In some cases, nevertheless, chloral has a marked stimulant effect. Both these drugs cure ordinary headache by contracting the arterioles, and thus shutting off a portion of the blood-current from the already distended veins, so as to give these last time to empty themselves. In sick-headache, when we have violent action of the sympathetic, and when the pain is neuralgic and due to the suddenly increased tension of the arteriolar walls, they usually fail; then guarana, strong tea, or alcohol, which dilate the vessels, prove effectual. Probably nitrite of amyl would afford speedy relief, but I am not aware of its having been tried in megrim.

Of medicines which more especially affect the functions of the spinal cord, belladonna in moderate doses contracts, while strychnia dilates the vessels. In large doses, belladonna also has the latter effect, when flushed face, intoxication, and occasionally trismus, supervene.

A good many experiments have lately been made with numerous remedies, by injecting them subcutaneously, apparently under the impression that the effect would thus be different in some way from the ordinary symptoms which follow their absorption through the alimentary canal. Although, when the drug is not such as to cause any local mischief, we administer it by this method with greater precision and celerity, still I would venture to point out that in the case of morphia, which may serve as a type, the effects are identically the same as would follow a dose given by the mouth, excepting only a mitigation of those caused by its actual contact with the alimentary canal. It is obvious, therefore, that with drugs which do not occasion embarrassing gastric or intestinal symptoms, the use of the hypodermic method will rarely be attended by any special advantages.

I trust the day is not very far distant when we may be able to predicate of all the medicines we employ, not only what each is expected to do, but also by what peculiar channel it effects this result. When we have attained absolute certainty upon these points, and when the vast multitude of compounds called into existence by organic chemistry—a field which has already yielded rich results to investigations of comparatively trifling extent—have been pressed into our service, then medicine will take its place among the exact sciences, and the healing powers of its professor will become, what is certainly very far from being the case now, a true measure of his scientific knowledge.

THERAPEUTIC MEMORANDA.

A CASE OF RHEUMATIC HYPERPYREXIA CURED BY ONE COLD BATH.

DR. WALKER'S case of rheumatic hyperpyrexia, published a few weeks ago in this JOURNAL, induces me to publish the following case, treated by my friend the late John Foster and myself about eighteen months ago.

Miss C., aged 18, was seized with acute rheumatism. The attacks were at first mild, but became afterwards rather more severe. For the first two days, her temperature was under 102. On the fifth day of her illness, it rose to 102.8, and remained between 102 and 104 for four days, when the fever gradually declined. She had pericarditis and endocarditis, and an attack of pleurisy with slight effusion of the left side. The fever had almost left her on the eighteenth day of her illness, and we considered her quite convalescent; but she had not left her bed. On the nineteenth day, however, in the evening, the temperature rose to 103.6; and at 11 the same night it was 104. Next day, at 5 A.M., it was 104.4; at 11, 105.4; at 12, 106. During the night, she had been very delirious; and as her temperature rose, she grew much worse. At 12, she was rapidly becoming comatose, could be roused with some difficulty, and had lost her sight. We determined to employ a cold bath. The following table shows with what effect she was put into the bath about 12.50.

12.55...106.2 in the rectum	2	...99.2 in the rectum
1 ...106.8 "	2.10	...99 "
1.5 ...106.2 "	3	...100 in axilla
1.10 ...104.6 "	4	...101.6 "
1.15 ...104.4 "	5	...101.2 "
1.20 ...103 "	6	...101.4 "
1.25 ...102.2 "	7	...101.4 "
1.30 ...101.4 "	8	...101.8 "
1.35 ...101.2 " left bath	9	...101.6 "
1.43 ...100.4 "	10.30	...102. "
1.50 ...99.8 "		

Unfortunately, I have no notes of the temperature of the bath; but, to the best of my recollection, we began with a temperature of 90, quickly reduced by the addition of ice to 60. The bath produced no bad effects, and only a very small quantity of brandy was given during its employment. As soon as the temperature began to fall, consciousness returned. There was no delirium; in fact, all the serious symptoms were removed during the day. Miss C. felt almost well. Next day, after the bath at 6 A.M., the temperature was 100.6; it then gradually fell, and at 1.30 it was 99. At 8.45, it was 99.6; and at 11.15, 100.2. The next day, the second day after the bath, the temperature fell to 99.6, and never rose higher. From this time, all fever disappeared, and the patient rapidly improved, and is now quite well.

SYDNEY RINGER, M.D.

TREATMENT OF WHOOPING-COUGH WITH CARBOLIC ACID INHALATION.

THE short abstract of my remarks on this subject has led Dr. Burchardt to infer that I considered the method of treatment of whooping-cough by carbolic acid inhalation as original. For many years, the volatile products of coal distillation have been known, or at least believed, to possess a distinct influence on whooping-cough. The most satisfactory account of the effect of the inhalation of the vapour of carbolic acid has been furnished to me by Mr. Harrison of Her Majesty's convict prison, Dartmoor, where a severe epidemic prevailed not long since, and where two apartments were used for the express purpose of trying the carbolic acid treatment. A report of these cases will, I trust, be sent to the JOURNAL by Mr. Harrison. The simple inhalation of carbolic acid vapour for a few minutes, such as is obtained from a jug or basin of boiling water, can not be compared to the effect produced by two or three days' confinement in the same room, the atmosphere of which is constantly and highly charged with the vapour of the acid; and if there be much difference in the results obtained by different practitioners in their observations on the effects of carbolic acid inhalation in whooping-cough, I should be inclined to attribute it to the method of inhalation adopted. With young children, it is by no means difficult to arrange the bed-curtains in such a way as to enclose the vapour of the acid during the hours of sleep; but, under any circumstances, effective inhalation is a matter of difficulty. I am indebted to Mr. Harper, of 16, Red Lion Street, Clerkenwell, for a simple and improved inhaler, constructed on a principle of which I pointed out the advantage in the paper alluded to by Dr. Burchardt.

(ROBERT J. LEE, M.D.,
Brit med Journal)

TREATMENT OF WHOOPING-COUGH WITH CARBOLIC ACID INHALATION.

As Dr. Burchardt of Berlin has written in the last number of the JOURNAL, claiming priority over Dr. Robert J. Lee in the use of the vapour of carbolic acid in the treatment of whooping cough, stating that he had used it in 1873, will you allow me to inform both those gentlemen that in the autumn of 1866 I employed the same remedy in the cases of my own children, and with wonderful benefit, after the failure of other remedies? The plan I adopted was to drop a few minims on to a piece of cotton-wool, and insert it into the bowl of a tobacco-pipe, directing the youngsters to smoke it, which they readily did, thinking it great fun. It is said that it is the last dog that kills the hare. Be that as it may, I certainly attribute their speedy recovery to it, after about a fortnight's continuance of the carbolic inhalation. There were five of them afflicted; and, not having previously been constantly in the house watching such patients, I candidly admit I did not thoroughly realise before what the sufferings of pertussic patients were. I am sorry now I did not publish their cases. My friends the late Drs. Salter and Tanner kindly saw them, and were aware of the treatment pursued. As I cannot appeal to them now as to the truth of my statement, I may mention that Mr. T. M. Stone, of the Royal College of Surgeons, who is so well known and respected by every member of the profession, and who is a frequent and welcome visitor at my house, perfectly remembers all the particulars.

As the use of carbolic acid is not without danger, I now prescribe the solution of chlorinated soda with permanganate of potash, in the form of spray, both for inhalation and disinfection; at the same time always ordering a small portion of iodine to be suspended in a chip box from some part of the room. In addition to this, I generally adopt the usual custom of giving an emetic at bedtime to dislodge the mucus, and an antispasmodic mixture of bromide of potassium with tincture of belladonna. With this treatment, a month or six weeks is the outside of the continuance of my cases of whooping-cough.

GEORGE P. RUGG, M.D., Clapham Road.

SURGICAL MEMORANDA.

REVOLVER BULLET ENCYSTED IN THE PALM: REMOVAL.

A BOY, 15 years of age, applied to me the other day with a hard mass exactly in the centre of the palm, and apparently, from the partial contraction and want of power over the middle finger, associated with the flexor tendons. Six months previously he had been playing with a revolver, and had been struck by its bullet just over the dorsal aspect of the wrist, where the scar of the wound was visible. The projectile was never found, the wound healed, and, beyond some little stiffness, no more was thought of the matter. A little time ago, however, the middle finger grew stiff and numb, and a hard body presented at the spot named. A surgeon had cut down on it, but thought better of interfering with the structure of the palm, and let it alone. I, however, cut cautiously down upon the mass and exposed the flexor tendon, and, on turning it a little on one side, found a small conical bullet firmly encysted beneath it, and completely enveloped with the bursal tissue common to the tendons. It lay immediately below the superficial arch, and close upon the digital nerve; I lifted it out and immediately closed the wound, placing a stout compress upon it. The interest of the case lies in the course taken by the bullet, its lying amongst such important structures for so long, and no untoward symptoms being set up by its presence or by the incision into the palm for its subsequent removal. It must evidently have passed through the first interosseous space to have gained the position in which I found it.

EDWARD BELLAMY, F.R.C.S.

TRACHEOTOMY IN CROUP AND DIPHThERIA.

IN the excellent paper "On Tracheotomy in Croup and Diphtheria", by Professor George Buchanan, contained in the BRITISH MEDICAL JOURNAL of the 4th of September, 1875, two signs are given as tending to show that the false membrane has extended into the smaller bronchial tubes, and that, therefore, the operation of tracheotomy is contraindicated, viz.:

1. The amount and loudness of the stridor, which is always great in proportion to the patency of the small tubes, and, therefore, less in proportion as the latter are filled up with false membrane.

2. A view of the naked chest, when, if the small bronchial tubes be

stopped with the membranous effusion, the muscular efforts at respiration are seen to be comparatively feeble and the chest to remain puffed out.

Some years ago, a remarkable case came under my observation which induces me to believe that occasionally there is a third sign indicating that the false membrane has extended beyond the trachea into the smaller ramifications of the bronchi, viz., the symptom of rapidly supervening coma. The following are a few notes of the case.

On a morning in December, I was called, at 11 o'clock, to see J. W. R., aged six years. The child was lying on the sofa quite comatose; the breathing was of a croupy character; but the latter symptom was not very marked, and the lips and face were of an intense livid hue. The father told me that he had taken his son out shopping with him the evening before, between 9 and 10 P.M. He had rather a cold on him at the time, but did not seem much out of sorts. He was put to bed; but, about midnight, he began to breathe heavily; and, towards 6 or 7 on the following morning, the respiration became very difficult. Soon after this, he began to be blue in the face. When I saw him at 11 A.M., he was in the condition described above. The child never regained consciousness, and died at 4 P.M. of the same day, about sixteen hours after the breathing had become first affected.

Post mortem examination, twenty hours after death. On opening the head, the brain and its membranes were seen to be exceedingly congested. On the inside of the larynx and trachea, was a complete cast of false membrane, extending into the right and left bronchi, and continued into the smallest ramifications of the bronchial tubes. The lungs were oedematous, but otherwise healthy.

This case was, of course, hopeless from the first, as there was every reason to believe that the false membrane in the minutest bronchi was thrown out simultaneously, or very nearly so, with that in the larynx and trachea.

GEORGE SCOTT, M.D., Southampton.

CASE OF URETHRAL STRICTURE: DILATATION BY THE LAMINARIA BOUGIE.

On the 21st of last June, I was consulted by a gentleman aged 45, who had suffered from symptoms of stricture for five years, which he attributed to a severe attack of gonorrhoea. Recently he had been troubled occasionally with attacks of retention, followed by the passage of thick urine. Owing to the reduction in size of the stream, he was induced to apply for relief. On examination with the elastic bougie, an organic stricture was detected, situated about four and a half inches from the meatus. A No. 3 silver catheter was, after some little difficulty, guided through the stricture. The patient being anxious to have the dilatation accomplished as soon as possible, I determined to attempt it by the gradual introduction of the laminaria bougie through it. With this view, a laminaria bougie, corresponding in size to No. 3 silver catheter, previously dipped in warm water and oiled, was introduced into the anterior part of the stricture, and retained there by firm pressure for half an hour. During its retention, the patient complained of slight smarting pain. The following day this was again repeated, a bougie one size larger being introduced further into the stricture. On withdrawal, the patient observed he was able to pass his water more freely. The next day an instrument one size larger was introduced, and retained for thirty-five minutes. A No. 8 gum elastic catheter was subsequently passed without much difficulty, and the patient continued to introduce it daily up to the 28th June, when he was able to substitute a No. 10. He now finds it necessary to introduce the instrument once a week.

In a case that recently came under my care, I adopted a similar line of treatment; but, owing to the density of the stricture, was obliged to have recourse ultimately to subcutaneous division.

SAMUEL LEE, M.R.C.S.

OPHTHALMIC MEMORANDA.

SEVERE PURULENT OPHTHALMIA IN A YOUNG CHILD, PROBABLY CAUSED BY DISCHARGE (NOT GONORRHOEAL) FROM THE PATIENT'S VAGINA.

The following is a short note of a case in which an attack of ophthalmia, resembling gonorrhoeal in severity, was probably due to the ordinary vaginitis of little girls. It is possible that outbreaks of severe purulent ophthalmia in schools may now and then start from such a cause.

Grace G., aged 2, was brought to me at the South London Ophthalmic Hospital on April 7th, with intense purulent ophthalmia of the right eye of four days' duration; the lids were much swollen and of dusky

red colour; the cornea could scarcely be seen, but was thought to be rather steamy. On the 14th, the other eye was attacked, but did not suffer so severely as its fellow. During the course of the disease, a central ulcer formed on the cornea of the worse (right) eye; perforation, however, did not occur. The severity of the case led me to inquire as to the possibility of gonorrhoeal contagion; nothing was discovered in support of this, but I found that the child was suffering from vaginitis with yellow puriform discharge, and considerable pain in micturition. It seemed, therefore, most probable that the child had inoculated its right eye with its own vaginal discharge; the ophthalmia in the second (left) eye being most probably caught from the first. Under the daily application of a ten-grain solution of nitrate of silver to the inverted eyelids, and the frequent use of an alum lotion, the ophthalmia was cured in three weeks; the vaginal discharge soon ceased with the use of alum injection and great cleanliness. A central opacity is still present on the cornea of the right (more severely affected) eye (July 19th).

EDWARD NETTLESHIP, F.R.C.S.

CLINICAL MEMORANDA.

HISTORICAL NOTE ON DIPHTHERITIC PARALYSIS.

The following quotations show that by one old author the existence of symptoms which we now recognise as paralytic was noted. This fact is of interest in connection with Dr. Johnson's able lecture on the relation between Croup and Diphtheria in the last number but one of the JOURNAL. The book from which they are extracted is entitled:—"An Historical Dissertation on a Particular Species of Gangrenous Sore Throat, which reigned the last year among the Young Children at Paris. Translated from the French of Dr. Chomel, which was printed at Paris in the year 1749; by N. Torriano, M.D., London, 1753."

"Miss Blossac the younger, aged 6½. . . . The patient did not begin or seem to be quite free and out of danger till the forty-fifth day of the disease, having always a pain in expressing herself, speaking through the nose by reason of the fallen uvula. I have since been advised that, for two months together, they gave her, in order to lessen the disagreeable speaking through the nose, a little camphorated brandy with equal parts of lukewarm water to draw up her nose, and she used the remedy with pleasure." (P. 31.)

"Miss Bonac was taken ill of the disease at home and was cured. . . . I have since learned that this patient, after the fortieth day of the disease, spoke very much through her nose, became *squint-eyed and deformed, but that, as she grew stronger, she also regained day by day her natural state." (P. 37.)

"The patients grow leaner and leaner daily, speak much through the nose, have great trouble to *articulate their words. . . . The fever lasts dangerous even beyond the forty-fifth day; the uvula is a long time trailing or pendulous; the patients are a long time very weak and languid." (P. 41.)

This very graphic writer leaves no doubt that the disease of which he treats was veritably diphtheria.

W. F. WADE, F.R.C.P., Physician to the General Hospital, Birmingham.

PATHOLOGICAL MEMORANDA.

TOTAL DESTRUCTION OF THE RIGHT LUNG.

The following notes, rough and imperfect as they are, of a *post mortem* examination which I made, assisted by another medical man, on the body of E. R., a girl aged about 18, will be interesting to pathologists. She had not been under my care, but the history of her case is as follows. Until within a few weeks previous to her death, she had been in service with a farmer, who, she alleged, knocked her down and kicked her; and to this she attributed her illness, which was characterised by a "dragging" pain in the side of the chest, lassitude, and debility. Leaving her service, she placed herself under the care of a doctor, who diagnosed her ailment to be pleuritic effusion, and, after some time, sent her to hospital. On coming thither, she was able to walk about the ward, but always with a languid air and feeble step. For two or three weeks before her death, she was confined to bed; her respiration became more difficult, her face somewhat dropsical, her colour rather livid, and she lay upon her back.

An inquest was held. On opening the thorax, we found the space previously occupied by the right lung filled with purulent fluid, and the

* sic in original.

lung itself totally destroyed. Its former connection with the heart was marked by a semicartilaginous substance not more than two ounces in weight. There was also some serous effusion in the pleura of the left lung, but the lung itself appeared healthy. The heart was of normal size. When we had proceeded thus far with the examination, we were summoned to give evidence as to the cause of death, which was plain enough; and, on our returning to resume the examination, the girl's mother prevented our doing so. It is to be regretted that we were in consequence unable to ascertain what pathological changes, if any, took place in the heart and other organs; but the two remarkable features of the case are: (1) that life was maintained until all but the whole of one lung was converted into pus, which was confined in the thorax; and (2) that, while this change was going on, not a drop of blood escaped from the countless vessels that penetrate the lung; while, *a priori*, sudden death from hæmorrhage might have been anticipated. The latter fact seems to show that the process of suppuration is sometimes sufficient to occlude even vessels of the largest calibre.

JEREMIAH DOWLING, M.D., Tipperary.

P.S. There was no fracture of any ribs, nor had there been any marks of violence on the girl when first seen by the doctor.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

GUY'S HOSPITAL.

EPITHELIOMA OF LIP INFILTRATING LOWER JAW: EXCISION OF LIP WITH ALL THE BODY OF THE JAW: RECURRENCE AND EXTENSION ALONG THE COURSE OF THE INFERIOR MAXILLARY NERVE TO BRAIN: CEREBRO-SPINAL MENINGITIS, WITH ABSCESS OF THE BRAIN: DEATH.

(Under the care of Mr. HOWSE.)

[Reported by Messrs. J. A. MASTERS and PEYTON.]

J. O., AGED 47, a miner, living at St. Agnes, Cornwall, was sent up to Mr. Howse on October 10th, 1874, by Dr. Henry Whitworth of that place, under whose care he had been for a short period. He was admitted into Guy's Hospital. He stated that, twelve years previously, he had noticed a small swelling, about the size of a pin's head, on the right side of his lower lip. For four years, this did not give him any pain, and hardly increased in size, though occasionally there was a little scab upon it. At the end of that period, it began to grow; he then went to a provincial infirmary, where it was cut out and caustics were applied. During the ensuing six years, it again and again recurred, and was treated sometimes by excision, sometimes by caustics. The latter he learnt to apply himself with partial relief. During the last two years, the growth had increased very much, and had proved very troublesome, giving great pain and discomfort. He had also a constantly severe headache, for the relief of which he had been in the habit of taking chlorodyne.

On admission, there was a gap on the right side of the lower lip about two-thirds of an inch in breadth by a quarter of an inch in depth, the result of the operative proceedings adopted in the country, and chiefly of the after application of caustics. The mucous membrane occupying this gap was healthy, except on the right side, where it was continuous with an ulcerated epitheliomatous growth about an inch and a half in diameter, extending from the lip to the adjacent alveoli, to which it was firmly adherent. Below this well marked tumour the mucous membrane, though not so prominent, was evidently extensively infiltrated with epitheliomatous elements. On the left side of the above described gap, numerous small nodules could be felt in the mucous membrane, and close examination showed that all this part was more or less infiltrated. At the left angle of the mouth, there was another raised ulcerated epitheliomatous swelling, projecting externally, and about as large as a walnut. Within the mouth, the mucous membrane on this side was much infiltrated, and firmly adherent to the jaw as far back as the first molar tooth. The man was pale, cachectic looking, of about medium height. His medical attendant, however, reported that, previous to the advent of these symptoms, he had been healthy and strong.

From the above account, it will be clear that none of the mucous membrane from one angle of the jaw to the other was completely clear of the disease, and that any operative procedure, to be successful, would involve taking away the whole of this enormous piece of skin.

Moreover, the growth was so firmly adherent, and so deeply infiltrated in the jawbone itself, that that also must be sacrificed. This was the less to be regretted, as there would not be enough skin to form a fresh mouth without its removal, although that below the jaw remained in a healthy state. The nature of the operative proceedings to be adopted, together with the chances of life, both with the operation and without it, having been fairly put before the patient, he elected to have it done.

On October 16th, chloroform was administered and the tongue transfixed with a silk thread and drawn forwards, to prevent it falling backwards on the larynx when the genial muscles should be subsequently divided. An incision was then made from the right angle of the mouth to the corresponding angle of the jaw; a second incision was made along the inferior margin of the maxilla down to the bone from one angle to the other, and the skin incisions were completed by a third, similar to the first, from the left angle of the mouth to the corresponding angle of the jaw. The skin-flaps having been dissected from the jaw, the inferior maxilla was next sawn through on each side behind the last molar tooth, the cut in each case passing obliquely downwards to the angle. The mylo-hyoid and genial muscles were then cut away from the jaw, and the mucous membrane of the floor of the mouth dissected from the alveoli as high as it was healthy. In this way, the whole of the body of the jaw was removed with all the epitheliomatous skin covering it. It was then found easy to bring up the skin from the chin and to press the two side-pieces inwards, so as to construct a new mouth, the lip itself being formed from the skin of the chin, and partially covered by mucous membrane from the floor of the mouth. The ligature through the tongue was fastened by strapping to the forehead, so as to prevent it falling backwards now that it was deprived of support from the genial tubercles. The hæmorrhage throughout was very slight. During the following fortnight, primary union took place along nearly the whole course of this very extensive incision, especially about the left side, the cure of which appeared complete. On the right side, two small sinuses remained inside the mouth which communicated with bare bone, and it was thought that there was a small piece of maxilla to exfoliate there, probably from the point where it was cut through. Food was at first given entirely through the nose four times in the day, a pint of milk being administered each time. Later on, an egg was mixed with each pint of milk. The tension on the tongue was loosened seventy hours after the operation, although no inconvenience was complained of; but the ligature was not entirely removed until three days later, in case of any accident occurring. Although it had been *in situ* nearly a week, the hole healed immediately. The temperature throughout remained about normal. On the 29th, he was permitted to try to get up, but found himself so weak, that he could only sit up for a short space of time. The condition of the mouth then was as follows. Complete union had occurred everywhere externally; there was a slight amount of swelling about the left side, about which he complained occasionally of pain. The lower lip, though fairly prominent, was low and not easily raised, so that the mouth was not naturally kept closed. This was probably due to the total absence of orbicularis oris in it, and it gave rise to a tendency in the saliva to dribble over the skin. The skin of the lip had itself become considerably inverted, so that the beard appeared to go right up to the mouth. It was thought that this condition of the lip might readily be remedied by another plastic operation, if everything else went on favourably.

During the following two months, he was able to get about the ward and to feed himself with soft food; but he always complained of more or less pain about the right side of the jaw and in the temporo-maxillary articulation; sometimes also running up the side of the head in the position of the auriculo-temporal nerve. As there was no sign of recurrence, and as the presence of bare bone in the sinus had been detected, it was thought that this pain might be due to more or less inflammation going on about the cut ends of the inferior maxillary nerve, due to the necrosis. For some time, a Hainsby's truss was worn, so as to support and press in the side of the face; but, as it seemed to inconvenience him rather than to give relief, it was omitted after about a fortnight's trial. He was able to articulate sufficiently distinctly to be understood.

On January 4th, he had rigors, the face became red, and a smart attack of erysipelas manifested itself. The jaw on the right side had remained up to this time in much the same state, the sinus discharging; but there was no sign of recurrence of the growth. The necrosed bone was not, however, yet loose. He was removed to the special erysipelas ward, and treated in the usual way. The attack, though never very acute, was persistent, so that it was the end of the month before he was able to return to Lazarus Ward. On January 28th, examination of the wound showed that a great change had taken

place in it. Fungoid epithelial granulations had sprung up thickly all round the open sinus; the swelling of the face had greatly increased, and had extended into the neck. Scarcely any bare bone could then be detected by probing.

He now became very rapidly worse; complained of constant severe pain in the head; the hearing became affected on that side; ptosis and external strabismus came on, with diplopia and anaesthesia of the right side of the face: all these symptoms clearly pointing to extension of the growth along the course of the inferior maxillary nerve, through the foramen ovale, implicating the base of the brain. On February 6th, he became quite unconscious, and died on February 8th.

Post Mortem Examination by Dr. Fagge.—Body much emaciated. The wound produced by the operation had healed, the skin passing into continuity with the mucous membrane at the base of the tongue. There was no trace of the growth here, nor were any of the glands in the neck cancerous; but, on cutting into the masseteric and temporal regions, it was found that there was in this part much diffused epitheliomatous growth, with unhealthy inflammation, attended with the secretion of ichorous pus and blackening of the tissues. This condition extended up to the base of the skull in the pterygo-maxillary region.

Looking now to the base of the skull internally, it was found that the dura mater in the middle fossa over the site of the foramen ovale was blackened and sloughy. This lay on a mass of soft granular whitish growth, which extended into the Gasserian ganglion and converted it into a roundish tumour. Underneath this, the bone was destroyed for a considerable space, forming an aperture oval in form and three-quarters of an inch in its long diameter, extending through the middle fossa. Through this aperture, the growth inside the skull was in direct continuity with that outside. The brain showed a single nodule of the same kind of growth about the size of an almond, which lay on the right side of the pons, exactly corresponding with the superficial root of the fifth nerve. It was not adherent to the pons itself.

The right middle lobe of the brain presented a black discoloured patch externally, which corresponded with the patch on the dura mater. In immediate connection with this was an abscess of considerable size in the brain, with shreddy discoloured walls, and containing a fetid brown ichor. The cavity of this abscess led straight into the descending cornu of the lateral ventricle, which was also filled with the same brown ichor, and its walls were shreddy and uneven. On the other hand, the left ventricle contained only a slightly turbid pus, and a little greenish pus in its posterior cornu.

The base of the brain was covered with a rather thick layer of greenish pus; some of this was superficial to the arachnoid, but much of it lay beneath it. The spinal cord showed a considerable quantity of inflammatory effusion beneath the arachnoid in its whole length. Towards the lower part, this at one spot amounted to a thick layer of yellow pus, which could be pressed out as a milky fluid. The lungs were in part oedematous, in part solidified. The greater part of the left lower lobe in particular was hepatised, and of a dark greenish colour, as if disposed to slough. The bronchial tubes also contained a fetid greenish-brown fluid. No secondary epithelioma existed in the lungs nor in any of the other viscera. Microscopical examination of the growth, both of that removed at the time of the operation as well as of that which recurred at the base of the brain, showed that it consisted of the same elements; viz., well marked epitheliomatous structures, with, however, much lymphomatous tissue. The bone of the jaw appeared to be quite healthy where it was cut through, and, indeed, everywhere else, except where the growth was adherent to it. A small portion of the soft tissue was cut out of the dental canal and subjected to microscopical examination; but no epitheliomatous elements were visible here.

REMARKS.—The recurrence of the growth three months after the operation makes it questionable whether, in spite of the very extensive operation here described, the whole of the growth was completely removed; whether, in fact, it had not even then involved the base of the skull about the pterygo-maxillary region, and possibly even the base of the brain itself. The very severe headache of which he had complained for some time previously lends some support to this view. Be this as it may, there can be very little doubt that, if this severer operation had been resorted to earlier, before the constitutional infection had become so well marked, perfect success would have been the result. Twelve years is an unusually long time for such a tumour to run its course unchecked, and yet, when operated on in such an advanced stage, give such a large measure of success as here attended it.

The fact that all the central part of the cicatrix of the first operation, performed eight years ago, was free from any recurrence of the growth is an interesting thing histologically. Epitheliomata tend to arise in

membranes provided with abundance of glands or cuticular appendages. As, in the cicatrix, all these structures were quite destroyed, there was but little tendency in the growth to form again here. But, in the margin of the cicatrix, where glands began to reappear, nodules of epitheliomatous tissue had formed themselves. Cicatrix is generally considered a weak tissue pathologically; i.e., more liable to pathological changes, to become inflamed and to break down, than the normal tissue of the part. But it is evident that, as far as the recurrence of an epithelioma is concerned, it must be considered the very reverse, and hence that, the more the glandular tissue in the neighbourhood of an epithelioma is cut away, the less risk there will be of the recurrence of the growth.

THE GENERAL HOSPITAL, BIRMINGHAM.

CASE OF HÆMOTHORAX FROM CANCER OF THE LUNG, SECONDARY TO THAT OF THE OVARIES.

(Under the care of Dr. RICKARDS.)

[Reported by Mr. THOMAS F. CHAVASSE, Clinical Clerk.]

E. H., AGED 40, a charwoman, was admitted into the hospital, August 19th, 1875.

Previous History.—She was the mother of five children, two only being still alive. She had always enjoyed good health until six weeks previously to admission, when she first noticed that she had slight shivering attacks. They were followed by a slight pain in the left side, extending back to the spine. The pain gradually grew worse, and at length became continuous, but aggravated when lying down, unbearable when resting on her right side, easier on turning over on to the left. This pain slowly increased in severity, and the patient began to suffer from great difficulty in breathing, and a very severe cough, in consequence of which she passed very restless nights. Being now compelled to give up her work, medical advice was sought, five weeks after the first symptoms had appeared. A week subsequently, by the advice of her medical attendant, she came to the hospital. Her menstrual periods had always been regular, usually lasting a week.

On admission, the patient was pale and pasty, somewhat emaciated, and with a careworn expression of face. Dyspnœa and orthopnœa were great. There was no pain in the chest; she suffered from cough, although to a less degree than before admission. There was no expectoration; tongue white and furred; bowels constipated. Pulse, 110; temperature, 99.2 degs.; respirations, 32. The urine contained a small quantity of albumen, and a few hyaline and faintly granular casts. On examining the thorax, there was every indication of the left pleural cavity being full of fluid. The circumferential measurement in the mammary line of the right chest was sixteen inches, that of the left, seventeen inches. The heart was seen and felt beating on the right side of the sternum, two inches from the right border of that bone. She was ordered an ether mixture with spoon diet and stimulants. August 23rd. The cough and dyspnœa were worse. Mr. Bartleet introduced a fine needle of the aspirator into the left side of the chest, between the sixth and seventh ribs, in the posterior border of the axilla, and drew off five ounces of fluid. After the operation, patient's breathing was markedly improved. The fluid drawn off was clearly not blood coming straight from the circulatory system, and it had the appearance of a mixture of blood and porter. On standing, it did not coagulate, but separated itself into two strata, the upper one fawn-coloured, the lower one purple.

August 24th. The cough had been troublesome, and the patient had had a bad night. Her breathing was better; she had no pain; dulness remained as before. She was ordered a mixture containing morphia and digitalis. Pulse, 100; temperature, 99 deg.; respirations, 30.

August 25th. She had slept well during the night. The cough was less troublesome; she perspired excessively; the dyspnœa was much relieved, and the patient expressed herself as being in no pain whatsoever. She commenced to menstruate. Some chicken was added to the diet.

August 26th, 1.30 A.M. The dyspnœa was very great. Respirations, 50; she was almost pulseless. The heart beating in the right axilla. The aspirator was used, and twenty-four ounces of fluid were drawn off, similar to that previously extracted. Pulse distinct, 132; respirations, 32. 11 A.M. She had slept a little after the withdrawal of the fluid. She was sweating profusely; pale in the face, but in no pain. She coughed a little, but the dyspnœa was much relieved. The heart beat near the sternum.

August 27th, 10.30 A.M. She had been very restless all night, and slightly delirious. Even now she was rather wandering, but could answer coherently when questioned. The breathing was not quite so laboured. The pupils were contracted; the tongue was coated, but moist. Thirst was extreme. The heart was pushed more to the right side than before.

2 P.M. An attack of dyspnoea came on as before, and before aspiration could be performed the patient died. At the *post mortem* examination the pleural cavity of the left side was found full of fluid similar to that which had been drawn off. The pleuræ, both costal and pulmonary, of the left chest were studded with very vascular cancerous growths. The lung on the same side was collapsed to the size of a duck's egg; and its surface was covered with similar deposits to those on the pleura, varying in size from a pea to a filbert. One of these cancerous nodules had softened, and bled into the pleural cavity. Several growths were also found in the right lung. Both ovaries were cystic, and contained nodules of cancer, like those found in the lungs. Some of the cysts were larger than hen's eggs. The uterus was enlarged. The other viscera were free from the growths. Microscopically, the nodules were seen to be composed of nuclei embedded in an abundant stroma. Here and there the remains of hemorrhages into the tissues were clearly perceived.

Remarks.—Dr. Rickards remarked that aspiration was repeated to prevent impending death by dyspnoea, for it was evident from the pulse, pallor, and perspiration, that the operation debilitated the patient. The attacks of dyspnoea were probably due to the encroachment on the right lung by the dislocated heart; a slight impairment of the right lung producing a great effect, since the function of the left was suspended. It is possible, also, that the direct pressure on the trachea by the fluid in the left pleura might have taken part in the causation of the dyspnoea. That cancer of both ovaries simultaneously was a rare condition. That, in this case, the same disease had affected two organs of the body far distant from each other, with one direct channel of communication, viz., the blood vessels. The blood from the ovaries going to the lungs, it would seem probable that any *materies morbi* carried in it from them would be stranded in the capillaries of the lungs, causing them, and no other organ, to be affected. Such was the case here. The multiplicity also of the growths, and their distribution in the lungs, argued in favour of these being due to secondary deposit. The implication of the left costal pleura was evidently due to local extension from the lung. There was nothing in the history of the case to lead one to suspect disease of the ovaries.

REVIEWS AND NOTICES.

ON THE RELATION BETWEEN DIABETES AND FOOD, AND ITS APPLICATION TO THE TREATMENT OF THE DISEASE. By ARTHUR S. DONKIN, M.D., etc. Pp. 186. London: Smith, Elder, and Co. 1875.

WHEN the student gets up the symptoms of "diabetes mellitus" for the purposes of diagnosis, he seeks out a typical case in the hospital, and he learns what systematic writers say of its special symptoms. He thus acquires a very distinct idea of a remarkably clearly differentiated disease. He concludes that there cannot be two opinions arrived at by unprejudiced observers as to the effect of treatment: this or that has only got to be tried a few times, and the good or bad result of it on such a peculiar set of morbid phenomena must be clear as daylight. Diabetes mellitus is diabetes mellitus, and it is nothing else. But when he comes to practise, it is to be hoped he will be observant enough to find that there are several classes of circumstances under which the disease of passing sugar in the urine presents itself—different in their accompanying phenomena, different in their results and indications for prognosis; and different, consequently, as tests of treatment. These are:

1. The temporary malassimilation of saccharine and amylaceous articles of diet, producing an evacuation of diabetic sugar, sometimes intermittent or alternating with healthy urine, sometimes ending in complete health, and sometimes in the manifestation of an uric acid diathesis or gout. Any of these results may happen without special treatment.*

2. The continuous malassimilation of an increasing proportion of the above-named articles, increasing more and more the amount of sugar excreted under equal circumstances. This state of things may be identified by the sugar entirely disappearing from the urine when no

* Some writers have designated these cases under the name of "hepatic glycosuria", a term we decline to adopt. The needless invention of a new generic name abets the medical world in a pernicious proneness to see difference in diseases rather than likeness—a proneness fatal to the progress of therapeutics. Moreover, there is no evidence of the liver being primarily at fault: in fact, the large quantity of animal sugar formed testifies in an opposite direction; for in all morbid affections of secreting organs, the secretion which its proper function is diminished, and it seems certain that a proper function of the liver is to secrete sugar. The apparent augmentation of a secretion in quantity is always due to the addition of something which is not a part of it at all.

food containing starch or sugar is taken, and reappearing when it is resumed.

3. When not only these carbonaceous aliments, but also the nitrogenous, fail to be assimilated, and such of their elements as are capable of being converted into sugar are passed away in that form; the whole of the food is waylaid and robbed in its way to the tissues, and the patient is tortured by a more and more ravaging appetite, and, at the same time, emaciated by starvation.

4. Where the essential tissues of the body (notably the nervons) are degenerated in consequence of the deficient supply of normal nutriment.

Now, the first form we should probably find to be the most common, if we analysed everybody's water every day; but it usually is discovered only accidentally; for cases of it, and also slighter cases of the second form, do not present at all the features which are distinctive of diabetes. The symptoms are, as enumerated by Dr. Donkin, "a general feeling of debility, considerable nervous and muscular prostration, lassitude and disinclination for bodily and mental exertion, occasionally a dull pain over the loins, loss of sleep, frequently dimness of vision, a feeling of numbness or loss of sensation over the surface of the thighs; a clammy condition of the mouth, without much thirst or preternatural dryness of the skin, which is frequently perspiring." But what are these symptoms other than those present at the commencement of all chronic diseases in which digestion or nutrition is affected? and if they should, as our author here suggests, be inserted in our text-books of diagnosis as the initial or earliest phase of diabetes, they would require to be repeated so many times over as the initial of other diseases, that an additional price, unrepresented by additional value, would have to be affixed to our manuals. We cannot but think that, instead of grumbling at not being *distingué* at an early period of its career, diabetes may congratulate itself on having the special sign of saccharine renal secretion to separate it from all other diseases in the nomenclature. At the same time, this well-marked symptom does not enable us to form a diagnosis of the different forms of the malady without long and careful investigation of the case—seldom, indeed, without waiting to see the result. Nor can we find in any of the monographs on the subject any other sign which can enable us to do so.

It seems probable to Dr. Donkin, as to us also, that the several forms in which the disease offers itself to our notice are stages leading to one another. He does not, indeed, say so categorically of the first of intermittent forms as he alludes to it only incidentally under the name of "glycosuria"; but we take leave to infer that such is his opinion. However, they are not stages which necessarily lead on to one another; for both the first and the second form often cease spontaneously, and more often merge their peculiarities in other morbid conditions. We meet, for example, with instances in old persons, to which Dr. Bence Jones was the first to call attention, of sugar being passed intermittently, and the urine in the interval being quite normal, without life being anywhere shortened by the disease. And in middle-aged men with an hereditary tendency to gout, we often find the first beginning of invalidism characterised by the appearance of sugar in the water. This ceases, and its place is taken by uric acid and lithates; and then, perhaps, by a swelling of the joints, and podagra fully declares itself—a disagreeable disease, indeed, but a subject of congratulation when it relieves one from the fear of confirmed diabetes.

The prognosis of the third form in which we encounter diabetes is necessarily bad. The duration of life depends on the more or less amount of nitrogenous food which can be assimilated; usually, but not always, bearing a proportion to the notable symptoms—emaciation, diminished temperature, thirst, dryness of skin, smell of hay in the breath, etc., familiar to the text-books.

Should any of the viscera break down into degeneration, as in the fourth form, death ensues in consequence of that failure, and is directly attributable to that cause. Should the brain get atrophied, the patient can be described as dying of "apoplexy"; if the lungs are affected, of "consumption"; or if the cellular tissue sloughs from want of nourishment, of "carbuncle"; and so on.

A consequence of the resemblance borne to one another by cases of which the termination is so different is a great difficulty in judging of the effects of treatment. There are few diseases for which so many cures have been confidently announced, and few in which the failure of these cures has been more positively shown. Of course, every curer is impressed, on beginning his treatment, without a moment's delay, on the finding of sugar in the urine; and if he have gained a reputation for this speciality, and takes care to analyse the secretions of all who come under his notice, the bulk of his list of diabetics will be formed of such as have a tendency to get well or to change into remediable cases. His statistics present, therefore, the most roseate hue of hopefulness. But, supposing he be a stern diagnosticator, who coldly resolves always to

make out what is the matter with a patient before he treats him, or a hospital physician who only cares for those had enough to admit into the wards, a very different inference will be drawn from his case-book. If he hold that the interesting cases reported by Dr. Dickenson prove the cause of diabetes to be a degeneration of the structures of the brain about the fourth ventricle, he must, indeed, leave all hope behind when he presents his record. Not so, if he consider these pathological changes to be a result, instead of a motive, power.

These considerations ought to be allowed full weight when we read, as in Dr. Donkin's pages, of cases reckoned by hundreds where a special treatment has been beneficial, and by tens where it has absolutely failed or appeared injurious in consequence of the inevitable progress of the malady.

Though it renders the logical evidence of remedial measures more difficult, the fact of diabetes being spontaneously removed is the greatest encouragement we can have to expect benefit from art. Every single disease capable of beneficial therapeutics, from a cold in the head to tuberculosis and aortic aneurism, offers examples of idiopathic cure. And, *vice versa*, where we have never heard of an instance of restored health without treatment, we probably waste our time in search of a cure by means of it. Why are physicians sceptical about panaceas for hydrophobia? Simply because no report of spontaneous recovery is known to them. But now that we have learnt what nature can do in diabetes, we should open our hearts widely to faith in the resources of art.

The special treatment with which Dr. Donkin's name is associated is the use of skim-milk as a diet; and the point of the volume now under review appears to be to show that it is in accord with the teachings of organic chemistry and physiology to expect advantageous results from it. By no means uncalled for, or too soon, is the urging of this point; for, on chemical and physiological grounds, the earnest and accomplished M. Bouchardat has specially cut out this useful article—the dietician's model food, the type of perfection, the precious gift of godmother Nature to her most precious wards—from the bill of fare of the diabetic. Boldly confronting in a good cause even such an antagonist as the trusted M. Bouchardat, Dr. Donkin contends that milk-sugar differs so essentially from cane-sugar, grape-sugar, and pure diabetic-sugar, that it is not converted into it, and does not appear again in that form in the renal excretion. "Belonging to a different class of sugars, milk-sugar does not undergo alcoholic fermentation in contact with yeast; and, in addition, it does not precipitate the oxide of copper when treated with the reduction test. On the other hand, it is subject to lactic fermentation by the action of ferments. On account of these intrinsic differences, lactose, as an ingredient of milk, cannot undergo the same metamorphic changes as glucose in the processes of digestion and assimilation in health (nor be converted into it in diabetes); its conversion into lactic acid being *direct* and *immediate*, not by *intermediate* changes, through which the latter pass into this substance. For this reason, which is perfectly intelligible, milk-sugar, unlike vegetable glucose, is assimilated, and the reverse of injurious in diabetes."

It must, however, be noticed that milk-sugar, in the presence of acetic and several other vegetable acids, and also of several mineral acids, and other substances, of which koumiss-brewers are aware, was long ago observed by Simon* to be changed into grape-sugar, and so become liable to alcoholic fermentation, etc., and presumably as injurious to the diabetic as native glucose. This must be always borne in mind in clinical experiments on the subject. Milk-sugar may be utterly perverted and rendered poisonous by admixture with other articles in the stomach—a pickle, or a glass of wine or of lemonade, some sulphuric or hydrochloric acid given as a tonic, and many other substances probably; whereas, taken quite alone, it may be the best of foods to the hungry patient.

It is not, then, a fair trial of Dr. Donkin's skim-milk treatment, if any other food be allowed to mix with it in the stomach. The safest way is to make it the exclusive article of diet; but if the patient absolutely refuse to be so restricted, then we must take care that it is wholly absorbed (and diabetics absorb very quickly) before another meal be swallowed. But we must not reckon these abortive observations as equal in scientific value to complete experiments.

The use of lactic acid by Professor Cantani, Dr. Balfour, Dr. Foster, and Dr. Ogle, is quite distinct from the treatment recommended by Dr. Donkin. They prescribed lactic acid as a remedy, intended to make other foods wholesome; he skim milk as a sole nutriment, which the mixture of other foods nullifies.

As to the quantity demanded, it appears that a patient can drink as much as a gallon and a half *per diem* (page 148); but that is an extreme ration; and, when the appetite is so keen, Dr. Donkin advises some of

the milk to be made into curd or "junkets". But much less than a gallon and a half will suffice, for much less will supply the calculated daily wants of the digestive organs. Each pint of skim-milk contains half its weight* of casein in a fluid state, which, in fact, is liquid bodily tissue. There is 72 per cent. of water in combination with it, and there is 72 per cent. of water in the primest beef.† Thus, in five pints of skim-milk, a man would get as much nutriment as in 3½ lbs. of beef-steak, which, in an exclusively meat diet, may be reckoned sufficient even to do a day's work upon.‡ This is enough to show that Dr. Dickinson is not exercising his usual thoughtfulness when he represents the treatment now under review as "a course of starvation". We think that Dr. Donkin has made out a case for at least a temporary trial in all but exceptional instances of diabetes.

The diabetic may prudently board with the pastoral Polypheme, and may hope to grow sturdy as his host. But he must not cast envious eyes at Acis and Galatea.§ Cheese, even though it be made of skim-milk, as in Holland and in single Gloucestershire, has been found by Dr. Donkin to increase the sugar in the urine. And cream, too, which M. Bouchardat commends, he denounces as injurious. We are very jealous of any reduction of diet in disease, and hope that repeated trials may test this exclusion before it is definitely judged. May not the cheese used have been made tasty by storing, which is well-known to develop a variety of new compounds? Ought not fresh curd-cheese to be tried? It may be toasted, and otherwise cooked, with advantage. And as to cream, likely enough it is noxious when mixed with milk; but may it not be taken alone? An encouragement to hope it may be so used is given by the rapid absorption and conversion into adipose tissue of cod-liver oil, which almost always increases the weight of diabetics.

On the critical and pathological part of Dr. Donkin's volume we make no remark, as it is not the point of the work.

SELECTIONS FROM JOURNALS.

SURGERY.

ROUX ON TUBERCULAR ARTHRITIS.—Dr. J. Roux (*De l'Arthrite Tuberculeuse*, in 8vo, pt. 1, p. 50, Paris, J. B. Baillière et Fils) announces the following conclusions in a recent *brochure*. There exists in the category of white swellings a truly tuberculous variety, which deserves to be distinguished from all points of view. The tuberculous nature of this arthritis is demonstrated both by pathological anatomy and by experiment. The etiological relations between tubercular arthritis and pulmonary tuberculosis are evident, and well known in a general way, but are not precisely defined in detail. The symptomatology of tubercular arthritis is obscure at present. The diagnosis, in the majority of cases, only reaches probability, and not certainty. The existence of tubercular arthritis is commonly an indication for active interference: resection or amputation.

ANKYLOSIS OF THE HIP-JOINT TREATED BY FRACTURE OF THE SURGICAL NECK OF THE FEMUR.—M. Tillaux, at a recent sitting of the Society of Surgery of Paris, presented a female aged 32, the subject of bony ankylosis of the hip-joint, for whom he had successfully fractured the surgical neck of the femur. The case was a very successful one. The disease occurred after childbed, and the limb was firmly ankylosed in the flexed position, with rotation inwards. The ankylosis was of a year's duration, complete and absolute. The patient was placed under chloroform; and M. Tillaux, placing himself on the left side, seized with both hands the lower extremity of the thigh, and, employing considerable force in drawing it outwards, broke it at the surgical neck; the crack being loud and clear, so as to leave no doubt in the minds of those present. The classic signs of fracture of the neck were observed. The limb was duly set in the straight position; and at the end of two months the patient had a straight firm limb, with only a slight lump from a very little shortening of the leg. This result M. Tillaux described as splendid. The method has no novelty in it; but, old as it is, he thinks it "infinitely preferable to the subcutaneous sections which are now fashionable with some surgeons, and are performed almost daily to counteract the effects of certain malformations."

* Dr. Donkin says three-quarters, but that hardly is consistent with M. Bousingault's estimates.

† 72 to 74 per cent. (Dr. Letheby).

‡ Chambers, *Manual of Diet*, p. 9.

§ *Ἰὰ γαλαταία* ("the cheese-farms") still en'rage the maritime village retaining the name of Acis, under the grumbling, smoking, one-eyed monster we now call Etna. The graceful myth, so familiar to all, is a good example of prehistoric physical history, which is easily unriddled at its birthplace.

BRITISH MEDICAL ASSOCIATION:
SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st, Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, OCTOBER 2ND, 1875.

THE TWO SYSTEMS OF EDUCATION.

AT the beginning of a session the present status of medical instruction comes before us for review ; and we turn naturally to the comprehensive and weighty address in which Sir R. Christison recently stated his experience and his views before the great assemblage of the profession in Edinburgh, at the late general meeting of the British Medical Association in that city. That address, as we have already pointed out, was a mine of solid ore ; it will have to be referred to and consulted by medical reformers for many years to come. Educational institutions, like all other institutions, originate in, and are the reflex of, the national mind ; and consequently great importance attaches to the history of such an influential educational institution as the Medical School of the University of Edinburgh. The Faculty of Medicine was initiated towards the close of the seventeenth century, by the establishment of a Chair of Medicine ; and by a process analogous to the "proliferation of tissue" and "specialisation of function", of which students will hear a great deal by and bye, chairs became multiplied, and the teaching of special subjects was entrusted to specially instructed men. We would emphasise the cardinal fact that, although no doubt the Chair of Medicine was originally established to supply a popular want, yet it took its origin as an offshoot from the Faculty of Arts, which in those days was regarded as the peculiar handmaiden of Theology. This mode of origin and alliance could not but impress certain characteristics upon the Medical Faculty, and the teaching became from the first *dogmatic*. The student was taught ideas prior to facts ; the indirect knowledge which is obtained from lectures, before the direct knowledge which is obtained from contact with things.

If we now look across the border, we shall see how different was the mode of origin of the institutions which gave character to the education of the great bulk of English medical practitioners. The Apothecaries' Company was incorporated by James I, and united with the Company of Grocers ; and it was only by a statute early in the reign of George II "that the two callings of barber and surgeon were broken into two distinct corporations". These institutions, therefore, arose by natural differentiation from ordinary trading establishments, and must have been called into separate existence because their members were already performing an indispensable social function. It might have been expected that, to the student trained under the direction of these institutions, practical aptitude would be the one essential requirement ; and there can be no doubt that these institutions have, on the whole, subordinated theoretical and systematic teaching to the acquirement of practical knowledge. The system of teaching fostered by them is what may be termed the *empirical* method. Each of these methods is properly a reflex of the mind of the nation in which it flourished. The dogmatic method is more adapted to the Scotch intellect, which finds its highest expression in a deductive philosophy ; while the empirical method is better adapted to the English nation, which was more largely influenced by the Baconian inductive philosophy.

Each of these systems had its advantages and disadvantages. The dogmatic method pursued in Edinburgh has had some splendid successes ; but many will be induced to think that, for the mass, the sys-

tem was largely alloyed with the elements of failure. If we glance, for instance, at the writings of Cullen, who may be taken as the highest exponent of this mode of teaching, it may be safely inferred that it was only a few of the highest order of intellects in his class who could follow his subtle reasonings. Starting from a few definitions, and an assumption with regard to the action of the solids, and of an occult power which he called the energy of the brain, he argued from principles down to facts ; and, when the students came afterwards into direct contact with the facts, their observations could not help being swayed and dominated by the system of the master. Nor was this all. Having been introduced to large generalisations prior to the facts and cases from which the generalisations were drawn, they carried with them a form of words without corresponding ideas. Hence they were totally unable to criticise the truth or falsity of the generalisations ; their independence of mind was lost, and an undue respect for the authority of the teacher inculcated. The consequence was, that the great bulk of medical men trained under this system inevitably degenerated into pedants, who were always ready to consult the nosology of the master, and find that this disease was caused by spasm, and to be treated by a sedative, and that by atony, and to be treated by a stimulant.

If we now turn to the results of the empirical method, there can be no doubt that this system produced a great many sound and useful practitioners. If its advocates could not boast of having so many brilliant successes as their opponents, they could at least plausibly maintain that they had fewer failures. If the knowledge imparted under this system was less, it was at least vivid, and always communicated in the way in which it could be most readily turned to practical account. The practitioners reared under this system were, however, often and largely deficient in general culture ; their treatment of disease was mainly determined by example and precept ; their minds could seldom ascend to take a grasp of general principles, and consequently were so cramped as to be deficient in powers of growth and expansion. But the greatest evil of all was, that the origin and traditions of the institutions under whose auspices they were trained kept up a trade association in the profession, so that it is to be feared that the highest aim of a great many practitioners was to induce their unfortunate patients to swallow as many bottles of physic and draughts as possible, so that they might be counted up in the day-book at the end of the day, as a grocer counts the number of pounds of tea or of sugar he retails.

It is not maintained that these methods of instruction were carried out in their full integrity either in Scotland or in England. The corrections of experience, and the collisions of thought from friendly intercourse and rivalry, induced the former to supplement dogmatic teaching by practical instruction, and the latter to give systematic lectures in aid of the means adopted for imparting practical knowledge. The mixed system is now in full operation both in the Scotch universities and in the English schools ; but it is still true to a large extent that it is the systematic teaching in the former case, and the practical instruction in the latter, which give character and tone to the training of the student.

The question which the medical reformer of the present day has to solve in this reference is not whether the dogmatic is better than the empirical method, nor the empirical than the dogmatic, but what combination of the two methods will give the best results. It will be observed that, although these two methods are mutually helpful, they are also antagonistic. Whatever of the student's time is devoted to practical instruction is a deduction of the time which might otherwise be devoted to receiving systematic instruction ; and *vice versa*. It becomes, therefore, very difficult to apportion the relatively short time for medical study duly between these two methods of imparting knowledge. Some reformers would get over the difficulty by extending the period of medical study to five instead of four years. This suggestion, however, does not find countenance from Sir Robert Christison ; and the arguments he adduces against it are, in our opinion, unanswerable. But he makes various suggestions for economising time ; not the least important being, that the student should "commence his professional

studies, not with the month of October or November, as is usual, but in the beginning of the previous May, so as to take his botany and natural history before commencing his statutory four years' curriculum". This device would practically extend the time devoted to medical studies by half a year; while, if it were generally adopted, it would by and by be possible to act upon Professor Huxley's suggestion, and detach zoology and botany from the subjects of medical study, and include them in the Arts curriculum. He also proposes to economise time by a redistribution of the subjects of study. He suggests that our present winter and summer sessions should be altered "to two equal periods of four months, with an interval of one month for holidays or graduation examinations"; and, by curtailing the less important courses of lectures, he would be enabled to lengthen the more important courses, such as "anatomy and practice of physic"; while a further margin would be left for practical study. This suggestion appears to us to be an extremely valuable one.

But, after economising the time of the student to the utmost by these devices, little enough of the four years remains for the practical and systematic study of the great subjects of medical education; and it becomes of extreme importance to distribute fairly the student's time between these methods of study, according to their relative values. Sir R. Christison is evidently afraid that the practical method is already encroaching too far upon systematic teaching, but in this fear we do not share; and we are compelled to dissent from his opinion that systematic is an essential preliminary to practical instruction. There can be no doubt that systematic teaching will always be succeeded by practical study; but it ought also to be, so far as is possible, preceded by it. Sir Robert Christison says, and no doubt with truth, that "in the same space of time the lecturer can go over in his systematic course three or four times the amount of details which the student can overtake in any plan of practical study". But this is the very reason why practical contact with the subject should come first. The knowledge imparted by the latter method being less in the same time, a greater opportunity is given to the mind to assimilate it. A true psychology dictates that the generalisations of science should be reached through the study of cases, and that the mind of the student should be introduced to principles through the medium of examples. The order of mental development is from the particular to the general, from the concrete to the abstract; and the order of education should pursue a parallel course, and should, therefore, be from the empirical to the rational. And, although we have no wish to advocate the revival of the Apothecaries' system of apprenticeship, its desuetude has not been all clear gain without loss. If there be one rule we would wish to impress upon the student more than another, on the eve of his beginning the study of medicine, after the usual exhortations of steadiness and enthusiasm in work, it is, that he should make a strenuous endeavour to acquire some practical acquaintance with every subject before attending the systematic course of lectures.

PSYCHOLOGY AND THE NERVOUS SYSTEM.

II.

WE first consider the anatomy of the substrata of visual ideas, although we must now and then at the same time speak of their modes of activity; that is, of their physiology. We wish to show that these substrata are not sensory only, but sensori-motor; we have to find out what parts of the periphery the sensory and the motor elements represent. We begin by drawing attention to the universal agreement that there are two qualities in bodies to which the two elements sensory and motor of the sensori-motor unit correspond.

The qualities in bodies we shall speak of are the Secondary and Primary, or, as Spencer calls them, the Dynamical and the Statical. In this article, we say nothing of the Secundo-Primary or Statico-Dynamical; we believe them to be estimated by retinal impressions and ocular movements represented in the cerebellum, these retinal impressions and ocular movements being symbolical of *pressures* and loco-

motor movements. On the other hand, chiefly from consideration of the facts supplied by cases of disease of the brain, we believe that colour and extension (secondary and primary qualities) are those qualities of bodies which are estimated by impressions and movements represented in the cerebrum; the retinal impressions and ocular movements representing these are symbolical of tactual impressions and movements. As it is not possible to make this difference of representation (cerebral and cerebellar) clear parenthetically, the reader may assume that we arbitrarily limit ourselves to the consideration of colour and superficial extension of bodies. We begin with the sensory element of the sensori-motor arrangement.

The secondary or dynamical qualities which we impute to bodies are such sensations as the bodies rouse in ourselves. We consider visual sensation—colour—only. But colour is a mental state; and we have to do with the correlated anatomico-physiological state. There is on the physiological side an excitation of an anatomical element, sensory or afferent. There is an impression on the retina, an excitation of optic nerve-fibres, and also of the very highest nervous centres connected with the retina and optic nerve. There is, indeed, no doubt that the secondary quality, colour, is parallel with an excitation of a sensory element. The popular notion seems to be, that there is nothing more in the substratum of a visual idea. This is, we think, a grave error; for bodies, besides being of some colour, are of some size and shape. By afferent nerves and centres we should obtain no notion of these primary qualities. We never saw, nor can we think of, a coloured object of no size or shape. Form is, indeed, more important than colour. Ruskin, who speaks at some length of the secondary and primary qualities of bodies in his *Modern Painters* (vol. i, p. 66), says: "He who has neglected a truth of form for a truth of colour has neglected a greater truth for a less one." For the estimations of these primary qualities, something more than sensory or afferent nerves are required. This brings us to the motor element of the substratum. For the estimation of size and shape, movement is absolutely necessary. There is wide agreement on this matter. Bain says: "In all that regards visible movement and visible form, the muscular consciousness, it is now contended, is the indispensable element; the optical sensations merely guiding the movements." (*Fortnightly Review*, April 1869.) This statement is very explicit. We have not, indeed, in this article to *prove* that ocular movements are as necessary in our seeing of objects as retinal impressions are, for that is the theory already "in possession". We shall, nevertheless, quote further high authority on the matter.

In his chapter (*Psychology*, vol. ii, p. 177) on the Statical Attributes of Body, Spencer says "that whether visual or tactual, the perception of every statical attribute of body [shape, size] is resolvable into perceptions of relative positions which are gained through *motion*." Again, vol. ii, *op. cit.*, p. 171: "Those motions of the eye required to bring the sentient elements of the retina successively in contact with different parts of the image, being themselves known to consciousness, *become components of the perception*." Again, p. 172: That "the primitive element out of which our ideas of visible extension are evolved, is a cognition of the relative positions of two states of consciousness in some series of such states consequent upon a subjective motion." Evidently the theory in possession is, that movement is essential in the estimation of the primary qualities of bodies.

Although proof of this cannot be demanded of us, we may give illustrations. There are many morbid conditions which show the importance of muscularity, or of action of nervous centres representing movements, in the estimation of the Extension of objects. By altering movements of our eyes, we alter the size of objects, if this expression may be permitted. For example, if we impress the retina with a flame, and thus obtain an after-image, we find that this varies greatly in size as we look near or into the distance. Yet the sensory element concerned—the retinal area affected—is unaltered during the differences of ocular adjustment. There is even more than this. By different adjustments of our eyes—that is, by altering the *motor* element—we may to some extent alter not only the size but the shape of these spectral images.

Thus, if we impress the retina by a circle, and then project the after-image on to an inclined sheet of paper, our spectral circle becomes oval; a spectral square becomes oblong. This is a very remarkable illustration, showing the importance of movement in the estimation of shape. In both cases, the retinal (sensory) element is unaltered. The differences in size and shape are owing to differences solely in the motor element. We have more to say on this after speaking of "ideal seeing".

We trust we have made a strong case for the belief that the substratum of a visual idea is not sensory, but sensori-motor; and that this anatomically corresponds to the long-standing division of the qualities of bodies into secondary and primary. We repeat that the retinal impressions and ocular movements are *symbolical* of tactual impressions and movements, by which latter the two qualities of Body are directly estimated.

One reason why movement is popularly ignored in considering the process by which we see objects is, that the retina being itself extended, an idea of extension of an object is supposed to result during the process, as it were, of its imprinting itself upon the retina. But a very little thought will show that this hypothesis starts with the question-begging assumption that the position of the several elements of the retina in regard to one another is known beforehand. Now, the relation of these elements to one another has to be learned before impressions on them can give a notion of extension; and it can only be learned by movements. (See Spencer's *Psychology*, vol. ii, p. 168.) Certain obvious objections arise here; but they are, we think, disposed of by Spencer's hypothesis of "organised experiences". We are born with nervous centres which represent the experience of the race; thus there is already at birth a rudimentary association betwixt particular retinal elements and particular ocular movements. In the chick, the association is almost complete. In the child, the associations, being only rudimentary, are gradually being developed; in the adult they are complete. Impressions on the retina, even when there is no actual or obvious movement of the eyes, give us a knowledge of shape and size, because the elements impressed provoke slight or nascent excitations in nervous centres for ocular movements. This statement may appear to the reader little better than a verbal one. Let him suspend his judgment until he has read, what will come later, on ideation occurring with strong excitations artificially limited to nervous centres.

So far as we know, the anatomical study of the substrata of states of mind has met with little favour at the hands of medical men. Centres for ideas has spoken of, but nothing is said of the anatomical constitution of these centres. Many physicians speak of a centre for the "memory of words", but the rule is that no attempt is made to discover the anatomical constitution of this centre. Dr. Hughlings Jackson, adopting an hypothesis of Bain, has long urged that the anatomical substratum of a word represents a highly complex articulatory movement; and this opinion seems to be confirmed by Ferrier's experiments. That movement should be represented in centres for ideas or memories of anything seems to very many an extravagant notion. "What can *movement* have to do with *ideas*? One is a physical process, the other a mental process." For, in spite of guarded definitions, many of those who thus criticise, seem to be unable to rid their minds of the notion that one is trying to explain mental states by nervous states. In reality, it is only said that movement enters as an element, not into ideas but into the anatomical substrata of ideas. Clearly, however, it does not seem strange to those who deny, or, perhaps we should say ignore, the motor element (efferent nerves and centres) to suppose that mental states arise during excitations of sensory (afferent) nerves. We may infer that those who, speaking at length of the sensory and say nothing of the motor element, believe that the anatomico-physiological process which goes on whilst we think of the shape and size of an object, is a sensory process merely. But we will speak of colour only. What we wish to point out is, that it is just as impossible to tell why we have the mental state colour from energising of certain sensory nerves and centres, as

it is to tell why we have ideas of shape from energising of motor nerves and centres. It does not, at first glance, *seem so* difficult, because the word "sensation" is often used in two senses. It is applied both to a physical state and to the mental state that occurs along with that physical state (see Mill's *Logic*, vol. ii, p. 436). For example, it is used for colour (mental state), and for the change which occurs in the optic nervous system whilst that mental state exists. This double use of the word leads to real confusion and to apparent simplicity. Thus, starting only with molecular changes in sensory nerves, we can with fallacious ease build up an orderly scheme of mental operations out of "sensory units", if we use the word sensation now for physical changes in afferent nerves and centres, now for the psychical states parallel with them. Physical states in this view evidently get so very fine in the penetralia of the highest divisions of the nervous system, that they fine away into mental states. There is, we believe, a double error in such systems. Physical states do not *become* mental states, and the substrata of mind are *not* merely made up of sensory (afferent) nerves and centres. The double meaning of the word sensation makes it fallaciously easy for us to "understand" how it is that we have mental states *from* the energising of afferent nerves and centres, whilst no thought is given to the much simpler assumption that mental states may arise *during* the energising of efferent nerves and their centres. It makes it seem easy for us to understand that energising of nervous arrangements representing only a sensory element, as retinal impressions, should give us visual ideas of objects whilst it leads to difficulty in accepting the opinion that energising of nervous arrangements representing articulatory *movements*, should give us ideas of words. The difficulty is just the same in the two cases. The real fact is that in neither case can we tell why during energising of cells and fibres we have ideas. This is so whatever the substrata represent.

The double use of the word sensation conceals the illegitimacy of certain comparisons and contrasts—as, for example, betwixt colour and active states of motor nerves and centres. Psychologically, the comparison and contrast would be betwixt colour and extension; anatomically and physiologically, betwixt excitations or discharges of sensory nerves and centres on the one hand, and excitations or discharges of motor nerves and centres on the other hand.

THE INCREASE OF LUNACY.

THE proposal to erect a third asylum for the county of Surrey has created much dissatisfaction among the Guardians of the various Poor-law Unions in that county, who held a conference at the Wandsworth Board of Works, on September 14th, to discuss the subject, and to devise, if possible, some means of avoiding the vast outlay with which they are threatened, in consequence of the increase of pauper lunacy. Their deliberations had a practical character given to them by an important letter from the Commissioners in Lunacy, in answer to an appeal made to them by the Chairman of the meeting, Mr. Simpson, setting forth their opinion, that a large number of the harmless idiots and epileptics, aged patients and paralytics, who now encumber all county asylums, might be properly placed in inexpensive buildings, containing few single rooms and otherwise simplified. In expressing this opinion, the Commissioners doubtless had in view institutions similar to the Leavesden and Caterham Imbecile Asylums, which were erected at a very moderate cost—much less than that entailed in the erection of an ordinary county asylum, with its expensive appliances for curative treatment—and which afford suitable and comfortable accommodation for the classes of lunatics enumerated by the Commissioners. It seems to us, that it would be judicious policy on the part of the county of Surrey at once to adopt and carry out the suggestion thus submitted to them. If the number of pauper lunatics in Surrey exceeds the existing accommodation, further provision is indispensable. And that provision will be more economically and satisfactorily obtained in the manner indicated by the Commissioners, than by any of the Utopian or objectionable schemes which were rife at the conference. A cessation

in the granting of public-house licenses will certainly not meet the difficulty for some time to come. The detention of the insane in work-house-wards has been authoritatively condemned, and no extension of that system will be tolerated, especially as the workhouses of the county of Surrey already contain upwards of 1,100 pauper lunatics. The boarding out of the pauper insane in cottages is not practicable to any great extent in a thickly populated county like Surrey, and has been already in some measure adopted, as about 130 lunatics are at present so boarded out in that county. The speakers at the conference were in error in referring to the practice of boarding out the insane in cottages as something characteristic of the Scotch lunacy system; the fact being that 12 per cent. of all the pauper lunatics in England are at present provided for in that way, against 22 per cent. so provided for in Scotland. We are yet without evidence that the insane in private dwellings in Scotland are better lodged or cared for than the insane similarly circumstanced in England, France, and other countries; at any rate, no further development of this system is to be anticipated south of the Tweed, and the only choice before the magistrates of Surrey is between a costly county asylum on the old model, and a cheaper imbecile asylum on the new one. Should they adopt the latter alternative, they may expect some but not an enormous saving, as the withdrawal of the quiet and imbecile patients and the substitution of recent and acute cases for them, will raise the rate of maintenance in the county asylums, and as even imbecile asylums are more expensive than workhouses to build and maintain. After all, modifications in the modes of accommodating the insane are mere palliatives with reference to the startling increase of lunacy or lunatics. It is in the application of medical science to the prevention and cure of mental diseases that our only hope of genuine succour lies.

THE House Committee of the London Hospital have determined to postpone any election to the post of Assistant Obstetric Physician for three months. This has been done with the view of allowing eligible candidates, not yet technically qualified, time to obtain the necessary qualification.

SURGEON-GENERAL SIR J. C. BROWN, K.C.B., of the Indian Medical Department, now on leave, is expected to return to Calcutta from the hills early in November, and will probably retire by the latter end of that month, by which time the tenure of his office expires, his services as surgeon-general having commenced on or about November 25th, 1870. Deputy Surgeon-General Beatson, his *locum tenens*, will be confirmed in his present appointment in November.

AT a sermon preached by the Rev. J. McConnel Hussey on behalf of the Brompton Hospital for Consumption, it was stated that the hospital now contained 257 beds; and that, in addition to the inmates, large numbers of out-patients were seen daily. The expenses amounted to nearly £16,000 *per annum*; of this sum, four-fifths, or £12,800, were entirely dependent on voluntary contributions, donations, and subscriptions.

WE have the great pain to announce the death of Professor Hughes Bennett of the University of Edinburgh. The wearing illness under which Dr. Bennett has suffered for some time has been known to most of his professional brethren; the touching fortitude with which he endured those sufferings, the brave determination with which he nerved himself to the last to the fulfilment of professional studies; and the force and vigour which animated his attenuated features when detailing the last great work which he directed, the Report of the Edinburgh Committee of the British Medical Association on the Antagonism of Medicines, fitly crowned the life of a man remarkable beyond any of his fellows for unflinching devotion to science, courageous defence of his personal and scientific convictions, unsparing denunciation of what he believed to be error, and resolute furtherance of the objects which he believed to be good for the university, the profession, and the science

which he loved so much. He died from the after-effects of lithotomy on a system weakened by constitutional disease. He bore himself nobly during life; and he faced death with courage, resignation, and faith. We shall, next week, endeavour to do justice to the life, works, and character, of this distinguished physician and biologist.

By a coincidence such as strikes the imagination forcibly in reviewing the moving panorama of worldly affairs, we have to notice in these succeeding lines the retirement, in full mental and bodily vigour, from London practice to a career of continued usefulness elsewhere, of a physician, friend, and namesake for whom Dr. Hughes Bennett, sixteen years ago, predicted with pain, but in obedience to the rules of scientific and clinical experience, a very early premature end. Dr. Henry Bennet, then in full practice in London as a gynaecologist, was, sixteen years since, warned by Dr. Bennett and others to set his affairs in order, and to retire from practice; for he was then suffering from lung-disease so acute and advanced that he could not, according to ordinary experience, count on more than six months' tenure of life. How bravely and well Dr. Bennet followed that advice; how wisely he abandoned his London labours, which had made him already famous, and were beginning to make him wealthy; how judiciously he applied to his own case the principles of treatment by climate and by personal hygiene; and how brilliantly he succeeded in reconstituting his health, is known to most men; for is it not told with clearness and graphic force in his varied writings; and have not thousands benefited by the application of the precepts and the imitation of the example which his experience afforded, and which his sound judgment and literary skill have recorded in books of universal repute and just popularity? Dr. Bennet retires this season definitely from practice in England, and will henceforth occupy himself solely with professional work during the winter at Mentone, leaving his summer free for well-earned relaxation. His career has afforded a rare example of versatile energy and steady well-directed thought. In saving his own life, he has been the means of guiding others into a path of safety little known, and hardly well-studied before he so accurately mapped it out.

THE retirement of Dr. Henry Bennet recalls the mind to a past era of uterine pathology. Trained by five years' work as *externe* and *interne* in the *services* of Velpeau, Jobert de Lamballe, Gendrin, Ricord, and their contemporaries in the Paris hospitals, he brought to this country a wide and varied knowledge of the new facts in uterine pathology which the speculum was the prime means of bringing to light. Fortified by his own observations over a large field here and in Paris, he overturned the school of which Lever and Ashwell were the exponents, and of which the leading gynaecologists of the day were disciples. Bennet unquestionably laid the foundation in this country of a new school, we may fairly say the new school of uterine pathology. He met with great hostility from a number of leading practitioners in the metropolis, but the truth steadily bore down all opposition; and when the fiat of disease removed him from his London practice, he had already won the confidence and convinced the reason of the profession generally, and was already earning an income of £4,000 a year, almost exclusively from consultation practice, and mainly from the country practitioners, who were less accessible to the influence of local metropolitan prejudices. In the battle which he fought, he soon found eminent fellow-combatants; and to speak of the uses of the speculum now as an essential basis of the investigation of uterine pathology and of clinical uterine treatment would be to expose oneself to the reproach of discoursing platitudes, as formerly it would have exposed one to the reproach of something little short of imposture and immorality.

THE remarkable success with which Dr. Henry Bennet has, under circumstances which called for the display of courage, judgment, and energy, twice carved out for himself a successful and useful career, recalls a *mot* of the late Dr. Henry Wright, a brilliant friend and pupil. Referring to his singular tact, energy, and judgment, Henry Wright used to say that "If Bennet were stranded on an iceberg in the Arctic

Ocean, he would infallibly create for himself a career among the whales, and end his life as consulting-physician to the North Pole, and director of a sanitarium at the Equator".

FOUND DROWNED.

"FOUND drowned", and "sudden death", are two pleasingly ambiguous forms of verdict in which coroners of the economic type, and juries of an easy turn of mind, are still wont largely to indulge. There are some circumstances in the evidence relating to Emma Chirms, whose body was found floating lately in the Worcester canal, which give peculiar point to the verdict. She was a servant; when last seen, she was "exceedingly cheerful", and "had never shown any depression of spirits". Further, "there was no evidence at all likely to suggest that the woman had committed suicide, or that she had recently suffered from melancholy". Whereupon, a boatman deposed that he had found her body floating in the water; and two policemen said that they had made a careful examination of the body, and had found no signs whatever of violence". Without further ado, without *post mortem* examination of any of the organs of the body, or of the contents of the stomach, the jury returned a verdict of "Found drowned". The intimation that the careful examination of the body is, at Birmingham, entrusted to two policemen, is, to be sure, an additional reason why no decent female should commit suicide; otherwise the utility of an inquiry of the sort, and the giving it a judicial character, seems anything but clear, unless indeed it were held in Middlesex, on a plan adopted to please the magistrates.

COLLEGIATE EXAMINATIONS.

THE Council of the Royal College of Surgeons will proceed to the election of three examiners on Wednesday, the 13th instant. Perhaps it will be interesting to them, and to the profession generally, to know the opinion formed just *half a century ago* by so great an authority as Sir Astley Paston Cooper, Bart., as to improving the manner of conducting the examinations of candidates for the diploma of membership of the College. In a letter addressed to William Lynn, Esq., Surgeon to the Westminster Hospital in 1825, when that gentleman was President of the College, he says:

"My dear Sir,—As I lecture this evening at 8 o'clock, I cannot possibly attend the meeting at the College. My suggestions for the improvement of ye examinations would be: 1st. That each person should attend two evenings; and that the first evening he should be examined in Anatomy, and the second in Surgery. 2nd. That each examiner should examine an individual applicant for examination, instead of two persons, as at present. Thirdly. That the person who examines in Anatomy should not examine the same individual in Surgery.—Yours very truly,

ASTLEY COOPER.

And, as showing the deep interest he took in this important matter, and desire to be present, he adds, by way of a postscript: "If I can, I will see you at 9 o'clock." This recommendation of just half a century ago is, we understand, likely to be adopted. Truly it may be said, "great bodies move slowly".

HEALTH OF THE CUSTOMS' OFFICERS.

THE report of Dr. Walter Dickson on the health of the outdoor officials of the customs possesses a peculiar interest, inasmuch as the complete system of registration of ages, occupation, dates and duration of sickness which prevails in the civil service give to these returns a greater exactitude than it is possible to attain in almost any other calling. The registration of sickness which necessarily prevails in the services gives it a special value and more exact data of the proportion of deaths to illness than is possible to obtain in private and public practice generally. The total strength of the outdoor establishment is 923, which, allowing for deductions from various causes, gives an average of 900. The mean age of those who died from disease or accident was 41 years, whilst those who were superannuated reached 56 years. The amount of sickness which occurred during the year among the staff was 534, the loss of time in consequence aggregating 11,223 days; whilst the deaths amounted, inclusive of two accidents, to 13 per

1,000, the average rate for several years past having been 12 per 1,000. This death-rate compared favourably with that of the whole metropolis, which amounted to 22.5 per 1,000. Dr. Dickson considers that this rate of sickness and death may be taken as being fairly typical of that of the adult community. We, however, are disposed to question this conclusion, inasmuch as the officers of the service are specially exposed to river fogs at all hours of the day and night, and hence peculiarly liable to disease of the respiratory organs. So apparent is this, that during the first quarter of the past year, when the fogs were most prevalent, there were 22 patients suffering from these diseases during 1,010 working days. In the last quarter, the same causes produced 36 patients; which aggregated 729 days. In the summer quarter, the patients numbered eight, and caused a working loss of 524 days. These latter cases may be therefore taken as chronic. During the summer months, gout causes a great amount of illness. The attacks seem to be irrespective of age, temperament, or personal habits, etc.; often most severe in abstemious men. In the majority of cases the malady is of hereditary character, and is influenced in a remarkable degree by the weather. Warmth and damp occurring in a generally dry season seem to be especially favourable to its development; on such occasions, as many as five cases have developed themselves. The return shows a remarkable immunity from zymotic diseases, notwithstanding the enormous number of foreign vessels which these officers have to inspect. The risk of contracting this class of disease, or of contracting or conveying infectious maladies, Dr. Dickson thinks is infinitesimally small. This may arise from the fact that the men are well fed and well clothed, and live generally speaking regular lives, without the weary anxiety and fluctuating income which fall to the lot of the artisan and lower middle class in other walks of life. They also, generally speaking, have an abundance of fresh air. Dr. Dickson's report is clear, concise, and full of useful information, and we should be glad to compare the health of his department with that of other branches of the Government service where similar strict records of sickness are kept.

SHALL WE DISPENSE OUR MEDICINES?

It is always well to hear both sides of a question. There is at present a strongly apparent current of opinion, among a large class of distinguished general practitioners, in favour of abolishing the old practice of supplying medicine, as a part of a general medical practice. On the other hand, a very large number, probably a considerable majority of practitioners still supply medicines. They contend that to cease to do so would be to cut off two-thirds of their income; and this not merely or mainly by reason of profit on the medicines, for the fee for attendance only is commonly as high as the old fee for attendance and medicine included, but because a prescription once given will often be used for years, and become even a family heirloom or the common property of a circle of friends, so that, as one practitioner lately wrote to us, "A patient subject to recurrent gout, who used to afford me an income of about £30 a year, has, since I gave him a prescription for a ten shilling fee, not been near me for three years; I meet him occasionally, and he salutes heartily sometimes with 'A famous prescription that of yours, doctor; it cost me only ten shillings, and I always have it made up when I feel the gout coming on, and it always cures me.' What is worse is, that he has given the same prescription to all his gouty friends, whom he would otherwise have recommended to me; and even the chemist makes it up now, and sells it as his 'famous gout pills and mixture'. Thus, for ten shillings, I have sold an income of, say fifty pounds a year; and I am not consoled by the reflection that my patient and his friends are really better off, for, though they are saving money, they are all, in all probability, abusing my alkaline colchicum mixture, and injuring their constitutions. But this warning they disregard, and, consequently, we are both probably worse off than we should have been if I had steadfastly refused to depart from the old ways." In America the rule is, we believe, pretty generally observed, that the prescription is not the property of the patient, but

of the doctor who writes it merely as a direction for this occasion, just as letters are ultimately the property of the writer; and that the fee pays only for the *user* of the prescription at the time mentioned on it. A chemist, therefore, will not make up a prescription more than once, unless redated by the writer, or by a qualified practitioner. Dr. T. H. Seyfert, in the *Philadelphia Medical Times*, advocates strongly, however, the return of medical practitioners to the practice of dispensing their own medicines. Among other things, he says:

"Perhaps one of the greatest inducements to recur to the old plan of dispensing, may be found in the pecuniary benefits to be derived therefrom. An eminent physician, in speaking of the general practitioners of England, declared that they would ultimately raise themselves to be the almost exclusive medical practitioners of the land; 'for low prices, with equal qualifications, will in the long run invariably carry the day'. People may be embarrassed in determining the qualifications of their medical attendants, but they are never confronted with this difficulty in estimating the expenses. Herein lies the chief attractive point of the 'homœopathic' practice. What can be more agreeable than to avoid taking the 'nasty medicine', which is almost as expensive as the doctor's visits? For this reason alone there are many who will employ these charlatans, while nature is working a cure, or until some alarming symptom induces them to drop the man of sugar and appeal to the wisdom of the 'old school' doctor, whom they usually regard as their 'sheet-anchor' in the hour of real trouble, but, like the sheet-anchor, he is only thought of when there is danger of a wreck. The druggist's bill is an item of no mean importance, particularly so to those in moderate circumstances, and we need not wonder that there exists a strong desire to escape a bill of this kind, which, in a case of tedious illness, is sometimes as large as that of the attending physician. It is said that a retired apothecary, upon being asked how he made his fortune, promptly responded, 'By selling aqua destillata'. Now, aqua *Schuykillensis*, though not so elegant, is in many instances quite as efficacious, and may be had for nothing. A few drops of aconite, nitre, or morphia disseminated through this vehicle will answer all the purposes of the same mixture put up in a bottle elaborately labelled, wrapped and tied, and will be the means of saving time, trouble, and expense.

"Many will be surprised at the number of remedies in daily demand that are, or can be, used in a very concentrated form, also at the number of solid substances capable of being held in strong solution. Dr. Squibb of New York has invented a ready way of accurately dispensing powerful fluids by using a pipette with a capacity of from one to thirty minims. This little instrument is used by plunging it into the liquid in the vial up to the minim mark which indicates the desired quantity, then, closing the upper end with the forefinger, the charge is transferred to the vessels in which the doses are to be mixed. Dr. Squibb also offers a list of forty-four articles of the active materia medica in their most potent and concentrated form.

"Did space permit, I might dwell upon the easy manner in which this mechanical duty may be performed, and enumerate the many valuable remedies that may be prepared in such a way as to occupy but a very small space in the pocket-case, from which they can be dispensed with advantage to ourselves and patients."

(*Brit. med. Journal*)

EPIDEMIC MEASLES AT FIJI.

THE account of Fiji during the continuance of the late epidemic, as described by an eyewitness in the *Sydney Morning Herald*, is of a most harrowing kind, recalling vividly Defoe's description of the plague of London.

"The death-rate is not yet made up, but the probability is that 40,000 Fijians died during the four months' plague. The native population of Fiji is now about one-third only of what it was when I landed here twenty-five years ago. Very few died of the measles, the majority dying of subsequent disease in the form of dysentery, congestion of the lungs, etc. Want of nourishment or starvation carried off thousands. All work was suspended for some months. You could pass through whole towns without meeting anyone in the streets, which were soon completely covered with grass. Entering a house, you would find men, women, and children, all lying down indiscriminately, some just attacked, some still in agony, and others dying. Some who were strong enough attempted suicide, and not always unsuccessfully. As the scourge became more permanent, four or five were buried together in one grave, and generally without religious service. In some cases, the dead were buried in the earthen floors of the houses; in others, just outside the house. The burials were hurried, and the probability is that some were buried alive. In many instances, the husband, wife,

and children all died. In one village all the women died, and in another all the men. It is interesting to read of the different mental effects produced by the tortures of disease. It is not surprising to find that some made fruitless appeals to their ancient gods. Some inland tribes, who had only recently embraced Christianity, considered that the disease was conveyed by the religious teachers, and they dismissed them, and then abandoned their new religion. Among these, some were for killing the teachers, but wiser counsels prevailed. It is said that one tribe buried alive the teacher's wife and children—whose husband and father had died of the plague—to stop infection. But while some in their distress fell back on their former superstitions, the greater number are said to have borne their calamity with fortitude, and to have suffered and died under the influences of Christianity."

THE PROPHYLAXIS OF CHOLERA.

THE BRITISH MEDICAL JOURNAL, of September 25th, contained a brief account of the opening meeting of the medical congress now sitting at Brussels. A letter from an occasional correspondent, giving his impressions of the *ensemble* of this interesting gathering, will be found in another column. Proceeding to the practical work of the congress in the section of medicine, the first question under consideration was the prophylaxis of cholera. M. Lefebvre, Professor at the University of Louvain, read his report on this question, and it was followed by a discussion, in which MM. Bonnafond, Sigmond, Semmolla (Naples), Dr. Drysdale, and Professor Lefebvre took part. The section ultimately adopted the following conclusions. I. The prophylaxis of Asiatic cholera should be based on as complete as possible an etiological idea of the disease.—II. Cholera is a specific disease; that is to say, it is produced by a morbid principle which is always alike, and it cannot be produced by other causes.—III. The essence of the choleric principle is unknown to us, in the same way as is the generating principle of small-pox, scarlatina, etc., but we possess very important information from the prophylactic point of view with regard to its origin, attributes, and the laws of its propagation and solution.—IV. Origin. The choleric miasma is spontaneously developed in certain countries of India, especially the Delta of the Ganges and the flat lands which surround Madras and Bombay. Springing from these original foci, it has migrated on different occasions to Europe, Africa, and America, constituting those different epidemics still within our memories. However, since these great epidemics, more limited explosions of Asiatic cholera have occurred. It is a question whether these explosions are due to the spontaneous production of the choleric miasma on the European soil, or if they must be attributed to the slow development of miasma, left as it were in reserve by the preceding Asiatic epidemic. This last is the opinion most generally adopted; but, however it may be, it is none the less true that the Indian cholera can acclimatise itself in Europe.—V. Attributes of the choleric miasma—1. This miasma becomes regenerated in the subject attacked by cholera, and is transported from hence to healthy individuals, in whom it induces the development of the disease; in other words, the cholera is essentially contagious. 2. The choleric miasma behaves after the fashion of soluble and volatile bodies; thus, it becomes dissolved in water, diffuses itself in the atmosphere, where it remains in a state of homogenous diffusion; that is to say, without accumulating in the sloping points. 3. The morbid power of the choleric miasma is less powerful and fatal in its action than other known miasmata and viruses. 4. It is not very lasting, and appears to be very easily destroyed, especially when the air is strongly ozonised. However, in certain confined conditions, sheltered from the air, it may last a long time. 5. This miasma is destroyed by a high temperature (1,000 deg. and more) and by a certain number of chemical agents with powerful affinities. This question calls for further study in order to arrive at a really practical precision and clearness. 6. Persons exposed to the action of the choleric miasma acquire after some time a kind of acclimatisation to it which protects them from the disease.—VI. Laws of the propagation of Asiatic cholera. The choleraic contagion is seated principally, perhaps exclusively, in the dejections of the patient (matters vomited, and especially intestinal evacuations). 2. It

may be carried from the sick person to healthy individuals by different vehicles, amongst which, after the ejecta, may be noted the patient, the corpse, the body linen and clothes worn by cholera patients, the rooms, ships, or carriages of which they have made use, the latrines, water which may have been contaminated by choleraic ejecta, say the air at a short distance only of some hundreds of metres, animals and merchandise which may have become impregnated with choleric miasmata.—VII. Choleraic impregnation and evolution. 1. The choleric miasma penetrates chiefly by the pulmonary and digestive passages. 2. The duration of incubation is generally very short. 3. Mental and hygienic conditions of a depressing nature favour the evolution of the choleraic poison.—VIII. The prophylaxis of cholera takes its rise from the following etiological ideas. The first indication is to destroy the original foci of the cholera in India and its secondary foci in Europe by sanitary works. The second maxim is to prevent the transport of the morbid principle into healthy countries by all really efficacious plans of isolation compatible with the exigencies of modern civilisation. The third prophylactic rule is to neutralise this principle by methods of disinfection still to be determined. The fourth precept consists in diminishing the ravages of cholera by well considered hygienic measures. Finally, the Congress hopes that the great sanitary works undertaken by England in India will be satisfactorily terminated, and will succeed in stamping out the Asiatic epidemic in its original home. The section admitted these conclusions with almost perfect unanimity. They are, in fact, the reproduction of those arrived at by the Vienna Congress in 1874. It will be observed that in these conclusions the word "quarantine" is replaced by "measures of isolation"; in fact, MM. Jaccoud, Sigmund of Vienna, and Semmolla of Naples have condemned the system of quarantine now in operation.

TRIPLETS IN A TENT.

DR. REES, Brightside, Sheffield, forwards to us a report of a case of triplets, which occurred at Canbrook, a suburb of Sheffield. The woman was confined in the open air in a gipsy camp, only sheltered by a blanket supported by saplings barely three feet in height. The children have since died, but the mother is doing well, notwithstanding the heavy rains and the fact of her lying on the bare ground. She has had seven children in this way before.

THE ARSENIC-EATERS OF STYRIA.

AT the annual congress of Natural Philosophers in Germany this week, Dr. Knapp is reported to have made some very interesting statements relative to the much-discussed practice of arsenic-eating in Styria. Among other things, he said:—

It is difficult to give any certain particulars as to the increase in number of arsenic-eaters. I have convinced myself that there exist many of them in Upper Styria, and also in Middle Styria; very many stable-boys, ostlers, woodcutters, and foresters are known to me as arsenic-eaters; even the female sex is addicted to the practice. Many began already at 17 or 18 years of age to take arsenic, and continued it to a great age. Most arsenic-eaters keep the matter secret, so that it is impossible to give accurate statistics. They all assign as their motives for indulging in the habit that it prevents illness; furthers their wish to look rosy and healthy; that it is a remedy against difficulty of breathing, and assists the digestion of indigestible food. A poacher in Upper Styria, who made experiments in my presence of eating arsenic, told me he had acquired courage by the habit. The appearance of the arsenic-eaters in all cases known to me is healthy and robust. I think only robust persons can become accustomed to the practice. Some of them attain a great age. Thus in Zeiring I saw a charcoal-burner upwards of 70 still strong and hearty, who, I was told, had taken arsenic for more than forty years. I heard, too, of a chamois-hunter of 81, who had long been used to eat arsenic. I never observed an arsenic cachezy in those addicted to the habit. It certainly happened once that such an arsenic-eater (a leather-dresser's apprentice in Ligist, 1865), while intoxicated, took too much, thereby poisoning himself severely. According to his own account, he had taken a piece as large as a bean. He entirely recovered, however, and ate arsenic afterwards, but more carefully. As far as my observations extend, white arsenic, namely, arsenic acid, As_2O_3 (also called flowers of arsenic), and the yellow arsenic, As_2S_3 (orpiment) are taken, and

that in a dry state, alone or on bread. The dose is, of course, very small at first, and is gradually increased, the largest quantity eaten in my presence by the poacher in Zeiring being fourteen *grammes*. A certain Matthew Schober, in Ligist, ate seven *grammes* and a half before me on April 17th, 1865. The intervals, too, at which arsenic is taken vary—every fortnight, every week, twice or three times a week. But all doubt as to the existence of arsenic eaters is now removed by the present experiments.

HYDROPHOBIA.

A CASE of hydrophobia terminated fatally at St. Thomas's Hospital on Saturday last. The victim, a boy, was bitten about five weeks ago.

CHOLERA IN INDIA.

WE learn from Indian advices that the usual outbreak of cholera which generally occurs at this season of the year has commenced. The epidemic, however, has not hitherto been of a severe character. At the latter end of August, several cases had occurred at the stations of Bhagoo, Ferozepore, Delhi, Morar, Lucknow, and Nowgong. The number of cases at each station was small, and the percentage of deaths not exceptionally high. Simla seems to be quite, and Umballa nearly clear of the disease, and the quarantine which was established at Kussowlie has been withdrawn.

THE WORCESTER INFIRMARY.

THE recent circumstances connected with the resignation of Dr. Inglis at the Worcester Infirmary, to which we have several times referred, have been considered at a meeting of the Worcestershire Medical Society held September 29th, 1875, when the following resolution was unanimously passed.

"This meeting has learned with much regret the differences which exist between the honorary medical staff and the Executive Committee of the Worcester Infirmary. Having confidence in the moderation of their professional brethren connected with it, this meeting assures them of their sympathy and approval in their attempts to obtain for themselves and their successors such protection by the rules as may be needful to secure them from unnecessary vexation in the responsible yet privileged position of honorary medical officers of that institution." This resolution confirms, and in all respects agrees with, the opinions which we have already expressed on this subject.

PECULIAR PEOPLE.

ISAIAH PAYNE, a member of the sect of Peculiar People, has been bound in the sum of £5 to come up for judgment when called upon by the Chelmsford magistrates. Considering that, through his neglect in calling in medical aid whilst his two children were suffering from fever, which terminated fatally with one child, and that his wife also caught the infection and died, the sentence appears to have been remarkably light. The wife was *particeps criminis* in the offence, as she refused to allow Dr. Fox, the medical officer of health, to enter the house. It is a fair presumption, therefore, to believe that she contributed to her own death by neglect of proper precautions; but it is certainly hard on the helpless children that parents should enjoy comparative immunity in the neglect of the commonest duties of humanity.

RECENT URBAN MORTALITY.

DURING last week, 4,874 births and 3,448 deaths were registered in London and twenty other large towns of the United Kingdom. The average annual death-rate was 23 per 1,000 persons living; and the rates in the several towns were as follows: Edinburgh, 17; London, Bristol, and Wolverhampton, 20; Portsmouth and Sheffield, 23; Dublin and Birmingham, 24; Glasgow, Leicester, and Sunderland, 25; Norwich and Newcastle-on-Tyne, 26; Manchester, 27; Liverpool, 28; Leeds and Nottingham, 29; Hull, 30; Oldham, 33; Bradford, 35; and Salford, 38. The average zymotic rate was 6.1; but was as high as 13.1 and 13.6 in Salford and Bradford. Scarlet fever was again fatal in Bradford and Bristol. Four fatal cases of small-pox were recorded in Leeds, where the disease threatens to become epidemic; the Small-pox Hospital in that town contained thirty-three small-pox patients on Saturday last, and, it is reported, that as many

more cases existed in different parts of the borough. In London, 2,127 births and 1,319 deaths were registered. The deaths were two above the average, and the death-rate was 20.0 per 1,000. There were 13 deaths from measles, 90 from scarlet fever, 12 from diphtheria, 49 from whooping-cough, 18 from different forms of fever, 125 from diarrhoea, and not one death from small-pox. In outer London, the general and zymotic death-rates were 16.6 and 3.6 per 1,000 respectively, against 20.0 and 4.7 in inner London. At Greenwich, the mean temperature of the air was 60.1 degs., or 4.7 degs. above the average of the week. Rain fell on each day of the week to the aggregate amount of two and a quarter inches.

SCOTLAND.

TYPHOID FEVER IN GLASGOW.

WE learn that an epidemic of typhoid fever has broken out in certain districts on the south side of the river. We understand that there are strong reasons to suppose that this epidemic owes its origin to milk from an infected farm, but it is not always easy to find absolute proofs of such a fact.

THE GLASGOW INFIRMARY AND THE HEALTH COMMITTEE.

IN reference to the Royal Infirmary, the dispute between it and the sanitary authorities of the city seems hardly at an end. As has been already noticed in these pages, the city local authority directed the attention of the infirmary managers to the fact that they were, in their opinion, illegally admitting cases of infectious disease from a conterminous local authority, without informing the sanitary authorities of Glasgow of the fact. The infirmary authorities were obviously in the wrong; but, instead of acknowledging their error, they have adopted the shabby and undignified policy of obstruction to the sanitary authorities of the city. They have been in the habit of supplying to the city a list of the cases of fever admitted to the infirmary, and the addresses of the patients; the only object of this being to allow the sanitary authorities to trace these cases, and use measures to prevent the spread of the disease. The policy adopted by the infirmary is to refuse such returns, simply out of spite, and so the public action of the Health Committee will be so far hindered. The infirmary authorities will soon awaken to the smallness of this policy when they find their subscriptions affected by it, and we have already heard of several subscribers who have refused their contributions till the matter is properly adjusted. The policy simply means this, if anything: We, the infirmary directors, are infallible, and having been found fault with—though we were in error—we refuse to have dealings with persons who can so far forget themselves as to impugn our infallibility.

IRELAND.

AT a late meeting of the Guardians of the Limerick Union, the salary of the medical officer was increased from £50 to £75 *per annum*.

LAST week, Her Grace the Duchess of Abercorn visited the Hospital for Incurables at Donnybrook, near Dublin, and distributed a large quantity of flowers among the patients, expressing herself much pleased with the Institution.

THE MAUNSELL MEMORIAL FUND.

WE are glad to state that the movement in favour of a substantial memorial to the late Dr. Maunsell has been successfully inaugurated, and has met with the unanimous support of the Dublin press. We would gladly quote the opinions of the Dublin journals with regard to our late friend, but it is sufficient to state that he was well known and much admired by Dublin editors. There were few Dublin journalists who were not willing to consult "Tom Maunsell", where medical,

sanitary, or Poor-law questions came to the front. We thank our Dublin cotemporaries for the generous manner in which they have written of our friend. At a meeting of the friends of the late Dr. Toler Maunsell, held on the 24th ult., Dr. H. Kennedy, Vice-President of the College of Physicians, presiding. The following resolutions were unanimously adopted: "That, considering the valuable services rendered by the late Dr. Daniel Toler Thomas Maunsell to the public and the medical profession, by his writings on the Poor-law and the Public Medical Services, and his zealous and untiring efforts to improve the position of the Poor-law medical officers throughout Ireland, his memory is entitled to some substantial mark of public respect." "That a subscription list be opened with a view of raising a Maunsell Memorial Fund. This fund to be applied to the educating and forwarding in life of Dr. Maunsell's family, who at present are insufficiently provided for." "That a committee, consisting of those present, with power to add to their number, be appointed with a view of carrying out the foregoing object." Dr. Speedy was appointed hon. treasurer, Drs. Grimshaw and Kenny hon. secretaries, and Mr. E. Spencer hon. assistant-secretary and treasurer. The treasurer announced that subscriptions to the amount of £130 had been already received, and that an account had been opened under the head of the "Maunsell Memorial Fund" in the Munster Bank, where, or by any of the committee or officers, subscriptions would be received. Dr. Haydon having been moved to the second chair, the proceedings terminated with a vote of thanks to Dr. Kennedy for presiding.

THE DUBLIN TENEMENT PROPRIETORS AND THE PUBLIC HEALTH ADMINISTRATION.

A MEETING was held on the 22nd ult. of the owners of tenement houses in Dublin. One object of the meeting seemed to be to try and oppose attempts to improve the sanitary condition of the dwellings of the poor in Dublin. The tenement owners were only represented by some twenty or thirty persons. The following circular fully expresses the objects of the meeting.

"SIR,—A society having been formed, entitled 'The House Proprietors', or Tenement Landlords' Protection Society', for the object of legally resisting the undue, unreasonable, unequal, unfair, oppressive, arbitrary, and often illegal proceedings of the sanitary authorities, as constituted in this city—we, without in the slightest wishing or meaning to offer any factious opposition to the administration of the Sanitary Acts, provided they be carried out in accordance with the true intention of the Legislature, do hereby invite every person having any interest in the matter to a cordial and determined co-operation, by at once joining the society and assist in making a stand against the virtual confiscation of our property, and to insist on evenhanded justice, as also to consider the means of remedying many grievances which we are obliged to submit to and suffer in connexion with the Landlord and Tenant Act."

We are disposed to believe, that the so-called "house proprietors of Dublin" will find that most of the ratepaying "house proprietors" in the better parts of the city will materially differ in opinion from them. The "virtual confiscation", we think, would more properly describe the position of the respectable citizens of Dublin, who are paying enormous poor and improvement rates as the result of the "rights" to breed disease and death, which are enjoyed by the tenement owners, who are possessed of about one-third of the city.

THE ROYAL COMMISSION ON THE FACTORY ACTS.

THE Factory Acts' Commission has held a sitting in Dublin. The information collected seems to have been of the scantiest character. We believe many persons willing to furnish information were unaware that the Commissioners were sitting in Dublin until the inquiry was nearly over. The inquiry elicited some very remarkable information with regard to the tailoring trade in Dublin. It seems that nearly all the tailoring business in Dublin is carried on upon what is called in trade phraseology "the sweating system", a plan not unknown in other towns. This system consists in a master tailor giving his work to an individual known as a "sweater", who seems to be a sort of foreman. This "sweater", it seems, is paid by the master by piecework. The

"sweater" employs a number of persons, men, women, and children, who make up work for him at a price much under that paid by the master tailor. This "sweating work" is all done at the workers' own houses, in order to avoid the Workshops Regulation Act, the result being that the work is carried on under most unhealthy conditions. It is stated that clothes are constantly made up in the most unhealthy and crowded tenements in Dublin; often in rooms with persons sick from contagious diseases. It is stated that but few of the Dublin master tailors have proper rooms for their workmen, and that members of the Public Health Committee of the city who are in the trade have their work made up under the sweating system. The Lord Mayor of Dublin himself is accused of promoting this system; while we believe that the statements are exaggerated to some extent, we have no doubt that there is too much foundation for some of the affirmations of the witnesses.

THE BELGIAN INTERNATIONAL CONGRESS.

[FROM A SPECIAL CORRESPONDENT.]

Brussels, 24th September, 1875.

THE Congrès Périodique International des Sciences Médicales, which is at present being held here, is now drawing to an end. To-morrow the meetings of the sections and the general meetings close; and a banquet in the Hôtel de Ville closes the proceedings.

This is one of the most interesting and active of medical organisations, and it is a pity that there are so few representatives of England here. Messrs. Bowman and Critchett, Dr. Chapman, and one or two others are present of their own accord; while America has sent six formal representatives, of whom, however, only two have as yet arrived. All other countries are well represented; even Turkey has sent three members to the Congress.

The arrangements differ greatly from those of the British Medical Association; and, while presenting the disadvantage of discouraging the element of individual original work, encourage a more thorough treatment of the leading questions of importance.

Weeks before the opening of the Congress, every member was made aware of the official subjects which had to be discussed; and, on the assembling of the Congress, these were minutely and conscientiously treated in the sections, and then brought before the general meetings for discussion and approval. The original communications followed in the section meetings after the official questions had been discussed.

The Congress was opened in the Palais Ducal by the King in person, and the members received the utmost hospitality from public and private quarters. The Secretary-General, M. Warlomont, has been kindness itself, and the kindness of him and his family to the strangers was most marked. The Bourgmestre, M. Anspach, gave a rout in the Hôtel de Ville, which was a brilliant success, and gave a tone of cordiality to the whole proceedings of the Congress. All the public works and museums were thrown open to the members, and the railway prices were diminished for them by one-half.

The Minister of the Interior gave a reception last night, and had provided everything that kindness could suggest for the pleasure of his guests.

The French *savants* are innumerable—it would be impossible to give the names of them; and men of eminence from Belgium, Holland, Denmark, Russia, etc., are all represented; while the German *savants* have sent Langenbeck of Berlin, Sigmund, Hebra, and Schmitzler of Vienna, and Grosz of Pesth.

The amount of work which has been got through is enormous, and I must content myself with a short notice of only a few points. The question of maternity hospitals was the most salient; and the warmth of the discussion was sometimes alarming, even for an assembly consisting mainly of our impulsive and animated French *confrères*. It was finally decided on the basis of suppressing large maternities and improving small ones.

Cholera received a great deal of attention, as also the question of prostitution.

In the Surgical Section, two days were occupied with the discussion of anæsthetics. Ether and chloroform were attacked and defended. Oré of Bordeaux and de Neffe were able advocates for the intravenous injection of chloral; and nitrous oxide found no one to say a word for it. I think I do not err in saying that the general opinion was that ether and chloroform are both sufficiently safe anæsthetics when carefully and skilfully administered.

The treatment of wounds was well discussed, though not at much length. Strangely enough, although the able orator who introduced the subject, Professor Debaïseux of Louvain, did every justice to the antiseptic treatment of Lister, it had not a single advocate whose appreciation of it was so thorough as it deserved, excepting Professor Langenbeck of Berlin. Some of the cases he had obtained by a method of his own, identical *in principle* with that of Lister, were as astonishing as the results obtained by Lister. Antiseptic surgery does not seem to suit the impetuous brilliancy of French surgeons.

To-morrow, little in comparison will be done, as the sections have finished the official programme.

MEDICAL ADVERTISING.

At a meeting of the North of England Branch of the British Medical Association, held at Sunderland on September 23rd—S. E. Piper, Esq., F.R.C.S., President—present, forty-one members of the Branch, Dr. J. W. Eastwood read a paper on the Prevalent Practice of Advertising Medical Works in the Non-Medical Press. At the close of the paper, Dr. Eastwood proposed the following resolution.

"That the members of this Branch regard the practice of advertising medical works in the non-medical press as injurious to the best interests of the profession, lowering to its dignity, and to be discountenanced by every means in their power."

The resolution was seconded by Mr. James Wilson, and supported by Mr. Mordey Douglas, Dr. Legat, and carried unanimously.

OPENING OF THE SESSION: REGISTRATION OF MEDICAL STUDENTS.

WE have more than once pointed out that the London medical student is subject to an unnecessary inconvenience in being called upon to "register" his tickets and the period of commencement of medical study at the Royal College of Surgeons, London, as well as at the office of the General Medical Council. The register of medical students of the General Medical Council is intended to supersede the individual registers of the separate examining boards, and is accepted in lieu of them by all the other medical corporations except the College of Surgeons. The reasons for the persistence of the College in maintaining its own registration, satisfactory at first, have now certainly ceased to have any weight. The registration of the College has always been exceedingly careful, and has been in the hands of an experienced officer, in whom the College places just confidence. It was not unnatural or unwise that it should hesitate to abolish a safeguard on which it had learnt to rely as a means of ascertaining that the initiation of study was duly effected, and that the full courses prescribed in the curriculum were duly undertaken; but we think now the accuracy and efficiency of the register of the Medical Council have been sufficiently secured by the tests of time and experience. We are very glad, therefore, to learn that the course which we have previously indicated as desirable is likely to be adopted, and that it is probable that this will be the last occasion on which medical students will be called upon to effect a double registration. The subject of our remonstrance has attracted renewed attention at the College, and it will probably be brought up for settlement at an early meeting of the Council.

GUY'S HOSPITAL.

AT Guy's Hospital, a large underground room, situated beneath the museum, has during the summer months undergone extensive alterations, to better adapt it for the preservation of subjects for dissection. This room is now capable of holding upwards of twenty subjects; and its ceiling has been so plastered as to prevent any escape of gases in the direction of the museum. The dissecting-room, demonstration theatre, and adjoining offices, have also been recoloured. On Wednesday last, we noticed eight subjects lying ready for dissection, and although some, as we were informed, had been preserved nearly two months, there was no odour likely to offend the susceptibilities of one quite unaccustomed to the atmosphere of a dissecting-room. In this respect the dissecting-room of to-day contrasts very favourably with that of former years, and the change is almost entirely due to the introduction of glycerine as a preservative. Not only is dissection rendered much more pleasant,

now that the bodies are carefully preserved, but it has become far less injurious to health—the diarrhoea of freshmen being much less frequent than formerly, whilst dissection-wounds are almost unknown.

The treasurer of the hospital is not yet sufficiently recovered from his recent illness to be able to be present at the introductory lecture to-day (Friday); in his absence the president, Lord Lawrence, is to distribute the medals and certificates gained during last session. The *Guy's Hospital Gazette*, which for a year has been conducted by the presidents of the Pupils' Physical Society, has just completed its sixth volume. During the recess, it has been a fortnightly journal, but, with the commencement of the new session, it will again appear once a week. It reports the principal medical and surgical cases in the wards, notes the surgical operations which are performed, gives occasional reports of the lectures by the staff, publishes a weekly list of the admissions into the wards, and details other most noteworthy incidents of the hospital. We are pleased to learn that it is well, though deservedly, supported by past and present Guy's men.

ST. MARY'S HOSPITAL.

THE authorities of this institution have taken advantage of the long vacation to effect very considerable repairs and alterations in the hospital buildings. More than 200 workmen have been engaged upon the work since the middle of July; and a portion of the building will be ready for the reception of patients during next week. It will be recollected by old St. Mary's men, that the water-closets were formerly placed at the ends of the wards, and were simply cut off from connection with the wards by double doors. They are now placed at the four angles of the building in four entirely new structures, and each water-closet is separated from its corresponding ward by a lobby having a thorough current of air from side-windows. The outer end of each ward is now occupied by three large windows, which, of course, afford extra ventilation. The committee have, however, still further increased the supply of fresh air to the wards by the introduction of numerous vertical tubes by which it is conveyed from both sides of the building, so that abundant supply is insured during all directions of the wind. The drainage of the building has been thoroughly examined, cleansed, and, where necessary, repaired. The out-patient department has been enlarged and improved. The whole of the interior of the building has been freshly painted, the ceilings lime-whited, etc., and the exterior has been cleansed and repainted. We understand that the cost of these works will not fall short of £10,000. In connection with the school department, we learn that a new class-room has been made, the museum freshly arranged, and thereby greatly improved, and that the mortuary and deadhouse have also been thoroughly renovated and repaired.

THE MIDDLESEX HOSPITAL MEDICAL COLLEGE.

THERE are few medical schools which have grown more rapidly during the last three or four years than the Middlesex, and some twelvemonths since it became evident to the authorities that additional accommodation would be needed to meet the requirements of the largely increasing number of students. With this object in view, extensive alterations and improvements have been made during the past vacation. In the first place, the chemistry theatre has been raised, and a new laboratory has been constructed over it, for the practical teaching of the chemistry class, while the room formerly used for that purpose has been rendered available for instruction in practical physiology. The dissecting room accommodation has been extended, and the sanitary arrangements have been perfected. A new curator's room has been built, and additional library space has been afforded for the disposal of a large and valuable collection of works generously presented to the school by the executors of the late Mr. Swann. The museum is now being furnished with new skylights, which will render every portion of it available for use, and greatly facilitate study. The office of curator of the museum has been associated with that of pathologist, an arrangement which is alike convenient and conducive to the practical teaching of morbid anatomy. Two college tutors have been appointed, and one of them is daily in attendance to advise students as to their reading and to explain difficulties; in addition to this, the College tutors hold classes in almost every subject comprised in the curriculum, rendering private instruction unnecessary. Mr. Hulke has been associated with Mr. De Morgan in the chair of Surgery, and the practical surgery class will be conducted by Mr. Lawson and Mr. Henry Morris. Mr. Thomas Taylor, late lecturer on chemistry, will deliver the first part of the chemical course this year, and the vacancy caused by the resignation of Mr. Hiesch has been filled up by the appointment of Mr. William Foster of Sidney Sussex College, Cambridge, to the chair of chemistry. Special attention is paid to the practical teaching in the wards and out-patient rooms, and the appointments of clinical clerks and dressers are so arranged that every student may hold both a clerkship and a

dressership for at least six months during his attendance on hospital practice.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.

THE winter session of this school will commence on Monday the 4th instant, when the introductory address by Mr. Davy, and the distribution of the prizes by the Rev. Canon Conway, are fixed for three o'clock, as the evening will be taken up with the triennial dinner at St. James's Hall.—We are requested to state that visitors will have an opportunity of going over the school buildings after the distribution of prizes.—This year, for the first time at Westminster, several subjects have been properly prepared and preserved so that the students will be able to commence dissecting without any loss of time.—Dr. Sturges was nominated on Tuesday, September 28th, for the post of Physician, and Dr. De Havilland Hall for that of Assistant-Physician. Their election by the governors, on Friday the 5th instant, is tolerably certain. The triennial dinner of the old students and friends of the Westminster Hospital Medical School will take place at the St. James's Hall, on Monday, October 4th, at seven p.m.; C. Holthouse, Esq., F.R.C.S., in the chair.

THE LIVERPOOL SCHOOL OF MEDICINE.

WE understand that Professor Humphry of Cambridge will be present at the opening of the Liverpool Royal Infirmary School of Medicine on Saturday, October 2nd, for the purpose of distributing the prizes; and that he will also be one of the guests at the annual dinner of the School, which takes place the same evening at the Adelphi Hotel.

THE MEDICAL SCHOOLS OF GLASGOW.

THE medical session in Glasgow will be opened on Tuesday, October 26th. We understand that Dr. George Buchanan, the Professor of Clinical Surgery, will inaugurate the session at the University by an address. The coming session at the University promises to be a very successful one. It may be remembered that at the beginning of last session there was some little inconvenience experienced by the fact that the Western Infirmary was opened for the reception of patients simultaneously with the opening of the classes. Of course, it could not be expected that matters would shape themselves at once into the most desirable form, and no doubt both teachers and students had to reconcile themselves to a few inconveniences. The experience of last session, however, has enabled the arrangements for the next to be satisfactorily made, and, no doubt, with all the modern appliances at the new hospital, matters will go on to the complete satisfaction of all concerned. We understand that, under the supervision of Dr. Joseph Coats, the pathological department of the hospital has been very completely arranged, and it is expected that the course of lectures this session will be held under much more favourable auspices than formerly. This gentleman now lectures entirely at the Western Infirmary, and on an independent footing, his lectures being recognised by the University as qualifying for degrees in medicine. Among the advantages which this session will present, we understand that this department will be furnished with a very complete stock of new microscopes, by means of which the course will be illustrated.

At the Royal Infirmary, the proposed school seems for this session to be in an expectant attitude. Dr. Cameron will lecture on surgery in the Infirmary, and his lectures have been recognised by the University. No other course has been recognised, we believe, on the grounds adverted to on a former occasion in these pages. The University is ready to recognise independent lecturers, but, if the Infirmary makes a complete school of medicine and arrogates to itself the appointment of lecturers on each branch, then the University will not give its countenance to such an arrangement. We are assured that a true competition would be welcome to many interested in the University; but, in order to do this, the Infirmary would require to recognise absolute free trade in teaching. Meanwhile, there is to be one other course of lectures at the Infirmary, that on medical jurisprudence, by Dr. William Mac Ewen.

QUEEN'S COLLEGE, BELFAST.

THE session here opens on October 10th. The lectures to medical classes begin on Tuesday, November 2nd. By far the greater number of students (medical) of Queen's College, Belfast, are matriculated. The matriculation examination will be held on Thursday and Saturday, October 21st and 23rd. There will be a supplemental matriculation on Tuesday, November 16th. Only after that examination will it be possible to state the number of medical students in attendance. The number last year was 215 for the winter session; the number of students during the summer session was 131.

ABSTRACTS OF
INTRODUCTORY ADDRESSES
 DELIVERED AT
**THE METROPOLITAN AND PROVINCIAL
 SCHOOLS,**
 On *OCTOBER 1st, 1875.*

ST. GEORGE'S HOSPITAL.

THE Introductory Lecture was delivered by Dr. ROBERT BARNES, Physician-Accoucheur.

Dr. Barnes observed that altered circumstances seemed to invite, if not to compel, those who have to give these addresses to select for their theme some of the wider and more general aspects of medicine; to endeavour to point out some of the relations of medicine to the public good; to expose some of the defects in the construction or administration of our laws that hinder the just and beneficent application of science to the public service. Thus, we may suggest to you some idea of the higher aims of the profession you have chosen, of the position you will occupy in relation to other professions and to society at large, and of the duties that devolve upon you in maintaining and extending that influence upon which the future welfare of mankind so largely depends. What was once called the "healing art" has now a far greater sphere than the term expresses. Medicine, in its modern sense and work, is "preventive" as well as "healing". Medicine is no longer simply an art directed to the alleviation or cure of individual suffering. Applied to the task of aiding in the administration of justice, of removing the causes of disease, of restricting or annihilating epidemics, of increasing the sum of national health, it becomes a moving power in government. State medicine, then, is the offspring and the complement of the "healing art". He hoped to be forgiven for pointing out that both religion and law will be strengthened the more they are brought into harmony with science. Each is the complement of the other two. But the day has come when science must lead. The last-born, perhaps, now that the day of her emancipation has arrived, the most vigorous, the most progressive, and therefore destined to exercise the greatest sway in the future. Theology and law are in their essence stagnant. Religion is wholly revealed. Presumption alone can add anything to its sublime and simple truth. Law, when not informed and vivified by science, is dogmatic—the slave of authority seeking a solution of its doubts in precedent, which is too often nothing more than error upon error crystallised by time. And so it must be with an almost purely subjective study. Deriving the bulk of his knowledge from oral or written tradition, the lawyer, according to the bent of his organisation, assimilates what he learns—makes it a part of himself. It thus undergoes a subjective transformation. And since men's minds differ in their constitution and construction, there results an infinite diversity of opinions, whilst there is no appeal but to the opinions of those who have gone before, and who from that very circumstance are more likely to be wrong than themselves. Hence those incessant conflicts in our law-courts, those frequent reversals of the decisions of one civil court by another, which are the despair of the uninitiated. If there were a court of appeal in criminal cases, reversals would probably be no less frequent; and still greater would be the difficulty of the Irishman, who, when asked to plead Guilty or Not guilty, replied, "Faith, how do I know till I'm tried". Recently the legislature has decreed certain changes in the machinery and proceedings of the law. He dared not, with profane hand, touch this mystery of mysteries. He hoped that the changes would result in more speedy justice and diminished bills of cost. There are certain flaws which are a real discredit to the law, which involve inconsistencies so gross as to be revolting, not alone to the scientific mind, but to the sense of the community. Of these, he instanced the well known practice when pregnancy is pleaded in bar of execution. The law directs that the prisoner shall be examined, not alone as to the bare fact of pregnancy—in itself sometimes no easy task for a skilled physician—but also as to whether she is "quick" with child. This latter fact it is often impossible to determine, and that for several reasons. In the first place, the so-called "quickening" is with many women an entirely subjective phenomenon—a sensation they think they perceive, but which is not perceptible by others. She may affirm that she is conscious of having quickened, and the examiner is not in a position to refute her assertion, because he or she may not obtain objective proof. In the next place, some women never consciously quicken at all, and the examiner may equally fail to

get evidence of the event; and many women quicken, or think they do, who are not pregnant. Again, the movement or impulse felt by the examiner, and which is presumed to be proof of a "quick" child, is often fallacious. The late Dr. Tyler Smith insisted that the movements felt by the mother and by the examiner were not produced by the child, but by the womb itself; and it is now known that these movements of the womb can be detected before the earliest period assigned for the quickening of the child. After all, then, it may be answered, the appeal was made to science in time, and no harm was done. The law directs the judge to empanel a jury of matrons, but does not preclude him or the Secretary of State from referring the decision to an expert. He did not believe that a pregnant woman, who pleads her pregnancy, will ever again be hanged on the verdict of a jury of matrons, unless, indeed, we are destined to see juries of matrons selected from legally qualified "medical women". This may happen when Macaulay's Lord Chancellor will be sitting on the woolsack with twins in her lap. Let us hope not before. But the absurdity, the barbarity of the law in this relation does not end here. The law of England makes it felony to attempt to procure abortion. All right-minded persons will admit the wisdom, the justice, the necessity of this provision. But then see how lamentable is the inconsistency of the law. It declares that a pregnant woman may be hanged; it makes it felony to attempt to procure abortion. Justice in this case sanctions—nay, commits homicide and foeticide, and with blind inconsistency punishes those who are guilty of the simple attempt to procure abortion. It is scarcely an extenuation to urge that the shocking consequences that would result if the letter of the law were rigorously carried out are practically avoided. It is no small evil that a law representing ignorance so gross should disfigure the statute-book, and that practice so clumsy and ridiculous should stain the records of our courts. The indirect influence of authorised error cannot fail to be pernicious. When the judges thus sanction the theory that the embryo in its early stage has no life, and may be treated as non-existent, how can it be expected that the ignorant masses will look upon the procuring abortion as a crime? This most deplorable doctrine is not accepted in other countries.

Here we are brought face to face with another relic of the age of ignorance which is still held in bigoted veneration. The irresponsibility of the insane is a question that is continually giving rise to the most painful discussions and the most conflicting decisions in our courts. In all civilised countries, it is a fundamental rule that responsibility is the attribute of reason, and, therefore, that insanity implies irresponsibility. In its dealing with this admitted principle, the courts practically abrogate the law. The judges, many years ago, in deliberation, put a definition upon the law, upon which their successors still hold themselves bound to act. This definition virtually declares that insanity does not carry irresponsibility. Their faith in the wisdom of their predecessors is absolute; their contempt for the teaching of modern science is unbounded. On a recent trial, a learned judge thus charged the jury: "It was not sufficient to show that the prisoner was insane, unless it was also shown that he did not know the nature of the act he was committing, or did not know that it was wrong. The jury must disabuse their minds of the medical notions as to insanity, for the reason that these medical men had not met the court upon the ground which they desired them to do, and that their opinions were founded on their own ideas as to what the law of insanity ought to be." Notwithstanding this charge, the jury, without any hesitation, found the prisoner not guilty, on the ground of insanity. What the judges declared to be the law was not really the law, but their arbitrary interpretation of it. We may claim the liberty to question whether this interpretation be the just one. It hangs upon an impossible postulate. No man who has been at one time sane, and therefore trained in accordance with the modes of thought of his fellow-men, can, even on becoming insane, be freed altogether from the influence of that training. The sense that killing is wrong may remain. It is transcendently absurd to look for a man so demented as not to know that striking another man on the head with an adze is likely to injure or kill him. Such a man can hardly be found in a lunatic asylum; and, *à fortiori*, can hardly be found out of one. He is a creation, not of nature, but a legal figment. Carried to its legitimate applications, the legal doctrine would simply abrogate the law of irresponsibility on the ground of insanity. The doctrine, then, must be revised by the light of science; for assuredly juries will continue to reject it. In spite of strong dictatorial charges, it is becoming practically obsolete, and it must at no distant date be given up even by the lawyers. The doctrine that it is right to punish, even to hang, madmen according to their knowledge of right and wrong, ought, in its logical application, to embrace a graduated scale of responsibility and penalties. The attempt to define the degrees in this scale will hardly be undertaken even by the trained analytical subtlety of lawyers. The truth is, that only one

line of demarcation is possible. That must be drawn with a resolute hand between sanity and insanity—responsibility on the one side, irresponsibility on the other. A not uncommon argument in favour of the legal interpretation is, that “the theoretical superiority of the medical criterion is far outweighed by the practical value of the judicial test. Its error on the score of excessive stringency is in practice corrected by the action of juries.” The fallacy of this reasoning is transparent. It is simply to assert that it is right to hang a madman if a jury will allow it. An argument of this genus was used—and too successfully—by the Attorney-General (Coleridge) who prosecuted the boy O’Connor for an attempted assault upon the Queen. He represented to the jury that it was better for the boy to be sent to prison for a definite term, than to an asylum. To prison he was sent; and there his insanity—the evidence in proof of which had been ridiculed at the trial—became manifest, and he had to go to an asylum after all. The prison did not cure him; it seldom does cure insanity. In that respect it is inferior to the gallows. The lecturer then referred to a matter immediately related to the theme: the mode of taking scientific evidence. He thought it would not be denied that, howsoever excellent the practice in force may appear to lawyers, it is eminently unsatisfactory to experts. Seldom, probably, does a scientific witness leave the box quite easy in mind as to whether he has spoken “the truth, the whole truth, and nothing but the truth”; and not seldom does he experience the mortification of finding what he said utterly wrested from its proper meaning by the perversity of counsel, or misunderstood by the court and jury. The theory that through the conflict of opposing counsel by examination and cross-examination, and the impartial interrogation of the court and jury, the truth is elicited, often signally fails in practice. The questions of counsel are generally prompted by hints gathered from books, or from experts sitting at their elbows. But they are very wary in accepting these suggestions. They may not understand them; and, if they do, they may in their discretion fear that the answer drawn will damage their case. Thus it constantly happens that the expert is only allowed to say so much of the truth as may suit the purpose of counsel, and every one knows how detached fragments of truth may be made to support a false argument. Those who are prepared to admit that the perfection of the practice in our courts is a question open to discussion, may probably see in the practice of foreign courts some points not unworthy of imitation. When an offence against the person is suspected, a judge of instruction appoints one or two experts to make the preliminary investigation; these make a formal report in writing, and this report is a document that has to stand the criticism of their professional brethren.

It must often happen that the scientific case as presented to a jury is inaccurate and imperfect, and that further inquiry would clear up all doubt. I am not lawyer enough to know whether the superior criminal courts have the power to do what a coroner or a magistrate sometimes does—that is, to adjourn a trial for the revision of the scientific conclusions; but I do not remember to have heard of such a course being adopted. Such a power of adjourning for further evidence would be the most efficacious check upon the perverse ingenuity of counsel in raising a cloud of doubt by insisting upon some defect or point omitted, and which could often be cleared up by proper reference. But this, the true scientific method, is not that of the law. As the case is presented, so it is dealt with. And here again we sometimes see the jury evades the difficulty by not agreeing to a verdict. A bungling proceeding, rather; for the result is simply a miscarriage of justice. In France, the president of the court may call for fresh scientific evidence, and appoint new experts; men so chosen are more likely to be free from bias than when they are chosen and paid by one side or the other. The way of taking the opinions of an expert in court is extremely ingenious. He is expected to hear the evidence; but he must not give his opinion upon it, for that would be to usurp the functions of the jury. He must answer upon a “hypothetical case” framed by the counsel upon data more or less accurately representing the facts given in evidence. It is not too much to say that the case so put often bears little resemblance to the true one; and the witness may be harassed by a number of discordant hypotheses. But the clumsiness of the process is best shown by the fact that it constantly breaks down; and judge and counsel are continually lapsing into common sense by putting questions directly bearing upon the case. The general effect of the mode of getting up evidence and of examining experts in courts of justice is to deter many of the best men from appearing as witnesses. This is a most serious injury to the public. In this way there is a virtual suppression or exclusion of the truth. Inexorable time warned him not to open new matter, or he might be tempted to say something about sanitary legislation. We have now a sanitary Parliament. Unfortunately, there are not half-a-dozen doctors in the house to inform and to control the overwhelming majority of

dilettants dabbles, or illegitimate practitioners in this branch of medicine; no very great success, therefore, has yet marked a policy whose intention is worthy of all praise. The most immediate result will at any rate be appreciated by our profession. The doctors are to do nearly all the work, with little moral help, at no small personal risk, for very little substantial pay. So much money is wanted for law, and for defensive and de-structive armaments, that we must economise somewhere. As a humble conservative, he ventured to hope that our chief will continue to educate his party to the conviction that a successful policy can only be carried out by a proper appeal to medical science, and a more liberal treatment of medical practitioners. The lecturer concluded by animating the students to a career of diligence, by reminding them of the glorious traditions of St. George’s. The light which illumined the immortal; Young, second only to Newton as a natural philosopher; Sir Matthew Baillie, one of those who laid the foundations of modern pathology; of Brodie, who for intellectual power was second to no surgeon of the present century,—had shed over the civilised world, shone with peculiar brightness here at the centre whence it beamed. These men might be called our scientific ancestors. But such do not die. Each had left his soul stamped upon works which would last whilst history recorded the achievements of genius for the delight, the instruction, and the welfare of mankind.

KING’S COLLEGE.

THE Introductory Lecture was delivered by Dr. JOHN CURNOW, Professor of Anatomy.

THE lecturer began by welcoming the students, and by referring to the changes in the medical staff during the past year, and to the completion of the new physiological laboratory, which is one of the most perfect in its teaching appliances either in Great Britain or on the Continent. After pointing out that the purpose of an introductory address was to benefit the student, and not primarily to instruct the lay public, he passed on to the question of “Medical Education, its Spirit and its Method”. Preliminary or general education was defective, and the standard low, and should be improved, in order that the student of medicine should not have to start under such disadvantages as at present; for, generally speaking, his training in the classics was very superficial, he possessed little knowledge of physics, and was entirely unacquainted with the most elementary facts and laws of biology. Those whose powers of observation and reasoning had been called forth during school-life had an immeasurable advantage; and the innovation by which a scientific training had of late years, in a few cases, taken the place of an early apprenticeship to the practical details of medicine and surgery, was greatly to be commended. The medical sciences were to be mastered in their liberal as well as in their technical aspects; for, although most students were fairly well informed in the latter, the benefits of mental discipline and of correct habits of thought were too little appreciated. Questions of mere utility were frequently allowed to overrule the advantages derived from a cultivation of the powers of observation and of the faculties of instituting proper experimental inquiries, and drawing just conclusions from them. Hence students rested too much on authoritative teachings, and made little use of their individual judgment, which was so necessary in their after-practice. Demonstration of everything that can be shown is the all-important means of education. Although this system had been greatly developed in late years, yet it was merely a return to the older plan of instruction, which had been temporarily thrust aside by the lecture-system, whose office was more to guide than to educate. Physiology particularly was now in need of this means for imparting a knowledge of its conclusions and the facts on which they were based; and the lecturer hoped that no penal regulations would retard the recent advances in extending or in teaching this science. Progress in medicine was “a function of two variables”, direct observation and novel experimentation; and an education of the faculties by which these could be secured was the chief essential. After showing that anatomy, physiology, and chemistry were the great means of obtaining this result, and referring to the care with which they were taught, as far as the healthy body was concerned, the lecturer thought that the teaching of morbid anatomy, and especially of pathology, might be improved and made more practical. He next adverted to the charms of scientific pursuits, especially of those which dealt with the phenomena of life; and to their uses in correcting the inevitable tendency of a purely mathematical training to lead us to expect definite results. In the medical sciences, probable and approximate data only could be obtained; and the anticipation of grasping all the factors engaged in the production of a diseased state, and of possessing certain and reliable means of combating it, was quite Utopian. The practical side or *art* of healing is, therefore, not necessarily dependent on theory; and

so especial care must be taken to acquire as good a knowledge as is possible by "bedside" study. Neither the scientific nor the practical excludes the other, but should be cultivated side by side. He alone is learned who reduceth his learning to practice; and practical skill without learning degrades our profession to the level of the days of barber-surgery and mediæval medicine. The history of medicine was then appealed to, in order to show that the scientific portion had reflected in every age the state of the sciences in general and the phases of speculative thought. Still a large amount of medical practice of great value was purely traditional; and this comprised the employment of many very important drugs. It was here that such scope was found for individual skill and dexterity. Some striking examples were quoted, where remedies had been neglected for long periods, and then again brought into every-day practice, so that the importance of tradition might be quite evident. The stages through which medicine had passed indicated that every succeeding age had drawn a wider circle round the knowledge of its predecessor; and the same process was still going on, and would go on in the future. Medical education two centuries ago was contrasted with the present method; and the address was concluded by pointing out the life-long nature of all education, the advantages of order, method, and a proper spirit in its pursuit, and the necessity of a never-ending patience for its consummation.

ST. THOMAS'S HOSPITAL.

THE Introductory Lecture was delivered by Dr. J. F. PAYNE, Assistant-Physician and Demonstrator of Morbid Anatomy.

The lecturer commenced by stating that he should take for his special topic the character and duties of the student, leaving further professional questions to other occasions. He thought the four years of student life would suggest by themselves far more than could be satisfactorily discussed in a single lecture. He thought the gradual disuse of the old words pupil and apprentice, and the gradual recognition of the position of a medical student in the commonwealth of learning, good signs. The profession of a student taken by itself was one of the highest a man could engage in, quite independently of its relations to after life. It was unfortunate that local and other circumstances had made medical students in England an isolated body, and not united them, as in other European countries, with the students of other faculties. But students should remember that, even if they did not strictly form part of an academical body, they might cultivate the academical spirit, a love of learning, a high standard of refinement, and a dignified *esprit de corps*. There was no reason why they should not attain these, as well as those did who were receiving what is called a liberal education. It was a mistake to draw too sharp a line between liberal and professional training. Studies not avowedly professional might be pursued in a purely technical spirit, as was often the case with classics and mathematics; while some professions, such as medicine, included in their curriculum a very great deal of what was necessary to make up liberal education. What is learnt is less important than how it is learnt. Medical studies offered, by their alliance with the physical sciences, all the advantages of one of the most powerful instruments of education—viz., scientific research. This alliance might be made as important to the medical profession as, after the revival of learning, the mastery of Greek and Latin literature was to the professions of law and theology. Their influence springs from their being associated with the dominant ideas of the day. But medicine is not only allied with the physical sciences; it is itself very largely imbued, if not wholly, with the scientific spirit. But it was necessary to inquire, What is the scientific spirit? This is difficult to fix in any form of words; but a very clear idea may be formed, by way of contrast, in tracing the history of an ancient pursuit like that of medicine, which has survived many phases of intellectual development. Examples were given to show how far medical science in former days fell short of scientific precision; and how greatly the moderns, though yet far from perfect, had improved in this respect. Some of the medical sciences were passed in review; and it was shown that, in anatomy and chemistry, the student possessed types of the two chief kinds of sciences, that of observation and that of experiment; while physiology, still in a transitional state, showed the immense increase of power gained by the introduction of experimental methods. Books were a great difficulty with the scientific student. Though continually misleading, by tempting the student to substitute words for things, they were still indispensable for understanding the things. The best style of text-book was that which, like a traveller's guide-book, was unintelligible without the objects. Some persons feared that too much science was now learnt in medical schools, and that the students became incapacitated for practical work. If this were true, it could only be because the so-called "science" was bad, and consisted of words only. True science is the

most practical of all things. Equally mistaken is the notion that there is some kind of practical science less rigorous and difficult than genuine knowledge, which may be a cheap substitute for it; but nothing of this kind can ever be useful in the long run. Finally, a word was necessary with regard to examinations. The present system had many evils; but in a practical profession, at all events, some system was quite indispensable, since the public demanded from us a guarantee of knowledge and capacity. The important thing for the student to remember is, that examinations are primarily for the benefit of those examined; and it is in a high sense most important to the candidate himself to know whether he is fit to undertake the responsible and arduous functions of a medical practitioner.

GUY'S HOSPITAL.

THE Introductory Lecture was given by Dr. STEVENSON, Lecturer on Chemistry.

The lecturer took up as his topic the Study of Medicine. He made reference to the varying esteem in which the profession of medicine had been regarded in different ages, showing that it has not been invariably in periods of the greatest culture and enlightenment that its professors have been most honoured. Taking a hopeful view of the future, he combated the assertion of Dr. Gregory, which has recently been publicly referred to, that medicine will soon cease to be considered a liberal profession; and asserted that on the members of the profession it depends whether medicine shall be regarded as a liberal profession or not. Should gain, greed, and applause be the aims of our profession, the worst anticipations may be expected to be fulfilled; whilst if knowledge of disease, culture, and an honourable professional spirit, be dominant, the medical profession need not fear adverse criticism. The qualifications necessary for the study of medicine were next touched upon, and thoroughness of study inculcated, the acquisition of accurate knowledge and a sound judgment. In the acquisition of these, the teacher can but assist; and, the requisite opportunities being given, it rested with the student to make right use of them. In the more detailed exposition of his subject, Dr. Stevenson drew a distinction between the preliminary and more scientific studies which first engage the attention of the student: the basis of medicine, and the study of medicine proper (in which term are included medicine and surgery in all their branches). When natural science first began to make rapid strides, too much was expected to be the immediate and direct result of scientific study: all our old notions were to be overturned and superseded. Such, however, has not been entirely the case; and now the mutual relations of science and medicine are, perhaps, better understood. Anatomy, chemistry, and physiology, were next considered; and then it was pointed out that these are ancillary to the study of clinical medicine, which, indeed, is to be the central object of the student. The mutual relations of patients and students were also dealt with. The desirability of making a study of preventive medicine and the use of statistics, in determining the healthiness or unhealthiness of communities, received notice; and it was urged that it should no longer be possible to say that medical men, as a rule, care nothing for sanitary science, and even view it with suspicion. The system of stimulating students by prizes was also defended, where not carried to excess; as also the moderate indulgence in manly sports. The lecturer concluded with an exhortation to the students manfully and at all times to do their duty to the profession and to their patients, and not cease the study of medicine when a qualification to practise it had been obtained, but to make it a life-long study.

SHEFFIELD MEDICAL SCHOOL.

THE Introductory Lecture was delivered by Dr. YOUNG, Lecturer on Materia Medica.

Dr. Young had much pleasure, in the name of his colleagues, in welcoming back the old students, as well as holding out a hearty reception to those who were there for the first time; he highly complimented the students of last year, and asked the beginners to take pattern from them in their industrious application to studies, kindly behaviour to each other, and general good conduct. He referred to the medical profession as a noble one, though sometimes basely represented in some of its members. There was in it more scope for all the finer talents with which an all-wise Creator had endowed humanity than in any other calling or profession. There was no doubt it was true, and he was sorry for it, that the practice of medicine and surgery had lost much of its inherent dignity by the ruling passion of modern times; viz., the spirit of trade. By many, a liberal art was degraded into a common trade; this is observable in manifold ways, such as in the great number of special hospitals; some necessary, no doubt, but the great ma-

tority more injurious than useful. Gave a short sketch of the early history of medicine, that from the earliest times, and amongst every tribe and race of men, certain believed-in remedies had always existed for the cure of disease; and, to give relief from pain, some of the most useful medicines of our *Pharmacopœia* were used in much the same way as now, such as opium, iron, etc. Still the development of the science had been slow; prejudices of one kind or another always being thrown in the way, retarding its progress. Instanced the valuable discovery of Jenner as an example: a discovery that had probably saved more lives than have been sacrificed on the battle-fields of the earth was for a considerable time ridiculed by many of the most eminent medical men of their day. In our day, a change for the better has taken place; anything good was now readily received and adopted. Hoped each student had considered what it was, as a medical man, he would have to do with; if he have, he will have found that medicine, in its broadest sense, is perhaps the most difficult of studies; it occupies itself with the most abstruse of all problems; viz., life and organisation, etc. This word "life" means a great deal; doctors must try to understand it as far as possible. You have to learn that each organ and tissue has a life of its own; its study seems exhaustless; it is, therefore, necessary for your own sakes that you give an enthusiastic diligence in all departments of the school; it is not by merely listening to a lecture on a given subject is going to make you master of it; he who trusts solely to his lecturer will probably fail; self, and self alone, can make a man master of any subject. Lectures are principally intended as a guide to study, etc. Your lecturer does not profess to do much more than simply steer the course you ought to take. You will find the agents used for the annihilation of disease are nearly all double-edged swords, able to cut two ways, able to destroy as well as restore; knowing which, it is your duty to leave nothing undone, so as to be masters of the science. The first things to be learned were anatomy, physiology, and chemistry; they were not the first by mere accident; it is on these three subjects that the great temple of medicine can be built. Referred to the results of the recent examinations of the Royal College of Surgeons in proof of this. The licensing boards were becoming more and more alive to the necessity of the first departments being not merely "crammed" into a man, but rooted and grounded in him. There was nothing to frighten beginners in the results of the examinations as published, only a wholesome lesson. The ignominy of being "plucked" is, in the great majority of cases, the result of non-self-reliance and application; it was a necessary a man should work, and, compared with what work is considered in these days, it was downright hard work. If any thought the study of the practice of medicine was a mere empirical art, a mere routine, he was much mistaken; if there were any here, the best advice he could give was, do not come back again; let this day terminate your medical studies. He then gave some hints as to how the first year's man ought to study. In anatomy, he specially impressed the importance of knowing well the osseous system before commencing the soft parts. Physiology was most important; it taught how the organs he dissected in the dead body acted in life. Chemistry was every day becoming more and more important; our large populations are calling loudly to medicine in sanitary matters. He advised the second and third year students to be good pathologists; he thought the importance of pathology was not sufficiently realised. He put great stress on the importance of a regular attendance in the wards of the hospital. In conclusion, he said he thought it advisable that medical men should not devote themselves exclusively to medical studies; they ought rather to give themselves up to the pursuit of general knowledge, keeping in view the main thing, but still cultivating such other branches as bear more or less upon medicine generally. Medicine was a progressive science, and could only be studied from a broad platform.

ASSOCIATION INTELLIGENCE.

YORKSHIRE, AND EAST YORK AND NORTH LINCOLN BRANCHES.

It having been decided by the respective Councils of the above Branches that the autumnal meeting shall be held conjointly at the York Museum on October 13th, 1875, members of these Branches intending to read papers or cases are requested to forward the title to either of the Secretaries on or before the 27th instant, so that a notice thereof may be included in the circular convening the meeting.

Dinner at the Station Hotel at 5 o'clock. Tickets (exclusive of wine) 7s. 6d. each.

W. PROCTER, M.D., York, } Hon.
R. H. NICHOLSON, Hull, } Secs.

York, September 18th, 1875.

COMMITTEE OF COUNCIL: NOTICE OF MEETING.

A MEETING of the Committee of Council will be held at the Office of the Association, 36, Great Queen Street, London, on Tuesday, the 12th day of October next, at Three o'clock in the afternoon.

FRANCIS FOWKE,
General Secretary.

36, Great Queen Street, London, W.C., September 23rd, 1875.

SOUTH-EASTERN BRANCH: COUNCIL MEETING.

A MEETING of the Executive Council of this Branch will be held at the Terminus Hotel, London Bridge, on Wednesday, October 6th, at 3.15 P.M.

CHARLES PARSONS, M.D., *Honorary Secretary.*
Dover, September 29th, 1875.

WEST SOMERSET BRANCH.

THE autumnal meeting of this Branch will be held at the Railway Hotel, Taunton, on Thursday, October 14th, at 5 o'clock.

The following question has been settled by the Council as the one on which members should be invited to express their opinion at the said meeting after dinner:—"Is the disuse of Bloodletting in the Treatment of Disease in accordance with the principles of Pathology?"

Dr. Cordwint proposes to read a paper "On Tissue-Change in Fevers".

Dinner (on the table at 5 o'clock), 4s. a head, exclusive of wine.

W. M. KELLY, M.D., *Honorary Secretary.*
Taunton, September 16th, 1875.

BATH AND BRISTOL BRANCH.

THE first ordinary meeting of the Session will be held at the York House, Bath, on Thursday, October 28th, at 7.15 P.M.: W. M. CLARKE, Esq., President.

R. S. FOWLER, Bath, } *Honorary Secretaries.*
E. C. BOARD, Clifton. }

Bath, September 24th, 1875.

STAFFORDSHIRE BRANCH.

THE second annual meeting of this Branch will be held at the London and North Western Railway Hotel, Stafford, on Thursday, October 28th, at 2.30 P.M. precisely. President, R. GARNER, Esq., F.L.S. The President-elect (H. DAY, M.D., F.R.C.P.) will deliver an address.

Dinner at 5 P.M. precisely. Tickets 10s. 6d. each, exclusive of wine.

VINCENT JACKSON, } *Honorary Secretaries.*
RALPH GOODALL, }

Wolverhampton, September 27th, 1875.

SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT.

THE next meeting of the above Branch will be held at the White Hart Hotel, Reigate, on Thursday, October 14th, at 4 P.M.; J. WALTERS, M.B., in the Chair.

Dr. Dady will read a paper on Tetanoid Affections associated with Imperfect Development of the Cranium.

Mr. Gandy: Notes on some Cases of Puerperal Fever.

Mr. Hallowes: Cases of Cerebral and Spinal Hæmorrhage.

Dr. Holman will move a resolution with reference to advertisement of medical works.

Dr. Walters: On the Treatment of Colles' Fracture, and will exhibit pathological specimens.

Dinner at the White Hart Hotel at 6 P.M. Tickets 6s., exclusive of wine.

JOHN H. GALTON, M.D., *Honorary Secretary.*

Woodside, Anerley Road, S.E., September 27th, 1875.

SOUTHERN BRANCH: SOUTH-EAST HANTS DISTRICT.

THE next ordinary meeting of the above Branch will be held at the India Arms Hotel, Gosport, on Wednesday, October 13th, at 4.30 P.M.

Notice has been received of the following communications:—

1. Dr. W. Hoare: Venesection.

2. Surgeon-General J. Mouat, V.C., C.B.: Pyæmia.

3. Dr. Ward Cousins: Case of large Cystic Tumour of Lower Jaw.

Dinner will be provided at 6.15 P.M.; charge 6s., exclusive of wine. Members intending to be present are requested to communicate with Dr. Kealy, Gosport, on or before October 10th.

J. WARD COUSINS, *Honorary Secretary.*
Southsea, September 23rd, 1875.

NORTH OF ENGLAND BRANCH.

THE autumnal meeting was held in the Queen's Hotel, Sunderland, on Thursday, September 23rd; the President, S. E. PIPER, Esq., F.R.C.S., in the Chair. There were present forty-one members and two visitors, one of whom was Professor De Chaumont, Netley.

Papers.—The following papers were read.

1. Dr. J. W. Eastwood: The Prevalent Practice of Advertising Medical Works in the Non-medical Press. Dr. Eastwood proposed; "That the members of this Branch regard the practice of advertising medical works in the non-medical press as injurious to the best interests of the profession, lowering to its dignity, and to be discontinued by every means in their power." The resolution was seconded by Mr. James Wilson, and supported by Mr. Mordey Douglas, Dr. Legat, and carried unanimously.

2. C. J. Jeaffreson, Esq.: Remarks on some of the Recent Advances in Surgical Pathology and Therapeutics.

3. Edward Jepson, jun., Esq.: The Mechanical Treatment of Intestinal Obstruction.—Mr. Jepson also showed a Tumour, "cystic", which had been removed *post mortem* from the neck. The tumour was about the size of a child's head.

4. G. B. Morgan, Esq., recounted the particulars of a case of Cystic Tumour of the Neck, which he had removed, and afterwards treated by the antiseptic treatment.

5. Dr. Ayre Smith: Report of a Case of Femoral Aneurism treated by Pressure. The pressure had been applied with the thumb. The patient was exhibited.

Dinner.—The members and their friends, to the number of thirty-four, afterwards dined together; the President in the chair; and the Honorary Secretary, Dr. Philipson, in the vice-chair.

MIDLAND BRANCH: QUARTERLY MEETING.

THE quarterly meeting of the above Branch took place at Matlock Bath on Thursday, September 23rd; A. H. DOLMAN, Esq., President. In consequence of the very unfavourable state of the weather, the attendance was not so large as expected. After inspecting Willersley Castle and Grounds (permission having been kindly given by the owner, F. Arkwright, Esq.), the members, to the number of twelve, adjourned to the New Bath Hotel.

Papers.—The following papers were read.

1. Beverley Morris, M.D., Nottingham: Spontaneous Cure of Ovarian Cysts.

2. W. Webb, M.D., Wirksworth: The Waters of Matlock.

3. J. W. Baker, Esq., Derby: Cases of Ununited Fracture.

Dinner.—A good dinner was duly discussed, and an agreeable evening spent.

PUBLIC HEALTH

AND

POOR-LAW MEDICAL SERVICES.

SOCIETY OF MEDICAL OFFICERS OF HEALTH FOR SOUTH WALES AND MONMOUTHSHIRE.

A MEETING of this Society was held at Neath on September 21st, when the following resolution was passed: "That it is expedient that a Society of Officers of Health for South Wales and Monmouthshire be formed, and it is hereby resolved that it shall be constituted."

The President and other officers were then elected for the ensuing year. *President:* T. J. Dyke, F.R.C.S. (Merthyr). *Vice-Presidents:* G. Ryding, M.D. (Neath), and Mr. D. P. Saer (Pembroke). *Treasurer:* E. Davies (Swansea). *Committee:* J. Rogers (Swansea), H. J. Paine (Cardiff), B. Thomas (Llanelli), R. Smythe (Abergavenny), G. Griffith (Pembroke), and W. M. North (Cardigan). *Secretary:* E. R. Morgan (Neath).

The meetings shall take place twice a year, on the last Tuesdays in March and September.

The Bye-laws were then framed, and ordered to be printed and circulated among all the Officers of Health, inviting them to co-operate.

About fourteen sat down to dinner, and a very pleasant afternoon was spent.

Mr. D. P. Saer (Pembroke), Vice-President, gave notice that he would read a paper on Disinfectants at the next meeting.

POOR-LAW MEDICAL APPOINTMENTS.

ADAMS, R. S., M.R.C.S., appointed Medical Officer for the Lymington District of the Lymington Union, *vice* N. Adams, Esq., resigned.
WATERWORTH, E. A., M.D., appointed Medical Officer for the Carisbrooke District of the Isle of Wight Union, *vice* E. P. Wilkins, L.R.C.P.Ed., resigned.

MILITARY AND NAVAL MEDICAL SERVICES.

AN INSTRUCTIVE INQUEST.

THE extreme economy with which the army authorities are endeavouring to carry out the "unification" of the Army Medical Department is leading to results of which the dark side was exemplified at a recent inquest at Aldershot, which is, we imagine, likely to attract the attention of all who are interested in the welfare of the soldier. It so happened that, after a considerable period of treatment in the insane ward of the Aldershot South Camp divisional hospital, a private of the 78th Highlanders managed to make his escape, and was found dead on August 24th, with his throat cut. On inquiring into the circumstances of the case, the coroner naturally expressed some surprise at the defective supervision which could render such an accident possible; and evidence was taken to show that, owing to constant changes in the medical attendants on the deceased, great confusion had arisen, not only in the records, but in the general arrangements of the hospital. Considering that the patient appears to have been transferred to the care of nine successive doctors within the space of one month, we can hardly wonder that this divided responsibility led to disastrous consequences, and that the coroner felt it his duty to censure in severe terms a system which seems specially devised to frustrate sound professional treatment. We understand that Sir Thomas Steele has ordered a court of inquiry to make careful investigation into all these facts; and we feel that further comment would be unbecoming until we learn the verdict pronounced by the thoroughly competent tribunal which will shortly assemble for this purpose.

OBITUARY.

THE LATE GEORGE ROSS, M.D.

GEORGE ROSS, Graduate of the University of St. Andrew's, M.D., L.R.C.P. Edin., M.R.C.S. Eng., etc., was born at Stonehouse, Devon, on August 2nd, 1815, and was educated at Penzance Grammar School. In 1832, he entered the medical profession as a pupil of Mr. T. G. Phillips of Albion Street, Hyde Park. During his stay with this gentleman, he attended St. George's Hospital. At an early age, he developed a taste for literature. When 20, he wrote leading articles on æsthetical subjects for a weekly paper, tales and poetry for a monthly magazine, and various reviews, including one for the Royal Academy. Soon after leaving Mr. Phillips, he went to reside with and assist Mr. Asbury of Enfield, in whose extensive practice he acquired a large amount of clinical experience. While at Enfield, he wrote various papers, amongst others those on Typhus Fever, published in the *Lancet* in 1842. A year or two after this, papers on Digestion and Nutrition appeared in the same journal. In these papers, he established from his experiments the fact then in dispute, that lactic acid was found in the stomach, but not in the intestines. He afterwards contributed to the same periodical papers on Albuminuria, Epidemic Influenza, Cholera, and some political articles. His first essay in political life occurred in connection with the "General Medical Protection Assembly". When the memorable National Association was established, overtures were made to him to undertake the office of secretary, which duty he accepted and performed for many years, and resigned only when its labours had become incompatible with increasing professional duties. During the time of his connection with the Association, and while that body was battling for professional rights, he wrote all the political leaders in the *Medical Times*. In the year 1852, Dr. Ross established, in conjunction with the late Mr. Yearsley, the *Medical Circular*, of which he was for many years sole editor. It was in this journal that he ventilated the idea of a system of cottage hospitals, following up the leader which appeared in the issue of August 8th, 1858, and in which the conception was first advanced by an article on September 22nd of the same year, wherein the scheme is more thoroughly enunciated. The general acceptance which this plan of suburban cottage hospitals has obtained is now well known in the profession, although it is not so generally known in whose fertile brain it originated. It was also in this periodical his remarkable annual addresses to medical students appeared.

About the year 1854, he became a member of the corporation of London, taking an active part in all sanitary business, such as improving

the dwellings of the poor, establishing baths and wash-houses, and especially in bringing to a successful issue the project of covering Smithfield with a new dead meat market, for which, on his retirement from the Common Council, a testimonial was presented to him by the Ward-mote which he represented. In the year 1869, Dr. Ross was appointed Medical Officer of Health for St. Giles's and Bloomsbury, which post he held, with the highest credit and usefulness, until his death. Dr. Ross filled various positions, and in all was an active and able worker. He was a member of the Commission of Sewers, of the Charity Organisation Society, Vice-President of the Society of Medical Officers of Health, a member of the Civil Engineering Committee and the Sanitary Subcommittee of the International Exhibition, 1874, etc. Dr. Ross was a man of whom the age has reason to be proud; always interested and active in every movement of progress and philanthropy, and earnestly employed in promoting the welfare of the masses. He was a man of great and versatile mental powers, who could think for himself and judge for himself. A student all his life; art studies as much occupying his hours of recreation as science his graver moments. His character was marked by devotion and indomitable energy; kind of heart and gentle of manner, he was loved and esteemed by all who knew him.

Dr. Ross married, in 1849, Mary, eldest surviving daughter of John Hunter, Esq., of 11, Hart Street, Bloomsbury, who, with three sons and one daughter, survive to mourn his loss. He departed this life on September 26th. *Requiescat in pace.*

G. L. COOPER, F.R.C.S.

We have to record the death of Mr. George Lewis Cooper, which took place on the 17th instant. The deceased surgeon, who was sixty-five at the time of his death, was a nephew of the late Samuel Cooper, F.R.S., for many years professor of surgery at University College, and author of the well-known surgical dictionary. He received his professional education at St. Bartholomew's Hospital, University College, and Paris, and was admitted a member of the College of Surgeons in 1834, and a fellow in 1843. Mr. Cooper was surgeon to the Bloomsbury Dispensary in Great Russell Street, the National Vaccine Institution, and teacher of vaccination at University College Medical School and at the Great Northern station. He was the author of *The Life of Samuel Cooper, Esq.*, in *Cooper's Surgical Dictionary*, vol. ii, new edition by Mr. Lane; besides numerous contributions to the medical periodicals.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, September 16th, 1875.

Archer, Robert Kendray, Cathcart Hill, Highgate
Dearden, John Alfred, Douglas, Isle of Man
Todd, John, Union Road, Tufnell Park, N.

The following gentlemen also on the same day passed their primary professional examination.

Cant, William John, Queen's College, Birmingham
Pratt, Alfred, Queen's College, Birmingham

The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, September 23rd, 1875.

Jackson, Ernest Carr, 91, Harley Street, W.
Scott, William Edward, 7, Robert Street, Hampstead Road

The following gentlemen also on the same day passed their primary professional examination.

Dell, Joseph Francis, Guy's Hospital
Harvey, Thomas Prickard, London Hospital

MEDICAL VACANCIES.

The following vacancies are announced:—

BRISTOL HOSPITAL FOR SICK CHILDREN—House-Surgeon. Salary, £100 per annum, with furnished rooms, coal, gas, and attendance. Applications on or before the 7th instant.

CITY DISPENSARY, Watling Street—Physician. Applications on or before the 8th instant.

COUNTY TIPPERARY INFIRMARY—Surgeon. Salary, £100 per annum. Applications on or before the 16th instant.

DENBIGHSHIRE INFIRMARY—House-Surgeon. Salary, £85 per annum, with board, lodging, and washing. Applications on or before the 16th instant.

DONCASTER INFIRMARY—House-Surgeon. Salary, £100 per annum, with board and lodging. Applications to be made on or before the 18th instant.

ESSEX and COLCHESTER HOSPITAL—House-Surgeon and Apothecary. Salary, £80 per annum, with board and lodging. Applications on or before the 7th instant.

GLOUCESTER COUNTY ASYLUM—Junior Assistant Medical Officer. Salary, £80 per annum, with board, lodging, and washing. Applications on or before the 18th instant.

HASLINGDEN UNION—Medical Officer for the Accrington District. Salary, £60 per annum.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST—Resident Clinical Assistant. Applications to be made on or before the 4th inst.

INVERNESS DISTRICT ASYLUM—Assistant Medical Officer. Salary, £70 per annum, with bed, board, and washing. Applications on or before the 14th instant.

LONDON HOSPITAL—Assistant Obstetric Physician.

NEWCASTLE-UPON-TYNE UNION—Medical Officer for the First District. Salary, £50 per annum.

NORTH WALES COUNTIES LUNATIC ASYLUM, Denbigh—Assistant Medical Officer. Salary, £100 per annum, with board, lodging, and washing. A knowledge of Welsh indispensable. Applications to be made on or before the 7th instant.

NORWICH DISPENSARY—Salary, £120 per annum, with unfurnished residence and apartments.

PEMBROKE UNION—Medical Officer for the First District.

RICHMOND INFIRMARY—House-Surgeon. Salary, £80 per annum, with board and lodging. Applications on or before the 25th instant.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road—House-Physician. Applications to be made on or before the 2nd instant.

ROYAL ISLE OF WIGHT INFIRMARY, Ryde—House-Surgeon and Secretary. Salary, £40 per annum, with board, lodging, and washing. Applications on or before the 25th instant.

SETTLE UNION—Medical Officer and Public Vaccinator for the Bentham District. Salary, £40 per annum, and fees. Applications on or before the 16th inst.

STROUD GENERAL HOSPITAL—House-Surgeon.

TIVERTON INFIRMARY and DISPENSARY—House-Surgeon and Dispenser. Salary, £100 per annum, with furnished apartments, coals, gas, and attendance.

TORRINGTON UNION—Medical Officer for the Peters Marland District. Salary, £43 per annum.

WEST NORFOLK and LYNN HOSPITAL—House-Surgeon and Secretary. Salary, £100 per annum, with board, lodging, and washing. Applications on or before the 2nd instant.

WEST SUSSEX, EAST HANTS, and CHICHESTER GENERAL INFIRMARY and DISPENSARY—House-Surgeon. Salary, £80 per annum, and £20 per annum as Secretary, with board, lodging, and washing. Applications to be made on or before the 23rd inst.—Assistant House-Surgeon to dispense. Salary, £20 per annum, with board, lodging, and washing. Applications to be made immediately.

WORCESTER GENERAL INFIRMARY—Physician. Applications on or before the 23rd instant.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

ADDY, Boughton, M.D., Lond., M.R.C.S., L.S.A., appointed Honorary Medical Officer to the Pendleton Branch of the Salford Royal Hospital.

BEVERLEY, R. Morris, B.A., M.D., M.R.C.P., appointed Physician to the Hospital for Women, Nottingham.

BOWER, David, L.F.P. and S., Arthroath, Forfarshire, appointed Resident Medical Superintendent to the Saughton Hall Asylum, near Edinburgh.

*DOUGLAS-LITHGOW, R. A., L.R.C.P. Ed., L.R.C.S. Ed., L.S.A., appointed Government Medical Inspector for the Port of Wisbeach by the Board of Trade.

*ELDER, George, M.B., C.M., appointed Surgeon to the Hospital for Women, Nottingham.

*PEELE, Edward, L.K.Q.C.P.I., L.R.C.S.I., appointed Physician to the South City Dispensary, Dublin.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTHS.

CLOSTON.—On September 25th, at Tipperlina House, Morningside Place, Edinburgh, the wife of *T. S. Clouston, M.D., F.R.C.P.E., Physician-Superintendent, Royal Edinburgh Asylum, of a son.

FOX.—On September 10th, 1875, at Widford, near Chelmsford, Essex, the wife of Dr. Cornelius Fox, Medical Officer of Health of East, Central, and South Essex, of a daughter.

OLIVER.—On September 18th, at West End Park, Harrogate, the wife of George Oliver, M.D., Lond., of a daughter.

WORKMAN.—On September 29th, at Titherley, Teignmouth, the wife of *Charles J. Workman, M.D., of a daughter.

MARRIAGE.

SPURGIN—STEWART.—At All Saints, Hull, on September 23rd, *William Henry Spurgin, Esq., of Maryport, to Emma, eldest daughter of the late Edward Stewart, Esq., of York.

DEATH.

LAWTON.—On September 23rd, at her father's residence, 34, St. Giles's Street, Oxford, Hannah Elizabeth, only daughter of J. R. Symm, and beloved wife of *Joseph Lawton, Surgeon, late of Torquay.

CHILD KILLED BY A CHICKEN.—We (*Atlanta Journal*, August 1875) find in the *Keme Daily Commercial* a notice of this extraordinary occurrence in the case of an infant child of Mr. A. J. Langley, living near Gadsden, Alabama. The child, eighteen months old, whilst at play in the yard, was furiously attacked by a rooster, knocked down, and spurred several times. Dr. Ewing, who attended, states that one stroke of the spur had entered the brain through an open suture of the skull, and resulted in death to the child. The doctor thinks this the first case of the kind in the history of the world.

OPERATION DAYS AT THE HOSPITALS.

- MONDAY** Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.
- TUESDAY** Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.
- WEDNESDAY** .. St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.
- THURSDAY** St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 3 P.M.
- FRIDAY** Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.
- SATURDAY** St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M. and 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

- WEDNESDAY**.—Obstetrical Society of London, 8 P.M. Dr. George Roper, "On Prolapse of the Funis during Labour"; Dr. Galabin, "On the occurrence in Normal Labour of Lateral Obliquity of the Fœtal Head"; Pr. Heywood Smith, "Notes of a Case of Ruptured Vagina during Labour, with recovery"; Mr. F. H. Gervis, "Report of a Case of Inversio Uteri"; and other communications.—Royal Microscopical Society, 8 P.M. Dr. C. T. Hudson, M.A., "On a new species of *Meliceita*".
- FRIDAY**.—Clinical Society of London, 8.30 P.M. Mr. Brudenell Carter, "On the Operation of Iridectomy, as performed for optical purposes"; Dr. Southey, "On a Case of Idiopathic Tetanus".

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

WE are greatly indebted to Dr. J. Norris Mackey, the honorary secretary of the Northern Counties (Scotland) Branch of the Association, for the kindly words in which he expresses, on behalf of the Branch, "the general feeling of continued appreciation of the manner in which the JOURNAL is conducted".

EARLY MENSTRUATION.

SIR.—I have recently been attending a lady in her confinement (Sept. 6th), which was difficult. Being a primipara aged 38, she was delivered with forceps of a fine female child, who on the fifth day commenced to menstruate, and continued to be "unwell" for nearly four days. Previously to this, she was very restless. I attributed this to her mother not being able to feed her: she was fed on milk and water. On the appearance of this discharge, she became quiet and good, and has continued to thrive.

I have mentioned this case to a gentleman (one of great experience) who has never seen a case in so young a child; another gentleman informs me it is of frequent occurrence. The youngest mentioned in the books I have looked into is nine months. Any one giving information on this subject will oblige me.—I am, etc., Wigan, September 25th, 1875. SAMUEL CATHCART.

W. A. CARLIN, M.D. (Lincoln).—Any person legally registered under the Medical Act, or under the Pharmacy Act, can dispense medicines. For the purposes of a hospital, a dispenser need not possess any registerable qualification, but it is desirable that he or she should have one.

GELSEMINUM SEMPERVIRENS.

SIR.—Under the heading "Selections from Journals", in the JOURNAL of September 18th, p. 368, there is an account of the "gelseminum sempervirens" as an anti-neuralgic. I should be glad to know where, or by what means, I can obtain this drug, or a preparation of it.—You will greatly oblige your most obedient servant, C. S. WILLS, Surgeon.

The Barracks, Ashton-under-Lyne, Lancashire, September 28th, 1875.

H. G. D. begs permission to thank the gentlemen who were kind enough to reply to his questions respecting medical practice in America.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

PRESENTATION COPIES.

THE Editor of the BRITISH MEDICAL JOURNAL will much oblige by giving an opinion on the following. B. has written a professional book on a special subject, and only advertises in the professional journals, but presents copies to several non-professional friends and well-wishers. 1. Does B. commit a breach of professional etiquette by so doing? 2. Has not B. a perfect right to present copies of his professional work to non-professional friends without laying himself open to the charge of acting unprofessionally? 3. Would you consider that this amounted to unprofessional advertising? C.

*. * B. has an undoubted right to present a few copies to personal friends of any of his works in which he has reason to believe that they feel a personal and friendly interest; but there is reason to doubt how far such a present would be acceptable or in good taste.

BIBLIOPHILE.—There is in the library of the British Museum an indited MS. of "John of Arden, giving the case of John of Gaunt having "a clappe and retention of ye urine". His works are in the library of the College of Surgeons.

POISONING BY LABURNUM.

MR. HENRY WILLIS, of 58, Old Broad Street, informs the *Times* that a horse was recently brought out of his meadow in very great pain, and afterwards vomited very much. The same circumstance occurred on two subsequent occasions, but not on the following days. Feeling sure that the horse must have eaten something poisonous, Mr. Willis examined most carefully a book upon the poisonous plants of England, and found that the laburnum was poisonous. He then cut down all the branches of laburnum within the reach of a horse. No harm has since occurred. This circumstance, he adds, fully confirms the paragraph in the BRITISH MEDICAL JOURNAL, which has been extensively quoted by the leading daily press, of so many children in Forest Gate School having been poisoned by eating the root of laburnum, supposing it to be stick-liquorice.

AN OLD MEMBER, A GUARDIAN, AND OTHERS.—Yes, there have been great changes in the regulations since you became a member. Consult our Educational Number, specially written for the object; it will give you all the desired information, both as to metropolitan and provincial schools. We cannot undertake to recommend particular hospitals.

PALPITATION OF THE HEART PRECEDING HEMIPLEGIA.

SIR.—Dr. Lane's very interesting cases of palpitation in connection with epilepsy, in JOURNAL of September 18th, call to my mind the following analogous case.

D. H., an exceedingly temperate man, aged 56, complained to me on May 25th of violent palpitation and "dizziness". The heart was quite healthy. On the 29th, symptoms of paralysis of the left side set in, deepening in intensity to total loss of motive power about June 5th. After some improvement, he had a relapse on July 2nd. On July 10th, apoplexy set in, and he died in twelve hours.

In this case, as in Dr. Lane's, there was probably paralysis of the inhibitory fibres of the vagus.—I am, yours faithfully, W. MUNRO, M.D., C.M. Cupar Fife, September 23rd, 1875.

DR. J. EWENS, Cerne Abbas, wishes to hear of some institution, in or near London or elsewhere, which receives *pauper* imbecile children not altogether suited for an ordinary lunatic asylum.

POISONING BY COAL-GAS.

SIR.—I am reminded by the interesting paper of Dr. Lockie in last week's JOURNAL of a nearly similar case that occurred to me nearly two years since. A press of engagements, however, prevented me taking notes of it at the time, but one or two salient points are strongly impressed on my memory. The patient was a youth of about 18, a gentleman's groom; he slept in a loft over the coach-house, and was found between eight and nine o'clock one morning by the coachman insensible in his bed, with the gas-tap fully turned. The coachman stopped the tap, threw open the window, and then for his own sake quickly descended the ladder. He ventured back again, however, in a few minutes, when the air had become more respirable. I was then sent for. I was much struck by the intense purple flush of the face and the heat of the forehead. The pupils were dilated, and very slightly sensitive to light. There was no sign of consciousness. There was vomited matter on the pillow and bedclothes, and a semi-fluid motion in the chamber utensil. I at first, in addition to directing as much air as possible into the room, applied only an evaporating lotion to the head; but there being no sensible improvement after a couple of hours, I then had a bag of ice applied to the head continuously. Within a very short time after this application, symptoms of improvement were manifested. On being loudly spoken to and shaken, there were some signs of consciousness, and these signs steadily increased, so that by the evening of the same day consciousness and sensibility were complete. The next day the patient was almost quite himself. The account he gave of the transaction was, that entering his room in the dark, he groped his way to the gas-bracket, first turned the tap, and then felt for his matches, but found the box empty, and so quickly undressed in the dark and tumbled into bed, forgetting, he supposes, to close the gas-tap. He had no recollection of having had his bowels opened in the night; but he must have got out of bed in a half-conscious state for this purpose, the poison seeming to have shown its first effect on the gastro-intestinal tract. He had taken nothing out of the regular way for his supper.

The practical point that impressed me in this case was the marked good effect of extreme continuous cold to the head.—I am, sir, yours etc., September 26th, 1875. T. MORLEY ROOKE, M.D. Lond.

MALTA FEVER AND CHAGRES FEVER.

DR. F. FEYRE PORCHER, Physician to the City Hospital, Charleston, S.C., writes to us under date September 8th, 1875:—"In reading the paper by W. C. M'Lean, M.D., C.E., in your number for August 21st, 1875, on "Malta Fever", I was struck with the resemblance which it seemed to bear to a form of fever sometimes brought here by persons who have contracted it in the Isthmus of Panama, and known as "chagres fever". I had several cases under my care, when physician to the Marine Hospital in this city, between the years 1855 and 1861, and there is a case in our City Hospital at present. This species or variety of fever may be well known to you; but I would state that it is distinguished by its protracted character, the absence of marked exacerbations, and high elevation of temperature, its not yielding to quinine, but requiring arsenious acid for its management, etc.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

PAYMENT FOR SICKNESS RETURNS.

SIR,—All district medical officers and some medical officers of health will, no doubt, be pleased to know that the Local Government Board consider "that it is competent for urban sanitary authorities, if they think proper to do so, to enter into an arrangement to pay district medical officers reasonable remuneration for supplying the medical officer of health with information which he requires for the efficient discharge of his duties." Why wait for death? Let us have sickness returns—was and is still the cry. But, it may be asked, Why wait for sickness? The new Public Health Act, in one of its rare compulsory clauses, provides that "it shall be the duty of every local authority to cause to be made from time to time inspection of their district, with a view to ascertain what nuisances exist calling for abatement under the powers of this Act, and to enforce the provisions of this Act in order to abate the same." It is evidently intended that the officer appointed by the local authority should not sit with folded hands waiting for nuisances, sickness, and death, to be reported to him; he should inspect his district, make house-to-house visitation, and search for, "in order to abate," nuisances injurious to health.—I am, sir, your obedient servant,
GEORGE RENDEL.

Treverbyn, Forest Hill, S.E., Sept. 20th, 1875.

THE BIOGRAPHER.—Yes, the gentleman in question agrees with a writer in the *Saturday Review*, that there are occasions when adherence to the maxim *De mortuis nil nisi bonum* is as idle as well as a foolish, and in some degree immoral, hypocrisy.

PREVENTION OF NAIL-BITING.

SIR,—To check nail-biting, I have found the best way to be the application of styptic colloid (tannin in colloid) in a thin line at the end of each nail. It dries on quickly, forming a film, the bitter taste of which acts as a reminder. It must be reapplied, however, whenever the hands have been washed.—I am, sir, yours faithfully,
T. C.

Erith, S.E., September 27th, 1875.

SIR,—In your issue of to-day's date, A Member says he would be pleased to hear of any suggestion for the cure of an inveterate habit of biting finger-nails. Before I began medicine, I did cure a college friend of mine of the same inveterate habit, and now for the benefit of A Member will relate the mode of treatment. I first made my patient promise that he would continue, or allow me to continue, any treatment till he was cured, being fully convinced that my mode would eventually succeed. The promise being given, I secured a good stout ruler and sat next to him during all the lectures, and when ever he attempted—for I did never allow him to get his fingers as far as his mouth to bite his nails—(finger-nails, I mean, for A Member is particular), I came down on his fingers with a vengeance. He first demurred, but, upon my reminding him of his promise, he allowed me to proceed. The cure was perfect in three weeks.

This treatment has the recommendation of being simple, safe, and effectual: the complication to be most dreaded is an acute attack of periostitis, but even this is less to be dreaded than the awful and "inveterate habit of biting finger-nails."

Hoping these suggestions will be of service to A Member, I remain, yours obediently,
C. F. C.

Staleybridge, September 25th, 1875.

GALVANIC SUTURES.—The application of galvanism in the form of galvanic sutures for the purpose of inducing the union by first intention of poorly nourished and imperfectly organised surfaces, has been first made by Professor Pipping-köld of Heisingfors. In vol. iii, No. 2, of the *Berlin Beiträge zur Geburtshilfe*, 1874, he reports two cases of vesico-vaginal fistula, which had resisted repeated attempts at an operative cure, and in which the surroundings of the fistula were composed chiefly of cicatricial tissue, the vitality of which was extremely low. These fistulae he united, after paring the edges, by means of alternate sutures of silver-plated copper and of iron wire, with the object of stimulating the low vitality of the parts, and in both cases with perfect success. That the supposed galvanic action of these sutures is not purely imaginary was demonstrated by his colleague Professor Hällstén, who found that when a silver and iron-wire suture were connected with the galvanometer, the maximum deflection of the needle of that instrument was 90 deg., the average deflection 35 deg.; when, on the other hand, the galvanometer was connected with two iron or two silver-wire sutures, the maximum deflection was 15 deg. to 20 deg., the average about 0 deg. This latter result would prove that every metallic suture, when bathed in the vaginal and vesical fluids, acquires a certain degree of galvanic power. Only a series of operations performed on cases which had previously withstood all attempts at cure by the ordinary suture would, of course, absolutely prove the value of this method.

CAPSICUM IN DELIRIUM È POTU.

SIR,—In the many notices of the treatment of dipsomania in your JOURNAL, the only forms in which I have observed capsicum recommended are either the tincture, or the powder made into pill or bolus, so that a man requiring a large dose must face either a terrifying number of bulky pills, a not very tempting draught, or certainly a very ugly bolus. I venture, therefore, to suggest capsicum as equally efficient, and, indeed, very agreeable, when made into pills, and nicely coated with sugar or otherwise. I have for some time used capsicum as an ingredient in some aperient and "dinner" pills, and prefer it greatly to the Cayenne pepper, which is not always easy to make into a good pill-mass, and of which even three grains will make as large a pill as most patients would care to swallow. Of capsicum I have never given more than half a grain, and do not pretend to say to what limit the dose may be safely increased, but of course to a much further extent. When I add to the above, that capsicum may be procured at about one shilling per ounce, I think I have said enough to obtain for it the notice of some of your readers. I have sometimes blended capsicum and its preparations for producing a hot smarting at the anus during and after defecation, but it generally ceases on discontinuing the drug. I should say that capsicum is sold generally as a thick viscid brown fluid.—I am, etc.,
W. J. HARAM WOOD, L.R.C.P. & S. Edin., M.R.C.S. Eng.

12, Red Lion Street, Boston, September 4th, 1875.

CHEMICAL POLYSYLLABLES.

In a recent paper on Muscarin in a German periodical, the authors refer to a non-poisonous principle in the *amanita muscaria*, which agrees in all essentials with hydroxathyltrimethylammoniumhydrat, and they remark that amanitin must be considered as a hydroxathyltrimethylammoniumbase.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, no later than Thursday, twelve o'clock.

PARTNERSHIP À LA MODE.

SIR,—Will you kindly favour me with your opinion on the following case? A and B. are in partnership on equal terms. A is a member of the Society of Apothecaries, and orders drugs for the firm and groceries for himself from the Hall. In settling accounts, A, as a member of the Apothecaries' Society, claims and appropriates the discount on the total amount including both drugs and groceries, although it is expressly stated in the deed of partnership that profits and losses are to be equally divided.—I am, sir, your obedient servant,
INQUIRER.

. This is a question which we hardly feel called upon to answer. It would, however, appear on the face of the facts, that discount on the purchase of drugs must be equally shared by both partners; it is otherwise on groceries, which are matters entirely outside the partnership.

W. L.—The following lines, a translation from the Greek pastoral poet Moschus, would perhaps, be applicable, though severe.

"His mind is wicked, but his speech is sweet;
His word and meaning are not like at all—
His word is honey and his meaning gall.
He is a mischievous, deceitful cild (fellow),
Beguiles with falsehood, laughs at the beguiled."

We are indebted to correspondents for the following periodicals, containing news reports, and other matters of medical interest:—The Bristol Daily Post; The Evening News; The Sheffield Post; The Metropolitan; The Hlyth Weekly News; The Edinburgh Daily Review; The Glasgow Herald; The Western Daily Press; The Merthyr Telegraph; The Leighton Buzzard Observer; The Bristol Daily Times and Mirror; The Derby and Chesterfield Reporter; The Lincolnshire Herald; The Sunderland Daily Echo; The Co-operative and Financial Review; The South Wales Daily News; The Macclesfield Courier; The Melbourne Argus; The Southampton Times and Hampshire Express; The Jarroo Express; The Birmingham Daily Post; The League Journal; the Sheffield and Rotherham Independent; etc.

Materialism. By J. M. Winn, M.D., M.R.C.P. London: R. Hardwicke, 19, Piccadilly. 1875.
Sanitary Report for the Province of Oudh. 1874.

REMARKS

ON

THE STUDY AND PRACTICE OF PUBLIC MEDICINE:

Being the Introductory Address delivered at the opening of the Winter Session in University College, October 4th, 1875.

By WM. H. CORFIELD, M.A., M.D. (Oxon.), F.R.C.P. (Lond.),
Professor of Hygiene and Public Health.

GENTLEMEN,—In opening the Session here, it is customary for the one who addresses you, either to lay before you an outline of the studies you are going to pursue during your career, and to advise you how best to prosecute them; or to discuss some topic of especial medical interest at the time; or to do a little of both. As most of the public lectures given on medical topics of late years have related more or less to sanitary matters, as sanitary questions absorb the greatest amount of interest at the present day, and as not only medical men but all classes of society are interested in them to the highest degree, as they are now made political affairs, and a prime minister comes to us with his famous paraphrase, *Sanitas sanitatum, omnia sanitas*; and, as the teaching of sanitary science was first started here on a separate footing, and is now being brought into a position of greater prominence, you will hardly be surprised if I consider it my duty as well as my pleasure, to seize this opportunity of attempting to impress upon your minds at the outset of your career, the extreme importance to you as future medical men, on whom will devolve the care of the health of so many others, of a thorough knowledge of the laws which govern the health of individuals and of the community at large, and of the means by which suffering, disease, and death, may be prevented. As you are all probably aware, sanitary science is not yet, like most of the subjects of medical study are, compulsory. Medical students are not obliged to attend lectures on the laws of health; so I want to show you to day how necessary it is for you as future medical practitioners to know something about those laws. Very likely and very naturally, the idea of many of you is that you come here to learn to be medical practitioners, to learn the art of healing, and not to learn how to prevent disease. Indeed, it may seem to you that, by studying to prevent disease, you are studying what is no part of your business. Now, let us consider this for a moment. Medical men study diseases from all points of view. They study how they arise, what their causes are, how they spread, how the pain they cause may be alleviated, and how they may be remedied. Medical men do all this of necessity in order that they may be able to practise their profession. They have to know more about diseases than other people do; they know the conditions of their origin, and how they spread; and they are thereby enabled to point out better than anyone else how they may be prevented. Are they not then bound to do so? Are they not bound (putting away selfish mercenary considerations) to use the knowledge they possess for the good of mankind and to make that knowledge as perfect as possible? Are not the claims of humanity of an importance vastly superior to any others which present themselves under the circumstances? And have not medical men always recognised this? Have they not studied the causes of diseases, and pointed out the ways of preventing them, from time immemorial? Hippocrates was the father of curative medicine—was he not also the father of preventive medicine? Did not Galen and Celsus, and those who followed them, instruct men in the art of preventing disease? Let us come to our own day, and let me call to your minds what our own Sir William Jenner has said on this subject. “To cure disease was the great aim of medicine in the last century. The idea of the vast majority of the public on medical subjects is the popular expression of the views held by the physicians of the generation just gone. The present popular idea of the science and art of medicine is, that it aims chiefly at the discovery of special cures for all special diseases.” And further on, “No one acquainted with the present state of the science and art of medicine will for a moment question that to prevent disease is its first and most important aim. That this is the great aim of medicine is a statement made in the opening lectures of all teachers of medicine, and in all their subsequent teachings they never lose sight of the fact.” So you will see that Sir William Jenner tells you the first important aim of medicine is to pre-

vent disease. Striving to cure comes after failure to prevent, the very fact of the disease being present showing that the means for preventing it have either not been taken or have failed. Or take the words of Sir William Gull, at the meeting of the British Medical Association at Oxford, “It is futile, if not worse, to speak as some do of leaving diseases to work out their own ends, as agents of a moral police. Medicine allows no such prerogative to our judgment. It is enough for us that diseases prevail to stimulate our best efforts for their prevention, without our asking a question beyond.”

Now let us consider some of the most remarkable discoveries that have been made by medical men to prevent disease spreading in the world. Who discovered the preventive of small-pox? It was an English medical man—Jenner—who made that discovery. Small pox was the most terrible and the most fatal epidemic that had ever appeared on the earth. You think, perhaps, that I am exaggerating. Not so. Read the accounts of the small-pox epidemics before the discovery of vaccination. Read of the fearful mortality they caused; equal to one-twelfth of the entire deaths of the whole community, and about one-half the deaths of children under ten years of age. Read of the disfiguration and the blindness caused by small-pox; to such an extent that almost all the population were marked with small-pox, while more than half the total number of cases of blindness were caused by it. And then you will agree with me that it was the most fearful epidemic that ever appeared amongst mankind; and you will see that, by showing us how to prevent its ravages, Jenner conferred the greatest possible boon on the human race, although he, at the same time, deprived medical men of much practice and of many fees. But who have pointed out the advantages of vaccination? Who have proved by statistics that by its small-pox can be abolished? Who have shown that the longevity of the human race has increased since it has been practised? Who but those the hope of whose gains is gone by its practice? Had medical men only practised vaccination on themselves and their families, they would have been a charmed race among the plague-stricken population, and they would have been able to enrich themselves at the expense of the lives of their fellow-men. They have never done this; but have, in spite of much opposition and much obloquy; in spite of misrepresentation of the grossest kind, by which ignorant, prejudiced, or interested persons, mislead numbers of their fellow-men—done all in their power to stamp out this terrible disease. Compulsory legislation was found necessary on account of the apathy and ignorance of the people. Compulsory vaccination has been successful to a certain extent, as we do not have anything like the number of deaths from small-pox that we had before its introduction; but why has it not been more successful? Why is so fearful an epidemic as the last one in this country and in France possible? Why but because the dictates of Jenner have not been thoroughly carried out? The reason has been shown by medical men; and it is that revaccination has not been practised, except to a very slight extent. I believe very few medical men have an idea of the absolute necessity of revaccination for the prevention of small-pox. It has been clearly proved that those who have been vaccinated in their infancy, and again at about the age of puberty, are much less likely to take small-pox than those who have not been revaccinated, or than those who have had it before; and while the latter, if they do take it, frequently have it much worse than before, and often die of it, revaccinated people almost invariably have it very mildly if at all. Out of nearly fifteen thousand cases treated in the metropolitan hospitals during the last epidemic, only four presented evidences of revaccination. We know its effects; but we do not take advantage of it to a proper extent. We have compulsory vaccination laws; but I was sorry to see a letter from the Local Government Board which seems to show that they allow the guardians of the poor to exercise their discretion whether or not they shall prosecute a man more than once for neglecting to have his children vaccinated. This is certainly very lamentable. We either have compulsory vaccination here, or we have not. I should like to see a law passed that a child should be vaccinated whether his parents liked it or not. That is what we want; for an unvaccinated child should no more be allowed to go about among the community than a lion or a tiger. The knowledge which we possess has only been partially applied here. We have not had a sufficient amount of education on the matter. They have gone further in these matters in Germany than we have. It has been stated, over and over again, by the antivaccinators, that in Germany small-pox epidemics are generally very severe, especially in Prussia, although compulsory vaccination is enforced. I thought that very strange, if true; and I succeeded in obtaining information respecting the statement from official sources at Berlin. I find that small-pox epidemics have been very mild in those states, especially of South Germany, where vaccination was compulsory; but frequent and severe in the kingdom of

Prussia, with the exception of Hesse Cassel, which has belonged to Prussia since 1866, and where vaccination has been compulsory. In those parts where vaccination has been compulsory, the deaths from small-pox have been very few. In Bavaria, they were 4 in a thousand; in the Rhenish provinces, 3.7; and in Saxony, 8.38 in a thousand, as compared with 16 in a thousand in London, and a percentage of 66.5 in a thousand in Germany, before the vaccination law was passed. In certain of the German states, there had been compulsory vaccination laws; but there had never been such laws in Prussia. The prevalence of small-pox in Prussia, with the marked exception of Hesse Cassel, brought the attention of the legislature to the matter; and, in March of last year (1874), a law was passed making the vaccination of infants and the revaccination of children of riper years compulsory for the whole of the German Empire. Thus Germany has set an example in this respect which other countries would do well to follow; and I doubt not that they will when they see the spectacle of a great empire in the centre of Europe practically free from small-pox—which will assuredly be the case in a few years' time if the law be stringently enforced. †

Do all you can, then, to encourage the practice of revaccination; do all you can to spread sound knowledge about it; do all you can to hasten the coming of the day when it will be made compulsory in the British Isles; and you will be benefiting your race, and following in the steps of the great and good man who left to the medical profession the means of abolishing small-pox, and who expected them to carry out those means. If the medical men of all ages had done nothing else, if they had saved no lives, if they had alleviated no pain, if they had prevented no anxiety; if from the time of Hippocrates to the day (still, alas, far distant!) when small-pox shall be as extinct as the dodo, the medical men of all countries had done nothing but fight against that disease, and had exterminated it, their existence would have been justified, their labour during all those years would not have been lost—it would have been amply rewarded.

But now let us look at some other diseases. Where are the black death, the sweating sickness, and the plague? Where is scurvy, that decimator of our armies and navies? They are where typhus fever will soon be, they are where enteric will be some day; they are where every disease which we conquer, the origin of whose existence we find out, the intricacies of whose paths we unravel, will be sooner or later; they are—practically speaking—abolished. Thanks to the labours of medical men of our own day, of Stewart, of our own Jenner, of Murchison, of Budd, and of many others in less degree, we know now not only the differences between typhus fever and typhoid or enteric fever, long confused, long entered under the same heading in the mortality tables; but we know the different conditions of their existence, the circumstances which favour each, and the ways in which they spread, and what to do to prevent their spread. This is why, I say, we may hope to abolish them. Until we know the special conditions under which a disease flourishes, we can only act on general indications; but when the special conditions are known, we can direct special attention to them.

And what about other infectious fevers, scarlet fever, measles, whooping-cough, and the like? Do we not know more about the ways in which they spread? Have we not come to see that isolation is the one great means to be used? Have we not come to see that special hospitals are necessary, to which patients with infectious fevers should be taken, to separate them from the healthy population? These diseases spread from family to family, chiefly by means of day-schools, and children belonging to an infected family, although apparently well themselves, should not be allowed to go to school, as they may carry infection in their clothes. I am sorry to see, from letters in the papers, that the visitors of the London School Board are obliging children who have had these infectious diseases to go to school directly they are considered well; and that they are also compelling children who live in houses where scarlet and other fevers are prevalent to attend school. It is to be hoped that they will soon be taught what they are really doing; they are spreading disease amongst the people. Another point of great importance, too, is that the clothes from people who have had a disease, or from infected houses, are sent to the wash and infect other clothes; and, in some cases, clothes infected with disease are sent to rag-shops, and the fever is sold with them to one or more customers. You can in these ways do much to prevent the spread of diseases. But you want to know more. You are liable at any time to be called upon to see a case of scarlet-fever or other infectious disease; and you are now expected to advise how to protect others and even how to disinfect premises and things. Your patients will not always allow a sanitary officer to be called in; but they may expect you to manage everything for them. It would be very desirable if a law were passed compelling all medical men to report every case of infectious disease

which comes under their cognisance to the medical officer of health of the locality; and then two ends would be attained: the medical attendant would not run the risk of losing his patients by reporting their houses, and the best means of preventing the spread of the disease would be taken promptly; for we can do much by isolation, by disinfection, by attention to general and special sanitary conditions, to prevent the spread of those diseases: though natural causes do far more than we can, luckily. I will give you an illustration. The fever case is the type of the epidemic; it has its different periods, its point of maximum intensity, and its decline. Suppose it were not so. Suppose that one man had scarlet-fever in the first week of the year, and gave it to two in the second, and these to two each in the third, and these four to eight others in the fourth, and so on—every person who took it giving it to two the week after, and to no more—a very moderate supposition—I say, if this went on from the first week in January to the end of July, the whole population of the world would have had it; and if it went on for fifty-two weeks, the people who would have had scarlet-fever during the year would people 4,500,000 worlds; and it would take, counting 90 per minute day and night, 100,000,000 of years to count the persons who would have had it. So you see it is very fortunate that there are causes at work in nature to put a limit to the spread of contagious diseases, and that epidemics come to a height before they go on very long. But all medical men are bound to study the methods for the prevention of disease, because the means for prevention are often the same as those for cure. Are not rickets, gout, rheumatism, and many chronic diseases, preventable? And are not the methods for preventing them the same as the means which must be used to prevent their becoming worse? Are not proper diet, pure air and exercise, more effective agents of cure than pharmaceutical preparations? And are you not, therefore, bound to make a special study of these and other hygienic agents? Remember always the maxim of Rollet of Lyons, "Medicine cures individuals; hygiene saves the masses"; and the dictum of the father of medicine, "Nature is the healer of diseases".

Up to quite recently, the public looked on medicine, as physicians did formerly, thinking that its first duty was to cure, to find a specific remedy for each disease, whether phthisis, cancer, or gout, scarlet fever, typhoid, or cholera. Now, the masses are more enlightened, and require medical men to prevent diseases—or, at least, to prevent them from spreading when they have arisen. A child has scarlet fever in a family—what does its father do? Does he expect the doctor to produce a phial containing a medicine which he will warrant to cure scarlet fever? Not at all. He hopes his child will get well under the doctor's care; but he expects the doctor to know how to prevent others of the family from catching the disease. And the more education is spread, the more will this be so.

But what can we do against our great endemic plagues, with phthisis at their head; that terrible scourge of our climate which takes from us so many in the prime of life whom we can ill afford to lose? Last year, in London, this one disease caused 8,255 deaths—one-ninth of the total deaths, and more than half as many as all the zymotic diseases. Many circumstances favourable to it have long been known, general unsanitary conditions, hereditary taint, bad food, bad air, certain employments—such as those in which the person is exposed to much dust; but it has been recently shown by Dr. George Buchanan (an old University College man) that the drainage of soil beneath towns reduces the death-rate from it in a most remarkable way—as much as fifty per cent. in one instance—and so knowledge is obtained which enables us to prevent a vast amount of suffering and death from it.

What shall we say of the great infant mortality, mostly from preventable causes? Let us hear again what Sir William Jenner says. "First among preventable diseases I will place one, the mortality from which, in London at least, is so great as beyond question to swell largely the death-rate of children under two years of age; and yet one that has no place in the Registrar-General's returns. I mean rickets, the English disease, as it was formerly called. Not one child ought to die from rickets itself, and death from its consequences ought to be extremely rare; and yet the mortality from rickets, from diseases which would not occur but for the pre-existing rickets, and from diseases which would be trifling but for the co-existence of rickets is enormous." And, again: "The causes of rickets are: poorness of the mother's blood, errors in diet, *i.e.*, feeding the child with food unsuited to its wants and to its digestive powers, and, as subsidiary causes, deficient light and impure air, produced especially by overcrowding of the sleeping-room. Poverty—inevitable poverty—plays a great part in the production of some of these causes." And Sir William Jenner continues: "Judging from my own experience, I should say that rickets so severe as to lead even indirectly to death, would be comparatively rare did the poor know how to feed a young child; were the poor aware of the

necessity of the infant being fed with food fitted to its age. Law can do something here; for it can make compulsory the teaching of the practical laws of health in all schools supported in any degree by the public money. Diffusion of practical knowledge is the great preventive remedy of rickets."

And now let us hear Dr. Ferguson on the *Degeneracy of the Factory Population*. In a letter, dated February 26th, 1874, he writes: "Within the last fortnight, six children have come to me, producing registers to prove thirteen, and in one case fourteen years of age. The heaviest of them weighed fifty-six pounds, and the tallest was half an inch over four feet. The average weight of the healthy factory child of thirteen years I find to be seventy pounds, and average height fifty-four inches." Thus, you see that the heaviest was fourteen pounds under average weight, or one-fifth too light; and the tallest five and a-half inches, or about one-tenth too short. He says, too: "I am meeting every week with cases like these, in which feeble children, overtaxed by working full time, either lose weight or grow at a very abnormally slow rate." And: "I am alarmed at the large and increasing number of physically feeble children coming to pass half-time. Many giving proof of nine years come before me, weighing not more than forty-one or forty-two pounds. I am constantly meeting with young persons, aged from fifteen to nineteen years, of not more than the average weight of a healthy factory child of thirteen, whom, when examined for half-time, I noted as physically feeble. For nine years I have closely observed, and am certain that each year the proportion of physically feeble children presented to me has gone on increasing, with the single exception of 1873."

Here is an alarming evil, and one which, if unchecked, will produce a permanent deterioration of the whole factory population. And what are the causes of it? The great cause is the same as the one pointed out by Sir William Jenner as the great cause of rickets—improper and insufficient nourishment. What is the natural nourishment of young children? What is the one perfect food which contains all the necessary substances in proper amount? Milk. Hear Dr. Ferguson again: "From long and careful trial, I find children in the mills to grow, on the average, between thirteen and sixteen years of age, nearly four times as fast on milk morning and night as on either tea or coffee. The exact figures are as four to fifteen. Drinking hot liquids is very destructive to the teeth. Not more than five per cent. of the children I examine have, at the age of thirteen years, sound teeth."

There are other causes, as drunkenness of the parents, and especially of the mothers, by which, of course, money is spent which would buy food; but the great cause is want of milk.

And how is milk to be got? Why is it so dear? Why is not milk more plentiful? To produce milk in large quantities, we want a great amount of luxuriant grass; and for this rich manure and plenty of water are required; and have we not got these? We have; but we do not use them. We deliberately throw them away. Impossible! It is only too true. The rich manure is the sewage of our towns. And now, I fancy, some of you have said to yourselves—"Oh! Corfield is going to lecture! It will be all about sewage!" Well, if an apology be necessary, it must be that the utilisation of sewage is the great question of the day, and must not be passed by. The only way to utilise it is to feed plants with it. It is now generally turned into rivers, to render them impure and unfit to drink. The sewage is generally turned into the rivers below the towns, so that the next town below drinks the water into which the sewage from the towns higher up the river has been emptied. In one town, the sewage is actually discharged about a mile above the place from which the town takes out its drinking-water; so that they pollute the water, and then filter and drink it—a most ridiculous circular system. And this is valuable manure that is thrown away. Why, the sewage of London has never been valued at less than one million sterling a-year, and yet that is thrown away, either entirely or almost so. Anything can be grown with it. Grass grows splendidly, especially Italian rye grass; this is the staple sewage crop, and is thoroughly good for cattle food. Cereals can also be produced in abundance with it, as well as vegetables, so that the sewage farmer can grow anything. I have seen oats grown with sewage manure, some ears of which were twenty-seven inches long—plenty of them were two feet long. And, to give you another example, strawberries of most excellent flavour have been grown with sewage, and one of them would not go into an ordinary tumbler. Italian rye grass is very suitable for cattle, and will produce ten cuttings, or eighty tons per acre *per annum*. Sewage-farms need not be swamps, as some people suppose, and they are not if the drainage be properly attended to. If sewage be passed through the soil, the effluent water is purified at all seasons of the year, even in winter when plant-growth is least. This is the way in which sewage may be made valuable manure, and it is the only way by which the refuse of towns can be turned into

food for cattle, and by them to milk, which is required to feed the starving, scrofulous, rickety infants in our great centres of population. The solution of the sewage question will afford the means of preventing the degeneracy not only of the factory population, but of the people in large towns generally.

Most of you, I dare say, have heard that several cases have arisen in which epidemics of typhoid fever, and in some instances of scarlet fever, have been traced to infected milk; and I think it is of extreme importance that there should be a Government enactment to have a sanitary inspection of all dairy farms. Remember, too, that we continue to waste our natural resources. A day may come when we shall not be able to get a sufficient supply from elsewhere. We have to rely on supplies from without, which may some day be stopped, and in the meantime we are turning into our rivers and into the sea an immense quantity of manure, and this in spite of the reports of Royal Commissions and Scientific Committees all recommending irrigation as the only remedy. The mention of irrigation leads me to speak of the works carried on now to insure a water-supply. We must hide our heads when we think of the works of the ancient Romans, though carried out by them more as a necessity. Who has not heard of the Roman aqueducts? Water had to be brought from a distance, because they could not raise it in Rome. Some of these aqueducts were forty miles long, and yet the Romans were supplied with three hundred gallons a head per day, while we in London think ourselves well off to get thirty gallons a day. Then the Romans gave us the pattern of our drains. Their great drain was not meant for a sewer, but to drain the ground around the forum, and it does so still. But works are now done more to insure the health of the community, and most of our gigantic works are carried out to this end. Look at the sewerage works in London by which the sewage of from 3 to 4 millions of people is removed continually; all the sewage is thrown away, but that is of less importance. We must first consider how to get rid of it, and, secondly, what to do with it in the way of utilisation. One of the reasons of the low death-rate of London, much lower than that of most large towns, and in parts as low as that of country parishes and small towns, is its excellent drainage. Then medical men are often expected to understand sanitary architecture, and it is the duty of every medical man to know all the important points connected with the supply of air, with the ventilation of rooms, heating and lighting, and even with the construction of drains and closets to a certain extent; for he is now liable to be asked questions relating to these matters. Every one is taking an interest in sanitary matters, both as regards houses and towns; and medical men, wherever they go, are supposed to be authorities on these things, and their opinion is frequently asked about them; and it is now necessary for medical men to study the broad principles of sanitary science, and, to some extent, the detailed facts, if only to keep up with, and ahead of, the knowledge of other people. If medical men are not to be authorities in matters which relate to the health of the community, who are? It is necessary for all medical men, but more especially for those likely to be charged with the care of the health of the community—to be medical officers of health—to study these matters. Some such appointments have long existed in certain towns, and especially in the metropolis. But by an Act of last session it was provided that all over the country sanitary authorities should be constituted and sanitary officers appointed. We are not to discuss here the constitution of these authorities or their fitness for performing the duties allotted to them by law; sufficient for us to know that such offices do exist, that there are men appointed all over the country to look after the public health, and that men must be ready to fill up such appointments as they are made or as they fall vacant. No doubt, in time, the appointments will be gradually increased, and the country will be divided into areas, with a superintendent medical officer of health over each, and local medical officers of health in smaller districts under him, and then there will be a much more complete system of supervision than can exist with the haphazard arrangement which we have at present. But be that as it may, the duties of such posts will be much the same as they are now; and such duties are very manifold, and men must be specially prepared for them. A medical officer of health has to give advice of very various kinds; he must be conversant with sanitary architecture, and must understand thoroughly all the pipes, traps, etc., which make up the sanitary arrangements of a house, and be prepared to advise, where improvements are necessary, what are the best suited to the case. He has, unfortunately, as yet no control over the building of new houses; and another desideratum is one pointed out by Mr. Liddle, and it is that a new Building Act should be passed which shall give the local authorities control in this matter, and make it compulsory that before a new house is allowed to be inhabited, the owner should obtain a certificate or license from the local sanitary authorities, only given after a satisfactory certificate from the

medical officer of health and the surveyor. It is true that the medical officer of health has long had power (by Torrens's Act) to report on houses which he considers unfit for human habitation, and that local authorities have had power to pull down or to close such houses, and that now by Mr. Cross's Act, passed last session, power is given to pull down whole areas of houses where they cannot be altered so as to be put in a proper sanitary condition. So far, so good. But we want, as I said, power over new houses. The medical officer of health must also be acquainted with all matters relating to air-supply and ventilation, especially of public buildings—theatres, churches, etc.—and with the sanitary arrangements of hospitals, workhouses, asylums, and prisons, which have long since been cleared of the jail fever; and someone has said that they are "the only places fit to live in". He must be prepared to advise in cases of overcrowding, and to give his opinion on all cases of complaints of nuisances of any kind, and to support that opinion by evidence if need be. He must be acquainted with all the methods for the removal of refuse matters, and know the advantage of each, and the conditions under which it may be applied. His advice is asked on all such important matters as the ventilation of sewers, the treatment of sewage, the cleansing of streets, etc., as well as on water-supply and purification. He must be acquainted with the injury to health which is caused by various trades and employments, and with the methods of preventing it, and also with the arrangements for keeping animals in a proper condition, slaughtering cattle and disposing of offal. He must be able to use his microscope, not to mention a number of other instruments of research. He must be acquainted with the ways in which epidemic diseases spread, and with the means to prevent them spreading. It frequently happens in practice that one man gets typhoid fever in a small town, and, because proper precautions have not been taken, the epidemic spreads all over the town. Another instance may be quoted. A boy comes home with the same disease to a village cottage, the medical man takes proper precautions, and there is not another case of the disease in the village; whereas, in the same village, before those precautions were taken, an epidemic had several times taken place. Thus there is now room for specialists. One versed in sanitary matters is often now-a-days consulted as to the sanitary condition of a house, especially where cases of fever have occurred. Then the medical officer of health must be a statistician, and, to a certain extent, know how to prepare statistical tables, and to draw correct results from them; and he must be an analytical chemist, too, to a certain extent, though he need not have such an extensive and accurate knowledge as that required by a public analyst; and he should also be acquainted with sanitary law and with the proceedings of law courts upon such matters.

All these various requirements make it necessary that he should study many branches of science. As Dr. Guy says, the science of hygiene "makes application of a knowledge remarkable for its amount and the great variety of sources whence it is derived".

And this is why hygiene has only so lately become a science. It is usually defined as the art of preserving the health; the art by which we contrive to lengthen our lives; but it is more than this: it is the science which studies the causes of diseases, and points out the means for the prevention of disease; for to prevent disease we must study its causes, we must find out the conditions which favour it, which tend to make it spread.

The earliest science is that of numbers, and it is the most perfect: mechanics and astronomy and the other physical sciences are all subject to the science of number, and are all wonderfully perfect because of it. Chemistry—the study of the composition of bodies—is making wonderful advances, but the Newton of chemistry has yet to come. Then biology—the science of life—of which the study of physiology is advancing so much in our day; pathology—the study of disease—all had to advance to a considerable degree of perfection before hygiene could be born; it links physiology—the study of healthy action—with pathology, and shows how we pass from health to disease.

The hygienist must be, in the first place, a good pathologist; he must be well acquainted with diseases, and especially with their origin. He must be a good physiologist and anatomist, for, unless he has made a study of what the normal condition of the human body is, how can he advise as to the methods for keeping it in that condition? He must be a chemist and physicist, and even a mathematician to a certain extent. The more he knows of geology and botany the better, and he must be familiar with meteorology. So a hygienist must be a physician; and this is why the universities require men to be B.M.'s before they attempt to take degrees or diplomas in State Medicine. Several of these are now created, and the University of London has established a diploma in this subject; provision has been made for the complete study of it in this College; and a laboratory is nearly fitted up, in which students will be able to perform for themselves analyses of sam-

ples of air, water, and various foods and drinks, and so learn to fulfil the duties required of them as medical officers of health and public analysts.

I hope I have especially impressed on all the importance of sanitary science to medical men, whether they undertake public duties or not, and that many of you will attend in the summer course on hygiene, if you do not enter for the practical work in the laboratories. Anyhow I wish you all success in your careers, and whatever branch of medicine you take up, remember that it is not only your duty but your privilege to prevent suffering, disease, and death, to the utmost of your power.

You have much to learn; do not put things off. Seize the opportunity. Do not waste your time; every day spent in idleness makes it more difficult to work the next day. On the other hand, beware of neglecting out-of-door exercise, so necessary for the health of the body and of the mind too. You cannot learn well and thoroughly unless you keep your bodies strong; the *corpus sanum* is essential to the *mens sana*. Do everything earnestly; be eager in your sports as well as in your work; mind that a few hours of real and genuine hard work are worth days of dawdling, and take as your motto the words of the immortal Hippocrates, words so especially applicable to medical studies, "Life is short, but art long; opportunity fleeting; experiment dangerous, and judgment difficult".

MEDICAL REFORMS:

Being part of an Address delivered to the Reading Branch of the British Medical Association.

By GEORGE MAY, F.R.C.S., President of the Branch.

The Practice of Midwifery by Women.—The Contagious Diseases Acts.—The Medico-Legal Relations of Insanity.

It is as President of the Reading Branch of the British Medical Association that I have the honour to address you to-day. It was my privilege to rock its cradle; I have earnestly watched its progress; and I ask you now to rejoice with me at its distinguished success. In spite of its earlier difficulties, it has become a great institution, an influential power. For the promotion of original researches, and for the investigation of subjects beyond individual enterprise, it extends its fostering aid; and for the expression of the opinions and wishes of our profession on questions which demand legislative enactment, it can now speak with an authority which cannot be disregarded. Among many subjects of professional and general interest, there are some which claim especial regard. The education of females to the practice of medicine is one of deep interest and importance. In the promulgation of all that relates to the laws of health, I believe we should find in co-operation with well-educated females a valuable and powerful help. I should hail the day when the entire department of midwifery were transferred to the charge of competent females. With opportunity to consult with male practitioners in cases of difficulty, I am of opinion that more satisfactory results would follow than by present arrangements. We know how anxious is the position of the practitioner when (detained by an obstetric engagement) he is unable to fulfil his other duties, be they ever so urgent; and we are all too painfully familiar with the difficulties and risks encountered by attendance on infectious cases while engaged in midwifery practice. It were well for the public interests if attendance on both classes of cases conjointly were held to be incompatible; and I do not see how disassociation could be made practicable, excepting by the substitution of female for male attendants in the entire department of midwifery. The subject is intensely important, and demands at our hands a serious and unselfish consideration.

The Contagious Diseases Act also demands attention from every member of our profession. The enthusiastic and well-meaning, but, I believe, misguided, efforts of numerous opponents of the Act (chiefly on asserted moral grounds) have given the subject more than ordinary interest. The condition of the unfortunate beings obnoxious to this Act is most deplorable. Very many of them are supplied from homes where both sexes and all ages are huddled together, where decency and self-restraint are unknown, and where prostitution would seem to be the natural, if not the inevitable, result. The wonder is not that many have fallen, but that so many have escaped the fall. When overtaken by disease, they are refused admission into many hospitals until evi-

dences of poisoned frame are too manifest. So long as they are physically capable of pursuing their vocation as their adopted means of livelihood, they are often compelled to be regardless of the existence of disease which is contagious, and so is multiplied *ad infinitum* the terrible scourge with which our profession is unhappily too familiar. The beneficent Act passed a few years ago by a wise and humane legislature is now sought to be repealed on moral pretexts. The outcast wanderer is encouraged to defy the law, to protect the *liberty* of her poor diseased body, and to reject the means of relief and cure, and a way opened to her of escape from her degraded and pitiable life. Certain members of the legislature have leagued themselves against the Act; and one distinguished member of the late administration has pledged his future life to its repeal. Even among our own profession there are some who are not satisfied with the Act. If the system of certificate be an inducement to immoral indulgence, surely this can be amended; and, in my judgment, opponents are bound in humanity to provide a satisfactory substitute before they inflict on the nation so terrible a calamity as the loss of the present Act. The British Medical Association, through its multiplied branches and its intelligent press, offers an excellent vehicle for collecting the medical opinion of the country on this most important subject.

In fulfilment of his foreshadowed intentions, our distinguished Premier has grappled with the Sanitary Acts. If within reasonable time he can bring them from chaos to order, and enact supplementary laws founded on our combined professional knowledge, and make them applicable to the entire kingdom, and compulsory instead of permissive, he will deserve a civic crown.

The medico-legal relations of insanity, the boundary lines of responsibility and non-responsibility for crimes committed under conditions of assumed mental disease, involve questions of grave import, and challenge the intelligence and soundness of our jurisprudence. A conference between distinguished members of the law, and of medicine (as suggested by Dr. Russell Reynolds), might lead to satisfactory results. We want a "forensic medical officer" whose professional training shall comprehend psychology, and all that may prepare him to analyse the ever-varying phases of mental aberration, to detect the crafty malingering, and to assist the judge in determining the *degree of responsibility involved in the act of imputed criminality*. And who so fitted as he? For such knowledge is special, and comes by patient labour, and not by intuition, as some have presumptuously asserted. The illustrious Casper, by his genius, energy, and unrivalled experience, contributed largely to establish a criminal code in Prussia, a model of wisdom and humanity; and secured for his country an enviable distinction, and for himself undying fame. I have ventured to make a brief allusion to some among many subjects which have engaged professional interest, and which well deserve the serious consideration of our great Association. I heartily commend it now to your increased favour and support, and earnestly pray that its councils may be inspired with wisdom to guide and direct its united intelligence to the advancement of science, the honour of our profession, and the good of mankind.

THE CASE OF THE LATE PROFESSOR HUGHES BENNETT.

By W. CADGE, F.R.C.S., Surgeon to the Norfolk and Norwich Hospital.

PROFESSOR J. HUGHES BENNETT died at Norwich on September 25th, 1875, aged 63.

A narrative of his illness, so far as it is known to me, particularly of the last complication which led to his death, will have a sad interest for those who knew and loved him as a friend or teacher; and a deep professional, as well as a sad, interest for those, and they have been many,* who, from time to time, have used their best skill and thought to detect and unfold the hidden cause of his mysterious case. I know not exactly when or how Dr. Bennett's first failure of health commenced; but it was many years ago. The most prominent and persistent of his early symptoms were those of a bronchitic and laryngeal affection, which were sometimes urgently alarming, sometimes almost recovered from, were readily reproduced, and did frequently recur up to the very last.

By slow degrees, his general health failed, he grew thinner, looked pale, and lost strength. A few years ago, it was discovered that he had diabetes; but this disappeared without any great rigour of treatment, and has not been thought or known to have recurred, except

occasionally and very slightly. On this point, however, there may be room for doubt. Since the first discovery and the first disappearance of the sugar, I have reason to believe that examinations of the urine have not been frequently made. In conversations and in answers to questions on this subject, Dr. Bennett always spoke of the diabetes as a thing of the past, and as not bearing with importance, or as having much influence, on his steady deterioration of health; at no time had he thirst or diuresis; and, therefore, the malady did not impress itself on his thoughts by the usual general symptoms. Very recently, however (in August), sugar was again found; and I have before me a paper containing observations on the urine made three times daily during the first half of September 1875; from which it is shown that, while the specific gravity and the quantity of the urine were but little, if at all, above the natural standard, sugar appeared and disappeared in a quite irregular and intermitting way. Thus, the urine passed during the night gave a dense deposit, with Fehling's test, on five out of fourteen days; that passed at mid-day on six, and that passed in the evening on four out of fourteen days; while in all the other observations, no sugar was found. During this period, his diet was very similar from day to day; consisting of fish, a little meat, pudding or tart, fruit and sherry; very little bread, and no potatoes.

If, as I have said, in this long interval between the first and last clear recognition of diabetes, the urine was but seldom examined, and, when examined, chanced to be free from sugar, it seems probable that glycosuria, in one of its intermittent and milder forms, existed throughout, and was the true and chief cause of the emaciation and debility which, on any other hypothesis, it has been found so difficult to explain.

Be that as it may, his health continued to decline. The last three winters he passed in the south of France, with some benefit, possibly, to his bronchial and laryngeal affection, but apparently without any effect on his general state. For many years, Dr. Bennett had suffered from occasional attacks of gout; and he was liable, too, to lithic acid deposit in his urine; occasionally, for several years, he had experienced some slight impediment and irritation in making water, which he thought to be due either to slight stricture or to prostatic enlargement. From time to time, a simple catheter was passed, but no stricture was discovered. Last winter, at Nice, he had rather more vesical irritation than usual. On his way to England, in June, he stayed for a time on the borders of the Lake of Geneva; and a letter I received from him on July 1st will best describe his condition.

"I have long been intending to write to you in consequence of a malady which has been creeping upon me for some years, but which now is causing me no small anxiety. Frequent micturition; pain in the back, long thought to be lumbago, but which I now know to be renal; sediments of uric acid, and attacks of acute gout in the right foot, and one in the stomach, have indicated, during the last, say four years, pretty clearly the general diathesis and approaching local disorder. About three months ago, at Nice, I was suddenly seized with pain during micturition, extending to the extremity of the urethra, and passed about a tablespoonful of bloody urine, mixed with gravel. The bladder was irritable for about twelve hours. Lying in bed, poultices, and some alkaline water, got rid of it. Since coming here, four weeks ago, I have been sensible of dull pain in the perinæum; had two more attacks of irritable bladder, passage of blood, etc. Whether all this signifies irritable bladder, prostatic or renal disease, or stone, I cannot tell. Can you suggest what should be done? I have given up wine, beer, acids, fruit, and sugar; take a good deal of milk, little meat; indeed, the desire for animal food is small. I continue pale, weak, and emaciated; I apply poultices to relieve local pain, and take about twenty grains of bicarbonate of potash thrice daily, in the slightly alkaline waters of this place; I also take fifteen drops of vin. sem. colch. every other night or so. It may be only gout, but I dread stone. My urethra is very irritable; and, the last time a catheter was passed, I nearly fainted. This was two years ago; and I was then assured that there was no stricture or prostatic disease, merely a weak bladder."

In July, he came to Norwich, looking more emaciated, pale, and ill than I had ever seen him. On carefully sounding, a stone was readily felt, apparently of some size; the bladder was capacious and healthy, and could retain nearly half a pint of urine; the prostate was slightly enlarged; the urethra very sensitive and irritable; the urine was clear, acid, specific gravity 1.020, and contained no albumen. He was much depressed by the knowledge that he had stone, but his innate force of character came to his aid; he looked the difficulty in the face, and was prepared at once to undergo treatment. It was not without difficulty that I induced him to go to Edinburgh in the first week of August; there were many reasons which made a visit there desirable; travelling did not add much to his troubles; and I confess that I was not without the hope that, once there, he would be persuaded to ask, and would

* As I am unable to give, with accuracy, the views, so I have purposely avoided using the names of any of the physicians and surgeons who have at any time been consulted by Dr. Bennett.

see the wisdom of accepting, the aid of one of his distinguished colleagues and friends. While there, he received much comforting and valuable advice and encouragement, but his symptoms increased in severity. He wrote on August 18th: "There is now much more irritation than when I last saw you; stooping and turning cause sharp pangs, and the close of micturition is very torturing." He returned to Norwich; and the question of operation, lithotomy or lithotripsy, presented itself. Either must be attended with the greatest hazard in one so worn and unhealthy; but the thought of doing without operation was simply intolerable, and not to be considered. In favour of lithotripsy, were the fair quietude and healthy condition of the bladder and urine; but there were serious drawbacks. Dr. Bennett was a man of high spirit and courage; but his courage fitted him rather to encounter one great risk than to endure the wear and tear of repeated operations, frequent use of instruments, and the probability (made more probable by the presence of glycosuria) of troublesome cystitis. The size of the stone alone could decide the point; and, to ascertain this, Mr. Clover kindly came down and administered nitrous oxide, followed by ether; while, with the lithotrite, I found that the stone measured $1\frac{1}{2}$ inches by 1 inch. Such a stone as this was fairly within the compass of lithotripsy in an otherwise favourable patient; but, in this case, I had not a moment's doubt that lithotomy, if carefully and accurately done, notwithstanding its greater immediate risk, afforded the best chance of complete recovery. In this view, the patient readily acquiesced; and, on the following day, September 16th, I removed the stone by lateral lithotomy, assisted by Mr. Crosse, Dr. Beverley, and Mr. Hooker. The nitrous oxide and ether was again used by Mr. Clover, with admirable effect; there was never a movement of the patient, nor the least headache or sickness afterwards. The operation was easy and satisfactory. The transverse artery of the perineum was large, and spurted freely; it was easily tied when the stone was removed; the blood was so thin, and so little disposed to coagulate, that every little vessel continued to ooze; and I deemed it best to plug the wound round a silver tube, rather than allow any quantity of blood to be lost. The stone was composed of lithic acid; it measured $1\frac{1}{2}$ by 1 inch, and weighed 193 grains. No more blood was lost, and urine passed freely afterwards. He suffered considerable aching pain in the wound for some hours; but it was gradually checked by half a grain of morphia introduced into the rectum at the time of operation, and twenty drops of Battley by the mouth two hours after. At night, he turned cautiously on one side, took twenty grains of chloral, and had some hours' sleep. Pulse 90.

September 17th. Urine plentiful; he had pain only when he moved. Pulse 96; temperature 102 deg. Tongue dry but clean. He had taken egg and milk and a few teaspoonsful of brandy in soda-water; he had frequent cough and expectoration, which caused temporary pain in the wound.

September 18th. The tube and part of the plug was removed; after which the bladder was able to retain urine and empty itself by the wound every two hours. This caused considerable pain in the parts from smarting and spasm; but in a day or two, when all the lint was removed, it abated, but never wholly ceased. Pulse 92; temperature 101 deg.

I need not record minutely the daily progress of the case. Suffice it to say, that for four or five days there was a good prospect of speedy recovery; he took food plentifully, and was in good spirits; and everything went on well so far as concerned the pelvis and bladder; the urine was easily caught and was clear, but loaded with sugar, with a specific gravity of 1030 to 1035. By degrees, however, the cough and expectoration became more frequent; and this, with the frequent spasm and larger amount of urine secreted, distressed him and prevented sleep. Opium by the mouth or bowel relieved for the time, but were apt to be followed by sickness; chloral did not act well, and signs of increasing debility showed themselves. The pulse continued from 90 to 96, but became weaker and weaker. Aphthous patches gathered on the tongue and throat, and made swallowing difficult, and thus the prostration went on; and death from sheer exhaustion took place on the 25th, the tenth day after the operation.

Post mortem examination, forty-eight hours after death. The body was emaciated; the surface pale and bloodless. The blood was thin, and transuded through the vessels and stained the tissues. Only one small clot in the right ventricle of the heart was met with.—The bladder was perfectly healthy; its muscular walls were rather thin and dilated; its mucous membrane was pale and smooth.—The prostate gland was enlarged to the size of a small apple; it projected somewhat like a cornice into the bladder, and on this projecting part there were traces of slight ecchymosis beneath the mucous membrane. The lithotomy wound was clean, and so slight that, looking from the bladder, none could be seen, and on closer scrutiny it was found that the knife had only divided the mucous membrane and had scarcely reached the left lobe—this, doubtless explains the power of

the bladder to retain urine the moment after the tube was removed.—The kidneys were slightly congested, but not unhealthy.—The liver weighed 4 lbs. 5 oz., and was healthy.—The spleen was greatly hypertrophied, and weighed 2 lbs. 12 oz.; texture firm, of natural colour and appearance.—The stomach and intestines were healthy.—The heart was large and flabby, and weighed 1 lb. 1 oz.; its valves were healthy; the left ventricle was empty; the right contained a soft clot; the aorta was deeply stained by the colouring matter of the blood; its walls were atheromatous, and there were several calcareous scales.—The lungs were emphysematous and oedematous; there was some dilatation of the small bronchi; at the apices there were some small patches of collapsed lung-tissue; no tubercle; the right lung weighed $1\frac{3}{4}$ lbs.; the left, $1\frac{1}{2}$ lbs. There were some old pleural adhesions on the right side.—The trachea and larynx were pale and healthy.—*Head.* On raising the calvarium, a soft tumour was discovered situated on the right side of the head, about an inch above the ear, between the dura mater and the bone. It was about the size of a hen's egg, and projected towards the brain, so as to produce a deep pit or hollow into which it fitted. The convolutions were flattened and pressed down, but not otherwise altered; no softening; no congestion. The dura mater covering the tumour was somewhat thickened. The parietal bone was thickened and hypertrophied around the circumference of the tumour; over it, there was thinning by pressure and absorption, and at one point, about the size of a shilling, all trace of bone had disappeared, and it was replaced by fibrous membrane. The tumour had a cystoid character, with a distinct investing membrane, and its contents consisted of a blackish pulpy material resembling the interior of a recent aneurism, or more closely of a myeloid tumour. Under the microscope, there were seen cells of various descriptions, plates of cholesterine, fatty granules, and altered blood-corpuscles.—The brain itself was anæmic, but not, on the whole, unhealthy; it weighed 47 oz. The optic thalami, corpora striata, pons Varolii, and medulla oblongata had a somewhat shrunken atrophied appearance, and were, perhaps, harder and tougher than usual. The arteries were healthy, and, to the naked eye, the texture of the brain around them seemed natural. I will make no comment further than to say that, so far as I have been able to ascertain, Dr. Bennett never suffered from headache, giddiness, or any symptom directly indicative of such a lesion as that just described.

I may add, that Professor Sanders of Edinburgh, who happened to be staying in Norwich, visited Dr. Bennett a day or two before he died, and was present and kindly assisted at the *post mortem* examination.

TWO CASES OF MICROCEPHALIC IDIOCY.*

By G. E. SHUTTLEWORTH, M.D.,

Medical Superintendent of the Royal Albert Asylum, Lancaster.

A BRIEF description of two microcephalic idiots, whose head-measurements are extremely small in proportion to the amount of intelligence they evince, may possibly be of some interest to the members of the Psychological Section of this Association. Both are at present resident in the Royal Albert Asylum, Lancaster; and although a short notice of the first case, quoted from a description by Dr. Ireland, who casually saw it in 1871, appears in the last edition of Bucknill and Tuke, I may, perhaps, be allowed to give a few additional particulars, both for the sake of comparison with the second case, and also on account of certain alterations in the physical and mental characteristics of the patient, which have occurred during the last four years.

CASE 1.—Frederick — is now eleven years of age, and has been under my observation in the Royal Albert Asylum during the last four years. He is a well-knit, straight-limbed boy, $46\frac{3}{4}$ inches high, weighing 47 lbs.; and, in spite of the peculiar conformation of his head, has a fairly intelligent expression, with large lustrous eye. The following are his head-measurements as given in Bucknill and Tuke, upon the authority of Dr. Ireland's observation in 1871, and, also, as recently taken by myself:

	1871.	1875.	Diff.
Circumference	$14\frac{1}{8}$ in.	14 in.	$\frac{1}{8}$ in.
From root of nose to spine of occiput (tape) ...	$7\frac{7}{8}$	$8\frac{1}{2}$	$\frac{1}{8}$ in.
Ditto calliper measure	—	$4\frac{1}{2}$	—
From ear to ear over vertex (tape)	$9\frac{7}{8}$	10	$\frac{1}{8}$ in.
Ditto calliper measure	—	$3\frac{3}{8}$	—
From ear to middle of forehead	$4\frac{1}{2}$	$4\frac{1}{2}$	—
From ear to middle of occiput	4	$4\frac{1}{2}$	$\frac{1}{2}$ in.

The two measurements made, as I believe, by comparable methods,

* Read before the Section of Psychology at the Annual Meeting of the British Medical Association in Edinburgh, August 1875.

would seem to show that the increase in the size of the cranium during the last four years depends upon development in the occipital and parietal regions, rather than in the frontal. From the photographs which I exhibit, and also from the diagrams illustrating contours of the head in various directions, which I have made with the aid of flexible wire, it will be seen that there is nothing distinctively pitheoid in the aspect or conformation of this boy's face or skull. Though his forehead recedes, there is no great flattening of the arch of the cranium; the skull is simply on a small scale. The profile, indeed, has somewhat of a bird-like aspect, and, it is remarked, bears strong resemblance to that of the so-called Aztec children exhibited in this country some twenty years ago.

The etiology of this case is by no means clear. Frederick H. is the son of a Yorkshire coachman; and both father and mother appear to be healthy, intelligent, steady-living people, without (so far as is known) any hereditary or acquired constitutional dyscrasia. He is the third of a family of five, all except himself being intelligent and well-formed. He was born at full time, after a rapid labour, consisting of but three pains; and his mother cannot recall any circumstance attending her pregnancy with him differing, in any respect, from the circumstances of her other pregnancies. It is impossible now to obtain any trustworthy evidence on the subject of premature ossification of sutures in this case, a cause assigned by Virchow for the occurrence of microcephaly.

The case, however, is chiefly remarkable for its mental characteristics. In Bucknill and Tuke, the boy is described as "quarrelsome and unmanageable", and, though comparatively intelligent, of a disposition the reverse of amiable. This is by no means his condition now. As a result, no doubt, of discipline, he is now well conducted and fairly sociable. Though unable to articulate clearly more than a few monosyllabic words, such as "look", "come", "see", etc. (which he uses appropriately), he has evidently a fair degree of understanding. Nothing appears to escape his notice; and, on my morning round, he is in the habit of persistently directing my attention to any new thing (such as a fresh toy or some change of clothing) which has fallen under his observation since he last saw me. At school, he tries to imitate writing on a slate, to match colours, and to join in the drilling exercises of the children. That he is able to carry on a train of reasoning may, I think, be deduced from the following incident. A few Sundays ago, having been kicked by one of his companions when walking in the grounds of the asylum, two hundred yards from the house, he left the nurse and children, and ran as fast as he could to the room in which I am in the habit of seeing patients; and, ejaculating "Look, look!", would not rest till I had examined his leg, and accompanied him to investigate the circumstances of his injury.

CASE II.—Albert —, a boy aged 7, has been under observation only since November last. He is a rickety, knock-kneed child, 34 $\frac{3}{4}$ inches high, 30 lbs. in weight; and, on account of the feebleness of his legs, at present not very active in his movements. His head-measurements are as follows:

Circumference	14 $\frac{1}{2}$ inches.
From root of nose to spine of occiput (tape)	9 $\frac{1}{2}$ "
Ditto	ditto	(callipers)	...	4 $\frac{1}{2}$ "
" ear to ear over vertex (tape)	10 "
" ear to ear (callipers)	3 $\frac{1}{2}$ "
" ear to middle of forehead	4 "
" ear to middle of occiput	4 $\frac{1}{2}$ "

Though the circumference of the head of this case is not so large by three-eighths of an inch as that first described, the microcephaly is less striking at the first glance. The superciliary ridges are more prominent than in the first case; but the forehead, though low, recedes somewhat less rapidly. The cranium itself is well vaulted. Like Frederick, this boy has a large lustrous eye and well formed features; and his mental characteristics are not dissimilar. He speaks but rarely, but, according to his mother's statement, is not devoid of the power of articulation, having, under the influence of excitement, used even dissyllabic words, e.g., "Jesus Christ". I cannot personally vouch for his ability to make any but simple ejaculatory sounds; but he certainly makes efforts at school to imitate the words he hears. He is, like Frederick, very inquisitive and observant, and is able to point out when they are named most of the garments he wears. He is, as Frederick used to be, rather quarrelsome and masterful; and was stated, on admission, to be at times dangerously violent.

The history of this boy is as follows. He is the youngest child of a family of eight; the other seven children, five of whom now survive, having been free from bodily and mental defect. There is a history of consanguinity between the parents' families, the father having been the mother's second cousin, and there had been instances of mental weakness and of phthisis in previous generations. During her

pregnancy with this child (who was born after the full period of gestation), the mother was in delicate health, much depressed in mind, and in the middle of pregnancy much affected by the shock of seeing one of her children fall violently on his head. This shock has been suggested by her as the cause of Albert's idiocy; but amongst all the circumstances just detailed there is not much ground for surprise that the child should be an idiot. Why he should be a microcephale is another question. One would not suppose that the rickety diathesis, of which the boy presents in his long bones unquestionable symptoms, is one in which premature ossification of the cranial sutures would be met with. Is it possible that the maternal shock referred to may have been an element in determining the abnormal conformation of the skull? I am aware that mothers' statements on these matters are to be received with very considerable caution; but I think they are not to be indiscriminately rejected.

I will not attempt to enter upon any general disquisition upon microcephaly. Suffice it to remark that the two cases just described do not lend any support to Vogt's theory of the pitheoid characteristics of microcephales.

CASE OF PARALYSIS OF THE SERRATUS MAGNUS.*

By SAMUEL WOODMAN, F.R.C.S.,

Consulting Surgeon to the Ramsgate and St. Lawrence Royal Dispensary.

THE recorded cases of paralysis of the serratus magnus muscle are not numerous, and in very few is the paralysis clearly complete. I have, therefore, thought it worth while to publish the following well-marked case.

Francis E., aged 39, after fifteen years in the service of the Trinity Corporation as seaman, was in November 1873 promoted to be lamp-lighter in a temporary ship, the lamps of which (eighteen in number), with reflectors and apparatus, were placed so high above the platform on which he stood, that *all the work was above the shoulder*. In six months after his appointment—i. e., about May 1874—he felt a weakness in his shoulder. At first, he says, "there was a dead sleepy feeling came down over the shoulder-blade"; and he had a difficulty in raising his arm. In the July following (about a year ago), in coming down the hollow mast of his light vessel, he missed his footing and fell twenty or more feet, bringing himself up by throwing out his elbows as breaks. He does not consider that he injured himself by this accident. Nor that it had any effect in increasing the affection of the shoulder. The abnormal sensations soon disappeared, but the "weakness" increased, and it is now many months since he has been able to raise the arm above the shoulder. He did not seek medical advice, but continued to do his work, using the left arm instead of the right; but, on returning home early in May last, after being two months on board his vessel, his wife for the first time noticed that his shoulder was "out", and he came at once to me.

On examination, it was found that the usual signs of paralysis of the serratus magnus were present; but the points particularly noticeable were the bulging of the ribs and the raising of the whole of the affected side (the right). In a state of rest, the tip of the right shoulder was an inch and a half higher than the left; and, in the anterior inferior triangle of the neck, the sharp superior angle of the scapula could be seen and felt projecting only an inch and a quarter from the clavicle. The lower angle of the scapula on the affected side was two and a half inches above and an inch and three-quarters nearer to the spine than that of the sound side. It projected one inch from the surface; and, on raising the arm forwards, it started out an inch and seven-eighths from the side. He was able to raise the arm so that the elbow was within two inches of the level of the nipple, but could raise it no higher. On lifting the left arm to an equal height, the measurement at a point corresponding to the acromial process of the sound side was three inches and three-quarters higher on the right than on the left side. The outline of the neck was formed by the levator anguli scapulae, which was much hypertrophied. The spine was considerably curved towards the affected side, but still the girth of the chest was two inches more on that side than on the other. The serrations of the muscles were very plain on the left side, but were not visible on the right. With the exception of this muscle, there was no loss of power whatever in the arm or shoulder; and, when his arm was once raised, he could hold on or pull as strongly as ever.

The application of the induced current caused no contraction of the

* Read in the Medical Section at the Annual Meeting of the British Medical Association in Edinburgh, August 1875.

muscles, as it has done in cases where the paralysis has depended on neurosis of the long thoracic nerve only; but I believe that in this patient the nervous power derived from the branches of the intercostal nerves, as well as that from the long thoracic, has been exhausted by great overaction of the muscle; and that atrophy of the muscle has accompanied it.

The bulging and elevation of the side arc, I think, caused by the efforts, repeated many times daily, to indirectly raise the arm a little higher by raising the side; and the muscles whose action causes it are the scapulari. The long thoracic nerve may be in this way subjected to unusual pressure, which must tend to aggravate the affection and to retard the recovery.

He has been treated by the daily application of faradisation and cold douches: his arm has been kept in a sling; and he has taken large doses of quinine and strychnia. Contrary to expectation, in two months very considerable improvement has taken place. How far this will extend remains to be seen.

ON TETANY.*

By JOHN HADDON, M.A., M.D., Eccles, Manchester.

THE history of the affection known by the name of "Tetany" is of very recent date as regards this country. In 1869, I met with a well marked case; but it was not until March 1870, when a second case came under my notice, that I found an excellent description of the symptoms in Trousseau's *Clinical Lectures*, and learned, for the first time, that the affection was already well known and named in France. It seems strange that our French neighbours should have seen so much of this affection, when in England it was unknown; and one is tempted to conclude that it had not been met with in this country. This conclusion, however, I fear would not be correct; and I am inclined to believe that, had Trousseau's lectures not been published, English medical literature might to this day have been silent on the subject of "tetany".

And here I cannot help remarking how necessary it is that each member of the profession when he meets with any disease or symptoms of which he cannot find any description in medical literature, should, as a duty, place his observations before the faculty in one of the many periodicals which we possess. Were this done, I feel confident that we would soon require new text-books; and perhaps our increased knowledge, instead of adding to the bulk of such books, would very considerably reduce the formidable dimensions which they threaten to assume.

However, probably the first notice of tetany in English medical literature was made by Dr. Moxon in *Guy's Hospital Reports* for 1870. The second notice of it is by Dr. Wilks in the *BRITISH MEDICAL JOURNAL*, June 10th, 1870. The next notice of tetany occurs in the *Edinburgh Medical Journal* for August 1870, where I recorded three cases which came under my observation. A fourth notice of this affection is published in the *BRITISH MEDICAL JOURNAL* of August 6th, 1870, by Dr. Broadbent; and the last which I have seen was by the late Dr. Currie Ritchie, in the same *JOURNAL*, on October 1st, 1870.

Thus, judging from the cases of "tetany" recorded in 1870, and remembering that Trousseau's lectures had been published but a short time before, I think the inference is warranted that the affection is not new in this country; and that we fail to find records of it earlier solely because it had not previously been described in our literature, and had no place in our nomenclature of disease. From March 1870, I saw no case until March 1875, when I met with two more, the particulars of which I shall now give with all possible brevity.

CASE I.—Mrs. T., aged 39, was married when twenty-five years of age, and had six children, the youngest being four years old. She had one abortion before the youngest was born, and two since, the last having occurred about six months ago. For the last two years, she had suffered from menorrhagia; and, during the past twelve months, she had had diarrhoea to the extent of five or six motions daily. About Christmas 1874, she was very sick, and had excessive diarrhoea, with great pain in the head; and at this time she states that her hands felt powerless. Menstruation, having continued for three weeks, ceased on March 5th, 1875. On March 8th, she had pain shooting from the back to the front of her head, and her thumbs felt stiff. In the afternoon of the same day, about three o'clock, she had an attack of tetany in the hands. On March 9th, at 1 A.M., she had another more violent attack, the feet being also affected. On March 9th, when I saw her about

10 A.M., I found her in bed. She was well nourished, and apparently a strong woman, but suffered from slight deafness. Her face was flushed, and she had an excited anxious aspect. The tongue was natural, she had no appetite, and was very thirsty. The bowels had been moved several times in the morning. The urine was abundant. She complained of great pain shooting from the back of the neck to the forehead, and some pain in the arms. She was perspiring freely. The muscles of the arms were rigid, and hard to the touch; and the thumbs were stiff and incurved. Her pulse was 80; and, with the exception of the pain in her head, she felt tolerably comfortable. I gave her one grain of opium, and prescribed half-drachm doses of bromide of potassium every hour. She remained very comfortable till 2.30 P.M., when she had the first dose of her medicine; and, in a very few minutes afterwards, she had another seizure. Having been sent for, I found her perspiring profusely, with a temperature of 97.4. Her arms and hands were alone affected. The arms were drawn out from the sides, the forearms flexed on the arms, the hand drawn towards the ulnar side of the forearm, the fingers flexed, and the pulp of the thumb rigidly fixed against the front of the forefinger. The head still ached, but her great trouble was pain in the arms. Her breathing appeared to be affected, as if she had a tightness across the chest. She had an aspect of great anxiety; and, looking first at one arm and then at the other, complaining of the pain, she trembled all over, and declared she could not live long unless she was relieved. The muscles of the arms felt hard and rigid, like ropes; and a marked fibrillary quivering could be distinctly seen in the ball of the little finger. Straightening the flexed parts, and rubbing them, gave her relief. In about half an hour, she began to improve, and soon was tolerably comfortable, although the hardness of the arms and incurving of the thumbs still remained. She had another slight attack at 6 P.M., and a still slighter one at 8 P.M., which was the last. At night, her temperature was 98.8 deg. Next day, March 10th, having passed a good night, she felt quite well, with the exception of some pain at the bottom of the back, and pain in the arms when they were touched. She was able to be up at night; and, next day, was about her usual household work.

I examined the urine of March 10th, and found it to be of specific gravity 1.017, with a copious deposit of urates. Acid caused much and long effervescence, and it contained one-fifth of albumen. On March 15th, it contained one-thirteenth of albumen; and since then I have not seen her.

CASE II.—Mrs. G., aged 45, was married when twenty-eight years of age, and had had seven children, the youngest being eleven years old. She had generally been a very healthy woman. Menstruation was always normal, and ceased twelve months ago. During the past two years, she had had diarrhoea more or less; sometimes having as many as twelve motions during the day, and as many in the night. The motions were very liquid, and small in quantity. There was no discharge *per vaginam*. She had pain in the abdomen, and in the small of the back. In the end of April 1875, she suffered from severe headache; at the same time, the bowels were excessively relaxed, and she had severe cramps in the hands and feet. On asking her to describe the cramps, she gave me a very good account of an attack of tetany. About the time of this attack, she noticed some spots on her skin, which is psoriasis. About the middle of March, when I saw her, she had a return of the tetany symptoms in the hands and arms. She took bromide of potassium, and was soon relieved. There was no albumen in the urine. She had spent much on medicine without any relief from the diarrhoea, which was caused by a constriction in the rectum; this having been dilated, the bowels acted regularly, and she considered herself well.

From the account I have given of these cases, some idea may be formed of the character of the affection, but no description can give you a correct idea of what you would observe by witnessing an attack. Trousseau gives a very full account of the symptoms in his *Clinical Lectures*. After following its history in France, he goes on to state that he at first thought the disease was special to nurses; and though he somewhat changed his opinion, still he says it must be admitted that nursing is its most frequent and active cause. It has also been supposed that menstruation, the puerperal state, pregnancy, and diarrhoea, are causes of tetany.

In one of the cases which I have related, menstruation had ceased; but diarrhoea, if we may call it such, existed, although, to speak correctly, it was really constipation.

In the other case, there were both diarrhoea and menorrhagia; and, in addition, albuminuria also.

Thus, in the one case, there was, as we may suppose, a retention in the system of what should have been excreted; while, in the other, there was a drain upon the system through the bowels, the kidneys, and the uterus. Upon what may be the real cause or true nature of tetany, we need not now speculate, since we have not a sufficient number of

* Read before the Medical Section at the Annual Meeting of the British Medical Association in Edinburgh, August 1875.

cases from which we might hope to arrive at a correct conclusion. Dr. Moxon has called attention to the resemblance between the symptoms of tetany and ergotism, which is certainly very striking. Still, whatever may be its real nature, it is an affection of great interest, considering the likeness it bears in some of its forms to tetanus. What Trousseau describes as the "grave form" will appear to most readers to differ very slightly at all from true tetanus; and yet we cannot suppose that Trousseau was mistaken in the diagnosis. This points to the necessity there is for further observation of tetany; and, therefore, I would urge all who have the opportunity to report any case they may meet with, seeing that by so doing they will add to our knowledge of this affection; and from it, as a stepping stone, we may be enabled to elucidate other allied and still obscure diseases, the real nature of which can at present, only be guessed at. (*Brit. med. Journal*)

ABSTRACTS OF

INTRODUCTORY ADDRESSES

DELIVERED AT

THE METROPOLITAN AND PROVINCIAL SCHOOLS,

On OCTOBER 1st, 1875.

ST. MARY'S HOSPITAL.

THE Introductory Lecture was delivered by Dr. RANDALL, Lecturer on Medical Jurisprudence and Hygiene.

Dr. Randall began by stating that, as the advice given to those entering their profession had been well-nigh worn out, and addresses on medical education had been often published, he should begin by touching on a hygienic subject, as a part of State Medicine, before dealing with the ethics and mental discipline of student life. He did not intend to dwell upon the air we breathe, the water we drink, and the food we eat, but on the earth as a receptacle for the dead; perhaps not a pleasant subject, but one exciting much interest and attention at the present time. The productive earth is health-giving and health-destroying, also a purifier and preserver, or antiseptic. After mentioning the health-destroying effects of the earth, and referring to its various conditions under which good and efficient drainage was the only preventative of disease, he proceeded to refer to the purifying action of some kinds of soil which acted by facilitating decay and preventing emanations; and then reviewed in detail the preservative qualities of different kinds of earth, and the modes adopted by some nations for preserving and others for destroying the body. He illustrated the result which dry and sandy soil seemed to have in not permitting decomposition by examples of the dry and calcareous vaults at Toulouse and Dublin, and of bodies found in Peru in a state of preservation, buried in those sandy regions, where the rain never falls, and the sand is rendered so perfectly dry as to cause absorption so rapidly, that putrefaction does not take place. He alluded to the dryness of Upper Egypt, to the localities of the catacombs both in Egypt and Rome, and to the mode of embalming the bodies in Egypt. The BRITISH MEDICAL JOURNAL of September 18th had given an example of the antiseptic power of the earth on bodies found at Greenwich, which had been buried for thirty years. He then explained the result of some experiments in the use of charcoal as proposed by Mr. Haden, and its adaptation to the double wicker coffin when kept above ground. The result was, that three or four inches of charcoal, in the intervening space between the inner and outer baskets, were not sufficient, nor six inches; it was not until twelve inches had been reached that offensive emanations and the evidence of ammonia, carbonic acid, and water charged with organic matter, ceased to be given off. Without disapproving of bodies being placed in wicker baskets so as to come into contact with the earth, he did not advocate Mr. Haden's plan of burying the dead with the known object of their being consumed and exhumed at the end of a certain time, that others might be placed in their stead. Do not our notions run counter to such expedients? Are we not imbued with the principles of inviolability of our graves and cemeteries? Is not the burial ground "God's acre"?

"I like that ancient Saxon phrase, which calls
The burial-ground 'God's acre.' It is just;
It consecrates each grave within its walls,
And breathes a benison o'er the sleeping dust."

If a cemetery be filled, is it not preferable to have a new one rather than that the ground should be disturbed and turned up? Let us remain where we have been placed; let that mould with which we are

mixed, and a part of which we form, remain quiescent, and not be made to form a fresh mould to imbibe the emanations and to purify the exhalations of that putrid body which will be put in our stead. In the words of the late Rev. Canon Dale: "For all must feel that an unbroken sod beneath the canopy of heaven is better, far better, than a pyramid which enterprise can penetrate, or a catacomb which curiosity can explore." And, further, to quote his words: "Grant that in less than a century even this wide space be fully occupied, yet the shady grove, the quiet walk, the graceful tree, the budding rose, the springing flower, yea, even the worn grey stone, will be profitable and pleasant to the living." The lecturer then referred to the proposal for burning our bodies called "cremation" as a heathen and pagan custom, which could not be approved of in a Christian country; the present proposal of burning the dead in reverberatory furnaces or near gas-works is something more than disagreeable; it appears revolting and almost brutalising. This dismal annihilation taught by the pagans has in it something so unsuited to the wants of a Christian world, that it takes us back to the ages when those barbarous customs were in vogue; as unsuitable to us as to have our bodies exposed on the summits of the "Towers of Silence", there to be devoured by the ravenous birds of the air, or to be thrown into the sacred Ganges a prey to the rapacious reptiles. The lecturer lastly referred to the great age of Egyptian mummies, one having been unrolled by Mr. Pettigrew, which he dates as being 1,430 years before Christ, or twenty-one years after the death of Moses; hence 3,305 years old: an historical wonder, which seems to make past things appear closer, and is one of the things that are like magnifying lenses, through which we can look at past times and bring them nearer.

Dr. Randall then addressed himself to those who were studying the profession, and more especially to those who were commencing. He exhorted them to consider well and reflect upon the exertions which would be required of them, and the amount of labour which was before them; they ought, with a determined mind, to fix their line of conduct, and repeat, "To be or not to be? that is the question!" Their answer should be a ready and quick one: "To be"—what those who have brought them up and nurtured them expect them to be; what their teachers desire them to be; what their school, for its honour and reputation, demands them to be; and what their conscience tells them to be—diligent, hard-working, attentive, and determined students. He reminded them that they had passed the school of their boyhood, and were now entering that of their manhood, and that the strict discipline of the school of their youth having ceased, they were now comparatively free agents, and their moral and mental discipline, regularity and orderly conduct, rested with themselves. Lecturers and tutors had been appointed to teach them, to assist, guide, advise, and encourage them; provision for studying and becoming acquainted with disease had been made for them. He said: The trench has been mapped out and dug; it is for you to lay the foundation, to lay a substantial and lasting one; to fill up this trench and raise it by degrees to a superstructure, a temple of knowledge, which, it is true, will take a period of four years to build, an apparently long time; therefore, the more likely to be well and firmly built, and well furnished. He pointed out to young beginners the necessity of making a good start with anatomy, histology, and chemistry, and the advantages of a thorough knowledge of each subject. He exhorted them in their moments of despondency and anxiety—for the most conscientious students were often the most anxious—to remember that determination and perseverance were more necessary for success than great talent or ability. After strongly recommending the study of anatomy, which he said required attention, observation, and memory, he reverted to chemistry and natural philosophy. He believed that chemistry had of late years been neglected, and he said: Chemistry has now become a most important element in your education, pray do not neglect it; without it you cannot study physiology advantageously, nor pathology, nor the principles upon which the treatment of many diseases is based. Under the present system of appointments, many or most of you may be coming sanitary officers, or have something to do with sanitation; without you assiduously go through a regular course of the elements and theories of that science, you will not comprehend its complications, or be able to cope with future difficulties. He advised the study of the laws of light, heat, and electricity, as this branch of physics had become a powerful factor in the treatment, diagnosis, and prognosis of disease. He illustrated this by different instruments now much used, including the microscope and clinical thermometer, which was an instrument as replete with safe diagnosis and prognosis as the stethoscope. Again, electricity and galvanism, as therapeutical agents, have made rapid strides in the last few years. The beneficial effects of these as remedies for the relief of pain, and the restoring of a paralysed limb to use and feeling, or as stimulants, tonics, and sedatives;

yes, even to the arresting of hæmorrhage, and of saving life, are now fully recognised. In the study of chemistry and physics, he said, the reasoning and calculating faculties will be brought up, and thus, in combination with the faculties whose exercise is required in the study of anatomy, a training of the mind will be formed, a necessary training, and as good and efficacious as could be found in the mental training of the best of our educational bodies. Soon you will reach the wards of your hospital, there to learn and diligently watch the symptoms and signs of disease, the action of remedies, and the means adopted to relieve pain and to cure. You may rest assured that if you begin well, and learn slowly and gradually and effectually, and are well grounded, you will attain your end, and enter life as a honest, efficient, and faithful practitioner. He who sows ought to reap. But if you have been idle, and careless, and inattentive, you will deeply repent of your conduct, you will have no confidence in yourself, nor be trusted by those who employ you.

"He that trusts you,
Where he should find you lions, finds you hares ;
Where foxes, geese. You are no surer, no,
Than is the coal of fire upon the ice,
Or hailstone in the sun."

You will not have the boldness of the lion—that is, commendable assurance and reliance ; nor the cunning of the fox—that is, wisdom and aptness gained from knowledge. But, truly, you will be as timid as hares and feel as foolish as geese. Your reputation will be extinguished like the coal of fire upon the ice, or melt away like the hailstone in the sun. He believed that there was a want of perfection in learning, and reminded them that the secret of being successful and accurate as students, next to perseverance, is the constant habit of reviewing the same subjects, daily, weekly, and monthly. In reviewing, he advised them to try and write what they remembered, for the habit of writing, by which you attain a facility of describing accurately, is of paramount importance, not only for the sake of learning well, but also with the object of attaining that art for particular occasions, when your knowledge will have to be tested at the different examining boards, and for competitive appointments. Remember, that if Bacon said that "reading makes a full man", he also said that "writing makes an exact man". He then earnestly recommended them not to enter into sports or games which would interfere with their attendance at lectures, or more important instruction in the wards. After some further remarks upon the line of conduct which the students ought to pursue during their studies, the lecturer in conclusion said : Educate your minds to thoughtful and careful study. The training which you will thus acquire will render you more fit to gain that most important knowledge to be acquired at the bedside ; it will tend to make you expert clinical observers and practitioners—the object of all your learning. Do not let this opportunity of acquiring knowledge pass by ; do not let this vast field of information run to waste ; store and husband it as you would the best riches of your professional life, and be assured it will form the backbone of a successful career in after days ; and thus, session after session, if you feel that you have been a real worker ; that you have employed your time diligently and assiduously ; that you have used the abilities with which God has endowed you to the best advantage, to the satisfaction of your own conscience and to that of your teachers, you will possess such an inward feeling of comfort and of pleasant reflection, that you will be able to exclaim with the French poet Lamartine—

"Le jour s'est écoulé comme fond dans la bouche
Un fruit délicieux sous la dent qui le touche,
Ne laissant après lui que parfum et saveur ;
Oh, mon Dieu ! que la terre est pleine de bonheur."

CHARING CROSS HOSPITAL.

THE Introductory Lecture was delivered by Mr. FAIRLIE CLARKE, Assistant-Surgeon to the Hospital.

The lecturer, after alluding to the recent death of Dr. Headland, to the improvements which had been made in the School premises, and the enlargement of the hospital, went on to address himself specially to the different classes of medical students. He said that he was particularly anxious to welcome those who were joining the School for the first time that day, and to give them some encouragement and counsel. He congratulated them on entering the medical profession at such an auspicious moment, when medical science was making rapid advances. He mentioned the subjects which would occupy their attention during the next six months, and gave them advice as to the best way of laying out their time. He said : "You are just taking the important step whereby you pass from boyhood to manhood, and it is not too much to say that everything depends on the use which you make of the time that is under your own control. Temptation rarely comes

during busy working hours ; it is in his leisure time that a man is either made or marred. Make up your mind firmly to your line of conduct, and follow your own course with decision and resolution. It is oftentimes more really manly to dare to say No than it is to fall in with the suggestions of those who may be older than yourself in years or in academical standing." He recommended a certain amount of reserve, in the first instance, in the choice of friends ; but assured them that they would find among their fellow-students not a few whom they might well be happy to gain as life-long friends. He pointed out that at Charing Cross a diligent student can always obtain one practical appointment after another as long as he remains *in statu pupillari*, whilst at the larger hospitals the students are often obliged to enter on the practice of their profession furnished with little more than the information that can be obtained from books and lectures. To the second year's students, who would now be expected to visit the wards regularly, Mr. Fairlie Clarke pointed out the great interest of in-patient practice, both on account of the severity of the cases treated and the more personal relations which are established between the doctor and his patients, and these personal relations cannot fail to draw out our sympathies. He said : "We seem to tread on sacred ground while we accompany the hopeless sufferer to the very verge of this world—to that bourne whence no traveller returns ; and this invests our profession with an interest and a solemnity entirely its own." He specially urged upon those students who held in-patient appointments the cultivation of a considerate way of going about their work, saying that this was quite compatible with a keen interest in the study of disease, and would be likely to win the confidence of the patients. To the senior students Mr. Fairlie Clarke said : "To you, more than to any group among us, is the welfare of this medical school confided. I do not underestimate the influence of your teachers ; but a great deal more than what we can do is what you can do. Our influence is exercised only occasionally ; yours is exercised constantly. We are placed here in authority, and we are all of us less disposed to accept the advice of those set over us than we are that of our equals. It is scarcely too much to say that what you are the younger students will be. Suffer me, therefore, to impress upon you one or two pieces of advice. Remember the weight that your example must of necessity have, and let no idle word, thoughtlessly spoken, sully the purity of the young minds that are joining us for the first time to-day. Let no word or act of yours cast ridicule upon the principles that have been learnt at a mother's knee and fostered under a father's roof. Let nothing induce you to suppose that idleness and dissipation are manly. There is no true manliness but in the diligent discharge of duty. If you, senior students, act in the spirit I have endeavoured to indicate, then hard work and good order will be general among the whole body of students. I often think, as I come within sight of Charing Cross, that the very situation of our hospital is a constant reminder to us to do our duty faithfully and in a high-minded way. We are here surrounded by monuments of national grandeur. To say nothing of Charing Cross as a great commercial centre, we are here near the Houses of Parliament, the chief offices of State, and the abodes of royalty. The improvements which are now in progress in our immediate neighbourhood are beautifying it, and making it more worthy to be, as it is, the great centre whence the influence of England goes forth over the whole world. Often, when I have been coming to my work here, I have bethought me of that bright morning in October 1805 when the English fleet bore down on the combined squadrons of France and Spain off Cape Trafalgar. It scarcely needs the inscription on the Nelson monument to remind us of the watchword, now become an English proverb, which was then signalled from the mast-head of the *Victory*, and which stimulated all to do their duty so gallantly. Or I have bethought me of Sir Charles Napier, the very soul of honour and rectitude, so independent in his bearing towards his equals ; so free from all time-serving and tuff-hunting ; so just and considerate to those under his command ; so kind and humane to those who were in trouble or distress. Or I have bethought me of Havelock, the very ideal of a soldier, an officer, and a Christian ; doing his work diligently and cheerfully, notwithstanding straitened circumstances and professional disappointments. It was not the stimulus of early success, nor the favour of princes, nor any lower motive, which carried him through the disappointing years that formed so large a portion of his military career. It was nothing short of a strong Christian principle which sustained him. The monuments of these great men have been erected in our immediate neighbourhood not merely to do honour to individuals, but also to keep alive in the breasts of each succeeding generation the virtues for which they were distinguished. And, if there be any class of the community who are likely to be influenced by the recollection of their noble deeds, it is surely the young men of England before whom life is just opening. Duty, honour, and the fear of God—these were the mainsprings in the

characters of the three heroes to whom I have alluded. If you, students of Charing Cross Hospital, are fired with the same principles, we need have no fears for the success of the session that opens to-day. It cannot fail to be a happy and a prosperous one; and we may leave in your hands the interests of this medical school, feeling confident that they are safe in your keeping."

LONDON HOSPITAL.

THE Introductory Lecture was delivered by Dr. BATHURST WOODMAN.

After some prefatory remarks on the mingled feelings with which such a meeting of old and new students must be regarded, the lecturer remarked that the history of eminent medical men refutes the common notion that the study of medicine has a tendency to create sceptics. Such is not the case. Celsus, the medical writer, and Celsus, who was answered by Origen, were separated by a whole century. Nor is it true that the medicine of antiquity was all a farrago of nonsense, or a collection of quaint conceits. A careful study of Hippocrates and other ancient writers disproves this, just as the medical and metrical precepts of the School of Salerno, or a view of the lavatory of Gloucester Cathedral, disproves the popular lecturer's notion that people never washed in the middle ages.

Vivisection was next alluded to; and, whilst its abuses, and the needless barbarities of Alfort, twenty years ago, were condemned *in toto*, the necessity for experiments on animals was insisted upon, and justified from the imperfections of our art, from the example of the wisest and best of its professors, and because human life and human happiness are infinitely more valuable than those of other animals. If those who oppose all such experiments could witness the scenes of horror often met with in our hospitals and in private practice, their opposition would be less keen. The late Sir Robert Peel's life had in all likelihood been saved, had chloroform only been more known when he met with his accident. But substances like chloroform must first be tested on animals. We must look to a healthy public opinion to regulate these experiments rather than to any sensational cries or legal enactments. Dr. Woodman next insisted upon the necessity of students earnestly resolving to train themselves for the practice of their profession. It is no longer possible to learn the medical art from any one manual, however excellent, or from any one teacher, however eminent. Every day increases our difficulties as to diagnosis of diseases. For example, a few years ago, only wall-papers of a peculiar grass-green colour contained arsenic in any quantity so as to be dangerous. Many people think that this is so now. But what is the fact? Since the general introduction of aniline colours and other new dyes, no paper, however sober its hue, can be trusted as free from arsenic till its purity has been tested by a careful analysis. Numerous examples were given of lead and other poisons in articles of food or clothing, and in cosmetics; and even medicines are often adulterated with dangerous ingredients; hence the necessity that a medical man should have at least some general acquaintance with chemistry and with arts and manufactures. A part of this at least should be gained before coming to a medical school. Parents and guardians were earnestly appealed to, to give their sons or wards, if about to enter the medical profession, a thorough grounding not only in English or modern languages, but in Greek, Latin, and elementary mathematics. From his experience as a teacher who had trained some hundreds of men to obtain the diplomas or degrees of almost every medical examining body in the three kingdoms, as well as from his experience as an examiner, he could confidently affirm that nine-tenths of the rejections and failures arise from imperfect preliminary education. When a student comes to the hospital and medical school, he ought not to be obliged to work at any lexicons or grammars save those of disease. The wards of the hospital should be his chief books. Let not the student be too proud to learn from any and everybody. All his teachers will not be equally eloquent or equally skilful; but much may be learnt from even the worst of teachers; much might be learnt from his fellows. Even a fisherman or ploughman may often be well read in the great book of Nature. Great men like Linneus or Agassiz know this, and act accordingly. If willing to be taught, the stores of knowledge in the London Hospital, now one of the largest in the metropolis, were shown to be almost inexhaustible. If the difficulties of the profession are increased, so are the facilities for learning. Here the student will meet with every possible aid from the staff. The lecturer showed that the London Hospital has never lagged behind in the march of medical progress. Its staff and its alumni have not only availed themselves of every scientific improvement, but have largely added to the general store. They were truly practical men, but their practicality was not that of ignorance, but of science. Students were encouraged to work for the prizes which

are offered at the London Hospital. This year, nine important prizes, whose money value alone exceeds £300, are to be given away. He defended the prize system. It had once been abolished at this medical school; but they were glad to resume it. He earnestly begged the students not to waste their first year, as too many have done. Let them remember, and never forget, that the great end and aim of their art is to cure, or at least to relieve. Lamartine has eloquently said:—"Le médecin guérit quelquefois, soulage souvent, console toujours." Let their aim be to multiply the cures. Depend upon it the public will never tolerate us, or pay us fees merely to stand by the bedsides of those they love as scientific observers, or as a sort of Greek chorus; for, although there are times when the highest wisdom is to hold our hand, lest we rudely put out the flickering flame of life, it far more often happens that we can do much to cure or relieve pain, if we only have the knowledge. But, to do so, we must learn all we can, and must be learning ever. Examples of successful treatment on scientific principles were given. Hopes were held out that even cancer and tubercle, those malevolent twins, might in time be conquered and disarmed by careful studies and proper experiments upon animals. The influence of fashion in medicine was deprecated; and the lecturer concluded by warning against the baneful influence of a dogmatic scepticism, which is often as injurious to the progress of the healing art as it is to the spiritual and eternal welfare of the man.

WESTMINSTER HOSPITAL.

THE Introductory Address was delivered by Mr. RICHARD DAVY, Surgeon to the Hospital.

Mr. Davy disapproved *in toto* of introductory addresses; but, at the request of the medical council of the hospital, conformed to custom. Both students and teacher preferred one day's pheasant-shooting to hearing or giving an introductory. As a surgeon, he should cut down his sermon from one hour to fifteen minutes, and his successor might still further reduce the volume of these fruitless harangues. After welcoming his audience, and referring to the changes in the hospital staff, the lecturer drew attention to reform in the practice of medicine and surgery. Far too much stress was laid on the necessity of elaborate teaching. Above all, a young man should be taught self-reliance. His own efforts would then pull him through, just as a vigorous constitution was the mainstay of recovery independently of elegant prescriptions and repeated visits. University discipline and residence were strongly insisted on. Healthy tone and lifelong friendships were acquired in this training, in lieu of an entire want of control now felt by hospital teachers over their pupils, and the acquaintance of these young men from the country with interestingly repulsive specimens of shark (*squalida*) known as London landladies. The payment and honours conferred on medical men were next criticised. Their salaries were simply miserable; hospital-physicians and surgeons were for the most part unpaid; Poor-law officers most piteously; surgeons in the services very badly; and young practitioners not at all. For seven years' hard work at the St. Marylebone Dispensary, he had received one guinea, and a very distinguished London assistant-physician had found that his salary equalled that earned by the man who put the skid on the "bus wheels at Holborn Hill. The lecturer had been taught how dignified the profession was. In his opinion, the British public introduced far more largely the element of impudence than dignity into practice; to become a baronet was the Ultima Thule, and in the nineteenth century one could not maintain even this dignity without payment. He considered that gratuitous work, and its consequent dignity, were subjects worthy of woman's consideration, and that ladies desirous of occupying a congenial sphere in the medical profession might ease the men's shoulders from upholding the work and dignities of unpaid appointments. The lecturer next quoted the word "charity" as a synonym for professional imposition—a bargain between the public and the medical man for gratuitous work; and upheld that less jealousy amongst themselves, and a far higher estimation of their own services to the public, would bring about reform. It was strongly urged that the medical element should be directly represented on all hospital boards. Mr. Davy challenged the authorities to show reason why ancient coroners should call upon qualified house-surgeons and physicians to give their evidence without fee. He would remind them of the two clowns in Hamlet;

"Second clown: But is this law?"

"First clown: Ay, marry, is't, crowner's 'quest law."

Why should the Registrar-General or Commissioners in Lunacy expect their skilled services for nothing? The lecturer strenuously advocated sanitary reform, and eulogised preventive medicine. He warmly supported the extension of the Contagious Diseases

Act, and was pained at the nonsense that had been let off over vivisection. Practical experiments were as important to them as to the Royal Artillery on Dartmoor; but their experiments were made to ascertain how much mischief they would do the dead, while theirs discovered how much good they could do for the living; and not only was the dissection of the living requisite, but also the dead, in gaining their knowledge. For this end, it behoved every hospital to insist on the performance of a *post mortem* examination (in case of death) as a condition of admission. In conclusion, the lecturer assured the students that their early prospects in life were most disheartening. Their toil and ambition might be equally great, but their pay and dignity would be equally small. They had to deal with an ignorant and proud people, and he advised everyone to resign at once any and every thought of becoming a medical man unless he possessed three qualifications: first, independence; second, an aptitude for, and love of, the profession; third, the readiness to pay a heavy premium in this world for his prospect of reward in the next.

MIDDLESEX HOSPITAL.

THE Introductory Address was delivered by Mr. B. T. LOWNE, Lecturer on Physiology. After some introductory remarks, the Lecturer said:

I do not know any theme which could be made more instructive than a brief history of scientific medicine. The antiquity of the medical art, and especially of surgery, is such that it may be said to have originated with the human race: indeed, some instinctive knowledge of this kind is almost universally ascribed to the higher animals, and perhaps not without reason, for every animal strives to preserve its own body from pain and injury. Hence experience must have guided the human race from the earliest times to seek medicaments, so that the origin of our profession is lost in the mists of tradition, and the earliest records represent the mythic centaur, Chiron, and his pupil, the deified Æsculapius, as the medical teachers and benefactors of mankind. Experience, unaided by reason of a close and accurate kind, is, however, but a blind guide, so that for unknown centuries men contemplated, and indeed worshipped, Nature; yet the efforts of the human mind were feeble when they strove to understand what they saw; unguided imagination produced vast theories, and but little progress was made towards even the faintest dawn of true science in the study of the phenomena of the universe. It was Hippocrates who first taught men the right way to attain a mastery over nature. Do not suppose the same difficulties still exist, such as Hippocrates must have overcome, but bear in mind that from his time the medical science never came up to his standard of excellence again for 2,000 years. It is true that our profession may well be proud of many of her votaries during that long period. Of these Galen was the most notable. He was the first whom the prejudices of mankind permitted to examine the anatomy of the human body, and thus he laid the foundation of anatomical knowledge. His reasoning powers, however, were not of a character to place him on a level with Hippocrates, yet the views he taught ruled the medical world with absolute tyranny for at least 1,500 years. It was not until the middle of the seventeenth century that medicine again became a truly scientific art; and the modern science took its birth in the master mind of Sydenham, whom I would call the father of our science. Sydenham was truly a second Hippocrates; but great changes had occurred in the world during this lapse of time; men's minds had been freed by changes in their religious tenets, culminating in the work of Luther. The greatest, perhaps, of men's inventions—the printing press—was actively engaged in reproducing the writings of the ancients, and in rendering the workings of men's minds permanent, so that they should defy even the ravages of time. Vesalius, even against the powerful antagonism of Fallopius, had shaken the authority of Galen in anatomy, and Harvey had discovered the circulation of the blood. Chemistry was an infant science during the lifetime of Sydenham, and owed its existence to the minds of Boyle and Beecher. The time was propitious—the bright dawn of science had commenced, and it wanted only a master mind to make medicine a most noble study. Sydenham laid its foundation on the work of Hippocrates, and Boerhaave took up the work where Sydenham left it. From that day to this, great names and great workers have never been wanting in the medical world—men with free enlightened minds seeking laboriously for truth, and finding it. Even to enumerate the names of those who have worked successfully at science would occupy many hours. I therefore propose to occupy your attention with the effect of the kindred sciences upon our own rather than with the work of individual men, however great their eminence. Perhaps physics have had the most important effect indirectly upon the science of medicine. I think the minds of men were directed to the

study of physics by the great cosmic discoveries of Kepler and Galileo, and the oceanic voyages of Columbus and his followers. Certainly Gilbert had written and published one of the finest models of physical research, in his great book on magnetism, twenty years before Bacon published his *Novum Organum*, which has often had the credit of instigating men's minds to experimental research. When once the exact nature of scientific investigation became thoroughly understood, it must have had a marked effect upon all kinds of research, and thus it happens that every individual is benefited by having some knowledge of exact sciences. The invention of the microscope must be regarded as an epoch in our science; but it was perfected so gradually that, although it must be regarded as an invention of the seventeenth century, it was not until forty years ago that it became a powerful instrument of research. With regard to the direct benefits received from physical science, we have the most beautiful adaptation of the science of acoustics in auscultation and percussion. The merit of the discovery of the former is due to the brilliant Laennec, and of the latter to Avenbrugger and Corvisart, early in the present century. These are undoubtedly among the most satisfactory and useful methods of discovering disease known to the physician, and the benefit afforded by their discovery to mankind is simply incalculable. Again, we have the more brilliant discovery of Helmholtz—one of the greatest philosophers the world has ever boasted—in the ophthalmoscope, which enables us to examine the retina, one of the most delicate structures in the body, and to work out the most difficult cases of ophthalmic disease. This instrument was entirely the work of induction and thought, and not of experience, so that a century intervened between the more obvious adaptation of acoustic properties by Laennec and the optical work of Helmholtz. After speaking of the influence of chemistry and physiology, and the possible results of the doctrine of evolution taught by Darwin, Hæckel, and Huxley, the lecturer concluded by saying:—Since such has been the history of medicine, it is clearly the duty of every student to acquire all the knowledge he can, both of the practice and theory of his art, and of the kindred sciences.

“One rule our life was fashioned to fulfil,
That he who tends Truth's shrine and does the best
Of Science with a humble faithful will,
The God of Truth and knowledge serveth best.”

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.

THE Introductory Lecture was delivered by Mr. HENRY E. ARMSTRONG, Lecturer on Botany.

The speaker, in his opening remarks, compared the giving of an introductory address for students who were afterwards to appear before medical licensing boards to certain eastern customs preliminary to the ceremony of marriage. He then cordially welcomed all students present. Each first year's man was urged to make his choice at once between the ordinary practice of the profession and that of the medical officer of health. The cause of the latter was warmly advocated. Practical advice was given to enable the student to spend to the best advantage the short term of his college curriculum. Among other matters, with reference to reading, the speaker said: “The food of the mind, like that for the body, to answer its purpose, should be carefully selected, slowly taken, in moderate quantities, and inwardly digested.” Extensive note-taking was discouraged, as tending to defeat the object of the lecture. The acquisition of eye-knowledge was strongly recommended. Students engaged in attendance at hospital were cautioned against theorising on the abnormal conditions of the body, whilst their knowledge of facts was crude.

Addressing those who, before the giving of another introductory address, would have left college, the speaker drew attention to several of the duties to the public and to patients, which would devolve on them as medical practitioners; advising, among other things, that conditions likely to affect the health of their patients or others with which the medical officer of health could interfere, should be brought to the notice of that officer. As practitioners, they would have to consider how the complete isolation of sufferers from infectious disease could be accomplished whilst the patient was in the bosom of his family, and whilst the medical attendant went daily, perhaps in his close carriage, from house to house. The experience of several years' management of the Newcastle Dispensary and Fever Hospital had convinced the speaker that a large amount of zymotic sickness was due to neglect of precaution on this head. The responsibility of advising on the food for infants was shown by the fact that, of upwards of 1000 deaths of children under one year of age in Newcastle during 1874, 19 per cent. died from diseases of nutrition.

Respecting duty to patients, the speaker observed that the charge of the sick was a trust of which the medical man would hereafter be called

to give account. He was bound to benefit his patient in every professional way, despising none, however trivial. In allusion to the administration of alcohol, the young practitioner was warned that, unless he were careful in its use and discontinuance, he might perhaps be the means of inducing habits of intemperance in his patients. In respect of duty to the profession, it was held to be incumbent on every medical man to uphold the reputation of the profession by promoting every object which can give weight to its opinion or dignity to its actions. For want of unity of action and opinion among medical men, much talent had been misapplied and time spent to no purpose, or so as to bring discredit on the profession. "What is needed is a great medical union under the direction of an acknowledged head, which shall be the recognised authority on subjects affecting the relation of medical men to each other and to the laity; which shall direct research, confirm opinion, sanction theory, regulate ethics, and, as the voice of the profession, decide on medical matters in general. Of all subjects relating to the honour and dignity of the profession, that which lies at the foundation, and the importance of which, in connection with its status, is perhaps usually underrated, is the mode of remuneration. So priceless to the sick are the services of the medical attendant, so sacred his duties in his own eyes, that, in comparison, the question of pecuniary recompense should sink into an insignificant matter of detail; but cannot do so, since the majority of doctors live not to practise, but practise to live." The speaker went on to state that, though self-denying, devoted, charitable, brave in facing danger, and an unostentatious benefactor to his race, the medical man calculated the remuneration for his inestimable services in such a way as to lay himself open to undeserved charges of cruelty and inhumanity. "According to the principle at present prevailing, the value of a medical man's services is not measured by the good he does, the evil he averts, or the anxiety and responsibility he incurs, but by the length of his attendance and the amount of physic he supplies. Non-dispensing practitioners charge only for advice, estimating it by quantity; others are content to set a price on their physic, and give the advice into the bargain: a mode of proceeding almost equal to that of Chinese physicians stating beforehand the cost of each drug they propose to administer for the consideration of the patient's friends, who, after much haggling, often end by striking out the more costly items from the prescription." In place of the present system of remuneration, that by stipendiary payment was advocated, as practised by the ancients and, at the present time, in clubs and provident dispensaries. The change would benefit the public, raise the status of the profession, and would be no bar to private practice, but would relieve it of many of the annoyances associated with its now semicommercial character, and clear practitioners of the stigma that, whilst professing principles of humanity, they adopt for their motto:

"Quærenda pecunia primum,
Virtus post nummos."

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

We observe that Dr. Joseph Rogers of Dean Street, Soho, is a candidate for the post of Medical Officer of Health for St. Giles's and St. George's, Bloomsbury, vacant by the lamented decease of Dr. G. Ross. Dr. Rogers is well and widely known as having for a long series of years given his best energies to the promotion of sanitary reform. He has taken an active part in most of the great sanitary movements of the day, and in all he has shown untiring industry and courageous public spirit. It cannot be doubted that he would prove a most earnest and public-spirited medical officer of health, and in every way a worthy successor to the able man whose services St. Giles's parish has lost.

MILITARY AND NAVAL MEDICAL SERVICES.

THE ARMY HOSPITAL CORPS.

Now that the regimental has been supplanted by the general hospital system in the army, the functions and responsibilities of the members of the Army Hospital Corps have, as a matter of consequence, been materially augmented. A code of regulations relative to its organisation and duties has recently been issued by the War Office, and will, doubtless, afford information and assistance to all connected with the medical care of our soldiery. The Hospital Corps is, we are authoritatively told, "an integral part of the Army Medical Department", and is to be composed of non-commissioned officers and men obtained from

the general ranks of the service, as well as recruits who have satisfactorily undergone a course of probation at the Royal Victoria Hospital, Netley. We trust and believe that great care and judgment will be exercised in the selection and training of candidates for employment in a corps on the manning of which the comfort and welfare of the sick of our army must in a large degree depend. The privates or orderlies are chiefly concerned in all that relates to the immediate nursing of the sick, and the care, cleanliness, and discipline of the wards, etc., under the supervision of non-commissioned officers, styled ward-masters. Other non-commissioned officers, specially selected, are assigned to particular duties, such as those of cooks, stewards, and compounders of medicines; the mode of performance of their respective duties being clearly specified in the published regulations. The corps is at present officered by some of the late apothecaries of the army, and by a few of the individuals who, under the old *régime*, were regimental hospital sergeants; but, in future, all vacancies in the commissioned ranks, will, except under special circumstances, be filled by the promotion of selected non-commissioned officers of the corps. The commissioned grades consist of a staff officer, who will be stationed at the office of the Director-General of the Army Medical Department, under whose orders the arrangement and distribution of the corps will be carried out by the staff officer, and of captains and lieutenants of orderlies, who will be allotted to districts, and act therein "in the capacity of adjutant and quarter-master, under the principal medical officer", taking instructions from the latter "on every matter connected with the employment of the corps and the duties of the hospital".

Although not expressly stated, we presume it is implied that the power of control over the officers and men of the hospital corps thus vested in the principal medical officer of the district will be by him delegated to the medical officer in charge of the hospital to which these officers and men are, for the time being, attached. Unless this be done, almost incessant references to the principal medical officer would, we apprehend, be necessitated, causing needless delay, detriment to efficiency, and, possibly, a disposition on the part of a pretentious subordinate to dispute or question the authority of the senior medical officer of the hospital, who, it is almost needless to say, we are of opinion, should be absolutely paramount in every particular connected with the administration of his charge.

With regard to the discipline of the Army Hospital Corps, the regulations do not convey to us as explicitly as we could desire the precise authority to whom this important matter is entrusted. All that appears to be certain is that the medical department is not empowered by these regulations to deal with discipline, or, in other words, cannot mete out punishment when deserved to the men who these same regulations teach to look to the officers of the medical department for reward and advancement. This appears to us to be an anomalous, undesirable, and unnecessary condition of things, only too likely to lead to confusion and disorder, which will be fraught with evil consequences to the sick. Why should the medical officer be considered less capable of maintaining discipline among his subordinates than, for example, the officers of the engineer and control departments? Why pick him out and place him in a position which no other master that we know of occupies with regard to his servants? The only surmise we can form is that the traditional and unaccountable jealousy of "doctors" entertained by the "military authorities" still exists. If this be so, a judicious application of common-sense pressure from without would, we doubt not, soon set things right. This is not an age which will tolerate caprice and prejudice, no matter where they exist, if it can be shown, as in the present case we believe it can, that such caprice and prejudice are likely to interfere injuriously with the treatment of the sick of our army, and to cast an invidious slur upon the medical department, which has ever deserved well of its country.

UNIVERSITY INTELLIGENCE.

UNIVERSITY OF CAMBRIDGE.

PROFESSOR HUMPHRY'S LECTURES.—Professor Humphry gives notice that the course of lectures on Practical Anatomy will commence on Monday, October 11th, at 9 A.M., and be continued daily till October 19th, after which they will be continued on Mondays, Wednesdays, and Fridays. The course on Anatomy and Physiology will commence on Thursday, October 21st, at 1 P.M., and will be continued on Tuesdays, Thursdays, and Saturdays. This course is intended for students of Natural Science as well as for medical students.

BRITISH MEDICAL ASSOCIATION :
SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st, Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

PSYCHOLOGY AND THE NERVOUS SYSTEM.

III.

WE now assume the truth of the hypothesis, that the anatomical substrata of our visual ideas are not sensory but sensori-motor processes. We may call them retino-ocular processes. So far anatomy. Now for physiology. As we have already said, the study of the degrees and conditions of excitation or discharge of nervous centres is a physiological study. Physiology deals with the *function* or active states of nervous arrangements. We have to consider what occurs in health, when we have visual ideas, *i.e.*, when we either actually see objects, or when we remember them (see them ideally).

There seems to be a popular notion that the two processes, seeing actually and seeing ideally, are not only different, but altogether different. There even seems to be a notion in some people's minds that, when we actually see an object, there is a physical process only, and that, when we remember it, there is a mental process only. We wish to insist that there is both a physical and a mental process in each kind of seeing. When we see the object actually, there is engaged a sensori-motor process having the constitution we have described; but, as we are at the same time conscious of the object, there is a correlated mental process. In seeing it ideally, there is, as the word ideally implies, a mental process, but there is a physical process here too. In actual seeing, the physical process is thought of, and the mental is ignored; in the ideal seeing, the mental process is thought of, and the physical ignored.

There seems to be another popular notion on this matter, a sort of compromise. It is this: during actual seeing, subordinate centres are engaged in receiving the retinal impressions and with the associated ocular movements; then there is a connection of this with a superior centre—the seat of the “idea” of the object seen by the inferior centre. In recollecting, the superior centre is alone supposed to be active. The fault here is, that nothing is said of the constitution of this superior centre. It is spoken of as a centre for ideation, as if no further analysis were required. The word ideal is probably to blame: we now discard this word, and, instead of actual and ideal vision, we speak of Presentation and Representation of objects. Our next task is to declare what we believe to be the real nature of the physical process in recollecting, being conscious, or, using the word once more, in ideal seeing. We hold that it is *fundamentally* like that of seeing the object actually. Before we point out this in detail, let us try to strengthen the position we take up by citation of authorities on such matters, Bain and Spencer. The following quotations, from Spencer's *Psychology*, refer to the physical processes occurring in recollection generally:

“In brief, those *vivid* states of consciousness which we know as sensations, accompany direct, and therefore *strong excitations* of nerve-centres; while the *faint* states of consciousness which we know as remembered sensations, or ideas of sensations, accompany indirect, and, therefore, *weak excitations*, of the *same* nerve-centres” [no italics in original].—*Principles of Psychology*, vol. i, p. 124.

Bain writes (*Mind and Body*): “Retention; Acquisition, or Memory, then, being the power of continuing in the mind impressions that are

no longer stimulated by the original agent, and of recalling them at after times by purely mental forces, I shall remark first on the cerebral seat of those renewed impressions. It must be considered as almost beyond a doubt that the *renewed feeling occupies the very same parts and in the same manner as the original feeling*, and no other parts nor in any other matter that can be assigned.”

Let us recapitulate. We have, in health, vivid ideas and faint ideas. That is to say, we have ideas in two degrees. For example, we see objects, and we can afterwards think of them when they are absent. There are presentation and representation. We can see them really, and can see them again ideally, for the word “ideal” will come in. First for the vivid ideas.

When we see and *recognise* external objects we have *vivid* visual ideas. There is then strong excitation of the retina, thence to the highest centres in the cerebrum, and back to the ocular muscles. There is complete and strong sensori-motor (as we have said, retino-ocular) action. This is what is fundamental, even if only diagrammatic, however many intermediate centres we may like to suppose betwixt the afferent nerves (optic nerves and retina) and efferent nerves to the ocular muscles. Next for faint ideas.

When we have faint visual ideas (think of objects when they are absent, “recollect” them, etc.) there occurs essentially the very same physiological process as in vivid ideation. There is a nervous discharge in each case. Moreover, the discharge occurs in the same anatomical series in each case. In faint ideation, there is slight or nascent excitation (discharge) of those highest centres to which, when we actually saw the object, the molecular impulses roused by the retinal impressions came, and from which the impulses to the ocular muscles departed. The reader will observe that there is a double difference. There is a difference both in *degree* and in *extent* of excitation. In thinking of objects (faint ideation) the central discharge is (1) slight and limited (2) to the centre. In actually seeing them (vivid ideation) it is (1) strong and (2) spreads from the periphery to the centre, and from the centre to the periphery. It may be said that this is stating in a slightly different way that there is a centre for an “idea” of an object which plays upon a subordinate centre for retinal impressions and ocular movements. Yet the important difference is that the higher centre we speak of is itself the lower centre “raised to a higher power”. It *re-represents* in greater complexity the very same impressions and movements which the lower centre represents. When we have the idea, the nascent excitation, however limited to the higher centre, is referred to the retina, and there is nascent ocular movement.

It is easy of proof that energising limited to centres, or, as we have just said, nascent movement, suffices in ideation. In cases of illusions, the patients have visions of objects which are necessarily owing in great part to central excitation. In hallucinations, the visions of objects are entirely owing to central excitations. In this case, the process is like, and also unlike, that occurring in actual presentation of objects. It is like it in that the energising of the centre is equally strong and possibly stronger. It is unlike it in that, no object being presented, there is no peripheral impression.

The direct proof that energising of nervous centres suffices in ideation is great. We must give it here for several reasons already indicated. *It is demonstrable that excitation limited to motor centres gives rise to effects referral by the mind to the muscles at the periphery of the body.* We could adduce striking facts from ophthalmic practice, but we prefer to state first a different kind of evidence. The facts of it are drawn from Weir Mitchell's masterly work on *Injuries of the Nerves*. There is no higher authority on the subject than this distinguished American physician.

It is well known that a patient “feels” his absent limb long after amputation; he has pains in his absent toes, or is disturbed by some less serious sensation. When a medical student, the writer took away for dissection a leg amputated below the knee. The patient was a man of somewhat feeble intelligence and very ignorant. He knew that the leg had been kept, and the day after, having ascertained that it was still

in existence, begged very earnestly, not at all in joke, that it might be scratched about the ankle, as it itched so much that it kept him awake at night. "Very many," says Dr. Weir Mitchell, "have a constant sense of the existence of the limb, a consciousness even more intense than exists for the remaining member. 'If,' says one, 'I should say I am more sure of the leg which ain't than the one which are, I guess I should be about correct.'" Dr. Mitchell writes also, "The sufferer who has lost a leg gets up in the night to walk, or he tries to rub or scratch it. One of my cases attempted, when riding, to pick up his bridle with the lost hand, while he struck his horse with the other, and was reminded of his mistake by being thrown. Another person, for nearly a year, tried at every meal to pick up his fork, and was so disturbed emotionally at the result as frequently to be nauseated, or even to vomit."

Sometimes the patient loses feeling of the existence of the limb, but that it is still represented in the nervous centres in all cases is probable. To quote Dr. Mitchell again, "Even in those who are least conscious of the missing part, I have amazed them by suddenly recalling it with the aid of a faradaic current applied to the nerves of the stump. It is not easy to forget the astonishment with which some of these persons re-awaken to a perception of the long-lost leg or arm." He continues, "I recently faradised a case of disarticulated shoulder without warning my patient of the possible result. For two years he had altogether ceased to feel the limb. As the current affected the brachial plexus of nerves, he suddenly cried aloud, 'Oh, the hand, the hand!' and attempted to seize the missing member." We will not, however, speak of this kind of feeling, as it might (erroneously, we think) be ascribed to representation of the lost limbs by the sensory nerves only, which used to come from, and still represent, the absent limb.* The patients feel as if they could *move* the fingers of the absent limb. Mitchell says, "A small number have entire and painless freedom of motion as regards all parts of the hand. 'My hand is now open, or it is shut', they say. 'I touch the thumb with the little finger', 'The hand is now in the writing position', etc. Between these cases and such as are conscious of an immobile member, every grade of difference as to motion is to be found. . . . In other words, the volition to move certain parts is accompanied by a mental condition which represents to the consciousness the amount of motion, its force and ideas of the change of place in the parts so willed to move."

But in these cases it might be said that the patient's account is not to be trusted. This criticism will not stand. Weir Mitchell says: "The influence of electrical currents on the nerves of the stump introduces into our calculations certain novel and puzzling considerations."

"If we faradise the track of the nerves in or above the stump, we may cause the lost fingers and thumb to seem to be flexed or extended; and, what is most remarkable, parts of which the man is conscious, but which he has not tried to stir for years, may thus be made to appear to move to his utter amazement. In one case, I thus acted on the nerves, so as to cause a thumb which for years was constantly and violently bent in on the palm to straighten out completely. On breaking the circuit without warning, the patient exclaimed that his thumb was cutting the palm again, and the same result was obtained by shifting the conductors so as to put the nerves out of the circuit." (*Op. cit.*, p. 359.)

But next it might be urged, that the patient's account of the results of faradisation is not to be trusted. But the patient is, fortunately for these experiments, not an anatomist, and thus he can be put surely to the test. Dr. Mitchell (*op. cit.*, p. 359) writes, "These impressions are correctly referred by the patient, so that faradisation of the musculo-spinal or the ulnar gives sensation of movement in related parts. It is,

* We will give one quotation from Dr. Mitchell's work as to the position of the absent limb. "E. C., aged 32, lost his left arm five inches below the shoulder, nine years ago. When shot, the thumb turned into the palm, and continued in this state of spasm, so that when, six hours later, the limb was removed, the nail of the thumb had cut into the palm. He several times lifted the thumb, but it always returned to the same place. For nine years the absent thumb still remains cutting into the palm. The coming of a storm makes the spasm more severe, and causes the fingers to close over it. The limb seems shortened six inches."

of course, impossible that the motor nerves stimulated should convey any impression centrally, and he must therefore conclude that irritation of sensory trunks may occasion impressions of muscular motion in the sensorium."

The above facts seem to us to bear strongly in favour of Bain's hypothesis, that what is commonly called the muscular sense is at least in great part a judgment from the "out-going" nervous current. Dr. Weir Mitchell seems to have arrived independently at the same or a similar conclusion.

DEATHS FROM CHLOROFORM.

ANOTHER death under chloroform is reported as having been the subject of an inquest held by Mr. Langham, the deputy coroner for Westminster. The patient was a man named Hawkins, aged 49, suffering with dislocation of the shoulder-joint. It appeared that he had his dislocation reduced, under chloroform, at St. Thomas's Hospital, at three in the afternoon, but after he reached home the bandage was disarranged, and the dislocation recurred, whereupon Mr. McHardy, resident medical officer at the Royal Pimlico Dispensary, was fetched at about 8 P.M., and he, together with Dr. Jones, proceeded, at the man's request, to administer an anæsthetic, and to reduce the dislocation. This was done under chloroform. Mr. McHardy stated in his evidence:

"Prior to the administration, I felt the pulse of deceased, and found it satisfactory. During the time of the operation, the deceased was certainly not in a state of anæsthesia, but at the moment of the reduction of the dislocation deceased gave a slight shudder, and a visible tremor passed over him. The chloroform was dropped from a proper drop-stopper bottle. When the tremor passed over deceased, Dr. Jones said, 'He is going', and I said, 'I fear he is gone'. Dr. Jones was just commencing to prepare for artificial respiration, when I took him by the heels, held him upside down, with an artery-forceps pulled his tongue forward, and tried other means for restoring vitality, but without success. The actual time of deceased's death was at about 8.30. Witness did not believe that the previous administration of chloroform at St. Thomas's Hospital at all accelerated the death of the deceased. The death was due to the second administration of chloroform, which produced paralysis of the heart. A *post mortem* examination of the body showed that the heart was perfectly healthy. Two drachms of chloroform were used, and that quantity was exceedingly little considering the mode of administration. There was no way of telling what the result of the administration of chloroform might be. Witness was quite prepared to see a patient die under chloroform at any operation, and he had seen three persons die under it."—Dr. Webb said that he had made a *post mortem* examination, and found the heart and other organs healthy. Looking at the whole of the circumstances, he believed that chloroform caused death, but that such administration was properly conducted.—The jury returned a verdict of death from chloroform, and that the chloroform was properly administered.

The verdict of the jury was a correct one on the evidence. We must point out, however, that an increasing responsibility attaches to the administration of chloroform under such circumstances. It is difficult not to feel that this accident was probably due, not to the administration of an anæsthetic, but to the injudicious selection of an anæsthetic. Either ether or nitrous oxide might, it is more than probable, have been administered with perfect safety.

Dr. Helweg, public medical officer at Odense in Denmark, relates, in the *Ugeskrift for Læger* for August 14th, a death during chloroform narcosis which had occurred in his practice. He gives the following details.

"A coal-measurer, aged 52, had, for more than twenty years, an ulcer on his left leg; it had been healed several times, but had as often recurred, as his occupation involved hard labour. Otherwise he was in good health, and for twenty years had not been confined to bed for any other illness; he had never complained of any symptoms indicating disease of the lungs or heart. Once only, as far as is remembered, having a not very severe attack of bronchitis, he was examined with the stethoscope; nothing was found beyond the signs of the above named disease. He was strongly built, thin, with well developed muscles: he had no appearance of cachexia, and was not addicted to the excessive use of brandy. During the last three-fourths of a year, he had suffered from his ulcer, which was of the shape and size of a

large child's hand, and was steadily becoming worse in spite of several months' rest and continuous treatment. The edges became very thick and hard, with round and hard excrescences as large as walnuts; the base was indurated and foul, and there was an offensive ichorous secretion. In order to overcome this condition, I decided to use the knife and the actual cautery, and had him removed from his miserable home into the infirmary. The operation was to be performed on July 3rd; and, as he was much frightened at it, chloroform was used. He lay on a bed with his neck and chest exposed, near an open window, in a spacious and lofty room. The administration of chloroform was undertaken by Mr. Windinge, who had been my assistant during the last year in the rather frequent surgical operations in our two infirmaries. The apparatus was the same which we are always accustomed to use; viz., a piece of linen folded in the shape of a funnel, with a small piece of cotton-wool at the bottom, and large enough at the wide end to completely cover the patient's mouth and nose. At the commencement of chloroformisation, the pulse was felt to be strong and regular, between 70 and 80; the breathing was perfectly tranquil. After two minutes, the stage of excitement set in; he became much congested in the face, cried out, and threw his arms and legs about. This condition lasted about two or three minutes. He then suddenly became quiet, and made two stertorous inspirations; the chloroform was removed by Mr. Windinge, with the remark that he was now in a state of anaesthesia. But at the same moment his face became livid; the pulse was completely imperceptible, and the respiration was at a standstill. Several windows were immediately opened; and having ascertained that the tongue had not fallen backwards, we sprinkled him with water and applied forcible friction over the cardiac; this was followed by two sighing inspirations, which immediately again ceased. He was several times taken from the bed and held with his head downwards; artificial respiration by regular raising and lowering of the arms was employed for an hour and a half; a hot iron which we had at hand was applied to the epigastrium and the soles of the feet (we had no induction apparatus); but all was in vain—he was dead. At the necropsy, the brain and meninges were found to be normal, neither remarkably congested nor anæmic. The lungs were healthy, very full of air and blood; there were many easily separable pleural adhesions, especially on the left side. The blood was dark and fluid. The pericardium was closely adherent to the heart, especially in front, so that it could not be opened without wounding the heart; but when an opening was made, the two layers could be easily enough separated by the finger or the handle of the scalpel. The heart itself was large, without fat, very lax and collapsed; its muscular substance was healthy, and the valves were normal. The abdomen was not opened. On examination, the chloroform was found to be pure, according to the pharmacopœial directions. The bottle used had contained fifty grammes (about one and a half ounce) of which scarcely one-half remained; but, as much was lost by being absorbed by the linen, it was impossible to say how much was actually inhaled. The inhalation was not continued more than five or six minutes, and even in this short time had been interrupted by the restlessness of the patient."

In commenting on the case, Dr. Helweg is disposed to attribute the death to the pericardial adhesion. The death, he says, was from syncope, produced by sudden paralysis of the heart. He does not think that the adhesion could have been detected during life, so as to afford a contra-indication to the use of chloroform.

The case of Hawkins, who died under chloroform administered to facilitate a second reduction of dislocation of the shoulder, presented some other features of a rather unpleasantly suggestive character. The story told by Mary Hawkins, the widow of the deceased, was, that on Tuesday last deceased complained of pains in his arm, and said that a policeman had injured his arm on the previous Saturday. The deceased was in Coldbath Fields from Saturday afternoon until Tuesday morning at seven o'clock, and upon his return from the prison, he made the complaint, and went with his daughter to St. George's Hospital, where they gave him some liniment. He had complained in the prison of the state of his arm, but the warders took no notice of him. On Wednesday last, he was worse, and witness took him again to the hospital, where the porter said that he was too late, although it was only 9.30 A.M., and that he must come another day. A paper was given to him on the first occasion, which stated that he ought to be at the hospital by nine. Finding that he could not be attended to, he walked to St. Thomas's Hospital, arriving there at 10.50; and, after waiting for two hours, he came back and said that the surgeons had

found that the arm was dislocated, that they had been trying to get it right but could not do so, and they intended to give him chloroform. Witness waited with him until two o'clock, and then he went again to the hospital, when the dislocation was reduced under chloroform. Soon after he reached home, however, the bandage "fell off", and the arm again slipped out of joint.

We say nothing about the bandaging, which may or may not have been satisfactory, for the bandages of restless out-patients do often "fall off" in a very unaccountable manner. But, according to this statement—1. The man was for two days the inmate of a prison cell, where his injuries were disregarded,—a serious reflection on the gaol authorities; 2. He is stated to have attended twice at St. George's Hospital without the nature of his very simple ailment being recognised or relieved. There is here something also which requires investigation. The out-patient casualties of hospitals not unfrequently make the reputation of bone-setters, not always illegitimately. It is a department which requires very careful supervision in the interests of the public as well as of medical education.

THE REVERSE OF THE MEDAL.

MR. DAVY has managed to achieve a very difficult feat: that of infusing a decided dash of originality into an introductory address. We start entirely in accord with Mr. Davy; for he plainly intimates his opinion that the series of annual introductory addresses are a troublesome nuisance, which might with advantage be abolished everywhere, as they have been at St. Bartholomew's Hospital School. His address at Westminster Hospital had this primary feature of originality, that he reduced the evil to its smallest dimensions, by limiting his address to a bare quarter of an hour. Then, from beginning to end, it was pithy, and pointed to grumble. Generally, introductory lecturers paint their picture in rosy colours. Diligence, study, good conduct, are sure of reward; very few men who deserve to succeed ever fail; and the work of the profession is its own exceeding great reward. The approval of his fellows, general respect, the dignity of appreciated self-sacrifice, are added to the peace of a good conscience. This is the side of the medal which is naturally displayed every year to attentive and hopeful audiences. Mr. Davy showed the reverse. From his earliest days, the student is the victim of sharks (*squalidae*)—the London landladies. The remuneration of the young medical man for professional services is either very small or nothing at all. Coroners and guardians, the Registrar-General and the Commissioners in Lunacy, combine to oppress him; his brethren are like Ishmaelites in their mutual intercourse. Medicine has three remedies to boast, it has been said: quinine for ague; iodide of potassium for secondary syphilis; sulphur for itch. Mr. Davy robs us of our last crumb of comfort in pointing out that these are all preventable diseases. Ague, no doubt, is being abolished; but so long as Mr. Stansfeld and his allies are so active as they now are, there is no reason to anticipate that free trade in syphilis will be limited; or that the propagation of the syphilitic poison among the civil population will be in any way limited, if even its ravages be not once more freed from all check among the soldiers and sailors of this country. There is, therefore, still likely to be a rag of credit left to the doctors in curing one preventable disease, which one section of the community are determined shall not be prevented if they can help it.

Mr. Davy's list of grievances is a very long one. He is particularly shocked by the state of subjection of certain of the medical officers of our hospitals. "Charity" is a synonym for professional imposition. He is particularly shocked at the position of the medical officers of the London Hospital.

"I must hold up the London Hospital to you as an example of miserable resignation of the medical to the lay element; these London Hospital officers (and excellent officers many of them are) must be very 'lions in love'; they have tamely submitted to have their teeth drawn and claws pared; and now submit to the dictates of a Committee on which the medical element is not directly seated. On hospital subjects, members of the staff are veterans; many of the lay Committee-men are

mere amateurs; there can be small doubt as to whom the well-being and progress of a hospital might be safely entrusted."

Mr. Davy's summing-up is couched in the vigorous language of despair.

"In conclusion, let me firmly assure you that your early prospects in life are most disheartening; your toil and ambition may be equally great, but your pay and dignity will be equally small; you have to deal with an ignorant and proud people; and I advise every one to resign at once any and every thought of becoming a medical man, unless he possess three qualifications: 1. Independence. 2. An aptitude for, and love of, the profession. 3. The readiness to pay a heavy premium in this world for his prospects of reward in the next."

This is a very dark picture indeed; but then Mr. Davy is evidently a Rembrandt in his art. His picture, however, making every allowance for the desire for picturesque effects, would have lost nothing if the lights were put in as well as these very dark shadows.

DR. ARTHUR FARRE, F.R.S., has been elected, we hear, Honorary President of the Obstetrical Society.

DR. STURGES will this week be promoted to the office of Physician to the Westminster Hospital, vacant by the resignation of Sir Duncan Gibb.

MR. THOMAS JESSOP, an ex-mayor of Sheffield, has offered the sum of £22,000 for the purpose of building a new hospital for women. The tenders for the building have been received and accepted.

M. WURTZ has definitively resigned his position as Dean of the Faculty of Medicine of Paris, a position which he has occupied during the last ten years.

THE Minister of Public Instruction of France has decreed the formation of a commission, whose duty it shall be to study the means of improving and completing the clinical teaching of the Paris Faculty of Medicine. The medical members of the commission are MM. Wurtz and Chauffard.

WE have received, through the courtesy of Dr. Goldie, an account of the rise and progress of the small-pox epidemic at Leeds. The origin of the epidemic appears to have arisen from a solitary imported case, of which no intimation had been given to the medical officer of health. The disease in consequence spread rapidly, and there are now about seventy cases in the town, and the total deaths on Wednesday amounted to eight.

MR. CARSTEN HOLTHOUSE has resigned the office of Senior Surgeon of Westminster Hospital. Mr. Holthouse, as our readers are aware, is now much occupied in the management of a Home for Inebriates, which has been recently founded under the auspices, and with the approval, of the most eminent members of the medical profession.

THE resignation of Mr. Holthouse leaves a vacancy in the staff of surgeons. Mr. Cooke, the Senior Assistant-Surgeon, is the next in order for this vacancy. Mr. Cooke is very favourably known to the profession by his works on Practical Anatomy, and is a promising and able surgeon. It is, however, probable that other candidates will be forthcoming. Among them we hear named Mr. Macnamara, lately Professor of Surgery in the University of Calcutta, well known for many valuable reports and writings, and for his investigations on cholera, but perhaps most generally known in this country as the author of an excellent Manual of Surgery.

THERE have been a great number of promotions and appointments at the Westminster Hospital and School during the last few years, so that the staff is mainly composed of comparatively young men. Mr. Cowell, who now becomes Senior Surgeon, is by a long way, we think, the youngest senior surgeon in London. Many of his seniors in practice are still only assistant-surgeons at metropolitan hospitals. Youth is, however, an excellent fault, if fault it be, in a surgeon, for with it should be allied vigour and self-devotion.

DR. ROBERT BARNES, the President of the Metropolitan Counties Branch of the British Medical Association, inaugurated the season by a *soirée* at Willis's Rooms on Wednesday evening. There were nearly eight hundred members of the profession present in the course of the evening. The rooms were decorated with works of art, and microscopes were shown by Mr. Pillischer and others. The String Band of the Royal Marines, Chatham, was in attendance. The hospitalities of the host were on a most generous scale. Among those present from a distance were Mr. Steele of Abergavenny, Dr. Parsons of Dover, Dr. Bowles of Folkestone, Mr. Hodgson of Brighton, and many others. The evening was singularly agreeable, and formed a most pleasing commencement of the season.

THE WORCESTER INFIRMARY.

THE executive committee of the Worcester Infirmary held another meeting on Monday, September 27th, but the difficulties in which the institution is involved seem as far as ever from being settled. In reply to their advertisement for a medical man to supply the place of Dr. Inglis, only two candidates offered themselves. One was immediately set aside; the other, Dr. Hunt of Birmingham, withdrew his application before the time of meeting. When requested to give his reason for so doing, he stated that his attention had been called to a paragraph in the BRITISH MEDICAL JOURNAL, in which the Editor expressed a hope that, until the reasonable requirements of the staff are satisfied, no medical man would come forward as a candidate for the vacant post. It was, he said, entirely in deference to this opinion that he had withdrawn his application. If all medical men were as ready to sacrifice their own personal interests to the good of the profession as Dr. Hunt has shown himself to be, such disputes as these would seldom arise, and when they did arise they would be settled satisfactorily. We trust that the difficulty which the executive committee find in filling up the vacancy in their staff will convince them that their first step ought to be so to alter their rules as to remove what we have from the first regarded as a real grievance; and which might at any future time press as hardly upon any other honorary medical officer as it has lately done upon Dr. Inglis.

THE INTERNATIONAL MEDICAL CONGRESS.

CONTINUING our *resumé* of the labours of the Brussels Congress, the next subject to which the members turned their attention was that of lying-in hospitals. M. Lefort demanded the suppression of large lying-in hospitals, and the dispersion of lying-in women in private domiciles. His ground for this requisition was, that one out of every twenty-seven women delivered in hospital dies, whilst in private practice the mortality is one in two hundred and two. He, therefore, proposed that women should be delivered in their own homes, and that the destitute should be lodged with midwives at the expense of the State. After a discussion, in which MM. Hiernam, Sigmund, Testelin, Hubert, Crocq, Gaillard, Forget, and Laussedat took part, the following conclusions were adopted: 1. The urgent necessity of radical reform in the system of child-bed relief. 2. Complete abandonment of large lying-in hospitals. 3. The replacing of large lying-in hospitals with schools for obstetrical instruction by small houses with separate rooms. 4. The establishment of a spare house placed in the neighbourhood, with complete separation in the medical direction, and the furnishing of the two establishments. 5. As wide an extension as possible of aid at the homes of the patients by affording every possible assistance to pregnant and lying-in women. In the section of Public Health, the first question discussed was the means of rendering healthy the workshops in which phosphorus was manipulated, in which MM. Magitot, Crocq, Gaillard, Verité, and Thibaut took part. The section unanimously expressed a wish that red or amorphous phosphorus should be substituted for common phosphorus, and cited terebinthene as an antidote to the effects of phosphorus, but without explaining its mode of action. They also recommended that the workshops should be thoroughly ventilated and very spacious. They point out that local affections induced by phosphorus may be removed by astringent gargles, and above all by the obligation imposed

on the manufacturers not to employ any workmen who have dental caries or any other affection likely to favour the noxious action of the phosphorised vapours. The members of the section likewise protested against the employment of children in workshops where phosphorus is used. In the section of biological science, a report was read by MM. Masius and Vanlair on the Vaso-motor Nerves and their Mode of Action, to which Professor Donders, though approving the totality of the conclusions, regretted that the authors, specially preoccupied with active dilatation, had somewhat lost sight of the vaso-constrictor nerves. M. Bouillaud, in reference to this paper, pointed out the analogy existing between the rhythmic movement of the arteries and the movements of the heart itself. He pointed out the consequences that every alteration of the arterial walls must, like the alterations of the cardiac walls, necessarily bring on in the mechanism of the circulatory functions. M. Bouchut set forth the results of the application of the ophthalmoscope to the diagnosis of cerebral affections. M. Leudet gave the result of his researches into the mental condition of alcohol drinkers in different classes of society. In the second section, a discussion arose as to which is the best anæsthetic agent, and the relative claims of chloroform, ether, and intravenous injection of chloral were discussed. Chloral found an eloquent advocate in Professor Oré; M. Deneffe also gave his adhesion to intravenous injections. Ether seemed to be in favour, particularly with the profession at Lyons; but this section did not come to any positive conclusions on this important subject. In the section of medicine, the subject of the use of alcohol in therapeutics was discussed by M. Dujardin-Beaumez, M. Semmola, and others. The conclusions arrived at were, that the section was of opinion that the number of the indications for the use of alcohol, both in acute and chronic disease, are much more limited than has been asserted by the too enthusiastic partisans of this therapeutic method. They went even further, and asserted that in a certain number of circumstances in which the members had recognised the true therapeutic value of alcohol, the indication might be equally well fulfilled by other agents forming part of the *materia medica*, in which cases they did not hesitate to recommend the latter, and prohibit alcohol, from the fear that its too frequent introduction into medicine should constitute for the lay public an encouragement to consume it without any reference to the pathological state, an encouragement which would derive considerable value from the scientific authority by which it was supported. The only circumstance which could incontestably establish the necessity for the administration of alcohol, and in which it could not be replaced by any other agent, was the showing of previous habits of drinking. In these cases, alcohol became indispensable; it constituted the only means which subsequently allowed the application of the therapeutic methods adapted to each particular affection, and replaced the patient in conditions under which the functions might be performed with more or less regularity.

ANCIENT HOSPITALS.

MR. B. H. COWPER writes in the *Daily News* an interesting note on this subject. According to Mr. Cowper, the list of early hospitals among non-Christians is not yet complete, for it appears from at least two Latin writers of the first century that something of the kind existed among the Romans. According to Cooper's Latin *Thesaurus*, a *valetudinarium* is "a place where men lie being sick; a sick man's lodging"; and Ainsworth calls it "an infirmary or hospital for sick folks", adding these words from *Columella* xi, 1: "Si quis sauciatus in opere noxam cepit, in valetudinarium deducatur." If anyone who was injured was to be taken to the hospital, it is clear that such an institution existed at the time. Seneca, who died under Nero, refers to such places in at least three passages which I have traced in his works. They will be found in *De Ira* i, 16, in the prologue to Book 1 of "Natural Questions", and in Epistle 27; nor can there be the shadow of a doubt as to their meaning. This interesting fact seems to be but little known, as I can find no allusion to it in any work on Roman antiquities which I am able to consult. With reference to the statement of Messrs. Green and Davis, that Beth Hachophshith, in 11 Kings xv,

5, was a free hospital, I fear it cannot be maintained. The words literally mean "a house of freedom", it is true, but the freedom is not that of the gratuitous, and is that of liberty as opposed to bondage. The comparatively modern application of the phrase to an hospital is not evidence of the original sense. Neither the Targum, nor the ancient Syriac, Latin, and Arabic versions suggest such an idea; nor do any other texts of the Old Testament. The true character of the house to which Azariah the leper was consigned is to be gathered from Leviticus xiii, 46, where it is ordained that the leper "shall dwell alone; without the camp shall his habitation be". Hence, the Targum simply says that Azariah "dwelt out of Jerusalem". The place was, therefore, an asylum or leper-house, and to Judaism belongs the honour of so humane an institution. The Christian reader may find the germ of the modern hospital in the parable of the Good Samaritan (Luke x, 34, 35), or at any rate an authoritative recognition of the principle. Basil of Caesarea gives the first reference, I have found, to hospitals for the relief of the sick among Christians, Epistle 371. This belongs to the fourth century.

A NOBLE WORK IN INDIA.

A LARGE medical and surgical hospital has been recently built at Jeypore, called The Mayo Hospital, which will be publicly opened by the Prince of Wales during his visit to India. This hospital is one result of the work which has been carried on in Rajpootana during the last nine years by Dr. Colin Valentine, a medical missionary. His career well illustrates what a man in this position may effect. In 1866, he was the means of saving the life of one of the queens of the Maharajah of Jeypore, when she had been given up by the court physicians. He was in consequence appointed private physician to the Maharajah, a post which he accepted only on the distinct understanding that he should be allowed to continue his missionary work. His connection with the court naturally gave him great influence, and he set on foot many plans for the amelioration of the people. Amongst these, we may mention gaol works, by which about a thousand prisoners, who formerly did nothing but fight and eat opium, were taught reading and useful trades; a school of arts, where skilled workmen, brought from Madras, Delhi, and other parts of the country, taught young men of all castes without distinction; a library, consisting of seven thousand carefully selected volumes, both in the native languages and in English; a museum; a philosophical institute, in which Dr. Valentine himself gave popular lectures on natural science; a board of health; a medical store, where dispensers are trained; and sixteen or seventeen local dispensaries, which have been opened in various parts of the country, and which are served by native doctors trained at the Agra Medical College. This is, indeed, good work for a man to have accomplished in ten years. But Dr. Valentine has yet further plans. He is anxious to found a medical training institute for the Urdu and Hindi-speaking provinces of India. He proposes that the institution should be capable of affording accommodation to forty or fifty boarders; that it should be presided over by an European or American medical missionary; that it should receive pupils from all the different mission stations, who should be trained not merely as medical men, but also as missionaries. With this institution it is proposed to affiliate a school for the medical training of European and Eurasian ladies, resident in India. Both branches of the institution would be under the same superintendance; but the male students will attend and graduate at the Agra College, while the female will receive their medical education separately, and within their own premises. To carry out this scheme, Dr. Valentine estimates that £5,000 will be required. We hope that the money will be raised without difficulty, as there can scarcely be a difference of opinion with regard to the importance of the objects in view. The proposal to found a female medical college in particular has our cordial sympathy. The percentage of deaths among women and children in India is out of all proportion to the population; and this must continue to be the case as long as the inmates of the zenanas are left to the care of ignorant and degraded native nurses. Whatever view

may be held as to the admission of women to the profession in this country, there is no doubt that, so long as the social customs of India remain as they now are, it is a most useful work to provide for the wants of its female population in some such way.

RUSSIAN MIDWIVES.

AMONGST the women who this year follow the courses appropriated to their sex in the Medico-Chirurgical Academy of St. Petersburg, the *Novoste* speaks of two peasant women (sisters), who were originally midwives at Tambow. When they made up their minds to enter the Academy, they set to work with the greatest zeal to acquire a knowledge of the subjects necessary for them to pass their examination. They worked for two years without any extraneous help whatever, so as to be able to pass this ordeal, and further testified to their strength of will by making the journey from Schazh to St. Petersburg on foot.

COTTON DISTRICTS CONVALESCENT FUND.

A CIRCULAR, signed by Lord Derby, Sir J. P. Kay-Shuttleworth, and Mr. J. W. Maclure, has been sent to all the hospitals in the cotton manufacturing districts anent the distribution of the surplus Cotton Districts Convalescent Famine Fund. The circular sets forth the scheme issued under the order of Vice-Chancellor Bacon for the management of the surplus of the moneys raised for the relief of the sufferers by the cotton famine, which is to be applied to the establishment and maintenance of convalescent homes, and is to be administered by a body of governors, some of whom are appointed in the scheme and called co-optative governors. Ten others are to be elected by the governing bodies or boards of management of hospitals or infirmaries containing at least forty beds, and situate within the districts comprised in the schedule to the scheme. The co-optative governors are vested with the power of making arrangements for the collection of the votes of the several governing boards, and having met for that purpose, the circular referred to has been sent out requesting the boards to meet on some day during the present month for the purpose of electing representative members of the governing body of the fund. Each governing body or board of management possesses one vote for every twenty beds.

THE CAMBUSLANG MURDER.

IT is announced that the sentence of death passed upon John Middleby or Tiernay at the last assizes in Glasgow has been commuted to penal servitude for life, after a special medical inquiry instituted by direction of the Secretary of State. The decision arrived at in this case seems to us unfortunate, and, indeed, indefensible. Tiernay was either mad, or not mad. If the former, he ought to be sent, not to penal servitude, but to an asylum, where he might have the benefit of suitable treatment; if the latter, he ought to suffer the penalty of his crime. The law of this country recognises no intermediate states of partial mental impairment between insanity and soundness of mind; and grave difficulties cannot fail to arise, and to complicate still further the already entangled and knotty question of criminal responsibility, if the principle be once admitted that there are graduations in the power of will, and, therefore, in culpability for offences. Obvious objections also present themselves to special medical inquiries instituted by the Secretary of State for his own edification. Such inquiries ought clearly to take place previous to the trial of any accused person in whom there is reason to suspect mental aberration; so that those undertaking them may be able to state their opinions, and the grounds on which they are founded, in open court, and may be subjected to cross-examination. No private inquiry resulting in the reversal of the finding of a jury and sentence of a judge can be satisfactory to the public. As matters at present stand, the defence of insanity bids fair to defeat the ends of justice, and to afford ready shelter to any one from the consequences of violation of the law. Thomas Johnson, who, during last summer, was committed to trial, charged with the murder of his father and mother, at Fordham, near Colchester, has never been brought to trial at all; because, subsequently to his commitment, and prior to the assizes,

he was certified as a lunatic, and removed to an asylum. No doubt this man was insane; but surely his sanity or insanity was a question for a jury. It is in the highest degree inexpedient that two medical certificates should be permitted to intervene between a prisoner and his trial, and indefinitely postpone or practically dispense with the latter. There can be no necessity to point out what terrible abuses might grow out of such a practice.

MEDICAL STUDENTS IN THE OLDEN TIME.

M. GERMAIN, Professor in the University of Montpellier, lately read before the Academy of Inscriptions a very curious notice on the *Liber Procuratoris Studiorum*, of which the manuscript is preserved in the Faculty of Medicine. This *Liber* is a register of one hundred and sixty-five sheets, containing the accounts of the administration of twenty-six deans of the medical school, who exercised their functions from the 26th May, 1526, to the 1st November, 1537. These deans or proctors, whose official title is in the statute of 1534, *Procurator Baccalaureorum et Studentum*, were charged to protect the interests of the students, and elected in general assembly before St. Luke's day, when the schools were opened. They exercised a sort of jurisdiction which could only be escaped by special permission, and had the management of all the revenues of student-bodies—revenues which consisted specially of multiplied fees, proceeding from every examination passed. The *Liber Procuratoris* affords very curious information on the constitution of the University, and the life of the students, who came not only from all the provinces of France, but from other countries also. Some of the deans were of Swiss and Italian nationality. The *Liber* mentions the matriculation of Rabelais in 1530. After having taken his diploma of Master of Arts in Paris, the future author of *Pantagruel* returned to obtain his licentiate and his doctor's degree at Montpellier in 1537. He even filled a professor's chair at the University, lectured on the *Prognostics* of Hippocrates, and presided over the anatomical school. The examinations extended to sixteen, without reckoning that for the Master of Arts degree, without which no grade could be obtained. There were four examinations for the Licentiate only, each consisting of four theses. The highest grade was the Doctor's degree, which was signalled by a kind of ovation. The recipient went to the Church of St. Firmin, conducted by the whole medical school, preceded by a band of musicians, to receive the insignia, amongst which were the works of Hippocrates. After having received the embrace of fraternity from the dean, the newly created Doctor distributed sweetmeats and preserved fruits to the bystanders. The organisation of the University was entirely religious. The students were obliged to hear mass every Sunday, under penalty of a fine for absence. The Dean and the Chancellor of the University were placed under the high authority of the Bishop of Maguelonne. All these regulations, however, did not prevent the students from leading very merry lives: every time a student obtained a degree, he made it a pretext for a feast with his comrades. M. Germain explained the etymology of the word "baccalaureat" to mean bay berries; but M. Thurst declares the true origin of the word bachelor to be *baccalarinus*, which means "a young unmarried man". The University of Paris always writes "baccalariatus". In English, also, bachelor means an unmarried man. Baccalaureatus is a more recent orthographical form, originating in a false etymology.

ARSENICAL CASKS.

SOME remarkable evidence was given at a recent inquiry into a case of poisoning by eating sheep's-head broth at Rotherham. A boy died, and half a dozen people were made seriously ill. This circumstance was fully accounted for when it was stated that the food was cooked in a saucepan in which clothes saturated with arsenic had previously been boiled; these had caught up the arsenic by being washed in a tub made from a cask which had contained that poison. The jury returned a verdict that the deceased Thomas Robert Jenkinson died from being poisoned by arsenic inadvertently administered in broth. They appended to the verdict an expression of opinion that the indiscriminate

selling of casks which have contained arsenic, which appears to be practised by some firms, is dangerous, and ought to be discontinued. The analyst's evidence showed that there was in the soup enough poison to kill twenty persons. The subject is sufficiently suggestive of general carelessness on the part of manufacturers of deadly poisons to be worth the attention of medical officers of health and inspectors of nuisances.

BRITISH MEDICAL DEFENCE ASSOCIATION.

UNDER this title, an Association for the prosecution of quacks recently came into existence, mainly through a correspondence in our columns, which has already done good work. It is now preparing for extension, and has issued the following preliminary circular.

"I am desired by the Provisional Committee to inform you that an Association of Registered Medical Practitioners has been formed for the purpose of suppressing, as far as possible, the practice of medicine and surgery by persons not legally qualified, and of maintaining the status and general interests of the profession. The efforts of the Association will be principally directed to enforcing the provisions of the Medical and other Acts, against those who, assuming to be duly qualified, impose upon the community at large, and practise to the detriment of the public health, and to the discredit and injury of the profession. Past experience teaches that the profession and the public have little to expect in the way of help in this matter from the General Medical Council, or the various corporations and licensing bodies, with, perhaps, one or two exceptions. It is, therefore, hoped that the objects of the Association will at once commend themselves to every registered practitioner. A general meeting of members of the profession interested in this movement will shortly be summoned for the purpose of electing a President, Council, and Committees, together with the necessary officers. Branch Associations are being formed in various parts of London and the United Kingdom. The East London Branch is already in active working order, being engaged in three prosecutions under the Apothecaries' Act. It is suggested that the annual subscription shall not exceed half a guinea; but donations to meet the preliminary expenses will be received with thanks. Should you wish to become a member of the Association, an early reply, with any suggestions you may have to make on the subject, will oblige."

The letter is signed by the Honorary Secretary (*pro tem.*) Mr. George Brown, 12, Colebrooke Row, Islington, London, N. Among the members of the provisional committee are given the names of thirty or forty general practitioners in different parts of the country.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

THE annual meeting of this Society was held in the Library of the Newcastle-on-Tyne Infirmary on September 30th. The report of the Committee showed that the Society was in a flourishing condition. The number of members was 141. The work done during the session 1874-75, both in amount and quality, compared favourably with that of previous years. The following is a list of officers for the year 1875-76:—*President*: S. W. Broadbent, Esq. *Vice-Presidents*: W. C. Arnison, M.D.; J. S. Denham, M.D.; F. Page, M.D.; G. H. Philipson, M.D. *Secretary*: Byrom Bramwell, M.D. *Committee*: H. E. Armstrong, Esq.; L. Armstrong, M.D.; G. T. Beatson, M.B.; M. Burnup, M.D.; C. Carr, Esq.; J. Frain, M.D.; G. B. Morgan, Esq.; J. Hawthorn, Esq.; J. Russell, Esq.

RECENT URBAN MORTALITY.

DURING last week, 5,459 births and 3,660 deaths were registered in London and twenty other large towns of the United Kingdom. The average annual rate of mortality was 25 deaths in every 1,000 persons living. The rate in Nottingham was 20; in London and Glasgow, 21; Norwich and Newcastle-upon-Tyne, 22; Edinburgh and Portsmouth, 23; Oldham, 24; Leicester, 27; Dublin, Wolverhampton, and Sheffield, 28; Liverpool, Bristol, and Bradford, 29; Birmingham and Manchester, 30; Sunderland, 31; Leeds, 32; and Hull and Salford, 35. The annual zymotic rate was 11.5 and 12.5 in Leeds and Hull respectively. The death-rate from diarrhoea in the eighteen English towns considerably exceeded the average for the week; it was as high as 7.5 and 9.0 in Leeds and Hull. Scarlet fever is still prevalent in Bristol, and fever still prevails somewhat at Portsmouth. In London, 2,368 births and 1,401 deaths were registered. The deaths exceeded

the average of the week by 28, and the death-rate was 21.2. There were 11 deaths from measles, 113 from scarlet fever, 12 from diphtheria, 44 from whooping-cough, 25 from different forms of fever, and 145 from diarrhoea; in all, 350 deaths from these diseases, equal to an annual zymotic rate of 5.3 per 1,000. The deaths referred to scarlet fever, diphtheria, whooping-cough, and diarrhoea were in excess, whereas those from the other zymotic diseases were below the average. The deaths of two boys, aged respectively 11 and 14 years, were referred to hydrophobia in St. Thomas's and Guy's Hospitals. In outer London, the general and the zymotic death-rates were 18.1 and 4.9 per 1,000 respectively, against 21.2 and 5.3 in inner London. At Greenwich, the mean temperature of the air was 55.1 deg., or 0.7 deg. above the average of the week. Rain fell on four days to the amount of 0.84 of an inch, of which 0.74 of an inch was measured during Saturday.

THE MEDICAL EDUCATION OF WOMEN.

THE professors of Queen's College, Birmingham, by a majority of nine to three, have passed a resolution to the effect that they cannot undertake the medical instruction of women students. This resolution, it is stated, was based on the objection that the admission of women would endanger the College as a school for male students, many of the latter having intimated their intention to withdraw if women were admitted. The resolution of the professors was communicated to the College Council, who have since unanimously resolved to decline to admit women students to the institution. The resolution of the Council, with their reasons for it, will be transmitted to the mayor, as representing the deputation which recently had an interview with the College Council.

SCOTLAND.

IN connection with the Chair of Natural History in St. Andrew's, Dr. Alleyne Nicholson announces his intention to deliver two courses of lectures during the approaching session; namely, one on zoology three days a week, and one on geology and palæontology twice a week.

PROFESSOR HUGHES BENNETT.

THE funeral of the late Professor Hughes Bennett took place on Thursday, September 30th. The funeral was a very quiet one, but a number of old friends among his professional brethren and others were present at the ceremony. His grave is close to those of his two old friends Professors Goodsir and Forbes.

VACANT CURATORSHIP IN EDINBURGH.

THE appointment of Dr. Bell Pettigrew to the Chair of Medicine at St. Andrew's has caused a vacancy in the post of Curator of the Museum of the Royal College of Surgeons of Edinburgh, and also in that of Pathologist to the Royal Infirmary. For the former appointment there are two candidates in the field, namely, Dr. Blair Cunynghame, assistant to the Professor of Pathology, and Mr. Andrew Wilson, Lecturer on Natural History in the Extra-Academical Medical School. Dr. Cunynghame is a Fellow of the College. The appointment is an annual one, and the emolument attached to it is £100 yearly.

UNIVERSITY OF EDINBURGH.

THE Winter Session in the University of Edinburgh opens on Monday, November 1st, with an address from the Principal, Sir A. Grant; the general work of the various classes commencing the following day. The Extra-Academical School opens the same day, when an address to the students will be delivered by one of the lecturers.

UNIVERSITY OF ABERDEEN.

AT the last meeting of the Aberdeen University Court, Professor Huxley, Lord Rector, presiding, Dr. McKendrick of Edinburgh, and Drs. Alexander Ogston and Rodger of Aberdeen, were elected Examiners in Medicine for one year. The appointments of assistants of

the professors were approved of. The Lord Rector agreed to draw up a reply to be sent to the Privy Council to meet the objections lodged against his scheme for the alterations of the medical curriculum lodged by the Edinburgh University Court. A motion was adopted, ordaining the Senatus Academicus to inform the Court of any projected lawsuit or permanent expenditure prior to entering upon it; Dr. Pirrie dissenting. At the close of the meeting, Dr. Pirrie expressed the thanks of the Court to Professor Huxley for the uniform courtesy and kindness he had shown members during his tenure of the office of Lord Rector. Professor Huxley replied. The election of a new Lord Rector is fixed for November 13th.

THE GOUROCK GRAVEYARD CASE.

THIS case came up again on appeal, but the sheriff adhered to the decision of his subordinate that the graveyard must be closed. In his remarks he says, "The population of Gourock is 4,000; 141 houses have been built since the last census was taken, and nearly the whole of these are let out in flats and half flats. It is absurd to suppose that a graveyard not amounting to half an acre is sufficient to meet the requirements of such a population."

FACTORY LABOUR.

THE Factory Acts' Commission sat in Edinburgh on Friday and Saturday, October 2nd, and heard a good deal of evidence, but none of it was of a very striking character. It appeared that the half-time system in connection with schools was not working at all satisfactorily, particularly in Dundee and Glasgow; partly because the "half-timers" were generally dirty and unruly, and partly because many of the certificates given were false. The evidence given by some of the leading papermakers went to show that it was absolutely necessary to employ boys to do nightwork, and that the nightwork had not been found prejudicial to the health of the boys. Several complaints were made by large printers, india-rubber factors, and others, that the present restriction put upon the number of hours in which girls and women were allowed to work, acted in a way very detrimental to their business, in which occasionally it was necessary to work overtime, and fresh hands had to be employed. A deputation from the Edinburgh Trades Council presented themselves for examination, and complained of the unhealthiness of many of the workshops, and of the practice of carrying work home, which was shown to prevail to a certain extent among the tailors, shoemakers, and others of Edinburgh. They desired, also, the appointment of more inspectors, and that all offences under the Act should be tried before the sheriff, and not before the unpaid magistrates. The Commissioners sat in London on Monday, October 4th.

IRELAND.

THE Ennis Town Commissioners have elected Dr. Dillon the sanitary officer of their township, at a salary of £15 *per annum*.

QUEEN'S COLLEGE, CORK.

DR. CHARLES BELL, late Demonstrator of Anatomy at Queen's College, Belfast, has been appointed to the Professorship of Anatomy and Physiology in Queen's College, Cork; whilst the vacant Chair of *Materia Medica* in the same institution has been filled up by the selection of Dr. Mathias O'Keefe, M.A., a graduate of the University.

IRISH SANITATION.

A CASE of some interest in a sanitary point of view has just occurred in the north of Ireland, but some of its features can hardly fail to raise a smile. The circumstances were briefly these. A young gentleman, a visitor at the favourite watering place of Portrush, had an attack of scarlet fever. The attack was slight, and, as the patient soon felt himself quite well, he went to a "Spelling Bee Entertainment", which was very numerously attended. His appearance on the platform was the

cause of some alarm to those who knew of his illness. A magistrate, who was present with his family, called the attention of the sanitary officer of the district to the fact. He wrote to the young gentleman remonstrating with him for his indiscretion, and pointing out that he had been guilty of a violation of the law. At the same time he requested him to avoid places of public resort. The patient, however, did not attend to these injunctions; and, in consequence, he received a summons from the Coleraine Board of Guardians to attend the petty sessions. This he might have done through a solicitor; but to the dismay of a crowded court he appeared in person. To make matters worse, his own medical attendant affirmed that if his presence at the "Spelling Bee" was dangerous, he was now in a condition to convey the infection yet more easily. A fine of £2, including costs, was imposed, and the offender immediately took out from his pocket two one-pound notes, and handed them to the clerk. The sanitary officer and the Board of Guardians are to be commended for taking cognisance of this case. It is most important that the public should understand that by failing to use due precautions against communicating infection they bring themselves within the action of the law. But in this instance the measures adopted were certainly somewhat ludicrous. The offender was summoned to a public court in order that he might be censured for appearing at a place of public entertainment. Justice certainly defeated its own ends, and the right thing was done in the wrong way.

DEATH OF DR. JAMES TUCKER OF SLIGO.

THIS much respected and esteemed member of our profession died on the 1st inst. at Sligo. Dr. Tucker held many appointments, including those of medical officer of health for Sligo, dispensary medical officer, medical attendant to the constabulary, medical inspector for the port of Sligo, and surgeon to the Sligo Rifles. He was the author of several essays on cholera, fever, and various sanitary subjects, and contributed reports on rinderpest to the Government, and a paper on the Roman thermo-electrical bath.

DUBLIN HOSPITAL SUNDAY FUND.

AT a late meeting of the Executive Council of this Hospital Fund, it was stated that the Governors of the Meath Hospital, and of the Convalescent Home, Stillorgan, desired to participate in the movement, and wished to be enrolled in the list of institutions which obtain grants from the sums collected. We regret to find that the Committee of the Adelaide Hospital still refuse to co-operate, and stand aloof, for some mysterious reason, from an undertaking in every way so desirable.

THE LATE DR. MAUNSELL.

WE are glad to learn that Sir Michael Hicks Beach has forwarded a contribution of £5 to the fund for the family of the late Dr. D. Toler Maunsell, of which Dr. Speedy is the Dublin treasurer, and Dr. Joseph Rogers, Dean Street, Soho, the London treasurer. Dr. Maunsell was an indefatigable and successful labourer in ameliorating the medical dispensary system in Ireland, and the public not less than the profession owe much to his labours.

TESTIMONIAL.—The students, officers, and inmates of the Bristol General Hospital recently presented Dr. Thomas Elliott, the house-surgeon, with a testimonial on the occasion of his resigning this appointment. The testimonial was in the form of a handsome walnut Davenport and silver plate, bearing the following inscription:—"Presented to Dr. Thomas Elliott, by the officers, students, nurses, and patients of the Bristol General Hospital, on his resignation of the house-surgeoncy. September 1875;" also a pocket instrument-case. The presentation was made by the chaplain, who bore testimony to the universal esteem in which Dr. Elliott was held by the patients under his charge, and to the high Christian principle which had actuated him in all his work during the three years he had been connected with the institution as its house-surgeon.

THE MEDICAL SCHOOLS.

THE following notes respecting the Metropolitan Medical Schools are in continuation of those published last week.

ST. BARTHOLOMEW'S HOSPITAL.

AT St. Bartholomew's Hospital, ten subjects for dissection have been at present received; eight of them having been preserved by Gorstin's fluid during August and September. They are in an admirable state of preservation, and we are told that the demonstrators of anatomy continue to believe this method of preservation to be the best hitherto adopted. Gorstin's fluid has been in use at St. Bartholomew's Hospital for about five years. During the past year, the collection of dissected specimens of human anatomy in the museum has been increased. The entry of new students is a large one, more than one hundred having already registered.

CHARING CROSS HOSPITAL.

THE winter session opened at this hospital with an introductory address by Mr. Fairlie Clarke, which was largely attended. The entry of new students has been very good, nearly 31 new students being already enrolled (October 6th); of this number, one being a free scholar. This number is exclusive of six gentlemen who have entered as occasional students. The practical teaching of anatomy is now entrusted to Mr. Rickman J. Godlee, M.B., M.S. The hospital is undergoing most extensive alterations and additions. New wards of the most recent construction are being built, and the entire hospital raised a storey. About £16,000, it is understood, will be laid out: thus the field for clinical teaching will be greatly widened. The library of the hospital has been entirely renovated, and has recently had a most valuable donation from the library of Mr. Hancock, the Consulting-Surgeon. In every department, the practical teaching of the hospital is thoroughly accommodated, the Governors having liberally assisted the school authorities in rendering the institution as complete in all details as possible. We are not aware when the office of Assistant-Physician, consequent on the resignation of Dr. Poore, is to be filled up.

ST. GEORGE'S HOSPITAL.

THERE have been no changes in the buildings at St. George's Hospital lately. During last year, there was added a new microscopic-room, which seems to answer its purpose very well, and where many of the students, under the able tuition of Mr. Watney, the demonstrator of histology, have done much good work; some of them having prepared large numbers of specimens, both anatomical and pathological. The lectures commenced on Monday, and the number of entries are about the average. In the dissecting-room, there were four subjects ready for dissection. Two of these have been preserved since July last, and it is difficult to say from the appearance which are the fresh ones and which those that have been preserved.

KING'S COLLEGE.

SEVERAL additions have been made to the College buildings. Amongst them, the chief is a complete physiological laboratory, comprising rooms for teaching (a) practical histology, and (b) physiological chemistry; each capable of accommodating about forty students; the former is lighted at the side from the embankment, and from the roof by a large skylight; the latter is fitted up on the plan of modern chemical laboratories; also an instrument-room supplied with all the instruments for modern researches; galvanometer, myograph, etc.; a supplementary large room for general purposes of teaching; and a private room for the professor of physiology, Dr. Gerald Yeo. The building of the laboratory has necessarily altered the dissecting-room, which is now much larger than formerly, and is one of the best lighted and ventilated in London. Dr. Currow started with three bodies ready for dissection, and has already more than twenty students at work. More rooms for students have been also built, and additions made to the other departments of the College. The chemical laboratory is now larger and better than before, and is removed to the new part of the building.

ST. THOMAS'S HOSPITAL.

SOME change has been made in the method of preserving subjects, and Mr. Howse's plan is now being tried. The dissecting-room has been almost entirely refurnished with tables and stools. Cases for fresh dissections have been arranged in the museum, and a new series is to be taken in hand. The number of subjects with which dissection begins is six. Mr. Rainey will give microscopical and special anatomical demonstrations daily during the winter session.

THE LONDON HOSPITAL.

THERE was a large attendance at Dr. Woodman's introductory lecture. The school buildings have undergone general repairs and alterations. The specimens in the museum have received many additions in the shape of new models, dissections, etc. There will be shortly a large addition to the library. The new wing will be opened early in January next; and as the nominal number of beds will be 850, of which 800 will be occupied, an increase in the resident medical staff will be needed. The election for the office of assistant obstetric physician is postponed, in order, it is said, to allow men to qualify for the post; but if it be intended to elect any one man, surely the other candidates should in justice be informed; otherwise they may put themselves to needless trouble. The lectures and demonstrations are going on as usual, but it is probable that certain fresh practical courses will shortly be added. One subject is now being dissected; others are in preparation. There is an average entry of new students.

ARMY MEDICAL SCHOOL, NETLEY.

THE winter session of the Army Medical School was opened on the 1st instant, the introductory lecture being delivered by Professor Longmore, C.B. The following is the number of candidates for commissions who have arrived to go through the courses of instruction: British Army, 15; Royal Navy, 7; Indian Army, 10; altogether, 32. Several surgeons of the Army and Naval Medical Services have also joined for the session. We noticed that Professor Parkes was not present at the opening address, and were sorry to learn that he was prevented from attending by a severe attack of sciatica.

THE OCTOBER DINNERS.

St. Bartholomew's Hospital.—There was as usual no special introductory address, but the annual dinner took place in the Great Hall and attracted a large number of old students and friends. Professor Humphry of Cambridge was in the chair, and amongst the visitors were the Treasurer, Sir Sidney Waterlow, the President of the Medical Council, Dr. Acland, Dr. Carpenter, Professor Abel, Mr. Thomas Stone, and many others.

Charing Cross Hospital.—The members of the hospital and school staff dined together privately at the Freemasons' Tavern, on the evening of the 1st inst. Dr. Julius Pollock occupied the chair.

St. George's Hospital.—On the 1st inst., the old and present students of St. George's Hospital dined together at Willis's Rooms, under the presidency of Dr. Paget of Cambridge. Between eighty and ninety past and present students assembled on the occasion. Amongst the speakers were the chairman, Drs. Barclay, Dickinson, and Barnes, and Messrs. Prescott Hewett, Timothy Holmes, Frank Buckland, J. A. Shaw-Stewart, and C. Dent, the present house-surgeon.

The London Hospital.—About seventy gentlemen attended the dinner, which took place at the "Albion." Dr. Andrew Clark occupied the chair, and was supported by Dr. Langdon Down, Dr. Letheby, Dr. Little, Mr. Curling, Mr. Jonathan Hutchinson, and others.

St. Mary's Hospital.—A *conversazione* was held after the Introductory Address, and was attended by a very large number of local medical men and others. The museum and theatres of the school were lighted up, and the usual refreshments were served, but the great centre of attraction was the dissecting room. This was brilliantly lighted, and in it was set out a very interesting collection of objects of artistic interest: Wedgwoods, bronzes, and pictures, with a display of microscopes, and surgical instruments. Dr. Randall had discoursed of modern methods of burial, and one of Mr. Seymour Haden's wicker coffins was shown.

The Middlesex Hospital.—The annual dinner of past and present Middlesex students took place on the 1st instant, at St. James's Hall, under the presidency of Mr. Campbell De Morgan. Nearly a hundred gentlemen were present; and the meeting was considered highly successful. Music was voluntarily rendered by Signor Garcia, Herr Ganz (who presided at the pianoforte), Dr. Roberts, and Dr. Semple. The toast of the evening was proposed by the chairman, Professor Flower, of the College of Surgeons, was present and spoke. Mr. Nunn humorously proposed the past and present students; and Mr. Oscar Clayton, in a pointed speech, returned thanks on behalf of the former, and Mr. Arthur Lucas spoke for the students of to-day.

St. Thomas's Hospital.—The annual dinner of old students took place on October 1st, at the Pall Mall Restaurant, Regent Street, and Dr. Peacock occupied the chair. About a hundred old students met together and revived old times. Amongst the most noticeable speeches were those of the Dean, Mr. T. Heckstall Smith, Dr. Alfred Carpen-

ter, and Dr. Bristowe; but the speech of the evening was made by Mr. Le Gros Clark, with his usual felicity of expression.

Westminster Hospital.—The triennial dinner of the old students and friends of the Westminster Hospital was held at St. James's Hall Restaurant, October 4th, 1875, at 7 P.M.; Carsten Holthouse, Esq., in the chair. Forty-five sat down to dinner, and amongst them we noticed Mr. Barnard Holt, Mr. Christopher Heath, Mr. Henry Power, and many of the present hospital staff. Mr. Holt returned thanks for the consulting staff, and Mr. Power and Mr. Heath for the present and past friends of the hospital. The dinner arrangements were well managed by Drs. Allchin and Grigg, honorary secretaries; to them and to the agreeable bearing of the chairman must be attributed the success of this pleasant *réunion*.

MEDICAL SCHOOLS AND HOSPITALS IN IRELAND.

CATHOLIC UNIVERSITY SCHOOL OF MEDICINE.—The Winter Session will commence on October 1st, with Practical Anatomy. The Lectures will commence on November 3rd. Anatomy and Physiology (Human and Comparative), Dr. T. Hayden, and Dr. R. Cryan, daily, except Saturday, 12; Anatomical Demonstrations, Dr. Hayden and Dr. Cryan, daily, except Saturday, 1; Chemistry, Dr. John Campbell, Mondays, Wednesdays, Fridays, 2; Surgery, Mr. Tyrrell, Mondays, Wednesdays, Fridays, 3; Medicine, Dr. R. D. Lyons, Tuesdays, Thursdays, Saturdays, 3; Midwifery, Dr. J. A. Byrne, Tuesdays, Thursdays, Saturdays, 2; Demonstrations in Dissecting Room, Mr. P. J. Hayes, Dr. C. J. Nixon, Mr. C. Coppinger, Dr. M. Kilgarriff, Dr. C. Gunn, Mr. J. Dillon. **Summer Session.**—Practical Chemistry, Dr. Campbell; *Materia Medica*, Dr. Quinlan; Medical Jurisprudence, Dr. MacSwiney; Pathology, Dr. Lyons; Botany, Dr. Sigeron; Natural Philosophy, Dr. Molloy; Logic, Dr. D. B. Dunne. **Prizes.**—At the end of the Winter Session. Prizes in each class: the Conolly Medical Exhibition, of the Catholic University, value £20, tenable for one year, and open to the competition of all students, after examination in Physiology, Physiological Anatomy, Chemistry, and Botany; the University Exhibition, value £20, after examination in practice of Medicine, Surgery, and Midwifery; at the end of the Summer Session, the University Gold Medal, value £7, for the best answering in Practical Chemistry, *Materia Medica*, and Medical Jurisprudence; Prizes in each class. **Fees.**—Each course, £3 3s.; except Dissections, £5 5s. A reduction of one-sixth is made to perpetual pupils paying the entire fees in advance, or in two instalments at the commencement of the first and of the second years. The School is in a central situation, and within a few minutes' walk of the principal hospitals of the city. It includes a Reading Room well supplied with medical books and periodicals, also an extensive and most complete Laboratory, in which students can pursue the study of Practical Chemistry, *Materia Medica*, and Toxicology. Further particulars may be learned from the Dean of the Faculty of Medicine, Dr. MacSwiney, 1, Hume Street, Dublin; from Dr. Quinlan, 29, Lower Fitzwilliam Street; from any of the other Professors; from the Medical Registrar, Dr. Hayes, 29, Westland Row; or on application at the School.

LEDWICH SCHOOL OF SURGERY AND MEDICINE.—The Lectures will be delivered by the following teachers. Anatomy, Surgical and Descriptive: Mr. Edward Ledwich, Mr. T. P. Mason, Mr. A. R. Glanville, and Mr. J. E. Kelly, five days, weekly, 1 P.M. Anatomy, Physiological and Pathological: Mr. T. P. Mason, Mr. Edward Ledwich, and Mr. J. E. Kelly, five days, weekly, 12 noon. A brief Course of Comparative Anatomy will be delivered during the Winter Session. Surgery: Mr. J. H. Wharton and Dr. J. K. Barton, M., W., F., 11. Medicine: Dr. Arthur W. Foot, Tu., Th., S., 11. Midwifery: Dr. J. Ringland, Tu., Th., S., 2. Chemistry and Natural Philosophy: Dr. C. A. Cameron and Mr. E. Lapper, F.C.S., M., W., F., 2. Practical Chemistry: Dr. Cameron. *Materia Medica*: Dr. B. F. MacDowell, M., W., F., 11. Botany: Dr. D. Toler T. Maunsell, M., W., F., 12. Forensic Medicine and Hygiene: Dr. R. Travers, M., Tu., Th., S., 12. Anatomical Demonstrations: Mr. T. P. Mason, Mr. E. Ledwich, Mr. A. R. Glanville, Mr. C. H. Robinson, Mr. M. A. Ward, Mr. J. E. Kelly, Mr. S. R. Mason, Mr. A. H. Ringland, Mr. R. D. Purefoy, Mr. R. Rainsford, Mr. F. T. Porter, Mr. H. J. K. Gogarty, Mr. Nixon, daily, in the Anatomical Dissecting Rooms. A Course of Operations to be performed by the Student, under the superintendence of the Lecturer (subjects, etc., included), £5 3s. Fee for each Course, £3 3s. The Dissecting Rooms open on October 1st, 1875. During the Summer Session, to commence in April 1876, the usual Courses will be delivered on Midwifery, Chemistry, *Materia Medica*, Botany, and Forensic Medicine. There are Endowments in favour of Students,

subject to the conditions prescribed by the Founder, in the following departments: Two in Anatomy and Physiology; Two in Minute Anatomy; Two in Practical Anatomy; One in Surgery. The usual Prizes in the other departments will be awarded at the termination of each Session.

This School, which has recently been rebuilt, is in a central situation, and is replete with every convenience. By its teachers, it is connected with six hospitals, five of which are medical and surgical hospitals, and one for midwifery and diseases of women and children.

Apply to Dr. Foot, Pembroke Street; Drs. Ringland, Ledwich, and Mason, Harcourt Street; Mr. Wharton, Upper Merrion Street; or at the School.

JERVIS STREET HOSPITAL.—Physicians, Dr. Stephen M. MacSwiney, M.R.I.A., Dr. William Martin. Surgeons, Mr. M. Harry Stapleton, Dr. J. Stannus Hughes, Dr. J. K. Forrest, Dr. Austin Meldon, Mr. James E. Kelly, Mr. M. J. Kilgarriff, Dr. E. W. Collins. The winter session will commence on November 1st. This hospital is in the immediate vicinity of the Catholic University and Carmichael Medical Schools. The surgeons and physicians attend daily from 9 to 11 o'clock. Medical and surgical lectures are delivered in each week, and clinical instruction is given daily by the physicians and surgeons. Operations are performed on Saturday mornings at 10. Practical Pharmacy is taught under the superintendence of the apothecary to the hospital. Resident pupils and dressers are selected from among the most attentive of the pupils, without payment of any additional fee. Two interns are appointed each half year, and are provided with apartments, fuel, etc., free of expense. Special certificates are given to the resident pupils and dressers who have performed their respective duties to the satisfaction of the physicians and surgeons. **Fees.**—For the winter and summer sessions (nine months), £8 8s.; for the winter six months, £6 6s.; for the summer three months, £3 3s.; perpetual pupils, £21, paid on entrance. For further particulars apply to Dr. E. W. Collins, 33, Lower Baggott Street, or to any of the Physicians or Surgeons.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.—These Hospitals contain 312 beds; 110 for surgical cases, 82 for medical cases, and 120 for fever and other epidemic diseases. A Dispensary for out-door patients is attached to the Medical and Surgical Hospitals. There is an extensive Pathological Museum, containing above 4,000 drawings, casts, and preparations, and a Medical and Surgical Lending Library. Two Clinical Lectures are delivered in each week, in addition to Bedside Instruction given daily by the Physicians and Surgeons. There will be a distinct Course of Lectures and Clinical Instruction in Fevers. A course of Practical Instruction in Ophthalmic Surgery will be given. The Hospitals are visited at 9 A.M. by the Physicians and Surgeons. Operations are performed on Wednesday mornings. Eight resident Clinical Clerks are appointed each half-year, and provided with furnished apartments, etc. The Dressers are selected from among the best qualified of the pupils, without additional fee. At the termination of the Session, premiums will be awarded in Clinical Medicine and Surgery. The Richmond Institution for the Insane, containing over 1,000 patients, adjoins these Hospitals. The Carmichael School of Medicine is also in the immediate vicinity of these Hospitals. Consulting-Physician, Sir D. J. Corrigan, Bart., M.D.; Physicians, Dr. J. T. Banks, Dr. B. G. M'Dowel, Dr. S. Gordon, Dr. R. D. Lyons; Assistant-Physician, Dr. R. J. Harvey; Consulting-Surgeon, Mr. J. Hamilton; Consulting Obstetric Surgeon, Dr. G. H. Kidd; Surgeons, Mr. W. Stokes, Dr. W. Thomson, Dr. W. T. Stoker, Dr. A. H. Correy; Ophthalmic Surgeon, Mr. C. E. Fitzgerald. **Fees.**—Winter and summer session (nine months), £9 9s.; six winter months, £7 7s.; three summer months; £3 3s.; Perpetual Pupils, £25 (paid on entrance). Resident Clinical Clerks, winter session, £21; summer session, £12 12s., including certificate of attendance.

ST. VINCENT'S HOSPITAL AND DISPENSARY.—The hospital is visited daily at 9 A.M. It is connected (by its medical officers) with three leading medical schools in its immediate vicinity. Medical and Surgical Clinical Lectures will be given three times weekly; operations on Fridays, at 10.30 A.M. At the beginning of each winter and summer session, two resident pupils will be selected by competitive examination. At the end of the winter session, an examination will be held in Clinical Medicine and Surgery, at which a senior and a junior prize will be awarded. A portion of all these examinations will be conducted at the bedside. Physicians, Dr. Francis J. B. Quinlan, Dr. Robert Cryan, Surgeons, Dr. Edward D. Mapother, Mr. William H. O'Leary, M.P. Surgeon Dentist, W. J. Doherty, L.D.S. Apothecary, C. T. Boland. **Terms of Attendance.**—Winter and summer sessions, £8 8s.; winter

session, £6 6s.; summer session, £3 3s.; Perpetual pupils, £21. Practical instruction in compounding medicines will be given. Further particulars may be learned on application to Dr. Quinlan, 29, Lower Fitzwilliam Street; Dr. Napother, 18, Merrion Square North; Dr. O'Leary, M.P., 38, York Street; Dr. Cryan, 54, Rutland Square West; or at the hospital.

ASSOCIATION INTELLIGENCE.

COMMITTEE OF COUNCIL: NOTICE OF MEETING.

A MEETING of the Committee of Council will be held at the Office of the Association, 36, Great Queen Street, London, on Tuesday, the 12th day of October next, at Three o'clock in the afternoon.

FRANCIS FOWKE,
General Secretary.

36, Great Queen Street, London, W.C., September 23rd, 1875.

YORKSHIRE, AND EAST YORK AND NORTH LINCOLN BRANCHES.

IT having been decided by the respective Councils of the above Branches that the autumnal meeting shall be held conjointly at the York Museum on October 13th, 1875, members of these Branches intending to read papers or cases are requested to forward the title to either of the Secretaries on or before the 27th instant, so that a notice thereof may be included in the circular convening the meeting.

Dinner at the Station Hotel at 5 o'clock. Tickets (exclusive of wine) 7s. 6d. each.

W. PROCTER, M.D., York, } *Hon.*
R. H. B. NICHOLSON, Hull, } *Secs.*

York, September 18th, 1875.

SOUTHERN BRANCH: SOUTH-EAST HANTS DISTRICT.

THE next ordinary meeting of the above Branch will be held at the India Arms Hotel, Gosport, on Wednesday, October 13th, at 4.30 P.M.

Notice has been received of the following communications:—

1. Dr. W. Hoare: Venesection.

2. Surgeon-General J. Mouat, V.C., C.B.: Pyæmia.

3. Dr. Ward Cousins: Case of large Cystic Tumour of Lower Jaw.

Dinner will be provided at 6.15 P.M.; charge 6s., exclusive of wine.

Members intending to be present are requested to communicate with Dr. Kealy, Gosport, on or before October 10th.

J. WARD COUSINS, *Honorary Secretary.*

Southsea, September 23rd, 1875.

SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT.

THE next meeting of the above Branch will be held at the White Hart Hotel, Reigate, on Thursday, October 14th, at 4 P.M.; J. WALTERS, M.B., in the Chair.

Dr. Dady will read a paper on Tetanoid Affections associated with Imperfect Development of the Cranium.

Mr. Gandy: Notes on some Cases of Puerperal Fever.

Mr. Hallowes: Cases of Cerebral and Spinal Hemorrhage.

Dr. Walters: On the Treatment of Colles' Fracture, and will exhibit pathological specimens.

Dr. Holman will move a resolution with reference to advertisement of medical works.

Dinner at the White Hart Hotel at 6 P.M. Tickets 6s., exclusive of wine.

JOHN H. GALTON, M.D., *Honorary Secretary.*

Woodside, Anerley Road, S.E., September 27th, 1875.

WEST SOMERSET BRANCH.

THE autumnal meeting of this Branch will be held at the Railway Hotel, Taunton, on Thursday, October 14th, at 5 o'clock.

The following question has been settled by the Council as the one on which members should be invited to express their opinion at the said meeting after dinner:—"Is the disuse of Bloodletting in the Treatment of Disease in accordance with the principles of Pathology?"

Dr. Cordwint proposes to read a paper "On Tissue-Change in Fevers".

Dinner (on the table at 5 o'clock), 4s. a head, exclusive of wine.

W. M. KELLY, M.D., *Honorary Secretary.*

Taunton, September 16th, 1875.

BATH AND BRISTOL BRANCH.

THE first ordinary meeting of the Session will be held at the York House, Bath, on Thursday, October 28th, at 7.15 P.M.: W. M. CLARKE, Esq., President.

R. S. FOWLER, Bath. } *Honorary Secretaries.*
E. C. BOARD, Clifton. }

Bath, September 24th, 1875.

STAFFORDSHIRE BRANCH.

THE second annual meeting of this Branch will be held at the London and North Western Railway Hotel, Stafford, on Thursday, October 28th, at 2.30 P.M. precisely. President, R. GARNER, Esq., F.L.S. The President-elect (H. DAY, M.D., F.R.C.P.) will deliver an address.

Dinner at 5 P.M. precisely. Tickets 10s. 6d. each, exclusive of wine.

VINCENT JACKSON, } *Honorary Secretaries.*
RALPH GOODALL, }

Wolverhampton, September 27th, 1875.

BORDER COUNTIES BRANCH.

THE autumnal meeting of the above Branch will be held at the County Hotel, Carlisle, on Friday, October 29th, at 1 P.M.

Gentlemen intending to read papers, or to be present at the dinner, are requested to give notice to the Secretaries.

STEWART LOCKIE, } *Honorary Secretaries.*
JOHN SMITH, }

Carlisle, October 2nd, 1875.

SOUTH MIDLAND BRANCH: AUTUMNAL MEETING.

THE nineteenth autumnal meeting of this Branch was held in the Council Chamber of the Guildhall, Northampton, on Wednesday, September 22nd, at 2 P.M.; HENRY TERRY, Esq., President, in the Chair. The following members were also present: Dr. Buszard; Dr. Bryan, honorary secretary and treasurer; W. Moxon, Esq., honorary secretary; H. Spurgin, Esq.; C. J. Evans, Esq., and Dr. James, of Northampton; Dr. Prior, and H. W. Sharpin, Esq., of Bedford; Dr. Newman, of Stamford; Robert De'Ath, Esq., of Buckingham; R. W. Watkins, Esq., of Towcester; Alfred Haviland, Esq., of Rothwell; George Hadday, Esq., West Haddon; G. H. Grindon, Esq., Olney; Dr. More, Rothwell; etc. Previously to the meeting, the members were entertained at luncheon by the President.

New Member.—Mr. Alfred Partridge Kingcombe, of Towcester, was elected.

Annual Meeting in 1876.—A letter was read from Dr. Bradbury, stating that the Cambridge and Huntingdon Branch was willing to hold a conjoint meeting at Bedford next year. It was proposed by Mr. Watkins, and carried:

"That the annual meeting of the South Midland Branch in 1876 be held at Bedford, under the presidency of H. W. Sharpin, Esq.; and that the Branch will be happy to combine with the Cambridge and Huntingdon Branch."

It was also proposed that the two above-named Branches, together with the East Anglian, should hold a combined meeting at Peterborough in 1877.

Papers.—The following papers were read and discussed.

1. On the Difference between the Geographical Distribution of Scarlet Fever and Typhoid Fever (illustrated by maps). By Alfred Haviland, Esq.

2. Suppression of Urine lasting five days: terminating fatally. By W. Newman, M.D.

3. Symmetrical Necrosis of both Femora. By W. Newman, M.D.

4. Notes of Nine Cases of Pyæmia occurring in Private Practice. By F. Buszard, M.D.

Votes of Thanks.—It was proposed and carried unanimously, "That votes of thanks be given to the authors of papers, to the president and ex-president, to the honorary secretaries; also to the mayor and authorities for the use of the Council Chamber."

The members separated at 4.30 P.M., after a very agreeable and instructive meeting.

VACCINATION.—Mr. Robert Manners Mann has been awarded by the Local Government Board the sum of £109 2s., as extra-payment for efficient vaccination. Mr. Mann is the officer for No. 3 District in the township of Manchester.—The Local Government Board have awarded the grant of £13 4s. to Dr. E. W. Orton of Bedworth, Warwickshire, for efficient vaccination in that district.

OBITUARY.

JOHN HUGHES BENNETT, M.D., F.R.S.E.

JOHN HUGHES BENNETT was born in London on August 31st, 1812, and died at Norwich on September 25th, 1875, in the sixty-fourth year of his age. He was educated at the Grammar and Mount Radford Schools at Exeter. His mother was a lady of brilliant intellectual powers, independence of spirit, and high culture, and from her he inherited many of those intellectual gifts and traits of character by which he was afterwards distinguished. It was she who cultivated his literary and artistic tastes, and trained him in the art of correct reading and elocution. From an early age, she was in the habit of causing him to read aloud in her presence the plays of Shakespeare, while she taught him the art of emphasis and gesture. To this must, no doubt, be attributed his well known histrionic power, which years afterwards gave an elegance and finish to his lectures and public speeches rarely to be met with. During part of his education, he resided along with his mother in various parts of the continent, more especially in France. Here he acquired a sympathy with the character and deeds of the gallant nation, which he retained throughout life. He commenced the study of medicine, 1829, as an articulated pupil to the late Mr. Sedgwick, surgeon at Maidstone, intending in due time to obtain the diploma of the Royal College of Surgeons and the license of the Apothecaries' Company. It is said that for a short time he was a student at St. Bartholomew's Hospital. As Mr. Sedgwick's pupil, he became an adept in the art of dispensing, and engaged in the routine work of a general practice. Even at this early period of his professional career, he appears to have developed an interest in pathological inquiry. He frequently assisted in *post mortem* examinations, and there is now before us a volume of notes made at that time which are characterised by much of the method and accuracy of description which may be observed in his matured writings. On one occasion, it appears, that he and another pupil made a *post mortem* examination without the knowledge or consent of his master. In this instance, zeal outran discretion. Mr. Sedgwick was angry; and, the consequence was, an abrupt termination to the apprenticeship. This incident, in one sense, was the turning point of his career. Had he continued with Mr. Sedgwick to the end of his apprenticeship, one can easily imagine how different his after life might have been.

After much anxious consultation with his friends, he resolved to pursue his medical education in Edinburgh. Accordingly, he enrolled himself as a student of the University in 1833. When he came to Edinburgh, it is said that he was unacquainted with any one, and it is a striking proof of his great talent, perseverance, and industry that, in the course of a very few years, he became well known, not only in Edinburgh, but throughout Europe. During his career as a student, he studied with zeal and assiduity; devoting his attention, however, more especially to anatomy, physiology, and pathology. He frequently alluded to two of his teachers as being men who exercised a great influence over him. The one was Robert Knox the anatomist, and the other John Fletcher the physiologist. The first he considered a model teacher who possessed the power of fascinating his pupils; the second he often spoke of as a man of profound learning and originality of mind, whose writings had fallen into unmerited neglect. Whilst a student, Dr. Bennett soon found a place among the foremost spirits of the day. He was one of the famous Brotherhood or "Order", founded chiefly by Edward Forbes, which had for its watchword ΟΙΝΟΣ, ΕΡΟΣ, ΜΑΘΗΣΙΣ (wine, love, learning), and which was "an union of the searchers after truth, for the glory of God, the good of all, and the honour of the Order, to the end that mind may hold its rightful sway in the world". He had as associates such men as the two Goodsirs, Edward Forbes, John Hutton Balfour, John Reid, Martin Barry, and Henry Lonsdale, all of whom afterwards became distinguished leaders in science. With them and others he took an active part in the affairs of the Royal Medical Society, of which in due time he became a President. In this arena, he cultivated the art of debate, and no doubt acquired by practice that fluency of speech and readiness in reply which were so serviceable to him in after life. He regarded the Royal Medical Society as one of the most valuable adjuncts to medical education and culture in Edinburgh, and a session rarely passed without the Society having the benefit of his powerful advocacy from the professorial chair. Whilst a student, he published two papers: the first, On the Anatomy and Physiology of the Otic Ganglion, in the *London Medical Gazette* of July 30th, 1836; and the second, being an Address to the Members of the Royal Medical Society, appeared in pamphlet form in December of the same year.

In 1837, he received the degree of M.D. with the highest honours, obtaining, on the recommendation of the late Professor Syme, a gold medal for the best surgical report; whilst Sir Charles Bell recommended his thesis as worthy of another. The title of his thesis was, *Inaugural Dissertation on the Physiology and Pathology of the Brain: being an attempt to ascertain what portions of that organ are more immediately connected with motion, sensation, and intelligence.* He was afterwards informed by Mr. Syme that he would have received a second medal, had there not been a rule that two medals could not be awarded to the same competitor.

After graduating, Dr. Bennett proceeded to Paris, where he studied for two years, and became President of the Parisian Medical Society; he also went to Germany, and spent other two years in the principal University cities. In Paris, he devoted his attention chiefly to the study of the use of the microscope in practical medicine, and also to clinical instruction in the hospital. The clear, precise, methodical style pursued by the French physicians harmonised with his own qualities of mind, and there is little doubt the system of clinical instruction which he afterwards successfully introduced into Edinburgh, was carefully elaborated by him while in Paris. Whilst on the continent, he wrote the following articles in Tweedie's *Library of Medicine*, vol. ii: (1) On the Physiology of the Nervous System, (2) Hydrocephalus, (3) Apoplexy, (4) Delirium Tremens, (5) Cephalalgia, (6) Epilepsy, (7) Catalepsy, (8) Spinal Irritation, (9) Spinal Meningitis, (10) Myelitis, (11) Hydrorachis, (12) Spinal Apoplexy, (13) Tetanus, (14) Hydrophobia, (15) Paralysis, (16) Barbers, (17) Otitis. In 1841, he also wrote in the *Bulletin de la Société Anatomique de Paris*, a paper entitled, Note sur le Développement de Nerfs particulières à la surface du Cervelet, in which he described the remarkable appearance of a number of nerves ramifying on the surface of the cerebellum of a man thirty-eight years of age, who died of acute pneumonia in the lunatic asylum of Heidelberg.

In 1841, he returned to Edinburgh, and in November he commenced a course of lectures on histology. One of the handbills announcing the second or summer course of lectures is now before us, and, as the matter is one of historical interest, it is as well to copy it *verbatim*. "Histology. Dr. Bennett, during the summer session, will give a public course of lectures on the Minute Structure of Organised Tissues, with reference to Anatomy, Physiology, Pathology, and the Diagnosis of Disease. These lectures will be illustrated by numerous preparations, diagrams, and demonstrations under the microscope; the latter by means of twelve achromatic instruments of great power, manufactured by Chevalier of Paris expressly for this course. An introductory lecture will be delivered on Friday, May 13th, at 11 A.M., in the class room, Surgeons' Square, and the course will be continued every Monday, Wednesday, and Friday, at the same hour, throughout the session; fee, £2 2s. Dr. Bennett will also give private courses on the Practical Manipulation of the Microscope. Each class is limited to six, and the time of lecture regulated by the wishes of the majority. The lectures embrace the optical and mechanical arrangements of microscopes, illumination, mensuration, optical illusions, mode of displaying objects, and every information necessary for the medical inquirer, in his examination of the animal textures in a state of health and disease; fee, £3 3s. 16, Pitt Street, May 2nd, 1842."

Prior to this date, histology was taught in a general way, and demonstrations of microscopical preparations were given by other teachers, notably by Dr. Allen Thomson, who held the Chair of Institutes of Medicine in Edinburgh, and who is now the distinguished professor of anatomy in the University of Glasgow. But it appears that Dr. Bennett was the first to teach the use of the microscope systematically, and it was he who first clearly recognised its great importance in the clinical investigation of disease. This course of instruction given by Dr. Bennett must also be regarded as the first attempt at the practical teaching of physiology and pathology made in this country. Even at this early period of his career, he appears to have held the opinion that every medical man should be skilful in the manipulation of the microscope, and more especially that the microscope should be always employed in the examination of diseased organs. At the time when Dr. Bennett commenced this course of lectures, the value of the microscope in pathological research was not sufficiently known in this country. So long as an organ showed no change in its material substance when examined by the naked eye, physicians called its affections functional, and the fact of microscopical changes of structure was overlooked. By instructing many of the rising members of the profession in the manipulation of the microscope, Dr. Bennett not only advanced the interests of the Edinburgh medical school by bringing its teachings to a level with those of continental institutions, but he stimulated many ardent minds to enter upon a new path of inquiry which led to fruitful results.

On October 1st, 1841, Dr. Bennett published his *Treatise on the*

Oleum Jecoris Aselli, or Cod-Liver Oil, as a Therapeutic Agent in certain forms of Gout, Rheumatism, and Scrofula, with Cases. This work is dedicated to Dr., now Sir Robert, Christison, and is an early evidence of the long friendship which existed between the distinguished President of the Association and Dr. Bennett. Whilst Dr. Bennett resided in Germany, cod-liver oil was extensively used in the treatment of chronic gout, rheumatism, and of scrofula, and he lost no opportunity of watching its therapeutic effects. So impressed was he with its value, that almost immediately on his return home, he published the *Treatise*, which at the time excited great interest in the profession. To him no doubt belongs the credit of having more especially urged its use in the treatment of many cases of phthisis pulmonalis. Cod-liver oil had been long known as a popular remedy in Scotland, more especially among the fishing populations of the north and north-east coasts. It had a reputation in Lancashire for the cure of rheumatism; and, according to Dr. Bennett, Dr. Kay, one of the physicians to the Manchester Infirmary in 1789, was the first medical man who prescribed it for the cure of disease. Still the general use of this valuable therapeutic agent will always be associated with the name of John Hughes Bennett.

In 1842, he was an unsuccessful candidate for the chair of General Pathology in the University of Edinburgh, when the late Professor Henderson was appointed. About this time, he became a Fellow of the Royal Society of Edinburgh, a Fellow of the Royal College of Physicians of Edinburgh, Physician to the Royal Dispensary, and Pathologist to the Royal Infirmary. As one of the physicians to the Royal Dispensary, he gave six winter courses, each of six months' duration, and seven summer courses, each of three months' duration, on polyclinical medicine. These classes were formed on the model of the German polyclinic, in which students are taught practically, under the eye of their teacher, to examine and prescribe for patients. The first course was delivered by Dr. Bennett in the winter of 1841; although it must be recorded that the same method, as applied to surgery, had been previously introduced into the Surgical Hospital, Minto House, by the late Professor Syme. The peculiarity of the course was that opportunities were afforded the pupil of himself interrogating the patient; examining the diseased organs or their products by means of the pleximeter, stethoscope, chemical reagents, microscope, etc.; and of thus forming his own diagnosis. The opening lecture, given in November 1845, was on the Methods of Studying Practical Medicine in different Countries, and the advantages of Polyclinical Instruction.

Whilst acting as pathologist to the Royal Infirmary, he worked with great diligence, and formed a private museum of morbid anatomy, containing about eight hundred wet, and three hundred dry, preparations. He also delivered six winter courses of lectures on pathology and practice of physic, in which the special feature was the demonstration under the microscope of all accessible morbid tissues and fluids, with arrangements permitting each student to see and examine them himself.

From 1842 to 1848, when he was appointed to the chair of Institutes of Medicine, rendered vacant by the transference of Dr. Allen Thomson to the chair of Anatomy in Glasgow, Dr. Bennett appears to have lived a life of incessant mental activity. For several years, he was proprietor and editor of the *Edinburgh Monthly Journal of Medical Science*, to which, in addition to ordinary editorial duties, he contributed numerous papers.

In this short story of his life for his professional brethren, could he read it now, nothing, we feel sure, would please him better than to find a simple record of what he did, without laudatory note or comment. With this feeling, we have looked over the journals and volumes of that period, and collated the titles of all the papers written by him. The following papers testify to his extraordinary power of labour.

1. On the Employment of the Microscope in Medical Studies; a Lecture Introductory to a Course of Histology.
2. On the Art of Percussion as applied to the Diagnosis of Thoracic and Abdominal Diseases (*Monthly Journal of Medical Science*, February 1842).
3. On the Parasitic Fungi found growing on Living Animals, with two plates (in the *Transactions of the Royal Society of Edinburgh*). In this important memoir, he confirmed and extended the observations and experiments of Gruby concerning the mycodermatous vegetations found in the crusts of the disease called *Tinea favosa*, or *Porrigo lupinosa* of Bateman; he announced the occasional existence of, and described, a plant found growing on the lining membrane or cheesy matter of tubercular cavities in the lungs of man; and he described and figured a plant found growing in the skin of the gold fish.
4. On the Vegetable Nature of *Tinea Favosa*; its Symptoms, Causes, Pathology, and Treatment; coloured plate (*Monthly Journal of Medical Science*, 1842).
5. Pathological and Histological Researches on Inflammation of the

Nervous Centres (*Edinburgh Medical and Surgical Journal*, October 1842, and October 1843).

6. On Anormal Nutrition, as observed in Softening, Suppuration, Granulation, Reorganisation of Tissue, Morbid Growths, etc. (*Monthly Journal of Medical Science*).—This paper was communicated to the Medico-Chirurgical Society of Edinburgh, November 9th, 1842.

7. Note on the Structural Changes of the Blood in the Hæmorrhagic Diathesis (*Monthly Journal of Medical Science*, 1842).

8. On Cracking of the Thumb caused by Dryness of the Sheath of the Tendons (Medico-Chirurgical Society, December 7th, 1842).

9. Pathological and Histological Researches on Inflammation of the Nervous Centres; two plates.—This important work may be regarded as the first positive addition to our knowledge of nervous diseases which has been made in this country by means of the microscope. He clearly established that the great characteristic of inflammatory softening is the presence of exudation-corpules about the minute vessels, and among the elements of the softened cerebral tissues.

10. Treatise on Inflammation of a Process of Anormal Nutrition; coloured plate. Edinburgh, 8vo, 1854.—In the summer of 1843, Dr. Bennett gave a course of lectures to the Fellows of the Royal College of Physicians and the leading members of the profession in Edinburgh on inflammation. They were illustrated by numerous demonstrations under a series of achromatic microscopes, and were calculated to show the importance of microscopical and chemical researches as a means of advancing pathology and the diagnosis of disease. These lectures were first published in the *Edinburgh Medical and Surgical Journal* for January and July 1844, and afterwards they formed the volume just mentioned.

11. On the Frequent Spontaneous Cure of Pulmonary Consumption, and the indications furnished by Pathology for its Rational Treatment (*Edinburgh Medical and Surgical Journal*, April 1845).

12. Case of Poisoning with Hemlock (*Conium maculatum*) (*Edinburgh Medical and Surgical Journal*, July 1845).—Read before the Medico-Chirurgical Society of Edinburgh on May 7th, 1845.—In this remarkable paper, he clearly proved, from a comparison between the symptoms of the case and those recorded as having followed the drinking of the *Kōkōreos* by Socrates, that the poison used at the State execution of criminals in ancient Athens was the same drug as our present hemlock.

13. Case of Hypertrophy of the Spleen and Liver, in which Death took place from Suppuration of the Blood (*Edinburgh Medical and Surgical Journal*, October 1845).—This celebrated paper contained the first recorded case of the disease now known as leucocythæmia. It formed part of a conjoined paper by the late Dr. Craigie and himself, entitled Two Cases of Disease and Enlargement of the Spleen, in which Death took place from the presence of Purulent Matter in the Blood. The first case was recorded by Dr. Craigie, and the second by Dr. Bennett.

14. A Lecture introductory to a Course on Histology and the Use of the Microscope (*Lancet*, May 10th, 1845).

15. Note on the Inoculability of *Tinea Favosa*—*Porrigo lupinosa* of Bateman (*Northern Journal of Medicine*, vol. iii, p. 202).—After inoculating his own scalp with favus matter, and performing similar experiments on many others, he did not succeed in proving that the disease might be communicated from one individual to another.

16. Pathological and Clinical Researches into the Nature and Treatment of Scrofulous and Tubercular Diseases (*Northern Journal of Medicine*, vol. iv, p. 210, et p. 273, 1846).

17. Case of Ovarian Dropsy in which both Ovaries were excised, terminating fatally on the seventeenth day from Strangulation of the Intestine.—This was a conjoint paper with Dr. Handyside, the present venerable lecturer on anatomy at Surgeons' Hall, Edinburgh. Previously to this case, the operation of ovariectomy had been performed 101 times with such doubtful success that the great surgical authorities of the day hesitated to recommend it. The record of this case was communicated by the authors to the Medico-Chirurgical Society of Edinburgh; and it led to a memorable debate, which probably had the effect of directing the minds of surgeons to the operation, with the view of collecting data for an accurate diagnosis of the disease, and of improving the method of performing the operation.

18. Pathological and Clinical Observations on Encysted Tumours of the Ovary (*Edinburgh Medical and Surgical Journal*, April 1846).—In this paper, Dr. Bennett advocated the use of the microscope in the examination of the fluid obtained by paracentesis, and pointed out certain microscopical differences between the fluid of an ovarian tumour and that obtained from the abdominal cavity in ascites.

19. On the Minute Structure and Chemical Composition of Tubercular Deposits (*Northern Journal of Medicine*, 1846).

20. How should Medicine be advanced? with a few words in reply

to the suggestions of Dr. Forbes (*Monthly Journal of Medical Science*, July 1846).—This paper formed the first of a valuable series of communications to this journal, entitled "Contributions to Pathology and Rational Medicine". Here he offered the following suggestions, as indicating how clearly he recognised what was required to advance medical science. He writes: "In conclusion, we have also a few suggestions to offer, which, if adopted, we think might be useful in furthering the cause we advocate. They are: 1. To encourage the idea among the profession which considers him to be the truly practical man who exercises a sound reason and judgment in the practice of medicine and surgery, based rather upon a knowledge of anatomy and physiology—morbid anatomy and pathology—than upon mere experience. 2. To encourage the habitual use of specula, stethoscopes, pleximeters, sounds, microscopes, and every instrument capable of bringing the products of disease under the immediate cognisance of the senses, and thus rendering diagnosis exact. 3. To encourage the study of pathological anatomy on rational grounds; that is, by examining all the organs in every case, investigating into the minute structure of every morbid product, and by obtaining a chemical analysis of these, and of the blood, whenever this is practicable. 4. To place in all hospitals connected with medical schools an officer well acquainted with morbid anatomy, and the modern means of cultivating it, whose duty it shall be to conduct the *post mortem* examinations, keep a minute record of each, teach morbid anatomy to the students, and publish a yearly report. 5. That in our public institutions, the history of disease should not be recorded by young men, inexperienced in observation, but should in all cases be dictated by the physician or surgeon. 6. To extend and give greater importance to clinical instruction, by introducing the system of bedside tuition, so advantageously practised in continental universities; and by taking care that those who teach are enabled to communicate to their pupils the manual dexterity and knowledge in the use of all those instruments essential to an exact diagnosis. 7, and lastly. To impress upon the legislature the necessity of introducing some system which will insure the appointment to our public hospitals of well educated physicians and surgeons, intimately acquainted with pathology and the principles of rational medicine: otherwise it cannot be reasonably anticipated that the extensive opportunities for observation which these institutions afford will ever be made available in advancing the healing art for the good of the community at large."

20. On the Elementary Forms of Disease (*Monthly Journal of Medical Science*, August 1846).

21. On the Presence of *Confervæ* in some Exudative Masses passed by the Bowels (*Monthly Journal of Medical Science*, September 1846).

22. Biographical Sketch of Dr. John Thomson, late Professor of General Pathology in the University of Edinburgh (*Monthly Journal of Medical Science*, October 1846).

23. On Anormal Nutrition and Diseases of the Blood (*Monthly Journal of Medical Science*, November 1846).

24. On the Causes and Development of Exudation (*Monthly Journal of Medical Science*, January, February, March, June, August, November, and December, 1847, and January and April 1848).

25. On Hypertrophies and Tumours (*Monthly Journal of Medical Science*, March 1847).

26. On the Fallacies of the Statistical Method (Medico-Chirurgical Society, July 7th, 1847). A speech in the debate on a paper by Professor Simpson on Etherisation.

27. On a New Form of Serous Inflammation, in which there was apparently no Affection of the Membrane (Medico-Chirurgical Society, June 13th, 1847).

28. Pathological and Clinical Observations on Cancer (*Monthly Journal of Medical Science*, October 1847).

29. On Encysted Growths (*Monthly Journal of Medical Science*, December 1847).

30. On the Structural Relation of Oil and Albumen in the Animal Economy, and on certain Physical Laws connected with the Origin and Development of Cells.—This paper was read to the Royal Society of Edinburgh, April 19th, 1847; it appeared in the *Proceedings* of that learned body of 1846-47, and condensed in the *Monthly Journal of Medical Science* for September 1847.

31. On a New Structure observed in a Tumour of the Tentorium. (Communicated to the Pathological Society of London; appeared in the Society's Reports, in the *Lancet*, and in the *Medical Times and Gazette* of April 1847.)

32. On Vascular, Cartilaginous, and Osseous Growths (*Monthly Journal of Medical Science*, October 1847).

33. On the Morbid Anatomy and Pathology of the Fever which has been prevalent in Edinburgh during the session 1846-47. (Communicated to the Medico-Chirurgical Society July 7th, 1847; *Monthly Journal of Medical Science*, October 1847.)

34. Report on the Physiological Action of Chloroform.—This report was made by a famous committee, of which Dr. Bennett was the reporter. It consisted of Drs. Alison, Christison, Douglas Maclagan, Taylor, Duncan, Roberts, Allen Thomson, and Gairdner. It was read to the Medico-Chirurgical Society on December 15th, 1847, and detailed numerous experiments made both on man and on the lower animals.

On the 13th July, 1848, Dr. Bennett was unanimously elected to the Chair of Institutes of Medicine. His chief opponent was Dr. Martin Barry, who had already acquired an European reputation by his celebrated researches on the ovary. As Barry could not sign the "tests" then in force, he withdrew from the contest.

Professor Bennett was elected to the Chair not merely on his merits as a physiologist, but because he was versed in pathology and therapeutics. It had always been the aim of former occupants of the chair—as, indeed, of all the medical chairs in the University—to give a practical bearing to their courses of instruction. At that time it was not considered to be the duty of the holder of the chair to teach physiology pure and simple as a branch of scientific inquiry, but to teach it by constant reference to the sciences of pathology and therapeutics. A candidate, therefore, required not merely to be an accomplished physiologist in the ordinary acceptation of the term, but likewise a physician; and not merely a physician, but also a pathologist. This view of his duty Dr. Bennett firmly held during his occupancy of the chair. He taught the Institutes of Medicine; and his class, to the ordinary student who expected to earn his bread by practice in the medical art, was one of the most popular and practically useful in his curriculum. In his later years, he viewed with dismay the tendency to divorce physiology from its practical relations to the wants of the profession.

From this time, Professor Bennett's energies were directed into two channels, and, to form a true estimate of what the man was and did, we must remember both. As professor, he now became one of the clinical teachers of medicine in connection with the University, and he also taught physiology from the professorial chair. Whilst his duties in the first position, and the demands made on his time as a consulting physician, prevented him from engaging in the special physiological researches which he probably would have done if he had had no clinical work, still the loss was more than compensated for by the great excellence he attained as a teacher of clinical medicine. In this department, he was unsurpassed. His system of instruction has served as a model to many who are now performing that duty in our various teaching institutions. The leading idea which prevailed in his mind was to teach the student method. Thus he was a teacher of the highest order. He was not content with merely communicating certain facts to the student, but he showed him how to observe and record facts for himself. Irrksome at first, his system was always appreciated by the better class of students. He taught them so that they soon became as great adepts as the master. Nothing annoyed him more than loosely recording facts. Precision was what he inculcated. All ambiguous phrases were struck out of the record of the case, and also all allusions to what was irrelevant matter. He had no faith in the encyclopædic method of case-taking. If there were no direct relation between an attack of measles at 8 years of age and an attack of pneumonia at 50, the reference to the former was at once repressed. He showed the student how to examine the organs and physiological systems consecutively and in the proper order. It was also his object to encourage the student to think. Often he disputed not only the accuracy of the facts the student gave him, but also the inductions he made from these. Sometimes, it must be confessed, he did so to test the student's mental power. Nothing pleased him more than to meet with a man who could hold his own in argument, and who gave evidence of intelligence and perspicuity. He regarded his course of clinical medicine as the sequence and complement to his lectures on the Institutes. As an examiner, Dr. Bennett was by most held in great dread. A good student had no cause to fear; but men who had no practical acquaintance with the subject were soon found out. He was one of the first to advocate the system of practical examinations. He was not severe upon students as to the number of facts they retained in memory, but as to their intelligent apprehension of the facts. If, by varying the question, so as to expose another side of the subject, the student were confounded, he was apt to think, sometimes too quickly, that the student knew nothing at all about it. As an examiner, too, he had a keen sense of the fact that he was performing a very responsible public duty.

In the class-room, Professor Bennett delivered lectures which were characterised by elegance of style and appropriate emphasis. Few were equal to him in this respect. His lectures were all fully written out, not because he would have had any difficulty in speaking from notes, but because he wished to avoid becoming diffuse. He never failed in interesting the crowd of students before him. His spe

talent of *extempore* speaking appeared to greatest advantage when, laying aside the manuscript, he proceeded to attack the positions of an adversary; and, as he was a man of strongly pronounced opinions of his own, this was by no means an uncommon occurrence. He was remarkably skilful in marshalling his arguments, and in presenting facts and views in support of his own position in the most attractive light possible. His advocacy was often somewhat one-sided, and had more of the character of that of a special pleader than the judicial summing up of a judge; but the practical effect on the mind of the student was either entirely to agree with the professor, or, if sharp enough to detect the fallacy, to adopt the opposite view more strongly than he would otherwise have done. Professor Bennett was the first in this country to recognise the necessity of teaching physiology in a practical way. Such a method of teaching physiology was what one would expect from his objective style of teaching any subject. He continued his course of histology from year to year, and to these were afterwards added courses on physiological chemistry and on physiological methods of research with the aid of those instruments of precision now employed by physiologists. This complete course of instruction was begun under his supervision by Dr. Argyll Robertson, and was further developed and improved by Professor Rutherford, the present occupant of the chair, and by Dr. McKendrick, who were successively his assistants.

In 1855, he became a candidate for the chair of the Practice of Physic in the University of Edinburgh. The other candidates were Dr. Alexander Wood and Dr. Laycock. After an exciting contest, the chair was won by its present distinguished occupant, Professor Laycock.

Whilst engaged in teaching in the University and in the Infirmary, Professor Bennett found time for much literary work. He took advantage of his position in the infirmary to obtain records of the cases which came under his care. These he published, with commentaries, from time to time, and ultimately they were collected to form his well known work *Clinical Lectures on the Principles and Practice of Medicine*, which has passed through five editions in this country, six in the United States, and has been translated into French, Russian, and Hindoo.

Continuing the record of his writings from this time to the end of his life, we find the following.

35. Case of Spontaneous Cure of Ovarian Dropsy by means of an Ulcerative Opening of the Cyst into the Bladder. Read before the Medico-Chirurgical Society, January 3rd, 1849.

36. On the Local Treatment of Chronic Eczema and Impetigo (*Monthly Journal of Medical Science*, August 1849).

37. On Tubercle in the Cerebellum (*Monthly Journal of Medical Science*, December 1849).

38. On the Treatment of Phthisis Pulmonalis (*Monthly Journal of Medical Science*, March 1850 and May 1850).

39. Introductory Lecture to Clinical Medicine (*Monthly Journal of Medical Science*, November 1849).

40. On the Classification and Diagnosis of Cutaneous Diseases (*Monthly Journal of Medical Science*, April 1850).

41. Case of White Blood. Medico-Chirurgical Society, March 20th, 1850.

42. Clinical Lecture on Favus, Pompholyx, Eczema, and Psoriasis (*Monthly Journal of Medical Science*, July 1850).

43. Report of Cases of Cardiac Disease in the Clinical Wards of the Royal Infirmary during the Second Half of the Summer Session, 1850 (*Monthly Journal of Medical Science*, September 1850).

44. Clinical Lecture on Examination of Patients (*Monthly Journal of Medical Science*, October 1850).

45. Clinical Lecture on Auscultation (*Monthly Journal of Medical Science*, November 1850).

46. Note of Microscopical Appearances in Dr. Sidey's Case of Hydrophobia (*Monthly Journal of Medical Science*, December 1850).

47. The Microscope as a Means of Diagnosis (*Monthly Journal of Medical Science*, December 1850).

48. On Leucocythemia, or Blood containing an unusual number of Colourless Corpuscles (*Monthly Journal of Medical Science*, January and April 1851).

49. Report of Cases of Nervous Disease in the Clinical Wards of the Royal Infirmary during the Winter Session of 1850-51 (*Monthly Journal of Medical Science*, March 1851).

50. On Leucocythemia (*Monthly Journal of Medical Science*, August and October 1851).

51. Colchicum in the Delirium and Coma of Scarlet Fever (*Monthly Journal of Medical Science*, August 1851).

52. Occasional Difficulties in the Diagnosis of Pneumonia (*Monthly Journal of Medical Science*, August 1851).

53. On the Treatment of Phthisis Pulmonalis, in which he advocated the use of the Crystal Palace as a great Sanatorium for the use of

Phthisical Invalids during the Winter Months (*Monthly Journal of Medical Science*, August 1851).

54. On Carbonaceous Lungs (*Monthly Journal of Medical Science*, September 1851).

55. Treatment of Laryngitis by Topical Applications (*Monthly Journal of Medical Science*, November 1851).

56. Report of the Cases of Pulmonary Disease treated in the Clinical Wards of the Royal Infirmary during the latter half of Summer, 1851 (*Monthly Journal of Medical Science*, January 1852).

57. On the Function of the Spleen and other Lymphatic Glands as Secretors of Blood (*Monthly Journal of Medical Science*, January 1852).

58. On Leucocythemia, or White Cell-Blood (*Monthly Journal of Medical Science*, April 1852).

59. Cases of Pulmonary Disease (*Monthly Journal of Medical Science*, January 1852).

60. Special Treatment of Phthisis Pulmonalis (*Monthly Journal of Medical Science*, February 1852).

61. Report of Cases treated in the Clinical Wards of the Royal Infirmary during the Winter Session, 1851-52 (*Monthly Journal of Medical Science*, March, April, and June, 1852).

62. On Aneurism of the Superior Mesenteric Artery and Aorta, Diagnosis of Aneurisms, Poisoning by Aconite, and the Treatment of Aneurisms by Valsalva's Method (*Monthly Journal of Medical Science*, July 1852).

63. Diseases of the Liver (*Monthly Journal of Medical Science*, August 1852).

64. On the Eruptive Fevers (*Monthly Journal of Medical Science*, October 1852).

65. Illustrations of Laryngeal and Pharyngeal Diseases which are frequently mistaken for, or associated with, Phthisis (*Monthly Journal of Medical Science*, December 1852).

66. On Functional and Organic Diseases of the Stomach (*Monthly Journal of Medical Science*, February and April 1853).

67. On the Pathology and Treatment of Pulmonary Tuberculosis, being reply to a letter from Dr. Markham (*Monthly Journal of Medical Science*, December 1853).

68. Notes on Hospital Practice (*Monthly Journal of Medical Science*, December 1854).

69. Letter from Professor Bennett to Editor of *Monthly Journal of Medical Science*, in reply to one from Professor Kolliker regarding Discovery of Leucocythemia. October 1855.

70. Speech on the Contagious Nature of Cholera (*Monthly Journal of Medical Science*, January 1854).

71. Structure of the Torbanehill Mineral as compared with that of Coal (*Transactions of the Royal Society of Edinburgh*, 1854).

72. On the Ectrotic Treatment of Small-Pox by Zinc Plaster; on the Treatment of Favus by Sulphurous Acid Lotion; on Transient Grinding Pain shown to be coincident with Passage of Biliary Calculi; on the Diagnostic Value of the Absence of Chlorides from the Urine; on a Case of Ovarian Dropsy (*Monthly Journal of Medical Science*, April 1854).

73. On the Treatment of the more Common Forms of Skin-Disease met with in Edinburgh (*Monthly Journal of Medical Science*, January 1855).

74. Clinical Notes (*Monthly Journal of Medical Science*, February 1855).

75. Practical Remarks on the Physical Diagnosis of Phthisis (*Monthly Journal of Medical Science*, January 1856).

76. A Clinical Investigation into the Diagnostic Value of the Cracked-Pot Sound (*Edinburgh Medical Journal*, March 1856).

77. Observations on the Results of an advanced Diagnosis and pathology applied to the Management of Internal Inflammations, compared with the effects of a former Antiphlogistic Treatment, and especially of Blood-letting. This paper was read before the Medico-Chirurgical Society on January 21st, 1857, and excited a great discussion, in which all the leading physicians and surgeons took part. Controversial papers appeared on the subject from the pens of Professor Alison, Professor Gairdner (now of Glasgow), and Sir Thomas Watson. To all of these, Dr. Bennett replied.

78. On Injections of the Bronchi in Pulmonary Diseases (*Edinburgh Medical Journal*, November 1857).

79. On the Classification, Pathology, and General Treatment of Morbid Growths (*Edinburgh Medical Journal*, December 1857).

80. Description of M. Groux, the subject of Congenital Fissure of the Sternum (*Edinburgh Medical Journal*, February 1858).

81. On the Molecular Theory of Organisation (*Transactions of the Royal Society of Edinburgh*, 1860; also in *Lancet*, May 5th, 1861).

82. On the Treatment of Pneumonia, with the Results of 105 Care-

fully Recorded Cases (*Lancet*, August 16th, 1862).—Paper read at the meeting of the British Medical Association, August 1862.

83. Twelve Lectures in the *Lancet* of 1863 on Molecular Physiology, Pathology, and Therapeutics, and their Application to the Treatment of Disease.

84. Therapeutical Inquiry on Acute Pneumonia (*BRITISH MEDICAL JOURNAL*, October 25th, 1862).

85. Facts and Arguments opposed to Dr. Bennett's Theory of Molecular Organisation, by Dr. Beale of London, with Dr. Bennett's rejoinder (*BRITISH MEDICAL JOURNAL*, February 7th and March 28th, 1863).

86. Letter on Medical Education (*BRITISH MEDICAL JOURNAL*, June 11th, 1864).

87. Physiological Aspect of the Sewage Question (*British Association Reports*, Bath meeting, September 1864).

88. On Cell-Pathology (*British Association Reports*, Birmingham meeting, September 1865).

89. Treatment of Pneumonia by Restoratives (*Lancet*, February 25th, 1865).

90. Further Observations on the Same (*Lancet*, December 23rd, 1865).

91. Observations on the Restorative Treatment of Pneumonia, being a reply to a *critique* in *BRITISH MEDICAL JOURNAL*, 15th November, 1865—16th June, 1866.

92. Treatment of Cancer by injections of Nitric Acid (*BRITISH MEDICAL JOURNAL*, November 24th, 1866).

93. Address in Medicine to the Thirty-fourth Annual Meeting of British Medical Association, at Chester, in August 1866, on the Present State of the Science and Art of Medicine.

94. On the Effects of Mercury on the Secretion of Bile, read at the meeting of the British Medical Association at Dublin, August 6th, 1867; and at the meeting of the British Association at Dundee, in the same year.

95. Letter on Education in Practical Physiology (*BRITISH MEDICAL JOURNAL*, September 21st, 1867).

96. Correspondence regarding the Teaching of Clinical Surgery in Edinburgh (*BRITISH MEDICAL JOURNAL*, May 9th, May 23rd, June 6th, 1868, and January 30th, 1869).

97. Report on the Action of Mercury on the Liver, published in the *BRITISH MEDICAL JOURNAL*; in pamphlet form in *Medicine in Modern Times*, edited by Dr. Acland of Oxford, in 1869; in the Report of the British Association, and lastly as a separate volume, published in Chicago in 1873.

98. On the Atmospheric Germ-Theory, a Lecture delivered before the Royal College of Surgeons of Edinburgh, on January 17th, 1868.

99. On the Pathology and Treatment of Uræmia, and the Use of Blood Letting (*Edinburgh Medical Journal*, June 1868).

100. Address in Physiology to the British Medical Association, at the Leeds Meeting, July 1869.

101. Interim Report on the Antagonism of Medicines, made at the Newcastle Meeting of the British Medical Association, 1870.

102. Report of further Experiments, demonstrating that Mercury has no Special Action on the Liver (*BRITISH MEDICAL JOURNAL*, January, 7th, 1871).

103. On the Therapeutical Effects of Chloral, Medico-Chirurgical Society, Edinburgh, April 6th, 1870.

104. Graduation Address, August 1871.

105. Researches into the Antagonism of Medicines: Report given at Norwich Meeting of the British Medical Association in 1874 (*BRITISH MEDICAL JOURNAL*), and afterwards separately published.

He also published another Graduation Address, and a paper on Physiology as a branch of general education; but the dates of these we have not been able to obtain.

His larger works are as follows:

1. *Clinical Lectures on the Principles and Practice of Medicine.*

2. *Pulmonary Consumption.*

3. *On Cancerous and Canceroid Growths.*

4. *An Introduction to Clinical Medicine.*

5. *Outlines of Physiology*, being a reprint of the article Physiology, in the last volume of the *Encyclopædia Britannica.*

6. *Text-Book of Physiology—General, Special, and Practical.* First editions of this work, published simultaneously in this country and in America, are nearly exhausted, and a French translation is in the press.

The above is as complete a record of his writings as we have been able to make. In all probability, important papers in other volumes may have escaped notice, but enough has been given to indicate a life of rare industry. Few men are capable of doing one-half of the amount of work.

Dr. Bennett received numerous honours both at home and abroad.

He was President for two years of the Medico-Chirurgical Society of Edinburgh, honorary member and *emeritus* President of the Royal Medical Society of Edinburgh; fellow or member of various scientific societies in London, Dublin, St. Andrew's, New York, Philadelphia, Boston, Paris, Brussels, Vienna, Berlin, St. Petersburg, Jena, Stockholm, Athens, Buda-Pesth, Copenhagen, Amsterdam, etc. He was also a Member of the Academy of Medicine of France, and about twelve months ago he received a special recognition from the French Government, entitling him to practise medicine in France.

No later than August, at the graduation ceremony of the Edinburgh University, he was honoured by receiving the degree of LL.D.; and on the same day a marble bust by Mr. William Brodie, subscribed for by his numerous pupils throughout the country, was presented in eloquent language to the University by Dr. Andrew Clark of London, to be placed in the library hall.

In middle life, Dr. Bennett was a strong, able-bodied man, capable of undergoing a great amount of physical and mental exertion. About ten years ago, however, his health began to give way, and he suffered from an affection of the throat. This trouble obliged him during one session to spend the winter in the south of France, and during his absence his duties were performed by Dr. Argyll Robertson. This period of repose appeared to have to a certain extent restored his vigour, but in 1869 he again fell into delicate health. At the Christmas recess of the session 1871-2 he was again obliged to obtain leave of absence for the remainder of the winter and spring. He proceeded to Mentone, in France, and in the summer time he returned to Edinburgh, and delivered a few clinical lectures. The winters of 1872-3 and 1873-4 he again spent on the Continent, and during his absence these three years the duties of the chair were discharged by his assistant, Dr. M'Kendrick. Repose, however, brought him no permanent gain of strength, and he resigned the Chair of the Institutes of Medicine in July last year. Last winter he spent in Nice; and although there seemed to be no distinct improvement in his health, he was able to engage in a considerable amount of consulting practice as a physician. He was present in Edinburgh at the late meeting of the British Medical Association, when his pale and emaciated appearance filled his friends with great alarm. It was interesting to observe at that gathering of medical men how desirous his numerous pupils, now scattered over the country, were to exchange a few words with, and grasp the hand of, their old master. We believe no honour of his previous life was more highly appreciated by him than that of his *alma mater* conferring upon him its highest scientific distinction, and he was also proud that his bust obtained a place among the many worthies whose statues now adorn the library hall of the University. Professor Bennett leaves a widow and a family of five. His only son, Dr. Alexander Hughes Bennett, is now practising as a physician in London.

To sum up the results of Dr. Bennett's arduous life, we may enumerate the following as being his chief contributions to the science and practice of his profession.

1. He was the principal agent in advocating the use of cod-liver oil in this country in the treatment of tubercular diseases.

2. He was the first systematically and practically to teach histology and the use of the microscope.

3. He was the first to introduce the systematic teaching of clinical medicine, with the aid of all the modern appliances now in use.

4. He was the first to show the great importance of the microscopic examination of diseased organs, and more especially of the great nervous centres.

5. He pointed out the errors in the prevalent method of treating acute inflammations of internal organs, and more especially of the lungs; and was highly instrumental in leading to the almost entire abolition of bleeding in these affections.

6. He condemned the indiscriminate drugging of patients much in vogue, and especially the too free use of mercury in syphilis and in diseases of the liver.

7. He was the first to record a case of leucocythæmia, and, while he did not at the time discern its true character, he contributed largely to its diagnosis and pathology, and also to the application of the discovery to an explanation of the functions of the lymphatic and blood glands.

8. He was one of the first to advocate combined labour in the prosecution of scientific inquiries, and to the principle of grants of money being given by public bodies for that purpose.

9. He contributed to physiology his well-known molecular theory of organisation which, if not adopted generally, has at all events led to a reconsideration of the question by the upholders of the cell-theory, and to considerable modifications in their views.

Professor Bennett was a man of a remarkably clear and vigorous intellect. His mind was severely logical. What he wanted in breadth

of view he gained in penetrative power. Few could grasp more quickly the essentials of a subject, or perceive the real point at issue. His quick mind soon detected fallacies in argument. The prevailing quality of his mind was *method*. He was methodical in all he did. It was this quality which made him so great a teacher: he not only taught facts, but methods; and thus he has done more for the University of Edinburgh as a teacher, than perhaps any other man in the century. His power of method was observable in all the relations of life. An accurate business man, there was nothing he sooner lost patience with than a slovenly manner of dealing with matters of business. He was a hater of pretensions and shams of all kinds, and was most unsparing in his ridicule of all such.

His power of sarcasm and his tendency to indulge freely in severe critical remarks upon the works of others, did not make him a general favourite with many of his professional brethren. He cannot be said to have ever attained the high position as a consulting physician which was his due. He was too much of a reformer, too pronounced and outspoken in his opinions; he had too little of the *suaviter in modo* to be a successful consultant. The same characteristics were displayed by him in his intercourse with his colleagues as a member of the Senatus Academicus of the University. Nevertheless, so great was their respect for and confidence in him, that, at a critical period in the progress of the Universities (Scotland) Bill in 1858, he was entrusted with the interests of the Senatus as their envoy to Parliament. In this position, he rendered most essential service by his ability and indomitable energy.

By those who knew him best, Dr. Bennett was much beloved. He shone in the social circle, or in his beautiful retreat on the shores of Loch Lomond. Some men command affection almost at first sight. Bennett was not one of these. Those who knew him longest had the greatest affection for him: they knew that beneath an austere and critical manner he had a kindly heart, and they were willing to overlook and forget his severe words, often too thoughtlessly spoken, and what might be regarded as his narrowness and intolerance, for the sake of his friendship. When his words injured the feelings of any one, he was ready, if this were pointed out to him, to express his regret, and usually in these circumstances he was apparently much surprised that his remarks had hurt the feelings of his friend. The severest criticism of his own doings never caused any feelings of resentment. After a hearty laugh at the attack, he immediately arranged his artillery for answering his opponent effectively. He was remarkable for fearlessness in expressing his opinions—indeed one of his chief characteristics was great personal courage. This was exemplified even to the end of his life.

When we saw him last, we were struck by his quiet subdued manner. Suffering, and time for quiet and sober reflection, evidently had produced a mellowing effect on his mind. The asperities of his character had disappeared, and he was calm and gentle. Probably things of time and sense were appearing before him in their true light, and he was preparing for the end.

Altogether he was a man of rare talent, high spirit, and fine taste. When all the controversies with which his name is associated will have been forgotten, the important services which he rendered to practical medicine will be even more highly appreciated than they are at present; meantime, the lesson of his life to us all is: "*Whatsoever thy hand findeth to do, do it with all thy might.*"

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, September 30th, 1875.

Harvey, Thomas Prickard, Pryland Road, Newington Green Road, N.

Kellard, James Thomas William Stentford, Trafalgar Place, Stoke, Devonport

The following gentlemen also on the same day passed their primary professional examination.

Anderson, Alexander, St. Bartholomew's Hospital

Betty, Samuel George, University College

Brown, Francis Wheeler, London Hospital

Harvey, Henry Frederick, University College

Hopkins, John University College

McGachen, Frederick William Dobson, London Hospital

MEDICAL VACANCIES.

The following vacancies are announced:—

BELLINGHAM UNION—Medical Officer for the Second District.

BIRKENHEAD BOROUGH HOSPITAL—Junior House-Surgeon. Salary, £60 per annum, with board and lodging. Applications on or before the 11th inst.

BROOKWOOD ASYLUM, near Woking—Second Assistant Medical Officer.

CHARING CROSS HOSPITAL—Dispenser. Salary, £100 per annum, and luncheon. Applications on or before the 20th instant.

COUNTY TIPPERARY INFIRMARY Surgeon. Salary, £100 per annum.

Applications on or before the 16th instant.

DENBIGHSHIRE INFIRMARY—House-Surgeon. Salary, £85 per annum,

with board, lodging, and washing. Applications on or before the 16th instant.

DONCASTER INFIRMARY—House-Surgeon. Salary, £100 per annum, with

board and lodging. Applications to be made on or before the 18th instant.

DORSET COUNTY HOSPITAL—House-Surgeon. Salary, £70 per annum, with

£10 additional as Secretary. Applications on or before the 20th instant.

EAST RETFORD UNION—Medical Officer and Public Vaccinator for the

Leverton District. Salary, £50 per annum, and fees.

GLOUCESTER COUNTY ASYLUM—Junior Assistant Medical Officer. Salary,

£80 per annum, with board, lodging, and washing. Applications on or before

the 18th instant.

HASLINGDEN UNION—Medical Officer for the Accrington District. Salary,

£90 per annum.

HOSPITAL FOR SICK CHILDREN, Manchester—Assistant Physician.

Applications on or before the 27th instant.

INVERNESS DISTRICT ASYLUM—Assistant Medical Officer. Salary, £70

per annum, with bed, board, and washing. Applications on or before the

11th instant.

LONDON HOSPITAL—Assistant Obstetric Physician.

NEWCASTLE-UPON-TYNE UNION—Medical Officer for the First District.

Salary, £50 per annum.

NORTH WALES COUNTIES LUNATIC ASYLUM, Denbigh—Assistant

Medical Officer. Salary, £100 per annum, with board, lodging, and washing.

A knowledge of Welsh indispensable. Applications to be made on or before

the 14th instant.

NORWICH DISPENSARY—House-Surgeon. Salary, £120 per annum, with

unfurnished residence and apartments.

PEMBROKE UNION—Medical Officer for the First District.

RICHMOND INFIRMARY—House-Surgeon. Salary, £80 per annum, with

board and lodging. Applications on or before the 25th instant.

ROYAL ISLE OF WIGHT INFIRMARY, Ryde—House-Surgeon and Secretary.

Salary, £40 per annum, with board, lodging, and washing. Applications

on or before the 25th instant.

SETTLE UNION—Medical Officer and Public Vaccinator for the Bentham Dis-

trict. Salary, £40 per annum, and fees. Applications on or before the 19th inst.

STROUD GENERAL HOSPITAL—House Surgeon.

SURREY DISPENSARY—Dispenser. Salary, £80 per annum, with furnished

apartments and coals. Applications on the 12th instant.

SUSSEX COUNTY HOSPITAL—Physician and Assistant-Physician. Applica-

tions on or before the 13th instant.

TIVERTON INFIRMARY AND DISPENSARY—House-Surgeon and Dispenser.

Salary, £100 per annum, with furnished apartments, coals, gas, and attendance.

TORRINGTON UNION—Medical Officer for the Peters Marland District.

Salary, £43 3 per annum.

UNIVERSITY COLLEGE HOSPITAL, London—Surgical Registrar. Applica-

tions on or before the 19th instant.

WESTMINSTER HOSPITAL—House-Physician. Applications on or before

the 26th instant.

WEST SUSSEX, EAST HANTS, AND CHICHESTER GENERAL IN-

FIRMARY AND DISPENSARY—House-Surgeon. Salary, £80 per an-

num, and £20 per annum as Secretary, with board, lodging, and washing.

Applications to be made on or before the 23rd inst.—Assistant House-Surgeon

to dispense. Salary, £20 per annum, with board, lodging, and washing. Ap-

plications to be made immediately.

WORCESTER GENERAL INFIRMARY—Physician. Applications on or

before the 23rd instant.

WORKSOP DISPENSARY—Resident Surgeon. Salary, £120 per annum, with

furnished apartments, coal, gas, and attendance.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

*JOSEPH, J. Raphael, Esq., late Surgeon Belgian Royal Mail Company, appointed a Surgeon Superintendent in the Queensland Government Service.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTHS.

HARRIS.—At the Borough Asylum, Norwich, recently, the wife of William Harris, L.R.C.P.Ed., Medical Superintendent, of a daughter.

MILLER.—At 15, Shandwick Place, Edinburgh, on October 1st, the wife of *A. G. Miller, M.D., of a son.

DEATHS.

HARRIS, Michael, M.B.Lond., Assistant Physician to the Children's Hospital, Pendlebury, near Manchester, younger son of Michael Harris, of 1, Pembury Road, Lower Clapton, at Manchester, on September 28th.

*MURRAY, Charles, M.R.C.S., in the 41st year of his age, at Waterloo Bank, Oldham, on September 29th.

PIGMENTARY DEPOSITS IN THE BRAIN AS THE RESULT OF MALARIAL POISONING.—Dr. Hammond of New York has presented a paper (Neurological Society) upon the above subject, in which he gave the results of clinical observation and experiments upon animals. He regarded the pigment in these cases as being of splenic origin. He was of the opinion that, especially in malarious districts, many nervous disorders were induced by the deposit of this pigment in the brain.

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAYGuy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAY..St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAY....St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 3 P.M.

FRIDAY.....Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.

SATURDAY....St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M. and 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

TUESDAY—Royal Medical and Chirurgical Society, 8.30 P.M. Dr. Dickinson, "On the Pathology of Chorea"; Dr. Greenhalgh, "On the Use of the Actual Cautey in the Enucleation of Fibroid Tumours of the Uterus".

WEDNESDAY—Hunterian Society. Council Meeting at 7.30 P.M.; General Meeting at 8 P.M., when Dr. Daldy will read a paper on the "Causes of Functional Cardiac Murmurs."

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

ERRATUM.—In the List of Prizes in the Medical Schools (JOURNAL, September 25th, page 408), the name "A. B. Prowse Giles", in the second line of the St. Mary's Hospital list, should be "A. B. Prowse".

THE DEVONSHIRE HOSPITAL AND BUXTON BATH CHARITY.

At the meeting of the Committee of Management, on October 2nd, 1875, Dr. Robertson, the Chairman, stated that for the quarter ending September 30th, 631 in-patients were admitted during the three months; and 536 were discharged as having been beneficially treated; 64 as no better; 19 were discharged at their own request; 2 were discharged for breach of rules; one left without report; 3 died in the hospital; and 153 remained on the books at the end of the quarter. The hospital contains 150 beds for patients; and the pressure on its capabilities becomes greater and greater. Notwithstanding the increased number of beds, from 100 to 150, during these recent years, the number of patients waiting for admission, during some weeks of the present year, has been greater than ever, reaching the very large number of 350, and necessitating a delay in the reception of applicants of six or seven weeks. During the three months, 132 out-patients have been received; and of these, 101 have been discharged as beneficially treated, 13 as no better, and 18 are described as having left without report.

In pursuance of the endeavour to obtain from the patients the results of the treatment six weeks after their discharge from the hospital, replies have now been received from 65 patients, and they convey the important information that 49 are stated to be quite well, 449 to be improved, 153 to be no better, and 5 to have died. The severity of the cases, their chronic character, their duration, and the limitation of the time spent in the hospital, ranging from three to six weeks, are considered to render this statement highly satisfactory.

MEMBER B. M. A.—You will find on page 352 of the JOURNAL for September 11th, a short account of the institutions which make the teaching of State Medicine a feature; and at page 407 of the JOURNAL for September 25th, the regulations of the Universities which grant degrees or certificates.

EARLY MENSTRUATION.

SIR,—I have observed frequent letters from some of your correspondents, calling attention to the so-called "early menstruation" of young infants. Any old experienced nurse will be able to tell them that the coloured discharge from young girls is of almost daily occurrence. I have had my attention called to it repeatedly.—Your obedient servant,
W. D. S.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

MAUNSELL MEMORIAL FUND.

Amount already acknowledged, £79 3s. 6d.

The following subscriptions, in addition to those already acknowledged, have been received.

Subscriptions will be received at the office of this JOURNAL, or by Dr. Joseph Rogers, Dean Street, Soho, London.

It is the intention of the Council of the English Poor-law Medical Officers' Association to have a special meeting in London, in order to promote the Memorial Fund.

AN APPEAL.

SIR,—Will you kindly allow me a corner in your JOURNAL to make an appeal to the charitable among your readers on behalf of the widow and family of a medical brother? The gentleman referred to, after practising some time in South America, settled in the neighbourhood of Edinburgh, where he resided to the time of his death. This event took place somewhat suddenly several months ago, and he has left a widow and family of six children (the eldest but nine years of age) in very straitened circumstances. The widow is a native of Chili, and has no relatives of her own in this country. As there is no prospect of her being able to support herself and her family here, she is naturally very anxious to return to her own country and friends.

It is with the object of assisting her to do this, that the present appeal is made. It is not considered prudent to mention names; but reference is kindly permitted to Drs. Warburton Begbie and Joseph Bell of this city, or to the Rev. J. Langwill, The Manse, Currie, near Edinburgh; the latter of whom, or the undersigned, will be most happy to receive contributions in aid of this charitable object.

I am, etc., J. JAMESON, L.R.C.S.E.

52, Rankellor Street, Edinburgh, October 5th, 1875.

Q. IN THE CORNER.—Every member will have an opportunity of expressing his opinion by filling up a form, which, by resolution of the last annual meeting, the General Secretary will issue under the direction of the Committee of Council.

MEDICAL PRACTICE IN AMERICA.

SIR,—The reply made a few weeks since to H. G. D. by a gentleman signing himself as an American M.D., was correct, except as relates to his first reply. The law in eighteen of the States of the Union is as strict as that in England as relates to medical men. No one is allowed to practise unless he be a regular graduate from some regular school of medicine, no matter whether allopathic or otherwise. The Board of Health of New York City prosecute all irregular practitioners; and in many States, if any one practise without a genuine diploma, he is liable to a fine of 1,000 dols. (£200) and imprisonment. The law is almost similar to that of Great Britain; and it has been my lot, during sixteen years' practice in dispensaries, etc., and privately, to meet with many characters. As one of the medical inspectors of health of the city of New York for several years, I am well acquainted with the laws,

I enclose my name, and would be pleased to communicate further in relation to American practitioners with H. G. D.—Yours, etc.,

AN M.D. OF THE NEW YORK COLLEGE OF PHYSICIANS AND SURGEONS (Medical Department, Columbia College.)

NOTICE TO ADVERTISERS.—Advertisements for insertion in the *BRITISH MEDICAL JOURNAL*, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, no later than *Thursday*, twelve o'clock.

DEGREES BY EXAMINATION WITHOUT RESIDENCE.

SIR,—In reference to the letters of Dr. Hitchman and M.D. Edin. in your recent issues, may I be allowed to point out that neither in the application to the Medical Council, nor in the resolution of that body thereupon, was any idea suggested of the registration of foreign medical degrees other than those obtained after strict examination? The *Medical Directory* at the present time rightly discriminates between degrees obtained after examination at foreign universities and those not so obtained, refusing to insert the latter; and that the Medical Council should exercise like discrimination with official authority is all that registered practitioners possessing foreign degrees can expect. The recognition of purely honorary degrees, wherever obtained, is clearly beside the question.

In conclusion, I would add, *à propos* of the letter of M.D. Edin. (ii) that university residence, rather than rigour of examination, is really the essential difference between the requirements for his own degree and for the degrees of the best foreign universities. Practitioners who have as students passed through what is virtually an academical course of study (though, it may be, not at a chartered university school), finding no M.D. examination of good character open to them in this country, are induced to obtain abroad academical testimony to their higher attainments; and experience having taught them the superior examinal value of their foreign degrees as compared with their British qualifications, they not unreasonably seek to be allowed to register the former as well as the latter.—Yours obediently,

A REGISTERED PRACTITIONER AND FOREIGN GRADUATE BY EXAMINATION.

SIR,—In the second letter of M.D. Edin., recently published in your *JOURNAL*, it is stated that Dr. Hitchman's letter was an argument against the registration of foreign degrees. I cannot agree with M.D. Edin., for all foreign degrees are not obtained in the same manner as that of Erlangen used to be some thirty years since. M.D. Edin. seems to think very highly of his own university degree, and rightly, too; but it would be folly in him to imagine that no foreign university grants degrees after examinations equally stiff with his own. Our insular position, I suppose, has, by restricting intercourse, contributed to generate a contempt for foreign degrees and diplomas, and an unreasonable notion of the importance of our own universities, which is often ludicrous, and always to be regretted. Does M.D. Edin. consider such degrees as those obtained at the universities of France, Berlin, Vienna, Brussels, Heidelberg, etc., inferior to his own? Perhaps he does; but, then, different people have different opinions. I quite agree with him in his remark, that M.D. degrees obtained with inadequate tests should have no place in our *Register*; but I cannot see why those degrees which are obtained after examinations, which in many cases are very much more difficult than those of some of our own university boards, should be ignored and refused registration. I have passed the ordinary examination for the degree which I possess, and I think it certainly hard that I may not register it, when I think that by paying £25 I may obtain F.R.C.S. Edin., and *L.D.S. M.R.C.P. Edin.*, both of which are registerable diplomas. M.D. Edin. had better refer to the *Medical Directory* for such names as Frederick and Hermann Weber, London; George Bodington, Dudley; S. Sutro, London; John Stanton, London; Samuel Smith, London; Henry Port, London; James Bennet, London; Thomas Laycock, Edinburgh; and then express his opinion about the value of foreign degrees. The *Medical Directory* admits all foreign degrees which are obtained after examination, but refuses those which have been bought; and I think the *Register* ought to follow its example, and at the same time refuse all honorary British degrees and diplomas.—I am, sir, yours, etc.,

M.D. GIessen.

LIFE INSURANCE CERTIFICATES.

SIR,—We all now and then receive, from some life insurance office, an application for a precise and detailed certificate as to the date and nature of the illness of which some patient has lately died—a certificate evidently required only for the safe management of the business of the insurance office—and yet not one of such applications that has reached me has been found to contain any fee. I scarcely know what fee to charge. The trouble of filling up these certificates is somewhat. In one now lying before me my signature is required in two places, and one is to be witnessed; still, the time and trouble required are much less than would be necessary in examining a candidate for life insurance; therefore, a less fee would suffice, and I should be glad to know what is usual. On one former occasion I wrote to the office, and was told I must apply to the friends of the deceased. This I object to utterly. Whatever fee is fixed on, ought to be sent by the office with the form desired to be filled in, and this we should all insist upon. I have known registrars question the right of a medical man to give a certificate of death to a savings' bank or provident institution; but I apprehend we have a perfect right to do so, provided we make a proper charge for the same, and provided it is not a copy of the certificate we furnish gratis to the registrar.—I am, sir, your obedient servant,

A COUNTRY SURGEON.

Brighton, October 2nd, 1875.

MEDICAL DIGNITY.

AT a recent meeting of the St. Pancras Board of Guardians, Mr. Fildey, the clerk, said that a certain medical officer for one of the wards in the south part of the parish called upon him, and handed to him a paper, in which was the following, in his own handwriting, and which had reference to the deputy medical officer of that ward.

"Subscription, medicine, and advice.—One shilling during illness only. Home visiting, if necessary. Three shillings weekly during illness only. Hours of attendance, daily (Sundays excepted): morning, from eleven to one; evening, from seven to nine o'clock. Medical officer, Mr. —, M.R.C.S. England, formerly House-Surgeon, — Hospital. All cash in hand, or advance. Patients to bring their own bottles. Dr. —, Surgeon, etc., etc. Dispensary will be closed on Tuesdays and Fridays, until further notice."

"This disreputable advertisement caught my eye the other day on the window of a dilapidated house in — Street; and as you take an interest, I hear, in the respectability of the party, inclose copy for your edification, which read to your Board, and then forward a copy to the guardians' solicitor.—*Ecce homo.*"

Mr. Joseph Salter thought this a very serious matter. The guardians owed a duty to the ratepayers; and if the Local Government Board would not consider their own responsibility in regard to this medical officer, the Board ought to consider theirs, and advertise at once for another.—The Board decided that the document brought forward by the clerk should be sent to the Local Government Board.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

TREATMENT OF WHOOPING-COUGH BY CARBOLIC ACID.

SIR,—Having seen the use of carbolic acid vapour highly spoken of in late numbers of your *JOURNAL*, as a treatment of affections of the respiratory organs, I think the following case, which came under my care last spring, may prove interesting.

On the 21st of February last, I was called to see a Mr. Marsh, and found him suffering from empyema, which, from the history, I found had followed a pleurisy of some weeks' duration. The disease was situated on the left side of the chest, and there was considerable bulging of the integuments at the fourth and fifth intercostal spaces. Ulceration had taken place into the lung, and an immense quantity of very fetid expectoration was flowing from his mouth, without much cough, and with very short intervals of rest. The patient was so greatly distressed, and apparently in such imminent danger, that I thought it expedient to make an incision through the walls of the chest, and so afford relief by giving another means of exit to the discharge. I was unwilling, however, to do this, on account of the proximity of the bulging portion of the heart and great vessels. I therefore ordered the patient to inhale the vapour of carbolic acid, by adding thirty drops of the acid to half a pint of boiling water. I ordered this process to be repeated every two hours. Not having very great faith in this treatment, I called early on the following morning, fully prepared and quite determined to make an external opening in the chest. I found, however, that this course was not necessary, for the expectoration, which had amounted to some pints of a very foul liquid during the previous day, had been reduced to a very few ounces during the night, the smell was gone, and the appearance was that of healthy pus. My patient was lying tranquilly in bed, with quite a happy expression, instead of labouring fearfully in an upright position, with a countenance depicting the utmost misery.

I will not take up more of your valuable space by making comments on this case; I will simply give two good reasons for my belief that the cure was due to the carbolic acid vapour treatment. They are these; in the first place, the disease had previously resisted other treatment, and the symptoms had gradually increased in severity until this was tried, when, according to the patient's own account, relief was almost immediate. The other is, that on the second day after I first commenced the use of the vapour, I ordered him to leave it off entirely instead of using it every four hours, as he was then doing. On my seeing him about twelve hours afterwards, I found him again sitting up, in considerable distress, and large quantities of fetid liquid coming away at intervals, though not to anything like the extent that it had done at first. My patient continued the treatment more or less for four or five weeks, and made a good recovery.

Hoping that this case may prove useful to others in the treatment of similar cases, I remain, dear sir, faithfully yours,

S. ALFORD, M.R.C.S., L.S.A.,

Member of the British Medical Association.

Stanhope House, Southsea, September 30th, 1875.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The *Bristol Daily Post*; The *Evening News*; The *Sheffield Post*; The *Metropolitan*; The *Blyth Weekly News*; The *Edinburgh Daily Review*; The *Glasgow Herald*; The *Western Daily Press*; The *Merthyr Telegraph*; The *Leighton Buzzard Observer*; The *Bristol Daily Times and Mirror*; The *Derby and Chesterfield Reporter*; The *Lincolnshire Herald*; The *Sunderland Daily Echo*; The *Co-operative and Financial Review*; The *South Wales Daily News*; The *Macclesfield Courier*; The *Melbourne Argus*; The *Southampton Times and Hampshire Express*; The *Jarrow Express*; The *Birmingham Daily Post*; The *League Journal*; The *Sheffield and Rotherham Independent*; The *Derbyshire High Peak News*; The *Liverpool Daily Courier*; The *National Food and Fuel Reformer*; The *Worcester Herald*; The *Norfolk News*; The *Worcester Chronicle*; The *North British Daily Mail*; The *South Science Review*; etc.

AN ADDRESS

ON

THE USE OF EMPIRICISM IN THE ART OF MEDICINE.

*Delivered before the Birmingham and Midland Counties Branch of the British Medical Association.*By WILLOUGHBY FRANCIS WADE, M.B., F.R.C.P.,
Physician to the General Hospital, Birmingham; President of the Branch.

An old poet commences his laudatory description of a medical man by saying,

"He was a very parfyt practisour".

We may see from these words that the author was well aware that an absolutely perfect practitioner is an impossibility—absolute perfection can not be qualified.

It is the ambition of most of us to merit such a compliment as Chaucer paid to his friend; and it is well to ask ourselves sometimes, Are our methods those best calculated to make us successful practitioners? A mere monetary success, whilst it may satisfy our trade, ought not to satisfy our professional instincts. The two things are not identical. The one depends largely upon qualities which would bring their possessor emolument if exercised in any business; the other requires qualities of mind and tones of thought which may or may not impress the outside world so favourably as they ought.

Our object, then, on the present occasion is to consider some general principles and modes of thought which may conduce to the more successful application of our scientific knowledge to the cure or relief of disease. As practitioners, we require not merely abstract science, but the capacity to utilise and apply that science to achieve the objects set before us; namely, the prevention, relief, and cure of disease. That is to say, we require to possess not only the science, but the art of medicine.

Many years ago, this science was so imperfect that we ourselves now have justly but little sympathy, and no respect, for it. But its professors, dogmatic and resolute, were determined that its precepts should even then be carried out in practice. Common sense rebelled against this tyranny. Men arose who said, if the results of treatment appear to us to justify the accuracy of your dicta, we will obey them; if, on the other hand, it plainly appears that these results show you to be wrong, we will not obey them: and this quite regardless of whether we can show wherein, scientifically, your error consists. We will go further, they said: if we can hit upon any plan which produces good results, we will adopt it; and this, though it may be diametrically opposed to what your science teaches, and, also, though we may be quite unable to offer any adequate explanation of the results we obtain. These persons were termed empirics, and their principle empiricism.

In coming down to our own times, and considering our own position, two questions suggest themselves.

Firstly: Is there any necessity to guard against science being so represented as to mislead us in practice?

Secondly: Does empiricism afford us any security against being so misled?

Having regard to the admitted imperfections of those sciences upon which our art is, as it ought to be, based, greatly as those sciences have progressed; and also believing that, in spite of great advances in the direction of freedom of opinion, dogmatism is not yet eradicated from the earth; I submit that the first question must be answered in the affirmative. It is unfortunately necessary to protest against an opinion which such a statement sometimes elicits; viz., that these views disparage science, and must lead those who hold them to ignore its advances. There is, in my opinion, no scientific discovery which may not become utilisable; I never hear one announced without saying to myself, Can I see my way to applying it to the purposes of the art of medicine? But there are many new facts which I cannot see my way so to utilise. I am conscious of no inconsistency in admiring and attempting so to utilise them, whilst I refuse to be led astray by hasty generalisations, illogical inferences, and fanciful speculations. The question really is, shall we base our art upon true scientific facts only, or upon these in combination with scientific fancies? A rigidly scientific mind could give but one answer to such a question. The truth is, that submission to pseudo-scientific teachings equally debases our art and discredits genuine science.

Admitting, then, which we do without any special disparagement of ourselves, that the human mind, when exercising medical art, may err, do the teachings of empiricism tend to limit its deviations from truth? In answer to this, I propose to point out some obvious—indeed, necessary—influences which empiricism exercises upon our modes of thought and action, results to which it leads, and practical guides which it may furnish in cases of doubt and difficulty, where exact science fails us; and to give some illustrations of results which may be obtained by reliance on these methods from cases which have happened to myself.

Our object, then, should be to obtain experience. The wise man, we know, profits by the experience of others; the fool, if by any, only by his own. Let us, then, respect the opinions of trustworthy observers and practitioners, even if we do not thoroughly understand them; but not if they are disapproved by our own temperate reason. We wish to learn what art can do for disease; and this necessitates that we should, in the first place, ascertain what nature can do—that is to say, the natural history of disease; this can only be satisfactorily noted in undrugged cases. We know that many diseases, of which some cases require energetic treatment, will, in many other instances, do perfectly well without any treatment at all. For example, pneumonia is such a disorder; so are all the exanthemata, even including typhus. I have often managed acute pneumonia without any drugs. I have my student notes of a pretty severe case of typhus so managed by Dr. Stokes in the Meath Hospital. Undoubtedly this is the proper way to deal with a large proportion of the cases of the ordinary exanthemata. This is an easy matter in a hospital, no doubt; but it is much easier in private practice, particularly amongst the higher classes, than many practitioners think. This is anything but a lazy method; it involves the closest attention to see that nothing is going wrong which drugs might set right. By this attention, we acquire the most intimate familiarity with the appearances and phases of disease. This familiarity may sometimes assist us in prognosis. In the beginning of the year, I was called to see a medical man who was evidently very ill. He had a solid pneumonic patch, apparently about the diameter of a crown piece, in the back of the left lung; and mucous *râles*, of medium fineness, over the back of both lungs. I was much alarmed; for patients do not die in pneumonia from the amount of solidification, but from congestive disturbance—for the most part unannounced by physical signs—of the unsolidified portions. Such disturbance may occur in any case; but is, on the whole, more likely to do so where the exudation is limited in extent. Free exudation seems to exhaust the force of the disorder. The next morning, he was better. A very favorable prognosis was now given. Why? Because the back of both lungs, over the greater part of their surface, had become solid, and there was no extension of the mucous *râles* to fresh portions. We know that, in ninety-nine cases out of a hundred, when the inflammation has ceased, an acutely solidified lung will resolve. The prognosis was justified by the result.

A still greater advantage of non-interference is found when symptoms do arise which we know indicate danger; and not merely justify, but require, our interference. We have perfect confidence that these are symptoms of the disease, and not of our treatment.

Drugs, especially strong ones, are edged tools with which it is proverbially dangerous to play. That which can do good, can do harm: though we find it difficult to realise this when our administration has the sanction of authority. One of the greatest responsibilities which falls upon us is, when we have to decide whether symptoms of a grave character are due to the disease or to the treatment.

The case, for example, is one obviously of the most extreme danger, the slenderest chance of safety remains; if we pursue the treatment, and if it be wrong, inevitable death. The treatment may have the sanction of authority. In older times, it was generally reckless bleeding: now-a-days, perhaps an equally unmeaning stimulation. If we change it, and success do not follow, we incur the gravest imputations. Under such circumstances, nothing but the highest sense of honour, of our duty to exercise our judgment for the benefit of our patient, regardless of the consequences to our own reputation, would induce us to interfere. We must, in such cases, have the courage of our opinions; and happily, occasionally, but only occasionally, our courage is rewarded by the event. Such a difficulty, no doubt, most frequently presents itself in consultation practice, not because the previous treatment had been careless or improper, but because we have not had the opportunity of watching its effects upon the progress of the disease. But the same dilemma has presented itself to me in cases over which I have myself had from the outset the fullest control, and in which I had exercised the greatest care and watchfulness. The chief dogma of empiricism is that the effect of a drug in the individual case in hand has to be determined, regardless of the effect it may seem—even justly seem—to have

had in a thousand apparently similar cases. Perhaps the most certain specific in any given disease is quinine in ague. It may fail. Some few years ago, a soldier contracted ague in India. He was treated in several military hospitals, and finally at Netley—an institution which is a credit to the profession and an honour to the country. Quinine had been continually and lavishly administered. Being invalided, he returned to Birmingham, and, at last, came into the General Hospital. He was more cachectic in appearance than any ague patient I had ever seen. His fever had for a long time previously presented a remittent, almost more than an intermittent, type; but he had no visceral enlargement. There could be no good in wasting more quinine because that drug is reputed a specific for ague. One specific having failed, we had recourse to the one next best in repute—arsenic. After taking five minims of Fowler's solution three times a day for a week, he was not only better, but had lost so much of his cachectic appearance, that I should not have known him; and he made a rapid and complete recovery.

One or two illustrations of the possible difficulty in sometimes determining whether the symptoms are those of the disease or of drugs used in its treatment may not be uninteresting.

Some years ago, I was consulted in the case of a lad who was suffering from diarrhoea, caused by the poisonous water of a surface-well. One child had died, the mother had with difficulty recovered, and the father was even then barely out of danger. The boy's symptoms had been most urgent; and, though the diarrhoea had, when I saw him, abated, other symptoms had set in of so alarming a character, that my colleague thought his recovery impossible. Indeed, so certain was he on this point, that, when I suggested the possibility of a favourable issue, he doubted whether I was really serious. I was obliged, therefore, to explain. Had the then symptoms been certainly and entirely due to the disease, my opinion would have coincided with his. But some of them, at least, were not inconsistent with their being due to opium, which had been administered very properly, but very fully. It seemed to me that, if he were suffering from opium-poisoning, and the opium were discontinued, he might recover; and he did. I think that infants may and do die from opium administered for diarrhoea, in a sort of collapse, without presenting the more common symptoms of opium-poisoning.

To give another example: An elderly gentleman had an attack of influenza. When recovering, but enfeebled, he one night had symptoms of collapse, for which stimulants were administered. As he remained in a condition which made the return of exhaustion not improbable, their use was continued. He regained no strength, lost his appetite, had constant pain at the epigastrium, with nausea and occasional vomiting, and a dry hard brown tongue. His only nutriment was a sort of custard containing brandy, which he took frequently in doses of one or two teaspoonfuls. Ever this aggravated the gastric disturbance. There was no fever. As he was not only very feeble but becoming daily more so, his condition was alarming. The gastric disturbance was so marked, and the only food he took was so offensive to the stomach, that it occurred to me that the brandy it contained might be the cause of his symptoms. On the other hand, dryness of the tongue is not uncommonly an indication for the use of alcohol. And further, of four medical men who had seen him quite recently, three were distinctly of opinion that his only chance of life lay in free stimulation. I resolved to make an experiment, and to stay for some hours to watch the result. Some custard was made without any brandy. Of the first teaspoonful he said that it was the only food he had taken for days that had not caused pain and a desire to eject it. In a few hours, his tongue was moist, and he made a good recovery, with but one relapse caused by a dose of brandy. Consideration of this case and of others, where the tongue is dry, teaches us this lesson. Dryness and brownness of the tongue dependent upon the state of the system at large are indications for the use of stimulants, but, when dependent upon the condition of the stomach only, are contraindications. But we cannot rely upon any single or invariable diagnostic in cases of this kind. We must consider the symptoms in their totality, and we must also look at each individually, if perchance we may obtain a clue. For example, in a very anxious case of fever in a child where things were going very badly, a certain amount of rigidity of the pulse seemed to contraindicate the use of alcohol, and it was resolved therefore to suspend its use and watch the result. This was satisfactory, and at that moment life was probably saved by the discontinuance of a drug, the use of which but a few days before had probably preserved it. Such examples might readily be multiplied did time permit. Perhaps enough have been given to show the importance of being guided in the administration of potent drugs, not by what we think they ought to do but by what we see them do. But unless we daily exercise our discrimination in simple cases, and so form a habit of exercising an unbiassed judgment, we can have no chance of acting with discretion in times of difficulty and danger,

often with all surrounding circumstances conspiring against our self-possession. How often, when coolness is most essential, do we see, in its lieu, panic. Want of education on this point is not from want of opportunity. It is the fashion nowadays to be carried away by the vague idea that almost everything is debility. And so, in vast numbers of chronic cases, a practitioner will go on giving iron, or cod-liver oil, or quinine, regardless of the obvious fact that in the particular case they do no good, or even do harm. Why does he not reconsider the case from the beginning, and lay down his treatment upon other lines? Because he has not accustomed himself to a candid consideration of the results of his treatment, and to dismiss with rigour that which has not been, though he may fairly consider it ought to have been, successful. Allow me here to interpolate a little note upon alcohol. We are in doubt sometimes whether it is wise to commence its administration in an acute disease. It is well known that a reduction in the rapidity of the pulse is the best test of its action being beneficial. Under such circumstances, it most rarely fails to do good. On the other hand, if it accelerate the pulse, it rarely fails to do harm. Now, it is not generally known that we can ascertain which effect it will produce in almost as little time as I have occupied in saying these few words. Give the patient what under the particular circumstances you would consider to be a full dose, taking care not to alter his position before or whilst doing so. Keep your finger on the pulse, which must have been carefully counted two or three times beforehand for not less than a full minute each time, and count it by the minute. Before two or three minutes have elapsed, you will probably find the rate altered; it may be that you may have to wait five or six minutes. The result of this test is a sure indication of the effect which proper doses of alcohol will have on the circulation. For example: Since this was written, a young girl in a state of extreme asthenia from shamefully neglected typhoid was admitted into the General Hospital. At the time the following observation was made, her pulse was 135. Two teaspoonfuls of brandy diluted with water were administered without disturbing her. Within a minute, her pulse was again counted, with the following results: First minute, 140; second, 140; third, 145; fourth, 145; fifth, 145. She died two days afterwards, and we found, as had been anticipated, most extensive ulceration of a large tract of the small intestines, and also a little peritonitis, but not, so far as we could discover, any perforation, though several of the ulcers were very nearly through. I have seen a similar case before, where, with extreme ulceration, brandy was very badly borne.

The proposition which we were just now considering was, that we should not adhere to a treatment which, though presumably in accordance with scientific teaching, was doing no good and might be doing harm. There is a converse proposition to which we will now turn. We should not interfere with a treatment which, though presumably contrary to scientific teaching, is doing good.

Sound principles sometimes involve their holder in great difficulties, as the following case will show. A young lady of noble family, a fact which, while it ought not to increase our sense of responsibility, certainly does not diminish it, had scarlatina. About a fortnight afterwards, she began to vomit, and nothing stayed on her stomach; various remedies were tried without any benefit. About eighteen hours before I saw her, she was ordered half a grain of opium every four hours. At the time of my visit, she felt better, and by the concurrent testimony of all her attendants, the vomiting had diminished in frequency and violence. There was no dropsy, but the action of the kidneys was almost suspended, and the excretion was nearly black, and, on boiling, became semi-solid. Here was an appalling dilemma. On the one hand, you will admit that nothing could be more opposed to scientific teaching than the administration of opium in a case of scarlatinal suppression. On the other hand, it had allayed the vomiting, and the free ingestion of liquid is in such cases of vital importance. A more orthodox treatment would, if it happened to re-excite the irritability of that most wayward organ, the stomach, defeat our object by preventing an adequate ingestion of liquid. Under all the circumstances, I elected, but with the most painful reluctance, to continue the opium. The only subsequent alteration in the treatment was that, three days afterwards, she had her food and drink tepid instead of iced. She made a rapid recovery. A medical friend afterwards asked my advice in a similar case, which I did not see. Mentioning the foregoing history to him, he tried opium, and, as he afterwards told me, with good effect.

This experience was afterwards turned to good account in another case. A farmer in Staffordshire broke his leg. For this, he was confined to bed for several weeks, enjoying excellent health till three days before I saw him. He had been seized with some pains in the upper regions of the abdomen, which became very violent, and were attended with incessant, or at least most frequent, vomiting and spasm of the abdominal muscles. The day previous, the storm had extended to the

kidneys, the secretion of which had become most scanty, blackish, mixed with lithic acid, and, on boiling, it became almost solid. The vomiting had been somewhat restricted by limiting him to water and thin gruel in very small quantities; but the attacks of spasm were still frequent and violent; and even in their absence he was not free from pain. For these latter symptoms, opium was an obviously appropriate remedy. But for the kidney-disorder, the most threatening to life, it would have appeared to me, and probably to many persons, most inappropriate but for two considerations: firstly, the history of the preceding case; for, judging by its secretion, the state of the kidney in the two cases could not be very dissimilar; secondly, the history of this man made it probable that the disordered innervation of the kidney was produced by the nerve-disorder of the part which was primarily the seat of pain, and, if so, was similar to it in kind, and for this latter no one would have hesitated to prescribe opium. We accordingly gave him opium, and with this he made a good though not uninterrupted recovery. Curious facts such as these stimulate us to seek for an explanation of them. It is no part of empirical medicine to reject or slight the plain interpretations of science; on the contrary, it earnestly seeks to know to what other apparently similar cases hints thus accidentally obtained may be usefully applied. The more perfectly we understand what has happened in the first case, the more certainly can we afterwards deal with subsequent ones.

Now, if we refer to experimental physiology, we find that, in the last few years, it has thrown great light on the subject of secretion. Glands cannot secrete unless their own arterial circulation be in a certain state of activity. This state depends directly upon the influence of the vaso-motor centre, which in its turn may be influenced, amongst other ways, by irritation of ganglionic nerves.

Now, as regards the kidneys, listen to what happens when the splanchnic nerves are divided. "The vessels of all the abdominal viscera are seen to be dilated. The portal system is filled with blood, the small vessels of the mesentery, and those which ramify on the surface of the intestine, are beautifully injected; the vessels of the kidneys are dilated, and the parenchyma is hyperemic." The blood-pressure under such circumstances is only 31 by the mercurial gauge. But galvanise the peripheral cut extremity of the nerve, and the mercurial gauge indicates a pressure of 115. We see here, then, if not the actual explanation of the *modus operandi* of opium in such cases as we have been considering, at all events, a promising clue to the mystery.

Here is another way in which the renal blood-pressure may be affected. The depressor nerve of the circulation "contains centripetal fibres, the function of which is to diminish the activity of the vaso-motor centre, and thereby diminish the arterial pressure". If this nerve be divided, and its central end excited, what follows? "If the abdominal organs are exposed and inspected during excitation of the depressor, they are seen, according to Cyon, to become congested. The effect is most perceptible in the kidneys, which change colour from pale to red and back again as the induced current is closed or opened." This chapter of physiology cannot yet be fully written, still less can its pathological correlative; but even now it affords hints of surpassing importance to us as practitioners, and the blanks in it are every day being filled up. It is only lately that sphygmographic observations have ascertained the presence of undue arterial tension in all the ordinary phases of albuminuria; viz., in Bright's disease and in the scarlatinal and puerperal forms. But, in many instances of these, it does not require any instrument but the finger to detect it. I remember, years ago, seeing two cases of puerperal convulsions in which it was most obvious in the rigid pulse; both were bled several times, and, after the bleeding, the tension disappeared, as did the convulsions, a return of which was each time preceded by returning rigidity. Both these cases did well. In such cases, we now administer chloroform, which may not improbably act by reducing arterial tension. Only this year I have seen two very severe and obstinate cases of scarlatinal hæmaturia with next to no drowsy; in both, the pulse was obviously and palpably rigid, though both patients were under 16. Other remedies failing, I tried the extract of Calabar bean in one case, and its action was so favourable in reducing the pulse-tension, and concomitantly the hæmaturia, that I also gave it in the other with equally good results. In the large and important family of hæmorrhages, alterations of arterial blood-pressure play a most important part. It is an old observation that slow pulse is not unfrequently a sign of an impending hæmorrhage. Now, slow pulse is often, especially in connection with hæmorrhage, but another term for increased arterial tension. The epistaxis of young children is not due to any undue congenital laxity of the nasal capillaries, but to, as I think, disturbance of the vaso-motor centre of either centric or eccentric origin. In older persons, a similar disturbance is present. The same remarks apply to hæmoptysis, regarding which I entirely concur with those who hold that it is not merely a possible but

a frequent cause of those changes in the lungs which produce phthisis; and this when it occurs accidentally in lungs previously sound. There is, in my opinion, no just basis for the dogma that, in cases where phthisis follows hæmoptysis, the latter has been caused by latent tubercle. Pulmonary phthisis is a disease which, as Broussais taught, has its origin in inflammation of some portion of the lung-structure to which the miliary tubercle is secondary. The general recognition which this truth is now happily obtaining, must exercise a most important and a most beneficial influence upon the treatment of consumption.

The singular disorder known as paroxysmal hæmaturia is probably a vaso-motor nerve-storm affecting the renal circulation. Some element of this kind is probably at or very near the root of gout and its multi-form expressions. The same may be said of some forms of diabetes and of spasmodic asthma.

Probably such a case as the following is to be thus explained. A woman has an attack of spasmodic asthma. She has had a few before; but in this one is brought to the hospital. The urine is found to contain an enormous amount of sugar, all trace of which disappears as the asthmatic attack subsides.

These opinions are speculative, it is true, but they suggest very important clinical inquiries, the result of which must furnish, and have in my hands already furnished, practical results. But it must not be forgotten that, even should it prove true that disorder of a nerve-centre is at the root of some of these affections, yet that disorder may be rather a suspension of action than a storm of active discharges. Even in hemicrania, it is doubtful to which of the two the pain is referable, though I am much disposed myself to the nerve-storm view, even in opposition to the opinion of Anstie on this question. The next subject shows how we may sometimes successfully puzzle out the treatment of cases which we are conscious of not understanding, and also how we may sometimes light upon the explanation of such cases after many years.

In a paper on the Treatment of Rheumatic Fever, published in 1863, I drew attention to certain cases of this disease which seemed to form a group by themselves. Almost suddenly, the type and aspect of the disorder seemed to change. A drowsy muttering delirium set in, accompanied, often for a short time preceded, by diarrhoea, the discharges being occasionally hæmorrhagic; dry brown tongue, diffused bronchitis affecting the smaller, if not the smallest, tubes, and not infrequently some pneumonia, appeared. The condition of the patients was always alarming, though fortunately none of them died. The indications for treatment were obvious: stimulants, stimulating expectorants, and astringents. The employment of these remedies left no room for the continuance of the ordinary alkaline treatment which, with certain qualifications, I then employed and still confide in. The alkalis were accordingly in each case discontinued. My attention was continually directed to these strange cases, in the hopes of lighting upon some explanation of them; but none came. In January 1872, I was attending in consultation a case of diphtheria, which was progressing favourably with iodide of potassium, chlorate of potash, and ammonia. But one morning we found him in a state of depression and somnolence, but without any distinct delirium. Things were going wrong, and it, therefore, became desirable to make a change. The state of affairs was one in which the experience of many has shown that acids and iron exercise a favourable influence, and I suggested that they should be tried. The anomalous and unfavourable symptoms soon disappeared, though the patient subsequently suffered from a severe and protracted attack of diphtheritic paralysis.

Some little time after this case occurred, I happened to come across Waring's account of the untoward effects of alkalis in certain constitutions. In some persons, however strongly indicated, they cannot be borne, as they produce great excitement of the nervous system and cerebral functions. In some, they apparently alter the quality of the blood, destroy the cohesive property of the blood-corpuscles, render the fibrin less plastic, induce a thin and liquid state of the circulating fluid; petechiæ appear on various parts of the body; the patient perspires profusely, becomes low-spirited and emaciated, and less capable than when in health of physical exertion; the assimilating functions are deranged, and serious disorder of the nervous system results. I could not but be struck with a certain family likeness between this class of symptoms and those to which I have previously adverted. The fact that, in the rheumatic cases, the alkaline treatment had been discontinued, and that, in the diphtheritic one, an acid treatment had been substituted, seemed to assume great importance. On the other hand, there are the facts that, in rheumatic fever, the system has over and over again been completely alkalisied without any deleterious effect being observable; that, out of a great number of cases of this disease treated by myself, a very few only had presented the above described symptoms, though in all alkalis had been freely employed. Whilst these opposing arguments compelled a suspension of judgment, there was

evidently abundant ground for submitting the matter to the therapeutic test on the first opportunity. Cases of the kind are rare, and consequently it was just two years before such an opportunity presented itself. I was attending, in conjunction with my eminent colleague Dr. Bell Fletcher, a medical friend suffering from severe and most complicated rheumatic fever. Symptoms of great depression, with muttering delirium and stupor, suddenly appeared. The kidneys, as we know, furnish us with a very reliable test of the alkalinity of the system, and, in this case, their secretion left no doubt that this alkalinity existed. The case appeared to both of us one of extreme gravity. I set before my colleague the views which have just been placed before you, and he agreed with me in the propriety of cautiously acting upon them. The result was most unequivocal. After the third dose of hydrochloric acid, the symptoms abated, and, coincidentally with this abatement, we found the urine faintly acid. Several examples have since shown me the great practical importance of recognising the facts just set forth, and the advantage of acting upon the inferences to be drawn from them. But the recital of them might be wearisome. It is at the same time necessary to add that this alkalinity may arise quite spontaneously; that is to say, in cases where no alkalies have been administered, and also in chronic as well as in acute diseases. It is not impossible also that we may sometimes infer the propriety of giving acids from the general symptoms alone, when chemical tests fail to demonstrate the presence of the alkaline condition. But then the acid must be given purely empirically; that is, only in consideration of its obviously producing a favourable effect, which it may do up to a certain point only, and this point may be very rapidly reached.

And now, in the last place, let me offer some suggestions as to our handling desperate cases—those in which we have run through the whole list of remedies likely to be successful, but without success; those in which we see that, unless some change occur, the patients' very hours are numbered. It is not merely because a person seems, or is, very ill, that his condition is desperate, because these very serious symptoms may have arisen suddenly, and we may have in reserve a reliable and appropriate remedy. The first thing to do is to determine to maintain one's self-possession. It is easily lost if we do not acknowledge to ourselves the probability of losing it. We have, then, to make a careful and cool review of the whole condition and circumstances of the case; to determine, in the first place, whether nature is more likely to pull the patient through without our assistance or with it. If we honestly think the former, it is our bounden duty to act upon that opinion, regardless of the odium we may incur by failure. Some time ago, I was called in to see a little girl who was in that typhoid condition we occasionally see at the end of scarlatina. She took her food well, but had extreme repugnance to medicine. Drugs have but little efficacy in such cases, whilst the maintenance of nutrition is all-important. There was a fear lest perseverance with medicine might set her against her food, and we advised that the best chance of her recovery lay in a reliance upon milk only. This confidence was not misplaced, for, after an arduous struggle, she recovered.

Sometimes the exigencies of the case compel us to do that which, under other circumstances, would be justly blameable. For example, in two cases last year I felt compelled to cause children's chests to be tapped with a simple incision, because there was not time to procure the proper instruments. It was a choice of two evils; and, though both did well, such a proceeding can, of course, only be justified by urgent necessity.

The object of reviewing a case is to see if we can determine what is the key of the position. This is a definite object; and if we can, as we sometimes may even in cases of great complexity, accomplish this, a great number of considerations are eliminated which before perplexed and distracted us. Sometimes this key is very remote, as in the following case. A young lady was suffering from asthma of the continuous kind, though paroxysmally exacerbated. There were also disturbances in various other functions. Two very able practitioners had exhausted their powers when I was called in. My powers were likewise exhausted; and, although she subsequently and slowly emerged from the attack, I could not conscientiously say that any of our prescriptions were of any benefit. Some two or three years afterwards, she had another attack, in which she was attended by one of her previous advisers and another very able practitioner. After matters had gone on for as long time as they had done before, I was again sent for. On careful reconsideration of the history of the two attacks, we recollected that about the commencement of each there had been a certain amount of dysmenorrhœa. The highways of medicine had not led us to our goal; and it was, therefore, justifiable to try the byways. Now, although almost every drug has been employed in asthma (Waring gives a list of fifty-two), I do not know that guaiacum has; but it is known to be efficacious in rheumatic dysmenorrhœa, and in

this patient there had been suspicions of a rheumatic element. Though much of the treatment had been directed against rheumatism, we resolved to try the guaiacum in full doses. A drachm of the simple tincture was given every hour. After the first dose, some relief was obtained; and after the third she fell asleep, the next morning was much relieved, and made a speedy recovery.

It is an useful dogma, that cases and the effect of drugs, though they may be rare, are not unique. When, therefore, we get a happy though casual result, we should store up the remembrance of it for future use. Some time after the occurrence of the preceding case, I saw a lady who had long suffered from attacks of true spasmodic asthma, which nothing had ever been found to produce any decided effect upon, though medicated cigarettes afforded slight temporary alleviation. Driven thus into a corner, I resolved to try the guaiacum, of the ammoniated tincture of which half a drachm was given every two hours with excellent results. It was a natural thing to advise that some of the drug should be kept at hand, and resorted to in case of another attack. This was done; but on the next occasion it completely failed. But now chloral-hydrate, given in small (about five-grain) doses every fifteen minutes, produced great relief after five doses. It is to be noted, that the first attack had lasted many days before the guaiacum was given; whereas the second time it was taken quite early. Here is another example of success attending treatment based upon such slight grounds that nothing would justify its adoption except the fact that the case was desperate, and indeed hopeless, as regards cure, though not as regards life, if treated in a more orthodox manner.

Diphtheritic paralysis is a disease as little, probably, influenced by drugs as any with which we are acquainted. It is true that there are certain drugs and classes of drugs which are recommended and used in its treatment. But it is not cured; it gets well. Some persons will say it always gets well; but it does not. I saw, a good many years ago now, a lad who, from paralysis of the muscles of the throat, could swallow nothing, and a part at least of what he did try to swallow got into his lungs. At least, there was a loose mucous rattle over the back of the chest, which seemed probably due to this cause. His debility and emaciation were extreme, and he died a few days afterwards.

Last year, I saw just a similar case in a young girl. In an attempt to swallow a little water in my presence, I thought she would have been choked. The voice was almost extinct; the arms and legs almost powerless and terribly wasted. She was dying of inanition; and, with the former case before me, it seemed almost a certainty that, unassisted, she could not live more than two or three days at the outside. Even when it gets well, diphtheritic paralysis generally, if at all severe, takes a long time—weeks or months—to do so. Nutritive enemata are a poor resource under such circumstances. Reflection on the former case had led me to the conviction that the only real prospect of recovery in a similar one would lie in frequent feeding through an œsophageal tube. My colleague said it would be impossible for him to undertake the passage of this sufficiently frequently. He asked me to take her into the hospital, and I readily assented; for, although considerably above the ordinary rank of hospital patients, the circumstances of her case made her eminently proper for admission. The parents, however, foolishly fond, absolutely refused the proposition, and urged me to do something for her at home. After many most earnest endeavours, we failed to move them. But what to do! I protest I could not at the moment have felt much more helpless had the undertaking been the bringing of the dead to life; the more so, that we know nothing of the pathology of this paralysis. In what part of the nervous system changes have occurred, what is the nature of these changes, are matters upon which our ignorance is absolute. One thing was vividly before my mind: the necessity that whatever agent we employed should be one capable of acting speedily. I happened to recollect that in the last century it was the custom to treat some affections of the throat with blisters to the back of the neck; indeed, they were used in diphtheria itself, but only in its early stages, not in the subsequent paralysis. I had myself seen curious and speedy results in some throat-inflammations from blistering the nape. Whatever effect blisters produce, is generally soon after their application. Upon grounds so slender, and for reasons so trivial, that in any ordinary case it would be a disgrace to act upon them, we resolved to apply a blister to the nape. I saw her no more; but some time afterwards I learned that within thirty-six hours she was able to swallow. She made a good recovery, though the paralysis of the arms and legs took their usual long time to disappear.

In the beginning of this year, a man was admitted into the General Hospital under my care suffering from diphtheritic paraplegia. With a person holding him on each side, he could just shuffle along the ward to his bed. I put a blister about an inch and a half wide the whole length of the back, by the side of the vertebræ. It ought to have been

wards during micturition at the umbilicus, welling up into the umbilical cup, filling it, and running over in such quantity that the parents had no reason to entertain any doubt as to the nature of the fluid. The urine was passed with difficulty by the urethra, and fell down from the orifice. No tumour was visible at the umbilicus; the prepuce was long, contracted, and adherent to the glans. Tincture of perchloride of iron had been applied to the umbilical aperture to produce contraction, but without avail. I operated for the phimosis according to Dr. Gordon's plan of slitting up the prepuce, as it seems to be very simple and efficacious. A *navus-needle* was passed between the glans and the prepuce, and out through the prepuce at the corona. The prepuce having been grasped longitudinally beneath the needle by a pair of strong forceps, as much of it as was thus embraced was cut away by running a knife through the tissues along the lower border of the forceps. The mucous membrane was separated with difficulty from the glans, then cut freely, and its edges fixed to the skin by two sutures. Dr. Redfern saw the child lately, and has written me to say that, since the operation, the mother has been "quite pleased to see the urine projected to some distance from the body in the natural manner. Very little urine has come through the umbilicus; but at one period some blood oozed away," which was readily stopped by the application of tincture of perchloride of iron. "When I last saw it," he continues to say, "there was scarcely any appearance of ulcer or opening of any kind."

In some instances where the cure after circumcision has not proved complete, it might be necessary, in addition, to operate directly on the urachus according to the plans already mentioned; but neither in patent urachus nor in umbilical fecal fistula can we reasonably expect a cure, so long as there is an obstacle to the passage of urine or feces by the ordinary route.

PROLAPSE OF OVARIAN CYST.

By A. W. STOCKS, M.R.C.S.,
Surgeon to the Salford Royal Hospital.

E. I., AGED 45, a fustian-cutter, pallid, slightly built, married, had three children; she was last confined about twenty-two years ago. She menstruated regularly up to two years ago, irregularly till eight months ago, and not at all since. About eleven years back, a tumour about the size of a walnut appeared at the anus when getting out of bed, becoming larger on exertion. It was accompanied by faintness and uneasiness, especially when sitting down. She was always constive, and could neither micturate nor defecate unless she replaced the tumour manually. She had lately experienced difficulty in coition. The lump had increased in size during the last ten months, and come down always while at work, producing a good deal of pain in the hypogastrium, more particularly when she was in the upright position. She felt best when lying down. The prolapse was large, being about the size of a small cocoa-nut.

March 15th, 1872, 12 noon. When she was placed upon the operating-table, and under the influence of chloroform, for the purpose of having the simple prolapsus ani, as it was supposed to be, relieved by operation, defecation took place, the contents of the bowel being expelled in such a peculiar manner as to lead to the further and more precise examination of the tumour. It was then discovered that the orifice of the bowel, instead of being at the most dependent part, was on the posterior aspect, and about half way between the edge of the anus and the lowest part of the prolapse. On introducing the finger into the rectum, a large mass was found to occupy the anterior fold of the prolapsed bowel, of globular shape, and capable of being encircled easily at its base. *Per vaginam*, the cervix uteri was found tilted forward and to the right side. The uterine sound could only be passed three-quarters of an inch, and a finger passed into the rectum could be easily approximated to the one in the vagina over the tumour, clearly showing an absence of continuity between the uterus above and the mass below. Moreover, on rubbing the tips of the fingers together, a hardened cord could be felt slipping between them. The conclusion, therefore at once arrived at was that this cord was the Fallopian tube, and that the tumour was a small ovarian cyst, which had fallen through Douglas's pouch, became entangled with the prolapsed rectum and protruded through the anus, dragging the uterus itself out of its normal position. It was evident that to give permanent relief it was necessary that this tumour should be removed. Accordingly, an incision was made in the anterior aspect of the prolapse parallel to the axis of the bowel, and, after breaking down some slight adhesions posteriorly, a small ovarian cyst was easily turned out. The pedicle was divided, after being secured by a strong hempen ligature, the end

of which was left hanging out of the wound, and the wound was drawn together by an uninterrupted suture. There was considerable hæmorrhage, and the flaccid bowel was left outside the anus.

At 5 P.M., she had slight vomiting, the skin was cool, hæmorrhage slight, and the prolapsed bowel was swollen. She expressed a feeling of relief and lightness about the rectum, and it was noticed that the ligature had slipped off the pedicle and lay outside the wound. The catheter was passed, and she took an opiate.

March 16th. The countenance was good, pulse 120, temperature 98.2 degs. She had vomited frequently up to 7 A.M.; most probably from the chloroform. There was slight pain in the hypogastrium and right iliac fossa.

March 17th. There was no tenderness. The prolapse was supported by a T-bandage. She went on well until the 24th, when she passed a solid motion involuntarily, as she did daily for some time.

April 5th. The tumour was much smaller.

April 9th. The prolapse was easily returnable.

April 16th. She walked about and felt more comfortable than she had done for a long while back.

April 23rd. The protruded portion of the bowel was about the size of a walnut. Defecation was fairly under her control, and she could draw the prolapse back without manual assistance.

1875, July 15th. The prolapse still existed, but was accompanied by no discomfort in, or obstruction to, either the act of defecation or micturition.

The tumour (the dried preparation of which is in my possession) was an unilocular ovarian cyst, and contained about 5½ ounces of brown, slightly viscid fluid, specific gravity 1.025. The ovary and fimbriated Fallopian tube were attached to it, and on it were found marks of slight adhesions.

This extraordinary case is of perhaps more interest from its singular pathological character, rather than from any peculiar practical surgical value. The numerous factors, each of which must have furnished its own particular but necessary influence in bringing about such an unusual result as a prolapse of an ovarian tumour through the anus, will, in all probability, be long looked for ere a similar instance will be recorded.

POISONING BY TOBACCO.

By E. R. MORGAN, M.R.C.S., L.S.A., Medical Officer of Health to the Neath Union.

THE history of the following cases of poisoning by tobacco is, I venture to think, of sufficient interest to merit a place in the JOURNAL. The manner in which the poisoning was effected is, as far as my knowledge goes, quite unique, not that I mean to say poisoning by tobacco is unknown; on the contrary, I know many cases are on record. By some means or other, some tobacco got into a well, the water from which was drunk by three persons, and in each very severe symptoms of poisoning were set up, causing death in one instance; how the tobacco was discovered, will be described more fully hereafter.

It happened in a large village called Ystalyfera in Glamorganshire, which at the time was in the district over which I had jurisdiction as medical officer of health; hence I took great interest in the cases, and investigated the facts upon the spot. The other details were kindly furnished me by Dr. Thomas.

On Wednesday, March 10th, 1875, Dr. Thomas was called to visit a man, aged 53, living in a row of five houses, called "Cwmtawe". He found him lying helpless in bed with very confused ideas, unable to swallow, with complete loss of power over his lower extremities, hands trembling, and skin clammy and cold; heart's action very feeble; pulse hardly perceptible; he did not vomit, but had constant nausea: it ought here to be stated that he had been a habitual smoker for many years. With such symptoms, Dr. Thomas's suspicions were immediately aroused; and forthwith he made minute examinations in the garden for any vegetable poisons, and as carefully inquired of the wife of the patient whether she had procured any drug recently from some itinerant quack or chemist; but from these sources nothing could be elicited to account for the symptoms, and so for the time his mind was obliged to rest satisfied that the case, in all probability, was one of vegetable poisoning, but what that poison was he was then unable to say.

The same morning a child, a nephew, aged four years, was taken ill, but not with severe symptoms. However, on the next day, the doctor's attention was drawn to him. The lad was very sick, prostrated, with severe pain in the bowels; their action was arrested, necessitating the use of enemata; throat parched; pupils dilated, fixed and staring; pulse scarcely perceptible at the wrist; head thrown back, almost

amounting to opisthotonos. These symptoms continued while the prostration became worse, until on Monday, the 15th, about twelve o'clock, convulsions came on; and at 5 P.M. the same day he died.

After death, the face was bloated and the eyes suffused; the head was thrown back. There was nothing else remarkable. An inquest was held; but I regret to say no *post mortem* examination was made.

On Sunday, March 14th, a girl, aged 6, was taken ill with the same symptoms as the other two. I visited the place; and, on the fifth day of her illness, examined her, when she complained very much of her head and throat, and the former was thrown back. The face was red and swollen; the skin hot and dry. Temperature in the axilla, 103.4 deg. Pulse 95, weak. The pupils were dilated. The tongue was thickly furred; the bowels confined. After a prolonged convalescence, she recovered.

In the same house, there were the mother and six other children, but the three mentioned were the only ones affected.

According to the evidence produced at the inquest, none of those who were not taken ill partook of the water from the well in which the tobacco was found; hence the explanation of the absence of any symptoms in them. The persons in the other houses of this row procure their supply of water from a spring near a railway, two hundred yards away. It seems, however, that one other house, making two in all, also had been accustomed to get water from the well first mentioned; but, for some unexplained reason, some time before the 10th March, they likewise had taken their water from the well near the railway.

The source of water-supply to those in the house who were taken ill was a small shallow well some hundred yards away, situated near a canal; and, upon examination, I found there a shallow well cut out of a steep bank, with a feeble but persistent spring at the bottom of it.

While a sister of the deceased (the one taken ill on the Sunday) was taking water from this well on Sunday (14th), she noticed some tobacco in the water, and drank some of it; but, thinking no more of it, did not touch it nor mention the fact at the time to anyone. But next morning she spoke about it; and the same evening Dr. Thomas was made aware of this.

He immediately communicated with the police, and requested a policeman to go and remove the tobacco forthwith. This was done on the following (Tuesday) morning, and it was proved that half a quarter of a pound packet was taken out, and the tobacco shown to be of the strongest quality, viz., shag. On examining the tobacco, it was quite evident from its appearance and taste that it had been in the water for several days.

And here was, without doubt, the solution of the cause of all the symptoms, the chain of evidence being complete; but, at the inquest, though I carefully examined all the witnesses (being allowed to do so through the courtesy of the Coroner), I could not solve the other mystery, viz., how the tobacco got into the well, whether by accident or through the wilful act of some person. The jury, therefore, were obliged to find an open verdict.

INJECTION OF PERCHLORIDE OF IRON IN POST PARTUM HÆMORRHAGE, RESULT- ING IN DEATH.

By H. W. BODDY, M.R.C.S. and L.S.A.,
Cheetham Hill, Manchester.

IN the absence of the usual medical officer, I was summoned, during the night of April 4th, to attend a protracted case of labour at the Prestwich Union Workhouse. The patient, Elizabeth H., aged 28, had been in labour about five hours; and during the last hour had, as the nurse informed me, made little or no progress. On examination, the head was found to present in the right oblique diameter of the pelvis, in the occipito-anterior position. The head was low in the pelvis, the forehead occupying the hollow of the sacrum. After waiting two hours, and finding no advance made by the head, the pains becoming weaker, and as no mechanical obstacle to the passage of the head was apparent, I proceeded to apply Roberton's long forceps. After application of the forceps, by assisting the pains with firm traction, the child was born, without difficulty, in from ten to fifteen minutes; being alive, of full size, and well nourished. The placenta was removed in about twenty minutes, in the usual way; and, immediately on its removal, I was alarmed by a sudden gush of about eight to ten ounces of blood following it. A flow of blood continued for a short time, until, by friction and pressure on the uterus, I caused it to contract, and the hæmorrhage was much diminished, but not entirely arrested. A binder was then firmly applied, and pressure kept up upon the uterus with the hand. The nates were kept sufficiently uncovered to see any external

hæmorrhage that should occur. The moment my hand was ever removed from the uterus it dilated, and a gush of blood poured forth; and though again, by pressure and friction, contraction was established, still the "thin red line" trickling over the nates reappeared after it was wiped away.

Having given several large doses of ergot, and having twice injected cold water into the uterus with but temporary good effect, I determined to adopt Dr. R. Barnes's plan of injecting into the uterus a solution of perchloride of iron. Accordingly, I made the solution recommended by Dr. Barnes (four ounces of liquor ferri perchloridi fortior to twelve ounces of water), carefully measuring both the iron solution and the water. An ordinary enema-apparatus was used; and after pumping the solution through the delivery tube a few times, to get rid of all bubbles of air from the apparatus, I introduced the pipe well up to the fundus uteri, a gush of blood occurring as I dilated the os for the passage of the tube. The nurse then worked the syringe, while I held the pipe in its position. The hæmorrhage ceased immediately on the injection of the solution; and, during the first part of the process, the patient made no complaint, and the uterus began to firmly contract. But during the latter part of the process, she began to be uneasy, complained of pains in the belly, then severe cramps of the flexors of the leg occurred; next she gave a shriek, crying, "Oh my belly"; a general convulsion took place, the eyes rolled and turned up, the skin became blue, the pulse ceased, and she expired. (All this took place during the last two or three strokes of the enema-syringe.) Artificial respiration was then kept up for some time without any good effect. The uterus was firmly contracted round the injection-tube, some little force being required for its withdrawal.

That the injection of the perchloride of iron was the immediate exciting cause of death, there can be but little doubt, as the patient conversed sensibly with me two or three minutes before the operation, and complained neither of pain nor of any other symptom. The hæmorrhage could not be the cause; for acting on Dr. Barnes's advice, of it being better to do it too soon than too late, as we cannot supply again blood once lost, the injection was used before the loss of blood had begun to affect the nervous system. Therefore, the convulsion cannot be confounded with those that occur at the closing scene of death from simple hæmorrhage.

The death was due, in my opinion, to excessive irritation and shock to the cerebro-spinal and ganglionic nervous systems; and my reasons are the following. During the first part of the injection, while the irritant action of the perchloride of iron was engaged in causing the strong tonic contraction of the uterus that occurred, the irritation to the sensory nerves was reflected no further than those nervous centres that preside specially over the reflex action of the muscles of the uterus. After contraction was established, the irritation, as it could not be further expended in causing more uterine contraction, seems to have been further reflected to the lower part of the spinal cord, probably through the uterine branches of the sacral plexus, and this would account for the cramp or violent contraction of the flexors of the leg. Passing higher up the cord, the irritation would next cause the general convulsion that took place; and the shock, at the same time, to the ganglionic system, would cause cessation of the heart's action through the cardiac nerves; the consequent blueness of surface arising from accumulation of venous blood in the capillaries of the skin.

It may be suggested that death occurred from entrance of the solution into the general circulation. But could absorption, to any extent, take place through a rigidly contracted uterus? If blood cannot pass through the walls of the uterus well contracted (and we know it cannot), is it possible for any other fluid to do so?

Again, it may be objected that cutting and cauterising operations are frequently done upon the uterus, no shock supervening. But I contend that the sensibility of the uterus in the pregnant and that in the non-pregnant state, are two extremely different things. Though it has not yet been proved that the nerves of the uterus are increased either in size or number during pregnancy, yet their power of conducting impressions, without doubt, is, as evidenced by the pain felt during the contractions, and by the reflex contractions, easily brought on during labour by irritating the os or cervix uteri. The area, too, over which an irritating and caustic injection would act is immensely increased in the uterus of a woman recently delivered.

My conclusion, then, is, without any doubt, that death in this case resulted from the action of the solution of perchloride of iron upon the lining membrane of the uterus. I considered at the time, and do so still, that I was justified, on the authority of Dr. R. Barnes, in using the iron injection. The patient would doubtless have sunk gradually had this not been done, and it seemed to me that it was the only chance for her life. But this case does not give much encouragement for the further use of Dr. Barnes's plan. If again forced to its

use, I should immediately cease injecting as soon as contraction of the uterus was set up. I proceeded further with it in this case, partly to thoroughly promote firm contraction, and partly to use up entirely the amount of fluid recommended by Dr. Barnes. In conclusion, I would observe, as this remedy is only upon its trial, that it would be for the welfare both of the public and the profession if all the unsuccessful, as well as the successful, cases in which it was used were published. Then it might be seen whether the results would be such as to justify its general adoption in these cases of hemorrhage.

GELSEMINUM SEMPERVIRENS AS A REMEDY FOR COUGH.

By J. ROBERTS THOMSON, M.D., M.R.C.P.,

Physician to the National Sanatorium for Consumption and Diseases of the Chest, Bournemouth.

No symptom in pulmonary complaints more frequently calls for treatment than cough. The skill and the resources of the physician are alike taxed by its persistency or its severity, by the failure of medicines to relieve, or by the intolerance of remedies by the patient. Any addition to our *Materia Medica*, therefore, which proves of real therapeutic value in the treatment of this symptom, calls for a patient investigation at our hands. I know that some will say, "Do not direct your attention too much to the treatment of cough in cases of pulmonary disease, and more especially in phthisis. Deal with the conditions which give rise to the cough, and trust, by so doing, to alleviate it." In most cases, however, this symptom is so urgent and so harassing that we must treat it. For this purpose, I believe we have in *Gelsemium sempervirens* a very valuable addition to our armamentarium. Of late this drug has received some attention in this country with reference to its action in nervous affections (see *BRITISH MEDICAL JOURNAL*, May 2nd, 1874, and September 18th, 1875; *Practitioner*, August 1875), but, so far as I know, little has been said with regard to its use in cough. I have administered it recently to a large number of patients suffering from pulmonary disease, as a cough sedative. The following cases will illustrate the results which have been obtained.

E. N., a young lady, aged 21, had a large vomica at the apex of the left lung. The rest of that lung was dull on percussion. Respiration was bronchial, and there was coarse crepitation both with inspiration and with expiration. The vocal resonance was bronchophonic. The upper lobe of the right lung was also the seat of limited softening. There was much troublesome cough, with copious expectoration. Tincture of gelsemium was administered in five-minim doses; this gave very great relief to the cough, which was most marked towards evening, the time at which the cough was most troublesome. The patient expressed great faith in the remedy, and preferred it to any other sedatives, of which she had had a great many. No bad effects were observed from its use. There was no nausea or sickness produced, and the appetite was not impaired.

N. T., a married lady, aged 30, had dulness on percussion over the upper half of the left upper lobe. Over the area of dulness there were bronchial breathing, fine crepitation, and bronchophony. She had a very irritable and spasmodic cough. The expectoration was very slight and mucopurulent. Eight-minim doses of tincture of gelsemium produced marked relief of both hacking and spasmodic cough. No unpleasant effect was produced by the remedy.

J. M., an unmarried woman, aged 26, had chronic phthisis in the second stage, over the whole of the left lung and the upper half of the right. She had an extremely irritable cough, especially in the night, which did not yield to any of the usual sedatives. Five-minim doses of tincture of gelsemium gave very great relief, and enabled the patient to get a fair amount of sleep.

J. H., an unmarried man, aged 35, had chronic phthisis in the third stage in the right lung. The deposit was scattered all over the left lung. His cough was very troublesome. Little relief was obtained from the usual remedies. Five-minim doses of tincture of gelsemium proved most useful in checking the cough. No unpleasant effects were noticed.

E. M., a young lady, aged 24, had congestion of the left apex, trachea, and larynx, and an excessively irritable cough, resisting all remedies general or local. Tincture of gelsemium in five-minim doses, combined with syrup of codeia, gave great relief.

J. G., an unmarried lady, aged 32, was subject to severe attacks of spasmodic asthma. Her attacks usually yielded best to bromide of potassium with belladonna; to this tincture of gelsemium was added, and the attacks were markedly much milder and of shorter duration. No unpleasant effects were observed.

A. B., a young lady, aged 23, had advanced phthisis. The cough was very troublesome. All the usual sedatives disagreed. Gelsemium gave relief to the cough, but could not be continued because of producing nausea.

These will sufficiently indicate the kind of cases in which I have found gelsemium useful. In some patients, when there existed much bronchial irritation, I have combined it with bromide of ammonium, tincture of squill, and syrup of codeia, and such a combination has often afforded very great relief. In no case, save the one last narrated, have I observed any unpleasant effect. In that, the nausea was only slight, but she was otherwise suffering so much that I did not think it right to persevere.

These results show that gelsemium has a marked power in subduing cough; that it acts probably as a nervous sedative; that it is useful when other sedatives have failed; that it seldom produces any unpleasant general effect; and that the kind of coughs in which it may be administered with advantage is very varied.

I believe further investigation will heighten our estimate of the value of this drug in dealing with so troublesome a symptom in the treatment of pulmonary complaints, and that a more extended acquaintance with its action will enable us to differentiate those forms of cough in which it is likely to be of most service. It is undoubtedly a remedy of no mean efficacy, and will, I feel sure, hold a permanent place in our list of *materia medica*.

SURGICAL MEMORANDA.

SYME'S OPERATION MODIFIED AND IMPROVED BY SAVING THE PERIOSTEUM OF THE OS CALCIS.

IN THE *BRITISH MEDICAL JOURNAL* of the 2nd ult. is a paper by Mr. Joseph Bell of Edinburgh, in which he describes a modified and improved method of performing Syme's operation by saving the periosteum of the os calcis. I beg to inform Mr. Bell that Dr. G. H. B. McLeod, in the Glasgow Royal Infirmary, has performed Syme's operation exactly in the same way as Mr. Bell describes. From 1869 till 1873, I saw Dr. McLeod perform Syme's operation about fourteen times, in all cases saving the periosteum of the os calcis, and with the greatest success. Since that time, I had occasion to perform the operation four times. In all the cases, I saved the periosteum of the os calcis. All the cases did well; in two of them a considerable amount of new bone formed in the flap, making a splendid stump.

JOHN AITKEN, M.B., Carlisle, N.B.

THERAPEUTIC MEMORANDA.

TREATMENT OF WHOOPING-COUGH WITH CARBOLIC ACID INHALATION.

IN THE *JOURNAL* of the 2nd ult., Dr. R. J. Lee has mentioned my name in connection with the employment of carbolic acid vapour in the treatment of whooping-cough. I am glad to have the opportunity of furnishing a concise account of the way in which it was used, and also of my experience of the remedy in question.

During the early part of the present year, I had under care about forty cases of the above affection (occurring amongst the children of officers connected with Her Majesty's Convict Prison, and not, as might be inferred from Dr. Lee's remarks, amongst the convict class). At the suggestion of Dr. Lee, I tried the inhalation of the vapour; but, owing to the number of cases on hand at the same time, and having only one inhaler on the spot, I was not enabled to apply the remedy separately to each case, as I should have wished. This difficulty was, however, in a measure, got over by having had two rooms placed at my disposal, the inner one of which was thoroughly impregnated with the vapour, made by boiling one part of acid with three of water. The little sufferers being then let into the apartment, the inhaler was kept in working order during the time they remained, generally about fifteen minutes; after which the door communicating with the outer room was thrown open. In this latter place, they were kept five minutes, and then, being well wrapped up, were despatched to their respective quarters; a distance which, at the most, did not exceed two minutes' walk. Great relief followed these inhalations; the distressing paroxysms accompanying the cough being especially alleviated; and the parents remarked that a good night's rest invariably followed after they had inhaled. This course of treatment was continued every other day for about five weeks, and proved eminently successful in all but two cases, in which

it caused some amount of bronchial irritation, and had in consequence to be discontinued. During the epidemic, two fatal cases occurred, both having suffered the previous winter from capillary bronchitis, being of weakly constitutions; these two had not inhaled the vapour. Two adult cases came under notice, one aged 28, the other 35. The inhaler used on the occasion was the same as that alluded to by Dr. Lee in the JOURNAL.

RICHARD HARRISON, L.R.C.P.Lond., Dartmoor.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

ST. MARY'S HOSPITAL.

CASES OF INTESTINAL OBSTRUCTION.

(Under the care of Dr. BROADBENT.)

1. *Obstruction of the Upper Part of the Small Intestine by a Band of Adhesion.* (Reported by Mr. G. M. Giles.)—Ed. M., aged 16, was admitted on Tuesday, June 1st, 1875. He had always been a very healthy boy. He came home three days ago from his work, feeling as well as usual, and went to bed at his ordinary time. About four o'clock in the morning, he was awakened by severe griping pains in the abdomen, feeling as if "he was all tied up in a knot". About an hour after this, he began to vomit "green shiny stuff". He had eaten nothing during the day but some corned pork and pie. About an hour after he began to feel ill, he had a stool, consisting of frothy, pinkish, offensively smelling stuff. Since then, he had had no motion, but had been incessantly sick. On Sunday night, his mother gave him a dose of half an ounce of castor-oil. On Monday night, he had two doses (half an ounce) of castor-oil. He had one pill on Monday morning and two doses of a mixture prescribed by a practitioner, which made him more sick. During the whole time he had been in much pain.

On admission, his countenance was anxious; he lay on his back, breathing slowly and regularly with his diaphragm as well as by his ribs. His abdomen was very tender, and marked across by the lines of two or three very much distended convolutions of intestine. Yet, on the whole, it was by no means distended. He was very thirsty, and had passed very little urine since he had been ill. Pulse 112, rather small and hard. Temperature in axilla, 99 deg. Resonance was good in both chests; also breathing. The heart-sounds were normal, but rather weak.

OBSERVATIONS.—The diagnosis, so far as it could be carried, was very clear, and the points of the case are well brought out in the report. First, it was obvious from the total cessation of the action of the bowels and from the vomiting, that there was intestinal obstruction. It was obvious also that the obstruction was high up. The very early setting in of vomiting pointed to this. There may be reflex vomiting in these cases, as in obstruction of the common bile-duct or ureter by calculus; but here it was evidently due to filling up of the intestine above the obstruction by food and secretion, and the short time in which this took place showed that there was no great length to fill, though, no doubt, secretion had been increased, and contraction of the intestinal walls provoked by the purgatives administered. More conclusive evidence of the situation of the obstruction was, however, afforded by a comparison of the degree of distension of the abdomen with the size of individual coils of intestine as seen through the abdominal wall. These were approximately as thick as the wrist; and, had any great length of bowel been distended to such a degree, there must have been extreme general tympanitis, whereas the abdomen was not at all greatly blown out. Further corroboration of the conclusion thus arrived at was furnished by the suppression of urine, attributable to the diminished surface for intestinal absorption. The nature of the obstruction was less easy to make out than the seat, but it clearly did not imply strangulation of the intestine, and was, therefore, probably not hernia: examination, however, was made for hernia, and the rectum was explored with negative results. Had there been strangulation for three days, the collapse would certainly have been greater, especially when the symptoms had been so acute. Peritonitis, again, was excluded, notwithstanding the tenderness on pressure, by the free movement of the abdomen in breathing; the general symptoms, moreover, were not quite such as would have attended inflammation of the peritoneum. There were no indications whatever of intussusception.

TREATMENT.—The question at once arose whether one of the surgeons should be requested to open the abdomen, as everything pointed to a condition capable of relief by operation. Had the only consideration been the risk attending the operation, no hesitation would have been permissible; but the boy had not had the chance offered by opium. Every physician has seen cases in which intestinal obstruction was complete so long as the violent peristaltic action set up by it or by purgatives continued, but in which, when this has been quieted by opium, the passage of the contents of the bowels has been permitted. The circumstances here were not promising, but it was thought right to make the trial. Accordingly, a grain of opium and a third of a grain of extract of belladonna were given in the form of a pill every four hours. Food by the mouth would clearly be of little use, and an enema of beef-tea was, therefore, ordered every three hours; a little brandy being added on the 2nd. The boy was permitted to drink water *ad libitum*, and milk if he wished. He was also supplied with ice.

The further progress of the case is as follows.

June 2nd. He was evidently weaker. He had passed nothing but one or two small pieces of fecal matter with a quantity of fluid from injection. Nothing was found to account for obstruction on examining the rectum. The abdomen was more distended and very tender, and occasionally a sudden contraction, apparently of the upper fibres of the transversalis muscle, caused spasmodic depression in the right hypochondriac region. His face expressed the most intense anxiety. He had passed no urine since yesterday. Pulse 126, small and weak. Hands cold. The pain was less severe, but was increasing again. Temperature 98.4 deg.

June 3rd. He was worse; intensely restless, so that there was difficulty in keeping him in bed. He was decidedly incoherent, and his expression was extremely anxious. Temperature 97 deg.; yet he complained of heat. The temperature of the ward was 72 deg. The extremities especially, and the surface generally, were extremely cold and clammy. The pulse was so feeble that it could neither be felt nor counted at the wrist, and barely at the carotid. The white mark produced by pressure of the hand took twenty seconds to disappear. After a dose of brandy, the pulse could be feebly counted as about 160 in the femoral artery. The abdomen was, if anything, less tense. He had strong priapism. Respiration was good. The urine was slightly smoky in colour, of acid reaction, and of specific gravity 1015; no albumen. At about 3 P.M., his breathing was very embarrassed, 48 per minute. After this, the breathing dropped to about 12 per minute, the previously restless limbs lay helpless, and in a short time respiration entirely ceased, the heart having apparently stopped first. He died at about 4 P.M.

POST MORTEM EXAMINATION.—The body was badly nourished, but well formed. The lungs were very healthy. The heart was normal; the right side contained a *post mortem* clot; the left side was empty. The liver, kidneys, spleen, and brain were all normal. On opening the body, three or four distended coils of small intestine were seen lying transversely across the abdomen, exactly as mapped out during life; below this, both large and small intestines were empty and contracted; one coil of the latter descended into the pelvis. The great omentum was adherent to the parietes on each side by very old adhesions. About five feet from the duodenum, the intestine was found, in the left lumbar region, sharply bent across an old adhesion band between it (the omentum) and a very large old caseous gland about the size of a walnut. Obstruction had taken place here, and the remainder of the small intestine and the entire large intestine were empty, and a considerable length of bowel lay in a cul-de-sac behind the left end of the stomach. There was no strangulation, but the distended portion was deeply congested.

With this case may be compared the following.

Thos. J., aged 52, was admitted February 6th. He had enjoyed good health, and the bowels had been regular till ten days before his admission, at which time a sharp pain suddenly came on in the lower part of the abdomen, and the bowels ceased to act. The pain gradually increased; the abdomen became much distended and very tender; and all food was vomited. The abdomen was enlarged to its utmost extent, and there were general tension and tenderness, with increased hardness in the left inguinal region. The tongue was dry and furred in the centre, clean and red at the edges. Pulse 80, short and sharp; heart-sounds normal. Urine passed freely. The vomited matters were yellow. The rectum was empty; a copious enema of gruel with castor-oil administered soon after admission was retained altogether.

OBSERVATIONS.—Here also there was obstruction of the bowels, without strangulation or peritonitis, either of which would have been ascertained with more urgent general symptoms. The cause could not be ascertained. The obstruction, however, was low down, and apparently in the large intestine, the abdominal parietes being everywhere

put on the stretch by the distended bowel. Purgatives had been given very freely without effect. The treatment now adopted was as follows: Opium one grain, and extract of belladonna one-quarter of a grain three times a day; an enema twice daily; in milk, beef-tea, and beef-jelly as food, with four ounce of brandy.

February 10th. At three days of treatment, there was no improvement. There was great pain in the abdomen, and the swelling and tenderness were the same or worse. He had very little sleep. Pulse 96. Temperature, 99.4 deg. Tongue dry and furred. Urine was passed freely. There was no action of the bowels, the enemata returning uncoloured. The enemata were discontinued; the treatment was otherwise the same.

On the 11th and 12th, the same state of things continued, but the patient was weaker. It was now proposed to aspirate the distended intestine; but, as a preliminary to this, a final exploration of the rectum was made, and feces were felt. An enema, therefore, was given, and a little faecal matter was for the first time brought away, after which, at an interval of six or seven hours, the bowels acted spontaneously and repeatedly, with great relief of all the symptoms.

There were several recurrences of the obstruction, with pain, distension, and tenderness of the abdomen and vomiting; and it was not till March 16th, after more than a month in hospital, that the patient could safely be allowed to leave.

In this case the cause of the obstruction remained obscure. In old people there is often with a daily evacuation imperfect expulsion of the feces, which accumulate and completely block up the lower bowel in some part of its course, most frequently perhaps at the sigmoid flexure, but sometimes higher. This did not appear to be the explanation here; the matters passed when relief was obtained not having the characters of an old accumulation. An instance of this kind was in the hospital in 1872. The patient, aged 72, was admitted on May 30th, having had no action of the bowels for five days. He was vomiting offensive matters; the abdomen was large, tympanitic, and tender, with special pain, tenderness, and hardness in the region of the caecum. The urine was retained, and had to be drawn off by the catheter. Purgatives and enemata had been given without effect, and the rectum was found on examination to be quite empty. A grain of opium was given every four hours; and at length, on the 5th and 6th of June, copious enemata were followed by the expulsion of enormous quantities of hardened feces, after which the patient was well, with the exception of weakness and cough.

HULL GENERAL INFIRMARY.

TRAUMATIC TETANUS: USE OF CALABAR BEAN: RECOVERY.

(Under the care of Dr. LUNN.)

[Reported by Mr. HENRY THOMPSON, House-Surgeon.]

JOSEPH W. S., aged 7, was admitted into the hospital on August 6th, 1875, complaining of stiffness and pain about his jaws. On July 26th, the patient had received a wound on the under surface of his left great toe, from a piece of broken pot, as he was running about the streets barefooted. The hæmorrhage, though profuse, was restrained by some cold water, and a poultice was applied by the child's mother. The wound apparently was healing; and there were no signs of irritation until August 3rd, when the patient was seized with "severe cramp" at the pit of the stomach; and, from the mother's account, he seemed to have been in a condition of opisthotonos, but accompanied by no difficulty of breathing or swallowing. The eyes were staring and prominent, but not suffused; and the patient perspired freely. The attack lasted for about an hour, after which the boy fell asleep; and, next morning, was allowed to run about the streets as usual. The mother, however, noticed that he could not speak distinctly, that he was somewhat bent forwards, and that his face was slightly distorted.

In the evening of this day (August 4th), the patient was again seized with general muscular rigidity, with marked contraction of the facial muscles, increased on attempting to speak, and accompanied by great pain in the abdomen.

On August 5th, the patient had no return of the cramp, and ran about the streets as usual.

On August 6th, the mother was advised to take her son to the hospital, as "there seemed to be something the matter with his face".

Prior to the attack, he had been much exposed to the weather, leading the life of a street Arab, and had been badly fed and clothed. For some months previously, he had been in a delicate state of health.

On admission on the morning of August 6th, it was noticed that he could not open his jaws to their full extent, the angles of the mouth were slightly drawn outwards, and his speech was thick and unintel-

ligible. Still, however, his countenance did not bear the expression of pain, nor was there rigidity of any other part of the body. An unhealed inflamed wound, about an inch long, was noticed on the under surface of the great toe. On the same evening, his bowels being constipated, he was ordered two grains of calomel; and this was followed, on the morning of the 7th, by a dose of castor-oil, but without any effect.

August 7th. He could still partially open his jaw at will, but the abdominal walls were noticed to be hard.

August 8th. At 3 P.M., a drop of croton oil and two grains of calomel were placed on his tongue; and, as the jaws seemed to be more fixed, he was ordered one-twelfth of a grain of extract of Calabar bean and fifteen minims of solution of morphia every two hours. At 10 P.M., an enema of castor-oil and gruel was administered. The administration of this produced a violent attack of opisthotonos, the jaws becoming rigidly closed, and the abdomen becoming as hard as a board. The attack lasted about five minutes, after which the trismus was more marked than it had been previously. The bowels were moved shortly afterwards; owing to some misunderstanding, the extract was discontinued from 11 P.M. on the 8th to 11 A.M. on the 9th.

August 9th. The rigidity of the jaws was more marked, and the risus Sardonius more apparent. The muscles, also, at the back of the neck, and those forming the boundaries of the axillæ and the walls of the abdomen, were rigid; but at no time, except during the paroxysmal attacks, were the feet or hands at all affected. He was ordered the same dose (one-twelfth of a grain) every half hour at 8 P.M.; as he had had a good sleep, the morphia was omitted.

August 10th. He had no severe attack, and was otherwise in the same condition.

August 12th. The patient seemed weaker, and the symptoms had increased in severity. He was ordered to have a quarter of a grain of extract of Calabar bean every half hour, except during sleep; also two eggs and three ounces of wine daily, in addition to the previous milk and beef-tea.

August 13th. He had another paroxysm during the night, waking up and screaming violently. The calomel was repeated, and it operated in four hours; the bowels not having been moved since the 10th.

August 14th. The trismus was less marked. The abdominal muscles were still rigid. The extract was continued in the same dose.

From this date, up to the 20th, he began gradually to improve; and, on the latter day, the Calabar bean was given every hour instead of every half hour.

August 22nd. The abdomen was more flaccid. On the 23rd, he was still improving, and was ordered to take the extract every two hours; on the 26th, every four hours; and, on the 28th, twice a day.

September 3rd. All the rigidity was gone. He could move his jaws freely. He was ordered to take a fourth of a grain of the Calabar bean extract daily.

September 5th. The boy was out of bed. There had been no return of the spasm.

September 8th. The Calabar bean was omitted, and he was ordered meat diet, and a drachm of cod-liver oil twice a day.

September 10th. He was discharged cured. He subsequently attended as an out-patient, and continued well.

Recoveries from traumatic tetanus, if not extremely rare, are, at all events, sufficiently so to render every case worthy of record: especially when, as in the present instance, they present peculiar features of interest. First of all may be noted the large quantity of the extract of Calabar bean taken. During the first three days, he took, on an average, about three grains daily. Then, during the next ten days, he took about ten grains daily. During the next seven, he took about five grains daily; and, after that, the quantity was gradually reduced to half a grain daily. Altogether, in twenty-six days, one hundred and thirty-three grains were taken—a daily average of about five grains. In the *Practitioner* for November 1874, is recorded a successful case in which one hundred and forty grains were taken in eighty-six hours; but the patient in that instance was an adult, and not a child of seven years.

Another circumstance to be noticed is the low temperature which existed during the attack. Only once (on the morning of the 7th) was the temperature 100 deg.; and, after the evening of the same day (when the thermometer registered 99.4 deg.), it was never above normal. On several occasions, it was a degree or more below normal; and, on the evening of the 17th, the thermometer only reached 96.3 deg. Several thermometers were used, in order to see if there might be a flaw in their registration. They had all been registered at Kew, and all gave about the same result. During the greater part of the illness, there was profuse sweating.

One favourable symptom was that the child was always able to swallow freely, except during the two or three paroxysms mentioned. The thorax, also, was never much affected, and moved freely with respiration, the breathing for some days being carried on without the aid of the diaphragm. In spite of the large quantity of the extract taken, it produced no physiological effect upon the pupils until the 13th; and, when the medicine was discontinued for a short time, they soon regained their former rather dilated condition. The extract of Calabar bean was quite fresh, and was obtained from Messrs. Battley and Watts, which was held to be a sufficient guarantee of its purity. The wound on the great toe, which, on admission, was rather inflamed, after being poulticed for a short time, cicatrised naturally.

SELECTIONS FROM JOURNALS.

MEDICINE.

THE OPHTHALMOSCOPE IN INTRACRANIAL DISEASES OF CHILDREN.—L. Heingel (*Fahrbuch der Kinderheilkunde*, vol. iii) in sixty-three cases of intracranial disease in children, found, in forty-seven, affections of the optic nerve or retina, or of both. There were eighteen cases of neuroretinitis; thirteen of neuroretinitis with congested papilla; four of congestion of the optic nerve; four of optic neuritis with congested papilla; two of consecutive atrophy of the optic nerve; six of atrophy (genuine?) of the optic nerve; and in sixteen the ophthalmoscopic appearances were normal. The cases are thus classified according to the disease: In thirty-one cases of tubercular meningitis of the base of the brain—fifteen of neuroretinitis, five of neuroretinitis with congested papilla, four of congestion of the optic nerve, two of incipient atrophy, one of atrophy, and four with normal fundus of the eye; in ten cases of the same disease with tuberculosis of other organs—three of neuroretinitis, one of optic neuritis with congested papilla, three of atrophy of the optic nerve, and four normal; in fourteen cases of cerebral tumour—five of neuroretinitis, two of neuroretinitis with subsequent atrophy, four of atrophy, and three normal; in two cases of œdema cerebri—congestion of the optic nerve. In the remaining seven cases (œdema and hyperæmia of the meninges, sclerosis of the brain, cerebro-spinal meningitis, and effusion in the cord), the fundus of the eye was normal. It was observed that neuroretinitis frequently appeared within a few days, and that in all cases it affected both eyes alike.

RHEUMATOID DISEASE IN DILATATION OF THE BRONCHI.—C. Gerhardt (*Deutsches Archiv für Klin. Medicin.*, vol. xiv) relates two cases to show that, just as puerperal fever may accompany pyæmia, and rheumatic inflammation of the joints gonorrhœa, so rheumatic affections of the joints may attend bronchial dilatation, as soon as the purulent secretion becomes stagnated through imperfect expectoration. In both cases, many joints were affected; and in one there was endocarditis, with consequent mitral insufficiency. He explains the connection between the primary disease and the joint-affection by supposing that the decomposed pus was absorbed and infected the blood. In both cases, expectoration was assisted by compressing the thorax during expiration. The dyspnoea and fever ceased under this treatment. Sphygmographic observation showed that the compression had no influence on the pulse, the arterial systole being prevented. In order to further assist respiration, Gerhardt has applied faradism during inspiration, and has endeavoured to assist expiration by compression.

TRISMUS NASCENTIUM.—Dr. Philip A. Wilhite reports fourteen cases of trismus nascentium and of trismoid, which he distinguishes as the acute and the chronic forms of the disease. The first symptom of trismus is inability to suck. This is pathognomonic of the disease. The child loses the power of seizing the nipple; and if the nipple should be forced between the jaws, it has no power of suction. The child seems to be indescribably distressed, moans, whines, cries, is colicky, sometimes has griping passages from the bowels, is restless, uneasy, sleeps badly, has hiccoughs, slight spasm of one or both upper extremities, then tonic rigidity of the whole muscular system with clonic spasms, which come on at intervals, and are often excited by touch or a noise. The expression of countenance is very peculiar, and can never be forgotten when once seen. The acute form terminates fatally in two or three days, sometimes in less time; while the chronic or milder form of the disease may continue for weeks and even for months—the child slowly wasting away to a mere skeleton, and dying of what was formerly called marasmus, but which is merely another name for gradual starvation. Dr. J. Marion Sims, many years ago, contended that this disease was not traumatic tetanus, but was caused by pressure, generally the result of an inward displacement

of the occipital bone, which always existed at birth, was kept up by the dorsal decubitus, whether in the cradle or the mother's lap, and which could be removed together with the symptoms of trismus simply by adopting the lateral decubitus. Dr. Wilhite cured seven of his cases by position alone, the other seven dying without treatment. He concludes that these cases justify the conclusion that trismus nascentium is the result of mechanical causes: the predisposing causes being protracted or tedious labour, and a too well ossified state of the fetal cranial bones. The exciting cause is undue pressure on these bones, more especially the occipital; while the immediate cause is undue compression of the medulla oblongata and the nerves originating from it. The cases given are all of one general character, and all go to show that the disease is the result of pressure exerted at the base of the brain. In all of them the pressure was produced by an inward depression of the occiput, differing, however, from the slightest to the greatest possible degree.—*The Richmond and Louisville Medical Journal*, July 1875.

PERIODICAL MELANCHOLIA.—Dr. William Suflet, after careful study of numerous cases, has observed that, although repeated attacks of melancholia in the same person are not unusual, yet they are generally very few and very far apart, and, if the patient do not entirely recover, he passes into a permanent state of melancholia, or into some other form of insanity. Loss of flesh invariably accompanies the attacks, and an increase in weight always follows as soon as they are over. The attack always commences with a subacute anæmia. The general anæmia continues during the entire attack, and disappears during the interval. The skin and the mucous membranes are pale; the pulse is small and feeble; the veins, on the contrary, are dilated and distended with blood. These phenomena are also quite constant, and admit of no exception. As regards the treatment of the disease itself, it is necessary to bear in mind that the psychical organ in this state is unable to produce any but painful sensations, and, therefore, all kinds of excitation, all impressions, even pleasant ones, have to be avoided, and the patient must be advised to keep quiet bodily and mentally. A few days' rest in bed is sometimes the most beneficial remedy. Exercise, travelling, admonition, and religious consolations only aggravate the psychical hyperæsthesia. On the contrary, everything that produces relaxation of the vaso-motor spasm and congestion of the brain acts beneficially. Thus, prolonged tepid baths, and, above all, opiates, though only palliatives, often make life endurable, especially in the variety of melancholia with great precordial distress. Other remedies which act similarly may also be tried, as inhalations of ether, chloroform, nitrite of amyl, chloral, etc.—*New York Medical Record*, August 14th, 1875.

INTESTINAL OBSTRUCTION.—Dr. A. B. Copeland reports a case of persistent intestinal obstruction relieved by placing the patient in an inclined position, administering large distensile enemata of warm water, and finally injecting tartaric acid and bicarbonate of sodium, and following them immediately with an injection of water.—*Atlanta Medical and Surgical Journal*, August 1875.

DIET OF INFANTS AFFECTED WITH ACUTE INTESTINAL CATARRH.—Dr. R. Demme, after an extended experience, recommends as the most appropriate food for infants affected with gastric or intestinal catarrh the following diet. Add from a quarter of a pound to a pound of beef, freed of fat, to two quarts of cold water, and let this stand from half an hour to an hour; then boil down to one pint; after cooling, skim off fat from the top, and filter. At each time of using (every two or three hours) without being warmed, this is to be mixed with freshly prepared rice or barley-water. In the intervals of meals, the latter should be given alone, best without sugar, to relieve the thirst. If this food be refused, Dr. Demme gives a drink made with the white of an egg, using, according to age, from one to three eggs in half a pint to a pint of water which has been previously boiled and cooled down to 98 deg. If the child's strength begin to fail, brandy in doses of from five to thirty drops is added to the rice- or barley-water from three to five times a day. With older children, a mixture of milk with the rice-water or barley-water may be tried.—*Boston Medical and Surgical Journal*, August 12th, 1875.

PATHOLOGY.

ABSENCE OF THE CLAVICLES.—In the *Archiv der Heilkunde*, vol. xvi, O. Kappeler describes the case of a girl, aged 16, in whom on one side there was only a rudiment of a clavicle, an inch and a half long, loosely connected with the sternum; and in the other, where also the cleido-mastoid muscle was absent, one only three-fifths of an inch

in length. Both humeri could be easily brought in front of the chest until they touched; and yet there was no functional disturbance, the absence of the clavicles being completely compensated by muscular action, especially as regarded the fixation of the scapulae.

CANCER OF THE THYROID BODY.—In the *Prager Vierteljahrsschrift*, vol. cxxvi, H. Eppinger relates an interesting case of cancer of the thyroid body. The tumour occupied the whole mediastinal space, from the sternum to the vertebral column, and from the jugular fossa to the diaphragm; it was firmly adherent to the sternum, and superiorly was intimately connected with the lower part of the thyroid body, the upper portions of which could still be recognised. It also extended into the lungs in the form of nodules as large as a fist. The heart and large vessels, the lungs and bronchi, and the œsophagus, were compressed. The presence of gelatinous lumps on various parts of the tumour and of gelatinous masses within the epithelial tumour-cells in the neighbourhood of the thyroid, indicated that the tumour originated from this body.

VISCERAL EPITHELIOMA.—H. Eppinger describes, in the *Prager Vierteljahrsschrift*, vol. cxxvi, a multiple finely nodulated tumour of the pia mater of the brain and spinal cord, with secondary deposits in the pleura, lungs, and pericardium. The masses, arising from the pia mater, followed the course of the vessels, and sent small processes, often several millimetres wide, into the brain. The growth was developed from the epithelial covering of the subarachnoid spaces, and from the perithelium of the cerebral vessels; and also (in the secondary deposits) from the epithelioid lining of the vessels.

SURGERY.

CURE OF CYSTITIS BY DILATATION OF THE NECK OF THE BLADDER.—Dr. Howe reports the case of a woman, aged 35, who had for more than a year been afflicted with a chronic cystitis, for which various remedies had been tried without avail. It was decided to try the effect of dilating the neck of the bladder, in order to give the organ a rest and to examine the inflamed membrane. She was placed under ether, and the urethra gradually dilated with Molesworth's dilator until it was large enough to admit a finger. The bladder was thoroughly washed out, and she was then placed in bed and given quinia in tonic doses. She complained of soreness about the urethra, and the urine dribbled from the bladder until the fifth day after the operation, when the sphincter muscle again resumed control. From that time, micturition was performed in a natural manner, without pain or uneasiness, and she entirely recovered.—*New York Medical Record*, August 14th, 1875.

NASAL POLYPI.—Dr. George Troup Maxwell "guarantees" that muriated tincture of iron is a radical cure for nasal polypi. He gives an example in the *Philadelphia Medical Times*. A carpenter had his nares closed with gelatinoid polypi, which always produced a feeling of discomfort, and sometimes considerable pain. The distension was at times very great, and caused some disfiguration. He had used a number of astringents without effect, but had never been able to summon the courage required to submit to evulsion. Dr. Maxwell injected about a drachm of the tincture of iron, reduced in strength one-half by admixture with water, into each nostril, holding his head back so as to retain the fluid in contact with the polyp a few seconds. This simple operation was repeated daily, and on the third day the masses began to slough and to be discharged. At the end of a week, their destruction seemed to be complete; the nares were pervious, and the sense of smell was recovered. The treatment of this case was more protracted than any he had before encountered, three or four days being usually sufficient. The delay in this case he attributed to the impacted condition of the nostrils, which prevented access of the tincture to any but a limited portion of the body of the polypi. As soon as the fluid gains access to the pedicle, the cure is rapid, because the death of the polyp is quickly effected. In this case, the injection was repeated the third or fourth time before the fluid could pass through the posterior nares into the pharynx. The irritation of the nares caused by the dilute tincture is trifling in severity, and of short duration. Dr. Keeder first proposed this treatment in the *Chicago Medical Journal*, September 1859; and Dr. Maxwell contributed three cases to the *St. Louis Medical Reporter*, 1867.

EXTIRPATION OF A TUMOUR OF THE BLADDER.—Dr. Carl Gusenbauer reports the case of a boy, aged 12, who was supposed to have a vesical calculus, but who was discovered by Professor Billroth to have a tumour of the bladder, and was operated upon by him in the

following manner. After the patient was narcotised, the lateral incision for removal of stone was made. The finger introduced into the bladder showed immediately that a tumour nearly of the size of the fist, with an uneven surface, projected from the posterior wall and extended towards the top of the cavity of the bladder. Owing to its size, it was found impossible to extract the tumour with the finger from the perineum. A suprapubic incision was then made, without injury to the peritoneum; and, to give sufficient room, both recti muscles were cut across at their insertion; a transverse incision into the bladder was also made. Professor Billroth soon came to the conclusion, after examination with the finger, that the use of the *érasaur* was not practicable or desirable, as the tumour possibly might be already adherent to the peritoneum, in which case the latter would have been so injured as to delay healing. He therefore decided to tear the tumour with his finger near its base, and to cut out the remainder from the wall of the bladder, after passing a ligature round to check bleeding. The extraction of the torn pieces of the tumour was not so easy, in spite of the large size of the incision, as would have been supposed. In dissecting out the pedicle, it was necessary to turn the bladder partly inside out. It then appeared that the tumour took its origin from the muscular coat of the bladder, but had not attacked the outer coat or the peritoneum. The plan was, in case the peritoneum had been opened, to close the hole with sutures. Two arteries were tied, and the ligatures brought out through the upper incision in the bladder. The wound in the bladder was not closed, but a drainage-tube was drawn through the bladder, and brought out at the incision in the perineum. There was no subsequent difficulty; and, in one month, the patient was discharged, perfectly well. The tumour was found to be a well-marked mixed tumour, principally a myo-sarcoma, but in places a myocarcinoma.—*Boston Medical and Surgical Journal*, July 8th, 1875.

PHYSIOLOGY.

ACTION OF EMETICS ON THE STRIATED MUSCLES.—The observations of Harnack and others have shown that many emetics and nauseants have a paralyzing action on the voluntary muscles. Among these are emetin, apomorphia, tartar emetic, cyclamin, asclepiadin, sanguinarin, delphinin, veratrin, and digitalin. Harnack has also (*Archiv für experim. Pathol.*, vol. iii) made experiments with copper and zinc salts, and some drugs derived from the organic kingdom, in order to ascertain whether this coincidence of effects is constant. But few experiments have hitherto been made on the action of salts of copper. In order to avoid, as far as possible, local disturbances, especially those arising from coagulation of albumen, he used the double oxide of copper and soda. In the frog, copper-salt acted distinctly as a paralyser of the striated muscles. A solution containing from 0.0075 to 0.015 grain of oxide of copper, injected subcutaneously, produced complete paralysis in a few hours; and 0.045 grain produced the same effect in an hour. In rabbits, paralysis of the circulation and respiration, and death, were produced in one case in a few hours after the subcutaneous injection of 0.075 grain of oxide of copper, and in another in a few minutes after the introduction of 0.015 or 0.022 grain into the veins. The striated muscles, especially those of the hinder limbs, completely lost their irritability, so that the strongest induction-current had no effect; there was no dyspnoea, nor convulsions. The pupils were dilated. Similar results were produced in dogs by the injection of 0.0375 grain subcutaneously or into the veins. Vomiting was not produced by this mode of administration; this is contrary to the statement of Orfila, but in accordance with that of Dalezky. Harnack found that the introduction of nine or ten grains into the stomach was necessary to produce vomiting. Of zinc-salts, Harnack used the pyrophosphate of zinc and soda and the valerianate of zinc. The action is similar to that of copper, but less certain. In frogs, the minimum dose required to produce complete muscular paralysis is 0.03 grain of oxide of zinc. In dogs, 6 or 7 grains introduced into the stomach or injected subcutaneously produced vomiting; 1.5 grains injected into the veins caused death. Various other metallic salts which have not a specific emetic property, such as those of lead, manganese, and tin, do not, according to Harnack, remove muscular irritability, unless given in lethal doses. The salts of mercury are not fitted for comparative experiment, on account of their violent local action. Harnack also made experiments on arsenic and colchicin. The former is derived from the root of *Asarum Europæum*, formerly officinal as an emetic and nauseant. In frogs, 0.15 grain given by the stomach had a distinct paralyzing action on the muscles; of colchicin, half that quantity produced the same effect. Harnack does not attempt to explain the cause of the connection between the emetic and paralyzing action of the drugs; but he considers it certain that the two actions have not a causal connection with each other.

BRITISH MEDICAL ASSOCIATION:
SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, OCTOBER 16TH, 1875.

LUNACY IN SCOTLAND.

THE Seventeenth Annual Report of the Commissioners in Lunacy for Scotland, on the condition and management of lunatics and lunatic asylums in that division of the kingdom, is a very elaborate specimen of statistical ingenuity. It may, perhaps, be questioned whether there is wisdom in pursuing with such intricate research the movements during twelve months of 7,936 insane persons, and whether a smaller volume might not have sufficed to convey to us all that it is desirable for us to know respecting madness in 1874 within the region of their research, but no question can possibly arise as to the arithmetical industry of the Commissioners. Perhaps the real secret of the figurative expansiveness and minute detail of their annual manifesto is to be found in the fact, that they have spacious leisure in which to compile it. The inspection of asylums (public and private), workhouses, idiot schools, and prisons in Scotland, occupied seventy-four days in the year to which the report refers; and as two commissioners, who visit singly, undertook that duty of inspection, just thirty-seven days of inspectorial work must have fallen to the lot of each of them. Allowing an ample margin for the time occupied in travelling and for an annual holiday, each commissioner must have had at least nine months for statistical studies; and it is not wonderful that, under such circumstances, they should have indulged freely in the harmony of numbers, and should, consequently, have fallen into some extraordinary vagaries. They have rung the changes on the returns made to them in the most assiduous manner. They have deduced conclusions from very insufficient data, and have apparently forgotten the great truth, now generally received, that manipulated statistics may be made to prove almost anything. They have actually gone so far as to formulate a law as to the exceptional seasonal progress of diarrhoea in asylums, founded upon two hundred and thirty-five attacks of that disorder occurring in one institution during a period of eight years. It will, we are sure, surprise the Commissioners to learn that their own official activity may be statistically shown to be subject to the same law that, according to their great discovery, regulates the prevalence of diarrhoea in Scotch asylums. Diarrhoea and the Commissioners are prevalent in asylums at precisely the same times. In the warmer months—July, August, and September—the attacks of the Commissioners and the bowel-complaint have a decided maximum, expressed with most emphasis in August; and in the colder months, notably in January, there is a second maximum, expressed with comparative feebleness. In the months of July, August, and September, forty-one establishments were visited by the Commissioners, and in October, November, and December, only eight. In January, sixteen establishments were officially afflicted, and in March only one so suffered. But there is a graver and more radical defect in the statistics of the Scotch Commissioners than mere absurdity and riotous profusion: preconceived notions and crotchets seem in some cases to have influenced their construction. Decided opinions have been adopted by the Board upon various questions, and no opportunity is lost of obtaining evidence in favour of the views which have been espoused.

Among the decided opinions which the Scotch Commissioners have

adopted, is one unmistakably hostile to lunatic asylums; and we think it is high time that the attention of the medical profession should be called to the effects of the policy with reference to establishments for the insane which the Commissioners are steadily pursuing. By slow, and, we had almost said, sly disparagement, the confidence of the public in lunatic asylums is being weakened and undermined. By calumnious criticism, asylums are being made to appear costly, clumsy, and inefficient institutions, mere blemishes on our civilisation. By often repeated praises lavished on other methods of providing for the insane poor, asylums are still further discredited; and, by gradual inroads on their essential characteristics, they are being refined away, in the evident but vain hope that they may vanish off the face of the country. The Commissioners are bent on subjugating asylums absolutely to their authority, in order that they may finally, as far as possible, extinguish them. What they dexterously call a widening of the principle of non-restraint is really the abolition of the distinctive features of an asylum. Boundary and airing-court walls are to be levelled, single rooms are to be dispensed with, locks are to be abolished, and very shortly we shall hear that medical officers are expensive superfluities. All this would be excellent if it were only reasonable. The Commissioners would deserve well of mankind if they could do away with the necessity for the incarceration of those who are bereft of reason; if they could relieve the sane from the burden of providing safe custody and treatment for the insane. But is such a result practicable? Has "grim-visaged madness smoothed his wrinkled front" under the charm of phrenological admonitions, so that, instead of "frighting souls" surrounded by every safeguard, it may now "caper nimbly" in any private dwelling? We fear not. We believe that the insane are still full of danger, and that the public safety and their own well-being demand that a majority of them should have their liberty restricted, and should be subjected to constant supervision and careful medical control. We anticipate that before long some atrocious acts of violence, committed by emancipated lunatics in Scotland, will open the eyes of the public to the necessity which exists for maintaining their lunatic asylums, with their medical organisation, intact, and will dispose once for all of the mischievous nonsense talked *ad longam* by a *doctrinaire* Board of Lunacy taking its case in Edinburgh, no member of which has ever had any practical experience in dealing with the insane.

Indications of the effects likely to flow from the policy of the Scotch Commissioners are not wanting even at the present time. The frequency of suicides in Scotch asylums is certainly not creditable to the Commissioners. Of 450 deaths occurring in Scotch asylums in 1874, seven were due to suicide, whereas of 4,180 deaths occurring in English asylums in the same year, only twelve were attributable to self-destruction. This comparison suggests that some Scotch asylums might be none the worse for airing-court walls and trustworthy locks; and the same conclusion is forced upon us by the fact, that 247 patients escaped from Scotch lunatic establishments in 1874. Then, among the nurses and attendants waiting upon the insane in Scotch establishments in 1874, 447 changes took place, ascribable to all kinds of causes, from voluntary resignation to undue intimacy with the opposite sex. Supposing that in these establishments there is, on an average, one nurse or attendant to every thirteen lunatics—and that calculation is within the mark—the startling conclusion confronts us, that the whole staff, male and female, of these establishments must have been changed in the course of twelve months. Surely a service in which so many changes take place must in some way be made exceptionally irksome or dangerous.

But the inconsistency of the Commissioners in matters referring to the administration of lunatic asylums is glaringly apparent in their own Report. On one page, they advocate the removal of airing-court walls, and express warm approval of the employment of 86 lunatics, male and female, out of an asylum population of 129, in farm and garden work during wet and boisterous weather; and, on another, they urge upon medical superintendents the propriety of abstaining from the use of branches of yew in decorating their wards, and of rooting up all labour-

num trees from their asylum grounds. Truly these paternal Commissioners are sometimes slightly contradictory in their injunctions. Let us, by all means, ameliorate the condition of the insane, but let us be guided by common sense in our philanthropic efforts.

It is to be regretted that, in their ponderous Report, the Scotch Commissioners have not given us more exact information respecting the condition of what they call single patients—those pauper lunatics who, to the number of about 1,500, are scattered over the country in private houses. We know that, in asylums where the most vigilant supervision is incessantly kept up, difficulty is experienced in securing the kind treatment, safety, and comfort of the inmates. What, then, must be the lot of those wretched beings who are farmed out in solitary places in the care of persons of a class rather lower than that from which asylum nurses and attendants are drawn, who are practically under no supervision, and who are so mentally degraded that they are incapable of reporting or of recollecting their own grievances? A trifling knowledge of human nature must convince us that some are reduced to a state of slavery, and that others are subjected to hard discipline and cruel privations. The Commissioners have furnished a very complete list of the accidents which happened in asylums during 1874. We much wish that an equally exhaustive record could be supplied of the mishaps that chequered the existence of single patients in that year. In them, however, black eyes, contusions, dislocations, wounds, scalds, and fractured ribs, find no historian; and when they die, there is no inconvenient *post mortem* examination. The Commissioners are quick to find fault with the dietaries in public asylums: would it not be advisable for them to procure some information as to what single patients feed on? They are critical as to the temperature of asylum wards: did they ever take thermometric observations in a hay-loft during a winter's night? They are extreme to mark the delinquencies of asylum nurses and attendants: have they ever ascertained the peccadillos of the custodiers of single patients? Upon many points connected with these single patients additional information is required; and we shall hope to have this defect remedied in future reports.

DEPARTMENTAL OFFICERS OF THE ARMY.

OUR attention has been called to the following War Office order, regarding leave of absence on account of illness to departmental officers of the army. It particularly affects the medical officers of the army now that they are no longer regarded as regimental officers, and have all become departmental officers.

When a departmental officer is sick at his station, whether in hospital or in quarters, his absence from duty on account of sickness will be recorded in the form upon which his pay and allowances are drawn; but no loss of pay or allowances will be entailed by such absence, if duly certified by a medical officer, and if not exceeding one month in duration. This absence on account of sickness need not be included in the period of leave with pay allowed by Articles 442 and 448 of the Royal Warrant of December 27th, 1870, if the general or other officer commanding at the station consider that the circumstances of the case warrant such a concession.

By the first part of this order, a medical officer who may be unfortunate enough to contract disease or injury in the performance of his duties, or who may be prostrated by the effects of an unhealthy climate to which he has been sent, is rendered liable to be further injured by being deprived of his pay and allowances, if his recovery do not take place within the period of one month. By the second part of the order, it is left to the discretion of the general or other officer in command at the station where the medical officer may have been seized with illness or met with injury, whether the absence from duty which his illness or injury has occasioned, even though it may be less than a month in duration, shall or shall not be deducted from the ordinary annual leave of absence to which all medical officers are entitled by the Royal Warrant alluded to in the order itself. A correspondent writing to us from Malta points out that for some time past a severe type of fever, commonly known as the "Malta fever," has been particularly prevalent

there, and that several medical officers have imbibed this fever while employed on duty there, and have been compelled to leave the station in consequence of it. The sequelæ of this fever are rarely recovered from, even under the most favourable circumstances, in less than three months, while they sometimes last much longer. Here is a case, then, in which the Government sends an officer to a station in which he is exposed to the risk of contracting illness of a severe type, and, having contracted it under circumstances entirely beyond his own control, he is then sentenced to loss of pay and allowances, and, it may be, all further leave of absence in addition, unless he recover and return to his duties within one month. As no one does recover, or can return to duty within one month, after being prostrated by Malta fever, the order shows the punishment which is to be meted out to him. The order, it may be noticed, contains no reservation or exception.

But it is not only the hardship of the order which is complained of; the most galling part of it is the partiality and unfairness of its application. It only applies to departmental officers; it does not apply to combatant officers. The combatant officer may have any amount of leave of absence within reasonable limits that is certified by a medical officer to be necessary for the recovery of his health, without losing his pay and allowances; the medical officer himself may not have more than a month without losing them. There are instances of combatant officers in plenty who have had a year's and two years' leave of absence for the recovery of health after illness contracted in the service, without loss of pay, and no one can say but they ought to have it under such circumstances. All that can be said is, that, if one officer doing duty in the public service have it, another ought to have it too; if the captain of a regiment have it, the surgeon attached to the regiment, whose risks and exposures are much greater, ought to have it also.

It has always been a matter of wonder to us why these invidious distinctions are made in army regulations. It is not now as it was in old times, when armies, in a great measure, fed and paid themselves by rapine and force; when the preservation of the health of the troops was unconsidered, and the sick and wounded were left to shift for themselves as they best could. Armies are now refined and highly organised living machines, in which the perfection of every part is essential to the integrity of the whole, in which no one member can be said to be more important than another member. The part on which the regular and systematic supply of food to an army depends, and that on which the preservation of health and cure of disease depend, are as essential to the efficiency and power of a modern army as the combatant part.

We cannot but regard the distinctions which are made in the order quoted above, and in hundreds of other orders similar to it which are issued by the military authorities from time to time, as relics of barbarism, as the mere continuance of customs handed down to us from the days when the fighting man in his armour was everything, and all others attached to an army were only "followers of the baser sort". Irrespectively of the injustice of forcing such distinctions on the differently functioned officers of the army at the present day, it strikes us as very remarkable that the impolicy of the proceeding should not prevent them from being applied to the detriment of the medical officers under existing circumstances. It is a matter of public notoriety that the medical service of the army is anything but popular; that, while an almost unlimited number of applications for the combatant ranks can be obtained, there is a difficulty in maintaining the requisite number of well educated surgeons in the army; and we should naturally have thought that the efforts of the military authorities would be directed, therefore, to rendering the medical branch of the army more attractive. The letters we are constantly receiving from medical officers, not from one station, but from nearly every quarter in which they are employed, sufficiently show that no such purpose of increasing a liking for the service is uppermost in the minds of the military authorities; at least no such view is entertained, if we may judge of intentions by published orders and practice. It is not possible that the prevailing dissatisfaction among the officers of the Army Medical

Department can go on without the usefulness of the department itself being more and more impaired, and, therefore, harm resulting to the public service at large; and we think that those who are invested with power in such matters may well take as a subject for their consideration, how far this objectionable state of things is due to the inequalities in treatment of combatant and medical officers, one of which is embodied in the order which forms the subject of these remarks.

DR. KUNDRAT, lately an assistant of Professor Rokitsky, has been appointed Professor of Pathological Anatomy in the University of Graz.

THE first meeting of the Society of Medical Officers of Health will take place this (Saturday) evening at their rooms in Crane Court, when the new President, Dr. George Buchanan, will read a paper On Some Directions of Scientific Work by Medical Officers of Health.

A MEETING of the Council of Poor-law Medical Officers will be held on Friday evening, October 15th, at eight o'clock, at Crane Court, Fleet Street, to discuss the future policy of the Association, to decide on the action of the Association in reference to the Maunsell Testimonial Fund, and for general business.

DR. SIBSON has been requested to deliver the first of the newly instituted annual series of Harveian Lectures of the Harveian Society of London. He has selected as his subject, "Bright's Disease and its Treatment, considered mainly in Relation with Arterial Tension from Blood-Contamination". The lectures will be delivered on December 2nd and 16th.

A FOREIGN visitor to Vienna recently placed in the hands of Professor Dittel, who had attended him through a severe illness, a sum of 5,000 florins (about £520) for benevolent purposes. With the concurrence of Dr. Hofmann, Director of the General Hospital, Dr. Dittel has applied the money to the foundation of a "Levien foundation for meritorious attendants and nurses in the Allgemeine Krankenhaus", among six of whom the interest is to be distributed half-yearly in equal parts.

A PARAGRAPH in the *Gazette* announces that the Queen has been pleased to give and grant unto William Cormick, Esq., Doctor in Medicine, who is actually employed beyond Her Majesty's dominions, in the medical service of the Shah of Persia, in which he holds the appointment of Chief Medical Officer attached to the heir-apparent to the throne of Persia, her royal license and authority that he may accept and wear the Insignia of the Second Class of the Order of the Lion and Sun, conferred upon him by His Majesty.

THE WORCESTER GENERAL INFIRMARY.

A SPECIAL meeting has been convened for the 29th instant, upon a requisition to the secretary, signed "by seven or more governors", under the rules, to consider the propriety of adding the following words to Rule 59, "But in case of the unavoidable absence of the honorary medical officer and his substitute, the house-surgeon shall attend to the out-patients of such absent officer."

DR. FERRIER'S RESEARCHES.

SOME of Dr. Ferrier's most brilliant experiments concerning the functions of the superficial parts of the hemispheres have lately been tested by counterinvestigations, some of which would seem to militate against the validity of the conclusions which he has drawn. As is now generally known, Dr. Ferrier found, by stimulating the cortical parts of the cerebral hemispheres, that certain spots exist, the excitation of which is constantly followed by definite and characteristic sets of movement. The area occupied by these spots is very small, and definitely circumscribed; and in the brains of dogs, cats, and rabbits, the topography of the active spots corresponds anatomically. All the movements produced are pur-

posive or expressional in character, and are such as we should attribute to ideation and volition. From these facts, he concludes that certain spots exist at the surface of the brain which act as voluntary motor centres, and whose function it is to originate combined movements. Dr. Dupuy made controlling experiments, in which, what he believed to be similar movements were produced by excitation of the cut surface after the removal of the parts containing the centres. These movements, however, Ferrier did not admit to be of the same constant character. With the object of clearing up that uncertainty, Dr. Burdon Sanderson undertook the following experiments, which he has described in a recent paper read before the Royal Society. Having produced some of the most characteristic movements in a cat, he localised the centres; these were found to correspond exactly with Ferrier's results. 1. He then severed the parts containing the active centres by means of a thin knife, without dislocation of the flap from the deeper parts; the centres being now irritated, the same results were produced as before the incision was made. 2. If the incision were made at a lower level, this was not the case. 3. When the flap was removed, spots were found on the cut surface, with the same topographical arrangement, by irritation of which the same movements were produced as in the case of the superficial centres: 4. By a horizontal incision, 10 or 12 millimètres deep, the upper and outer part of the corpus callosum was reached. Excitation of this part produced still more distinctly the characteristic movements; the relation of the active spots remaining strictly the same. From these facts, he concludes, "that the superficial convolutions do not contain organs which are essential to the production of the combinations of muscular movements now in question". This conclusion would at first sight appear to be directly opposed to the leading principle of Ferrier's views; however, this is not so. Ferrier does not pretend that the nerve-fibres which conduct the impressions to the several groups of muscles start directly from the cortex of the hemispheres, but rather from the ganglia at the base of the brain and spinal cord; the cortical centres being concerned merely in the effort of the will in originating the movements, the influence being then transmitted along fibres passing through the medullary substance to reach the corpus striatum. The excitation, in any part of their course, of the bundles of fibres which transmit the influence, is shown by Burdon Sanderson's experiments to be productive of similar effect, and to act as a substitute for the will.

PROSECUTION OF A MIDWIFE FOR MALAPRAXIS.

DR. JULES BERGER, in the *Gazette Obstétricale*, September 20th, 1875, relates the particulars of the examination of the bodies of two patients, which were exhumed twenty-five days after burial, on a coroner's order. Pelvimetritis in the one case, and pelvi-metroperitonitis in the other, were found to be the causes of death. In each case, the soft tissues around the uterus, the vagina, etc., were much bruised and torn, and were gangrenous. The position of the rents was such as to preclude the possibility of the foetal head having been the cause of these injuries. It should be stated that the bodies were in a good state of preservation. Evidence was given to show that the forceps had been employed in both cases, and left in the vagina many hours, during which time the midwife had made frequent attempts to extract the head. On being interrogated, she admitted having used the forceps twenty-four times in thirty labours, and had also performed the Cæsarean section with a razor, *post mortem*, on a patient who died under her care. On being further questioned, she showed the most lamentable ignorance of the most elementary points in the application of the forceps; and when examined with the mannikin, passed the blade over the back of her hand on the neck of the uterus. Other deaths were clearly proved to have occurred from the same cause; and in consideration of these, and of her having practised illegally without usurping the title of midwife, she was sentenced to fifteen months' imprisonment, fifty francs fine for the crime of homicide by imprudence, and ten francs fine for each contravention of the law—twenty-four in all—amounting to two hundred and forty francs, with, in addition, the costs.

POISONING BY RED BERRIES.

THE case of the child Frederick Shed, who, according to the recent verdict of a Surrey jury, met his death "from poison from eating deadly nightshade", requires notice for several reasons. So far as the newspaper report goes, it seems evident that the child was poisoned by eating some berries which were mistaken by him and his elder brother (aged 11) for "hawgaws", by which doubtless they meant the fruit of the hawthorn. This would indicate that the berries were red, and, if so, can have had nothing to do with the deadly nightshade (*Atropa Belladonna*), which, as is well known, has dark blue-black berries as big as a cherry. Have we here, then, another instance of the old confusion of the very distinct woody nightshade (*Solanum Dulcamara*), so abundant in the hedges, with deadly nightshade? This seems very probable; and, if so, the case is particularly worth remark, as death from poisoning by dulcamara has rarely been recorded. Though the young twigs of this plant still remain official in the *Pharmacopœia*, many practitioners believe the drug to be quite inert. On the other hand, dulcamara has been highly extolled by others as a most efficient medicine. Probably the quantity of solanine (which, there is no doubt, possesses narcotic properties) is larger in the berries than in the vegetative portions of the plant. We have no details of the case before us; but Mr. Steele of Richmond examined the stomach *post mortem*, and from his evidence the jury returned their verdict. An examination of a single seed would readily determine the plant eaten, whether, as is most probable, *Solanum Dulcamara*, or possibly *Bryonia dioica* or *Tamus communis*, both red-berried bryonies common in hedges, and both poisonous plants. But deadly nightshade can have had nothing to do with the case, and it is to be regretted that no one connected with it seems to have had a sufficient acquaintance with English plants to point out the mistake.

MEDICAL EDUCATION OF WOMEN.

OUR Birmingham correspondent writes:—It has been already stated that the Council of Queen's College, before giving a decided answer to the deputation which waited upon them with reference to the above subject, requested the opinion of the professors of the College. The latter, at their first meeting, were so equally divided in opinion, that an affirmative resolution was supported by nearly half of those present: eventually, a resolution to confer with the honorary staff of the hospital, before replying to the Council, was carried by the casting vote of the chairman. The conference which was then summoned was somewhat heterogeneous; it included gentlemen who were both hospital officers and college professors, others who were only the former, and others only the latter—for instance, the professors of classics and mathematics. This, perhaps, was not unreasonable, considering that all were interested in the matter, but it is to be remembered in estimating the medical bearing of the result. A resolution was proposed to the effect, "that the staff and the professors were unable"—afterwards altered to "not prepared to give the desired instruction". An amendment to the effect, "that the hospital staff would oppose no obstacle to clinical teaching, if the College Council admitted the said students", was also placed before the meeting. In support of the former, some speakers referred to the moral evils likely to result; others to the pecuniary loss and the probability of a fresh school being opened if professional feeling were offended; but it was noteworthy that almost every speaker said that he had no objection to the medical education and admission of women *in the abstract*, showing certainly a progress in liberal feeling since the debate of two years ago. The example of Edinburgh was quoted as a warning. On a division, twelve voted for the resolution and nine against. This being reported in due course to an adjourned meeting of the college professors, including again a non-medical element, the voting became more decisively in the negative, being nine to three. The professional feeling of the neighbourhood had been found to be much against the admission of women; and in several instances parents offered the fees for new students conditionally only; and others (all medical men, we believe, having already sons in the College) gave

conditional notice of their withdrawal. This should be mentioned, not as evidence that the question was settled by the money considerations (for the deputation had offered to make good any loss), but as evidence of the risk of alienating professional support. There were also difficulties arising out of the amalgamation of the two hospitals, and the formation of a "conjoint clinical board" in the sense that gentlemen felt bound not to force colleagues into a position of antagonism; one hospital being bound by charter to teach college students, the other not being so bound, but yet having taken part in a joint educational board. It was felt, moreover, that Queen's College was now prosperous; but to make innovations without strong and general professional support, was to run the risk of reviving difficulties from which it has only comparatively lately freed itself. We desire to make it clear that in this case there exist special difficulties complicating the general question of female medical education; and that whilst a number of representative medical men have given in their adhesion to it in the abstract, the actual deciders have had to consider more the interests of their institution. This is expressed by the terms of the resolution, to which the College finally agreed, and which was forwarded, with all due courtesy, to the Mayor of Birmingham, as representing the deputation. Concerning the resolution, we have further to remark that it was proposed and seconded by non-medical members of the Council. There were only three non-medical members present, and of these two were clergymen. It has been reported as carried "unanimously", though it would be more correctly described as *nomine contradicente*; inasmuch as a leading medical member, not agreeing, declined to vote. The wording of the resolution, which has not yet been published, was nearly as follows:—"That the Council of the Queen's College, after having conferred with their professors, and with the members of the hospital staffs, are constrained to decline to admit women to the medical classes in Queen's College. Without expressing any opinion on the general question of the medical education of women, the Council find that the difficulties as to their admission at Queen's College are so serious, and the risks so great, that they do not feel justified in imperilling the prosperity of the institution of which they are for the time being the trustees."

MYOPIA AND STRABISMUS.

THE Paris Academy of Medicine has been the arena for a discussion on myopia and strabismus, in which the disputants were M. Giraud-Teulon and M. Guérin. M. Giraud-Teulon, in an important communication, had insisted on the value of the ophthalmologic examination for military conscripts, and, in the course of his remarks, had called attention to the alarming increase of myopia, depending directly on much use of the eye in delicate work. This over-use of the eye plays a great part in the development of the infirmity. The deformities which accompany it are not of themselves hereditary. He called to mind the recorded labours which give the explanation of these facts, especially the well known ones of Donders, his own, and some others. M. Guérin blamed M. Giraud-Teulon for not having stated that there is a muscular myopia due to the retraction of the recti muscles, and that, when these are cut, the disturbances of refraction cease, as M. Guérin has demonstrated in his writings. What M. Guérin has advanced at the present time might have had some semblance of truth in 1841, the time when he first enunciated these opinions, but M. Giraud-Teulon demonstrated to him that his former observations were absolutely without scientific exactness, and that they have been refuted by thousands of observations made by conscientious men of science, who have easily demonstrated the following points. Persons attacked by strabismus are almost always first attacked by disturbances of refraction. Myopia is commonly coexistent with divergent strabismus. Hypermetropia, formerly confounded with presbyopia, is common with convergent strabismus. Myopia and hypermetropia depend on a lengthening or shortening of the posterior segment of the eye, but not on modification of the anterior portions nor of the cornea. The deformities which accompany myopia are progressive, and occupy the posterior segment of the eye.

Children are not born with this deformity, but they may have the tendency to acquire it, and especially under the influence of assiduous work, which develops it rapidly. The muscles of the eye do not make the accommodation; that depends on the accommodatory muscle, the intrinsic muscle of the eye. In order to prevent the development, aggravation, and multiplication of these troubles of refraction, it is important to adopt approved measures of ocular hygiene, and to recommend the timely use of correcting glasses. The facts which have led M. Guérin into error, are cases of difficult sight and of amblyopia, but not real disturbance of refraction.

OUTBREAK OF TYPHOID FEVER ON BOARD THE SCHOOL-SHIP
"CORNWALL."

TWENTY-ONE boys have been admitted into the Seamen's Hospital from the school-ship *Cornwall*, of which nineteen are suffering from typhoid fever. The authorities of the hospital have been obliged to limit the number of patients sent from the *Cornwall*, as, owing to the great pressure at the present time upon the beds at the Seamen's Hospital, it has been thought impossible, or at any rate unwise, to take a larger number of cases. During the present week, many other cases of typhoid have broken out on board the *Cornwall*, all of which have been placed in hammocks on board, and steps have been taken to secure their complete isolation. The authorities of the *Cornwall* have displayed praiseworthy energy in endeavouring to grapple successfully with the outbreak. The number of training-ships in the Thames at the present time, and the frequent outbreaks of fever and other diseases which have occurred on board these different vessels during the past few years, render it imperative that the authorities of those institutions should combine for the purpose of establishing a hospital on shore nearer to their anchorage than Greenwich, to which invalids from these ships could be at once sent. Last year, the authorities of the *Worcester* sent forty cases of scarlet fever to the Seamen's Hospital, many of which were injured by the exposure and change of temperature which their removal to the hospital necessitated. If the managers of these school-ships undertake the control of so many boys of comparatively tender years, they should be compelled to take all needful precautions to insure the perfect health of these children. We hope this matter will be taken up at once by the proper authorities, and that immediate steps will be taken to remove what is at present a great and constantly increasing evil.

CULTIVATION OF CINCHONA IN INDIA.

ACCORDING to the *Indian Medical Gazette*, the total number of plants in the permanent plantations at Darjeeling now amount to 2,765,000, including 2,390,000 red bark, 354,000 yellow bark, and 21,000 hybrid trees. The cultivation of cinchona calisaya has so far proved a failure. This species is much richer in quinine than any other—contains, indeed, according to Mr. Wood's analyses, about 6 per cent. (of its bark) of pure quinine in a total of 7.4 per cent. of alkaloid. The propagation of this plant would, therefore, greatly simplify the process of manufacture, and yield almost pure that form of alkaloid which has commended itself to physicians, on the basis of a vast experience, as the best febrifuge known. The plants grown from seedlings were, however, found, even after a selection of the richest varieties for seeding, to yield a very small proportion of alkaloid and little or no quinine. The propagation of the species is, therefore, in future to be accomplished by means of cuttings, and this method will obviously admit of a slower multiplication of plants. While the cultivation of cinchona calisaya has thus so far failed, that of cinchona succirubra has proved a brilliant success, and that of the other varieties is exceedingly promising. Mr. Wood estimates that the plantations are capable of producing a minimum of 366,000 lbs. of bark yearly, which should yield 12,810 lbs. of alkaloid. He has perfected a process, by means of which this alkaloid can be produced easily and cheaply, and estimates that, after paying a fair percentage on capital, in addition to cost of manufacture, the product can be sold at 12 annas per ounce. This alkaloid consists mainly of cinchonidine and cinchonine. The question is, is this alkaloid, and

is cinchonidine, which is its main constituent, equal or nearly equal to quinine as a febrifuge? The trials which have been already made have given very favourable results; but, under the orders of the Surgeon-General, an extended trial of both cinchonidine and of Mr. Wood's mixed alkaloid is now being made throughout the presidency, and the virtues of these preparations will be thus very thoroughly tested and sifted. The enterprise, which is now culminating in these very promising proceedings, is one of the most benevolent which any Government has ever undertaken, and we most cordially congratulate India on the measure of success which has been already obtained and the greater success which appears still possible.

PANCREATIN.

At the last annual meeting of the American Pharmaceutical Association, a paper in answer to the following query was read by Professor E. Scheffer: "Is pancreatin converted into peptone when it is digested with acidulated pepsin?" The writer stated that he was enabled by his experiments to assert positively that pancreatin, when brought into the stomach, became destroyed; and that it, therefore, could have neither physiological nor therapeutic effect when administered internally.

THE MARRIAGE OF BLOOD-RELATIONS.

DR. HELLIOT has written a very interesting thesis on this subject (*De l'Influence de la Consanguinité*, Delahaye, Paris). In his conclusions, he rejects marriage between blood-relations up to the degree of cousin-german inclusively. The bad effects of consanguinity increase in proportion as the degrees of relationship approximate; and he afterwards cites some cases of incest, whence there originated beings whose cerebro-spinal system was absolutely defective. M. Heliot has taken great pains to show to what extent the partisans of consanguinity have perverted the facts of statistics to their advantage. He has shown that good results may occur in spite of consanguinity, but not as a consequence. The example of the Jewish race, so often quoted, is a bad one, since, according to M. Heliot, there is a remarkable predominance of deaf-mutism amongst that nation, an affection which is the most ordinary result of consanguinity. A defective argument has likewise been drawn from the breeding of animals, since in that instance breeding, by bringing together all the conditions favourable to the development of the individual, specially ends by creating a kind of artificial creature, in which certain excellencies of flesh or of swiftness predominate, but which cannot be considered as a creature worthily representing the qualities of the species. Adverse statistics and the most remarkable figures are to be found in the writings of Boudin, which have been the foundation for nearly all other writers on the same subject. With regard to deaf-mutism, the percentage of it is 18 amongst cousins-german, 37 in marriages between uncle and aunt, and 70 in those between nephew and aunt. In China, where consanguineous marriages are prohibited, Mr. Brown did not meet with any deaf-mutes. Other lesions and defects were met with, but deaf-mutism is the one of which the history is the most striking. Lesions of the cerebro-spinal axis are those most frequently found, and deaf-mutism belongs to them. M. Heliot, therefore, rejects the known observations of anthropologists, which only prove that in certain races no changes have taken place, notwithstanding consanguinity; he also points out that in these cases there is more distant relationship between the married couples than true consanguinity. He admits that morbid lesions in the parents aggravate the probable condition of the children; but, in his opinion, heredity plays but a very secondary part. In fact, whilst paying attention to the other consequences of consanguinity, he specially recalls to mind the facts of deaf-mutism, and observes that deafness scarcely ever shows itself as an hereditary disease. A large part of his work is devoted to the relation of cases which have come within his own knowledge, as well as of others borrowed from various writers. He remarks that individual observation has much value, often more than an inquiry quickly made in a given country. He concludes by deciding that there is no favourable degree of consanguinity. It may doubtless occur that there may

be no consequent change, but it creates a special aptitude, in virtue of which the fruits of these marriages may show change, even if the parents be healthy and vigorous. Civil and religious laws have, therefore, wisely proscribed consanguinity, and the physician ought to advise against these unions, especially in the near degrees of relationship. A decidedly opposite view of the effects of these marriages will be found in the current number of the *Westminster Review*. An article on the Marriage of Near Kin, which is, in fact, a review of a work bearing that title by Mr. A. H. Huth, comes to the conclusion that marriages between cousins should not be discouraged, but that unions between persons of nearer degrees of relationship are inexpedient.

PSYCHOLOGY AND THE NERVOUS SYSTEM.

WE publish in another column a critical letter from Dr. Crombie. Our critic no doubt overlooked the number under the heading "Psychology and the Nervous System", or he would have inferred that what he was criticising was only the first instalment of an article. The evidence which he supposes the writer to have forgotten is given in Nos. 2 and 3. We will reply to his criticisms, however, as carefully as we can. We see no contradiction in the statement that a problem is insoluble, and that it is a problem in metaphysics. Which of the great metaphysical problems has been solved? One of the most recent philosophical writers (Fiske, *Cosmic Philosophy*, vol. i, p. 126) says, "Metaphysics means a set of inquiries beyond the reach of Physics". He is not simply referring to the supposed accidental origin of the word. He says (p. 130) of the disputes of metaphysics, "that they have never led, and can never lead, to anything but an endless renewal of dispute, *in secula seculorum*". He says of the subjective method, by which he means the metaphysical method, that "its eternal impotence is illustrated on every page of scientific error". We are well aware that so distinguished a man as Mr. Lewes now thinks that "metaphysical problems have, rationally, no other difficulties than those which beset all problems". (*Life and Mind*, vol. i, p. 5.) But then he uses the word metaphysics as a name "for the highest generalisations of research"; he coins the new word metemperics, which "detaches from metaphysics a vast range of insoluble problems, leaving to it only such as are soluble". However, as we mentioned in our article (Part 1), Mr. Lewes does not consider the problem of the nature of the connection betwixt mental and physical states an insoluble one. Our reason for dwelling on the distinction betwixt nervous states and mental states is, that they are being continually confounded. Our mere statement that the problem is insoluble would have been, with many, of no avail. Attempts are being constantly made to explain mind in terms of matter. Mind is sometimes said to be a force. The will is said to influence matter. It is absolutely necessary to insist again and again on the distinction. Nor are we singular in doing so, as the quotations and references in our article show. Let us quote further authority on the absolute distinction there is betwixt mental states and nervous states, and on the insolubility of the problem as to the nature of the connection. Laycock says: "Under the guidance of text-books, you will too often meet with useless metaphysics. You will read of 'palsy of the will'; that 'pain excites' this and the other; that 'the mind plays' upon the nerves like a performer on the keys of a piano; and therewith you will be led into fallacies in observation and practice. Now, the changes which, in nerve-tissue, coincide with the evolution of energy or force, always result from the communication of force or energy to the tissue, and never from mere states of consciousness." (*Med. Times and Gazette*, Jan. 14th, 1871, p. 31.) Spencer says: "Though accumulated observations and experiments have led us by a very indirect series of inferences to the belief that mind and nervous action are the subjective and objective faces of the same thing, we remain utterly incapable of seeing, and even of imagining, how the two are related." (*Prin. of Psy.*, vol. i, p. 140.) Elsewhere Mr. Spencer writes: "We can think of Matter only in terms of Mind. We can think of Mind only in terms of Matter. When we have pushed our explorations of the first to the uttermost limit, we are referred to the second

for a final answer; and when we have got the final answer of the second, we are referred back to the first for an interpretation of it. We find the value of x in terms of y ; then we find the value of y in terms of x ; and so on we may continue for ever without coming nearer to a solution. The antithesis of subject and object, never to be transcended whilst consciousness lasts, renders impossible all knowledge of that Ultimate Reality in which subject and object are united." (*Prin. of Psy.*, vol. i, § 272.) It was, indeed, needful for him to urge the distinction as strongly as he could; for, in spite of this and other equally explicit statements, Mr. Spencer has had to declare that the doctrine of Evolution does not involve materialism. Clifford writes (*Fortnightly Review*, Dec. 1874): "The assertion that another man's volition, a feeling in his consciousness which I cannot perceive, is part of the train of physical facts which I may perceive, this is neither true nor untrue, but nonsense; it is a combination of words whose corresponding ideas will not go together." Mill, speaking of colour, says: "Whatever number of hidden links we might detect in the chain of causation terminating in the colour, the last link would still be a law of colour, *not a law of motion, nor of any other phenomenon whatever.*" (*Logic*, vol. ii, p. 4.) Tyndall says: "Granted that a definite thought and a definite molecular action in the brain occur simultaneously, we do not possess the intellectual organ, nor apparently any rudiment of the organ, which would enable us to pass by a process of reasoning from the one phenomenon to the other." These distinguished men urge the distinction, and at the same time insist on the insolubility of the problem as to the nature of the connection betwixt mind and matter. Mr. Huxley, at a meeting of the Royal Society, *à propos* of Ferrier's experiments, spoke to the same effect as Tyndall. Lewes says: "Such is the argument urged in a hundred different quarters." Why do these distinguished men, believing the two things to be associated, urge that the nature of the connection betwixt them is unknown, when they believe also that the problem is altogether insoluble? For the simple reason, that there are some who do not make the necessary distinction, but write confusedly as if psychology and the physiology of the brain were universally agreed upon to be one and the same thing. Mr. Lewes does not belong to this class. To quote a *Westminster Reviewer*, Mr. Lewes "at least knows probably more about philosophy than any living author". Those to whom we refer are those who write as if the distinction had never been made; Mr. Lewes writes, knowing all that has ever been written on the matter. But Dr. Crombie wishes to know why, when, without prejudice to the question advanced, almost any view might be taken of the enigma—the connection, namely, in question—was it made so much of? Why, because we are bound to protect ourselves against the inference sure to be drawn by many of those who ignore the distinction, that we are endeavouring to give an account of mind in terms of anatomy and physiology; whereas our task was the far humbler one of giving some account of the *substrata* of mind. We wished also to urge on those who think the problem soluble, or who see no difficulty about it of any sort, that, supposing they were right, to give a materialistic or even a morphological explanation of mind is not to give an anatomical and physiological explanation; and that a mere materialistic explanation was in effect only a clumsy substitute for psychology. In stating our own opinions plainly, we do not ignore that many will hold other opinions; indeed, we quoted in terms of respect the opinions of G. H. Lewes, who considers the metaphysical problem to be soluble. For the truth of the statement that the unit of composition of speech is a proposition, authority is easily adduced. Dr. Thomson (*Outlines of the Necessary Laws of Thought*) says that the most obvious signification of language is, that "it is a *system* of articulate words". Bain says (*Logic Deductive*, p. 44): "Every portion of knowledge conveyed in language.....takes the form called in Grammar a *Sentence*: in Logic, a *PROPOSITION*." He adds that "A Proposition mentions two things, and is, therefore, made up of at least *two names*." (Italics and capitals in original.) In his *Grammar*, p. 5, he writes: "Speech is made up of separate sayings, each complete in itself, and containing several words; and these sayings are Sen-

tences." Dr. Crombie seems to suppose that the unit of speech is a single word. Bain says (*op. cit.*, p. 5): "A single word does not give a meaning"; and also: "Any complete meaning is a sentence". Again (*op. cit.*, p. 148): "Every sentence consists of two parts: the subject and the predicate." Possibly, however, Dr. Crombie's objection is to the expression "unit of composition". We can give good authority for it, and for the use of it in the sense in which we used it. Herbert Spencer, when speaking of a certain arrangement of afferent, efferent, and centripetal nerves, with a ganglion-cell, calls this arrangement the "unit of composition of the nervous system". Yet it may be that Dr. Crombie only means that he would prefer to take a word as the unit of speech, rather than take as a specimen of the unit of speech the proposition he quotes from our article. He does not know, it may be, what the word "process" can mean in the proposition criticised. We used the word because it not only implies an association of sensory and motor nerves, but a particular fixed order of association which is the order of action. The action of the sensory nerve precedes that of the motor nerve. This is, we admit, contrary to usage; but we should not have thought it possible that the novel use of the word would have led to any difficulty. We are sorry to find, too, that another expression, "experiments of disease", is considered misleading. It may be understood, Dr. Crombie seems to think, to imply that an inanimate agency is an experimenter. It never occurred to us as possible, we confess, that any one could take the expression other than metaphorically, especially as in the sentence containing it we use the expression "the experiments, *properly so called*, of Hitzig and Ferrier." Metaphorically speaking, we do not think there would be any great impropriety in calling the perturbations of Uranus, by which Neptune was discovered, an "experiment made by gravitation". But we do not think either of the phrases "ingenious"; we should have thought them too commonplace for criticism.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

At a special meeting of the Council on Wednesday last, for the election of three Fellows to be members of the Court of Examiners, Mr. J. E. Erichsen was elected in succession to Mr. Henry Hancock, and Messrs. F. Le Gros Clark, F.R.S., and W. S. Savory, F.R.S., were re-elected. We foreshadowed this point by the recent publication of a manuscript letter of Sir Astley Cooper, in which he urged the separation of the functions of surgical and anatomical examiners. The College progresses slowly. It has at length reached Sir Astley Cooper's wise suggestion. Certainly no better selection could have been made than of the eminent surgeon and teacher whom it has chosen.

THE CLINICAL SOCIETY OF LONDON.

THE first meeting of this vigorous Society was held last Friday, when, as will appear from our report of the same at page 509, the papers read were of the usual high interest. The President introduced to the meeting the eighth annual volume of the Society's *Transactions*, and subsequently read the names of some twelve or fifteen gentlemen who had been proposed for membership. The discussion on Mr. Pick's very interesting case of Compound Fracture of Patella, treated by Lister's antiseptic method, was wisely adjourned to the next meeting, when we shall hope to hear the opinions of some of our best surgeons on this most interesting of surgical questions.

THE TREATMENT OF INEBRIATES.

A PAPER on this subject by Dr. Crothers, published in the *Philadelphia Medical and Surgical Reporter*, contains this significant statement. "Since 1848, there have been received at the Albany Penitentiary, under commitment, 24,500 persons, of whom 21,057 confess to habits of inebriety." The Albany Penitentiary has been in existence twenty-seven years. Its reputation has become national, from its strict discipline and excellent financial management. Only one convict has ever escaped; and the earnings of the prisoners over all expenses have been 243,901 dollars; an average of 9,033 dollars per year. In the medical treatment of delirium tremens, which is the most common phase of

inebriety amongst the prisoners, hydrate of chloral is heroically administered. Nutritious food, bathing, and saline drinks, are also resorted to freely. The first thing, after the delirium has in a measure subsided, is to get the patient employed; to occupy his mind. If he be in the hospital, and cannot leave it, he is employed in sorting and covering books, or labelling packages. If he can go out, some work is given him which requires his undivided attention. This constitutes the general course of treatment. The result is that those employed recover rapidly, and but few cases are developed after the prisoners have come here. Those cases which remain in the hospital or cell until complete recovery takes place average from ten to twenty days longer than those treated by the plan last mentioned. Over twelve hundred cases of delirium tremens are noted on the records, with only forty-three deaths, showing how far this general plan has been successful. Full details of the treatment employed, both for male and female inebriates, are given in the interesting paper, from which we quote the general conclusions:

- "1. Experience indicates that inebriates of all grades can be made producers, and to more than earn their cost of living.
- "2. Whether curable or not, in the full meaning of the word, they can all be reformed, benefited, and made industrious for a time; a positive gain to themselves and the world.
- "3. The diseased will and physical force of the inebriate must, for the best results, be guided and controlled by the normal reason of another.
- "4. As in other diseases where perfect obedience to the dicta of the physician is absolutely essential, so in inebriety, submission, restraint, and faith must constitute the first elements of treatment.
- "5. The sharp discipline of prison life is particularly fitted to strengthen and develop the feeble impulses and to control the diseased longings, in which consists the beginning of true reform.
- "6. Labour of body and mind, in a moderate degree, is a powerful aid in breaking up the old channel of thoughts and giving the mind new responsibilities.
- "7. The experience and success of this institution, among the worst and least hopeful of patients, founded on two principles, military discipline and occupation of body and mind, indicate the most hopeful promise of future results.
- "8. The hints embodied in these facts, if carried out practically in an asylum, would be a clearer literal answer than is usually given to the oft-repeated question, 'Can you really cure a drunkard?'"

YET ANOTHER DEATH FROM CHLOROFORM.

WE are indebted to Mr. Johnson Smith for the following report on a further fatal case of chloroform-inhalation, which must be added to the terrible list. On the morning of the 6th of October, a seaman named Robert Summers was taken into the surgery of the Seamen's Hospital, for the purpose of having an operation performed upon him, for the removal of a small superficial sequestrum from the posterior surface of the left thigh-bone near the knee. The patient was fifty-six years of age, stout and muscular, presented no external signs of organic disease, and, beyond a slightly marked arcus senilis, none of structural decay. He was anxious, timid, and very sensitive to pain. During the administration of chloroform, he passed rapidly into the stage of excitement, and then struggled very much for about five minutes. At the end of this period, when he was quiet but not quite unconscious, Esmarch's bandage was applied to the left leg and thigh, and above this the constricting elastic band. Shortly after this had been done, the patient's face became livid, and the respiration irregular and noisy. After the man had been turned over to the left, and the tongue pulled forwards by means of hooked forceps, these symptoms passed off, and the breathing and pulse became good, and the face regained its natural colour. It was then decided that the operation should be done, but that no more chloroform should be given; and after this no other attempt was made to administer an anæsthetic. After the elastic bandage had been removed from the limb, and just as the sinus leading down to dead bone was about to be laid open, the patient, who had previously appeared to be half-conscious, again became livid, and again breathed noisily and irregularly; then, after an interval of a few seconds, both pulse and respiration suddenly ceased. During the following twenty minutes, attempts

were made to restore animation by Silvester's method, galvanism, intravenous injection of ammonia, frictions, and application of cold to the chest-walls, but without the slightest indication of any change in the lifeless condition of the patient. The chloroform in this case was administered by means of a long cone made of flexible material, which was open at both ends. Two doses of chloroform were given, and the total quantity administered did not exceed one drachm. A *post mortem* examination was made on the following day. The body was that of a stout man, and the subcutaneous cellular tissue of the trunk and the peritoneal folds of the abdomen were loaded with fat. The lungs were much congested, but in every other respect quite healthy. There was considerable deposit of fat on the surface of the heart; but the muscular structure of the walls of this organ was firm, ruddy, and of healthy appearance. All the cavities contained much fluid blood. The cardiac valves were all competent and free from deposit. The aorta was atheromatous. The surface of the liver was much puckered, and presented one small pale nodule (syphiloma). The kidneys were granular and contracted. The arteries at the base of the brain had rigid and diseased walls. The arachnoid, especially at the base, was thickened and very opaque. The membranes on the upper surface of the cerebral hemispheres were much congested. Surely these incessant fatalities from the use of chloroform plead trumpet-tongued for the adoption in its stead of what is avouched on high authority to be the safer anæsthetic—ether.

THE MEDICAL SOCIETY OF LONDON.

THE Lettsomian Lectures this year will be delivered by Dr. C. Theodore Williams, on the Influence of Climate in the Treatment of Pulmonary Consumption. The annual oration will be delivered by Mr. Erasmus Wilson, F.R.S. The subject of the essay for the Fothergillian Gold Medal in March 1876, is "Cataract and its Treatment"; and in March 1877, "Pyæmia". Essays competing are to be sent before the 1st of the previous November. The opening meeting of the 102nd Session will be held at the Society's House, 11, Chandos Street, Cavendish Square, on Monday, October 18th, at 8 P.M. The following papers will be read: Dr. Routh, on Hyperpyrexia, viewed specially in its surgical aspect; and Dr. Thorowgood on a Case of Acute Pneumonia.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

THE opening meeting of the twentieth session of this Society was held on Friday, October 8th, at the Royal Kent Dispensary; Dr. John Anderson in the chair. The following officers were elected for the session 1875-76. *President*: J. N. Miller, M.D. *Vice-Presidents*: Thomas Creed, M.D.; J. P. Purvis, M.R.C.S. *Council*: J. Anderson, M.D.; G. Hughes Cable, M.R.C.S.; William Carr, M.D.; William Churton, M.R.C.S.; Ralph Gooding, B.A., M.D.; Frederick Moon, M.B.; W. Lockhart, F.R.C.S. *Treasurer*: Prior Purvis, M.D. *Secretary*: H. K. Hitchcock, M.R.C.S. *Librarian*: J. B. Laundry, L.R.C.P. The next meeting will be held on Friday, November 5th, at 8 P.M., when Dr. Braxton Hicks will read a paper.

MANCHESTER PROVIDENT DISPENSARY ASSOCIATION.

A CORRESPONDENT writes:—The medical men connected with the provident dispensaries here are extremely dissatisfied with the treatment they have received at the hands of the General Council, and with the results of the practical working of the scheme here. A meeting has just been held to consider the recent resolution of the Central Committee deciding to admit friendly societies to the benefits of the provident scheme. It is regarded by the staff of the provident dispensaries, and by most of the general practitioners of Manchester and neighbourhood, as likely to be highly injurious to general practice, and a direct violation of the terms of the original scheme, upon the faith of which the Association received the support of a small section of the profession here. A protest, signed by nearly the entire staff, was sent to the General Council some time since; but, with the greatest infir-

ference to the interests of those concerned, the determination of the Council has been pushed to extremities. Great indignation is felt at the studied disregard of the feelings and views of the profession in this city; and, as a result, almost all the medical men who have given any countenance to a scheme, the principle of which is undoubtedly a good one, have decided to cease their connection with an Association which in other respects is found to offer but a miserable remuneration for an eminently extensive and unceasing expenditure of time and labour. A great deal more in connection with the imperious treatment of the medical men concerned in this movement will be placed before the profession in a short time.

EAST LONDON MEDICAL DEFENCE ASSOCIATION.

UNDER the Apothecaries' Act, this Branch of the British Medical Defence Association recovered, last week, two penalties of £20 each from persons who were illegally practising in the East-end of London. In both cases, registered medical men endeavoured to protect the defendants (one of whom keeps a large druggist's shop) in their practice; and we are informed that their conduct for so doing is to be brought under the notice of the English Branch Medical Council at its meeting in November or December next.

BATTERSEA PROVIDENT DISPENSARY.

THE Committee of the Battersea Dispensary have had under their consideration what steps it was desirable to take to adapt the institution to the altered condition of the parish. After careful deliberation, they have unanimously decided to adopt the provident system. The dispensary was founded in 1844, when Battersea was a mere village; and its regulations are hardly suited to a populous suburb, of which a large proportion of the inhabitants belongs to the well-to-do artisan class. In reconstructing the dispensary upon the provident basis, the Committee have introduced a novel feature. They propose to divide the members into two classes; first, those whose weekly earnings do not exceed thirty shillings; and, secondly, those who are receiving from thirty shillings to fifty shillings. The former class will be expected to pay one penny a week, the latter twopence, with proportionate payments for children. We are glad to see this experiment tried. It is a step in the right direction. There can be no doubt that many of those whom it is proposed to enrol in the second class are as much in need of a system of "sick assurance" as their poorer neighbours.

THE HOSPITAL FOR WOMEN AT NOTTINGHAM.

THIS institution, which has been recently opened, appears to have been started under circumstances which have caused much local professional annoyance. Mr. G. Elder, the surgeon to the Hospital, is reputed to have been the prime mover in the affair; and so quietly was it managed, that, until an announcement appeared one morning in the Nottingham journals stating the fact that a new Hospital for Women had been opened the day before, scarcely a medical man in the neighbourhood had heard that it was likely to come into existence. The members of the profession resident in the town assembled at the dispensary on the 1st instant, to consider the circumstances under which the institution had been established, and to discuss the question whether such a hospital was required at the present time. Dr. Ransom occupied the chair, and twenty-four other gentlemen were present. It was moved by Dr. Hatherly, seconded by Dr. Brookhouse, and carried unanimously: "That, in the opinion of this meeting, the Hospital for Women recently opened in this town is unnecessary and undesirable." It was also resolved unanimously, upon the proposition of Mr. Littlewood and Mr. Ellam: "That this meeting disapproves of the mode which has been adopted in establishing the Hospital for Women, by which existing institutions have been discredited as a justification for founding the new one, and by which the medical officers are appointed without the customary publicity." Twenty-four other medical men resident in Nottingham, forming altogether a large majority of the local members of the profession, have since signified their approval of the foregoing resolutions. We have seen a pamphlet which attempts to

detail the *raison d'être* of the new institution, and which is full of specious reasoning, liable to take with the public, but known to be fallacious by those who are really acquainted with the facts of the case. Thus, insufficiency of accommodation in the wards of the General Hospital, which is almost invariably on the male side, in consequence of the number of accidents happening at Nottingham, has a prominent place assigned it amongst the circumstances which necessitate the new building: whereas women, whose cases are suitable for admission, are scarcely ever sent back for want of beds. Then the statistics of the mortality after ovariectomy in the Samaritan Free Hospital on the one hand, and in five other large metropolitan hospitals on the other hand, are given, to "show that, in a small hospital, results may be obtained which cannot be approached in general hospitals." After which, one is scarcely prepared for the statement that, "at the commencement, it is thought desirable to limit the work (of the new hospital) to the relief of out-door patients". It will be instructive to watch how Dr. Morris, the physician to the new hospital, and who occupies a like position at the General Hospital, will manage to discharge his somewhat antagonistic duties at the two institutions. Can he do it? The medical posts in the new hospital were not thrown open to the whole profession in Nottingham, but were quietly filled, without previous advertisement of any vacancy. A hospital is a public institution; and it is a bad omen when its founders shun publicity in establishing it.

WESTMINSTER HOSPITAL.

A CORRESPONDENT writes:—The appointment of Surgeon to the Westminster Hospital, rendered vacant by the resignation of Mr. Holt-house, seems likely to afford some little excitement to the governors. Mr. Thomas Cooke, who has lately been having some passages of arms with his colleagues, has issued a circular to the governors of the Westminster Hospital, informing them that "it is his painful duty to undeceive them" as to the institution being under their control: and alleging that the affairs are managed by a private and self-constituted body of men. It is rumoured that he will not be nominated a candidate unless he previously resigns the post of assistant-surgeon; and he states in his circular: "My resignation, as thus demanded, in face of the organised opposition which every candidate must now encounter who is not the *protégé* of your medical staff, would be courting defeat; it would be wilfully throwing away the five best years of my life." Certain statements respecting the election and retirement of Dr. Gibb are given as an extract from the minutes of the special meeting of the Council, which are worthy of reproduction. "Dr. Gibb made a statement to the Council wherein he mentioned his desire and intention of retiring in twelve months if his present promotion was not opposed. It was proposed and seconded, and carried, that the *handsome offer* of Dr. Gibb, in the interests of the school, be accepted; and that those present *pledge themselves* not to oppose that gentleman's election." Mr. Cooke goes on to say: "I am now opposed, in my turn, by the selfsame constituted body who opposed Dr. Gibb, and who managed to procure his removal from the hospital without your knowledge and consent." A list of Mr. Cooke's *Tablets*, published October 1875, accompanies the address, together with extracts from the medical journals in the form of reviews. The mode of electing medical officers in some hospitals is still far from perfect; and it is high time that some standard of knowledge, as well as capability of imparting that knowledge, be adopted as the ground of a man's election, and not the uncertain and unsatisfactory method at present in vogue.

SCOTLAND.

THE death-rate of Leith, for the week ending October 9th, is reported at the very low figure of 13 per 1,000.

THE executors of the late Mr. T. B. Campbell of Edinburgh have intimated a legacy from his estate to the Royal Infirmary of £500, and to the Convalescent Home of £250, free of legacy duty.

THE annual mortality report of the borough of Dunfermline shows a death-rate of 22 per 1000, of which nearly one-half were children under five years of age.

IT may interest the friends and admirers of the late Dr. Hughes Bennett to know that an excellent and lifelike portrait of this distinguished physician was painted shortly before his death by Miss R. Solomon; and is now on view at her studio, 12, Fitzroy Street.

UNIVERSITY OF ABERDEEN.

AT the statutory meeting of the University of Aberdeen, held last Saturday, Dr. W. Stephenson of Edinburgh, and Dr. J. W. Smith-Shand of Aberdeen, were formally inducted to the chairs of Midwifery and Medicine, the former in the room of the late Dr. Andrew Inglis, the latter replacing Dr. Macrobin, who resigned in the spring. Dr. Carpenter has written to decline being put in nomination for the Lord Rectorship of Aberdeen University, in consequence of the responsible duties attaching to the office.

THE EDINBURGH POLICE BILL.

ACCORDING to the draft of the Edinburgh Police Bill, which is to be brought forward next session, powers are asked to take over the Princes Street Gardens from the present proprietors, and throw them open to the public, at the expense of the city. By another clause, the Council are empowered to acquire part of the lands of Inverleith, for the formation of an arboretum in connection with the botanic gardens, and to defray the costs out of the police funds. The medical officer of health is to be empowered to have filthy houses cleaned at the expense of the owner or occupier; and disorderly houses may, after a second conviction, be shut up. Touching drainage matters, it is proposed to form the whole burgh into one drainage district, and it is further provided that everything in the nature of watercloset apparatus, sewers, drains, etc., shall, in future, be authorised and constructed by the local authority, and a plan of these be lodged with a public officer, and a register kept, to which access may be had on payment of a fee. As regards existing works, the burgh engineer is empowered to report on any case that involves danger to health, and the local authority to provide proper works at the expense of the owners. Dairies, it is proposed, are to be licensed by the magistrates, the license to be renewed annually on a certificate from the medical officer of health. With regard to infectious disease, it is proposed to enact that notice of every case be given to the medical officer of health, and that any medical practitioner failing to do so shall incur a fine not exceeding forty shillings. These are a few of the provisions which appear among a number of clauses relating to other subjects connected with municipal and police routine.

NEW HOME FOR INCURABLES FOR GLASGOW.

THE new home for incurables from Glasgow and the rest of Scotland, was formally opened on the 6th ultimo by Lord Shaftesbury. It is situated at Broomhill, and is the result of a large bazaar held in Glasgow in March last, at which £14,000 was realised. The site which, including the grounds, is eight acres in extent, is a most suitable one for the purpose, and the house upon it will, at present, accommodate about one hundred persons, but additions will probably be made to it as may be required. It is proposed to establish several cottage homes in connection with it.

IRELAND.

QUEEN'S COLLEGE, CORK.

THERE have been several new appointments at Queen's College, Cork. Among them are those of the professorship of *Materia Medica*, and the professorship of *Anatomy and Physiology*. The latter chair has been filled by the appointment of Dr. Charles, a distinguished graduate of the Queen's University, who for several years has been

demonstrator under Professor Redfern at Belfast. His appointment gives universal satisfaction. (In last week's JOURNAL, it was stated by mistake that Dr. Charles Bell had been appointed to the professorship.) For the first-mentioned chair there were two candidates, Dr. Macnaughten Jones, well and favourably known as a rising physician and contributor to medical literature; and Dr. Matthias O'Keefe, who, for many years, has been connected with the medical teaching of Cork. The latter gentleman has been elected; and though, doubtless, the Senate acted in the best interests of the school, the appointment is not apparently so universally acceptable as the other.

PHARMACEUTICAL SOCIETY OF IRELAND.

THE following gentlemen were appointed Examiners at a meeting of the Council held last week:—Latin, English, and Arithmetic: Edward W. Collins, M.D. Materia Medica and Botany: Walter George Smith, M.D. Pharmaceutical and General Chemistry: H. Draper. Practical Pharmacy: Robert Montgomery. The Examiners hold office for one year, but are eligible for re-election.

MEMORIAL TO THE LATE SIR JOHN GRAY, M.P.

IT is intended by the friends of the late Sir John Gray to erect a memorial to his memory, in testimony to whose ability, scientific knowledge, indomitable energy and perseverance the citizens of Dublin are mainly indebted for an abundant supply of pure water. Subscriptions to a considerable amount have been already received, as the deceased gentleman was respected and esteemed by a very large section of the community. It is not at present determined, we believe, what form the memorial will take; but we hope something better than the usual "statue" will be inaugurated on this occasion.

WATER-SUPPLY OF MULLINGAR.

A MEETING was held last week in the Town Hall, Dr. Dillon Kelly, J.P., in the chair, to consider the subject of a water-supply for this town. Resolutions advocating efficient sewerage and a plentiful supply of pure water were put before the meeting, but the majority of those present rejected each resolution as it was brought forward, although it was stated that the meeting was merely a preliminary one to ascertain the cost of these improvements, and for this purpose the Lord of the Manor had subscribed £50. Explanations and arguments proving useless to influence the benighted residents, the meeting was dissolved; and Mullingar is likely to remain for some time longer one of the filthiest and most defective, as regards sanitary measures, of any town in Ireland.

ULSTER HOSPITAL FOR CHILDREN.

THE annual meeting of the friends of this benevolent institution was held on the 6th instant at Belfast, the chair being occupied by Sir John Savage, J.P. The medical report showed that the total number of patients to whom medical relief had been afforded during the past year was 4,724, almost 1,000 new cases more than during the preceding twelve months. Of these, 638 were treated at their own homes, and 146 were received into hospital for intern treatment. The committee of the hospital have not thought it desirable to set apart an operating-room, or to incur the expense of instruments and appliances, believing that the Royal Hospital is sufficient to meet these demands, and deprecating opposition to any other hospital; only such cases as required hospital treatment for their restoration to health have been received into the wards. After complimentary allusions to the zeal and success which characterised the labours of the medical staff, the meeting separated.

THE MEDICAL SCHOOLS.—The registration of students at the Royal College of Surgeons is not completed at the time of our going to press; but we learn that up to this time the gross number is 1,540. St. Bartholomew's, we believe, stands at the head of the list.

MEDICAL ADVERTISING.

AT a meeting of the East Sussex District of the South-Eastern Branch, held on Wednesday, September 22nd, the following resolution, proposed by Dr. Parsons of Dover (Branch Secretary), and seconded by Sir J. Cordy Burrows, was carried unanimously.

"That, in the opinion of this meeting, the practice of advertising medical books in the public papers is derogatory to the interest and dignity of the profession, and likely to occasion social inconvenience and annoyance, and should, therefore, be abandoned."

CHOLERA IN INDIA.

THE following information regarding the general distribution of cholera in India during July and the first half of August we gather from the *Indian Medical Gazette*.

Bengal.—The disease has greatly subsided, being reported from fewer districts and represented as declining in these. In Calcutta, the registered deaths in July only numbered 31, and the disease has not been much heard of. A few cases occurred in some parts of the twenty-four Pergunnahs district about the middle of July; but the disease was decreasing at the end of the month. Central and Western Bengal appear to have been exempt, with the exception of Hooghly, in which there was a little cholera during the first half of August, and Moorshedabad, where the disease was prevalent from the middle to the end of July.

From Eastern Bengal and Assam, no reports of cholera have come; but the province of Orissa has suffered somewhat severely. The occasion of the outbreak was, as usual, the festival of Juggernath in Pooree. This took place on the 5th of July, and the disease broke out in the town of Pooree and along the pilgrim routes. It was mainly limited to these, but seems also to have prevailed in a scattered way in some of the villages of the interior. The pilgrim routes passing through the adjoining districts of Balasore and Cuttack were also affected. The disease subsided throughout the province as August advanced.

In Behar, the disease has generally been subsiding. In Patna, it was still prevalent in July; but continued to decline throughout that month and up to the 12th of August. In Gya, there was a good deal of cholera prevailing in July, more especially in the west of the district; but it decreased considerably during the first half of August. In Shahabad, the disease had disappeared by the first week of that month. In Sarun, too, it was reported to be but mildly prevalent during the last half of July. There was an outbreak at Deoghur in the Sonthal Pergunnahs early in August; and the disease lingered in the district of Julpigoree throughout the period under notice. In Chota Nagpore, a few cases continued to occur in Hazareebaugh and Singhboom up to the middle of August; and there was a pretty severe outbreak in the Palamow subdivision of Lohardugga throughout July and the first two weeks of August.

Nepal.—Katmandoo has been visited by rather a sharp outbreak which appeared about the middle of July and lasted to the end of that month, reappearing in milder form in the first week of August.

North-Western Provinces.—Cholera still lingers in the districts mentioned in our last number; but it is uniformly on the decrease, and has not affected any city or cantonment with the exception of a few cases among the followers of the 35th N. I. at Cawnpore.

Central Provinces.—The disease has spread and increased somewhat in these provinces. Outbreaks have occurred in the following districts: Belaspore, Raipore, Betul, Bandara, Nagpore, Nimar, Hushungabad, Nursingpore, Wurdah, and Sumbulpore. The disease exhibited a tendency to increase as August advanced.

Central India.—The disease continued to haunt the Bheel villages and prevail in Malwa, but not with great concentration or severity.

Rajputanah.—Outbreaks occurred in Marwar, Ulwar, Tonk, and Kotah in July, but the disease disappeared towards the end of the month, except in Tonk, where it continued to prevail.

Hyderabad.—The disease was very prevalent and severe throughout the entire province during July, but seemed to be decreasing in the early part of August.

Punjab.—Cholera has been extending in this province. The districts affected have been Delhi, Umballa, Jullunder, Kohluk, Hissar, and Simla. The disease was not, however, very intense anywhere, and did not threaten to become so.

The Simla outbreak has now subsided. No details regarding it have reached us. At Dhurnsala also, the outbreak in the 2nd Goorkas has passed away. Among Sepoys and camp-followers, 94 admissions and

36 deaths had taken place between the 3rd and 31st of July. The Sepoys were moved into camp with advantage. A sharp outbreak has occurred in the city of Umritsur: 260 admissions and 99 deaths had occurred between 28th July and 7th August.

LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.

THE Introductory Address was delivered on Thursday, October 2nd, by Dr. EDWARD H. DICKINSON, Lecturer on Comparative Anatomy and Zoology, and Physician to the Liverpool Northern Hospital.

After some introductory remarks, in which he congratulated the school on the circumstance that the meeting which he addressed was presided over by one of the great leaders in the van of scientific progress and improved medical education in this country—Professor Humphry of Cambridge—Dr. Dickinson said that he had intended to take as the text of his address the Times and Writings of Hippocrates. He was led to make choice of this subject, partly from personal taste and some little previous acquaintance with it; partly from the fact that, as far as he was then aware, it had not been similarly utilised of late years; but chiefly from the conviction, which had often forced itself upon him, that far too little knowledge exists as a rule among the younger members, at any rate, of our profession, of its early history and condition, as disclosed to us in the writings of the illustrious patriarch. In August, however, he found that his scheme had been thoroughly anticipated by Dr. Begbie of Edinburgh, in his able and scholarly address delivered at the recent meeting of the British Medical Association. He had been led, therefore, in a great measure to alter his original design, and proposed to give a brief sketch of the state of medicine among the ancients generally. The early history of the healing art and its origin and development as an element of civilisation must, he thought, ever possess the deepest interest for its present disciples, and vast stores of useful information and sound instruction may assuredly be derived from the contemplation of its records. The lecturer then referred briefly to the origin of medicine, and to its existence among the Egyptians, Hebrews, Chinese, Persians, and Hindoos, and the early Greeks. Having given a sketch of the Aesclepiæ, he spoke of Hippocrates, whose birth he regarded as having taken place under happy auspices, occurring as it did at a time when the empire of literature, philosophy, and art in Greece was approaching the zenith of its fame. Among the associations by which he was surrounded in his earlier days, it was, perhaps, the less to be wondered at that the brilliant genius and powerful intellect of Hippocrates should have developed apace, and ripened into that penetrating sagacity and clear judgment which enabled him to free himself from the trammels of ignorance and superstition, and to rise like a star in the dim twilight of barbarism. He found medicine in a condition scarce deserving the appellation of an art; he left it raised to the dignity of a science. Hitherto, the sole guide for practice had been experience and observation of the casualties of disease, and a vast accumulation of traditional data; no attempt had been made to draw inferences from these, or to arrange them into anything like a definite classification. Effects were observed, their causes disregarded; symptoms arrested attention according to their severity, the measures for their relief rested upon the uncertain memories of previous successes, or the vague suggestions of individual caprice. For Hippocrates it was reserved to rescue the name of medicine from the grasp of charlatany, and from a vast chaos of undigested facts to found a new system of practice, based upon the combination of sound reasoning with experience, and upon the true principles of philosophical induction. Hippocrates was wont to recognise the all-pervading presence of some mighty and invisible power, "the hypothesis of a principle", which he denominated "Nature" (*φύσις*). This he believed to be the essential spirit of all vitality, promoting and modifying growth, preserving the functions of the body in health, and tending to restore them when disturbed by disease. Hence, he held that the physician should be nature's minister, and should seek to foster rather than retard her operations. Yet he fully appreciated the frequent necessity for extraneous interference; and, when the exigencies of the case demanded it, his practice was fertile in resource, and prompt and unflinching in action. That Hippocrates was pre-eminently a student of nature, as we in the present day understand the term, is evidenced everywhere throughout his writings, and his descriptions of its varying phenomena, and of many forms of disease, the types of which are but little, if at all, altered in our own day, are singularly apt and distinctive. Hence, we can understand the very close attention he always paid to prognosis, in which he acquired such marvellous skill as to earn for himself the title of the "Oracle of Cos". He fully recognised the importance of prophylactic and sanitary, as well as remedial therapeutic measures, and laid great stress, there-

fore, upon the proper regulation of diet, baths, and exercise. He was apparently the first who drew special attention to the nature of epidemics, and to the influence upon the animal economy of such external agencies as climate, water, and situation; and his treatises upon these subjects (*Ἐπιδημιῶν* and *Περὶ ἀέρων, ὑδάτων καὶ τοσῶν*) display in every line the discernment of their author, and the wonderful accuracy of his observations. As to the knowledge of anatomy possessed by Hippocrates, this must have been very small indeed. It seems probable that he never had an opportunity of dissecting the human body, so that all he knew on this subject must have been gathered from examination of the lower animals. This being so, and with such meagre and insufficient materials at his command, can we cease to wonder at and admire the marvellous genius and sagacity of this man, which enabled him to accomplish so much in his own day, and in many cases to foreshadow truths which were only established long centuries afterwards. Assuredly it may be predicated of Hippocrates that he was—

"One of the few—Nature's interpreters—
The few whom genius gives as lights to shine",

and that as he did more for the science of medicine than any or all that preceded him, so also has he never been surpassed in any after age as a glory and ornament to our profession.

Dr. Dickinson then referred to the sects of the Dogmatists and Empirics, to the influence of Plato and Aristotle, to the school of Alexandria, to the introduction of human dissection and its practice by Herophilus and Erasistratus—who may be regarded as the pioneers of strict anatomical research, to Aesclepiades, Themison, Celsus, Dioscorides, Aretæus, and Galen, to the decline of the Alexandrian school, and to the last of the great schools of medicine in ancient times, that of Arabia and the Saracens. Having given some advice to the pupils of the school as to the manner in which they should pursue their studies, he concluded as follows.

"The history of ancient medicine has doubtless been long familiar to many of my hearers; for others it may, perchance, have had something of the charm of novelty. I have sought to-day—how imperfectly I am but too conscious—in the former case to refresh old memories, in the latter to stimulate attention to the fuller consideration of a subject which is not one of mere curiosity and passing interest, but of real importance and practical utility to every man who seeks to follow his profession in a liberal and philosophic spirit. For, inasmuch as the great object of all history is to deduce from the past instruction for the future, let us not forget that—no less from the fallacious doctrines, rash experiments, and mistaken methods of treatment adopted by our forefathers, than from their diligent researches, faithful observations, and ingenious discoveries—we may learn an invaluable lesson; that so, profiting by their experience, we may accept the true and reject the false, and, avoiding the resuscitation of exploded errors, may arrive at 'sober conclusions in theory, and successful treatment in practice'.

"Finally, I would say that, while I have endeavoured to attach due importance to the achievements of the ancients, I would altogether deprecate the character of a mere *laudator temporis acti*. For I firmly believe that in no department of modern civilisation does what is termed 'the march of intellect and of progress' more strongly exhibit itself than in the recent advancement of medical science. Thanks to the keen spirit of inquiry which is abroad, to the improved means and appliances for diagnosis which we possess, and, above all, to the many able and earnest workers in our midst, the mists are fast clearing away from the pathology of obscure diseases; new and invaluable physiological facts are being daily elucidated; and new therapeutic and operative measures adopted with success. Theories and opinions are, it is true, still too often at variance amongst us, and the proverbial disagreements of doctors continue to afford food for the sarcastic pleasantry of the multitude. But let us hope that, as each year rolls on, while independence of thought and originality of research still retain their vigour, there may be an increasing unity of thought and harmony of action throughout the ranks of our profession—the sure results of a perfected standard of knowledge. So that, still retaining a grateful memory of the good work done by our predecessors, and not ceasing to gather instruction from 'the garnered wisdom of the past', we may be able to re-echo, in no vainglorious spirit, the proud words of that well-greaved Greek, Sthenelus the son of Capaneus,

"Ἡμῶν ἴσ' τοι πατέρων μέγ' ἀμείλικον εὐχόμεθ' εἶναι."*

LEEDS SCHOOL OF MEDICINE.

MR. T. R. JESSOP, Lecturer on Surgery and Surgeon to the Infirmary, delivered the Introductory Address.

After referring to the changes which had taken place in the staff of the school, and of the transference of the chemical class to the York-

* Homer's *Iliad*, iv, line 405.

shire College of Science, the lecturer said that, with all that had been and was being done, the modern system of teaching medical students was very faulty. "Formerly it was required of every one seeking admission to the ranks of the medical profession, that he should complete an apprenticeship of five years; and the custom was to spend these five years under the roof of a busy practitioner, away from all schools and hospitals, where he became initiated into the general routine of practice, gained familiarity with the more obvious properties of drugs, learned to recognise the leading symptoms of the commoner ailments, acquired some dexterity in performing the minor surgical operations, made practical acquaintance with the art of midwifery, and obtained possession of that indescribable quality we name 'tact'. And all this before entering upon hospital work, or the attendance at lectures. Two or three years more were then devoted to systematic school and hospital work, and as if, in consideration of so much time having been spent as a pupil, all test of efficiency were thought to be superfluous, a license to practise was granted after the merest farce of an examination. At the present day, the student is required, first, to give evidence of some proficiency in ordinary school work, and then to spend four years 'in the acquirement of professional knowledge'; after which, and on arriving at the age of twenty-one, he may present himself for examination at almost any of the licensing corporations. With regard to the preliminary examination, there cannot, I think, be two opinions. . . . That the institution of compulsory examinations in classics, mathematics, and general knowledge has already done much to increase the calibre of the average medical student is a fact that must be patent to every lecturer who is old enough to look back upon the times when the translation of a paragraph from Gregory, or from Celsus, was looked upon as the most formidable barrier between the student and the duly qualified practitioner. So far our modern system is in advance of the old. But when we come to examine the curriculum laid down for the guidance of students whilst prosecuting their professional studies, we shall find, I think, that our system is most faulty. Four years of professional study are now considered sufficient to produce a fully equipped and competent medical man! At the age of seventeen a youth may leave school, at twenty-one he may have received authoritative permission to announce himself to the world as ready to undertake the management of all diseases alike! He may throw off all dependence upon others, and accept the full responsibility of the lives of his fellow-creatures. Surely, if this be so, it should be provided at least that these four years shall be well spent. After carefully looking through the regulations of the College of Physicians, the College of Surgeons, and the Society of Apothecaries, which together give the country its chief supply of medical practitioners, I have come to the conclusion that these corporate bodies, in framing their regulations, have been vieing with each other in an endeavour to obtain general incompetency in the candidates for their diplomas, by requiring an acquaintance with such a multitude of subjects—most of them of a comprehensive character—in so short a space of time, as to secure that none shall be effectually mastered. From seventeen to twenty-one, in the opinion of the College of Physicians and Surgeons, a student may imbibe a competent knowledge of anatomy, general anatomy and physiology, chemistry, botany, materia medica, practical pharmacy, forensic medicine, pathology, morbid anatomy, midwifery, medicine, and surgery—I wonder the failures are not more numerous! It says much for the perseverance of the race of medical students, and not a little for the teaching in our schools of medicine, that so large a proportion succeed in giving evidence of having obtained such an amount of information upon so large a number of subjects as to satisfy the requirements of their examiners. One result of this too rapid learning I am sure will follow, viz., that much of what it is considered necessary to know at the time of examination, will thenceforth, without an effort to save it, be allowed to pass away from the memory for ever. Further, the regulations of the two Colleges fail utterly to make provision for anything like a practical acquaintance with disease, as it is met with in ordinary practice. . . . In the manner of our professional studies there is still ample room for improvement. Were I advising as to how a young man should be educated for general family practice, this briefly is the plan I should map out for him. Six years should be devoted to professional studies, commencing at the age of seventeen. The first two of these should be spent in the house, and under the immediate superintendence of an intelligent and successful practitioner, who would undertake to teach him the art of compounding medicines, such minor medical and surgical proceedings as are daily to be seen in his consulting room, and the general routine of his practice. He should be moreover permitted occasionally to visit a few patients, under the guidance, of course, of his master. And lastly, during these two years, he should, by attendance on lectures, by reading, and by studying, make himself thoroughly acquainted with chemistry, materia

medica, and botany. After the completion of his first two years, he should be entered in the usual manner as a student at a medical school, and for the next three years his whole time should be devoted to the duties of the school and the hospital. The first of these would be occupied almost exclusively with anatomy and physiology, the second should include, along with anatomy and physiology, the more advanced subjects of midwifery, surgery, medicine, etc., whilst the third should be given wholly to medicine, surgery, and the whole range of clinical work. During this period there should be no obligation on his part to do anything outside the hospital and the school. Then finally would come the last of the six years—perhaps the most important of all; and during this I would recommend that he return to the house of a well-occupied practitioner, who would be able and willing, under his own guidance, to find him employment in superintending the surgery, visiting patients, and the attendance upon midwifery, leaving him at the same time ample opportunity for perfecting his observation of hospital work. Some such a curriculum as this would do away with the disadvantages by which the students of former days were so heavily handicapped, and would at the same time, if wisely made use of, ensure, with much greater certainty than is the case under our present system, a competent knowledge of every department of our profession." In concluding his address, Mr. Jessop said:—"In having selected and laid side by side, as the subjects of my address, on the one hand some of the imperfections, as I conceive them to be, in the regulations provided for securing the education of our students—imperfections which are the direct offspring of competition amongst the medical corporations—and which, I confess, I have no hope of seeing swept away, except with the corporations themselves; and on the other a synopsis of some of the principal topics which have given occupation to the surgical world during the last few years, I have been actuated chiefly by the desire to point out to you how, by taking upon yourselves to remedy the defects in the curriculum mapped out for you by the examining bodies, you will be best consulting your own interests; and by the hope that in impressing your minds with the ever-advancing character of the work we are all engaged in, I shall be able to create in you a strong desire to keep abreast with all that is being done for the progress of our art. If I have succeeded in these, it will be my happiness to have sown seed which, if carefully tended in the future, will not fail to yield an abundant harvest, to the advantage equally of the patients committed to your charge and yourselves."

SPECIAL CORRESPONDENCE.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

New School of Anthropology.—Proposed Free Medical School.—Prevention of Dampness in Habitations.—Dangers of the Abuse of Alcoholic Liquors.—Lectures in the Faculty of Medicine.

THE recently sanctioned law for the liberty of instruction in France is already bearing fruit, as great and numerous reforms are being effected in the educational institutions throughout the country, both public and private. You are aware that Government had the monopoly of these institutions; but since the new law they are open to private enterprise, the great Universities not excepted, so that any individual, or association of individuals, may now open an University or College independently or in conjunction with the State. We have just had an example of the latter combination in Paris, by the founding of a school of anthropology by that indefatigable and encyclopædic *savant*, M. Broca, who, it will be remembered, is also the principal founder of the Anthropological Society of Paris. Most men have their own *forte*, but it would be difficult to say what M. Broca's *forte* is, for his knowledge is so extensive that I would venture to say there is scarcely a single branch of science that he is not conversant with, or thoroughly master of. He is as an accomplished mathematician as he is a surgeon, and as great an historian as a physiologist—he is withal a great orator. But if he have a *forte* it is certainly anthropology, or, as he terms it, the science of man. The school he has just founded is to form part of the Faculty of Medicine of Paris, and is to be supported by private subscription. The following are the professors appointed to the new school of anthropology, with the subjects of which they to treat; M. Broca, anthropological anatomy; M. Dally, ethnological anthropology; M. de Mortillet, prehistorical anthropology; M. Hovelacque, linguistic anthropology; M. Bertillon, demography and medical geography; M. Topinard, general anthropology; names that will guarantee certain success to the undertaking if it required nothing else but talent. Until now, there has been for all France but one chair of anthropology, viz., that filled by M. de Quatrefages at the

Museum of Natural History attached to the Jardin des Plantes of Paris. Thanks to Professor Broca's personal efforts, to the co-operation of the Faculty of Medicine of Paris, France now possesses six additional chairs of anthropology, which is the crowning act of the learned professor's life-long efforts to raise the science of anthropology to a higher standard than it had hitherto occupied in this country; and, in attaching the new institution to the school of medicine, he wanted to show how intimately connected was a knowledge of anthropology with the art of healing.

Efforts are being made to found a Faculty of Medicine in Paris independent of the Government institution; and, in order to complete the clinical arrangements, the originators of the free school made an application to the hospital board to allow them a certain number of beds in the State hospitals for clinical instruction, but the application was refused.

The salubrity of habitations is a question intimately connected with the public health, and, among the causes of insalubrity, dampness of the walls and floors of lodging-houses may be ranked among the principal. Many plans have been from time to time devised to remedy the evil, such as paper coated with lead, different sorts of cement, asphalt, etc., but with varying success; besides which, these different means have been found too costly and often impracticable. The difficulty, however, seems to have been solved by a M. Sebillé, an architect, who has taken out a patent for his invention, which consists of injecting all ceramic materials, such as bricks, tiles, etc., with the tarry products, resulting from the distillation of coal in the manufacture of gas for lighting purposes. The bricks, etc., thus injected, become perfectly impermeable to humidity. This plan is inexpensive, and easy of application in all countries.

On a visit to the School of Medicine lately, I was attracted to a notice that was posted up on the wall, which rather startled me, as it was on a subject which one would hardly expect to meet with at such a place. The notice was headed, "The Dangers of the Abuse of Alcoholic Liquors". The document is a very curious one, but is, nevertheless, very instructive, and deserves to be posted up on all the walls where alcoholic liquors are drunk. I have not been able to ascertain who the author or authors are, but the document is not official, as it is not signed by the Dean of the Faculty; it has evidently emanated from some temperance or other philanthropic society. After having referred to the physiological and pathological effects of the different alcoholic drinks on the system, the writer describes the dangers of the abuse of alcohol in these terms. "Besides the long list of ailments and actual disease of the various organs, the confirmed drinker is subject to that form of necrosis termed Alcolohism, which is the result of the saturation of the entire system with the deadly liquor; and this impregnation of the system is also manifested by certain indelible signs, and may be read on the very countenance of the patient in the form of the various acnoid affections, redness and thickening of the skin of the nose, and permanent congestion of the conjunctival vessels; the body is covered with boils or carbuncles, and the patient generally becomes gouty. Moreover, it has been proved by experience, that drunkards are more susceptible than others to the influences of sporadic, epidemic, and endemic diseases, such as small-pox, typhoid fever, dysentery, and even cholera, which latter seems to single out the drunkards in its progress through a town or city. Acute diseases are aggravated, and, from being simple curable affections, often become intractable to treatment, or, if the patient be not carried off, the convalescence is indefinitely retarded. As regards surgical affections, the influence of alcoholism is even more marked in these cases; it compromises the cicatrisation of wounds, and the success of operations, and an ordinary wound, whether accidental or otherwise, assumes a much more serious character in a drunkard than in a sober person; the ambulances of the commune furnished sufficient examples of this fact. In a very able report, drawn up by Professor Verneuil on the subject, he cited several cases in which those wounded patients, who were addicted to the use of spirituous liquors, succumbed in the space of thirty hours, and, in many cases, earlier, even before any aid could be afforded." What a terrible warning for drunkards!

The Winter Session for 1875-76 begins at the School of Medicine on November 3rd, and the following courses of lectures will be delivered during that period: M. Gavaret, on Medical and Biological Physics; M. Duguet, on Medical Pathology; M. Sappey, on Anatomy; M. Chauffard, on General Pathology and Therapeutics; M. Wurtz, on Biological and Medical Chemistry; M. Dolbeau, on General Surgical Pathology; M. Le Fort, on Operations and Apparatus; M. Robin, on Histology; M. Lorrain, on The History of Medicine and Surgery; MM. Sée, Béhier, and Lasègue, on Clinical Medicine; MM. Richet, Gosselin, Verneuil, and Broca, on Clinical Surgery; M. Depaul, on Clinical Obstetrics; M. Blachez, on Diseases of Children.

ASSOCIATION INTELLIGENCE.

SOUTHERN BRANCH: DORSET DISTRICT.

THE next ordinary meeting of the above Branch will be held at the Dorset County Hospital, Dorchester, on Wednesday, October 20th, at 4.30 P.M.

Dr. Aldridge will read a paper on the Hygienic Treatment of Disease.
Mr. Ewens: Case of Operation for the Cure of Hypospadias.
Dinner at the King's Arms Hotel, at 6 P.M. Charge 5s., exclusive of wine.

WILLIAM VAWDREY LUSH, Weymouth } *Honorary Secretaries.*
C. H. WATTS PARKINSON, Wimborne }
October 8th, 1875.

SHROPSHIRE ETHICAL BRANCH.

THE annual general meeting of the above Branch will be held at the Lion Hotel, Shrewsbury, on Wednesday, October 27th, at 1 P.M.: President, RICHARD WILDING, Esq.; Vice-president, JNO. RIDER, Esq.

Dinner will be served at 3.30 P.M. punctually, for the convenience of the country members. Tickets, exclusive of wine, 7s. 6d. Members have the privilege of introducing friends, on transmitting their names to the President.

Members intending to read papers, etc., will oblige by communicating their titles on or before the 21st instant, to

JUKES STYRAP, *Honorary Secretary.*
Shrewsbury, October 12th, 1875.

BATH AND BRISTOL BRANCH.

THE first ordinary meeting of the Session will be held at the York House, Bath, on Thursday, October 28th, at 7.15 P.M.: W. M. CLARKE, Esq., President.

R. S. FOWLER, Bath, } *Honorary Secretaries.*
E. C. BOARD, Clifton. }
Bath, September 24th, 1875.

STAFFORDSHIRE BRANCH.

THE second annual meeting of this Branch will be held at the London and North Western Railway Hotel, Stafford, on Thursday, October 28th, at 2.30 P.M. precisely. President, R. GARNER, Esq., F.L.S. The President-elect (H. DAY, M.D., F.R.C.P.) will deliver an address. Dinner at 5 P.M. precisely. Tickets 10s. 6d. each, exclusive of wine.

VINCENT JACKSON, } *Honorary Secretaries.*
RALPH GOODALL, }
Wolverhampton, September 27th, 1875.

BORDER COUNTIES BRANCH.

THE autumnal meeting of the above Branch will be held at the County Hotel, Carlisle, on Friday, October 29th, at 1 P.M.

Gentlemen intending to read papers, or to be present at the dinner, are requested to give notice to the Secretaries.

STEWART LOCKIE, } *Honorary Secretaries.*
JOHN SMITH, }
Carlisle, October 2nd, 1875.

NORTHERN COUNTIES OF SCOTLAND BRANCH: ANNUAL MEETING.

THE annual meeting of the Northern Counties Branch of the British Medical Association was held within Gray's Hospital, Elgin, on Saturday, September 18th. Dr. Ross (Inverness) took the Chair; and, after some preliminary business had been transacted, he vacated it in favour of Dr. Vass of Tain, the President-elect. Dr. Vass delivered an address on the subjects of prospective legislation, treating of such matters as the control of inebriates, cremation, vivisection, and the admission of ladies to the practice of medicine.

Paper.—Dr. ROBERT S. TURNER (Keith) read a paper on the Sanitary Condition of Villages and Rural Districts, which gave important details of the sanitary condition of the locality.

Abnormal Births.—Dr. DUFF (Elgin) read a paper on cases of abnormal births which had occurred in his practice. Two were cases of acephalous births, in one of which the skull from the superciliary ridge round to the occipital protuberance was entirely wanting. In the other, the bones of the skull were rudimentary. In both cases, brain-matter was

There was, further, a strange connection between the disorders; sometimes the chorea appeared first and the rheumatism afterwards. In many cases of chorea there was enfeeblement of mental power, after lasting some time; also a paralytic condition of the limbs. He did not agree with the theory of embolism of the minute vessels of the brain.—Dr. HUGHLINGS JACKSON had found embola in the small arteries of the brain in two cases; but in other cases of death from chorea no embola had been found—as in a case of tubercular meningitis with choreic movements. On the other hand, Dr. Bastian, in three cases, found what he regarded as thrombosis (rather than embolism) of the small vessels of the corpus striatum. The pathology of chorea was still an open question; and clinical as well as pathological evidence must be brought forward. Embolism did not lead to anæmia, but to hyperæmia, and a greater supply of blood to the nerve-cells. Red softening was due to plugging of the vessels. Prevost and Cotard had found that the injection of tobacco-seeds into the carotids of dogs produced obstruction in the arteries of the brain. In retinal embolism, there were extravasations in the neighbourhood of the vessels. He thought that embola could produce the appearances described by Dr. Dickinson. As to fright, he believed that it was an exciting cause, not acting unless there were some predisposition. Dr. Barnes had said that, if embola were the cause of chorea, they must have an unerring instinct leading them to the middle cerebral artery. Now, tobacco-seeds injected into the carotid went mostly to the middle cerebral; and embola were rarely met with in other arteries of the brain. Surely the frequent occurrence of rheumatism and endocarditis with chorea was in favour of the theory of embolism. When chorea occurred in adults, it was generally in puerperal women; and, if hemiplegia were met with in these, we should not hesitate to say that there was thrombosis. There was a difference of opinion among authors as to whether hemichorea more affected the right or the left side. He had found, in 20 cases, that the right side was affected in 14 and the left in 6. It was sometimes argued that, if chorea depended on physical changes, patients would not recover so readily as they do. But there is no plugging of the large vessels; and patients have recovered from lesions sufficient to cause not only chorea, but also hemiplegia—and this in spite of a great part of the lesion remaining. He referred to a case of recovery from hemiplegia in which, at the person's death some years afterwards, several convolutions were found affected, and a part of the corpus striatum destroyed. The absence of symptoms during the existence of lesion might be explained by compensation. There was a resemblance between hemichorea and hemiplegia, both in the parts affected and in the order in which they were affected. The early affection of the face was opposed to the view of the seat of the disease being in the spinal cord. He believed the corpora striata to be the seat of the disease.—Dr. DICKINSON, in replying, pointed to the symmetrical character of the morbid changes as an argument against the theory of embolism.

CLINICAL SOCIETY OF LONDON.

FRIDAY, OCTOBER 23rd, 1875.

SIR WILLIAM JENNER, Bart., M.D., D.C.L., F.R.S., President,
in the Chair.

New Volume of the Society's Transactions.—A copy of the eighth annual volume of this series was presented by the President to the meeting with the remark that, if not quite so bulky as some of its predecessors, it was yet full of valuable papers, and especially rich in good illustrations.

A Method of Performing Iridectomy for the Improvement of Sight.—MR. BRUDENELL CARTER read a paper on this subject. He commenced by referring to the cases in which it was desirable to excise a portion of the iris in order to make an artificial pupil, on account of opacity of the central portion of the cornea or of the crystalline lens; and mentioned the disadvantages attendant upon an iridectomy of the ordinary shape, which extended too far towards the ciliary border of the iris, and uncovered too much of the margin of the crystalline lens, thus diminishing the acuteness of vision by spherical aberration of the rays of light. He described the best attainable artificial pupil in such cases as a V-shaped opening; its base continuous with the natural pupil, and its apex directed towards the ciliary border of the iris; and mentioned the endeavours of Mr. Bowman and of Dr. de Wecker to make such an opening; the former by passing a knife under the iris, and cutting it against the cornea; the latter by thrusting one blade of a pair of scissors between the lens and iris, and the other between the iris and cornea, and cutting a slit in the membrane by closing them. The slit made by either of these methods would gape to the desired extent; but the author condemned both methods as being dangerous,

and very liable to produce traumatic cataract or dislocation of the lens. He pointed out that, if Dr. de Wecker's scissors were introduced closed into the anterior chamber, through a small opening in the corneal scleral margin, and suffered to expand, the iris would rise in a little plait between the blades, and that this plait would be excised by closing them, leaving the pupil which was wanted. The piece excised remained on the upper surface of the closed blades, and was readily withdrawn with them, aided by the final outflow of aqueous humour, or might as readily be removed from the anterior chamber by fine iris-forceps, from which the teeth had been filed away. The author had operated in this manner upon thirty eyes in sixteen patients, with no mischance except the production of traumatic cataract in the second eye operated upon; and he believed that such an accident would be effectually guarded against by directing the blunt extremities of the scissor-blades forwards towards the centre of the cornea. Four patients, each operated upon in this manner in both eyes, were present for exhibition to the Society, but only one of them was introduced into the meeting-room; in this case, the patient (a boy) had blue iridid, and the new pupils were well shown. As compared with other methods of making an artificial pupil, the author claimed for this the important merit of simplicity. After the first puncture was made, a single instrument was introduced once into the anterior chamber, was opened, closed, and withdrawn. The iris remained *in situ*; was neither seized, twisted, or dragged out of the eye, and had no opportunity of contracting any adhesions with the external incision. After a small amount of practice, it was not difficult to regulate both the breadth of the piece removed and its extent towards the periphery, and thus to obtain an artificial pupil of the best shape, of determinate size, and in any position which might be desired, with a minimum of injury or disturbance to other parts of the organ. It need hardly be said that, for the relief of tension, the operation would be almost, if not altogether, valueless. (*Went down to journal*)

MR. A. T. NORTON inquired if the operation were advised for nebulous cornea only, or for retinal affections as well.—MR. SPENCER WATSON remarked that, from the diagrams exhibited, it would appear that the operation was designed to give a pupil as near the pupillary margin as might be, to avoid the spherical aberration which rays of light received in passing through a pupil situated near the edge of the cornea. The same result might be attained by making the pupil upwards and inwards. Good results followed this plan, if the cornea were in its usual position in the eye. The object of doing iridectomy upwards and inwards was to make it less displeasing to the patient, the artificial pupil in that position being less noticeable than if made elsewhere. But in some cases the cornea was opaque in that situation; then, of course, the new pupil could not be made in that direction.—THE PRESIDENT remarked that the advantage claimed by Mr. Carter for his method was the mode of removal of the iris rather than the situation of the incision.—MR. CARTER said that was so. Very often good results were attained by the plan mentioned by Mr. Watson; but there was no choice of positions when the opacity covered all but one small part of the cornea.

Idiopathic Tetanus.—Dr. SOUTHEY gave particulars of this case. The patient, a railway ticket-collector, well nourished, aged 21, came into St. Bartholomew's Hospital. Fourteen days previously, he had remained for some hours in wet clothes, two days after which tetanic symptoms had supervened, and had been treated, without apparent improvement, by moderate doses of chloral. On being seen at St. Bartholomew's, he was sensible, able to move his arms, unable to move his legs, and had trismus. His skin perspired profusely. Temperature, 100 deg.; pulse, 120; respirations, 40. The muscles of certain regions felt hard and were tender. Attacks of opisthotonos, lasting from two to five minutes, came on about every hour. The bowels were confined; the urine was scanty and high-coloured. Fluid food only had been given. The treatment after admission consisted of one pill of calomel and opium, followed by a mixture of bromide of potassium (one drachm) and conium juice (two drachms), to be taken every three hours. Stimulants were discontinued, and the diet consisted only oficed milk alternately with beef-tea. Great quietness was enjoined. The skin of the body was hyperæsthetic, and exposure to draughts of air excited the tetanic spasms. For the first three days, the bowels did not act, and the spasms increased in violence and frequency. He was then ordered thirty grains of compound jalap powder, to be repeated every three hours until the bowels acted, and he was to be put into a bath, temperature 98 deg. Three doses of the powder had to be given; after the bowels were opened, the trismic spasm was lessened. On the fifth day, the bowels acted four times copiously. Temperature, 98 deg.; pulse, 120; respirations, 30. On the sixth day, three attacks of tetanic spasm occurred. After this date, the patient steadily improved, and no further spasms were observed. No wound or splinter could be found upon the patient's body after most diligent search. The

invasion of the disease, as well as its declension, was gradual. The improvement coincided with the evacuation of the bowels. Purgatives have been highly commended in tetanus, the normal peristaltic action of the intestines being invariably arrested so long as the spasms are severe and continuous, and returning coincidentally with the cessation of the spasms. But Dr. Southey did not think this indicated the administration of purgatives, which he considered might produce damage, precisely as excitation of the cutaneous nerves was harmful. He had given the compound jalap powder, almost against his own will, when perhaps the bowels would have been naturally opened without its aid. The tepid bath was employed daily, sometimes for nearly an hour, and had a marked tranquillising effect. Bromide of potassium was commenced only on the thirteenth day of the illness. If cases of tetanus survived this date, they often recovered; but the drug seemed to be specially indicated physiologically for the disease. Dr. Wood had recorded the results of its administration in sixteen cases, nine of traumatic tetanus (all of which recovered), and seven of idiopathic tetanus, with five recoveries.

The PRESIDENT inquired what was the usual result of tetanus when it had already lasted twelve days, at which date, in this instance, the bromide had been begun. He thought that, if patients suffering from tetanus were alive at the fourteenth day, they began about that time to recover.—Dr. SOUTHEY assented to that statement.—The PRESIDENT also remarked that the quantity of succus conii which had been given was much larger than the quantity administered to Dr. Southey's patient.—Dr. BURNEY YEO said that Dr. J. Harley had given two ounces before attaining decided effects.—Dr. CAYLEY said that no symptoms were produced by doses of less than an ounce in a case of torticollis in which he had prescribed the remedy. He had given as much as two and a half ounces for a dose.—Dr. JULIAN EVANS mentioned a case in which a patient suffering from tetanus was immersed for a fortnight in a warm bath, and recovered.—Mr. EASTES asked where the statement was made that nine cases of traumatic tetanus treated by bromide of potassium had all recovered. The effect of the drug in those instances was very unlike the usual effect of medicines in tetanus.—Dr. SOUTHEY stated that the statement was made by Dr. Wood at page 280 of his work on *Materia Medica and Therapeutics*.—Dr. BURNEY YEO remarked that the results in those nine cases certainly differed from the results obtained in this country. He thought that Dr. Southey had rather undervalued the treatment by purgation. A friend of his had treated a case by injecting chloralhydrate subcutaneously, and found that no result was produced, unless sufficient were given to produce a small abscess at the point of injection. After recovery, the boy was covered with the scars of hundreds of abscesses. Just as in that case the counterirritation of the skin produced by the drug had appeared to lull the spinal cord, so he also thought purgatives might be useful by acting as irritants of the intestinal canal, thereby perhaps drawing away from the spinal cord some of the impressions which would otherwise excite it.—Dr. SOUTHEY remarked that the records of the temperature were in the paper, but that the thermometer was never very high in this case. The worst cases of the disease were those in which the temperature was high. He had read Dr. Wood's paper, and had determined beforehand to try the bromide in any suitable case. At the same time, he was sceptical of the value of any one kind of treatment. As regarded Dr. Yeo's statement, he (Dr. Southey) thought that good was likely to result from the action of calming rather than from that of irritating agents applied to the peripheral nerves. Cold should be strictly warded off, and for this reason perhaps the hot bath had been employed. If the extreme irritability of the surface were allayed, the patient's recovery seemed to be helped. If bromide of potassium did diminish the irritability of the spinal cord, one could understand the benefit to be derived from its use. Did not purgation usually follow rather than precede the commencement of the improvement? In other words, was not the return of peristaltic movements in the intestinal canal amongst the earliest signs of abatement of the disease?

Salicylic Acid as an Antiseptic.—Mr. CALLENDER brought forward a series of cases illustrating the use of this agent as an application to wounds. The acid was used in various ways, and the three following preparations were the ones chiefly employed:—*a.* Phosphate of soda, 3 parts; salicylic acid, 1 part; water, 50 parts. *b.* Salicylic acid, 1 part; olive oil, 49 parts. *c.* Salicylic acid, 1 part; bicarbonate of soda, half-a-part; water, 100 parts. In addition to these, however, it was occasionally used combined with borax, or in the form of an ointment with prepared lard; and a preparation of the acid with mastic and spirits of wine was tried, but had to be abandoned by reason of the irritation caused, as it was thought, by the ingredients combined with the acid. Seven cases in which the acid had been employed were narrated. In three of the cases, a vesicular eruption was caused by the

acid, and necessitated its withdrawal. In one case, it was followed by considerable local irritation, which was relieved by the withdrawal of the acid. In a case of excision of the elbow-joint for strumous disease, the wound was washed out with salicylic acid, and was dressed with solution "a" on Japanese paper. There was considerable discharge from the wound, and the granulations were pale and flabby; the dressing after a time was changed to carbolic acid, when the granulations became florid and the discharge was reduced to a minimum. In the remaining two cases, the wound healed rapidly under the application of salicylic acid. From these cases and from other observations, Mr. Callender arrived at the following conclusions. Putting together its good points, he found that salicylic acid was free from odour, and so far was acceptable to the patients; that wounds healed under its influence, and, during the progress of the repair, were free from bad smells; that, unless strong with spirit, or but little diluted, it did not cause local pain. Its bad points seemed to be these: that, above the strength of 2 per cent., it caused local irritation, with some constitutional disturbance; and, if the patient had a delicate skin, even the weak preparation was a source of trouble; that there was more discharge from a wound dressed with salicylic than there was where carbolic acid was used; that its influence upon a recent wound, as after an operation, was not so efficacious against the occurrence of decomposition as was that of carbolic acid, chloride of zinc, or of boracic acid; that the repair of a wound was less active, and the granulations, if any, were more flabby than when other simple or antiseptic dressings were employed. On the whole, while admitting its use as a local application to be fairly commendable, Mr. Callender thought it inferior in its antiseptic properties to other agents, and did not consider it to be a remedy meriting the strong recommendations which had been given it by some of those who had made trial of it.

The PRESIDENT remarked (in the absence of Mr. Callender) that, from the paper, it would seem that the vesicular rash in the case in which its appearance was noted was local only, and occurred solely where the acid came into contact with the skin. He himself had seen a lady with a large burn dressed with salicylic acid, in whom a good deal of constitutional disturbance and a general rash, very similar to the rash of scarlatina, had been produced by the dressing with the acid. After a time, the rash returned, when the same dressing had been resumed. He could not find that the surgeons who had principally used the acid had noticed any rash to follow its employment. The rash in his patient had been quite general; it covered the face and all parts of the body. The dressing quite destroyed all fetor; there was no smell at all from the wound, which was a very large one.

Extensive Wound of the Knee-joint treated by Lister's Antiseptic Method.—Mr. PICK reported the case. The patient, aged 18, a sawyer by trade, was working a small circular saw by means of a treadle, when his knee came into contact with the saw, causing a severe wound. When he was admitted into St. George's Hospital, there was found to be a longitudinal wound in front of the left knee-joint, four inches in length, and with jagged and lacerated edges. The wound had completely divided the patella, and extended some distance into the left condyle of the femur, producing a groove about an inch in depth in this bone. There were several fragments of bone and cartilage lying loose in the wound. The two halves of the patella were widely separated from each other, and the interior of the joint freely exposed. The patient was an apparently healthy man, and was reported to be temperate in his habits, and it was, therefore, determined to make an attempt to save the limb. Every part of the wound, including the interior of the joint, was first carefully sponged with a solution of carbolic acid, and all the loose fragments of bone and cartilage were removed. The edges were then brought together with cat-gut sutures. Just before the last stitch was tied, the interior of the joint was injected with a solution of carbolic acid of the strength of 1 in 40. The wound was then dressed with carbolic oil, silk, and shell-lac plaster, and put up in a swing cradle. During the progress of the case, for some days there were some febrile excitement and free discharge from the wound. The pus, however, was perfectly natural, and free from odour. About fifteen days after the accident, a large abscess formed on the outer side of the thigh, some distance above the joint; this was opened, and discharged freely. Throughout the time that the man was in the hospital, the discharge, though considerable, was never in the slightest degree offensive; and, after the first few days, there was no fever and no pain. At one time, he became somewhat low and emaciated from the free suppuration, and required a considerable amount of stimulants. Five months after the accident, he was discharged with a firmly ankylosed joint. Now, three years after the accident, he was strong and hearty, and stated that he enjoyed good health. There was firm bony ankylosis of the joint, and he was quite strong on the limb, and able to earn his living as a stoker at a gas factory. Mr. Pick remarked that cases of compound fracture

of the patella had received but scant notice in our ordinary text-books of surgery, most of them dismissing the subject with the remark that such cases required immediate amputation; but that the admirable and exhaustive paper of Mr. Poland, in the fifty-third volume of the *Medico-Chirurgical Transactions*, had put the matter in a new light. And it was in consequence of the cases there narrated, that he had determined to make an attempt to save the limb. His principal object, however, in bringing forward the case was to elicit the opinion of members present on the value of the so-called Lister's antiseptic dressing. Mr. Pick stated that he had the very greatest confidence in its efficacy, not so much because it retarded suppuration and hastened union, as that it promoted healthy suppuration and prevented decomposition of the pus. He was of opinion that the reason that some had not found any sufficient good from it was, because they had not been sufficiently particular in their manner of using it.—The discussion upon this paper was adjourned to the next meeting.

CORRESPONDENCE.

MORTALITY FROM RICKETS.

SIR,—Dr. Corfield, in his Introductory Address at University College on the 4th instant, quoting Sir William Jenner, says: "First among preventable diseases, I will place one, the mortality from which, in London at least, is so great as beyond question to swell largely the death-rate of children under two years of age; and yet one that has no place in the Registrar-General's Returns. I mean rickets, the English disease, as it was formerly called."

In a "supplementary table of causes of death" in the annual report of the Registrar-General the number of deaths from rickets has been returned for nearly twenty years. On reference to this table, it will be found that, during the five years 1859-63, there were 324 deaths in England from rickets; in the following five years, the number rose to 535; and further increased to 731 during the years 1869-73. In proportion to one million persons living at all ages, these numbers were 16.1, 25.0, and 32.1 in the three periods respectively; the great and rapid increase shows the urgent necessity of following Sir William Jenner's advice as to the teaching of practical laws of health being made compulsory in all schools supported by the public money. The children now being taught should have no excuse for perpetuating the evils resulting from improper food, from deficient light, and from air insufficient in quantity, and therefore soon rendered impure and unfit for respiration.—I am, sir, your obedient servant,

Forest Hill, October 12th, 1875. GEORGE RENDLE.

ON PLASTIC OPERATIONS.

SIR,—Seeing that you have opened your columns for the discussion of this subject, permit me to say, that I happened to see the case referred to in Dr. Wolfe's paper in the JOURNAL of the 18th instant. I, in common with others who watched the case, and saw it nearly a month after the operation, could not help being struck with the remarkable result so readily obtained. It appears to me that Dr. Wolfe's method of performing plastic operations does away with the need for skin-grafting, when one can get such skin-flaps, cut to shape, to adhere so nicely by first intention. I think, however, that Dr. Wolfe has scarcely done justice to the merits of his case. Indeed, it would not be easy to do so. Such a case requires to be seen to be duly appreciated. I noticed the omission of one interesting step in the demonstration; namely, having made the last flap larger than was requisite, he cut it to shape, and, after adjusting the portion required, he replaced the superabundant piece on the forearm, where it adhered perfectly without loss of cuticle even. Dr. Wolfe seems to have endeavoured to compress the result of various experiments into a few sentences, whilst I am sure a more detailed account would have been highly interesting.—

Yours faithfully,
Glasgow, September 25th, 1875. J. W. BEATTIE, M.D.,
Army Medical Department.

PUBLIC HEALTH

AND

POOR-LAW MEDICAL SERVICES.

THE NEW ADULTERATION ACT.—On October 1st, the Sale of Food and Drugs Act (38 and 39 Vic., cap. 63), passed last session, came into operation. It repeals all the Adulteration of Foods Acts hitherto passed, and contains severe penal clauses with respect to the adulteration of food and drugs. Any person mixing or colouring any

article of food with any ingredient injurious to health, with the intent that the same shall be sold in that state, shall be liable to a penalty of not less than £50 for the first offence, the second to constitute a misdemeanour, for which a person convicted shall be liable to be imprisoned for any period not exceeding six months, with hard labour. By Section 4, the same penalties apply to persons mixing drugs with injurious substances, except for the purposes of compounding and selling the same. Under a penalty not exceeding £20, a seller is prohibited from selling any article of food or drug which is not of the nature, substance, and quality of the article demanded by the purchaser, with certain exemptions as to preparations of food, etc. A penalty not exceeding £20 is incurred by any person who, with the intent that the same shall be sold in its altered state without notice, abstracts from any article of food any part of it so as to affect injuriously its quality, substance, or nature. By Section 12, power is given to the proper officers to purchase articles of food, etc., for analysis; and Section 17 imposes a penalty not exceeding £10 upon any person refusing to sell an article of food for that purpose. The forging or uttering of a false warranty is made punishable by imprisonment with hard labour for any term less than two years. Labels stating that articles are mixed will give protection to the seller. By Section 30, special provision is made for the examination of all tea imported, giving power to the Commissioners of Customs, in case the tea is mixed with other substances or with exhausted tea, to deal with it as they think proper, or have it destroyed.

POOR-LAW MEDICAL APPOINTMENTS.

ROBERTS, Arthur, M.R.C.S. Eng., appointed Medical Officer of the North District of the Keighley Union, vice T. H. Cockcroft, M.D., resigned.

MILITARY AND NAVAL MEDICAL SERVICES.

MEDICAL CONSCRIPTION.

FRENCH students who have not yet satisfied the military law by entering as "aide-major" in the army of reserve or territorial army, have received a final warning from the Minister of War, that, failing such inscription, they will be incorporated as private soldiers in the various regiments on whose books their names are already entered.

COMPULSORY SERVICE OF MEDICAL CADETS.

A GOOD many French naval medical cadets (*aides médecins de la marine*) have, it seems, tendered their resignations after obtaining the degree of doctor, with a view of entering upon medical practice. This is contrary to an engagement which they sign on entering the navy, to serve for ten years after obtaining the degree of doctor. Admiral Montaignac has issued an order announcing that, in future, such resignations will not be accepted. It will be remembered that a late Board of Admiralty had prepared a similar scheme of naval medical cadetships for the English marine service, with a like view to insuring the bondage of naval medical officers during a fixed period, however unpalatable the service might be. The BRITISH MEDICAL JOURNAL obtained cognisance of this scheme, after its approval by the heads of the service, but just before its promulgation. The strength of our protests against such a scheme, and the result of our communications with the leading students in the Metropolitan medical schools, brought about a series of meetings in the schools, and raised such a storm of angry protests in anticipation, that the scheme was never officially promulgated, but was forthwith consigned to limbo, whence we trust it will never be disinterred. The French authorities will, we believe, find in the end that the best way to make their medical service efficient is to make it popular and attractive. Compulsory bondage is a very poor way of recruiting officers, and can never supply men of high character or having the *esprit de corps* and the ambition which are the soul of efficient service.

EUROPEAN SOLDIERS' CHILDREN IN INDIA.

A PORTION of the remarks on the excessive mortality of soldiers' children in India, and the means of reducing it, made in our leading article of the 18th ultimo, receives an apt and practical illustration from the subjoined extract, for which we are indebted to the *Madras Times*.

Bangalore is a large military station in the Madras Presidency, situated on a plateau three thousand feet above the level of the sea. Speaking generally, we are disposed to think that double this altitude would produce a race of recruits even superior to those referred to, and of whom Bangalore has so much just reason to be proud. But he this as it may, we are at one with our contemporary, in thinking that, as a matter of State policy, this question of rearing our soldiers' sons in healthy hill climates in India, with a view to their ultimate enlistment in

the army, has not received by any means the amount of attention it merits. It is fortunate that the obvious and proper mode of dealing with the subject of recruit-breeding, by the removal of the families to the mountain ranges, is identical with that which should, and we hope will be, adopted to prevent the enormous mortality by which our soldiers' children on the plains of India are now, one year with another, literally decimated. "Only the other day, we saw it stated that the 45th Regiment and Royal Artillery at Bangalore, had obtained several excellent recruits from among young men born and bred at that place; and there is certainly no reason to suppose that the sons of our soldiers, reared upon the Indian mountains, should not make as good and valuable soldiers as their sires, if duly cared for. Let the Government, we say, calculate the cost of a British soldier as he lands at Bombay from London, and then estimate the expense of rearing a soldier's India-born child on the Indian hills, and we are much mistaken if the one charge, all things considered, would not be much the same as the other. For the Indian boy, apprenticed as it were to the Government, would, at an early age, be taught some useful trade, and could be made to turn his labour to the Government advantage, as, for instance, in ordnance work, cartridge manufacture, and so on. Let the Government further take into consideration the difficulty of obtaining recruits at home, as well as the kindness it owes its soldiers, as a great employer of military labour; and we think it will be admitted that, although the State has done much, it has not done all it might do to cherish these poor little waifs for the service of the country in the future."

NAVAL MEDICAL APPOINTMENTS.

BIDDULPH, Surgeon R. W., to the *Euphrates*.
HART, Staff-Surgeon Mark A., to the *St. Vincent*.
MASON, Fleet-Surgeon G., to the *Undaunted*.
MITCHELL, Fleet Surgeon John F., to the *Penelope*.
MOORE, Staff-Surgeon Francis H., to the *Newcastle*.
NEWLOCK, Surgeon Edward R., to the *Teeser*.
PULSEY, Surgeon W. H., to the Haulbowline Hospital.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, October 7th, 1875.

Boswell, Alexander, Disraeli Road, Putney
Johnstone, William, Seaford, Liverpool
Low, Frank Harrison, Aberdeen House, Blackheath

The following gentlemen also on the same day passed their primary professional examination.

Reeve, Henry, London Hospital
Roberts, Henry William, Guy's Hospital

At the Preliminary Examination in Arts, held at the Hall of the Society, on the 24th and 25th September, 1875—145 candidates presented themselves; of whom 32 were rejected, and the following 113 passed, and received certificates of proficiency in general education—viz., in the First Class, in order of merit:

1. F. S. Pridden. 2. C. Filaby. 3. A. V. Bernays, F. C. B. Butler, J. F. Easmon, S. de Cardonnell, E. Elmsall, P. Garrard, C. J. Harper, W. L. Preen, F. C. Selous, C. L. Stow, E. G. Williams, and G. J. Wilson.

In the Second Class, in alphabetical order:

C. D. Adams, J. B. Adams, R. A. Bazire, D. Bennett, E. J. Biden, R. A. Biddall, A. Bosanquet, H. Bourcheier, J. L. Bousignac, P. Brown, C. G. Bunn, H. P. Butler, S. Butterworth, J. F. Caddy, J. A. Caldwell, G. H. Capes, H. W. Carr, W. I. Clarke, E. S. Cockell, W. S. C. Collins, C. A. R. A. Colmer, E. R. Cree, W. H. Crosse, H. W. T. Crow, B. H. Dale, E. Davies, J. D. Davies, W. J. S. Davis, P. H. Day, B. J. Dorrian, J. M. Douglas, J. B. Dreaper, H. W. Edis, F. W. Elliott, E. Evans, F. Farmer, S. Farmer, W. A. Fenton, J. W. Field, H. E. B. Flanagan, C. L. Gill, G. T. Girdler, P. Hall, J. Hammond, E. Hazel, N. Hildyard, F. Hitch, W. Holt, A. R. Jacobs, F. Jones, G. M. Jones, R. B. Knowles, T. L. Laxton, F. R. Le Cocq, A. Lee, J. J. Lewis, R. Lewis, J. P. Little, E. H. Lucker, L. Mark, L. Matheson, G. McKee, E. J. Moberly, Peter Monti, H. Parsons, W. H. C. Payne, J. H. Powell, L. Prentice, F. W. Prideaux, J. D. Priest, T. Rhodes, J. T. Richards, J. M. Rogers, C. Rowley, R. F. Shaw, W. F. Sicard, G. E. Skinner, A. Slate, W. Slater, S. Smyth, A. Sharland, W. C. Steele, H. H. Sturge, C. A. A. Taylor, A. B. Thorald, F. F. Thorne, A. W. Veness, A. J. Verrall, J. E. Viney, J. Waldron, A. Ward, G. B. Waterhouse, F. S. Watson, J. G. Webb, W. S. Webb, J. Whitehouse, R. J. P. Wilson, O. Withers, and F. Woore.

MEDICAL VACANCIES.

The following vacancies are announced:—

ASTON UNION—Medical Officer for the Sutton Coldfield District.
BELLINGHAM UNION—Medical Officer for the Second District.
BLOOMSBURY DISPENSARY—Surgeon. Applications on or before the 20th instant.
BOARD OF WORKS, ST. GILES'S DISTRICT—Medical Officer of Health. Salary, £150 per annum. Applications on or before the 23rd instant.

BROOKWOOD ASYLUM, near Woking—Second Assistant Medical Officer.
CHARING CROSS HOSPITAL—Dispenser, Salary, £100 per annum, and luncheon. Applications on or before the 20th instant.
CHRISTCHURCH UNION—Medical Officer for the Eastern District. Salary, £100 per annum, and fees. Applications on or before November 6th.
COUNTY TIPPERARY INFIRMARY—Surgeon. Salary, £100 per annum. Applications on or before the 16th instant.
DENBIGHSHIRE INFIRMARY—House-Surgeon. Salary, £35 per annum, with board, lodging, and washing. Applications on or before the 16th instant.
DONCASTER INFIRMARY—House-Surgeon. Salary, £100 per annum, with board and lodging. Applications to be made on or before the 18th instant.
DORSET COUNTY HOSPITAL—House-Surgeon. Salary, £70 per annum, with £10 additional as Secretary. Applications on or before the 20th instant.
EAST RETFORD UNION—Medical Officer and Public Vaccinator for the Leventon District. Salary, £30 per annum, and fees.
GLOUCESTER COUNTY ASYLUM—Junior Assistant Medical Officer. Salary, £80 per annum, with board, lodging, and washing. Applications on or before the 18th instant.
HASLINGDEN UNION—Medical Officer for the Accrington District. Salary, £60 per annum.
HOSPITAL FOR SICK CHILDREN, Great Ormond Street—Physician.—Assistant-Physician. Applications on or before the 28th instant.
HOSPITAL FOR SICK CHILDREN, Manchester—Assistant Physician. Applications on or before the 27th instant.
MIDDLESEX HOSPITAL—Two Resident Physicians' Assistants, and One Resident Obstetric Assistant. Applications on or before the 30th instant.
NEWCASTLE-UPON-TYNE UNION—Medical Officer for the First District. Salary, £50 per annum.
NORTH SHIELDS AND TYNEMOUTH DISPENSARY—House-Surgeon and Dispenser. Salary, £120 per annum, with furnished house, gas, coals, etc. Applications to be made on or before November 1st.
PEMBROKE UNION—Medical Officer for the First District.
RICHMOND INFIRMARY—House-Surgeon. Salary, £80 per annum, with board and lodging. Applications on or before the 25th instant.
ROYAL FREE HOSPITAL, Gray's Inn Road—Junior Resident Medical Officer. Applications to be made on or before the 27th instant.
ROYAL ISLE OF WIGHT INFIRMARY, Ryde—House Surgeon and Secretary. Salary, £40 per annum, with board, lodging, and washing. Applications on or before the 25th instant.
ST. GEORGE, HANOVER SQUARE, PROVIDENT DISPENSARY—Physician-Accoucheur. Applications to be made on or before November 3rd.
ST. SAVIOUR'S UNION, Surrey—Dispenser at the Southern Dispensary. Salary, £120 per annum. Applications on or before the 18th instant.
SETTLE UNION—Medical Officer and Public Vaccinator for the Bentham District. Salary, £40 per annum, and fees. Applications on or before the 19th inst.
STOCKWELL FEVER HOSPITAL—Temporary Assistant Medical Officer. Salary, £3 per week, with board, lodging, and washing. Applications, with testimonials, to be made at 3 o'clock on the 22nd instant.
STROUD GENERAL HOSPITAL—House-Surgeon.
TIVERTON INFIRMARY and DISPENSARY—House-Surgeon and Dispenser. Salary, £100 per annum, with furnished apartments, coals, gas, and attendance.
TORRINGTON UNION—Medical Officer for the Peters Marland District. Salary, £4:3 per annum.
UNIVERSITY COLLEGE HOSPITAL, London—Surgical Registrar. Applications on or before the 19th instant.
WESTMINSTER HOSPITAL—House-Physician. Applications on or before the 26th instant.
WEST SUSSEX, EAST HANTS, and CHICHESTER GENERAL INFIRMARY and DISPENSARY—House-Surgeon. Salary, £80 per annum, and £20 per annum as Secretary, with board, lodging, and washing. Applications to be made on or before the 23rd inst.
WORCESTER GENERAL INFIRMARY—Physician. Applications on or before the 23rd instant.
WORKSOP DISPENSARY—Resident Surgeon. Salary, £120 per annum, with furnished apartments, coal, gas, and attendance.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

BROWN, Walter, L.R.C.P., appointed House-Surgeon to the Royal United Hospital, Bath, *vice* E. S. Greensill, M.R.C.S.Eng., whose appointment has expired.
*CASSAN, Theodore, L.R.C.P.Ed., appointed House-Surgeon to the Royal South Hants Infirmary, Southampton, *vice* F. C. Clark, M.R.C.S.Eng., resigned.
FOSTER, William, Esq., of Sidney Sussex College, Cambridge, elected to the Lectureship on Chemistry in the Middlesex Hospital Medical School.
HEALE, Alfred Lawson, M.R.C.S.Eng., appointed House-Surgeon and Secretary to the Royal Hants County Hospital, Winchester, *vice* W. R. Smith, L.R.C.P.Ed., resigned.
PINK, Thomas, M.R.C.S.Eng., appointed Resident Surgeon to the Royal Seabathing Infirmary, Margate, *vice* O. R. Richmond, L.R.C.P., deceased.
PROCTER, Thomas, M.R.C.S.Eng., appointed Resident Medical Officer to the York Dispensary, *vice* W. A. Mawson, L.R.C.P., resigned.
RENNY, Archibald W., M.B., appointed Resident Medical Officer to the Royal Stirling Infirmary, *vice* A. Purves, M.B., resigned.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the communication.

MARRIAGES.

THOMSON—COX.—At Beechwood, Inchee, on the 6th instant, by the Rev. A. B. Connel, M.A., William Thomson, M.D., of Peterborough, to Jessie Methven, only daughter of George Addison Cox, Esq., of Invertostrachs, Perthshire.
WOODMAN—ALLEN.—On October 9th, at St. Mark's Church, Torquay, by the Rev. John Sawyer, M.A., *John Woodman, F.R.C.S., of Exeter, to Catherine Louisa, second daughter of the late Rev. John Allen, M.A., Rector of North Huish, in the County of Devon.

OPERATION DAYS AT THE HOSPITALS.

- MONDAY** Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.
- TUESDAY** Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.
- WEDNESDAY** .. St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Erompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.
- THURSDAY** St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 3 P.M.
- FRIDAY** Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.
- SATURDAY** St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M. and 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

- TUESDAY**.—Pathological Society of London, 8.30 P.M. Dr. Cayley; Hydatid Cyst of the Liver which burst into the Lung. Dr. Crisp; Fractured Bones of Gorilla. Dr. Crisp; Rickets in Young Pheasants. Dr. Peacock; Supra-renal Capsular Disease. Dr. Peacock; Ulcer of Stomach. Mr. Heath; Calculi of Cystic Oxide. Mr. Heath; Epithelioma of Tongue and Jaw. Dr. Dawse; Subarachnoid Hæmorrhage of Cord. Dr. Dowse; Thrombosis of Internal Carotids. Mr. Butlin; Uncommon Form of Carcinoma of Breast. Dr. Greenfield; Tumour of Anterior Cerebral Artery. Dr. Hilton Fagge; Carcinoma Lipomatousum of Kidney. Dr. Barlow; Tubercle of Pancreas.
- FRIDAY**.—Clinical Society of London, 8.30 P.M. Adjourned discussion on Mr. Callender's "Cases of Treatment of Wounds with Salicylic Acid," and Mr. Pick's "Case of Treatment of Wound of Knee-joint with Carbolic Acid"; Mr. T. Holmes, "On a Case of Ligature of Femoral Artery with Carbolised Catgut"; Mr. Haward, "Case of Lymphadenoma"; Dr. Murchison, "Case of Acute Cancer of the Liver, with Pyrexia, in a man aged 24"; and "Case of Abdominal (Hepatic?) Abscess without elevation of Temperature".—Quekett Microscopical Club (University College), 8 P.M.

NOTICES TO CORRESPONDENTS.

- CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.
- PUBLIC HEALTH DEPARTMENT**.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.
- AUTHORS** desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.
- CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.
- WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**
- COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.
- A PROVINCIAL STUDENT**.—The next primary and pass examinations for the diploma of membership of the College of Surgeons will take place respectively on the 6th and 12th of the ensuing month, and the first and second Fellowship examinations on the 19th and 25th respectively. See our advertising columns.

DEATH FROM CHLOROFORM.

- SIR**,—With reference to the case of death from chloroform commented upon in last week's JOURNAL, I beg to state that I am not the "Dr. Jones" that administered the chloroform, as I find several of my friends supposed. I feel called upon to remove any misapprehension on this point, as I have so very strongly condemned chloroform in the JOURNAL as an anæsthetic.—I am, etc., THOMAS JONES, 19, Chapel Street, Belgrave Square, S.W., October 12th, 1875.

RAPID DESTRUCTION OF THE LUNG.

- SIR**,—In reading Dr. Cowling's case of total destruction of the right lung, I was reminded of a similar one which occurred some time ago in the practice of a friend since deceased. The patient, a young woman, had been ailing, as she said, for some months previously to coming under my friend's care (about two weeks before her death), and had complained of pain in the right chest, with great lassitude and debility. An attack of acute pleurisy came on in a very few days after my friend saw her, and an amount of effusion quickly followed, as was for the first time diagnosed. She died suddenly from an overdose of morphia, given to her by the nurse. The case occurred in a public institution, and an inquest was held. We found, on making the *post mortem* examination, the lung entirely destroyed, and the space previously occupied by it filled with thickish pus. The left lung contained a few tubercles in its apex. The heart was apparently healthy. There had been no hæmorrhage, as far as could be ascertained, during her illness.—I am, sir, yours, etc., EDW. COTTEW, L.R.C.P. Edin., etc.

Holloway Road, October 14th, 1875.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, no later than *Thursday*, twelve o'clock.

TRACHEOTOMY IN CROUP AND DIPHTHERIA.

To show that the operation of tracheotomy is not always hopeless, even when the smaller bronchial tubes are affected by the diphtheritic membrane, I may mention that in one case which came under my care in December 1870, that of a young woman, aged 23, in whom loud diphtheritic stridor was audible throughout both lungs, and who was rapidly becoming livid, I performed tracheotomy, as a last resource, and the patient made a good recovery.—RIDGWAY LLOYD, St. Alban's.

GELSEMINUM SEMPERVIRENS AND HYDRASTIS CANADENSIS.

SIR,—If your correspondent Mr. C. S. Wills will apply to Messrs. Ferris and Co., Bristol, they can supply him with the tincture of gelsemium sempervirens, which is made from the yellow jasmín, and has for some time been in use as a homœopathic remedy. Permit me here to mention another substance lately introduced into this country—viz., hydrastis Canadensis—long known and used in America, and fully described in the United States *Dispensatory*. During the years 1850 and 1851, when in the United States service, several of the men under my charge contracted syphilis and gonorrhœa of a virulent character when at Sault St. Marie. The head of the medical department advised the use of an infusion (Sijj ad Oj aq.) as an injection, and externally to sores, etc. The result was very satisfactory; and one advantage attending it, there was no pain or irritation caused by it. I have since prescribed it in this country with good effect. The "eclectic" preparation, "hydrastin", is said to be not as useful as the infusion, not containing the volatile and astringent principles, to which many think its curative action to be due. The root is to be used in making the infusion.—I am, etc.,

Stroud, October 5th, 1875.

THOS. PARTRIDGE, L.K.Q.C.P.

SIR,—In answer to your correspondent Mr. Wills, in last week's JOURNAL, the gelsemium sempervirens can be procured of the General Apothecaries' Company, Berners Street, London, W.—Yours faithfully,

October 4th, 1875.

HAMILTON CRAIGIE.

PERILS OF OBSTETRIC PRACTICE.

THERE is, we think, a tendency at present in the public mind to regard the occurrence of all cases of death in childbirth with more than common suspicion, as though almost implying blame to the medical man. We find in the *Ulster Gazette* a notice of an inquest on such a case, in which the body was actually disinterred by coroner's order. A *post mortem* examination was made by Dr. Palmer of Armagh, and Dr. Gilmore of Castleblaney. It appeared from the evidence that the deceased had been confined, and was attended by a midwife. She was delivered of a child; but as she was likely to have twins, and as the old woman in attendance could not help the mother, a medical man was sent for. When he arrived, he saw that the woman would not live, so he obtained the services of a second doctor. The friends of the deceased alleged that the deceased was injured by the first doctor; but the evidence and the *post mortem* examination clearly showed that there was no ground for the charge, and the friends were sent home wiser than they came. The jury found an unanimous verdict of death from natural causes, and that the deceased was properly treated by the doctor. The medical man in this instance was called by "a red ticket". He has held his office as dispensary medical officer for more than thirty years, and bears a high professional character. The tendency to throw causeless blame on the practitioner in such cases greatly increases the responsibilities of obstetric practice.

MR. JOHNSON.—Messrs. Clark and Savory were both elected members of the Court of Examiners in 1870: the former gentleman is also a member of the Council of the College.

FOREIGN GRADUATES IN GREAT BRITAIN.

SIR,—After carefully reading all the letters which have appeared in your JOURNAL concerning the registration of foreign degrees, it appears to me clearly an injustice to foreign graduates in medicine that they may not register their degrees obtained after examination. Some of your readers will, no doubt, be surprised to hear that there are resident in the British isles at the present time no fewer than 225 foreign graduates who have obtained their degrees after undergoing examinations at their respective universities. Of this number, there are 38 of Heidelberg, 19 of Erlangen, 19 of Giesse, 18 of Paris, 17 of Berlin, 15 of New York; 13 of Brussels, 8 of Montreal, 6 of Würzburg, 6 of Pisa, 6 of Philadelphia, 4 of Pennsylvania, 4 of Göttingen, 4 of Toronto, 4 of Munich, 4 of Tübingen, 4 of Pavia, 3 of Leyden, 3 of Kingston, Canada; 3 of Leipzig, 2 of Bonn, 2 of Vienna, 2 of Jena, 2 of Strasbourg, 2 of Berne, 2 of Louvain, 2 of Liège, 1 of Zurich, 1 of Stuttgart; 1 of Königsberg, 1 of Padua, 1 of Hanover, 1 of Groningen, 1 of Drenthe, Holland; 1 of Ferrara, 1 of Rostock, 1 of Harvard University, 1 of Chicago, 1 of Geneva. U.S.: 1 of Halifax, Canada; 1 of Ohio, 1 of San Fernando, Lima; and 1 of San Marcos, Peru. None of these degrees have been obtained without examination. Would it not be well for a memorial to be presented to the Medical Council, begging them to reconsider their decision on this point; and suggesting that all foreign graduates may register their degrees, providing that they can produce sufficient testimony to satisfy the Council that they have obtained their degrees after examination; and providing, also, that they have besides at least one British qualification registered under the Medical Act. If this would not do, perhaps some of your readers may suggest a better plan. It is high time we were doing something, if we wish to see foreign degrees in the next Register.—I beg to remain, sir, yours truly,

M.D. GIESSEN.

* * The power of the Medical Council in the matter is limited by Act of Parliament. At present they cannot, even if they would, register any foreign degrees obtained after 1858. Our correspondent will probably have observed (see JOURNAL, July 10th, page 45) that the matter is likely to be taken into consideration by the Medical Council.

T. E. H. J. (Liverpool).—The subject of Marriages of Consanguinity has been much discussed by medical writers. The general conclusion appears to be, that where there is no hereditary taint of constitutional disease or weakness, the marriages of first cousins are not open to physiological objection; but that where there is any such taint, it is likely to be transmitted in a more intense degree. Dr. Gilbert Child and Dr. Bemiss are two prominent writers on the subject. Mr. G. H. Darwin recently read an able paper on the subject before the Statistical Society. In the *Sanitary Record* for March 27th, 1875, there is a brief abstract of it. Mr. Huth has lately published a volume, discussing the whole question elaborately; it is issued by Messrs. Longman and Co. The first article in the *Westminster Review* for the current quarter reviews the subject very ably.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

"PSYCHOLOGY AND THE NERVOUS SYSTEM."

SIR,—Why is the above article, published in your last issue, so puzzling? Is it so on account of the newness of the doctrine advanced, or on account of the newness of the mode of advancing it? As to the first, that "the function of the brain is the co-ordination of impressions and movements", there are said to be several kinds of evidence. "This evidence has recently been presented in a pamphlet, of which this article is in great part a summary." But in what part of the article does the evidence appear? After looking through it several times, forwards and backwards, nowhere is such evidence to be found, beyond a statement to the effect that the best reasons for belief in the doctrine "are the facts of the experiments of disease". (Would it be considered ingenious to speak of "the facts of the experiments of gravitation" in the exposition of a physical problem? or, indeed, to represent any inanimate agency, as disease mainly is, as an experimenter in its own department?) It is also suggested that there would be a marvellous breach of the principle of continuity in the nervous system if the doctrine were not true; and it is twice asserted that "the anatomical substratum of a visual idea" (a particular instance of the doctrine) "is a nervous arrangement representing certain retinal impressions and particular ocular movements". But in what sense does this amount to a summary of evidence? Then, if the nature of the connection between mental states and physical states be, as we are several times told, irrelevant to this doctrine, and, worse than that, is in itself an insoluble problem, why is so much perplexing discussion devoted to it? Perplexing, indeed, it is to be told that "there is no *more* difficulty as to the connection between physical states and mental states, if the physical states are, as we affirm, nervous arrangements for the co-ordinations of movements and impressions; because the problem is an insoluble one, whatever the physical states may be". If one makes up one's mind that a problem is insoluble, does it therefore follow that all difficulty connected therewith is for ever abolished all the world over, as well as in our own cranium? But, having arrived at such a conclusion, how are we to account for the next proposition? "The nature of the connection between physical and mental states is not a problem either in psychology or in anatomy and physiology; it is a problem of metaphysics." Is this meant, then, as a sly innuendo for those who study what is insoluble—that is, the problems of metaphysics on the hill retired, or is it really a little confusion of thought that will sometimes, as in humbler productions, inweave itself even with leading articles? But why, when almost any view might be taken of the enigma, the connection namely in question, without any prejudice to the doctrine advanced, was it made so much of to the entire forgetfulness of the evidence that was to be summarised from the pamphlet?

Some of the very novel distinctions and definitions of very ordinary terms seem also in need of some further explanation. On what philological grounds or authority is it stated "that the unit of composition of speech is of words arranged so as to form a proposition"? The unit of the composition of sums is then, perhaps, of numbers arranged so as to form a lump sum; but, to our thinking, one word looks more an unit of speech than any such string of words as forms, on a given model, the least proposition. "The anatomical unit is a sensori-motor process". Is the word process to be understood in this connection in the same sense as in the expression "a bony process"? or, as it is used in the more familiar phrase, "a peculiar process"?—I am, sir, yours faithfully,

Aberdeen, Sept. 28th, 1875.

CHAS. M. CROMBIE, M.B., C.M.

EARLY MENSTRUATION.

SIR,—I have now under my observation a girl aged two years, who has regularly menstruated for some time. She is in perfect health, and her courses, which are in every respect natural in colour, occur every month, causing her much discomfort and pain. I may also mention another curious case; my patient, a girl aged 8, had been subject to fits for two years when I first saw her. The regularity with which they recurred (about every four weeks), induced me to ascribe them to some uterine derangement, particularly as she complained at the same periods of intense pain over the pubes and sacrum. Upon examining her, I discovered the pubes covered with thick black hair, and a perfectly formed penis (excepting the absence of urethra), over two inches long, and capable of complete erection. Below the penis is a rather large urethra, and on each side a large and pendulous vulva, which has very much the appearance of testicles; so much so, that the parents always had their doubts as to the sex of their child, never having consulted a medical man previously. The symptoms from which she suffers every month are similar to what occurs before and during ordinary menstruation.—I am, etc.

M.D.

SIR,—In the JOURNAL for October 2nd, a letter appears from Mr. Cathcart, giving an account of a case where a discharge, similar to that of menstruation, occurred in an infant five days old. I am inclined to think such cases are not very rare, although I cannot just now lay my hands on any published account of the subject; meantime, for the sake of eliciting further information, and in response to your correspondent's appeal, I beg to enclose the notes of two instances which I have met with in my own practice.—I remain, etc.,

Manchester, October 4th, 1875.

CHAS. J. CULLINGWORTH.

CASE I.—Mrs. D., aged 26 (who had already been pregnant four times previously, and borne two children at term), was delivered of a healthy and well nourished little girl on November 23rd, 1871. On the 27th of the same month, a little dark bloody discharge began to issue from the child's vagina; every napkin was distinctly stained; and I made myself sure by inspection that the flow really took place from the genital organs. This continued for four days, being greatest on the 30th, and then gradually diminishing, until on the following afternoon it altogether ceased. There was nothing abnormal about the appearance of the genital organs, and the child's health did not seem at all disturbed. The mother was greatly distressed lest her infant should present an example of precocious menstruation: the discharge, however, did not reappear during the eighteen months which elapsed before the family left England.

CASE II.—On the 22nd May, 1875, Mrs. R., aged 33, was confined of her first child, an unusually healthy and well developed little girl. On the evening of the 27th of the same month, a little discharge of blood was noticed trickling from the infant's vagina: about midnight, the napkins were so decidedly stained that the nurse came to my house in considerable alarm. The discharge continued until the evening of the 29th, becoming gradually less during that day. The child's health remained unaffected, and up to the time of writing (October 4th, 1875) there has been no repetition of the phenomenon.

In this case, as in the former, I made an ocular examination on several occasions, in order to be satisfied that the discharge issued from the vagina.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

JABORANDI.

SIR,—I am anxious to try the effect of "jaborandi". Will any of your readers who have tried it, kindly inform me the ordinary dose and strength of the infusion, and whether they have found it an useful medicine?—Your obedient servant,
October 1875.

A. D. P.

QUEKETT MEMORIAL MEDAL FUND.

We see it stated in the *Monthly Microscopical Journal*, that a large sum of money, which was subscribed some years ago to the Quekett Memorial Medal Fund, to provide a medal to be called the Quekett Medal, and to be given in the discretion of the Council, if possible annually, to such members of the society who, in the opinion of the Council, has best promoted the interest of microscopical science, has never been given.

DOSAGE OF MEDICINES.

In the section on Posology, in his useful little handbook on the art of prescribing, Dr. Handzel Griffiths says: "No greater service could be performed by the colleges or the great medical societies than the formation of a committee of competent men for the special investigation of the question of dosage; for it is a subject which is as yet only in its infancy, and the best knowledge which exists about it is undoubtedly confined to a very small section of the medical profession." The suggestion appears to us to be one of importance and interest.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Bristol Daily Post; The Evening News; The Sheffield Post; The Metropolitan; The Blyth Weekly News; The Edinburgh Daily Review; The Glasgow Herald; The Western Daily Press; The Merthyr Telegraph; The Leighton Buzzard Observer; The Bristol Daily Times and Mirror; The Derby and Chesterfield Reporter; The Lincolnshire Herald; The Sunderland Daily Echo; The Co-operative and Financial Review; The South Wales Daily News; The Macclesfield Courier; The Melbourne Argus; The Southampton Times and Hampshire Express; The Jarrold Express; The Birmingham Daily Post; The League Journal; The Sheffield and Rotherham Independent; The Derbyshire High Peak News; The Liverpool Daily Courier; The National Food and Fuel Reformer; The Worcester Herald; The Norfolk News; The Worcester Chronicle; The North British Daily Mail; The Social Science Review; etc.

COMMUNICATIONS, LETTERS, &c., have been received from:—

CLINICAL LECTURE ON SURGICAL DIAGNOSIS.

Delivered in University College Hospital,
On October 11th, 1875.

BY CHRISTOPHER HEATH, F.R.C.S.,
Holme Professor of Clinical Surgery.

GENTLEMEN,—As the Special Professor of Clinical Surgery, it is my special duty to instruct you to the best of my ability in the diagnosis and treatment of surgical disease and injury. Much of my teaching must necessarily be at the bedside; but the clinical lecture which I shall deliver each Monday in this theatre will give me the opportunity of commenting more freely upon the cases you will find in the wards, than would be convenient before the patients themselves. The weekly clinical examination of actual patients by yourselves, or, at least, by the seniors of the class in your presence, will also, I hope, help to train you in the diagnosis of surgical cases; and I propose to devote this lecture to giving you some practical hints on the subject.

Many surgical injuries and affections are so obvious that no great skill is required for their recognition; but, on the other hand, similar outward appearances may depend upon very different causes; and it is here that the skill in diagnosis of the surgeon gives him the advantage in prescribing appropriate treatment. Symptoms may be conveniently divided into "objective" and "subjective"; the former being those open to the observation of the surgeon, the latter those experienced only by the patient. It is to the objective symptoms of disease and injury that I propose to direct your attention to-day; for I do not mean, on this occasion, to bring a patient before you, but simply a living model with no special ailment, to illustrate some points in diagnosis.

It must be your great object to cultivate your eye, hand, and ear; and you cannot safely omit the use of any one of the three. Practically, one uses, as a rule, the ear first; because you are bound to hear something of the patient's own account of his ailment, in order to know to what part of his frame you are to direct your attention; though you must not put too much trust in a patient's own account, and still less in his diagnosis of his own malady. Thus, pain referred to the knee frequently depends upon disease of the hip, and pain in the loins from supposed kidney-disease, upon stricture of the urethra. The eye will take in many of the leading features of a case at a glance, such as the general aspect of the patient, his mode of walking or standing, etc.; and, when the affected part is exposed to view, it will in many cases, if sufficiently practised, complete the diagnosis. Let me warn you, however, against "jumping to conclusions" too rapidly; for those who are foolish enough to pride themselves on rapidity in diagnosis not unfrequently make mistakes, which a little more time would have enabled them to correct. You can no more afford to leave out steps when tracing the nature of a case by progressive induction, than you can venture to omit one or more tests when examining a complicated fluid in the chemical laboratory. Lastly comes the hand, which may require to be fitted with various instruments for special purposes; but which, in its simplicity, is the surgeon's most powerful ally if properly educated. The much-talked-of *tactus eruditus* is to be acquired by all who will take the trouble to practise their fingers in the manipulation of healthy and diseased subjects, and will, at the same time, use their mental powers. For, of course, no amount of examination of a patient will tell you what is the matter with him, unless you elaborate the facts thus ascertained in a mind which has been trained by previous study to comprehend the importance of the several symptoms; and this is the reason why, at first, beginners must be at a disadvantage, lacking the experience necessary for a clear appreciation of symptoms. You will find, however, that with a little help from the surgeon, you will soon begin to see the "why" and the "wherefore" of diagnosis and treatment; and let me beg of you not to be afraid of asking questions—so long, at least, as the questions are put for the purpose of increasing, and not of displaying, your own amount of information. One pitfall I must just allude to; and that is the tendency to over-elaboration of a diagnosis which besets some men, and seems to stick to them through life. They never can take the plain obvious facts of a case, and from them draw a conclusion; but must dig and delve so deeply that they sometimes get, so to speak, "out of their own depth", and never come up

again so far as any utility to the patient in question is concerned. Superficial carelessness is bad; but too great profundity is not much better.

And now I bring before you a man with no special deformity or ailment, in order that I may be able to show you a few noteworthy points which you can readily appreciate at a little distance, and which will assist you in studying disease and injury in the wards. With his back towards us, you have the opportunity of examining a healthy spine; and you may notice that, while the spinous processes are readily visible in the dorsal region (and particularly when the arms are folded), they are not so visible in the lumbar, and still less so in the cervical, region, where they are covered by muscles and ligaments, the seventh, or *vertebra prominens*, being the only one really seen or felt. Here, in a healthy adult, we have the average anterior and posterior curves in the lumbar and dorsal regions; but you must remember that, in young children, the spine is nearly straight, while in disease we may have great exaggeration of either curve. Thus, in the back, we find *cyphosis*, or angular curvature, the result of caries of the vertebra; while in the loins we have *lordosis*, an exaggeration of the healthy curve, and generally connected with old hip-disease. Of the latter, I now place an example before you; and, of the former, there is an instance in No. 1 Ward, in a man whose foot I removed last week.

The model is now standing at "attention", with his knees straight; consequently the two sides of his pelvis are perfectly even; and you see that a tape carried between corresponding points on the two sides is horizontal. Let us now make him "stand at ease", with the left knee bent and foot slightly advanced, and you see that at once the left side of the pelvis is lowered. But this is not all. Corresponding with the obliquity of the pelvis, we have a lateral deviation of the spine to the left in the lumbar region; and if the man could sufficiently relax his muscles at the moment, we should have a curve in the opposite direction—to the right—in the dorsal region. By placing a book beneath the right heel, and thus increasing the obliquity of the pelvis, I exaggerate the lumbar curve; or, of course, by tilting the pelvis in the opposite direction, I could throw the spine over to the opposite side. Of course, the same thing holds good if the patient be seated instead of standing; for, by tilting his seat, we are able to produce a marked lumbar and a certain amount of dorsal curve at will. Fortunately, we have here to-day also a case of old hip-disease, in whom the obliquity of the pelvis is well-marked, and the resulting twist of the spine better seen than in the healthy subject. You see, then, how important it is in any case of lateral curvature to ascertain whether it depends upon some obliquity of the pelvis (from atrophy of one leg or old hip-disease), or upon other causes; and you also see what effect upon an existing curve may be produced, as has been well pointed out by Mr. Barwell, by raising the side of the pelvis by means of a thickened sole or a sloping seat.

Turning, now, to the neck and shoulder, I pass my finger along the clavicle, which is subcutaneous, and shows its curves well enough in a thin muscular subject. The notch between the clavicles is important in connection with aneurisms of the great vessels of the neck; but the inner end of the bone is very rarely dislocated, except by extreme violence. The outer end of the clavicle is continuous with the acromion process, and I now run the chalk along them; but it may be dislocated (as we have lately seen), and then the flattened end of the bone is readily felt beneath the skin. If I make the man swing his arm round, you will be able to appreciate better than you perhaps have hitherto done the great range of motion in the sterno-clavicular articulation, which, in fact, admits of "circumduction", and has a most important relation to the movements of the arm.

There is no joint, I suppose, about which more mistakes are made than about the shoulder. An "obscure injury about the shoulder" has often damaged a surgeon's reputation, because he has not sufficiently studied the anatomy of the part to be quite sure of his diagnosis and treatment. The chalk-line I have already made marks the bony arch formed by the clavicle and acromion; but you will notice that the head of the humerus projects beyond this in front, and gives the roundness to the healthy shoulder. There is a hollow immediately behind the head of the humerus and below the prominent acromion; and another in front, to the inner side of the head, in which the coracoid process can be more or less distinctly felt, according to the muscularity of the subject. In the healthy subject, there is just room to lay the finger between the coracoid process and the head of the bone. When the head of the humerus is *dislocated*, the roundness of the shoulder is lost, and the acromion stands out prominently beneath the skin, with a depression below it; while the head can be felt in some unnatural position, and out of its proper relation to the coracoid process. The direction of the whole limb is altered too; so that the patient cannot place his hand on the opposite shoulder with the elbow touching the chest-wall, as he can in health. In a *fracture* of the neck

of the humerus, the roundness of the shoulder is not lost; but there is a depression below the head, which does not move when the arm is rotated, unless, indeed, the fracture be impacted. The two accidents may be combined; but this is a rare complication.

When I turn the model with his back to you, and make him raise his arm, you will appreciate how important the movements of the scapula are. The deltoid alone can only raise the arm to a right angle with the trunk; and the subsequent elevation of the limb depends upon a rotation of the scapula on the ribs, so that the angle comes forward to the margin of the axilla. The scapula is held in its place by the muscles passing from the spine to its base, and by the serratus magnus. If these be paralysed, the scapula falls forward, and the power of the arm is greatly lost.

Let us pass on to the elbow. With the forearm bent, you see at once the prominent olecranon process of the ulna. When this is broken off by falls on the elbow, the fragment is drawn up by the triceps, and an interval can be felt between it and the bone, which, however, is rapidly filled up by the effusion immediately following any injury to the elbow-joint. A much more common result of a fall on the elbow, however, is an injury to the bursa which lies between the subcutaneous triangle of the olecranon and the skin. In health, this bursa cannot be recognised, except in individuals whose occupation has produced enlargement of it—*e. g.*, miners or sweeps; for though it is technically called the "student's bursa", I must confess to have never seen an enlargement of it due to long poring over medical treatises. When the bursa is inflamed, it causes a swelling over the olecranon, which is evidently quite superficial, and does not mask the general outline of the joint, as would be the case were the effusion in the articulation. You may remember that, last week, a patient with suppuration of this bursa was treated by an early and free incision in Ward I.

The condyles of the humerus are readily felt in this thin arm; and you will notice that the internal is the more prominent, and stands out beneath the skin. Immediately behind it is the groove in which the ulnar nerve lies, as you may ascertain for yourselves by "twanging" it; and then comes the olecranon, with only just space for the nerve between the bones. This close relation of these two prominent points of bone is of great service in the diagnosis of dislocation of the forearm; for, so long as they lie close together, the deformity cannot be caused by a dislocation of the ulna. The outer condyle is more rounded; and immediately below it is the head of the radius, which can be felt rotating when the forearm is pronated or supinated. It is not often dislocated, for it is firmly held by ligaments; but it is sometimes thrown forward, and then prevents complete flexion of the forearm, by coming against the front of the lower end of the humerus.

At the wrist, you may notice that the end of the radius is lower down than that of the ulna, and that the styloid processes of both bones are to be felt. Dislocation of the carpus from the radius is rare; but separation of the lower epiphysis of the radius is by no means uncommon in young persons, and is sometimes mistaken for dislocation. The triangular fibro-cartilage which binds the radius and ulna together at the wrist, sometimes becomes displaced in children who are dragged forcibly by the hand, and then the little patient cannot supinate the forearm and hand; but if you hold the hand firmly, and then supinate, you hear a slight click, and all is well. It is well always to bear in mind that, in supination, the bones of the forearm are parallel, and in pronation are across one another; so that supination in the posture in which fractured bones of the forearm should be set, although it is convenient, when the bones are firmly held by splints, to turn the thumb upwards—*i. e.*, to place the hand midway between pronation and supination.

In the hand, I need only point out that the superficial palmar arch does not correspond precisely to any one of the lines in the skin of the palm; but its convexity reaches generally to the middle one of the three, while the deep arch is much nearer the wrist. The bifurcation of the digital arteries is between the heads of the metacarpal bones, and about midway between the line to which I have referred and the web of the fingers; so that incisions should always be made in the line of the fingers, and not between them. As you may have, early in your career, to amputate a crushed finger, I would remind you, also, that the prominence of each knuckle is formed by the proximal bone of the articulation; and that the joint through which the knife must pass is below this in every case.

Descending to the groin, you see that the fold of the groin corresponds to Poupart's ligament; and an inguinal hernia is above, while a femoral hernia is below, this line—at least at first. Of course, a large inguinal hernia will descend into the scrotum, and a large femoral hernia may turn up over Poupart's ligament, and closely simulate the inguinal variety. But you ought to have little difficulty in distinguishing them if you will invaginate a piece of scrotum (or labium in the

female) on the forefinger, as you see me doing, so as to carry the finger into the external abdominal ring. This will enable you to settle at once whether the protrusion has taken place through the inguinal canal or not. Let me also remind you always to ascertain the presence of two testicles in the scrotum; for an undescended testis may closely resemble a hernia, especially if inflamed.

The pelvis is so firmly bound together that a dislocation of one of the innominate bones can only be produced by extreme violence; but disease of the sacro-iliac joint is by no means uncommon, though often overlooked; and one leading symptom is lameness, which is erroneously referred to the hip-joint. But if I make the man before us stand on one leg, you will see at once how the whole weight of the body falls upon the corresponding sacro-iliac joint while he is throwing the other leg forward; and it is this which gives rise to the pain, and prevents the walking of a sufferer from sacro-iliac disease. Taking this man, who has a healthy pelvis, I may compress his two innominate bones without giving any pain; but a woman who has recently had a severe labour, and has, perhaps, incipient sacro-iliac mischief, will cry out at any such rough treatment, though the steady support of a good pelvic belt would give her great comfort, and restore her powers of locomotion.

The hip-joint in health is freely movable in all directions, as you see, and independently of the pelvis; but, the moment the joint is inflamed, the muscles instinctively contract, and fix the joint to some extent; and then, when the limb is moved, it carries the pelvis with it. This man's back is naturally more curved than a child's; but even in him, if I make him lie flat on the table, you will see that the thigh can be fully extended without tilting up the pelvis, and so increasing the curve of the lumbar spine. In a child, whose back is naturally flat on the table, the effect of early hip-disease is readily seen (as I have frequently demonstrated to many of you); for the attempt to bring the thigh down, at once elevates the pelvis, and causes that curvature of the lumbar spine which, in old hip-disease, becomes permanent.

The prominence of the great trochanter will vary in different individuals, according to the muscularity of the buttock and the length of the neck of the femur; and it is important, therefore, to compare the two sides in every case of suspected disease or injury. The head of the femur can be indistinctly felt on deep pressure, either in front of or behind the trochanter; and, in health, the two move together; for if the trochanter can be freely moved by rotating the femur without affecting the head of the bone, it is clear that the neck must be broken. The length of the neck will very much affect the power of rotating the limb; thus, if the neck be shortened, either by an impacted fracture or the absorption of old age, the arc in which the upper part of the thigh moves will be found to be much smaller than in health. When I stretch a tape from the anterior superior spine of the ilium to the tuberosity of the ischium, you see that, in health, it touches the top of the greater trochanter; now, if the bone were dislocated or the neck broken, the trochanter would be above or below this line.

When the knee is extended, you see the patella forming a prominence in front of the femur; but, when the joint is flexed, it sinks into the hollow between the condyles. With the leg fully extended and the muscles relaxed, there is, as you can prove in your own limbs, considerable lateral movement of the patella possible in the healthy joint; and the mistake is sometimes made of attributing this mobility to the presence of synovial effusion. When fluid is poured into the knee-joint, however, not only does the patella float so as to be freely movable in any position of the limb, but the synovial pouches on each side of and above the patella are distended, and give the characteristic roundness to the knee. If one kneel down on a flat surface, and particularly if the body be bent forward, as in scrubbing a floor, the patella and the bursa between it and the skin are exposed to considerable pressure; and hence the chronic enlargement of that bursa, termed "housemaids' knee", which causes a globular swelling in front of the joint, altogether different from that of effusion. Kneelers on hassocks or foot-boards do not run any risk of the housemaids' fate; for the pressure in their case comes on the tubercle of the tibia, and the bursa between it and the *ligamentum patellæ* would suffer if the pressure were sufficiently prolonged—but I never met with such a case. In falling with the knee bent, the patella reaches the ground first, and receives the force of the impact, which may simply bruise or cut open the bursa; or, if very severe, may "star" the patella itself. The transverse fracture of the bone is produced through the effort of the patient to save himself, by which the great extensor muscles catch the bone across the condyles, and either break it or rupture the ligament; then the upper fragment is drawn up in front of the femur, and a space is left in which the condyles can be felt, as in a patient recently in the wards.

With the knee flexed, the rounded outlines of the condyles can be readily felt resting on the top of the tibia; and a little distance below

the outer condyle can be seen the head of the fibula—which bone, let me remind you, does not enter into the formation of the knee-joint. The existence of the semilunar fibro-cartilages between the femur and tibia is hardly appreciable in health; but their existence must not be forgotten, as occasionally, in violent wrenches of the knee, one of them becomes displaced, giving rise to extreme pain and inability to use the joint, which are most satisfactorily treated (as also are dislocations of the patella) by a little of that judicious violence for which “bone-setters” have a reputation.

At the ankle, we see at once the prominences of the two malleoli, between which the astragalus fits closely when the foot is at right angles to the leg, less so when the foot is pointed; so that, in this position, some amount of lateral movement of the foot is possible. The fibula is altogether posterior to the tibia, and its malleolus is longer than the internal. The lower third of the fibula is subcutaneous, and its fracture (Pott's fracture) is therefore readily recognised. The tendons of the various muscles surround the ankle-joint; but the only one to which I need call your attention is the *tendo Achillis* at the back, in which, when ruptured, the division is readily both felt and seen. When I flex the knee and point the toes, you can see how completely the muscles of the calf are relaxed; and this is an important point in the treatment of a divided tendon, or of a dislocation of the foot, or oblique fracture of the tibia.

The prominences of the foot are chiefly important as guides to the amputations; thus the tuberosity of the scaphoid on the inner side marks the transverse tarsal joint, or site of Chopart's amputation; whilst the base of the first metatarsal on the inner or prominent fifth metatarsal bone on the outer side, marks the position of Hey's amputation. The metatarso-phalangeal joint of the great toe is not unfrequently diseased through gout or the pressure of boots which have developed a bunion; and other toes are not unfrequently deformed from the same cause. The only surgical point with regard to the toes that I need mention is that the base of the first phalanx is more expanded and more deeply placed than young operators are apt to imagine.

I have thus run briefly through the more salient points on the living body which it is important for you to recognise thoroughly in health before attempting to treat disease; and, in future lectures, I shall have to direct your attention to matters regarding which the knowledge acquired to-day will be of service in enabling you to recognise deviations from the standard of health.

THE TREATMENT OF ANEURISM OF THE ARCH OF THE AORTA BY MEANS OF GALVANO-PUNCTURE.*

By T. M'CALL ANDERSON, M.D.,

Professor of Clinical Medicine in the University of Glasgow.

I SHALL, in the first place, read the notes of two cases of aneurism of the arch of the aorta, in which galvano-puncture was employed with success, and afterwards refer shortly to the rules to be observed in carrying it into effect.

James Dunn, aged 36, clothlapper, was admitted into the Glasgow Royal Infirmary on December 19th, 1873, complaining of cough, pains in the shoulders and nape of the neck, and inability to swallow solid food. He had led a very irregular life, admitted having had gonorrhœa several times, and, for the last six years, he had been very intemperate in his habits. For three or four years, he had been more or less troubled with cough; and, for two years, he had complained of pain in the region of the heart, and of gradually increasing dyspnoea, but he never spat blood. About eight weeks prior to admission, as the result of a wetting he thought, the cough became more severe and was accompanied by sore-throat and pains in the shoulders and nape, especially on the left side. This was soon followed by gradually increasing difficulty in swallowing solid food, which was sure to return into his mouth unless it were thoroughly masticated; the seat of the obstruction he referred to the top of the sternum.

On admission, he was found to be a well formed and well-nourished man, but in his face were mirrored the ravages of his favourite vice. His tongue was coated with a white fur, his appetite was good, and his bowels regular, but he had great difficulty in swallowing solid food. The urine was normal. He was much troubled with cough, and bronchitic rales were audible throughout the chest, especially at the bases of the lungs. The air entered both lungs with equal freedom,

and the respirations were natural; his voice was unaffected, and the pupils natural.

On examination of the circulatory system, the heart was found to be somewhat depressed, and the left ventricle the seat of dilated hypertrophy, while a soft systolic, probably communicated, murmur was heard at the apex. At the upper part of the front of the chest, there was dulness on percussion, measuring three inches from above downwards, and extending from one inch to the right to one inch and a half to the left of the sternum. In the second left intercostal space close to the sternum, there were some fulness and pulsation, and, on auscultation, a soft systolic murmur was heard. There were also fulness and pulsation in the suprasternal notch, but no murmur was audible in that situation. The pulse was 74, regular, and of fair strength, and the pulses at the wrists and in the carotids were not unequal.

Shortly after admission, the symptoms became much more alarming, the fulness and pulsation in the second intercostal space became much more pronounced, and the dysphagia so great that he could not even swallow fluid food, and required to be supported by means of nutritive enemata. This was on January 2nd, 1874. On the 20th, it was noted that the difficulty of swallowing was not nearly so great, and he could then take fluid food as on admission. The fulness in the intercostal space, however, had so much increased, that there was a distinct appearance of tumour a couple of inches in breadth, and projecting three-quarters of an inch above the level of the surrounding chest-walls. This swelling was very soft, almost fluctuating indeed, and was the seat of expansion as well as pulsation; the murmur remained as on admission.

On January 12th, galvano-puncture was performed, an insulated needle connected with the positive pole of the battery being inserted into the most prominent part of the aneurism after the skin had been frozen with ether-spray, and a zinc plate connected with the negative being applied to the chest-wall in the vicinity of the tumour; a large piece of sponge moistened with salt water intervening, however, between the plate and the skin. The operation was continued for an hour; four cells of the battery being employed for the first half hour, and six for the second. The patient felt no inconvenience or pain during the operation, and, on removing the needle, there was no hæmorrhage. After the operation, however, there was pain in the tumour and increased uneasiness in the nape of the neck and left shoulder; this was speedily relieved by the application of iced cloths. On January 20th, the swelling was thought to be smaller and finer, and the patient could swallow better.

On January 23rd, the operation was repeated as before, the needle being inserted a little higher up and nearer the sternum than on the first occasion, and again upon February 5th; but this time six cells were employed for the first half hour, and eight for the second, and, on removing the needle, there was a considerable jet of blood. No report seems to have been taken after the third operation until March 13th, when the swelling was stated to be much firmer, but the patient had been a little hoarse, and had been spitting a little blood.

On April 16th, galvano-puncture was repeated for the fourth and last time, and, in the beginning of May, being weary of the confinement and feeling pretty well, he insisted upon leaving the hospital, although strongly urged to remain. Before leaving, an examination showed that the aneurismal swelling, which was firm and hard, had fallen almost to the level of the surrounding surface. It still pulsated, but no murmur could be heard over it. He continued occasionally to spit a little blood, and still complained of pain in the shoulder and nape of the neck. The difficulty of swallowing had varied much latterly; sometimes he had a good deal of dysphagia, while at other times he could swallow almost anything.

From the history I have given, it will be seen that this was by no means a promising case for operation, and the improvement was all the more remarkable if we take into account his dissipated habits, and the fact that, during the treatment, through inadvertence, he frequently got up and walked about the ward for several hours.

Let me compare this case with a somewhat similar one, of which, however, I need only give a short outline, as I have already published it.

Mrs. H., aged 41, married, millworker, was admitted into the Glasgow Royal Infirmary, November 8th 1871. Two years and a half before this, she began to complain of a “violent beating at her breast”, and of hoarseness. This was followed by a feeling as if a heavy weight were pressing upon her chest, and she complained of lancinating pains between the shoulders, which extended down the left arm. Eighteen months previous to admission, she observed a swelling in the front of the chest about the size of a small hen's egg.

On inspection, the swelling was seen at the lower and inner part of the left infraclavicular space, and implicating also the upper sterna

* Read before the Medical Section at the Annual Meeting of the British Medical Association in Edinburgh, August 1875.

region. It was about three inches and a half in diameter, and its apex was about an inch and a half above the surface. Pulsation, expansion, purring tremor and dulness, and tenderness upon percussion, were well marked over it, while there was a distinct systolic murmur audible over a pretty extensive area, but most distinct in the situation of the tumour. The left ventricle was the seat of dilated hypertrophy, and the pulses in the radials and carotids were weaker on the left than on the right side of the body; but there was no alteration in the pupils, no dysphagia, no trace of spasm of the glottis although the voice was hoarse, and air entered both lungs pretty freely, although there was considerable dyspnoea.

During the month of March, the swelling gradually became more prominent and softer, and accordingly galvano-puncture was resorted to. The operation was performed four times, on the 4th, 9th, and 25th April; and, on the 27th August, in the same way as in the last case; and, on 26th October, the following was the report. "The symptoms of dilated hypertrophy of the left ventricle remain as at the period of admission; but, for some time, an apex systolic murmur has been audible, distinct from the basic one, and which was not present at an earlier date, or was obscured by the aneurismal one. The tumour is now only about a quarter of its size before galvano-puncture was resorted to; and it is for the most part very solid, even more so than the surrounding healthy parts of the chest. There is now no trace of purring tremor, and the pulsation is much diminished, especially in the central, softest part of the swelling; the systolic murmur, too, is much softer than formerly, but there is no change in the pulses. The patient feels in the most perfect health, and her only complaint is of a feeling of pulsation within the chest." She left the hospital at this time, but was seen again on the 4th March, 1873, six months after the last operation; and she was then in even better health than when the last report was taken.

Before leaving the hospital, she was warned to avoid everything in the shape of mental excitement or bodily exertion, and that she must consider herself an invalid for the rest of her life; and this is the way in which she carried out these instructions. On March 5th, she resumed work, her principal occupation consisting of carrying heavy loads of goods upon her shoulders. This she continued for four months and a half; during which time she not only worked all day, but also engaged in arduous household work at night. About the middle of September, most of her underclothing having been stolen, and having exposed herself, in consequence, without these garments, she was seized with a hard dry cough, and to this was soon added retching, which she encouraged by putting her finger into her throat. It is not, therefore, to be wondered at that she sank on January 7th, 1874, 498 days after the last operation.

On *post mortem* examination, the aneurism, which implicated the whole of the transverse and descending portions of the arch, was found to be completely filled with firm, pale, fibrous, and stratified clots; but, at the lowest part of the tumour, the blood had forced its way between the stratified clots and the walls of the aneurism, and penetrated into the left pleural cavity, on a level with the middle of the anterior edge of the compressed lung.

Notwithstanding the ultimate result, it must, I think, be admitted that this case is an illustration of as perfect a cure of aneurism as it is possible to expect from treatment. For, had the patient been so circumstanced as to be able to avoid bodily exertion, she might have continued in comparative comfort for an indefinite period of time.

With these cases for my text, let me refer shortly to the rules which, as far as my reading and experience go, it is desirable to observe in the treatment of aneurism by electrolysis.

1. *The kind of Electricity.*—The induced, as well as the continuous, current has been employed. A successful case of this kind has been recorded by Mr. Eyre. (*Lancet*, July 30th, 1853, p. 94.) The patient, a soldier, in the prime of life, had an aneurism of the left external iliac artery, about the size of a fowl's egg, which pulsed strongly, and was the seat of a murmur. There were œdema and much pain in the limb. Two long, fine needles were introduced an inch within the sac, each being connected with the wires of a galvano-magnetic machine. The operation, which was accompanied by pain in the groin and violent agitation of the whole body, was continued for twenty minutes. It was followed by severe inflammation, which threatened the patient's life; but, in three weeks, the threatening symptoms subsided, and the patient was cured. The successful result in this case was due to the setting up of adhesive inflammation, which filled the sac with lymph, and was fraught with much danger. Now, it is infinitely safer to attempt a cure by means of chemical than by means of inflammatory action; and, therefore, in every case, the continuous-current battery should be employed; although, even then, unless we are careful, the same result may follow.

2. *As to the kind of battery*, this is of less consequence, provided it is in good working order, and has large cells, so as to increase the chemical effects. I have always employed one of Stöhrer's large-celled batteries; and, in using it, it may be as well, with the view of intensifying the chemical effect, to add to the fluid in each cell, as recommended by Althaus, two drachms of a solution of chromic acid, sufficiently concentrated to impart to it the colour of claret. (*A Treatise on Medical Electricity*, by Julius Althaus, M.D., 3rd ed., p. 294.)

3. *The needles* should not be very thick, but very sharp, and should be oiled before being introduced; and, what is of the utmost importance, they should be insulated to within about half an inch of the point: for we must aim at acting upon the blood in the aneurism only, and not upon the walls of the sac, skin, and intervening tissues. This can be done, as recommended by my friend Dr. John Duncan of Edinburgh, a gentleman who has laboured earnestly and successfully to improve our knowledge of electrolysis as a means of treatment, by coating them with vulcanite. The unsuccessful result of a case upon which I operated in 1873 (reported in the *Lancet*, June 13th, 1874), I attribute in part to the use of needles which were not insulated. These were sent to me along with a Stöhrer's hospital battery; and, therefore, it is all the more important to give a warning against their employment. I have generally only used one needle; but there can be no harm in the introduction of two or more, especially if the aneurismal tumour be extensive.

A point of much moment, and with regard to which there is great difference of opinion, now is:

4. *Whether the Needles should be connected with the Positive or Negative, or both Poles.*—The balance of opinion seems to be in favour of connecting them with both poles. "I have no doubt whatever," says Althaus (*op. cit.*, p. 651), "that the most effective application of the current is that where both poles are inserted into the sac. This mode of application is also that one employed by Ciniselli and Dr. Duncan of Edinburgh. Both poles are useful in different ways; the positive produces a small firm clot, and the negative a large soft one. Where only one pole is in the sac, the resistance encountered by the electricity is so great that a much larger galvanic power has to be used to produce any effect at all; and, even then, the effect of that pole which remains outside is lost." And yet one of the most successful cases reported by Althaus in the volume from which I have quoted was one of the cases operated upon by me, in which the needle was connected with the positive pole, and in which a weak current was employed. For my part, I prefer connecting the needles with the positive pole only, because I have found it efficient in practice; because the clot which forms at the positive pole, though small, is firm and hard, while that which forms at the negative is soft and bulky; and because, on withdrawing the needles, hæmorrhage is much more apt to occur; thus showing that the clot is not of a satisfactory character. Hæmorrhage, too, is a disagreeable complication; it frightens the patient, and excites the circulation; and, besides, serious injury to the aneurism may result from the manipulations carried out with the view of arresting it.

5. There is much difference of opinion, also, as to the strength and duration of the current. For my part, I am clearly of opinion that it is often used far too strong. Thus, in a case operated upon by Althaus, and many equally striking ones have been published, he says: "I applied the current of from ten to twenty-five cells of Smee's battery; so that the positive and negative pole were alternately in contact with each needle, the changes being made every five minutes, so that the whole process lasted twenty-five minutes. The patient complained much of pain, particularly when the changes were made. For the first two days, the tumour decreased considerably in size, but afterwards it increased both in size and pulsation; redness and œdema extended around it in all directions, and the patient died. At the autopsy, the whole of the cellular tissue around the tumour was found loaded with lymph, and much indurated. This diffuse inflammation extended the whole way up the neck, rendering the dissection extremely difficult." (*Op. cit.*, p. 648.) I prefer, then, to use a weak current, and one which gives rise to little or no pain, and which does not excite serious inflammation; and, in the two cases just reported, I never employed more than eight cells of Stöhrer's large battery as a maximum, and never continued the operation for longer than an hour at a time. Now, it must not be forgotten that, in using a weak current, at all events, we do not aim at suddenly coagulating the whole of the blood in the sac, but desire the formation of a small firm clot, from which, as a centre, we hope to ensure the gradual deposition of successive layers of fibrin from the blood; so that, for the first few days after galvano-puncture is practised, those who are not alive to this circumstance may fancy that the operation has failed.

Lastly, the number of operations, and the length of the intervals between each, must depend upon the effect of those which preceded them.

The rules which I have ventured to suggest as applicable to the electrolytic treatment of aneurism are, of course, likely to require modification as our experience of it increases; but this, at all events, may be affirmed, that the dangers of the treatment are by no means serious if they are adhered to. Thus violent inflammation is not likely to occur if a weak continuous current of electricity be employed for a moderate space of time; while slight irritation is not an unmixt evil, and may be allayed by the application of iced cloths. It naturally occurs to one that clots produced by galvano-puncture, and which at first are soft and presumably easily detached, are likely to be swept into the general circulation, and to give rise to embolism; but, as far as our experience has hitherto gone, this happily seems to be rather a theoretical than a practical difficulty, and one which appears to me all the less likely to occur if the needles be connected with the positive pole alone. The gas which is generated during the operation, no doubt, in part, finds its way into the circulation; but this takes place so slowly and in such small quantity, that no danger is to be apprehended from it. The operation, then, need not cause us much anxiety from the above points of view; but it comes to be a question—and to this the attention of medical men practising galvano-puncture should be specially directed in the future—whether the consolidation of that portion of the aneurism in particular which approaches the surface may not, in some cases at least, favour the extension of the disease in other directions, and lead to internal pressure-symptoms, and to rupture into internal organs.

HYDATID DISEASE:

AS ILLUSTRATED BY SPECIMENS CONTAINED IN THE PATHOLOGICAL MUSEUMS OF THE METROPOLIS AND ELSEWHERE.

By T. SPENCER COBBOLD, M.D., F.R.S., F.L.S.,
Correspondent of the Academy of Sciences of Philadelphia.

I.

ALL who really desire to advance the healing art must by this time be well aware that so desirable an end can only be obtained by continuous labour, directed towards the perfecting of our knowledge of the origin, diagnosis, pathology, and mode of preventing the occurrence of the obscurer forms of disease.

As obtains in the case of hydatids, there are certain maladies affecting both man and beast which are so intimately related to one another that the physician, surgeon, scientific pathologist, and veterinary practitioner are all alike interested in their study; but in the prosecution of investigations of this kind it becomes more and more evident that the principle of division of labour requires to be exerted to the utmost. In the acquisition of the following data, I have been obliged to content myself with employing only such intermittent hours of leisure as I could gather or steal from other occupations at varying intervals during the last ten years.

The pathological collections in the metropolis abound in rare and remarkable illustrations of hydatid disease; most of the preparations being practically known only to such few members of the medical profession as have been at some time or other officially connected with the museums. Not without justice, curators often complain that their work is turned to little account; therefore, in the matter of parasites, I have resolved to utilise their labours without reserve. My past connection with the Edinburgh University Anatomical Museum, and subsequently with the collection of the Middlesex Hospital Medical College, has convinced me that few persons are aware how much solid information may be gathered by a patient study of the contents of these great store-houses of the results of disease. Valuable as the catalogues are, it is often necessary to make a close inspection of the preparation in order to arrive at a correct interpretation of the facts presented.

Although the entozoa preparations in the museum attached to St. Bartholomew's Hospital are, comparatively speaking, few in number, there are some choice specimens of hydatid disease. There is a remarkable case in which hydatids invaded the right half of the bones of the pelvis; death resulting from suppurative inflammation of the cysts. This patient, a woman, had also another hydatid cyst which was connected with the ovary. Amongst the series contributed by Dr. Farre, there is a case represented where a large cyst containing numerous hydatids "occupied the pelvis of an infant and produced retention of urine", which ultimately proved fatal. There are also several fine examples of hydatids from the omentum (Dr. Farre's case); besides a good specimen of acephalocysts connected with the vesiculæ seminales. There are two other cases in which these larval entozoa were passed with the urine. At the time when I made my inspection, the entire series re-

presented twenty-five separate cases, of which only one appeared to have been published in detail (Mr. Evans's case, *Medico-Chirurgical Transactions*, 1832). In addition to the above, I must not omit to particularise also two instructive preparations illustrative of a case in which an hydatid was lodged in the right half of the cerebrum. This was from a girl in whom head-symptoms showed themselves a year before death, and in whom there was partial hemiplegia of the left side. I may add that there is also in the series a doubtfully genuine example of hydatids of the breast.

The collection in connection with the Westminster Hospital contains several highly interesting specimens of entozoa (one of which I believe to be altogether unique), but it is by no means rich in the matter of hydatids. Out of a score of preparations of parasites of various kinds, only four (apparently representing the same number of cases) are hydatids, all of which appear to have been connected with the liver. Two are certainly so; one of the latter (Mr. Holthouse's case) showing calcareous degeneration.

The museum connected with St. Mary's Hospital Medical School, in addition to several liver cases, contains one interesting example of hydatids of the lung (Dr. Chambers's case); and also three valuable preparations illustrating Mr. Coulson's remarkable case of hydatids affecting the tibia. One of the preparations shows the bone itself, which was eventually removed at the joint, the operation having been performed by Mr. Spencer Wells.

Here, perhaps, it will not be out of place to mention as a fact of special clinical interest that I have encountered records of no fewer than nine other similar cases where hydatids have chosen to take up their abode in the tibia; generally selecting the head or upper part of the bone. Some of my notes have been mislaid; but, speaking from recollection, one of the choicest specimens which I have examined is contained in the pathological museum connected with the Nottingham Hospital.

When I first went over the collection of the Middlesex Hospital Museum, I found it to contain fifty-four preparations of entozoa, of which some fourteen only were true hydatids, representing as many separate cases. There are now upwards of a score of preparations of hydatids; several of the cases having already had ample justice done to them by Dr. Murchison in his well known memoir (*Edin. Med. Jour.*, Dec. 1875). Amongst the most interesting preparations, I would especially call attention to two fine and genuine specimens from the kidney, another very large example of an hydatid situated between the bladder and rectum, a simple acephalocyst removed from the orbit (Mr. Hulke's case), and the hydatid removed from the axilla by the late Mr. Charles Moore. There is a jar containing hundreds of hydatids that were taken from the thoracic cavity of a dissecting-room subject, who was reported to have died of phthisis; and there is another preparation of an hydatid of the heart, which also proved fatal, without there having been the slightest suspicion entertained as to the true nature of the disease. For this fine preparation, the museum stands indebted to Dr. Moxon of Guy's Hospital. Several of the liver cases have a special interest of their own; but, for the present, I will only further call attention to the small bottle full of minute hydatid vesicles, all of which were removed from the interior of the tibia. The history of this case has been lost; and, unfortunately, the bone from which the parasites were taken does not appear to have been preserved.

SIX MONTHS AMONG THE BASUTOS OF SOUTH AFRICA.

By E. B. HARTLEY, M.R.C.S. Eng., District Surgeon, British Basuto Land.

I VENTURE to think that a short sketch of six months' practice among the Basutos of South Africa may not be altogether uninteresting. The Basutos belong to the Bechuana tribe, and reside along the western side of the Malutis, which range of mountains separates their country from Natal, about latitude 30 deg. S. Their doctors appear to be aware of the existence and therapeutic value of many roots and herbs growing in the country, but at this early date of my settlement in it, and on account of the secrecy observed in the collection and uses of these medicines, I am at present unable to give any information. In the setting of fractures they display much skill; but as regards the removal of tumours, necrosed bone, and severe surgical diseases, they are entirely ignorant. I was called a short ago to see a fracture of the shaft of the radius which had been put in the correct position of mid pronation and supination with the arm lying in a small mat of reeds, which, from its comfort, easiness of adaptation, and lightness, appeared to be an apparatus worthy of being copied by more civilised nations.

From the simple lives and sobriety of the people, medical diseases of a severe nature are uncommon, and, for this reason, it is easier for me to say what there are not, than what there are.

Among a large number of patients, I have only encountered two cases of phthisis, and I think I am able to trace its origin to the subjects of it having suddenly resumed their native costume of a blanket and nothing, after wearing European costume for some time. This leads me to the question as to the desirability of this part of South Africa for consumptive patients. The experience of the just passed summer, with its daily thunderstorms, and consequent dampness of the ground, leads me to consider Basuto Land itself unsuitable for such cases, but I hear Bloemfontein and its neighbourhood extolled on all sides.

Rheumatism of a chronic nature is very common, which may be attributed to the native villages being situated among the rocks and on the sides of mountains. In very many cases, the present generation of Basutos has spent its youth in caves to escape the attacks of their many enemies. The disease appears to yield readily to alkalis. Dysentery and diarrhoea are constantly met with, especially among infants.

The most rapidly fatal among surgical diseases I have encountered is a species of diffuse cellular inflammation, occurring generally in the arm, which appears to arise idiopathically in old people. The symptoms consist of a hard brawny swelling of the hand and forearm which rapidly spreads, and, in about forty-eight hours, proves fatal. The disease does not appear to run on to sloughing, nor have I been able to trace any cause for its appearance, such as a bite from a snake, or poisoned wound. Neither can I give the *post mortem* appearances, on account of the repugnance of the natives to any interference with their dead. Fatty tumours flourish in large numbers; and here the surgeon has a fine field for the employment of his knife. The native doctor is entirely baulked in this department, and satisfies himself with numerous small scarifications, with a result which can be easily foreseen. Thanks to the vigorous constitutions of the Basutos, the after-treatment is wonderfully successful; union by direct contiguity or by first intention taking place in almost every case.

I will now proceed to relate two interesting cases which have been under my observation within the last few weeks. Their uncommonness must be my excuse for sending this communication.

CASE I. A Mosuto, aged about forty, presented himself with the history of having received a bullet-wound in the left groin seven years ago in the Dutch war. When he received the shot, he was on horseback, and leaning over the horse's neck, with the hope of shielding himself from the enemy. He had ever since been troubled with a slight discharge from the wound and intense pain on walking in the buttocks, where he felt sure he could occasionally feel the bullet. Nine medicine-men of his country had endeavoured to remove the foreign body, but their attempts did not seem to go further than scarifications of the gluteal region, which was absolutely covered with innumerable small cuts. An European surgeon had also made explorations, without any definite result. On examination, a small opening appeared exactly midway between the symphysis pubis and the anterior superior spinous process of the ilium in front, from which a little pus escaped on pressure, and behind, just level with the posterior superior spinous process, was a prominence such as one might expect to find as the point of exit of a bullet. In this latter, was a small opening which admitted a probe, and as the tissues around were much hardened and thickened, I hoped here to find the bullet encysted. But my probe passed obliquely downwards along a canal into the substance of the glutei muscles; and, as I found it too short, I desisted for a couple of days until I could procure something longer. In the interim, my patient discovered a hard substance, four inches lower down deeply in the muscles. On a second examination, to my delight, I hit upon a hard substance at the depth of about a forefinger and a half, and on cutting directly upon it, by the aid of a bullet-forceps I extracted what must once have been a conical bullet, indented and bent all over. I concluded its wandering course must have been directed in this curious way by the crest of the ilium, which it must have skirted, and have lodged for a time in the superficial position before mentioned, to work its way, gradually, by the force of its own gravity, to the depth where it was finally discovered.

CASE II appears to my mind of a nature not frequently met with, and one which gives the surgeon warning not to be over hasty in his diagnosis, and still less so in performing severe operations. A Basuto woman presented herself with a large tumour of the face, causing her appearance to be even more repugnant than nature had intended. The tumour was extremely hard, and apparently adherent to the bone. The patient stated it had been coming for three years, and caused her considerable pain; latterly, it had much increased in size. It entirely blocked up the right nostril, causing great distension of the cheek of the same side, pushed up the nose, and extended about half way across

the upper lip and along the alveolar process of the upper jaw, the gums being much distended. Two of the incisor teeth were loose, and protruded from their sockets. I considered the growth too low down for it to have any connection with the antrum, and, from the history, I feared the superior maxillary bone would require removal. Being unwilling to undertake so severe an operation without due caution, I ordered the woman to return to her village for a couple of months, and to visit me again. On her second appearance, the tumour had much increased in size, and the pain was worse than ever. The hardness had, however, given place to a distinct feeling of fluctuation, and, having consulted Druitt's *Surgery*, where there is a very similar case of Sir Wm. Fergusson's recorded, I considered my case to be one of dropsy of the antrum. On extracting the canine tooth, a large quantity of coffee-coloured viscid fluid poured away, and with it disappeared our quondam tumour. After a daily probing of the antrum, and the application of pads to restore the original appearance of the features, the patient returned to her friends in a few days, delighted at the loss of her horrible deformity, and wonderstruck at the simplicity of the cure.

AGES AT DEATH FROM THREE ERUPTIVE FEVERS.*

By JOHN W. TRIPE, M.D.,
Medical Officer of Health for Hackney.

THE tables on which this paper are based have been compiled to show what are the ages at which small-pox, measles, and scarlet fever are most fatal, and consequently to furnish information as to the chances of attack from either of these diseases at the ages mentioned in the tables. I have also added the necessary percentages for comparison of the deaths at all ages for the same years as those for which the zymotic deaths have been taken. The deaths from all causes during these years, 1868-72, in all England amounted to 2,516,468; those from small-pox to 48,435, from measles to 47,341, and from scarlet fever to 112,412. The death-rate from measles was, therefore, 188, from small-pox 192, and from scarlet fever (the most fatal) 447 per 10,000 deaths from all causes. It must also be remembered that these years include the greatest epidemic of small-pox which we have had since our modern system of registering deaths was begun, and that, therefore, the death-rate from small-pox, as given above, is in excess of the average of thirty years. I have not included fever, because I am convinced that many deaths are registered as being caused by it which should have been attributed to some other diseases, such as hydrocephalus, cerebritis, etc.

Per Milleage of Deaths at different ages in England, 1868-72.

Ages.	0-1	1-2	2-3	3-4	4-5	Total under 5	5-15	15-25	25-45	45-65	65 and upward.	All ages
Small-pox	149	53	43	40	51	350	208	177	207	54	4	1000
Measles	200	376	190	101	53	920	72	3	4	1	0	1000
Scarlatina	65	147	165	149	120	646	316	22	14	2	0	1000
All causes	246	80	38	25	18	407	62	57	130	148	196	1000
Number living,	29.8	27.2	26.6	25.9	25.5	135	226	184	262	146	47	1000

The deaths from small-pox during the first year of life were much more numerous than I should have expected, and show the necessity for early and efficient vaccination. The proportions of deaths from small-pox at different ages under 5 were as follows: under 1 year, 149; between 1 and 2 years, 53; between 2 and 3 years, 48; between 3 and 4 years, 49; and between 4 and 5 years, 51; making a total of 350 deaths per 1,000 under 5 years of age. Between 5 and 15, there occurred 208 deaths per 1,000; between 15 and 25, 177 deaths; between 25 and 45, 207 deaths; between 45 and 65, 54 deaths; and above 65, only 4 deaths in each 1,000 deaths from small-pox in England. On comparing the mortality from small-pox with that from "all causes", we see that the death-rate during the first year of life is higher from both than in any other, although in a much less proportion from small-pox than from "all causes", and a somewhat similar ratio is obtained for the next year of life. Between 2 and 5 years, the proportion of deaths from small-pox remained nearly the same as for the age of 1 and 2, having been 53 for the second year of life, and 48, 49, and 51 per 1,000 for each of the other years, whilst for deaths from "all causes" the numbers were respectively 80, 38, 25, and 18 per 1,000 deaths. The totals under 5 are 350 per 1,000 from small-pox, and 407

* Read before the Public Medicine Section at the Annual Meeting of the British Medical Association in Edinburgh, August 1875.

from all causes. Between 5 and 15, the ratio of deaths from small-pox was more than three times as great as the ratio from "all causes", as, out of each 1,000 deaths from small-pox there were 208, and only 62 per 1,000 from "all causes". At 15-25 and 25-45, there were respectively 208 and 177 per 1,000 deaths from this disease; whilst from "all causes" the ratios were 57 and 130. Above 45, small-pox was less fatal in proportion to other diseases, as only 58 out of each 1,000 deaths from small-pox occurred in persons who were 45 years or older, whilst 344 deaths out of each 1,000 from "all causes" were registered amongst persons aged 45 and upwards. I certainly was not prepared to find that so large a proportion as 35 per cent. of all the deaths from small-pox happened in children under five years old; which indeed shows either that vaccination is not properly performed, or else that it is not done at all on a considerable proportion of the population. A comparison between the death-rates at different ages from measles and scarlatina points rather to imperfect vaccination than to non-vaccination as the causes of the large early mortality. We find that only 8 per 1,000 of the deaths from measles happened amongst persons above 15, and 992 amongst those who were below that age; whilst there were only 38 per 1,000 deaths from scarlet fever in persons above, and 962 in those below 15 years. On the other hand, there were no fewer than 442 in each 1,000 deaths from small-pox amongst persons above 15, against 558 in those who were below that age. These figures prove, I think, that the protection by vaccination is nothing like so perfect as that afforded by an attack of small-pox, otherwise the death-rate above 15 would have corresponded more closely with those of the other eruptive fevers. The table also shows that the death-rate from measles in children under 5 years old is more than double the proportion of deaths from "all causes", as 920 deaths from measles out of each 1,000 died under that age, against 407 per 1,000 from all causes. The most fatal age for measles is between 1 and 2 years, as no fewer than 376 per 1,000 deaths from this disease were registered in children who were above 1 and below 2 years of age. There were 200 under 1 year, 190 between 2 and 3, 101 between 3 and 4, 53 between 4 and 5, and 72 only between 5 and 15 years of age.

These data are rather important as regards a question sometimes asked by anxious mothers, viz., What are the chances that a child will have the measles? By referring to the tables, we have some information to guide us. It is certainly to be regretted that a corresponding paper has not been written on the ages at which attacks from the diseases occur, as we could then have ascertained whether or not the mortality at these early ages arise from the severity or the frequency of the attacks.

The ages at death from scarlet fever differ materially from those of measles and small-pox. During the first year of life, only 65 out of each 1,000 deaths occurred, against 200 from measles and 149 from small-pox. In the next year of life, between 1 and 2 years of age, it is more fatal, as 147 deaths were registered in each 1,000 from scarlet fever; but, between 2 and 3, this disease produced its largest mortality; viz., 165 per 1,000, and the next largest between 3 and 4 years of age; viz., 149 per 1,000. Between 4 and 5 years, the mortality was at the rate of 120 per 1,000, making a total of 646 per 1,000 under 5 years of age; between 5 and 15 years of age, the number of deaths from scarlet fever was very large; viz., 316 per 1,000, against 208 from small-pox, 72 from measles, and only 62 per 1,000 deaths from all causes. Above 15 years of age, the number of deaths from scarlet fever are comparatively few, as only 38 deaths per 1,000 from this disease were registered at these ages, against 531 per 1,000 from all causes.

I have appended the number of living at each age in 1,000 inhabitants of England for comparison with the mortality at each age. We see that there were 135 children under 5 years of age alive in each 1,000 persons of all ages, and that there were consequently 865 persons per 1,000 alive at all ages above 5 years old, or nearly six and a half times as many. It is, therefore, evident that the 350 deaths which occurred from small-pox, the 920 from measles, and the 646 from scarlet fever out of each 1,000 deaths from these causes, took place in less than one-sixth part of the whole population. As so large a proportion of persons died from scarlet fever between 5 and 15 years of age, I calculated the numbers at 5-10 and 10-15, and find that 26.0 per cent. occurred at the former, and only 5.6 per cent. at the latter. It is, of course, impossible to ascertain how many persons per cent. have suffered during their lifetime from measles and scarlet fever, and who have been vaccinated or suffered from small-pox; but it would be very interesting to obtain some statistics in the matter. At present, we are accustomed to say that such a person has had scarlet fever, small-pox, or measles, and is not likely to have it again; but, as regards measles especially, the immense proportion of deaths under 5 years of age points to a diminishing liability to the disease as age increases, as well

as to an immunity acquired by an attack in childhood. The extremely small mortality from scarlet fever in persons above 15 years of age probably points in the same direction, although my experience is certainly in favour of a larger proportion of the population under 15 having suffered from scarlet fever than from measles. Be that as it may, the age of attaining comparative immunity from an attack of measles, either by the protection afforded by a previous attack, or from age, appears to be 5 years, whilst from scarlet fever it is about 15, and small-pox about 40 years of age. If the table should impress forcibly on the medical mind these facts, that, after 5 years of age, only a very small proportion of deaths take place from measles; that less than 10 per cent. of the deaths from scarlet fever occur after 10 years of age; whilst similar immunity from small-pox is not reached until about 40 years of age,—this brief paper will not have been written in vain.

ON FRACTURE OF THE NASAL BONES: A CLINICAL NOTE.

By **SAMPSON GAMGEE, F.R.S.E.,**
Surgeon to the Queen's Hospital, Birmingham.

MY attendance was requested on the 29th August ult., to a gentleman

who, in an assault, had sustained a fracture of the nasal bones just below their union to the frontal. The blow, which had been given on the right side, had bruised the whole cheek, and driven the nose to the left, so as to produce very perceptible deformity, in spite of the care taken to prevent it by appropriate plugging. Pressure with the finger on the left side of the nose readily restored its symmetry; and, with a view to the construction of an apparatus to maintain graduated pressure, I sought the assistance of Messrs. T. P. Salt and Son, our local surgical mechanics. The annexed woodcut represents the instrument which they devised

and constructed. Its use has proved perfectly satisfactory, and no lateral deviation is now perceptible.

The instrument consists of three parts: viz., a spectacle-frame, from which the glasses have been removed; a nose-saddle, with forehead piece made of gutta percha, accurately modelled to the contour of the parts; and a screw with cushion.* The spectacle-frame is attached to the saddle by a metal loop, in which it moves freely in a horizontal plane, the free ends of the spectacle-frame being fastened at the occiput by a ceinture of ribbon; from the forehead piece, which is a continuation of the saddle, proceeds a padded band, passing over the head, and fixed to the ribbon aforesaid, so as to prevent, in conjunction with the spectacle-frame, both lateral and vertical movement. An oval aperture is cut in the saddle, as shown by the engraving; and a steel spring is fastened to the forehead piece or mask, passing in a direction nearly parallel with the nose, and exerting its force in a line opposite to that which the distortion has taken; through the spring, a screw works, having at its extremity a small padded cushion, so disposed as to press on the fractured bones with any degree of force which the surgeon may think desirable. The arrangement of this instrument allows the pressure to be nicely graduated, and, at the same time, prevents the instrument from being displaced—an accident which will, under other conditions, easily happen.

* In the sketch, the screw is shown on the right side. It was on the left in the particular case for which this instrument was devised.

DR. TRENDELENBURG, known as the inventor of the plan for plugging the trachea in cases of operation on the mouth, has been appointed Professor of Surgery in the University of Rostock; and the vacancy consequently made in the office of director of the surgical department of the hospital at Berlin has been filled by the appointment of **Dr. Max Schede** of Halle.

OBSTETRIC MEMORANDA.

THE USE OF PERCHLORIDE OF IRON IN POST PARTUM HÆMORRHAGE.

I HAVE read with much interest the instructive case of death from the injection of perchloride of iron for *post partum* hæmorrhage, which was published with praiseworthy candour by Mr. Boddy in the last number of the JOURNAL. As it does not appear that there was any *post mortem* examination, it is difficult to pronounce with certainty as to the cause of death, but I have little doubt myself that the fatal result was due to the escape of some of the fluid through the Fallopian tubes into the peritoneal cavity; and this case points out a danger that may very possibly attend the use of this valuable remedy. According to Mr. Boddy's account, the first result of the injection was to stop the hæmorrhage and cause firm contraction of the uterus. The severe pain and other alarming symptoms came on "during the last two or three strokes of the enema-syringe". "The uterus was firmly contracted round the injection-tube, and even little force being required for its removal." We can easily understand how, when the escape of any fluid from the os uteri was thus prevented, and also when the cavity of the uterus was so reduced by the same contraction as to be incapable of holding sixteen ounces of fluid, the increasing pressure might force some of the solution through the Fallopian tubes. To guard against such a danger, I would suggest the use of a double tube, so as to provide for the ready egress of the fluid from the os uteri; for it is a great pity that so valuable a remedy should be discredited for want of some simple precaution of this kind. JOSEPH GRIFFITHS SWAYNE, M.D., Clifton, Bristol.

CLINICAL MEMORANDA.

DIABETES MELLITUS IN A CHILD FOUR YEARS OF AGE.

As cases of diabetes mellitus in children are very rare, the following report may be deemed of interest.

J. L., aged 4, was brought to the surgery on the evening of December 1st, 1874. Until recently, the boy's health had been good, as had been that of the parents; but, about three weeks previously, the father's attention was drawn to an unusual thirst, and frequent calls to micturate on the part of the child. The boy complained of no pain, but appeared listless and disinclined to make any exertion whatever. The skin felt singularly dry and harsh, and the tongue was thickly coated with dry brownish fur. Nothing was prescribed at this time beyond careful diet, and a sample of urine was directed to be forwarded. On December 3rd, the appearance of the child had changed remarkably, the loss of flesh having been very marked since last date. The amount of urine passed during twenty-four hours had been exactly three quarts. It was light coloured, clear, except for slight mucous clouds, and of specific gravity 1035. On being tested for sugar, it gave evidence of a very large proportion. The diet of the child was directed to consist chiefly of milk, and light animal diet, with brown bread. A mixture, containing bicarbonate of soda and tincture of hyoscyamus, was ordered, together with an opiate at bedtime. On December 4th, the patient's appearance was unchanged. The quantity of urine passed had much diminished, but the exact amount was not ascertained, in consequence of the boy having passed some in bed. Its specific gravity was 1032. On December 5th, the boy was much worse. Emaciation had progressed with wonderful rapidity. There was great difficulty in persuading him to eat anything. The urine was kindly examined quantitatively by Mr. Baker, and the amount of sugar was found to be twenty-eight grains in the fluid-ounce. On December 6th, he died. No necropsy was made. JOHN BENSON, Sheffield.

FRACTURE OF THE NECK OF THE FEMUR IN AN OLD WOMAN.

At the end of July 1869, a lady, sixty-eight years of age, accidentally stepped off the platform at one of the Metropolitan Railway Stations, and fell into the roadway. She was conveyed to her home in the neighbourhood, where her medical attendant diagnosed fracture of the neck of the right femur. When I saw her, on the third day after the accident, I found the right limb considerably shortened, everted, and quite useless. There were also considerable swelling and contusion over the hip. The pain experienced by the patient when we attempted to move the limb precluded our forming a definite diagnosis as to the fracture being within or with-

out the capsular ligament. The limb was brought into its proper position, and there maintained by a long splint and a perineal band. The patient bore her confinement exceedingly well, and before two months were passed was lying on her sofa with the limb in excellent position. For the last three or four years she has been walking about without the aid of a stick, and with but slight lameness. At the end of last June she died of chronic liver-disease, when I was fortunate enough to obtain permission to examine the seat of the old injury.

POST MORTEM EXAMINATION.—The body was much wasted. The great trochanter of the right side was more prominent than the other; but this prominence was more apparent than real, on account of the wasting of the muscles just below the right iliac crest. Careful inspection of the two limbs showed that the right had undergone a shortening of exactly one-third of an inch. For the sake of comparison, the upper end of each thigh-bone was removed. (The two specimens were to be seen in the museum of the Association at Edinburgh during the late meeting.) The neck of the right bone was slightly shortened, and its base thickened. There had evidently been extracapsular fracture, with firm bony union. The first effect of the fall was, I take it, to break off the neck just below the anterior intertrochanteric line; the continuance of the shock brought the base of the neck into violent contact with the inner side of the great trochanter, which was then splintered off. The pieces have become so firmly united, that the exact lines of fracture can scarcely be indicated with certainty. And, which is worthy of remark, there is not the least trace of that redundancy of new bone which is generally described as being characteristic of the union of the pieces in this variety of fracture. Indeed, were it not possible to compare the two bones, it is probable that a sceptical examiner might ascribe the changes in the broken bone to chronic rheumatic disease, more especially as there is some erosion of the articular cartilage.

REMARKS.—In an aged person, the neck of the femur will more likely give way on the inside of the capsular ligament than on the outside, and from a slight injury, such as a trip or stumble. But, as is well known to be the case, a heavy fall, or a severe blow upon the outside of the great trochanter, will give rise to a fracture outside the capsule. By the light of short comparative tables, such as may be found in most works on this subject, a diagnosis as to the exact position of the line of fracture as regards the capsular ligament should, at any rate on paper, be simple and sure enough. But in some, I might say in many, cases, the diagnosis must be uncertain. Following the advice of Sir Astley Cooper, many surgeons will not attempt to keep in confinement a patient in whose case they have diagnosed intracapsular fracture; whilst, should the seat of fracture be supposed to exist outside the capsule, the patient would have to submit to the treatment by the long splint. What becomes of the cases where the diagnosis is uncertain? I am of opinion that all cases of fracture of the neck of the femur should be treated as if the surgeon anticipated a bony union. If the patient cannot bear the confinement in bed, nor the weariness of the extension of the limb, then, whatever be the seat of the fracture, he must be liberated, at any rate for a time. This plan of treatment will in any case give the patient the best chance of a good result as regards union. Suppose the fracture to have been within the capsule, no harm can have been done with due care. On the other hand, supposing that an extracapsular fracture be diagnosed as intracapsular, and no apparatus applied, the patient will have a comparatively useless limb all his days, and we have done him an irretrievable wrong.

EDMUND OWEN, F.R.C.S.

A RARE CASE OF SPINA BIFIDA.

THE following are the particulars of an interesting case of spina bifida which recently came under my notice. A. G. M., a male, was born on September 19th, 1875, and died on the 29th of that month. There was nothing to remark in the birth except a slight gush of fluid after the shoulders had passed over the perineum, the cause of which was discovered as soon as the child was separated from the mother. At the lower part of the back, and over the lumbo-sacral region of the spine, was found a loose cap of integument, thick below and of a purplish mottled appearance, but thin and membranous above, where it was perforated by a round hole, into which I could easily insert the tip of my index finger—evidently the ruptured sac of a spina bifida. The sac was covered with a layer of cotton-wool, and supported by a broad flannel roller. On the third day, the dressing was changed, as it was soiled with a greenish yellow gummy secretion, smelling rather offensively, and lint dipped in a solution of carbo-glycerine (subsequently changed for carbolised oil) was applied. There was a slight puckering round the hole above mentioned, which was now almost closed, and the sac was gradually filling out. Two days later, Sept.

23rd, the sac was much fuller, and presented the appearance of a large tomato. The following are the measurements taken at this date by a tape carried over the surface of the swelling: oblique (right to left), 3¾ inches; transverse, 3¾ inches; vertical (in the median line), 3 inches. After having dressed the case as usual, I left, and the nurse informed me, on my visit the following day, that, on applying the flannel roller rather firmly, the sac burst, and a little water and blood oozed out. Her statement was borne out by the appearance of the sac, which was again flattened and collapsed, though there was no orifice to be seen. From the 25th to the 27th, the sac rapidly filled; there being now no puckering. The tension from the contained fluid (which I estimate at between five and six ounces), together with the straining from a smart attack of diarrhoea, again threatened rupture of the sac. Although the child was convulsed during this period, and up to the time of its death, the spasmodic movements had little effect upon the swelling. Below a line drawn round the body at the level of the umbilicus, the muscles were much dwindled, and there was scarcely any motor power, but more on the left side than on the right. Sensory power was lost altogether, as pinching and pricking did not make the child cry or wince in the least. On the 27th, the measurements of the tumour were as follows: oblique (right to left), 5¼ inches; transverse, 5½ inches; vertical, 5 inches. The circumference at the base was 7½ inches. An opportunity was afforded of opening the sac after death. It was found to be filled with a turbid blood-coloured fluid, on draining which off, the cauda equina, surrounded by a fibrous clot, was seen traversing the bed of the tumour; three large nerve-cores were exposed on each side—the last breaking up into a leash of nerves. There was congestion of the spinal cord and upper part of the membranes of the sac.

WM. FRANCIS HAZEL, M.R.C.S.E.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN.

ST. THOMAS'S HOSPITAL.

CASE OF ACUTE TETANUS AFTER CRUSHED FINGERS: TREATMENT
BY NITRITE OF AMYL: DEATH.

(Under the care of Mr. WAGSTAFFE.)

WE are indebted to Mr. Campbell, the dresser of the case, for the following notes.

Samuel O., aged 10, was admitted into Leopold Ward on Tuesday, August 10th, 1875. The boy came to the hospital on Tuesday, August 3rd, at 11.15 A.M., with his right middle and ring fingers severely lacerated on their palmar surface, the middle finger being in by far the worst condition. His mother stated that he had been run over by a cart. The ring finger was strapped; but the middle finger required also three sutures. Warm water dressing was applied over both, and the hand rested on a splint. He came to the hospital the two following days. On Friday, he did not come; and on Saturday his middle finger was found to be much swollen, the redness and swelling extending over all the dorsal surface. The sutures were, therefore, taken out; but, in doing this, the wound was torn open; besides, it was offensive; and a lotion of chlorinated soda was ordered to be used, instead of warm water dressing. He came on the following Monday, and the middle finger then looked very bad, but the ring finger was improving. On Tuesday, August 10th, he attended with tetanic symptoms. He could hardly open his mouth; his neck was rigid; he cried on being spoken to. His mother stated that he had some difficulty in opening his mouth in the morning, and that his neck was very stiff; but, from the boy's own account to the sister, it would seem that the difficulty in swallowing had begun the previous evening. He was at once admitted into St. Thomas's Hospital, and was ordered an ounce of castor-oil in milk, and twelve grains of hydrate of chloral every three hours. During the afternoon after admission, the most marked peculiarity was his grin and the stiffness of his jaws, neck, and abdomen. The nurse of the ward stated that, on the evening of the same day, at about seven o'clock, and again about nine, he had tetanic spasms twice; his back was arched; he stretched out his hands convulsively; his legs and his abdomen also were very rigid, and he could hardly swallow, a teaspoonful of milk taking at least a minute to go down. The night-nurse stated that, while she was on duty, he had great difficulty in swallowing. His arms were very rigid; the abdomen was slightly so; and the

legs were *not at all so*. He swallowed a quarter of a pint of milk from the time of admission to nine the next morning.

August 11th, 9 A.M.—The patient suddenly became worse; he swallowed with greater distress than before, clenched his teeth, foamed at the mouth slightly, and clutched tightly the sister's hand. Mr. Wagstaffe decided that the fingers ought to be amputated. The chloral was stopped, and nitrite of amyl, to be taken every half-hour, was ordered.—11 o'clock. The fingers were amputated by Mr. Potter, the house-surgeon, a V-shaped incision being made on the back of the hand. The wound was washed with a weak solution of chloral-hydrate. The patient could swallow milk much more easily. The nitrite of amyl was increased to two minims every half-hour.—12.30. A most violent spasm came on about this time; the patient's jaws were firmly clenched; his tongue was severely bitten; his breathing seemed to have ceased, and his pupils were contracted. The jaws were forced open; Mr. Potter was sent for, and the boy's life was saved for the time by means of artificial respiration. Mr. Wagstaffe, being sent for, ordered two minims of amyl-nitrite every quarter of an hour. The patient was still able to swallow milk from time to time.—2 o'clock. Slight spasms had occasionally occurred since the last severe one at 12.30. Respirations, 54; pulse, 120. The patient had been since 11 A.M. in a profuse perspiration about the head and face.—2.30. Slight spasms occurred at various intervals.—3 o'clock. One minim of nitrite of amyl was ordered every half-hour, instead of two minims every quarter of an hour. About this time, he was observed to look much bluer.—4 o'clock. The patient looked decidedly bluer than at 2.30. The cheeks were blanched. There was still no difficulty in swallowing small quantities of milk from time to time.—5 o'clock. Brandy and milk were swallowed without any special difficulty.—5.20. A severe spasm occurred. The jaws were forced open; Mr. Potter and Mr. Wagstaffe were sent for, and artificial respiration was tried, but without avail. The patient had swallowed half a pint of milk since 9. Some time previous to his death, the sterno-mastoids became very rigid; his abdomen was hard throughout; the intercostal muscles were slightly rigid for some time. The temperature at the time of death was, in the axilla, 99.6 deg.; in the groin, 103.4 deg.

At the *post mortem* examination, which was made by Dr. Greenfield, the special morbid features were found in the lungs and brain. The lungs were of a dark colour, especially behind, where there were several spots of subpleural ecchymosis. All except the front borders appeared imperfectly expanded, and presented small spots of lobular collapse, which, on section of the lung, were found most abundant in the upper lobe and at the superficial parts of the lower lobe. The pulmonary veins contained dark fluid blood, and the bronchi a blood-stained frothy mucus. The spinal cord presented no special features to the naked eye, and was not abnormally vascular. On the brain, the veins were very much congested, and the same venous congestion was noticeable in the grey and the white substance; but there was no sign of active hyperæmia or inflammation. The lateral ventricles were full of blood-stained serum.

REMARKS.—The symptoms in this case were very acute, and it was evident that only temporary relief was given by the treatment. Still the effect of the nitrite of amyl is worthy of record. The most distressing symptom from the first was the difficulty of swallowing, and this, together with the spasm of different muscles, was not in the least relieved by chloral; but it was evident that the influence of the amyl-nitrite was for a time beneficial. One minim was administered by the mouth, at first every half-hour, with the effect of diminishing the spasms, so that he was able to swallow with comfort. The dose was increased after two hours to two minims, and then to two minims every quarter of an hour, sometimes inhaled and sometimes swallowed, and, after about two hours, was reduced to one minim every half-hour. During all this time, the spasms had almost disappeared; but very marked lividity came on with a spasm, which carried him off. It is difficult to say to what extent the amyl induced this lividity, or whether the cause of death was simply referable to the disease; for, as is well known, cases of tetanus frequently terminate with the symptoms which here existed. But it appeared as if the drug greatly diminished the most distressing symptoms. The *post mortem* appearances did not throw much light upon the question.

CORK DISTRICT LUNATIC ASYLUM.

CASE OF MICROCEPHALIC IDIOCY.

(Under the care of Dr. J. A. EAMES, Resident Medical Superintendent.)
For the following report, we are indebted to Dr. Ringrose Atkins, Assistant Medical Officer.

In connection with the two interesting cases of "Microcephalic Idiocy" brought forward by Dr. Shuttleworth, and published in the

JOURNAL for October 9th, the following case, as a further illustration of the amount of intelligence compatible with a brain deficient in size, may be worthy of record.

The subject, Denis S., a male patient, aged 32, was admitted into this asylum, for the second time, in February 1860. Beyond the facts that his father was dead and his mother blind, that he had no brothers or sisters, and that no relative had been insane, his history had not been obtained. Previously to his second admission, the lad, it appears, had endeavoured to earn a livelihood as a labourer. He now stands 58 inches high, and weighs 7 stones 1 lb. The measurements of the head, taken with a tape, are as follows: Circumference, 18 inches; from root of nose to occipital protuberance, 10 inches; from ear to ear transversely, 9½ inches; from middle of forehead to middle of ear, 5 inches; from middle of ear to occipital protuberance, 4 inches. The abnormality in configuration exists chiefly at the vertex and occiput, both of which are flattened; more especially the occiput, which is on a level with the back of the neck. The face is large in proportion to the cranium proper, which gives the entire a peculiar appearance. The forehead is somewhat receding, though not markedly so; the malar bones are prominent; the chin is narrow, and the lower lip slightly protruding. The mouth is small, and there is no arching of the palate. The ears are diminutive; and the growth of hair on the head and face is scant. The neck is small and well formed. The shoulders are broad, and the bony points prominent. The girth of the chest is thirty inches; and the length of the arm from the acromion to the tip of the second finger is twenty-six inches. The sexual organs are largely developed. The legs are slightly bowed, the feet small and well formed. His muscular development is fair, and he walks firmly and well. His respiratory, circulatory, digestive, and urinary systems are healthy; and he eats well and sleeps fairly. His sight and hearing are tolerably good; the colour green, however, appears to predominate in his chromatic range of vision; as, when shewn any object, he almost invariably says that its colour is green. His power of taste, also, appears to be somewhat defective, as he does not apparently distinguish between solutions of salt and of sugar.

Mental Condition.—When called by name, he comes readily, and answers questions regarding himself rationally. He cannot, however, sustain a conversation; as, after a few minutes, his attention wanders, and he goes off into a medley of English and Irish words wholly unintelligible. His power of memory is remarkable; he recollects his parents' Christian names, and appears pleased when he mentions that of his mother, as if the recalling her name to his mind was attended with pleasurable recollections. It is difficult, however, to draw him out on this subject. He can correctly name and explain the use of almost any article shown him—those which he rarely or never sees in his daily life now, equally well with those ordinarily in use around him; failing, generally, only in the colour of the object presented. This he can evidently only do by recalling to his memory past experiences which he gained previously to his being brought to the asylum. His disposition is gentle; he is quiet and inoffensive, and not easily angered; he is apparently happy and contented, and is cleanly in his habits and person. From inquiries, I find that, during his fifteen years' residence in the asylum, he has sensibly improved both in his habits and intelligence; and, as he now is, his mental capacity is much greater than that of many of his class around him, whose heads are of normal size and configuration.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.

A FIFTH YEAR'S CASES OF LITHOTOMY.

(Under the care of Mr. VINCENT JACKSON, Mr. KOUGH, and Mr. NEWNHAM.)

OF the examples of stone in the bladder admitted into the hospital during the year 1874, the following eight cases were operated upon by lateral lithotomy. The publication of this series gives, with the reported cases of the four previous years, a total of forty-eight lithotomies, all (excepting two) being successful. The age of the youngest patient operated on was two years; and that of the oldest, seventy-one years.

CASE I. John Rock, aged 71, was admitted January 7th, under Mr. Vincent Jackson. The symptoms, which had lasted five or six years, were very severe, and had severely tried the man's constitution; and, in addition, he was suffering from an atheromatous condition of the aorta and other vessels, the heart's action being also very feeble. On February 19th, lateral lithotomy was performed, the stone being removed with the forceps. Its weight was 565 grains; its composition uric acid. On February 28th, he died of bronchitis and exhaustion.

CASE II. Thomas Williams, aged 12, was admitted March 3rd, under Mr. Vincent Jackson. The duration of symptoms was five years. On

March 12th, lateral lithotomy was performed, the stone being removed with the forceps. It weighed 640 grains, and was composed of oxalate of lime. On May 26th, he was discharged cured.

CASE III. Samuel Grainger, aged 50, was admitted March 24th, under Mr. Vincent Jackson. The duration of symptoms was two years. On April 9th, lateral lithotomy was performed, the stone being removed with the forceps. Its weight was 200 grains; its composition uric acid. On May 26th, he was discharged cured.

CASE IV. James Crutchley, aged 3, was admitted April 11th, under Mr. Vincent Jackson. The duration of symptoms was twelve months. On April 23rd, lateral lithotomy was performed, the stone being removed with the forceps. It weighed 87 grains; and consisted of uric acid. On June 2nd, he was discharged cured.

CASE V. Joseph Beckett, aged 11, was admitted April 11th, under Mr. Newnham. The duration of symptoms was uncertain; said to be twelve months. On April 23rd, lateral lithotomy was performed, the stone being removed with the forceps. On September 21st, he was discharged cured.

CASE VI. James Wordesley, aged 4, was admitted May 25th, under Mr. Newnham. The duration of the symptoms was uncertain. On June 4th, lateral lithotomy was performed, the stone being removed with the scoop. It weighed 55 grains; and was composed of uric acid. On July 21st, he was discharged cured.

CASE VII. George Lyton, aged 19, was admitted July 3rd, under Mr. Kough. The duration of symptoms was two years. On July 9th, lateral lithotomy was performed, the stone being removed with the forceps. Its weight was 352 grains; and its composition oxalate of lime, with a coating of phosphates. On October 13th, he was discharged cured.

CASE VIII. Ernest Marshall, aged 5, was admitted August 14th, under Mr. Kough. On August 20th, lateral lithotomy was performed, and two small stones were removed with the scoop. The weight was 28 grains: the composition uric acid, with a shell of phosphates. On October 13th, he was discharged cured.

REVIEWS AND NOTICES.

ESSAYS AND PAPERS ON SOME FALLACIES OF STATISTICS CONCERNING LIFE AND DEATH, HEALTH AND DISEASE; with Suggestions towards an Improved System of Registration. By HENRY W. RUMSEY, M.D., F.R.S., etc. London: Smith, Elder and Co. 1875.

THIS collection of essays and papers, which were originally published or read at different times during the past twenty years, forms a welcome and important contribution to the history and progress of State Medicine and of sanitation during that period. For more than a quarter of a century, the name and talents and energy of Dr. HENRY W. RUMSEY have been almost continuously identified with sanitary progress, and with the crusade against the ignorance and apathy which, like a spell, seemed to neutralise all efforts to raise the standard of health among the people. Like most reformers, Dr. Rumsey has probably suffered disappointments of two kinds: disappointment at the slow rate of sanitary progress, and disappointment because the progress attained has not always taken the exact form which he would have wished and which he had advocated. It is true that many of the reforms for which Dr. Rumsey has consistently laboured are still postponed to a future date, and of these we may specially mention the registration of diseases and of still-births, and a complete certification of the causes of death; but the passing of the Public Health Act of 1872 marked the commencement of a new era in hygiene, and laid the foundation of a national sanitary organisation. The creation of responsible sanitary authorities throughout the country, with medical officers of health as professional advisers, has effected many of the results which Dr. Rumsey hoped to attain by the appointment of medical superintendents.

The Births and Deaths Registration Act of 1874, moreover, although falling far short of what ardent sanitary reformers like Dr. Rumsey could have wished, still made some concessions in the direction of their aspirations. The registration of births was rendered compulsory; and, although no provision was made for the registration of still-births, it imposed some restrictions upon the burial of still-born children, especially with a view to check the burial of deceased children as still-born. On the other hand, not only those who wish to increase the accuracy of mortality statistics, but those who put the highest value upon the security of human life, must sympathise with Dr. Rumsey in

his disappointment, that no provision was made in this Act for securing the services of a "skilled certifier" in all cases of death in which a certificate of the cause of death cannot be obtained. In this particular, the system of registration of deaths in England is still inferior to that in operation in many parts of the continent and in the United States. Here a legally qualified informant may go to the local registrar and register the death of any person, and, by stating that there was no medical practitioner in attendance on the deceased, can complete the registration, assign the cause of death as convulsions, consumption, apoplexy, or old age, according to his fancy or inclination, and get a certificate or authority for burial. That all such cases will eventually be made the subject of "medico-legal" inquiries is the deliberate conviction of all sanitary reformers; and, in many of the essays before us, this subject was handled nearly twenty years ago in a manner which is still full of freshness and point.

The first part of this volume of *Essays* consists principally of those which deal with what may be called the machinery of registration, and especially with Dr. Rumsey's scheme for the "scientific superintendence of mortuary registration". These papers abound with suggestions which have in part been adopted, in part superseded by reforms of a different character having the same object in view, and are in part still the subject of agitation and discussion. It is matter for regret, that the state of Dr. Rumsey's health at present prevents him from affording to the sanitary progressist party the continuance of his invaluable assistance.

The second part of the volume has for a heading "Essays on the Fallacies of Vital and Sanitary Statistics". The general scope of these essays appears to be, to point out the various sources of error and inaccuracy which militate against the trustworthiness of vital statistics in general, and especially of death-rates taken as a test of sanitary condition. The first paper in the volume opens with the following sentence. "All who are interested in the cause and progress of sanitary science are aware of the invaluable aid it has received from the publications of the Registrar-General. They are in fact our first text-books in the study of hygiene—the very accidence of our grammar." This opinion, however, Dr. Rumsey has apparently seen occasion to modify. In the second part of the volume the author insists on the deficiencies and imperfections on which the statistics published in the weekly, quarterly, and annual reports of the Registrar-General are constructed. Without determining the limit of error arising from these imperfections, or showing that actual mischief has resulted from the publication of the Registrar-General's figures, Dr. Rumsey urges that "the indiscriminate appeals so often made to the rates of mortality threaten to become a public nuisance"; and, in another place, speaking of populations differently constituted as to "ages, classes, industries, habits, and closeness of aggregation", declares "comparison of their temporary death-rates, for practical objects, a mischievous absurdity". As these and other similarly expressed opinions appear throughout Dr. Rumsey's papers that are especially devoted to what he calls the "Fallacies of Statistics", and as these opinions have been extensively quoted, it may be useful briefly to notice the grounds of his attack upon the value of death-rates.

The rapid progress which has recently been made in enlisting public interest and sympathy in sanitary matters is in great measure due to the easy comprehension of the numerical test of sanitary condition which has been afforded by the published "death-rates" of the Registrar-General; that is, the calculated ratio of deaths to population. That this numerical test has been incalculably useful in bringing home to popular conviction the vast waste of life in towns as compared with rural districts, and in such towns as Liverpool and Manchester, compared with London and Bristol, it is impossible to deny. Further, it is evident that if this numerical test were to be surrendered, and no other could be found to take its place, the cause of sanitary progress would receive a severe check; for it is to the emulation between different communities to reduce their death-rates that the improved sanitary condition of many of our large towns is mainly due. It appears somewhat paradoxical to find so earnest a sanitary reformer as Dr. Rumsey urging that what he calls the "indiscriminate" use of death-rates should be discontinued. Let us enumerate a few of the grounds on which this course is recommended.

Our census enumerations, it is said, are imperfect. Certainly they are, and, although they probably become more correct at each enumeration, it is Utopian to expect that so gigantic a work, which requires an army of 30,000 men to perform the preliminary work, will ever be free from imperfections, although a great step in the right direction would be made if the enumerations were held every five instead of every ten years. It is true that our birth and death registers are susceptible of improvement, and that our 3,000 registration-officers are not all animated with an intelligent appreciation of the sanitary value of

their labour. Dr. Rumsey and his disciples appear to lose sight of the fact that, when civil registration was established, its value from a sanitary and statistical point of view was scarcely dreamed of, and that the few pounds a year earned as registration-fees by so large a proportion of our local registrars will not in all cases secure intelligence, much less zeal and public spirit.

Another ground for disapproving of the death-returns is, that the causes of death are often carelessly and loosely returned, and in a certain considerable proportion not certified, either by medical practitioner or by coroner. This again is true; and yet, while our returns of the causes of death are year by year improving, would it be wise to cease all efforts to turn these causes of death to useful account? Then the proportion of deaths to population as a numerical test of sanitary condition has been pronounced "mischievously delusive", because it takes no account of the varying proportion of the sexes, of the proportion of the persons living at the different ages, of the influence of class and occupation, and of migrations of population.

All these charges of imperfection, both in the sources of information from which our vital statistics are derived, and also in the scientific accuracy of the calculated rates of mortality, are sufficiently well founded, and they must be frankly acknowledged to exist. The really important question, however, is, whether the actual effect of any of these sources of imperfection, or the combined effect of them all, is sufficient to destroy the value of this convenient and useful numerical test, the death-rate. The extreme limit of error from these various sources of imperfection has recently been proved to be very small. The influence of sex has scarcely an appreciable effect on the death-rate of populations showing the extreme variation in the proportion of the sexes found in any aggregations of population. The age-distribution of town populations, in their extreme variations, has also been shown to produce an utmost effect of from 1 to 2 per 1,000 in the annual rate of mortality, which, so long as town death-rates range from below 20 to more than 35 per 1,000, is insufficient to destroy the value of these rates for comparative purposes. The same result has attended the effort to show the effect upon the general death-rate of the continuous migration of healthy lives into towns. This is scarcely appreciable in the general rate at all ages, although its influence is great upon the rate of mortality at those ages at which the migration takes place. The effect of class and occupation upon calculated death-rates may also be disposed of. The Registrar-General, we will suppose, points out that the death-rate in St. James's is 15 per 1,000, and in St. Giles's 30 per 1,000; and draws the obvious conclusion that the sanitary condition of the former is far better than that of the latter; and further, that much sanitary work is called for in St. Giles's. Is this the less true, or in any way "mischievously absurd", because the class and occupations of the two populations differ so widely? The fact remains, that the costermonger and his family in St. Giles's die at double the rate of the denizens of St. James's. The main object of sanitary effort is to reduce this disparity in death-rates and sanitary condition; and the decrease of death-rates in improved dwellings for the working classes is an answer to such assertions as that all the world cannot live in St. James's, and that, therefore, it is useless to compare the death-rates of well-to-do communities with those of the working classes.

While strongly recommending the perusal of these essays of Dr. Rumsey's to all students of vital statistics, and to those generally interested in sanitary subjects, we have pointed out the reasons which lead us to hesitate in agreeing with his objections against the publication and acceptance of death-rates as trustworthy, though broad, indications of sanitary condition. In the future, when the present wide variations in death-rates shall have yielded to the effect of sanitary progress, it may be necessary to invent some more accurate numerical test than the general death-rate; at present, no such more accurate test has been suggested.

In conclusion, we are bound to call attention to one or two assertions in Dr. Rumsey's essays which have frequently been mischievously applied. The first that calls for notice is the theory, that a high birth-rate in a population, and the consequent large proportion of infants and young children, produces and explains the fact of a high death-rate in that population. This theory has recommended itself so strongly to the sanitary authorities of large towns, where both birth- and death-rates are almost invariably high, that it is tenaciously upheld, although its fallacy has been conclusively exposed. The simple fact is that, even under present conditions, the rate of mortality among children under five years of age is about the same as that among persons aged sixty years and upwards; and that the death-rate of a population depends as much upon the proportion of elderly persons as upon that of young children; moreover, that the proportions living at these extremes of life have a compensating tendency. For instance, the proportion of elderly persons is almost invari-

ably low when that of children is high, and *vice versa*; this has the effect of contracting the influence of age-distribution upon the general death-rate within very narrow limits. It has been shown, moreover, that this disturbing influence, so far as it goes, is of an exactly opposite character to that imagined and propounded by Dr. Rumsey and his disciples. The normal death-rate, calculated according to the English Life-Table, for all populations in which a high birth-rate prevails, with accurate allowance for its age-distribution, is invariably lower than is the normal death-rate in populations with a low birth-rate, calculated in the same way. The large proportion of infants and children in the high-birth-rate populations is more than compensated by the large proportion of young adults at those ages when the rate of mortality is very low, and by the small proportion of elderly people.

The objection which is made in these essays to the use of annual rates of mortality in the Registrar-General's Weekly and Quarterly Returns, if tenable, would be a severe blow to the utility of these publications. The substitution of weekly rates and quarterly rates would render the rates wellnigh useless to the public, who would not easily learn to comprehend and appreciate at their proper value half a dozen standards for measuring mortality. It is also very certain that if mere facts, without any calculated rates, were given to the public in these Returns, the influence of public opinion and interest in sanitary matters would be incaleculably weakened.

Dr. Rumsey says: "A diminution in the rate of mortality will be found to coexist generally with an augmentation of the rate of sickness. The very triumphs of advancing medical art are probably attended by an average prolongation of the helpless and infirm conditions of life." Again, as the result of "improvements in domestic management and medical treatment", we are told that "Chronic diseases, or at least functional disorders, have increased. Vital force is lowered. Man's work is arrested; his duties are unperformed; his objects fail, though he still lives. Weakly diseased children are now mercifully helped, as they never were in the olden time, to grow into weakly ailing adults, who, in their turn, propagate with an abnormal fecundity an unsound progeny. Is this true sanitary progress? Does it deserve the ostentatious parade of a decreasing death-rate?"

This theory of the evils and dangers which may be feared from a declining death-rate appears to us to be as fallacious as it would be disastrous if true. It savours of a fatalism which is inherently antagonistic, not only to sanitary progress, but to the best interests of the medical profession.

Dr. Rumsey's republished *Essays* are a welcome addition to sanitary literature; and, although we do not agree with the assertion that the publication of general death-rates can ever degenerate into a public nuisance, a perusal of the work cannot fail to be useful to those whose duty it is to elaborate and explain the causes of the wide variation in local death-rates. We trust, moreover, that ere long we may be able to welcome the reappearance of Dr. Rumsey in the active division of our foremost sanitary reformers. Although much has been achieved in recent years, we have not yet arrived at that stage in the affairs of sanitation when we can afford to "rest and be thankful", and we can ill afford permanently to lose the services of Dr. Rumsey in the sanitary arena.

NEW BOOKS AND NEW EDITIONS.

AMONG the new books of the season which we desire at once to welcome, are the first fasciculi of two important illustrated works, of which Messrs. J. and A. Churchill commence this month the publication.

Mr. JONATHAN HUTCHINSON has long been known to have exercised uncommon industry and zeal in the collection of a vast amount of clinical surgical material, including a rich series of drawings and photographs of notable cases, and especially of such as exemplify important or doubtful points of diagnosis or treatment. From this accumulation of varied and interesting matter he now produces selected examples, and commences what will be, we doubt not, a classic work in British surgery, under the title of *Illustrations of Clinical Surgery*, consisting of plates, photographs, woodcuts, diagrams, etc., illustrating surgical diseases, symptoms, and accidents; also operative and other methods of treatment; with descriptive letterpress. Each fasciculus contains four large plates. The present fasciculus gives admirable plates of Frontal Encephalocele, including three portraits from different subjects; a most interesting and instructive plate of Ivory Exostosis of the Orbit, with a good and suggestive history; a plate with three fine coloured illustrations of Rodent Ulcer, a subject which

Hutchinson, Hulke, Moore, and Arnott have done most to elucidate; and three capital and instructive illustrations of different varieties of Chancre. Mr. Hutchinson promises a quarterly fasciculus. The price at which these plates are issued is very moderate indeed. We trust that Mr. Hutchinson will continue his publication regularly, and that it may meet with the great popularity which it deserves. It is long since an undertaking more creditable to British surgery has been commenced.

The Atlas of Skin-Diseases, edited by Dr. TILBURY FOX, is also a very welcome addition to our medical literature. The plates are partly the well known and admirable coloured drawings of Willan and Bateman retouched and improved, and partly new plates designed to complete their scheme and to correct some of the deficiencies of their portraiture of skin-disease. Part I leaves nothing to be desired; and at the publishing price, which is less than half of that at which the original issue of Bateman and Willan was made, these excellent plates will no doubt be highly acceptable to a large number of practitioners and teachers. Dr. Fox's letterpress is concise, clear, and accurately written. He is, of course, a thorough master of the subject.

WAGSTAFFE'S *Manual of Osteology*, just issued by the same publishers, has many of the qualities likely to be most appreciated by students. It is excellently illustrated, and the descriptions are short and untechnical. If modern examiners are satisfied with the kind of descriptions here given, we have nothing to say; but they are so brief and scanty, that this book, attractive as it is, by no means fulfils the desiderata which we recently indicated; and it does not, in our opinion, supersede the necessity for a fresh edition of Ward's *Osteology*, the only good descriptive book on the bones which has, in our opinion, yet appeared.

The Medicinal Plants: being Descriptions, with original Figures, of the Principal Plants employed in Medicine; and an Account of their Properties and Uses. By ROBERT BENTLEY, F.L.S.; and H. TRIMEN, M.B. London: J. and A. Churchill.—Professor Bentley and Dr. Trimen are two of our best botanical authorities, and both are well acquainted with the wants of students and practitioners. Forty years have elapsed since any work devoted to the illustration and description of the pharmacopœial plants has appeared. This profusely illustrated work, which appears in parts, will fill in a void in medical literature. The illustrations are by David Blair, and are beautifully executed; they are worthy of the text, and that is high praise.

MR. ISAMBARD OWEN'S *Tables of Materia Medica* (Churchills, London) is an useful little compilation, showing in a very condensed form the *Pharmacopœial* preparations, and the methods employed in making them; the processes of extraction of alkaloids and organic principles commonly employed in medicine; a tabular statement of doses; the contents of compound preparations; and the proportion of active ingredients in some of the principal preparations. It will be useful as an *aide-memoire* to students and practitioners.

DR. ATTFIELD'S admirable *Manual of Chemistry, General, Medical, and Pharmaceutical*, appears in its sixth edition. The numerous additions and corrections, and the introduction of a valuable series of illustrations in this edition, show that Dr. Attfield is by no means content with resting on his laurels. Himself a practical and successful teacher, each edition bears marks of the determination to make this book in all respects respond to the needs of students. It is an excellent class-book.

SELECTIONS FROM JOURNALS.

THERAPEUTICS.

HYPNOTIC PROPERTIES OF LACTATE OF SODA.—W. Preyer of Jena, in a communication to the *Centralblatt für die Medicinischen Wissenschaften* for August 7th, states that numerous experiments and observations have shown him that a feeling of weariness and sleepiness, and even a condition very closely resembling or identical with natural sleep is produced, when a concentrated watery solution of lactate of soda is injected subcutaneously or introduced in large quantity into the empty stomach, provided that strong irritation of the senses be avoided. In many cases, also, sleep was produced when the lactate of soda was not given as such, but the materials were afforded for its abundant formation in the digestive canal; as after drinking highly concentrated solutions of sugar, and after the abundant use of fresh, and especially of sour, milk, and of sour or sweet whey. There were great differences in regard to the time, duration, and intensity of the sleep. It appeared to occur more readily in young than in old animals; in animals having

high than in those having low reflex excitability; more readily in mice, cats, pigeons, and frogs, than in rabbits and guinea-pigs; more readily in small than in large animals, and in a low temperature than in a high one. In man, also, considerable individual differences were observed. While one would be seized with almost invincible drowsiness soon after the use of a quart of coagulated milk or a glass of highly concentrated solution of sugar, or after taking into the empty stomach a solution of 12 grammes (3 drachms) of lactate of soda in 120 grammes of water, this effect was not produced in another. In order to obtain data for an investigation of the causes of this varying action, Preyer invites practitioners, in cases where it has hitherto been the practice to procure sleep by means of opium or chloral, to inject subcutaneously concentrated solutions of lactate of soda, or to give as drink large quantities of solution of sugar, or milk-serum, or condensed milk, and to communicate the result either in published papers or by letter. He remarks, also, that the lactate of soda deserves investigation as an antipyretic, and also as a calmative in mania and in certain forms of convulsive disease, on account of its property of speedily inducing weariness during muscular action. In all cases where sleep was produced by lactate of soda, Preyer found the respiration deepened and reduced in frequency, the reflex irritability diminished, and, in warm-blooded animals, the temperature lowered—especially when large doses were given. Larger doses of the lactate than were necessary to produce sleep were borne without the least injury. The sleep produced cannot be distinguished from natural sleep. When the animals awake, they do so in the natural way, become lively in a few moments, readily take food and drink; and, if left to themselves, readily fall asleep again, to awake quite lively. Lactates of potash, magnesia, and lime cannot be recommended as substitutes for lactate of soda.

EXTERNAL USE OF CARBOLIC ACID IN CERTAIN SKIN-DISEASES.—Berndgen (*Allgem. Medicin. Centralzeitung*, No. 20, 1875) uses with good effect in chronic eczema a solution of 5 parts of crystallised carbolic acid in 10 parts of diluted spirit and 120 of water. The solution is applied to the diseased parts every morning by a camel's-hair pencil. In cases of shorter duration, he uses a 20 per cent. watery or oily solution as a lotion or embrocation. In acute eczema, carbolic acid is injurious. The solution in water and spirit is very successful in psoriasis. In psoriasis inveterata he uses a solution of 2.5 parts of carbolic acid in 10 each of spirit and distilled water; here, however, the application must be omitted after three or four days, on account of the irritation which it produces. In prurigo, a 5 per cent. solution is recommended.

PHYSIOLOGICAL AND THERAPEUTIC ACTION OF NITRITE OF AMYL.—In his experiments on nitrite of amyl, Berger (*Allgem. Medicin. Centralzeitung*, 1874) found that, in non-curarised dogs, whose vagi nerves were divided, the division of the cervical spinal cord below the atlas was followed by a lowering of the blood-pressure when the vapour of nitrite of amyl was introduced into their lungs by artificial respiration. The lowering of the blood-pressure by nitrite of amyl is, therefore, not dependent on the vaso-motor centre in the medulla oblongata. The frequency of the pulse in warm-blooded animals was always increased; the respiration retarded by fatal doses. With regard to the therapeutic action of the nitrite, Berger used it in hemicrania, only in the spasmodic form, and not in all cases of this. In epilepsy, it has some effect even in cases with a vaso-motor aura; but it has no influence on the disease itself. He found it beneficial in some cases of angina pectoris, and without effect in bronchial asthma, hysterical convulsions, and tetany. Berger used it with success in two cases of acute cerebral anemia with severe fainting. The preparation must be pure, and at least should not have an acid reaction. The dose usually given was 2, 5, or 10 drops.

SALICYLIC ACID IN DIABETES MELLITUS.—The *Boston Medical and Surgical Journal* for September states that an opportunity has recently been afforded in the Columbia Hospital Dispensary, of testing the efficacy of salicylic acid in diabetes mellitus. The disease manifested itself in a coloured woman, past middle age, and had existed three years when the patient was put under medical treatment. The symptoms were characteristic: cataracts in both eyes, and at least fourteen per cent. of sugar in the urine, by Fehling's test. The patient had been under various forms of treatment without avail. About a year ago, the carbolic-acid treatment was instituted with marked general improvement, and the reduction of the amount of sugar in the urine to seven per cent. The diet, of course, was regulated as far as possible. Four months ago, when salicylic acid first began to attract the attention of the profession, it was substituted for the carbolic acid; it was given finally, as experience proved it to be well borne by the sys-

tem, in ten-grain doses (in pill) three times daily. The urine for several weeks past had been registered as containing 0.3 to 0.5 per cent. of sugar, and the quantity had at last fallen to traces not sufficient to be registered by Fehling's test. The amount of urine passed in twenty-four hours was reduced to the normal quantity. All the symptoms had been correspondingly relieved, and the diet had been made more liberal in starchy substances.

SUBCUTANEOUS INJECTION OF NITRATE OF STRYCHNIA IN NERVOUS DEAFNESS AND IN DISTURBANCE OF INNERVATION OF THE INTRINSIC MUSCLES OF THE EAR.—Dr. R. Hagen of Leipzig writes in the *Centralblatt für die Medicin. Wissenschaften*, August 11th, that he first began to use subcutaneous injection of strychnia in nervous deafness in the autumn of last year. After having become acquainted with the results obtained by Dr. Nagel of Tübingen from the same remedy in amaurosis and amblyopia, he has employed the treatment in a considerable number of cases with unmistakable effect and long continued good result. He generally uses a one per cent. aqueous solution of nitrate of strychnia, injecting it twice weekly into the integument over the mastoid process, for the most part using no other remedies. The injections are of no use in subjective noises in the ear.

COLUMN FOR THE CURIOUS.

ST. BARTHOLOMEW'S HOSPITAL.—1729, July 12th. Thursday, at a meeting of the Governors of St. Bartholomew's Hospital, Robert Gay, Esq., Representative in Parliament for the city of Bath, resigned his place of surgeon to the said hospital.—1730, January 24th. Thursday morning, a General Court was held by the Governors of St. Bartholomew's Hospital, when was present the Right Honourable the Lord Mayor, the President, and several others the governors; at which time, Samuel Palmer, Esq., a very eminent surgeon, was unanimously elected treasurer of the said hospital, in the room of Robert Williams, Esq., deceased; he was proposed by Sir John Williams, Knight, one of the present sheriffs, who, in a very eloquent speech, recommended him as very worthy of so considerable a trust.—1729, September 13th. On Saturday last, one of the patients in St. Bartholomew's Hospital, being it is supposed in a disordered state of his senses, violently assaulted Dr. Tyson, one of the head physicians, as he was talking to another patient in the ward; but help immediately coming, the fellow was secured. In the scuffle, the doctor fell against the locker of a bed by which the cap of the knee was put out, and his arms were very much bruised.—1729, August 23rd. Dead, Dr. John Radcliffe, formerly of St. John's College in Oxford, and Fellow of the College of Physicians, Physician to St. Bartholomew's Hospital. A gentleman of excellent parts and sound learning; whose only crime was his singular modesty, which hindered him from being an ornament to his profession.

BARBAROUS PUNISHMENT: A SURGEON'S OCCUPATION.—1729, March 29th. On Wednesday, Thomas Hayes, formerly the commander of a merchantman, stood in the pillory at Charing Cross, for the hour of twelve to one, when a surgeon, attended by the prison officers, got upon the pillory, when Mr. Hayes sat down in a chair placed for that purpose, and then the surgeon with a dressing-knife cut his left ear entirely off, delivered it into his own hands, and then the officer took it from him and betwixt his finger and thumb held it up to the view of the spectators, pursuant to his sentence at the Court of King's Bench, for forging a bond of £560, upon Mr. Edward Longbotham, also formerly the commander of a merchantman. He was a plain elderly man with grey hair, and was not pelted by the populace, which was very numerous.—1728, February 22nd. On Tuesday, came on before the Lord Chief Justice Raymond, at Westminster, the trial of Japhet Crook, alias Sir Peter Stranger, upon an indictment for forging two deeds of conveyance to himself, of an estate in Essex belonging to Mr. Joseph Garbutt, and afterwards for mortgaging the estate as his own for £2,500. After a hearing of about four hours, the jury brought him in guilty of the indictment; which being grounded on a statute of Elizabeth, he is to be put into the pillory, to have both his ears cut off by a surgeon, then his nostrils to be slit, and to suffer perpetual imprisonment.

INOCULATION DANGERS.—1732, April 15th. The nephews of the Honourable Sir Thomas Lyttleton, one of the Lords of the Admiralty, were lately inoculated for the small-pox, the eldest of whom, aged twenty years, died. The other is in a fair way of recovery, the pox having broken out in a more kindly way.

H. W. DIAMOND, Twickenham.

BRITISH MEDICAL ASSOCIATION:
SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, OCTOBER 23RD, 1875.

REPORTS OF THE SCIENTIFIC GRANTS COMMITTEE OF
THE BRITISH MEDICAL ASSOCIATION.

IN this number, we commence the publication of an important report on the effects of certain cathartic medicines on the biliary secretion of the dog. This research, which is a fit successor to the report of the Edinburgh Committee of the Association on the Action of Mercury, Podophyllin, and Taraxacum, on the Biliary Secretion, is the first of the new series to be carried out under the auspices of the Scientific Grants Committee of the British Medical Association. Dr. Rutherford details a series of experiments which he performed in the Physiological Laboratory of the University of Edinburgh, with the assistance of M. Vignal. The value of such investigations in the hands of so skilled and careful a worker can scarcely be overestimated, as it goes straight to the root of our daily practice. There is perhaps no branch of medical science which is at present making more rapid strides, or undergoing more radical changes, than pharmacology; and new light is daily being shed upon the action of our most important drugs by experiment in the physiological laboratory. In these researches, one is often struck with the close agreement between the teaching of modern physiology and clinical views which originated in mere empiric speculation. At times, however, we find that the desired object is attained in a manner hitherto quite uncomprehended, and only explicable by the most recent physiological knowledge; and it but too often happens that we discover that some of our remedies are as far from accomplishing the exact end for which we administer them, as were the many specifics which were reluctantly abandoned by our ancestors, and of which we now read with a smile of pity and contempt.

It is quite time that we should cease to assume, and that we should commence to ascertain, the mode of action of medicines; that we should examine what we believe, together with the grounds of our belief. In these days of accurate physiological research, we should no longer be content with the ancient dogmas upon which many physicians still act, less from conviction than from habit; but we should rather investigate the *modus operandi* of therapeutic and toxic agents with all the precision and care which our improved methods admit.

It is obvious, that the more we know of the exact action of a medicine, the less chance we have of abusing it, as we restrict it to those cases in which we know there is a certain object to be attained which we can attain in a certain manner. In thus restricting the internal use of drugs, we confer a boon upon mankind; for it must be admitted that, even at the present time—which we think so enlightened—there are many physicians who employ powerful drugs on the theory that they must do something; and thus, from mere habit, they make the *primæ viæ* of their patients a thoroughfare for useless, if not pernicious, medicines.

These experiments require to be prominently brought forward, be-

cause practical men oftentimes care but little for such physiological research, and they do not reflect upon the fact that, each time they give a dose of medicine, they perform an experiment which may lead to most important results, if its administration be followed by careful clinical observation of its effects.

The slowness with which experimental results influence general practice is well exemplified by the very subject of this report. Twenty years ago, Kölliker and Muller tried the effect of calomel on dogs with biliary fistula, and they found that the amount of bile secreted was more often diminished than increased by the action of that drug. Two years afterwards, Scott and Mosler found that, in all cases, large doses of calomel caused diminution of both the fluid and the solid constituents of the bile, and they failed to find the mineral in the secretion. However, any discredit which was subsequently thrown on mercury depended rather on its clinical failure than upon these experiments, and few seriously doubted its efficacy as a cholagogue, even after the report of the Committee of the Medical Association which was published under the experienced guidance of Dr. Bennett in 1868. From this report, it appeared that the several preparations of mercury have no influence whatever upon the liver, except to reduce the amount of bile secreted, as was also seen to be the case in purgation by means of podophylline. These views met with but little favour from the practical members of the Association, and appear to have had no material effect on the frequency with which the drug was administered. It seems but natural that physicians should not be inclined to accept the results of experiments on animals as a satisfactory proof of the exact mode of action of medicines upon man. The physiological evidence of the similarity of the effect of many drugs on man and the lower animals becomes, however, daily more and more convincing, while not a single fact of weight has been put forward by clinical observers to shake the belief of the physiologist that mercury and the cholagogues have exactly the same action on dogs and many other animals as on man.

The question remained *in statu quo* until the year 1873, when Röhrig published an account of a series of experiments which he had performed with the object of finding out what circumstances influenced the biliary secretion. He came to the conclusion that the amount of bile formed depended more upon the character and amount of blood circulating in the intestinal vessels than upon the tension of the hepatic capillaries. During his extensive investigation, he tried the effect of various purgative medicines on fasting dogs, and the results he obtained are most interesting, as they form a striking contrast with those obtained by Dr. Bennett's committee. Röhrig did not use exactly the same medicines; but he found that several purgatives—viz., croton-oil, colocynth, jalap, aloes, rhubarb, senna, and sulphate of magnesia—acted more or less powerfully on the liver, increasing the flow of bile, and recalling its secretion after it had ceased. His experience of calomel did not materially differ from that of the Committee of the Association. Thus, while there was no actual contradiction concerning any special drug in the two results, the Committee found that, in dogs kept on a regular diet, the amount of bile was always diminished by purgation. Röhrig found that in fasting dogs the biliary secretion was notably increased by the same means. Can both these statements be correct? This is the question to be answered by the investigation now reported. Feeling confident of the accuracy of the method used by the Committee, of which he was himself an active member, Dr. Rutherford now checks the results arrived at by Röhrig by repeating his experiments with a somewhat altered and improved mode of procedure. He records the amount secreted every fifteen minutes, and the variations which occur are represented in the form of a curve. He also made frequent analyses, by which an accurate idea of the solid constituents of the bile could be formed; while the alimentary canal was carefully examined *post mortem*, and the amount of intestinal irritation noted.

Tested by this method, croton oil did not appear to deserve so high

a place as a hepatic stimulant as is stated by Röhrig, and there was evidence of so much intestinal irritation, that its use was abandoned. Podophylline increased greatly the amount of biliary secretion, and was found to act much more energetically when previously mixed with bile, which acted as a solvent. The marked increase in the amount of bile, attributed by Röhrig to the action of aloes, was in all respects confirmed by three experiments. Rhubarb proved a much more powerful hepatic stimulant than Röhrig's experiments led him to suppose; repeated doses causing renewed increase in secretion, and analysis demonstrating that, notwithstanding the great increase in quantity, the solid constituents were present in the same proportion as in the normal bile. Senna somewhat increased the amount of secretion, and at the same time rendered the bile more watery. Colchicum was found to act decidedly as a cholagogue, the rapidity of secretion being much increased. Scammony and taraxacum had also a cholagogue action, but in a less marked degree.

On the other hand, calomel failed to produce any increase in the biliary secretion, a decided diminution occurring in all but one case, and in every one the bile was rendered more watery. Gamboge and castor-oil had not a marked effect, while the secretion was diminished after alcohol had been injected into the stomach.

From these results, it would appear that certain medicines given in proper doses to fasting dogs do cause an increase in the secretion of bile; but it is certain that mercury is not one of these agents.

The reporter believes that energetic purgation tends to hinder the secretion of bile, and thinks that the diminution which was found by Dr. Bennett's committee to follow the administration of podophylline probably depended upon the fact that its severe purgative action impeded the absorption of food, and thus lessened the amount of bile formed. He conceives that the administration of any remedy which acts both as a hepatic and an intestinal stimulant to an animal before the process of digestion is complete has two distinct effects: first, to increase the amount of bile; and, secondly, to diminish the absorption of food and bile from the small intestine.

The precise mode of action of these cholagogue medicines the author does not pretend to have definitely settled, the chief object of the investigation being merely to ascertain the facts of the case. Some reasons are, however, adduced for believing that the agents are absorbed into the portal circulation, and act on the liver directly in passing through that organ.

The reporter disclaims any intention of reopening the old discussion as to the cholagogue effect of mercury on the human subject, and he distinctly points out that the present researches are to be regarded simply as a contribution to comparative physiological pharmacology. At the same time, he invites clinical investigators to compare the results he has obtained by experiment with those which may be observed in human pathology and therapeutics. It is to be hoped that this report may enlist into the ranks of precise clinical observers some of those physicians who are in the habit of giving their five grains of blue pill, with equal confidence in its efficacy and indifference as to its mode of action.

We publish this report in a form which renders it suitable for separate binding in a volume; and various reports to the Scientific Grants Committee by other investigators, which we shall publish *seriatim*, will be issued in a similar form. Thus these reports may be bound so as to form a distinct and accessory volume to the JOURNAL, which will, we trust, have a great permanent value. This will serve to give a distinct place in the medical library to labours of a kind eminently calculated to widen and render more secure the bases of the progressive art and science of medicine. It is too much the tendency of the day to divorce pure physiological study from medicine. It is our aim to maintain them in an indissoluble connection equally profitable to both.

PROVIDENT INSTITUTIONS AND HOSPITALS.

VI. CIRCUMSTANCES OF PATIENTS.

IT must be manifest that our comments upon this large subject would be incomplete, unless we devoted one article at least to the consideration of the circumstances of the patients who frequent our hospitals and dispensaries. It is interesting to note the great advance which Hospital Reform has made during the last five years. In 1870, the mind of most hospital managers was a blank so far as the great questions of (a) who were, and who were not fit objects of charity; (b) how many patients ought to be seen by each honorary officer in a given time; (c) were the hospitals frequented by many of the well-to-do classes; and (d) ought any steps to be taken by the committees of management to obtain definite knowledge on one or all of these points, or did their duties begin and end in providing the means whereby the honorary medical staff were enabled to minister to the wants of all applicants sent to them with a governor's letter? It cannot be denied that the old custom of leaving it to the provident habits and independent feeling of the working and lower middle classes to abstain from using the hospitals, except when compelled to do so by long illness or other equally necessitous causes, had a strong hold upon many of the older practitioners and laymen who formed the majority of the managers of these charitable institutions. These were loath to believe that the high wages, full work, and general prosperity of a class would tend rather to lessen than increase that honourable feeling of independence and determination to avoid, if possible, the acceptance of anything which seemed to bear the mark of a charitable gift, which they had been accustomed to regard as one of the most admirable traits in the character of the respectable portion of the lower orders of Englishmen. Nor can we help sympathising with these gentlemen in their anxiety to put the best face on the matter, and to stave off inquiry as long as possible; for they were fearful lest our hospitals, by a too rigid system of inquiry into the circumstances of the applicants for relief, should fall into a greater evil, by causing the really deserving poor to suffer by the delay which might ensue before the patients obtained the relief which their cases required, and by thus lessening the very aim which the founders had in view, viz., to afford instant medical relief of the best kind obtainable to that large class of deserving recipients who inhabited the poorer districts in the immediate neighbourhood of the hospitals. However, the small band of reformers worked quietly on, and the gradual growth of their opinions is clearly indicated in the proceedings of the committees of management of the large London hospitals. In 1872, St. George's Hospital commenced an inquiry into the circumstances of the out-patients; at the London Hospital, the house-committee, in the following year, devoted much time and attention to the same subject; and their example was immediately followed by the authorities of University College, Charing Cross, and the Westminster Hospitals. Each hospital, of course, took a different means of pursuing the object they all had in view; thus, St. George's Hospital accepted the proffered aid of the Charity Organisation Society; the London issued a series of questions to each member of the honorary medical staff; whilst University College and Westminster appointed special committees to examine and report upon the whole question; and the council of Charing Cross Hospital referred it to the medical committee of the hospital. During the present year, the Royal Free Hospital, the Westminster Hospital (the recommendations of the earlier committees not being considered satisfactory), the Children's Hospital in Great Ormond Street, the Great Northern Hospital, St. Mary's, and King's College Hospitals, have all taken up this subject, and, with the exception of the two last named, at which the inquiries are not completed, all have introduced considerable modifications into their respective systems. No inquiry has been undertaken at either of the three largely endowed hospitals, viz., Guy's, St. Bartholomew's, and St. Thomas's.

One provincial hospital, the Queen's, Birmingham, in the latter part of 1873, instituted an inquiry with the aid of the Charity Organisation

and Mendicity Society; and the Manchester Infirmary, as we explained in a former article, has adopted the provident scheme in connection with its out-patient system.

Before we proceed to analyse the result of these various inquiries, we wish, very briefly, to deal with an objection raised against all of them by many people, and notably by Mr. J. C. Wordsworth (*vide* JOURNAL, vol. i for 1875, page 761), on the ground "that a large proportion of those who write on, or inquire into the cause of, hospital abuse, seem to ignore that form of the abuse which concerns the in-patients of our hospitals, and treat only of out-patients". The reason—for we admit the general truth of this assertion—is not far to seek. All who have had experience in hospital administration will readily admit that the peculiar conditions which attach to all in-patients, are quite absent when we have to deal with the large number of persons who flock to the out-patient departments for temporary relief. When a patient is admitted into the wards of a hospital, he is placed under a *constant* supervision of the honorary medical staff and the authorities. His circumstances can soon be ascertained from his habits, the friends who visit him, and the inquiries which are made from time to time as to his welfare.

We have had frequent opportunities of testing the efficiency of this check upon the admission and retention of improper cases; and we are convinced that, where abuse has taken place, it has been, as a rule, with the knowledge and tacit consent of the honorary medical officer under whose care the patient happened to be. This gentleman has argued, no doubt, that, although the patient in question could pay a reasonable fee for his or her attendance, still the fee would not remunerate him for the constant additional care which the case would require if it remained at home, and were attended to by the anxious but indifferent nursing which friends are always willing to afford. He doubtless consoled himself, in these cases, with the reflection that the severity of the case and the clinical interest attaching to it justified him in admitting it to the wards of a general hospital. We have merely mentioned the worst kind of abuse to which the in-patient departments of hospitals are liable, because we are convinced, from the watchful eye which the managers keep upon the circumstances of the in-patients, that the abuse practised by this class of patients is very small indeed. In proof of this, we may quote the result of an inquiry by the Charity Organisation Society into the circumstances of the in-patients found on a given day in the wards of the Queen's Hospital, Birmingham. Eighty-eight cases were examined; and it was found that only two cases—exclusive of the accident ward, which, from the nature of the cases, it would not be fair to include—were unsuitable. The real reason why writers upon this subject refer so little to the in-patients is, because their experience in hospital administration teaches them that the ease with which an improper case can be at once detected and expelled renders it comparatively easy for the managers to prevent entirely the admission into, or at any rate the retention of improper cases in, the hospital wards.

We must now examine the results arrived at and the conclusions formed by the managers of the various hospitals at which inquiries have been instituted. We would here state, that our own observations lead us to the conclusion that the patients to be found in the out-patient waiting rooms of the London hospitals are, as a rule, in much poorer circumstances than those usually met with in the provinces. It seems to us, after close observation, that the London hospitals are abused in a totally different way from the provincial hospitals. For, whereas a large number of paupers, or of people on the verge of pauperism, are found in attendance at the London hospitals—and it is by offering facilities to this class, which properly belongs to the Poor-law medical officers, that abuse creeps in—in provincial towns, on the other hand, the out-patients, as a rule, are drawn in the main from the well-to-do working and lower middle or small shopkeeper classes. If this be borne in mind, it will throw much light upon the result of some of the conclusions come to by the London managers. The St. George's authorities found that they were justified in rejecting the following cases for the reasons assigned: 31 parish cases, 22 able to pay, 8 left on hearing of inquiry, 5 soldiers' wives, and 1 soldier, 1 police constable, 1 pensioner of Chelsea Hospital; making

a total of 69, who, for various reasons, were not received as out-patients. Of 24 other cases referred to the Charity Organisation Society, 11 were found suitable, 6 were refused, and 7 did not return. This inquiry cannot be regarded as in any way a complete one, if we except the last 24 cases; because only a few out of the whole number of out-patients (9,797) were really sifted thoroughly. Nevertheless, it is obvious that considerable abuse did exist in 1872, and, we have no doubt, does now exist at St. George's Hospital.

The London Hospital, situated as it is amongst one of the poorest populations of the metropolitan district, has, doubtless, many of the pauper classes daily attending the out-patient department. We regard the report of the House-Committee as one of the most curious pieces of hospital literature which has ever been issued. It is evident from the first that the more influential portion of the Committee felt convinced that very little, if any, abuse prevailed at their institution. The report states (a) that—out of a total of 43,808 *genuine* out-patients, 24,754, for various reasons—all accidents, minor casualties and accidents; in-patients requiring further treatment as out-patients; patients of special departments, dental and maternity cases—hardly came within the scope of the inquiry; thus leaving, after deducting 2,960 renewals, 16,094 ticket cases, "which alone admit of any sifting to shut out improper applicants"; (b) that a large number of these cases were sent by the clergy in poor and populous east end districts, who, they consider, "may be presumed to have the best acquaintance with the wants of the surrounding poor"; (c) that "many persons in receipt of parish relief doubtless obtain assistance"; and "that many in addition would receive additional benefit if provided with food and clothing, as well as medicine" (many of these also belong to the pauper class); (d) that "improper cases do apply, and do receive gratuitously medical aid, which they ought to obtain for payment elsewhere"; and the Committee proceed to report that, having every confidence in the careful inquiries made by the governors and clergy, who mainly distribute the out-patient tickets, "they believe that by far the larger proportion of the London Hospital out-patients are (as stated by the majority of the staff) suitable recipients of hospital charity". We regret we cannot quote at greater length from a report which so ably represents the views and conclusions of those who believe that no great abuse attaches to the present out-patient system. It is universally admitted that this hospital is well managed, and that it is governed by some of the ablest administrators of the present day; still we cannot but regret that the House-Committee did not see the importance of testing the accuracy of the conclusions which they formed on hearsay evidence—or, more correctly speaking, on the impressions of the majority of the medical staff who have already too much to occupy their attention, without troubling themselves about the circumstances of the patients they have to attend—by calling in the aid of the Charity Organisation Society, and giving them an opportunity of investigating the first thousand or so cases which presented themselves for treatment. Again, they rely too much upon the care exercised by the governors and the clergy in the distribution of the tickets; for it has been shown, over and over again—to instance one case by Dr. Heslop of Birmingham, only recently—that practically the ticket system is no check whatever upon hospital abuse. Will the authorities of the London give the Society an opportunity of testing the class of patients they treat? We hope they will; because if they can show that no abuse exists at their hospital, having probably the largest out-patient department in London, either by the treatment of the well-to-do, or, of what we suspect to be far more likely, of pauper cases, they will have proved, we are bound to admit, that little real abuse exists, at any rate, in London; but if they fail to do so, we are convinced they, and all the other managers of London hospitals, will soon put a stop to abuse of this kind by decided and united action. There is, we fear, too great a love of permissive legislation in this matter; too strong a desire to let well alone; too much taken upon trust, and far too little decisive action.

The authorities at St. Mary's, at University College, and at Charing Cross, have all arrived at nearly the same conclusions as the London Hospital: viz., that little, if any, abuse takes place at their respective

EXPERIMENTS ON THE BILIARY SECRETION OF THE DOG.

BY WILLIAM RUTHERFORD, M.D., F.R.S.E.,

Professor of the Institutes of Medicine in the University of Edinburgh; and

M. VIGNAL.

INTRODUCTION.

THE influence of mercury, podophylline, and taraxacum upon the biliary secretion of the dog was some years ago investigated by a committee, of which Professor Hughes Bennett was chairman and reporter. Dr. Arthur Gamgee and Dr. Rutherford were the two junior members of the committee, upon whom devolved the task of performing the experiments. On the recommendation of the committee, they resorted to the method of establishing permanent biliary fistulæ in dogs; they then gave the animals a fixed diet, and analysed the bile secreted daily before and after the administration of various substances, and they observed that "spontaneous diarrhœa, dysentery, and purgation produced by pilula hydrargyri, calomel, corrosive sublimate, and podophylline, always diminished the solid constituents of the bile, and, with one exception, the fluid portion of the bile also" (*British Association Reports*, 1868, p. 229). The observations were made with such laborious carefulness, that the truth of these facts need not be called in question. It is not intended to reopen here the controversy raised by opinions expressed regarding the interpretation of these and other facts, it being the object of the present report to give the results of experiments performed by a different method.

Two years ago, Röhrig ("Experimentelle Untersuchungen über die Physiologie der Gallenabsonderungen"—Stricker's *Jahrbücher*, 1873, p. 240) performed a number of experiments on the effect of various substances on the biliary secretion. He observed the rate of the biliary flow from temporary fistulæ in fasting curarised animals before and after the injection of purgative agents into the stomach and intestine. He found that large doses of croton oil greatly increased the secretion of bile, and that a similar effect, though to a less extent, was produced by colocynth, jalap, aloes, rhubarb, and senna, and sulphate of magnesia—the potency of these agents as hepatic stimulants being in the order mentioned. He found, moreover, that castor-oil had little effect, and that calomel, while it seldom recalled the biliary secretion after it had ceased, nevertheless somewhat augmented it when it was taking place slowly.

Röhrig's statement with regard to calomel does not much differ from that made by Hughes Bennett's committee, and he made no experiments with podophylline and taraxacum; nevertheless, he did find that certain purgative agents, when given to animals that are *fasting*, increased the biliary secretion, while the committee found that in *non-fasting* animals, purgative action induced by podophylline, calomel, etc., diminished the amount of water and solids of the bile secreted in the twenty-four hours.

It appeared to the reporter that the subject should not be allowed to remain in its present position: accordingly, he undertook the following research, and invited the co-operation of Monsieur Vignal, who had come to do some work in the physiological laboratory of the University of Edinburgh.

METHOD OF EXPERIMENT.

All our experiments were performed on dogs that had in nearly every instance fasted about eighteen hours. After paralysing the animal with curara, and establishing artificial respiration, we opened the abdomen in the linea alba, and tied a glass cannula in the common bile-duct, near its junction with the duodenum. To the end of the cannula which projected from the abdomen we attached a short India-rubber tube, and to the end of this again a short tube of glass, drawn to a narrow aperture, so that the bile might drop from it. The gall-bladder was then compressed, in order to fill the whole tubing with bile, and the cystic duct was clamped to prevent the return of the bile to the gall-bladder, and so compel all the bile secreted by the liver to flow through the cannula. The wound in the abdominal wall was then carefully closed; and in all our later experiments the animal was thoroughly covered with cotton-wool, in order to quickly restore it to its normal temperature.

Röhrig estimated the velocity of the biliary secretion by counting the seconds that elapse between the fall of the drops from the orifice of the tube. A single trial convinced us that this method is extremely laborious, and by no means accurate, seeing that it does not permit continuous observation for any length of time. Moreover, we saw that the degree of viscosity of the bile caused a variation in the size of the drops, and, therefore, in the intervals between their fall. We therefore abandoned this for the more accurate method of allowing the bile to flow into a fine cubic centimeter measure, and recording the quantity secreted every quarter of an hour. In addition to constant collection of the bile, this method has the great advantage of permitting a graphic representation of the results. We, moreover, took the trouble to analyse the bile in many cases, and to make *post mortem* examinations of the alimentary canal; points entirely omitted by Röhrig, but which, nevertheless, have yielded valuable results.

Until it is attempted, one might suppose that this mode of experiment is extremely simple, but it is by no means so simple as it appears. It is needful to manipulate the abdominal viscera with great care, and to avoid all dragging at the bile-duct, otherwise the secretion of bile becomes so irregular that the experiment may be useless. The cannula must be very carefully retained in a position which will permit its moving with the diaphragm, but will prevent it from twisting the duct, and thus impeding the exit of the bile by forming a valve at its orifice.

The respiration requires to be maintained with great regularity, otherwise the biliary flow is rendered unequal by irregular diaphragmatic compression of the liver. Moreover, if the respiration be deficient, the secretion of bile is always diminished (Röhrig). In the cases indicating the biliary secretion in these experiments, some of the oscillations are probably owing to varia-

tions in the respiration, especially to variations in the amount of diaphragmatic compression of the liver; for we were obliged to have the respiration kept up by the hand, and this is never so regular as a machine. Notwithstanding this, however, the main results of the experiments are perfectly clear.

As is well known, curara is of great value in such experiments, for, by paralysing voluntary movement, it prevents the irregular outflow of the bile, which certainly follows irregular contraction of the abdominal muscles; and if care be taken to give doses just sufficient to produce this paralysis, the biliary secretion is not apparently affected; but if too much be given, the heart is rendered weak and irregular, and the secretion of bile diminishes.

Lastly, it is essential that the fall of temperature which follows the opening of the abdominal cavity be speedily recovered, otherwise the biliary secretion may be abnormally low at the outset of the experiment.

SECRETION OF BILE IN A CURARISED FASTING DOG.

In all the illustrations, the numbers under the horizontal line indicate the hours during which the secretion of bile was observed, while those to the left of the vertical line indicate in cubic centimeters the amount of bile which flowed from the cannula; the dots in the curve indicate the quantities of bile collected every quarter of an hour. The vertical dotted lines that cross the curves in the illustrations indicate that something was given to the animal. In all such experiments the amount of bile first collected is usually much greater than that at subsequent periods. This apparently results from the sudden diminution in the resistance to the exit of the bile which follows the opening of the duct. The first one or two collections are therefore not reliable indices of secretion, and they are consequently omitted from some of the curves altogether.

The solution of curara employed in all the experiments was a filtered aqueous solution, every minim of which contained one milligramme of the poison. The solution was always injected into the jugular vein.

Experiment 1. Dog weighing 7.6 kilogrammes.*—Twenty milligrammes of curara were injected into the jugular vein (at *a*, Fig. 1). The abdomen was then opened, and the cannula placed in the common bile-duct, as above indicated. The wound in the abdomen was closed, the animal enveloped in cotton-wadding, and the bile collected. As the experiment proceeded, the effect of the curara gradually wore off, owing to its elimination, and it was necessary to inject from two to four milligrammes from time to time (*b*, *c*, *d*, *e*, *f*, *g*, Fig. 1). If the curve be examined, it will be observed that these doses had no apparent effect on the biliary secretion. Large doses weaken the heart, and diminish the secretion possibly on that account; but doses so small as those given in these experiments have apparently no effect, and therefore their administration is not indicated in subsequent curves.

The secretion of bile in this case was fairly regular. After falling until the middle of the third hour, it increased for a time and then fell somewhat. At the eighth hour it was slightly below what it had been at the close of the first.

Fig. 1.—Secretion of bile in a dog that had fasted eighteen hours. Curara only given. *a*. 20 milligrammes; *b*. 2 mill.; *c* and *d*. 4 mill.; *e*, *f*, *g*. 3 mill. of curara injected into vein.

Fig. 2.—Secretion of bile in a dog that had fasted nineteen hours. Curara only given. The unbroken curve joins the readings of the bile, that were actually taken every quarter of an hour. The broken line and triangles indicate what was probably the real secretion of bile when the outflow was irregular. (See text.)

Experiment 2. Dog weighing 15 kilogrammes.—In this experiment the secretion of bile with doses of curara similar to the above was again observed. The biliary flow was not so regular in this case. It will be noticed (Fig. 2) that a high and a low reading succeed each other more than once. It is just possible that this may have been owing to a variation in the facility of exit of the bile, owing, perhaps, to some slight shifting of the cannula. The real amount of biliary secretion in such cases would probably be more nearly represented by taking the mean of the high and the low reading, as indicated by the dotted line and triangles.

Composition of Bile in a Fasting Dog.—Analyses were made of the bile secreted by the second dog during the first, fourth, and last hours of the experiment. The following are the results.

TABLE I.—*Composition of Bile secreted by a Dog paralysed by Curara after fasting eighteen hours.*

Experiment 2.	Bile secreted during		
	First Hour.	Fourth Hour.	Last Hour.
Water	89.53	89.58	89.55
Bile-acids, pigments, cholesterin, fats	8.73	8.68	8.71
Mucus	0.71	0.72	0.72
Ash	1.03	1.02	1.02
Total	100.00	100.00	100.00

* A kilogramme is 2.2 pounds.

It therefore appears that in the progress of the experiment the composition of the bile remained almost precisely the same. This is remarkable, seeing that the animal had been deprived of water for so long a time, and, moreover, seeing that the entrance of the bile into the intestine had been cut off. It should be mentioned that in taking the bile secreted near the beginning of such experiments for analysis, we were always careful to eliminate that which had been expressed from the gall-bladder into the cannula.

ACTION OF CROTON-OIL.

Röhrig has placed croton-oil at the head of his list of hepatic stimulants, with the statement that in doses from eighteen drops to a "teaspoonful" it has an exciting effect on the biliary secretion even under the most unfavourable circumstances (*lib. cit.*, p. 250). This substance was therefore made the subject of our first experiments with cholagogues.

Experiment 3. Dog weighing 7.3 kilogrammes.—Considering the small size of this dog, the secretion of bile was unusually great. This probably resulted from digestion being incomplete; for, although the animal was fed seventeen hours before the experiment, at death a quantity of elastic tissue, and a greyish fluid resembling chyme, were found in the stomach. After the secretion had fallen very low, fifteen grains (about thirty drops) of croton-oil, in sixty minims of almond-oil, were injected directly into the duodenum (at *c*, Fig. 3). The dose was a large one, but not so large nor yet so small as the quantities given by Röhrig. After half-an-hour, the fall in the bile-secretion was arrested, and a slight rise took place. Towards the close of the experiment, the pulse became extremely weak.

AUTOPSY.*—The mucous membrane of the upper three-fourths of the small intestine was intensely red, especially in the duodenum, the colour of which resembled that of claret. There was evidence of impending purgation in the small intestine. The weak pulse at the close of this experiment, together with the violent intestinal irritation, suggested that the collapse had been occasioned by the drug, and that a smaller dose should be given in the next experiment.

Experiment 4. Dog weighing 5.9 kilogrammes.—This animal had refused almost all food for nearly two days. Six grains of croton-oil in sixty minims of almond oil were injected into the duodenum (at *c*, Fig. 4). No increase of the biliary secretion followed. The pulse became so weak that the experiment was ended two hours and a half after the oil was given.

Fig. 3.

Fig. 4.

Fig. 5.

Fig. 3.—Secretion of bile in a dog. Digestion incomplete. Fifteen grains of croton-oil injected into duodenum at *c*.

Fig. 4.—Secretion of bile in a fasting dog. Six grains of croton-oil injected into duodenum at *c*.

Fig. 5.—Secretion of bile in a dog that had fasted eighteen hours. Three grains of croton-oil injected into duodenum at *c*.

AUTOPSY.—The oil had found its way into the stomach. The gastric mucous membrane was of a claret colour. There was slight redness of the duodenum, but no evidence of purgative action.

Experiment 5. Dog weighing 3.1 kilogrammes.—In this experiment, only three grains of croton-oil in sixty minims of almond-oil were injected into the duodenum. A decided increase in the biliary secretion began within an hour after the injection. The secretion soon reached a maximum, and then fell in the course of two hours to the same level as before the injection. (Fig. 5.)

AUTOPSY.—A portion of the oil was found in the stomach, and another portion half way down the small intestine. The gastric mucous membrane was intensely red. There were patches of slight redness here and there in the duodenum. No evidence of purgative action.

These experiments led us to doubt the great potency of croton-oil as a cholagogue; and, seeing that probably no one would think of giving this irritant for the purpose of stimulating the liver, we laid it aside.

* In all cases, unless otherwise stated, the autopsy was performed immediately at the close of the experiment.

ACTION OF PODOPHYLLINE.

Experiment 6. Dog weighing 15.3 kilogrammes.—The secretion of bile fell very gradually (Fig. 6). Ten cubic centimeters of water were injected into the duodenum at *w*. There being no apparent effect, 100 cc. were injected at *w'*. The slight rise in secretion that ensued at the end of an hour may have been owing to this; but it is not likely, seeing that water is absorbed with rapidity. At *p*, ten grains of podophylline, suspended in 10 cc. water, were injected into the duodenum; and it is probable that the rise in secretion two hours afterwards was due to the podophylline.

AUTOPSY.—The mucous membrane of the duodenum, and to a slight extent below it, was very vascular, and this part of the intestine contained a considerable quantity of a slightly brown fluid, thereby affording evidence of a purgative effect.

Fig. 6.

Fig. 6.—Secretion of bile in a dog that had fasted nineteen hours. *w*, 16 cc. of water; *w'*, 100 cc. of water; *p*, ten grains of resina podophylli in 10 cc. of water injected into duodenum.

Fig. 7.—Secretion of bile in a fasting dog before and after injection into the duodenum of eight grains of podophylline in 10 cc. of water at *p*.

Fig. 7.

Experiment 7. Small Dog.—Eight grains of podophylline in 10 cc. of water were injected into the duodenum (*p*, Fig. 7). Before this, the bile-secretion was low, and remarkably regular. The distinct rise in the secretion an hour after the injection was probably owing to the podophylline, but the experiment was not continued sufficiently long to show the full effect. At death, there was increased redness of the duodenal mucous membrane, but no distinct evidence of purgative action.

Experiment 8. Small Dog.—Eight grains of podophylline in 25 cc. of water were injected into the duodenum (*p*, Fig. 8). The subsequent increase in the biliary secretion was most marked about four hours after administration, but by the end of the sixth hour the effect had greatly diminished.

Fig. 8.

Fig. 8.—Secretion of bile in a dog that had fasted nineteen hours. Eight grains of podophylline in 25 cc. of water injected into duodenum at *p*.

Fig. 9.—Secretion of bile in a dog that had fasted eighteen hours. Six grains of podophylline in 9 cc. of water injected into duodenum at *p*.

Fig. 9.

AUTOPSY.—The upper part of the small intestine contained a viscous brownish fluid. As the small quantity of water injected had probably been absorbed, the intestinal contents were regarded as distinct, though not abundant, evidence of purgative action. The mucous membrane, to the extent of about eighteen inches below the pylorus, was extremely vascular. The remainder of the intestine was pale. A small quantity of mucus was found in the stomach, the mucous membrane of which was pale.

Experiment 9. Dog weighing 6.6 kilogrammes.—Six grains of podophylline in 9 cc. of water injected into the duodenum (*p*, Fig. 9). The subsequent rise in the bile-secretion is very evident. The secretion attained its maximum between three and four hours after the administration of the podophylline. As in the previous case, the effect on the liver had very greatly diminished by the end of the sixth hour after administration.

AUTOPSY.—There was distinct, though not abundant, evidence of purgative action in the small intestine, and decidedly increased vascularity of the mucous membrane in its upper two-thirds; nothing remarkable in the stomach or large intestine.

Probably every one will be struck by the slowness and the small extent of the purgative action in these experiments, notwithstanding the large doses of podophylline. That this was owing to the insolubility of podophylline in water is probable, from the two following experiments. Zwicke, Hagentorn, and Köhler having shown (Fraser's Report, *Journal of Anatomy and Physiology*, v, p. 393) that convolvulin, elaterin, and some other substances have no purgative action unless they come in contact with bile—which, therefore, appears to be a solvent for them—it occurred to us that the tardy action of the podophylline might be owing to the non-entrance of the bile into the intestine. Accordingly, in the next experiment the podophylline was suspended in bile.

institutions; and yet not one of them has ventured to institute a searching examination into the circumstances of their patients, but has simply relied upon the impressions of those who they consider best capable of giving an opinion. The truth of the matter is that, for some reason or other, the lay-committees are inclined to avoid their legitimate work by throwing too much responsibility upon the honorary medical staff, who are already overworked, and who have neither time nor inclination to fill the rôle of amateur detectives.

We shall not refer at length to the reports of the special committees of the Royal Free, the Children's in Great Ormond Street, the Great Northern, and the last report of the Westminster Hospital because they have all recently appeared in the JOURNAL. Let it suffice to say that the Westminster authorities will find, we fear, that the medical staff will be unable to perform all the work they have placed upon them; and that the plan adopted (so recently as June 25th) at the Children's Hospital, of prescribing for no patient a second time, unless the hospital letter have been stamped by the Committee of the Charity Organisation Society for the district in which the patient lives, is worthy of the close attention of all hospital managers.

The Royal Free Hospital, and the Queen's Hospital, Birmingham, are the only two institutions where the authorities have had the courage to put this matter into the hands of an independent body familiar with the work of accurate investigation and the impartial weighing of evidence. In each case, the aid of the Charity Organisation Society has been invoked, which has investigated, at the former, 641, all free, and, at the latter, 366, all ticket, out-patient cases.

The following table shows the result.

	ROYAL FREE.	QUEEN'S.	Total.
	Free Cases.	Ticket Cases	
1. Number who could afford to pay a Private Practitioner.....	12	64	76
2. Number who can afford to pay to Provident Dispensary.....	231	Not stated	231
3. Proper Applicants	169	260	429
4. Parish Cases.....	57	6	63
5. False Addresses	103	34	137
6. Information refused	69	2	71
	641	366	1007

We have here reliable data upon which to ground an opinion. It will be seen that, out of 1,000 cases, less than one half (429) are declared to be fit applicants for relief; and this number would be considerably smaller if those of the Birmingham cases who could afford to pay something to a provident institution had been deducted from the 260 who are declared, in the absence of such provision, to be proper applicants. Again, this table clearly shows the truth of our assertion that provincial hospitals are chiefly abused by the well-to-do classes; for, whereas the London hospitals do a large share of the Poor-law medical officers' work, the pauper cases in London being five times more numerous than at Birmingham, the well-to-do, on the other hand, were ten times greater at the latter than at the former institution.

It is worthy of remark that the abuse is equally great under the ticket as under the free system. In the face of the facts here brought clearly before hospital managers, we appeal to them most earnestly to give the system of investigation as pursued at the Royal Free and Queen's Hospitals a fair and impartial trial, in the interests alike of the philanthropic public who support these institutions, and of the really deserving poor, who, under the present system, are often debarred from obtaining that amount of attention which their cases so urgently require.

THE death of M. Marbœuf, the originator of *crèches*, or infant nurseries, is announced.

THE French Institute has awarded the 'ecennial prize of 20,000 francs (£800) for 1875 to M. Paul Bert work on the effects of barometric pressure.

DR. JÜNGKEN, the Senior Professor of the Faculty of Medicine in the University of Berlin, died on September 8th, at the age of eighty-two.

THE order of the Red Eagle, of the third class, has been conferred on Dr. Litzmann, the well-known Professor of Obstetric Medicine in the University of Kiel.

TWO new medical journals have appeared in Paris, already well provided in that respect. The new aspirants to professional favour are *Le Paris Médical*, edited by M. Fort; and *Le Journal d'Hygiène*, edited by M. Pietra Santa.

A NEW school of anthropology has been founded in Paris. Courses of lectures on the various branches of the science have been arranged, and are to be delivered at the *École Pratique* by MM. Broca, Dally, Mortillet, Hovelacque, Topinard, and Bertillon.

THE Royal Commission to inquire into the practice of subjecting live animals to experiments for scientific purposes, met at 13, Delahay Street, on Tuesday and Wednesday. There were present—Viscount Cardwell, Mr. W. E. Forster, Sir John B. Karslake, Mr. T. H. Huxley, Mr. J. Eric Erichsen, Mr. R. H. Hutton, and the Secretary, Mr. N. Baker.

A LETTER published in the *New York Medical Record*, states that Professor Gross's *Manual of Military Surgery* has been translated into Japanese. The Surgeon-General-in-Chief of the Sanitary Service of the Japanese gave orders for the translation to be made, and has forwarded a copy to Dr. Gross, with a very complimentary letter.

THE first meeting of the Pathological Society for the season, under the presidency of Mr. Pollock, was very well attended. The papers, too, were of considerable interest. For want of discussion, however, the meeting flagged; and, although the sight of the very good specimens shown, and the brief and accurate accounts given, well repaid the trouble of attendance, there was a want of animation in both speakers and audience which must, in the end, affect the popularity of the Society. For this state of things, various remedies may be found. In the first place, speakers at the Pathological Society may with advantage, as a correspondent suggests, whose half-jocose criticism we print next page, take a little more trouble in preparing their notes. There is a middle course between oratorical display which is out of place here, and studied neglect of all the graces of speech and manner which make even plain narratives acceptable; and young gentlemen fresh from the last number of Virchow's *Archives* or Stricker's *Yearbook* need not superciliously flourish the last long word or the newest fragment of a view under the noses of their seniors without deigning to explain what they mean, or why they have "thought this specimen perhaps of some interest". The Society is very grateful to those who will take the trouble to clothe their thoughts in neat and pointed phraseology, and to avoid the manner of "throwing bones to a dog" which has come to be fashionable among a certain section of young pathologists. The meekness, patience, and bewilderment with which some of the less learned members of the Society sit out these displays are worthy of more compassionate consideration. The cheerful surprise and timid applause which greeted some attempts of Dr. Greenfield to tell his story with something of point, finish, and scholarly grace, may encourage others to follow his example. But nothing could move the Society to discuss; and so the meeting, though instructive, was decidedly dull.

WE are very glad to hear that a well conceived effort will probably be made by the Council of the Pathological Society, at the instance, we believe, of Dr. Green, one of the secretaries, to elicit some organised attempt at encouraging comment by classifying specimens. Thus a night might be set apart for specimens of syphilitic pathology, a night for specimens of cancerous disease, or of vascular disease, etc. Specimens would be got together in greater numbers, and experts would be en-

couraged to take an active interest in discussing collections of specimens which specially touch their labours. This seems to us a practical and fruitful suggestion.

"AN Old Man from the Country" writes to us:—"I was last night again at the Pathological Society. It was very warm, very crowded, and, I suppose, very successful. But, as even success will bear to be enhanced, I should like permission to make a few ill-natured remarks, such as my age, ignorance, and condition suggest, and as their possible usefulness will perhaps excuse. As an old man, I am perhaps inclined to resent the advantage which 'the boys' have over us oldsters at the Pathological Society. They have it all their own way, and do nearly all the talking and all the applause. I should not mind it so much—for I see my betters frequently sitting mum for a whole session at the feet of very young Gamaliels—if the boys bore their blushing honours more gracefully or attractively. But there has gradually stolen over the Pathological Society a mortal dullness and a cynical puritanism which make the meetings a very different sort of thing now from what they used to be. At half a dozen meetings which I have attended during the last year, I have been painfully affected by the solemn gloom of the proceedings. Deadly liveliness is perhaps the natural characteristic of these scientific funereal rites over *post mortem* specimens. But even the manner of the undertaker varies, and not all his men are mutes. The approved oratorical method which has gained favour at the Pathological Society of late years is a sort of bald and lingering stutter. There is no attempt to give completeness or point to the description, nor any effort to please, interest, or animate the audience by such attention to manner, diction, and method as may clothe the dry bones of a *post mortem* note with busy interest. The discussions which follow—if discussions they can be called, in which nothing is discussed—are commonly intervals of painful silence, in which the President slowly peruses the faces of the uneasy persons before him with an ever-deepening expression of sadness, until the despairing conviction that nobody has anything to say on the last mooted 'subject of interest' overpowers him, when he whispers solemnly to the secretary, and proceeds with the announcement that, 'as no gentleman has any observation to make, we shall pass on to the next specimen'. It does, however, in my experience sometimes happen that a gentleman rises precipitately from a back bench at the last moment, and, from a safe corner, asks 'whether in the last case (one of broken ribs) the speaker examined the urine', or if it were a case of, say, intestinal obstruction, 'whether he used the ophthalmoscope during life'. The answer is sometimes a triumphant affirmative, and sometimes a disconcerted negative, on receiving which the querist subsides without further comment. I am, for my part, however, obliged to him for having broken the spell. His success generally induces some one else, at a later stage, to ask 'whether Mr. A. has looked through the *Transactions* of the Society for the last twenty years before bringing forward his specimen; if he had, he would have found that he (Mr. B.), fifteen years ago, described a specimen which, in various particulars, did not greatly differ from that which Mr. A. has to-night shown'. I do not know whether this style of discussion is as agreeable to all the other members of the Society as it is to me; but I often think that, although the sight of the preparations has been very instructive to me, it hardly repays me for the mental torture which I have suffered from the *gaucherie*, coldness, and mismanagement which often make perhaps the most valuable of our London societies one of the least attractive."

ACONITE.

FROM an elaborate series of observations (*St. Thomas's Hospital Reports*, New Series, vol. v), Dr. John Harley reports conclusions which indicate that, if it be conceded that aconite ameliorates the febrile condition, it does not much control it; and that it cannot in any degree anticipate or cut short the pyrexial stage in a disease (relapsing fever) against which, if it did possess the febrifuge properties ascribed to it, its influence ought to be most marked.

THE CLINICAL SOCIETY.

IN addition to the subjects advertised last week in the *BRITISH MEDICAL JOURNAL* for discussion at the meeting of the Clinical Society to-night (Friday), Mr. Hutchinson will exhibit an infant with a very curious tumour of the skull; and a patient with a peculiar sore upon the tongue, of probably malignant nature.

COVENTRY AND WARWICKSHIRE HOSPITAL.

ON Tuesday evening, a deputation from the "working men" met the general committee for the purpose of handing over the receipts from the Hospital Saturday collection, a sum of £219 : 12 : 5. This is the second year the working men have come forward to assist the funds of a hospital which has been hitherto considerably in debt, and the amount collected on the present occasion shows an increase of £50 on the results of last year's Hospital Saturday, while the expenses of collecting have been only £6 : 10 : 6. One great element of success has been the system of instituting periodical collections in the various manufactories and workshops, either weekly, monthly, or quarterly; and it is hoped, as this idea becomes more ventilated and more earnestly worked, a considerable income will be derived from this source. The working men are represented on the managing committee of the hospital, four being elected annually, so that they may have a voice in the disposal of funds which they have collected.

RECENT URBAN MORTALITY.

DURING last week, 5,323 births and 3,489 deaths were registered in London and twenty other large towns of the United Kingdom. The annual average rate of mortality was 24 per 1,000 persons living; and varied as follows: in Portsmouth it was 17; Edinburgh and Glasgow, 21; London, Birmingham, and Sheffield, 22; Leicester and Wolverhampton, 23; Newcastle-upon-Tyne, 24; Norwich, 25; Sunderland and Manchester, 26; Dublin, Leeds, Liverpool and Hull, 27; Bristol, Bradford, and Nottingham, 28; Oldham, 30; and Salford, 31. The annual zymotic death-rate in the 18 English towns ranged from 2.5 and 2.9 in Norwich and Wolverhampton, to 9.0 and 9.2 in Oldham and Salford. The fatality of scarlet-fever continues to increase, and was greatest in Bristol, Bradford, Oldham, Nottingham, and Salford. Enteric fever is somewhat prevalent in Portsmouth. In London, 2,325 births, and 1,442 deaths were registered. The births exceeded by 24, and the deaths by 41, the average numbers of the week. The 1,442 deaths included one from small-pox, 23 from measles, 122 from scarlet-fever, 9 from diphtheria, 37 from whooping-cough, 29 from different forms of fever, and 78 from diarrhoea; in all, 299 deaths. Scarlet-fever was least fatal in the central, and most so in the south, groups of districts; the fatal cases were especially numerous in Haggerston, Rotherhithe, Peckham, and Deptford. Different forms of violence caused 44 deaths. The Asylum District Fever and Small-pox Hospitals at Homerton and Stockwell contained 320 patients on the 16th instant, of which 53 were under treatment for fever, 250 for scarlet-fever, and one for small-pox. In outer London, 460 births and 228 deaths were registered; and the general death-rate and zymotic death-rate were 15.6 and 3.5 per 1,000 respectively, against 21.8 and 4.5 in inner London. At Greenwich, the mean reading of the barometer was 29.29 inches; the mean temperature of the air was 45.8 deg., or 4.9 deg. below the average of the week; the mean degree of humidity of the air was 82; the direction of the wind was variable; the horizontal movement of the air averaged 10.3 miles per hour; and rain fell on five days, to the amount of .48 of an inch.

GERMAN ASSOCIATION OF NATURALISTS AND PHYSICIANS.

THE forty-eighth annual meeting of the German Association of Naturalists and Physicians was held in Gratz from September 18th to 24th. The session was opened with an address by Professor Rollett; after which the Association was welcomed by the Statthalter of Styria, the Burgomaster of Gratz, and the Governor-General (*Landeshauptmann*) of the province. It was announced that considerable sums had been contributed towards defraying the expenses of the meeting by the Em-

peror of Austria, the *landtag* of Styria, and the municipal authority of Gratz. A letter was read from Herr Stremayr, Minister of Instruction, expressing his regret that his official duties prevented him from accepting the invitation to be present which had been offered to him. There were no fewer than twenty Sections, among which the following were of medical interest:—Section 7. Anatomy and Physiology: President, Professor Stilling. Section 9. Internal Medicine and Dermatopathology: President, Professor Korner. Section 10. Surgery: President, Professor Gurlt. Section 11. Ophthalmology and Otology: President, Professor Blodig. Section 12. Gynecology and Obstetrics: President, Professor R. von Helly. Section 13. Psychology: President, Professor von Krafft-Ebing. Section 14. State Medicine, including Hygiene and Veterinary Medicine: President, Professor A. Schauenstein. Section 15. Military Medicine: President, Professor Mundy. Section 20. Diseases of Children: President, Dr. Steffen. It was decided to hold the next meeting in Hamburg. The Vienna medical papers, in giving a summary of the proceedings, comment on the somewhat defective character of the arrangements; pointing out especially that the sittings of the medical sections are so timed as to clash with one another, and that sufficient information as to the place and time of meeting, and of the subjects, is not given; and that the "daily journal" is devoted to relating what *has been done* instead of—what is rightly regarded as of more importance—giving notice of what *is to be done*. We shall endeavour to give a notice of some of the papers read in the sections.

THE MEDICAL SOCIETY OF LONDON.

THIS Society opened its session on Monday in its rooms in Chandos Street. There was a strong muster of the members of Council and of Fellows, with an unusually large number of visitors. The consequence was that the ventilating arrangements of the room were severely taxed. Since the last session, Tobin's patent tubes have been applied, but the current of cold air so supplied was quite inadequate to the requirements of the audience. The escape of foul air is met by the shaft of the star burner, but that will not secure a sufficient supply of fresh air. The necessary supply of fresh air into the highly heated apartment was wanting in the new arrangement, which might not be in efficient working order. One of the speakers alluded to the warm reception given to the Fellows, but the oppression was too pronounced to permit the *double entendre* to be accepted as a joke. After the exhibition of a case of cleft-palate, the President, Dr. Routh, gave an address on the interesting subject of Surgical Hyperpyrexia. The subject matter was furnished by five cases which had recently occurred under his care. In several of the cases, the sharp uprise of sudden hyperpyrexia was well shown. The treatment adopted was that of the iced-water bath, and in every case the cold bath was followed by a decided and immediate fall of the temperature, which in one or two instances did not rise again to the same height. In several cases, the difference of temperature in the vagina and axilla was well marked, and several degrees of difference were found at times; the vaginal temperature being invariably above that of the axilla. In one case, the new apyretic agent *jaborandi* was given with marked effects. The different points touched upon in the paper gave room for a discussion, in which many present took part. From a copy of the bye-laws, with proposed amendments, being hung up for the inspection of the Fellows, it appears that extensive changes are to be made in them.

POISONING BY GOAT'S MILK.

ACCORDING to recent German journals, several cases of poisoning by goat's milk have occurred in Rome. The cases, which all occurred in one locality (Borgo Rione), had the character of cholera, and some of them that of well marked cholera. In some of the cases, recovery took place in twenty-four hours; but most of the patients were ill four or five days. The severity of the symptoms was in direct relation to the quantity of milk used. On veterinary examination, the goats were found to be in perfectly good condition. In their pasture, however,

were found four poisonous plants; viz., *Conium maculatum*, *Clematis vitalba*, *Colchicum autumnale*, and *Plumbago Europæa*. On making a chemical examination of the milk and also of the vomited matters, Professor Ratti found in both colchicin, the passage of which into the milk was thus most probably the cause of the poisoning. It is well known that goats can eat with impunity hemlock and tobacco; but that they also eat colchicum, which acts as an intense poison on cows and other animals, was hitherto unknown. It has been suggested with reference to these cases, that *Momordica elaterium* may have played a part in them as well as colchicum; but Professor Ratti has shown that the elaterium is avoided by goats when they meet with it in their pasture.

NEWS OF LOUISE LATEAU.

A LETTER from Dr. H. Boëns of Charleroi to M. Festaerts, editor of the *Sculpel*, gives some details of the actual state of Louise Lateau, "the mystic of Bois d'Haine". During an illness which lasted about a month, the "stigmatic" bleeding stopped, and the "ecstasies" were replaced by hysterical faintings. Afterwards, the former state of things recurred. M. Boëns, who has set a watch on the family, declares that he is in a position to affirm and prove that Louise Lateau eats and drinks copiously, and performs all the ordinary functions of nature. He adds that "she frequently rubs and scratches with her nails and with a rough cloth, especially during the night, the places where the blood flows; and keeps up on these spots, even mechanically during sleep, pressure with her fingers, so as to maintain a condition of local congestion". Dr. Bourneville, in a recent monograph (*Science et Miracle*), describes a hysterical patient of M. Charcot, who likewise suffers from bleeding of the skin, preceded by pain and convulsive phenomena, with religious hallucinations. The bleedings here also frequently occur at the "stigmatic" localities.

RAT-EATERS.

A SOCIETY has recently been formed at Gembloux, in Belgium, of rat-eaters (*rato-phages*). The members meet once a week: each meeting ends with a grand repast, in which the rat occupies the principal place. This society, following the example of the *Société Hippophagique*, wishes to destroy the prejudice attaching to the flesh of these little animals. With this object, a Belgian *savant* relates that the ancient Romans ate grey mice, seasoned with acorns and chestnuts. Buffon tells that the inhabitants of Martinique take pleasure in eating mice, and hold the musk-rat in esteem as an article of diet. Climbing rats form one of the staples of food in Cuba and Jamaica. Rat's flesh, however, counts its enemies as well as its friends. A mediæval Arab writer, Eby-Bachthar, declared that eating rat's flesh produced great *intellectual weakness*.

THE LATE DR. EDWARD JOHNSON.

WE have this week to record the death of Dr. Edward Johnson, aged 60, who died on Saturday, the 16th instant, at his residence, 19, Cavendish Place, where he had been in practice for fifteen years. Dr. Johnson was well known in professional circles as an able practitioner and an accomplished gentleman; these qualities, together with his amiable disposition and high character, endeared him to a large circle of friends, by whom his loss will be deeply felt. He was a graduate of Edinburgh, but had also studied in Dublin and Paris, and in his earlier years had served in the navy as assistant-surgeon; but the humiliating treatment to which in those days assistant-surgeons were subjected induced him to leave the service. He commenced practice in London in the neighbourhood of his late residence, and rapidly succeeded. For many years, his practice was large, and chiefly amongst the middle and upper classes. His patients were personally attached to him, not only as a kind and skilful medical attendant, but as a friend upon whose advice and judgment they could at all times depend. His death was caused by aneurism of the aorta, involving the innominata and pressing on the trachea, as well as interfering with the pneumogastric nerves. Several prolonged attacks of asphyxia occurred during the two days preceding the fatal event.

THE "CORNWALL" OUTBREAK OF TYPHOID.

SINCE the date of our last report, more cases of typhoid have occurred on board the school-ship *Cornwall*, stationed off Purfleet, six of which have been admitted to the Seamen's Hospital, Greenwich, making, with those previously in the hospital, twenty-six. As many as twenty-eight, however, remain under treatment at Purfleet, where the boat-house has been fitted for their accommodation on shore, nurses being obtained from an institution in town. The entire number of sick at present amounts, therefore, to fifty-four, or about one-fourth of the number of boys on board. The cause of the outbreak is being investigated by the sanitary authority of the river; meanwhile, suspicion is directed to the water-supply, which is obtained in the following manner. An empty open twelve-oared pinnace is towed by another boat every morning from the ship to a jetty, where water is conveyed by pipes above to the river side; India-rubber hose is then attached to the terminal pipe, the stopcock is turned, and the empty boat partly filled, taken back to the ship, and the water pumped out into iron tanks on the lower deck, whence it is distributed by pumping when required, the boat lying alongside uncovered till next day, when the journey is repeated. This mode of water-carriage is open to grave objection; for an uncovered boat, occasionally used (as we understand that this one is) for the conveyance of passengers and stores, is exposed to sources of contamination, such as cannot fail to suggest themselves to anyone acquainted with the most elementary principles of sanitary science. We understand that a similar mode of conveying water in bulk in an open boat was formerly employed by the *Warspite* training-ship, and that, during its continuance, diarrhoea was extremely prevalent among the boys, although the boat was supposed to be cleaned out regularly. It was then determined to well whitewash the boat, and cover it in, and since this has been done it appears that cases of gastric irritation have greatly diminished. We are glad to find that the *Cornwall* has, since the outbreak, effected a reform in this particular, and that the water is now brought from shore in casks. We trust that the authorities of the various other training-ships on the Thames will profit by the lesson afforded by the *Cornwall*, and look carefully to the purity of their water-supply. We learn that, setting aside the present outbreak, only one stationary ship, during the present year, has furnished a case of zymotic disease to the Seamen's Hospital, namely, the *Arethusa*, which sent a boy suffering from typhoid in January. The first case of the *Cornwall* series was sent to the hospital on September 21st. It was a well marked and rather severe case of enteric fever, with the usual symptoms. On October 5th, four others were admitted; and, finally, the number reached twenty-six. These cases presented considerable variety as to symptoms, complications, and course, the majority presenting the ordinary characters of rose rash, diarrhoea, usual temperature, variation, and course; others, again, were examples of a low form of pneumonia, which, bearing in mind its probable origin, might be termed pythogenic, and which is interesting when we consider that it is perhaps oftener than we are aware an unrecognised indication of insanitary conditions. A third and small class were of a still more ambiguous type, being cases of pyrexia, with slight tonsillitic inflammation, cephalalgia, and cervical myalgia, and ending in complete defervescence in about eight or nine days. Isolated cases of this kind would probably be classed as "catarrhal", and are, therefore, very instructive. Headache was a marked feature in nearly all; several were delirious; bronchitis and pneumonia were frequently present; deafness, epistaxis, and slight albuminuria occurred in two. In several instances, the evening temperature in the axilla reached 105 deg. Fahr. Dr. Ralfe, who has charge of the cases, has treated them with quinine, stimulants, as a rule, being avoided, and all are progressing favourably. In concluding our observations on this subject, we wish to call attention to the inconvenience and risk attending the present mode of conveying boys suffering from fever in open boats from their ships to the Seamen's Hospital, and to renew the hope we expressed last week, that the authorities of the Thames training-ships will bestir themselves to combine to provide a hospital for the recep-

tion of cases like the present, so that, if the necessity should again arise, they may be prepared to meet the emergency with promptitude and efficiency.

SCOTLAND.

THE Kilsyth Local Authority met on Friday to consider what steps should be taken to prevent the spread of small-pox, which has assumed an alarming phase during the past week—upwards of eighteen cases were reported. It was resolved to call a special general meeting of the Local Authority for the purpose of erecting a hospital for the small-pox and fever patients, and a committee was appointed to look out for a site.

A CENTENARIAN.

THERE died a few days ago in the Tobermory poorhouse, a man, named John McMillan, who had reached the age of 104 years. He was a native of the parish of Kilmore, and had spent the greater part of his life there. Till within the last few months, he retained all his faculties, and was able to walk about and do the ordinary work of the poorhouse.

THE SANITARY CONDITION OF CARLUKE.

At the last meeting of the Sanitary Committee for the parish of Carlisle, Dr. Littlejohn's report of his visit to Carlisle on the 25th ult. was read. The document, a long one, went to show that the village was in a very unsatisfactory condition as to sanitary matters. The lower portions of the village were especially bad, the whole sewage flowing from the higher to the lower streets. In John Street, there was a most disgusting sewage smell. In the public school, he found the air vitiated, stifling, and unbearable, and saw relays of children standing at the door to get air. He had samples of four wells tested by an analyst; only one of them was found to be a "fairly pure water" for drinking purposes—all of them were unsuitable for washing. The sanitary condition of the place could never be put on a satisfactory footing unless water were brought in by the Local Authority, as the supply from wells was inadequate. The report was laid on the table to be considered at a future meeting.

WEST OF SCOTLAND CONVALESCENT SEASIDE HOME.

At the sixth annual meeting of this institution, Sir Peter Coats, who presided, stated that, since the opening of the institution six years ago, the past year had been the most satisfactory both in the number of patients admitted and in the support of the public in contributions. The number of convalescents taken in was 1,547, an increase of 323 over the previous year, being made up of 742 men, 726 women, and 79 children. There were 117 in the home at the beginning of the year, and 126 at present; there had been two deaths during the year. The institution is supported by subscriptions, donations, etc., of about £2,000 from the general public, and about £1,000 from workmen engaged at public works.

LINTHGWOG LOCH.

A MEETING of the Local Authority to inquire into the alleged unsanitary condition of this loch received a report from their medical officer corroborating that of Professor MacLagan, and showing that he had found the south side in an extremely polluted and filthy state, and dangerous to the health of the inhabitants in the vicinity. The Committee sent the following answer to the Board of Supervision, who had requested the Local Authority to take immediate steps to remedy the evil.

"While it is admitted that from the sewage of Lintithgow there are considerable accumulations in the loch, which may, if not checked, prove injurious to health, it is denied that such accumulations have hitherto had that effect. The death-rate of Lintithgow has been below the average of other similar towns, and at present eels, perch, roach, and other kinds of fish abound in the loch. But assuming that things may get worse instead of better unless something be done to

check growing accumulations, the Local Authority submit that, in the circumstances, Her Majesty's Commissioners of Works, who claim the control and management of the loch, ought to be called upon by the Board of Supervision to afford the requisite remedy by from time to time dredging and cleaning it."

THE LAST CASE UNDER THE OLD ADULTERATION ACT.

LAST week, a druggist in Greenock was charged at the police-court with having sold two ounces of citrate of magnesia, which, on analysis, was found to be a preparation containing carbonate of soda, tartaric acid, sugar, sulphate of soda, and a small portion of citrate of magnesia. Mr. McGowan, public analyst, deposed to having found these ingredients in the sample he analysed. From the evidence of a number of witnesses called for the defence, it appeared that what is generally sold in chemists' shops as citrate of magnesia, consists mainly of carbonate of soda and tartaric acid, with a little sugar, and does not contain a trace of citrate of magnesia. Evidence was also given to the effect that none of the ingredients were injurious to health. The Public Prosecutor asked for a conviction, contending that there was no need to prove that the mixture was injurious to health. The magistrate considered the case not proven. It was the last case to be tried under the old Act.

A MILK EPIDEMIC OF TYPHOID FEVER IN GLASGOW.

IN the JOURNAL for October 2nd, we briefly noted that an epidemic of typhoid fever had broken out in Glasgow, and that there were strong reasons for believing that it owed its origin to milk from an infected farm. An elaborate report from the medical officer of health enters into the question, and shows that the epidemic has had the origin indicated. The report itself is a somewhat long document; and it may be sufficient here to state that, from a house-to-house visitation of certain streets in which the disease was prevalent, the following results were obtained. There were 367 persons using milk from the suspected dairy only (called Dairy X in the report); and, of these, 55 had typhoid fever, and 14 had suspicious sickness. There were 116 using this milk partially; and among them, there were three cases of typhoid, and 16 of suspicious sickness. On the other hand, there were 579 individuals not using this milk; and there was only one case of typhoid, and no case of suspicious sickness. The medical officer points out the difficult nature of the inquiry, and hints that infected milk is oftener the cause of such outbreaks than we can prove it to be. He winds up with the two following lessons which these facts are calculated to teach.

"1. He is satisfied that, if rural authorities throughout the country made a special inspection of the sanitary arrangements of all the dairy-farms, examining particularly the water-supply, and insisting on improvements in the domestic arrangements of washing-houses, the sites of manure depôts, etc., more would be done to exterminate enteric fever both in the country and our large cities than by any other procedure which could be adopted. 2. He is afraid that milk-agents in the large cities are not sufficiently alive to the duty which is imposed upon them, as upon all dealers in articles of food, of seeing to the purity of the article which they sell; and he hints to dairykeepers who are anxious to extend their business, that they should at once introduce a reform in this respect, and seek to satisfy themselves and their constituents that they are furnished with clean and pure milk from tidily kept farms, where no disease is known to exist.—The board wisely directed that this report should be printed in a pamphlet form, and that a copy should be sent to the Board of Supervision, with a request that they should communicate with the local authorities around Glasgow, and require them to enforce the precautionary measures suggested by Dr. Russell."

We heartily endorse the recommendations of Dr. Russell; and we may add that experience has already proved, on a large scale, how well such precautions work. These, and many similar precautions, have been carried out now for some time under the direction of a medical board, consisting of Dr. Murchison, Dr. Sieveking, Dr. Whitmore, and Dr. Hardwicke, by the Aylesbury Dairy Company in Bayswater; and in no instance have the strictest precautions been found to interfere with the requirements of a large business.

IRELAND.

ROYAL COLLEGE OF SURGEONS OF IRELAND.

ROBERT MORTON, M.B., Fellow of the College, of Castleblaney, and Dr. M. J. Malone, Fellow of the College, of Limerick, have been elected examiners in preliminary education in room of Drs. Tweedy and Woodhouse.

THE WEEKLY RETURN OF DEATHS.

DURING the week ending October 9th, the deaths in Dublin represented an annual mortality of 23 in every 1,000 of the population. Zymotic diseases proved fatal in 37 instances. Of these deaths, 4 were caused by fever, 3 by scarlet fever, 4 each by measles, diphtheria, and whooping-cough, and 16 by diarrhoea. The deaths of 12 children were referred to convulsions. In Belfast, there were registered 7 deaths from scarlet fever, 3 from diarrhoea, 4 from fever, 2 from diphtheria, and 1 each from measles and whooping-cough. Four deaths from scarlet fever were registered in Londonderry, and a like number in Cork.

MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS.

THE following have been appointed office-bearers for the ensuing year. *President*: Samuel Gordon, M.B. *Vice-Presidents*: Lombe Athill, M.D.; Sir Dominic J. Corrigan, Bart., M.D.; Alfred Hudson, M.D.; William Stokes, M.D., F.R.S. *Council*: J. Hawtrey Benson, M.D.; J. M. Finny, M.D.; Thomas Fitzpatrick, M.D.; A. W. Foot, M.D.; T. W. Grimshaw, M.D.; Thomas Hayden, F.C.P.; James Little, M.D.; Stephen M. Mac Swiney, M.D.; J. W. Moore, M.D.; C. J. Nixon, L.C.P.; John M. Purser, M.D.; W. G. Smith, M.D. *Honorary Secretary*: G. F. Duffey, M.D.

COMPULSORY VACCINATION.

At a meeting of the guardians of the North Dublin Union held last week, a memorial was read which had been received from the guardians of the Keighley Union, Yorkshire, asking the board to co-operate in endeavouring to obtain a repeal of the compulsory vaccination law. As a reply to this request, the guardians unanimously passed a resolution approving of the system of compulsory vaccination, and declining to support the memorial. The following extract from the document in question is amusing: "That, regarding vaccination as a doing of evil that good may come, and the vaccination law as a sin against God and man, we, the Keighley Guardians, most respectfully memorialise you to aid us for the highest and most benevolent motive that can animate you, in our efforts to set free the entire country from the cruel despotism of compulsory vaccination," etc.

THE QUARTERLY SUMMARY OF THE REGISTRAR-GENERAL.

DURING the quarter ending on Saturday, October 2nd, 2,246 births and 1,705 deaths were recorded in the Dublin Registration District. The birth-rate was equal to an annual ratio of 29 births in every 1,000 of the population; and the mortality was at the average rate of 22 deaths in every 1,000 persons living. The annual rates of mortality per 1,000 during the quarter in seven other Irish towns, ranged in order from the lowest, were as follows:—Sligo, 14; Galway, 15; Limerick, 20; Cork, Londonderry, and Waterford, 22; and Belfast, 25. In Dublin, 23.2 per cent. of the deaths registered were due to zymotic diseases, and were equal to an annual ratio of 5 per 1,000 of the population. The deaths from zymotic diseases in the corresponding quarter of last year were 540. The 1,705 deaths in Dublin included 140 from diarrhoea, 51 from fever, 45 from whooping-cough, 38 from measles, 28 from scarlet fever (against 250 in the corresponding quarter of last year), 25 from croup, 11 from erysipelas, 9 from diphtheria, 207 from phthisis, 47 from cancer, 105 from bronchitis, and 47 from pneumonia. In Belfast, 253 deaths, or 22.5 per cent. of the total deaths registered, were due to zymotic diseases: of these, 88 were referred to diarrhoea, 60 to measles (which had killed 114 persons in the preceding

quarter), 57 to scarlet fever, 23 to fever, 15 to whooping-cough, 8 to diphtheria, and 2 to small-pox. In Cork, 21 deaths were registered from scarlet fever; and in Londonderry the same disease caused 42 deaths, or one-fourth of the total deaths registered during the quarter. In Dublin, the death-rates at different ages in 1,000 persons living were as follows:—73.2 in every 1,000 children under 5 years of age; 5.2 in every 1,000 persons from 5 to 15 years; 6.1 per 1,000 persons aged from 15 to 20 years; 10.9 per 1,000 persons aged from 20 to 40 years; 21.5 per 1,000 between 40 and 60; 55.8 per 1,000 between 60 and 80; and 102.2 per 1,000 aged 80 and upwards. The mean temperature of the air in Dublin during the quarter was 58.9 deg.; at Greenwich, it was 60.7 deg.; and at Glasgow, 56.7 deg. The rainfall at Dublin during the thirteen weeks measured 8.532 inches; at Greenwich, 10.13 inches; and at Glasgow, 10.91 inches.

SCARLATINA.

SCARLATINA exists to a considerable extent in various parts of Monaghan; and Dr. Burke, Inspector of the Local Government Board, has recommended that the guardians, as the sanitary authority, should use their influence with the managers of the public schools in the district, with a view of having them closed during the prevalence of the disease; which suggestion the guardians have signified their intention of complying with. In Londonderry, during the last three months, forty-two deaths were registered as occurring from this affection, a number equal to one-fourth of the total deaths.

QUEEN'S UNIVERSITY IN IRELAND.

THE degrees obtained by candidates who passed the University examinations of the year 1874-75, were conferred on the 15th instant at Dublin Castle, by his Grace the Duke of Leinster, Chancellor of the Queen's University. During the present academic year, 490 candidates have been present at the University examinations, and of these about one-third have undergone two University examinations within that period; 320 have come up to the standard required by the examiners, 46 have obtained the degree of doctor in medicine, 38 have passed for the degree of master in surgery, and 30 for the diploma in midwifery. Thirty-two candidates have been successful in seeking the degree of bachelor in arts, and fifteen of these are returned as having highly distinguished themselves. The Senate has passed a special grace for conferring the following honorary degrees: that of Master in Arts on Robert Hart, Inspector-General of the Maritime Customs of the Empire of China; that of Doctor in Science upon Peter Tait, Professor of Natural Philosophy in the University of Edinburgh, and on James Thomson, Professor of Civil Engineering in the University of Glasgow, etc. At the annual meeting of Convocation held on the 14th instant, a resolution was passed to the effect that they were of opinion that the salaries of the present professors and officers of the Queen's University and Queen's College are inadequate; and that provision should be made for their superannuation, as has already been made in the Universities of Scotland.

THE MAUNSELL MEMORIAL FUND.

IT is with much pleasure that we notice the continued prosperity of the Maunsell Memorial Fund. Not only has the fund received the unanimous support of all the leading members of the profession in Dublin, and made steady way among the provincial practitioners of Ireland, but it has also enlisted the support of many leading men not belonging to the profession; thus it is with great pleasure that we notice among the subscribers to the fund the names of the Lord Chancellor of Ireland, the Chief Secretary for Ireland, and the Secretary of the Irish Local Government Board. The support of such high officials as these show unmistakably the great appreciation in which Dr. Maunsell's services were held by those who had to deal practically with the question which he discussed in his writings. We hope that those in England who have benefited so much by Dr. Maunsell's writings, will not fail to add their contribution to the Maunsell Fund

through the hands of Dr. Rogers, its London Treasurer, or through the medium of our own office. We may remind our English friends, that the "Rumsey Fund" has supporters in Ireland, and Local Committees have been established in Dublin and Belfast; and we trust that this generous effort of Irishmen to honour the name of an English medical practitioner may be fairly reciprocated by the co-operation of Englishmen to honour an Irishman who laboured in a different part of the same field. The contributions to the Maunsell Fund now amount to over £350. We trust that the list will not close until every Poor-law medical officer in Ireland has contributed his "mite".

KING AND QUEEN'S COLLEGE OF PHYSICIANS.

AT the annual stated meeting of the College, held on St. Luke's Day (18th instant), the following officers were elected for the ensuing year: *President*, Samuel Gordon, M.B.; *Censors*, Lombe Athill, M.D. (*Vice-President*), Arthur Wynne Foot, M.D., Thomas Hayden, M.D., J. W. Moore, M.D.; *Registrar*, J. Magee Finny, M.D.; *Treasurer*, Aquilla Smith, M.D.; *Examiners in Midwifery*, Edward B. Sinclair, M.D., Fleetwood Churchill, M.D.; *Professor of Medical Jurisprudence*, Robert Travers, M.D.; *Representative on the General Medical Council*, Aquilla Smith, M.D.; *Agent to the Trust Estates*, Charles U. Townshend; *Law Agent*, Charles Woodward.

UNWARRANTED CHARGE AGAINST HOSPITAL OFFICERS.

AT a recent inquest held in Dublin, on the body of a little boy who died in Jervis Street Hospital, from the effects of an injury, an attempt was made by the boy's father to prove that the boy had been "brutally murdered" by the surgeons of the hospital. It is scarcely necessary to say that, the charge was unfounded; but we regret that several attempts have been recently made in Dublin to transfer the "cause of death" from the "accident" to the surgeon. We believe such cases were unknown before the occurrence of the celebrated cases in which charges were made against eminent Dublin surgeons; in one case, at the Richmond, and in the other, at St. Patrick Dun's Hospital. A certain Dublin newspaper recently attempted to raise the question, as to whether a patient died of an accident or of the "treatment" received in another Dublin Hospital. All these charges were utterly without foundation; but, when we consider the uncertainties of the law and the vagaries of juries, especially of coroners' juries, we may congratulate the surgeons of Jervis Street Hospital that they were protected from further vexatious proceedings by action of the coroner's jury. The jury considered any adjournment unnecessary, as most of the surgical staff of the hospital were voluntarily present to answer any charge that could be made against them, and there was not the slightest foundation for the opinion expressed by the child's father. The following verdict was returned: "That William Ormond died in Jervis Street Hospital on October 11th, 1875, in consequence of injuries resulting from a fall accidentally received on July 19th, 1875. We are of opinion that deceased was treated with every kindness and skill by the surgeons of Jervis Street Hospital, and that he had had the advantage of more than ordinary care and attention."

MILITARY AND NAVAL MEDICAL SERVICES.

MOVEMENTS OF ARMY MEDICAL OFFICERS.—Surgeon-Major J. B. Hamilton, M.D., and Surgeon E. M. D. FitzGerald, M.D., have sailed for India in H.M.S. *Malabar*, on exchange.—Surgeon-Major W. M. Skues, M.D., has returned home from Malta after a tour of duty at that station.—Surgeon-Major J. G. Leask, M.B., has been ordered to take up duty at a home station after a tour of service in India.—Surgeon A. G. Bartley, M.D., has been appointed for duty to the Army Service Corps, *vice* Surgeon J. H. Ussher, M.B., who has been posted to Armagh.—Deputy Surgeon-General Best, after a long service in India, is about to join the staff at home. Mr. Best went out to India in 1868, after his exchange from the 68th Light Infantry, and has completed five years' service in the East in the rank of Deputy Surgeon-General.

MEDICAL ADVERTISING.

At a recent meeting of the East Surrey District of the South-Eastern Branch, held at Reigate on October 14th, the following resolution, proposed by Dr. HOLMAN, and seconded by Mr. E. H. GALTON, was carried unanimously:

"That, in the opinion of the meeting, the practice of continuous advertising of medical books in the non-medical papers is derogatory to the interest and dignity of the profession, and should be abandoned."

In commending the resolution to the meeting, Dr. Holman took occasion to point out that it did not reflect on advertising in medical journals; although even that practice was, in his opinion, carried to excess in the present day. He feared that books were but too often written to obtain notoriety and publicity for their compilers; not because these authors, as they would wish to be styled, were capable of imparting any specifically new information with regard to the subjects they took in hand. He considered that the far more objectionable practice of continuously advertising medical works in non-medical prints, could only be for the sake of drawing the attention of the public to the author in his professional capacity, and therefore as a practice which tended to lower the members of a liberal profession to the level of tradesmen, or of a charlatan vaunting his own nostrums. Dr. Holman considered the specialists to be peculiarly open to animadversion on this score; and remarked, that the only part of the human body which had not been repeatedly written upon and advertised was the much neglected umbilicus, which, up to this time, had escaped the notice of those gentlemen who sought at the same time to benefit the public and themselves by somewhat illegitimate means.

THE MEDICAL SCHOOLS.

THE annual registration at the Royal College of Surgeons of gentlemen pursuing their professional studies at the eleven recognised metropolitan hospitals has been brought to a close, and the return forwarded to Mr. Charles Hawkins, the Government Inspector. It appears that St. Bartholomew's Hospital takes the lead with 326, followed by Guy's Hospital with 311; University College, 283; St. Thomas's Hospital, 188; St. George's, 144; the London, 116; King's College, 115; the Middlesex Hospital, 97; St. Mary's, 87; Charing Cross, 61; and the Westminster, 26. The new entries, in which much interest is taken, are as follows: St. Bartholomew's, 116; Guy's, 91; University College, 84; St. Thomas's, 47; St. George's, 42; Middlesex, 32; King's College and St. Mary's, 30 each; the London and the Charing Cross, 26 each; and the Westminster, 11. Total, 535. The following table of the comparative increase in the number of students during the past decade will, no doubt, be read with some interest.

In 1865,	the number of students registered was	1,013.
1866,	" "	1,027.
1867,	" "	1,125.
1868,	" "	1,194.
1869,	" "	1,241.
1870,	" "	1,298.
1871,	" "	1,475.
1872,	" "	1,496.
1873,	" "	1,608.
1874,	" "	1,745.
1875,	" "	1,754.

The returns from the provincial schools have not yet been received.

QUEEN'S COLLEGE, BIRMINGHAM.

THE Introductory Address was delivered on October 1st by the Rev. W. H. POULTON, Warden of the College.

He commenced by apologising for the fact that he, a non-professional and non-medical man, should deliver the first lecture. Some of their friends might take it as strong evidence of the truth of the assertion they so industriously circulated, that the College was a priest-ridden institution. He considered, however, that it might be taken as an indication of the entire unanimity which existed between the two departments—medicine and theology—of the College. As to the impossibility of the two classes of students mixing together, he held it to be an entirely groundless fear. Each class, he believed, would act most beneficially upon the other.

He wished to lay before them that day one or two points connected with medical education which had been often in his thoughts. Since his connection with the hospital, many changes for the better had been brought about, amongst which was the substitution of a primary examination in general literature in place of the old system of apprenticeship. He thought most of them would agree that that change had tended to raise the general standard of education amongst the students, and to stimulate them to further efforts in the prosecution of their professional studies. It was also to the advantage of the students themselves.

The point to which he desired chiefly to draw attention was the length of time that students might waste in attendance at the national school and hospital. This concerned more especially parents and guardians, who must feel great anxiety about their sons and wards. A young man passed his preliminary examination, and registered his name as commencing his professional education. Neither the examining boards nor the London or provincial schools, however, trouble themselves much as to how long a time elapsed before he presented himself for examination. In his experience, he had known young men hanging about the college and hospital for seven, eight, nine, and even ten years, without presenting themselves as candidates for examination. No doubt this deterred many parents and guardians from allowing their sons to enter the profession. Nor was this waste of time injurious only to young men themselves. It had a baneful effect on their fellow-students. At universities, this was obviated by there being a fixed time within which certain examinations were expected to be passed. In the case of medical students, he could not but think that some similar restrictions might without any hardship whatever be made. They might fairly ask examining boards to help them. They might make some difficulty about accepting any student who presented himself for examination after the prescribed period, or they might make the examination more stringent, according to the number of years by which the limit had been passed. This latter alternative he should much prefer. After a time, it might be possible to shorten the limits first recommended. Of course, there would be difficulties in the way of the adoption of such a course; but he did not see why some considerable change for the better might not be made in the direction he had indicated. Some examining boards might attract students by the looseness of their examination; but, if the more important examining boards would take up the matter, the more insignificant ones might safely be left to their well merited obscurity.

He wished also to say a few words in the matter of prizes. The tendency of the present day appeared to be to multiply prizes out of all proportion to the perseverance expended on their acquisition. He believed, if the prizes were fewer, and if the standard required were fully known, more would be thought of being successful, and there would be more competition amongst the students. It seemed somewhat worse than a farce to award a medal or certificate to a student who did not show even the most elementary knowledge of a subject, simply because he happened to be the only competitor. He should be very glad if they could give a higher value to their prizes by raising the standard required for a medal and certificate, and by making some condition as to the number of competitors. He believed it would be found to create more *esprit de corps* amongst the students. Could they raise the standard required, the teaching body would have more inducement than they now had to support the claims of old students in anything for which they were nominated.

Having referred to the munificent gift made to the College by Mr. G. P. Wragge out of the Ingleby Fund, and expressed the hope that many wealthy Birmingham manufacturers would follow the example, the lecturer said he would conclude with a few words to the students. He advised them to foster the spirit of *esprit de corps* amongst them, and to work with earnestness and perseverance, beginning at the commencement of the session. He urged them not to regard attendance at lectures as waste of time, and not to neglect the theoretical or book work for the practical. He knew that there was a tendency amongst them to try and excel in the practical before having laid the foundation of the theoretical, and warned them that the practical would not be of so much assistance to them in passing examinations as they might imagine. Regarding the question of assistantships, he suggested whether it would not be better to discard them altogether in first and second year students. He again impressed upon the students the necessity of laying a good foundation of knowledge during the first session, and of passing the first professional examination next April twelvemonth. Sincerely he welcomed them all to the College, promising them all assistance in their studies, and urging upon them the advisability of so conducting themselves as to maintain the high character of the institution.

ASSOCIATION INTELLIGENCE.

SHROPSHIRE ETHICAL BRANCH.

THE annual general meeting of the above Branch will be held at the Lion Hotel, Shrewsbury, on Wednesday, October 27th, at 1 P.M.: *President*, RICHARD WILDING, Esq.; *Vice-president*, JNO. RIDER, Esq.

Dinner will be served at 3.30 P.M. punctually, for the convenience of the country members. Tickets, exclusive of wine, 7s. 6d. Members have the privilege of introducing friends, on transmitting their names to the President.

Members intending to read papers, etc., will oblige by communicating their titles on or before the 21st instant, to

JUKES STYRAP, *Honorary Secretary*.

Shrewsbury, October 12th, 1875.

BATH AND BRISTOL BRANCH.

THE first ordinary meeting of the Session will be held at the York House, Bath, on Thursday, October 28th, at 7.15 P.M.: W. M. CLARKE, Esq., *President*.

R. S. FOWLER, Bath, } *Honorary Secretaries*.
E. C. BOARD, Clifton. }

Bath, September 24th, 1875.

STAFFORDSHIRE BRANCH.

THE second annual meeting of this Branch will be held at the London and North Western Railway Hotel, Stafford, on Thursday, October 28th, at 2.30 P.M. precisely. *President*, R. GARNER, Esq., F.L.S. The *President-elect* (H. DAY, M.D., F.R.C.P.) will deliver an address. Dinner at 5 P.M. precisely. Tickets 10s. 6d. each, exclusive of wine.

VINCENT JACKSON, } *Honorary Secretaries*.
RALPH GOODALL, }

Wolverhampton, September 27th, 1875.

BORDER COUNTIES BRANCH.

THE autumnal meeting of the above Branch will be held at the County Hotel, Carlisle, on Friday, October 29th, at 1 P.M.

Gentlemen intending to read papers, or to be present at the dinner, are requested to give notice to the Secretaries.

STEWART LOCKIE, } *Honorary Secretaries*.
JOHN SMITH, }

Carlisle, October 2nd, 1875.

SPECIAL CORRESPONDENCE.

BIRMINGHAM.

[FROM OUR OWN CORRESPONDENT.]

Queen's College: Admission of Women to the Medical Profession.—The Ingleby Lectureship and Scholarship.—Medical Session.—Introductory Addresses.—Meeting of the Birmingham and Midland Counties Branch.

THE annual meeting of the governors of Queen's College was held on Tuesday; and, in the absence of the President, the Mayor of Birmingham was voted to the chair. He proposed the following resolution: "That the governors are of opinion that competent women desiring to pursue the medical profession should not be refused the necessary facilities for obtaining instruction; and the governors accordingly request the Council to reconsider its recent decision on the subject." He reiterated certain arguments of the deputation, remarked somewhat severely upon the "Conference" and its resolution, and read the reply of the Council (as already given by your correspondent); and said that the general public knew nothing of the risk and difficulty alluded to. In reply, various members of the Council and other medical men stated reasons for their course of action (reasons which have been already summarised in the JOURNAL of last week); and based partly upon moral considerations, partly upon the present prospects of the College, the adverse feeling of the body of the profession, and the existing arrangements at the Conjoint Clinical Board. Finally, the Mayor withdrew his resolution; remarking, however, that the professional feeling and regulation "seemed to amount to trades-unionism of the worst kind"—[no, no]—"if they desired that restrictions should be imposed to prevent a few women from entering the medical profession." He alluded, also, to the possible establishment of a rival institution,

which is commonly supposed to refer to the "Mason Scientific College" now building.

In the Annual Report of the College, allusion is made to a donation of £2,000 from the trustees of the late Dr. Ingleby. This endowment is to be devoted to an "Ingleby Lectureship" and "Ingleby Scholarship" for the cultivation of obstetric medicine.

The medical session opens with an entry of twenty-five new students, and active work in the lecture and dissecting rooms. At our visit to the latter, we could not but observe its comparative cleanliness, and the absence of the foul effluvia usual in our student days. A subject of six weeks' age was admirably preserved by the injection of glycerine with carbolic acid; but, as it requires nearly a gallon of this, the expense is a drawback to its use. The last subject had been injected, Dr. Pope informed us, with chloral-hydrate—half a pound to six pints of water—according to an American plan, which, so far (*i.e.*, for ten days), had answered well; the colour of the parts was remarkably well retained.

The introductory addresses of the session were very good, and attended by large and appreciative audiences. They were both addressed more particularly to students, rather than dealing with topics of general interest. The address at the College by the Rev. W. H. Poulton, the Warden, referred particularly to the evil of men delaying their examinations, and "hanging about for eight, nine, or even ten years". At the universities, men were always expected to pass within a certain time; and he thought the examining boards and medical schools ought to make some similar regulations.

The Introductory Clinical Address was given by Mr. Alfred Baker at the General Hospital, and was devoted to considerations on the position of medicine formerly and at present, the necessity for cultivating the intellectual powers, and taking advantage of all opportunities for practical work. He "would summarise all he had to say in the sentence—Imitate John Hunter".

The first meeting of the Branch for this session was signalled by the delivery of the address by Dr. Wade, which you have already given to the profession. The meeting was a very large and representative one; and, in the after-speeches of Dr. Fletcher and Dr. Heslop, cordial expression was given to the very general feeling of obligation to Dr. Wade, and of sincere satisfaction of seeing him again amongst us after a trying illness.

CORRESPONDENCE.

MR. DAVY AND THE LONDON HOSPITAL.

SIR,—I have read with regret the abstract of the introductory lecture delivered to the students of the Westminster Hospital by Mr. Richard Davy, published in the JOURNAL of this week. I believe the students at this school will discover that their teacher has not drawn a faithful picture of their future prospects; for I am sure it would indeed be easy to show, by the examples of a large number of young medical men now living, that "their early prospects are far from disheartening"; that their "toil and ambition", if honestly applied, will be amply rewarded both in "pay and dignity" while they are yet young men. But it is no part of my intention to occupy your space with arguments to disprove these statements of the lecturer; my desire is to repudiate in emphatic terms the truth of those portions of Mr. Davy's lecture which refer to the relations which exist between the House Committee of the London Hospital and the medical officers. Allow me to state that, in the following remarks, I am expressing only my own individual opinions, and narrating only my own experience as an individual member of the staff; that I make no pretence to express the views of any one of my colleagues; they will, I am sure, deal with Mr. Davy's utterances as they severally feel disposed.

For a period of nearly eleven years, I have been a member of the staff of the London Hospital, during which time the working of my department and the performance of my duties have brought me into contact with the representative, the mouthpiece in fact, of the House Committee a very large number of times. From this gentleman (the house-governor), I declare I have always received the greatest possible kindness, consideration, and attention; never to my knowledge have I made to him a request that has not at once been complied with, no matter what outlay the execution of my wishes involved. I have never suggested an alteration or modification in the arrangements of my own department, that has not either been immediately adopted, or the inexpediency of the suggested alterations has been pointed out to me in the most courteous manner; in fine, by the representative of the Committee, I have been invariably treated like a prince. Again, during these eleven years, I have on a considerable number of occa-

sions been brought into actual communication with the House Committee itself; on every such occasion, without one single exception, I have been treated most generously; my wishes and my grumbings have alike received an amount of their consideration which I have often subsequently discovered they did not deserve. On no single occasion has my Committee ever made the smallest attempt to dictate to me how or in what manner my work was to be done, from my first introduction to them at my election until now; a generous thoughtfulness, an earnest desire to serve me, and a perfectly evident resolution to leave me unfettered in the working of my own department, have invariably characterised the conduct of the House Committee to myself. Sir, if this be "tamely submitting to have my teeth drawn", then I am perfectly prepared for the next nineteen years to go about without a tooth in my head. If this be the treatment involved in having my "nails pared", then to the quick I will be shorn of these useful appendages. I know not if Mr. Richard Davy would honour me by placing me in his list of "excellent officers"; but this I know, that he has sadly misrepresented the relations which exist between the medical staff who have the professional work of the hospital to do, and the executive who manage and conduct in a manner, I venture to assert, beyond all praise the large and efficient institution in question. No, sir; Mr. Davy is mistaken; on this occasion, he has hit the wrong nail on the head; let me assure him it is not the existing relations between the staff and committee that are at fault; it is the relations existing between the several members of the medical staff itself that is the one weak spot at the London Hospital. Had Mr. Davy desired to teach us something, he would have left the House Committee alone, and he would, in old-fashioned plain Saxon language, have told us that a house divided against itself cannot stand; that it is a sad and pitiful sight to see one-half the staff living and working at the same hospital in direct and open enmity with the other half. He would have told us that it is useless to spend large sums of money in advertising new prizes and fresh scholarships, so long as it is notorious to the whole world that we are torn and rent asunder with internal bickerings, dissensions, jealousies, and backbitings. He would have told us that our school will stand still and lack prosperity until we have learned to bear and forbear one with another; and, lastly, he would have told us that it is not manly or generous to button-hole prominent members of the House Committee, and, under the mask of zeal for the well-being of the hospital and school, exalt ourselves at the expense of our colleagues; he would, in a word, have told us that, to be a happy, useful, prosperous staff, we must first learn to forgive, as we hope to be forgiven.

I am, dear sir, yours faithfully, JAMES PALFREY.

Brook Street, Grosvenor Square, October 23, 1875.

WESTMINSTER HOSPITAL.

SIR,—In your last number, you called attention to a circular issued by Mr. Cooke to the governors of the Westminster Hospital, impugning the conduct of his colleagues and the mode in which, of late years, the elections have been conducted.

I deeply regret to see such ungrounded and erroneous statements circulated, which a very little care and reflection on the part of Mr. Cooke would have obviated. Take such a statement as this: that out of ten promotions and appointments that have taken place during the last four years, in every single case through the influence of the "Council", only one gentleman has presented himself to the governors for election. During the last eighteen months alone, no less than two elections have been severely contested, although in one case the opposing gentleman withdrew on the morning of the election. I am informed that, during many years, the "Council" have only twice expressed any formal opinion on the candidates, or exerted any influence on the elections. It may be incidentally mentioned that the term Council was applied two or three years ago to the old institution of "Committee of Lecturers", which has existed from time immemorial, to avoid confusion and mistakes. At the time of effecting the change, the assistant medical officers, non-lecturers, were admitted, amongst whom was Mr. Cooke.

The "combination" spoken of to "subvert the authority of the governors", proves to be a friendly dining club of the medical staff and lecturers, started for the object of promoting good fellowship and friendly discussion on matters of school-government. It has met but twice. Mr. Cooke, we are informed, was present on each occasion; and is, therefore, in a position to substantiate or not this statement. I can hardly believe that any one could have made such a charge without having substantial grounds for doing so.

Mr. Cooke states that his resignation has been demanded in the face of an organised opposition; he appeals to the governors for protection. It seems to have been the custom, time out of mind, for all candi-

dates holding junior appointments to resign before seeking the votes of the electors for senior offices. It is, in my opinion, an excellent, usual, and salutary rule. I am, however, informed, that no formal demand has been made for Mr. Cooke to resign. Whether justly or unjustly, Mr. Cooke seems to have made himself very unpopular with his colleagues. I believe I am justified in saying the whole medical staff and lecturers are unanimous in their opposition to his candidature. The questionable taste of dragging Dr. Gibb into the *mille* is the more to be regretted, as I believe he retired on the most friendly footing with his colleagues, and without professionally ever having had a word of variance.

The "Council" of the Westminster Hospital, I believe, fully realise their responsible position of public trust. A medical school should never be viewed as a private undertaking; and it is to be hoped the earnest endeavour of this school to raise its name and reputation will be crowned with success. Their staff is a remarkably young one—no great fault, as with youth there is energy. What can be done by a medical school by a judicious choice in its staff is well exemplified by the rapid rise, of late years, of Middlesex and Charing Cross Schools. Mr. Cooke's antagonist is Mr. C. N. Macnamara, a gentleman who has already made his mark in the profession in India. Westminster is to be congratulated if it be able to secure the services of so able a man, and who is so well qualified to do honour to the profession and its school. Should Mr. Cooke be unsuccessful, he has no cause to complain. To be senior assistant-surgeon in five years is no bad position. Mr. Cooke is a young man, and may have a brilliant future in store for him; but such an object is not likely to be obtained if he be not more careful in his facts and statements.

I am, sir, yours faithfully, W. C. GRIGG, M.D.

AN APPEAL.

SIR,—In your issue of the 7th of August, you were good enough to publish the following appeal.

"Sir,—I respectfully invite the attention of the medical officers of the public services to the following particulars of a sad case.

"An assistant-surgeon—whose name it is not, perhaps, necessary to give, but which can be given to any subscriber who desires to know it—lost his health in the Crimea; and, after a lingering illness, died from softening of the brain, leaving a widow and five children in circumstances of extreme destitution. This officer's ill-health was not brought on by imprudence or bad habits. Those who have interested themselves, and whose names are given below, know that his habits and conduct were always such as to command the respect of his friends. It must also be added that he made such provision as he could for his family by insuring his life in the Army and Navy Insurance Office, afterwards amalgamated with the 'European'. It is useless to add that no benefit was derived from this insurance, as this office disastrously failed. When this occurred, the state of the assistant-surgeon's health was such that a second insurance on his life was impossible. For several years before his death, he supported his wife and family, and met all the expenses of his long illness on his half-pay of eight shillings a day. Not having served for ten years on full pay, his widow is not entitled to a pension.

"It is proposed to raise a sum of money for the purchase of an annuity for the benefit of the widow, who at this time depends on the charity of her neighbours for daily bread for herself and children.

"The following gentlemen will be happy to receive subscriptions in aid of this fund: Major-General Lewis, Shirley, Southampton; Lieutenant-Colonel Begbie, Shirley, Southampton; Dr. Parkes, F.R.S., Surgeon-General Longmore, C.B., and Surgeon-General Maclean, C.B., Royal Victoria Hospital, Netley.

"I am, sir, your most obedient servant, W. C. MACLEAN, M.D."

This appeal has been most kindly responded to; and I have to announce that Messrs. Atherley, Hankinson, and Darwin, Bankers, High Street, Southampton, who have been good enough to take charge of the fund, have in their hands the sum of £178 19s., contributed for the purpose indicated in the appeal. I have in every instance acknowledged the receipt of contributions, with the exception of the sum of five shillings in postage stamps, sent by H. P., R.N., whose address I did not know, and who wished "his mite" to be acknowledged in this way.

The sum is not inconsiderable, but it is quite inadequate to meet the requirements of the case. I have been advised that my appeal was published at the most unsuitable time of the year, when all the world was on the move, and when many professional men were abroad seeking relaxation. I, therefore, venture to ask you to give space in your columns once more to my appeal in behalf of this widow and her children.

I am, sir, your obedient servant, W. C. MACLEAN.

Royal Victoria Hospital, Netley, October 19th, 1875.

REPORTS OF SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, OCTOBER 6TH, 1875.

WILLIAM S. PLAYFAIR, M.D., Vice-President, in the Chair.

BEFORE entering upon the ordinary business of the evening, Dr. PLAYFAIR alluded to the loss sustained by the Society by the death of its Honorary President, the late Sir Charles Locock, who had rendered valuable aid to the Society when it was first formed by accepting the Presidency and taking a special interest in furthering the aims of the Society. He announced that the unanimous feeling of the Council was in favour of asking Dr. Arthur Farre to accept the vacant post, which was received with acclamation by the Fellows present.

Retention of a Pessary.—Dr. GERVIS exhibited a pessary removed from a patient, aged 56. Fifteen years previously, it had been introduced into the vagina to relieve prolapsus of the womb. Four years ago, she began to feel a weakness in the lower back; two years ago, her legs became weak, and she was unable to walk without assistance. For six months, she has been nearly bed-ridden. For the last six months, she had had discharge from the vagina, occasionally tinged with blood, and highly offensive. She could neither stand nor walk, and was able to move her legs in bed with difficulty; being attacked two or three times during the night with cramp in them. On examination, a large round metallic pessary was found imbedded in the vaginal walls, and was removed by the aid of bone-forceps; a considerable quantity of brownish purulent discharge, horribly offensive, escaping. All the paralytic symptoms were relieved after its removal.—Dr. CLEVELAND remarked that, apart from the interest attaching to the long impaction of a foreign body in the vagina, there was the notable fact that a quantity of highly offensive putrid matter must have been locked up for a considerable time without the supervention of septicæmia. The case tended to show, in connection with the recent debate before the Society, the necessity for the coexistence of some peculiar condition of the general system before absorption of morbid matter, followed by blood-poisoning, could be effected.—Dr. BANTOCK had met with a similar case to that given by Dr. Gervis; the pessary being oval in shape, and composed of horse-hair covered by India-rubber.—Dr. ROGERS referred to a case he had before mentioned to the Society, of a boxwood pessary, which had been left in eighteen years, and had been forgotten by the patient.—Dr. EDIS also alluded to a similar case he had brought before the Society, where a large oval pessary of the size of a goose's egg had been left in the vagina for eleven years. The case had been supposed to be cancer.—Dr. PLAYFAIR thought these archaic instruments would soon be out of use. He wondered why the ulceration had not extended into the bladder and rectum. As regarded Dr. Cleveland's remark, he had noticed that fetid matter of intense virulence might be present, provided there was an absence of an absorptive surface of a freshly formed wound.—Dr. GERVIS, in reply, stated that in removing the pessary a slight laceration took place. The fetid fluid passed over it, and yet there was no septicæmia.

Fetus and Placenta from a Syphilitic Subject.—Dr. HAYES exhibited a placenta and still-born fetus from a patient, aged 22, affected with syphilis. The placenta was pallid, soft, and friable; the villi packed with fat globules. The fetus appeared healthy. There were two questions involved in explanation of the death of the fetus: whether it resulted from syphilis, or from fatty degeneration of the placenta.

Monstrosity.—A report by Drs. AVELING and HAYES on Mr. Wallace's case of monstrosity was read; also on a specimen exhibited at a previous meeting.

A Case of Complete Inversion of the Uterus occurring immediately after Labour was communicated by Mr. FREDERICK H. GERVIS.—The patient, aged 41, was delivered of her sixth child after a slow and tedious labour. The placenta was adherent. After waiting twenty minutes, it was felt projecting through the os, and was gently drawn down, when the uterus was found to be inverted. The placenta was immediately peeled off. The hæmorrhage was slight; but, on looking up, the patient was found to be in a state of syncope, and apparently dying. Brandy and ammonia were administered; and, after the patient had rallied somewhat, the inversion was reduced, counterpressure being applied externally to the cervical ring. Galvanism was applied to contract the uterus after its return. The patient recovered perfectly.—Dr. GALTON remarked that the mode of reduction mentioned by the author, although successful in this case, was one hardly to be recommended in general. The author described the reduction as effected by pressing two or three fingers up into the fundus of the uterus. This plan would necessitate the passage of four folds of uterine tissue through the os

instead of two folds, which would alone require to be passed through, were the reduction accomplished by the more mechanically correct, and usually recommended method, of grasping the whole body and returning first the part latest in coming down.—Dr. GRIGG inquired whether there were any severe cramps and pains in the thighs as well as shock. He remembered a case in his own practice where the uterus came down with the greatest ease without any traction having been exerted.—Dr. BANTOCK thought the treatment was confirmed by the result. He did not agree with the preceding speaker, Dr. Galton, in thinking that the uterus was doubled up by pressing in the fundus, for it was stated that the body of the uterus felt hard. It appeared to him that the reduction began at the cervix.—Mr. GERVIS explained that the uterus was exceedingly rigid and hard, and it was difficult to get a fold of the uterus. Whether the fundus or the cervix went up first, he did not know. In a previous confinement, she had had severe cramps.—Dr. CLEVELAND wished to inquire more minutely as to the amount of traction on the cord that had been used. He could conceive that, owing to the administration of ergot before the expulsion of the placenta, especially if it happened to be adherent, the uterus might take on that irregular and spasmodic action which, with only moderate traction on the cord, might eventuate in inversion.—Dr. GERVIS remarked, with reference to Dr. Cleveland's suggestions as to the production of inversion, that so accurate an observer as Dr. Tyler Smith had in one instance seen the uterus invert itself; and it was now generally allowed that this accident could arise quite independently of traction. He asked whether any Fellow present had ever seen the inverted uterus reinvert itself. He had read recently of such a case; but imagined it must be, at all events, an occurrence of extreme rarity.—Dr. HAYES observed that when it was considered what difficulty sometimes occurred in removing the placenta, the cord giving away first, it was scarcely probable that Mr. Gervis could have exerted sufficient traction to produce the inversion.—Dr. AVELING remarked that inversion might be caused by *vis à tergo*, and even *post mortem* from the development of gas in the abdomen.—Dr. GRIGG mentioned a case occurring five days after labour, where no ergot had been given.—Dr. ROGERS had only seen one case, which he replaced by means of an air-pessary. He thought Mr. Gervis's plan was the best.—Dr. GERVIS referred to a case reported in one of the early volumes of the *Transactions*, where the uterus had reinverted itself.—Dr. WILTSHIRE admired the courage and candour of Mr. Gervis in bringing forward his case. After fifteen years' experience in practice, he would scarcely use immoderate traction; still, the process of inversion might have been commenced before. It was a question whether it was not better to peel off and not to pull.

Lateral Obliquity of the Fœtal Head.—Dr. GALABIN read a paper on the occurrence in normal labour of lateral obliquity of the fœtal head. After entering into the views formerly accepted, that there is normally a lateral obliquity of the fœtal head to the plane of the pelvic brim, he asserted his belief that the conclusion indicated by theory is confirmed by observation, namely, that in easy labours there is no perceptible lateral obliquity; but that, if the head meet with considerable resistance, an obliquity is produced in most cases of such a kind that the right parietal bone lies deepest in the plane of the brim.—Dr. PLAYFAIR thought the Society was very much indebted to Dr. Galabin for his erudite paper. The point at issue was one of great interest; and he had failed to satisfy himself whether obliquity really existed or not, or whether Dr. Galabin's suggestions were sufficient. Dr. Galabin had not mentioned a very elaborate treatise on the subject by Dr. Hodge.—Dr. GERVIS concurred as to the value of Dr. Galabin's paper. It would appear to favour the opinion that there was no necessary contradiction between the two opposite views, but that obliquity of the head, depending upon some undue pelvic resistance, was essentially a character of a labour in some degree abnormal, while in perfectly normal labour, the equilibrium between the propulsive force and the resistance of the parturient passage, being, as Dr. Galabin expressed it, stable, obliquity did not occur. If further research proved this view accurate, it would account for much of the present dissonance of opinion.—Dr. GALABIN thanked the Society for their patient attention. The subject was more interesting with a fœtal skull and a pelvis than in describing dry mechanical details.

Dissection of a Pregnant Uterus, with Placenta Prævia and Uterine Fibroids.—Dr. J. BRANTON HICKS read a paper on a dissection of an uterus, pregnant about three and a half months, the placenta being prævia, and fibroids extensively developed in the uterine walls. Attention was directed to three points: 1. Whether there were a circular sinus at the margin of the placenta; 2. The distribution of the curling arteries in the decidua serotina; 3. Whether there was any change induced by pregnancy in the fibroma. The first point was doubtful, and had yet to be carefully examined. As regards the second, the decidua processes, consequently the separation into lobules,

commence later than the third and a half month; and there was no proof that any branch from the supplying vessels of the serotina passed into the intervillal space. As to the third point, the fibres were about four times larger than in the ordinary fibroma, very much more distinct and separable from one another; a few had attained the size of the colossal fibre of the ordinary pregnant uterus.—Dr. EDIS observed that, if the fibres in the fibroma increased during pregnancy, there was no reason why they should not equally be involved in the process of involution following parturition, the same as with the ordinary uterine fibres.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, OCTOBER 19TH, 1875.

G. D. POLLOCK, F.R.C.S., President, in the Chair.

THE PRESIDENT drew attention to the just completed volume of *Transactions*, a copy of which was shown.

Hydatid of the Liver bursting into the Lung.—Dr. CAYLEY exhibited a hydatid cyst of the liver, which had burst into the lung of a man who had been admitted into the London Fever Hospital as having typhoid fever. There were dyspnoea, and, at the back, dullness. The first impression was that it was a circumscribed empyema. A small hydatid cyst was then expectorated, after which the aspirator was used, and two pints of fluid removed. The trocar was left in. Hydatids were still expectorated freely. Other openings were made, and the cyst was washed out. The man was ultimately choked by an accumulation of hydatids in his trachea. On *post mortem* examination, it was found that there was a large hydatid cyst of the liver communicating with a ragged opening. The liver was displaced by the cyst, and could be felt below the ribs in life. There was no other disease.—Mr. MAUNDER asked if the admission of air into the cyst in the tapping had led to any decomposition.—Dr. CAYLEY said that it had not.—Dr. LEARED said that in Iceland the operation was often performed by Dr. Hjaltein, who tapped the cysts, and then injected them with iodine. The operation was very successful.

Diseased Suprarenal Capsules.—Dr. PEACOCK showed two suprarenal capsules from a case of Addison's disease. They came from a female who had to undergo examination to be passed as a Government emigrant. She was not very well; but a mixture of iron and quinine did her much good. After some interval of time, she was admitted into St. Thomas's Hospital under his care. At the time, she was remarkably bronzed all over, including the mucous membrane of the mouth. She had then been in bed some time with sickness and vomiting, and with incomplete syncope at times. She died suddenly. At the *post mortem* examination, no disease was found in the body, except in the suprarenal capsules. Some old cretaceous tubercles, however, were found in the lungs. The patient was naturally of very dark complexion, with brown hair. Some time before, she had suffered from eczema, and was much darker afterwards. The case altogether was a very characteristic one.—Dr. GREENFIELD said that the suprarenal capsules had not yet been subjected to a thorough microscopic examination. Some sections, however, were shown. One capsule was very markedly affected with the usual changes. One point he would like to draw attention to, and that was the very extensive adhesions of the abdominal viscera found in this case. He had seen the same thing in other cases of Addison's disease. The adhesions were remarkably tough and firm, and in them were found small fibrous bands, with pearl-like nodules in them, and these were most frequent near the suprarenal capsules. The right capsule was adherent to the liver. The spleen was enlarged and tough. The pigmentation of the tongue was peculiar; it avoided the papillæ, all the three forms alike, which were quite white, being pale from the anæmia present.

Ulcer of the Stomach.—Dr. PEACOCK brought forward a case of ulcer of the stomach, from a man, aged 42, a potman by trade, who was admitted into St. Thomas's Hospital after having swallowed some sulphuric acid a short time ago. A curious point was this, that at times there was a distinct tumour in the epigastrium, which tumour was hard and solid. Then came on vomiting, after which the tumour partly disappeared. From this, it was thought that there was some old standing disease, as well as the sulphuric acid poisoning. The man lived three weeks in the hospital; and, after death, most extensive ulceration of the stomach was found.

Congenital Disease of the Aortic Valves.—Dr. PEACOCK exhibited a case of congenital disease of the aortic valves, from a girl aged 12. An aortic double (obstructive and regurgitant) murmur was found, and with it a presystolic murmur at the apex. The characteristic pulse was present. The girl was subject to attacks of sickness. Her temperature was always low; and, when tested by different thermometers of various

makers, was found only to be about 95 deg. She was generally torpid, and usually found asleep. After a time, albuminuria set in, followed by ascites. On examination after death, it was found that there were but two aortic valves; the raphe of the two cusps which were blended in one, could, however, be detected. The aortic orifice was contracted, and the mitral narrowed. The girl never had rheumatic fever. The heart was a very large one for such a child, and weighed nineteen ounces and three-quarters. The stomach was ulcerated.—The PRESIDENT asked if there had been any change in the circulation in the case.—Dr. PEACOCK answered in the negative. The case was well known to Dr. Greenfield, who sent it to him. The patient had been ailing for years, but there was no acute disease. He had once thought it a case of intrauterine endocarditis, but now regarded it as one of arrested development. The semilunar valves were formed by the looping up of the endocardium, which then divided into three sections; this last process had been arrested.

Cerebral Hemorrhage.—Dr. DOWSE related a case of hemorrhage into the pons Varolii and fourth ventricle, in a woman aged 66. She was a healthy woman till two years ago, when she became suddenly unconscious, and remained so for three days. There was complete left hemiplegia, with impaired sensation on the same side. Her mind became affected after this; and she was subject to right side convulsions. The temperature of the left side was 2 degs. higher than the right one. The convulsions of the right side were followed by facial palsy on the right side; and then coma set in, accompanied by stertorous breathing; and, after twelve hours of this, she died. When the brain was removed, it was found that the pia mater was gorged with blood; there was subarachnoid hemorrhage in both lateral lobes of the cerebellum, more marked over the right temporo-sphenoidal convolutions. The right hemisphere was much diseased. The right centrum ovale showed two or three irregular cavities extending upwards to the grey matter of the anterior and posterior central convolutions. A great portion of the brain-substance had undergone a yellowish brown staining from hemorrhage of old date. At the base was found a mass of recently extravasated blood, the result of hemorrhage from the left half of the pons Varolii, which was totally destroyed. The right half was also invaded by the hemorrhage, and the fourth ventricle was full of blood. The arteries were atheromatous.

Subarachnoid Hemorrhage of the Spinal Cord.—Dr. DOWSE showed a specimen of subarachnoid hemorrhage of the spinal cord. The man from whom it was taken had been healthy, but a hard drinker; and, ten days before his admission, had been working in the sun, when he suddenly felt a great pain in his head, followed by giddiness, vomiting, and unconsciousness. After five days in hospital, he felt much better, and had a walk; but came home, had a fit, chiefly affecting the right side, then became comatose, and died three days afterwards. The coma was not complete; the special senses were lost, except hearing, which was least affected; there was almost general hyperæsthesia. The pulse was 120; respirations 30; temperature 103.3 deg. There was no palsy of the seventh pair; reflex excitation of the facial muscles was easily induced, most on the left side. There was rigidity of the limbs; the arms flexed; the legs extended. The urine was retained. On the day of his death, his pulse was 160; respirations 44; temperature 106 deg. On the *post mortem* examination, the vessels of the dura mater were found gorged with blood, and blood was extravasated over the cerebellum and the hemispheres. The anterior lobes alone were unaffected. At the base of the brain was a mass of clotted blood. The vessels were not atheromatous. When the cord was removed, it was found covered with hemorrhage between the arachnoid and the pia mater, alike over the anterior and posterior surfaces.

Thrombosis of the Internal Carotid Arteries.—Dr. DOWSE drew the attention of the Society to a case of thrombosis of the internal carotid arteries. The patient, a woman, aged 66, had tottering gait, exophthalmos, a dull intellect, and a dilated heart. When walking about the ward, she was seized with incomplete hemiplegia of the right side. Next day, there was partial consciousness, with both aphasia and amnesia. The arm was worse than the leg. There were pain and hyperæsthesia in the affected limbs. Ten days afterwards, she suddenly lost the use of the left side, the intellect became more confused, and she sank into profound coma, which lasted thirty-six hours. On *post mortem* examination, there was found marked enlargement of the anterior half of the right hemisphere, which was of deep pink colour. The left hemisphere was pale, and softening was commencing. There was chronic arachnitis, with accumulation of fluid. The vessels were atheromatous. Thrombosis was found in the carotids, which were completely occluded.

Cancer of the Breast.—Mr. BUTLIN showed a case of uncommon carcinoma of the breast. It was removed by Mr. Savory from a woman aged 43. It had existed a year, and was as large as an egg. It really was colloid cancer, and cells with a homogeneous material

were found amidst fibrous trabeculae. The alveoli were small, and the colloid material not so fluid as usual.

Intra-cranial Aneurism.—Dr. GREENFIELD exhibited a case of aneurism of a communicating artery of the circle of Willis. The man, a bricklayer, fell from a scaffold thirteen feet high. There were symptoms apparently of concussion. The man ultimately died suddenly. There was a coroner's inquest, which returned a verdict of death from disease of the heart; no such disease existing. At the *post mortem* examination, was found a scalp-wound, with hæmorrhage on the dura mater and on the upper surface of both hemispheres. Blood was coagulated around the medulla oblongata and the cord. The hæmorrhage was most marked at the pons. There was a laceration. Coagula were found in the fourth ventricle, continuous with the blood at the pons. The basal vessels were atheromatous. The origin of the hæmorrhage was not found; it was, however, from two distinct effusions, one quite recent. When the parts were washed, an aneurism of the size of a sweet pea was found in the anterior communicating artery, which had ruptured at its posterior portion. The first hæmorrhage arose from perforation of the sac, to which the fit was owing; the second, just before death, was due to pressure on the fourth ventricle.

Tumour of Cerebral Artery.—Dr. GREENFIELD showed a tumour of the left anterior cerebral artery. There was thrombosis, followed by fatal softening. The man had suffered from apoplexy a week ere being admitted into the hospital, and his leg was weak. He had several slight apoplectic attacks in the hospital, and had slight left ptosis. His memory was bad, and his speech affected. Had a severe attack. He died of bronchopneumonia, with a temperature of 106 deg. The right middle cerebral artery was atheromatous, and one patch nearly choked it. There was no softening. On the left side, the corpus striatum and the white matter of the left hemisphere were affected. The vessel which supplied the anterior part of the corpus striatum instead of the normal left middle cerebral was choked; the optic nerve was compressed by the tumour, which also pressed on the middle cerebral artery. The patient had had syphilis, of which resultant scars were left. In this case, the corpus striatum was supplied by the anterior instead of the middle cerebral artery.—Dr. SEMPLE referred Dr. Greenfield to a case related by him, which, however, turned out not to be identical.

Enteric Fever.—Dr. HILTON FAGGE showed a fresh specimen of enteric fever. The man, aged 23, came off a ship in which no other person was ill; he had the ordinary symptoms of typhoid fever, rose spots, etc. He came in on the 8th. The temperature at first was 104 deg. The pulse was high. There was bronchitis. The man fed well. On the night of the 17th, he had a difficulty in swallowing and died. He had been hoarse throughout. At the *post mortem* examination, two points of disease were found; one spot at the ileo-cæcal valve, and another above; in the latter was a breach of surface. Peyer's patches were healthy. The mesenteric glands were swollen and red, spleen not enlarged. The lungs were emphysematous; the large bronchial tubes contained froth. The larynx was ulcerated; and the ulceration communicated with a cavity in front of the arytenoid cartilages. There were linear ulcers on the vocal cords. The epiglottis was ulcerated with a slough. The gall-bladder contained mucus, but no bile. Dr. Fagge had several times found the gall-bladder without bile, where the patient had been fed at repeated intervals; under these circumstances the bile passed off without needing to be stored in the gall-bladder.

Syphilitic Disease of Viscera in an Infant.—Dr. COUPLAND exhibited the viscera of a child, aged three months, bearing well marked evidence of syphilitic disease in the liver, heart, and lungs. There was a large patch on the convex surface of the liver; and syphilitic infiltration of the heart, not amyloid, but gummatous cell-growth. Lancereaux had seen nodes in the heart in congenital syphilis. It was brought to the hospital in early morning, and died in a few minutes. The liver was enlarged, reaching down to the iliac crest, and on its surface was a large yellow mass, which included nearly the whole left lobe. It consisted of semitransparent material. There were smaller isolated nodules. The heart was almost square, and its apex quite square. The left ventricle bulged even through the interventricular septum with the right ventricle. Its walls were of a pale buff tint. There was a nodule in the right lung. The mother was aged 26, and had one child living, two dead, and a miscarriage. This child, she said, had had a cold in its head, and spots on its bottom. A proper microscopic examination had not yet been made. In the heart, there were small round cells betwixt the muscular fibres, and masses round the branches of the coronary arteries. In the liver were round cells; and also the lungs, pressing on the alveoli.—The President requested that the microscopic examination be given at length at the next meeting.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

NORTHERN COUNTIES' ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

THE autumn meeting of the Association was held in the St. John's Library Room, Keswick, on October 6th. The Chair was occupied by the President, R. ELLIOT, M.D., Carlisle. The following gentlemen were nominated for election. *As Member*, J. Mackie, L.R.C.S., Medical Officer of Health, Darlington. *As Associates*, J. W. Eastwood, M.D., Dinsdale Park; G. H. Philipson, M.D., and Luke Armstrong, M.D., Newcastle-upon-Tyne; A. A. H. Knight, M.D., Keswick. After the completion of the routine business of the meeting, on the motion of Mr. J. M. FOX, seconded by Mr. J. SPEAR, M.R.C.S., H. J. YELD, M.D., was elected President-elect of the Association. The following papers were read: On the results to be expected from the carrying out of the Artisans' Dwellings Act. By II. J. YELD, M.D.—On the Powers and Duties of Medical Officers of Health. By J. M. MacLagan, M.D.—Notes on Food-Inspection. By Henry E. Armstrong, M.R.C.S.—Two Years' Experience of the Cockermouth Village Closet System. By J. M. FOX, M.R.C.S. The reading of each paper was followed by discussion.

SIR,—For some time past, many of my patients have been much annoyed by having post-cards like the enclosed sent to them by the public vaccinator of this district months, in some cases, after the child had been vaccinated by me, and the certificate duly transmitted to the vaccination officer. Will you kindly suggest a remedy against this growing nuisance? The town-crier is sent round periodically to warn the inhabitants that if they have not their children vaccinated by this public officer at the next public vaccination they will be subject to a penalty. Is there any clause in the Vaccination Acts or in a public vaccinator's contract to warrant this? A great number, being ignorant of the law on the matter, think from this proceeding that they are compelled to have the operation performed by the said officer, no matter whose patients they may be, and only find out their mistake by inquiry.—I am, etc., B. J. GLISSAN, Lic. Physician, etc.

. It rests with the guardians and the vaccination officer (not with the public vaccinator) to notify to parents the times at which public vaccination is performed. If the guardians choose to take exceptional means (even by the employment of the town-crier) simply to give publicity to the arrangements for public vaccination, they are clearly within their right. But the law merely requires the vaccination of children, not their vaccination by the public vaccinator; and a notice "to warn the inhabitants that if they have not their children vaccinated by the public officer they will be subject to a penalty" is obviously unwarranted. Our correspondent should make complaint to the Local Government Board, forwarding one of the cards issued by the public vaccinator to whom he refers.

OBITUARY.

MICHAEL HARRIS, M.B. LOND.

ON September 28th, Dr. Michael Harris, Assistant-Physician to the Children's Hospital, Pendlebury, died at Manchester, in the twenty-seventh year of his age. After a distinguished career at Guy's Hospital, he passed the M.B. examination of the University of London in 1872, obtaining honours in midwifery, and the first place, with the gold medal, in forensic medicine. He was at one time House-Surgeon to the Evelina Hospital, Southwark, and in 1873 was appointed Demonstrator of Anatomy in the Liverpool School of Medicine. In July of this year, he removed to Manchester, and was elected to the post of Assistant-Physician to the Children's Hospital at Pendlebury only a few days before his death.

ALEXANDER GEORGE HOME, M.D.

WE have to record the death of Dr. Alexander George Home, Fellow of the Royal College of Physicians, Edinburgh, which took place at his residence, Mount Eolus, Portobello, on September 17th. Dr. Home was son and heir of Captain Alexander Home, R.N., of Whitfield, and commenced his medical career at the University of Edinburgh, obtaining a membership of the Royal College of Surgeons at the age of nineteen; he became Resident Surgeon of the Royal Infirmary, Edinburgh, in the place of the late Professor Syme, and held that situation for a period of two years, taking out his degree of M.D. at the University of Edinburgh at the age of twenty-one. He attended hospital practice in Paris for six months, visiting many of the hospitals on the Continent; and thereafter obtained a commission as Assistant-Surgeon of the 2nd Dragoon Guards, in which regiment he served for fourteen years,

until his promotion to the Staff as Surgeon at Gibraltar. Previously to leaving the regiment, he was presented with a handsome testimonial, consisting of a breakfast-service of silver plate, by the private soldiers and their wives, as a mark of their esteem. After serving as Staff-Surgeon and medical attendant on the Governor, Sir Robert Wilson, at Gibraltar, for two years, besides holding several local appointments, on the application of the colonel and officers of the 2nd Dragoon Guards, he was reappointed Surgeon to his old regiment, in which he continued to serve until the expiry of twenty-six years' service, when circumstances occurred that rendered it necessary for him to reside near his property. He took up his residence in Portobello, and was elected Provost of that town, which office he held for three years, and took an active interest in the welfare of the burgh. He was also a Justice of the Peace for the County of Midlothian, and was a regular attender on the bench of the County Court. He was a widower, and has left two sons to inherit his property.

JAMES SNOW, F.R.C.S.

MR. SNOW, for many years the Senior Surgeon to the County Hospital, the Asylum, and Christ's Hospital, Lincoln, died last week, at the age of ninety-five. He passed his examination at the Royal College of Surgeons as far back as 1802, and was the senior member of that body. He was elected an honorary fellow of the College in 1843. Mr. Snow was a Justice of the Peace for Lincoln, and formerly surgeon to the 3rd Regiment of the Lincolnshire Militia.

UNIVERSITY INTELLIGENCE.

UNIVERSITY OF CAMBRIDGE.

STATE MEDICINE.—The next examination in State Medicine at Cambridge will begin on Tuesday, June 13, 1876. Any person whose name is on the *Medical Register* of the United Kingdom may present himself for it, provided he is twenty-four years of age. Information respecting the examination may be obtained by application to Professor Liveing, Cambridge.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, October 14th, 1875.

Collier, Herbert, Bohemia House, Turnham Green
Ellis, Joseph Watson, Willingham, Cambridgeshire
Flood, John, Penton Street, Islington
Mathias, James, Penycuod, Bloncyffos, South Wales
Norris, Richard Hill, Birchfield, Birmingham
Walmsley, Francis Henry, Higher Broughtoo, Manchester

The following gentlemen also on the same day passed their primary professional examination.

Blake, George Farncombe, Queen's College, Birmingham
Jackson, Robert Alexander, University College
Merriman, William Semple, Manchester Royal School of Medicine

UNIVERSITY OF CAMBRIDGE.—The following gentlemen passed the examination in State Medicine, on October 14th. The examiners were Dr. G. E. Paget, Dr. A. W. Barclay, Dr. E. A. Parkes, and Mr. Dewar.—Examined in Part I only.

Simpson, J., M.D.

Examined in both Parts.

Bird, P. Hinckes, F.R.C.S.
Britton, T., M.D.
Carpenter, A., M.D.
Cunningham, J., M.B., C.M.
Drew, S., M.D.
Dunlop, A., M.D.
Earle, B. N., M.B.
Fosbroke, G. H., M.R.C.S.
Harrison, C., M.D.
McBeath, W., M.D.

Mason, H. H., M.R.C.S.
Morison, J., M.D.
Nicholson, E., M.R.C.S.
Phillips, H. H. E., M.D.
Saunders, C. E., M.D.
Steele, S. T., L.R.C.P.E.
Swete, E. H. W., M.D.
Turner, G., L.R.C.P.L.
Underhill, A. S., M.B., C.M.

MEDICAL VACANCIES.

THE following vacancies are announced:—
ADDENBROOKE'S HOSPITAL, Cambridge—House-Physician. Salary, £65 per annum. Applications on or before November 2nd.
BIRMINGHAM and MIDLAND FREE HOSPITAL FOR SICK CHILDREN—Acting Physician and Extra Acting Physician. The Extra Acting Physician will have to attend on three afternoons in each week, and will receive a salary of £60 per annum. Applications on or before November 3rd.
BOARD OF WORKS, ST. GILES'S DISTRICT—Medical Officer of Health. Salary, £150 per annum. Applications on or before the 23rd instant.

BROOKWOOD ASYLUM, near Woking—Second Assistant Medical Officer.
CHRISTCHURCH UNION—Medical Officer for the Eastern District. Salary, £100 per annum, and fees. Applications on or before November 6th.
HOSPITAL FOR SICK CHILDREN, Great Ormond Street—Physician.—Assistant-Physician. Applications on or before the 28th instant.
HOSPITAL FOR SICK CHILDREN, Manchester—Assistant Physician. Applications on or before the 27th instant.
HUDDERSFIELD INFIRMARY—Physician.
LEICESTER AMALGAMATED FRIENDLY SOCIETIES MEDICAL ASSOCIATION—Resident Medical Officer. Salary, £175 per annum, with residence, coals, and gas. Applications on or before November 2nd.
MIDDLESEX HOSPITAL—Two Resident Physicians' Assistants, and One Resident Obstetric Assistant. Applications on or before the 30th instant.
NORTH SHIELDS and TYNEMOUTH DISPENSARY—House-Surgeon and Dispenser. Salary, £120 per annum, with furnished house, gas, coals, etc. Applications to be made on or before November 1st.
RICHMOND INFIRMARY—House-Surgeon. Salary, £80 per annum, with board and lodging. Applications on or before the 25th instant.
ROCHDALE INFIRMARY—House-Surgeon. Salary, £100 per annum, with board, lodging, and attendance. Applications on or before November 6th.
ROSS UNION—Medical Officer and Public Vaccinator for the Third District. Salary, £100 per annum. Applications on or before the 25th instant.
ROYAL FREE HOSPITAL, Gray's Inn Road—Junior Resident Medical Officer. Applications to be made on or before the 27th instant.
ROYAL ISLE OF WIGHT INFIRMARY, Ryde—House-Surgeon and Secretary. Salary, £40 per annum, with board, lodging, and washing. Applications on or before the 25th instant.
ST. GEORGE, HANOVER SQUARE, PROVIDENT DISPENSARY—Physician-Accoucheur. Applications to be made on or before November 3rd.
TONGUE and FARR, District of, County of Sutherland—Medical Officer. Salary, £150 per annum, and house.
WESTMINSTER HOSPITAL—House-Physician. Applications on or before the 26th instant.
WEST SUSSEX, EAST HANTS, and CHICHESTER GENERAL INFIRMARY and DISPENSARY—House-Surgeon. Salary, £80 per annum, and £20 per annum as Secretary, with board, lodging, and washing. Applications to be made on or before the 23rd inst.
WORCESTER GENERAL INFIRMARY—Physician. Applications on or before the 23rd instant.
WORKSOP DISPENSARY—Resident Surgeon. Salary, £120 per annum, with furnished apartments, coal, gas, and attendance.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

BABER, Edward C., M.B., appointed Resident Medical Officer to the Atkinson Morley Convalescent Hospital at Wimbledon.
BASKERVILLE, John D., L.R.C.S.I., appointed Honorary Surgeon to St. Bartholomew's Hospital, Chatham.
BERNARD, Armand, M.B., appointed Medical Officer to the Liverpool North Dispensary, *vice* T. Walby, L.R.C.P.Ed., resigned.
BUCHANAN, Walter, M.R.C.S.E., appointed Honorary Surgeon to St. Bartholomew's Hospital, Chatham.
CHAMBERS, Eben., M.B., appointed House-Surgeon to the Chester General Infirmary.
*DUFFEY, George F., M.D., appointed Lecturer on Materia Medica in the Carmichael School of Medicine, Dublin.
FOULDS, Samuel, L.R.C.P., appointed Surgeon to the Chesterfield and North Derbyshire Hospital, *vice* C. Booth, M.D., resigned.
GLASIER, Charles, M.B., appointed House-Surgeon to the West Norfolk and Lyoo Hospital.
HALL, F. de Havilland, M.D., appointed Assistant-Physician to the Westminster Hospital, *vice* O. Sturges, M.D., promoted.
*HART, Neville, M.B., appointed House-Physician to the Queen's Hospital, Birmingham.
IMLACH, F., M.D., appointed Medical Officer to the Liverpool North Dispensary, *vice* J. Lewtas, M.B., resigned.
LE QUESNE, Edwin J., M.R.C.S.Eng., appointed Assistant House-Surgeon to the Metropolitan Free Hospital.
McEWEN, Allan C., L.R.C.P.Ed., appointed Visiting Surgeon to the Chester General Infirmary, *vice* E. Chambers, M.B.
POWELL, Harold M., M.R.C.S.Eng., appointed Visiting Medical Officer to the General Hospital for Sick Children, Manchester, *vice* W. A. Renshaw, M.R.C.S.Eng., resigned.
STURGES, Octavius, M.D., appointed Physician to the Westminster Hospital, *vice* Sir G. D. Gibb, M.D., resigned.
*SYMPSON, Thomas, F.R.C.P., appointed an Honorary Surgeon to the Liocola Lunatic Hospital, in the room of the late J. Snow, Esq.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTH.

HEWITT.—On October 14th, at Winkfield, near Windsor, the wife of T. Hewitt, M.D., of a daughter.

MARRIAGES.

KING—WICKHAM.—On October 19th, at St. Mark's Episcopal Church, Portobello, by the Rev. J. M. Cotterill, Thomas Radford King, M.D., to Agnes Jane Wickham, only daughter of the late Benjamin Wickham, Esq., Royal Navy.—No cards.
PUICK—METCALFE.—On October 12th, at the Parish Church, Harrow, by the Rev. Robert Pnuck, father of the bridegroom, William Puick, M.B., C.M., L.R.C.S., of Newmill, Huddersfield, to Margaret Aone, only daughter of the late Robert Metcalfe, Esq., of Rigg House, near Hawes.

DEATH.

ROBINSON, John Edward, M.R.C.S.Eng. and L.R.C.P.Edin., second surviving son of Edward Robinson, Esq., Westwith, Rotherham, aged 27, on October 15th.

OPERATION DAYS AT THE HOSPITALS.

- MONDAY**Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.
- TUESDAY**Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.
- WEDNESDAY** .St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.
- THURSDAY** ...St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 3 P.M.
- FRIDAY**.....Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.
- SATURDAY** ...St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M. and 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

- MONDAY**.—Medical Society of London, 8 P.M. A Clinical Evening.
- TUESDAY**.—Royal Medical and Chirurgical Society, 8.30 P.M. Dr. Greenhalgh, "On the Use of the Actual Caustery in the Emucation of Fibroid Tumours of the Uterus"; Dr. Lawton Moss, "On Pathological Absorption Spectra"; Mr. E. J. Spitta, "On a Movable Model of the Larynx".

NOTICES TO CORRESPONDENTS.

- CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.
- PUBLIC HEALTH DEPARTMENT**.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.
- AUTHORS** desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.
- CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.
- WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**
- COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

MORTUARIES FOR COUNTRY PARISHES.

SIR,—I shall be very glad to receive any practical information on the above subject. I wish to put up a small building—probably on the ground belonging to our village hospital—for the reception of the bodies of those dying in the neighbourhood, whether of infectious or of other diseases, in preference to leaving them in their small and crowded cottages. I contemplate constructing the building so that a wheeled-bier may be taken into it, but it need not be larger than would be necessary for three bodies. Any plans, details of expense, etc., will be thankfully received by
J. LEE JARDINE.

Capel, Dorking, October 19th, 1875.

ASSOCIATE (King's College).—The painting of Sir William Fergusson is at present suspended in the office of the Secretary of the College of Surgeons, where you will, doubtless, be able to see it. The admirable engraving of it by Mr. Joubert can be obtained by applying to that gentleman.

ETHICS OF CONSULTATION.

SIR,—Mr. A., M.R.C.S., attends Mr. B. For some reason, Mr. B. declines to be attended by Mr. A. any longer. He is, however, attended regularly by Mr. C. (Mr. A.'s unqualified assistant), who is met in frequent consultation by Dr. D. I should like to ask your opinion of Dr. D.'s conduct, medico-ethically, in this case.—I am, etc.,
PARSONS.

* * We do not understand why any medical men's "unqualified assistant" is allowed by him to attend a patient who declines his own services; but if he allow his assistant to continue attendance, it can only be as his deputy; and Dr. D. probably regards his consultation as with Mr. A. by deputy, and only regards Mr. A. in the matter.

THE SYPHON STOMACH PUMP.

SIR,—The use of the siphon stomach evacuator is no novelty. I have used it in my practice since 1863; and have twice during the last month used it for cases of poisoning by laudanum—once in consultation with Dr. Bell of this town, and again in my own surgery. I have always given the credit of its application to the late Mr. Samuel Smith of Leeds. I am, etc.,
BRADFORD, October 17th, 1875. J. DOUGLAS LAWRIE.

WILLIAM HARVEY.—Sir James Paget, in his Records, says it is one of the brightest features in the history of St. Bartholomew's Hospital, that the great discoverer of the circulation, "Physiologiae lumen, Anglie immortalæ decus", was four-and-thirty years its physician, more honoured by its governors, and exercising a greater influence in its affairs, than any medical officer before the time of Abernethy.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

THE SUPPOSED POISONING BY DEADLY NIGHTSHADE.

SIR,—The report which appeared in the London papers of the inquest on the child Frederick Shed, whom the jury found to have been poisoned by deadly nightshade, conveyed the circumstances but very imperfectly; and some further particulars which came out in evidence, particularly with reference to the medical aspect of the case, may not be uninteresting to your readers, and may remove the impression that great ignorance of English plants was shown at the inquiry.

In the afternoon, the deceased I was given some blackberries and hawthorn-berries, as they thought, by his brothers and sister. About nine o'clock in the evening, deceased, according to the evidence of the mother, was seized with an attack of vomiting, which lasted till 2 A.M., when he became comatose and partially insensible. Mr. C. H. Steele, surgeon, of Kingston (not Richmond), attended the child at 8 A.M., and found him evidently moribund. The pupils of the eyes were much dilated, the countenance pale, and the limbs purple and cold. The necropsy showed the membranes of the brain to be very much congested; and the stomach was very much inflamed and congested, as was also the large intestine. Mr. Steele added, in his evidence, that from these symptoms, and the appearance of the vomit, he believed that death had resulted from poisoning by atropa belladonna; and the coroner having suggested that the berries of that plant might have been given in mistake for blackberries (not "haws", as you seem to infer, the jury then returned a verdict in accordance with the medical opinion.

Not being a medical man myself, I content myself with simply giving an outline of the evidence, leaving you to draw your own conclusions. Perhaps after reading this, particularly the statement as to the pupils being dilated, you may think that it was a case of belladonna poisoning after all.—I am, sir, yours obediently,
W. H. TRIGGS, Reporter to the *Surrey Comet*.

Kingston-on-Thames, October 16th, 1875.

* * We are obliged to our correspondent for his communication, which gives some further details of the medical aspect of the case. It does not, however, satisfactorily appear that an examination of the contents of the stomach or bowels was made with the object of accurately determining the plant to which the berries belonged. There is no difficulty in distinguishing the seeds of belladonna and dulcamara. We are still induced, on the whole, with the evidence before us, to consider that the latter was the poison, for several reasons. The deadly nightshade is a rare plant, and is not known to grow anywhere in the neighbourhood of Ham, unless it may be in gardens or where planted, being in a wild state confined in the county of Surrey to the chalk range and its vicinity. Blackberries are so well known to all children, that they are little likely to mistake other fruits for them; and when belladonna-berries have been eaten, it has been for their tempting cherry-like appearance, and not in the belief that they were blackberries. With reference, too, to the dilatation of the pupils, this cannot be considered decisive as regards the poison taken, as the symptom is common to several of the solanaceous alkaloids, and has been observed in poisoning by dulcamara, though not constantly present in experiments with that drug and with solanine.

CARDIFF MEDICAL SOCIETY.—At the ordinary meeting, on October 6th, 1875, James Milward, Esq., President, in the Chair—present: Drs. Paine, Edwards, Taylor, Buist, and Sheen; Messrs. Fiddian, Nell, and Trehearne—it was resolved: 1. That in the opinion of this society it is desirable that the hours of attendance in the surgery be curtailed, and that patients should not be attended to after 8 P.M., except in emergencies. 2. That a copy of this resolution be sent to each member of the society.

A NOBLE WORK IN INDIA.

SIR,—Your remarks about "a noble work in India" during the last nine years in Jeypore, by Dr. Colin Valentine, omit all mention of the efforts that had previously been made in the same city for these very medical institutions by Dr. C. Burr, unenvied medical officer to the Jeypore Political Agency; and it is, I think, only fair to that officer that his work should be recorded, as I think you will agree with me that the initiation commenced with him. In 1858-59, Dr. Burr commenced a small midwifery hospital for the instruction of native midwives in the practice of midwifery according to European practice, and carried it on for years up to 1866, with a result that these educated midwives were frequently called in by the native *dhairs* (or midwives) in any difficult cases; and also, it was said, that infanticide was often prevented. I know that up to 1866 this institution was carried on, and a fair amount of success reported. In 1862 or 1863, a small medical school to teach natives European medical practice was established; and when I examined the students in 1864, a fair knowledge of the anatomy of the bones, materia medica, and dressing of wounds, besides the general routine of hospital work, had been attained. Dr. Burr was assisted by an alumnus of the Agra Medical College, then under Dr. G. Playfair. The hospital, however, was bad, being an old native building, ill adapted for a hospital. Dr. Burr obtained a large number of casts, etc., from England, and the first picking of the lock of native prejudice was overcome. It was no small matter even to attempt dissection in so bigoted a city as Jeypore; but this Dr. Burr did, and it has no doubt that the way was paved for further improvement. At the time Dr. Burr commenced the school, I suggested the advisability of the Jeypore State maintaining a number of students at the Agra Medical College, sufficient for the wants of Jeypore, where (in Agra) all appliances, good hospital, staff, and medical college, were in full working order.

The employment of prisoners, when they were imprisoned in the old native goals, was a matter of impossibility; but about 1865, the new goal was near completion, and one of the ends contemplated by Sir H. Lawrence, who suggested the new goal, was the employment of the prisoners; and, if I mistake not, various articles were made in the new goal as early as 1866.

I have always understood since I left India, that the school of arts was under the direct superintendence of Dr. H. Fabek of the Bengal Medical Service. Except with respect to the last, my position as superintendent of the dispensaries in Rajpootana for nine years, from 1858 to 1867, gave me every opportunity of knowing what was being done; and I only think it fair to bring to your knowledge what was done before Dr. Valentine's proposals, to show that they were not altogether original, and also that some heed of recognition is due to others, who were not even hinted at in your article. I of course do not enter now into the causes which rendered Dr. Burr's efforts less successful, or it may be said, so unsuccessful, that they have been quite forgotten.—Your obedient servant,
J. M. LOWNDS, M.D., late Surgeon to the

Egham Hill, Oct. 14th, 1875.

Rajpootana Agency.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Powke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

CANCER-DOCTORS.

"CANCER-DOCTORS," says the *Atlanta Medical and Surgical Journal*, "have some 'ways that are dark and tricks that are vain,' like Bret Harte's 'Heathen Chinee.' Their system appears to be the same in outline wherever the rascals exist, and is essentially as follows. 1. He who aspires to the dignity of 'Cancer-Doctor' must provide himself with an efficient caustic or caustics, which may be used in the form of a powder, paste, or plaster. 2. The quack must disguise the articles by suitable colouring materials, and stoutly deny that they are caustics. 3. He must advertise largely that the great Dr. Tumorsmash will 'take out the cancers without the use of a knife or caustic, and without pain,' and guarantee the cure. 4. When the patients flock in, he must pronounce everything a cancer, whether it be a wart, corn, fatty tumour, ulcer, necrosis, sarcoma, or what not. Now he is ready, and his success will depend upon his enterprise in carrying out the plan. Honest John Leatherhead, the shoemaker, has observed a lump upon the surface of his thigh—in fact, an encysted tumour. It gets in the way of his lapstone, gets hit with his pegging hammer, and, when it is hammered too much, becomes swollen and tender. Mrs. Leatherhead has read Dr. Tumorsmash's handbill, and advises John to go and see him. John, who has eyed the swelling for many a month with fear and suspicion, determines to have a talk with the great man, especially as his 'consultations are free.' He dresses in his best, and presents himself. The quack views him from head to foot, and draws him out into conversation, to gauge the 'size of his pile.' He then looks at the encysted tumour, and, with solemn and ponderous dignity, pronounces it a cancer of the most malignant type. John turns pale, and his leather head shakes on his shoulders. Can he be cured? Yes, says Dr. Tumorsmash, but it will cost five hundred dollars. Leatherhead pleads poverty, but finally pays one hundred dollars in advance for a guaranteed cure. 'I believe you take out cancers without pain,' says he. 'Certainly,' replies the quack; 'that I always do. However, I must put you under a course of preliminary treatment for a few days. This preliminary treatment is a little painful, but you can bear it, and then I will remove the tumour without the slightest suffering.' Dr. Tumorsmash now administers a good dose of morphia; next he surrounds the tumour with a circle of adhesive plaster to protect the skin, and claps on his caustic. This hurts severely, but then it is only 'preliminary treatment'; and meanwhile he lirts the morphia vigorously to keep Leatherhead as quiet as possible. After a proper number of hours, when he judges that he has produced a sufficiently deep slough, he removes the caustic and applies poultices. The pain now ceases, and the poultices are continued until the eschar is fully separated from the living flesh. Now the quack is ready for his grand operation of removing the tumour 'without pain.' The patient's friends assemble, the poultice is removed, and the surface sponged clean. Dr. Tumorsmash discourses as follows: 'My friends, I have called you in to see one of the triumphs of modern science. If you look at this tumour, you will see how wonderfully my medicine discriminates between the cancer and the natural flesh. Look at this deep groove (pointing to the line of demarcation): that was the boundary of the cancer, and you see that this wonderful remedy has followed the disease everywhere exactly up to that line, and has nowhere gone a hair beyond it. It has the property of killing the cancer to its remotest roots, and has no effect on healthy flesh. I will now proceed to remove it.' Suiting the action to the word, he gracefully seizes the rotten mass with his forceps, and lifts it out of its cavity 'without pain.' Leatherhead is amazed and profoundly grateful. In the course of three months the ulcer is healed; and for the rest of his life he and Mrs. Leatherhead never weary of sounding the praises of Dr. Tumorsmash."

MEDICAL APPOINTMENTS.

SIR,—Would it not be well for the Council of our Association to review the position of the members with respect to the public on the one hand, and on the other to medical appointments, with the object of discovering whether the custom obtaining in such matters, however well suited to the past, be out of harmony with the present, and, if necessary, of initiating such changes as should readjust present relations? That there is a misunderstanding between the public and ourselves is evident. The public believes any man undertaking hard work is paid either in money or in its equivalent; and whether the appointment be styled honorary or not, so long as it is voluntary the practical worldly wisdom of the age considers the man who accepts it a fool, so far as he has not had regard to his own interests; whilst we on our side, somewhat weakly [and sentimentally, pluming ourselves on our title, are conscious in nine cases out of ten that, neither directly nor indirectly, are we recompensed for our labours. Does this redound to the dignity of the profession? Most certainly not. Charity begins at home; and the profession actually needs the yearly gift it makes to the charities of the country of the sum our gratuitous services represent. There are plenty of men in the Council not afraid of being called mercenary; and to such men I would leave the first steps to be taken, confident that, if taken, they will in six years have conferred a great blessing on our successors, and at the same time have done wrong to nobody.—I am, yours, etc.,
A MEMBER.

THE FLEXIBLE CLINICAL STETHOSCOPE.

SIR,—In your JOURNAL of September 25th, Dr. Brunton states that an instrument, of which you gave a notice on September 4th, was in daily use in the Royal Infirmary, Glasgow, and that it was made for and used by Dr. Tannahill. In reply to our inquiry respecting the instrument in question, we find that the many advantages claimed for our new clinical stethoscope did not exist in the one referred to by Dr. Brunton. The following communication, received from Dr. Tannahill (with permission to publish), will be the best reply we can give to Dr. Brunton's letter.

"Eden Villa, Lenzie, Glasgow.

"Dear Sir,—In reply to your inquiry, I have to state that, when fever physician to the Glasgow Royal Infirmary many years ago, I used a stethoscope *different* somewhat in details of construction from that described by you, but embodying the principle on which yours is made. The ear-piece in my stethoscope was broad and slightly concave, and of course was *not* intended, like yours, to enter the ear, nor had it the lateral perforation which you describe. Both the chest-piece and ear-piece in my stethoscope were fixed to the tube. My object in having the instrument made was to diminish the danger of infection from typhus fever when auscultating cases of that disease. I found that, in regard to acoustic properties, it gave me all the advantages of the ordinary stethoscope, while it enabled

me to examine the case at a much greater distance from the patient. When my appointment in the infirmary expired, the stethoscope was left in the hospital, and I cannot tell what became of it. In my private practice, the want of such an instrument was less felt; and, as it was less portable than the ordinary instrument, I have continued to use the latter. At the same time, I am convinced that the principle of such a stethoscope is good, and that for fever and dispensary practice it is a decided improvement on the ordinary instrument.—Yours truly,
"To Messrs. Arnold and Sons."
"R. D. TANNAHILL.

The above letter will be the best and most conclusive evidence we can produce that the new clinical stethoscope invented by Drs. Reid and Morrison is different in construction and general details from the instrument invented by Dr. Tannahill.—We remain, sir, yours respectfully,
ARNOLD AND SONS.
35 and 36, West Smithfield, October 1875.

VELASLIUS (St. Mary's).—It is called the Whartonian duct, after Thomas Wharton—one of the most celebrated anatomists in the latter half of the seventeenth century, who was the discoverer of the duct of the submaxillary gland. It was Francis Glisson who discovered and described the capsule of the liver, and whom Boerhaave calls *omnium anatomicorum exactissimus*.

FOREIGN DEGREES BY EXAMINATION.

SIR,—Permit me to ask M.D. Giessen, who publishes in the JOURNAL of this day a list of foreign graduates whose degrees are not registrable in England, whether the holders of British qualifications are recognised by the countries in which the various universities named are located? Can a medical man with a British qualification practise his profession in those countries with the legal sanction of the various governments? If this be not allowable, and the practitioner is fined, imprisoned, or expelled from the state or country, unless he possess a degree or license from the medical authorities of those states or countries, why should we in England permit the holders of their degrees to register here, and walk over us broad-shod? In France, Spain, Chili, and Peru (I cannot speak from experience in regard to the German States), no one, except a holder of a qualification granted by the medical bodies of those respective countries, is allowed to set up or practise in them as a medical man; no matter how high his qualifications are, and especially if British, these go for nothing. His British professional training and examinations, though equal, if not superior, to any in the world, are yet of no avail in those countries. Why, then, let me ask, should we recognise and register a degree given by them? We may, it appears, open our flood-gates for the gratification of foreign graduates, but we ourselves must be shut out from the countries which grant degrees asked to be registered and recognised here.—I am, sir, yours truly,
A MEMBER.

REMARKS

ON A

CASE OF ABNORMAL DISPOSITION TO SLEEP, ALTERNATED WITH CHOREIC MOVEMENTS.*

BY WILLIAM T. GAIRDNER, M.D.,

Professor of Medicine in the University of Glasgow.

THE following case was recently brought under my notice, in consultation with a medical friend, on whose experience and skill entire confidence may be placed as regards such details as were not under my own observation. If I abstain from mentioning his name on the present occasion, it is simply because his absence from this meeting makes it impossible to appeal to him; while a too close indication of the locality might possibly lead to uneasiness within the bounds of a very small family circle, living in strict retirement in the country. Within my own personal experience, the phenomena of the case are unique, and I am, therefore, led to suppose that a brief statement of them may be acceptable to the members of the British Medical Association. I am also not without hope that some curious statements of a more or less parallel kind, or some useful suggestion bearing on treatment, may be the result of the present communication. It has, indeed, occurred to me since drawing up this narrative of facts, to submit a condensed statement of the case in conversation to several individual members of the profession who have kindly assisted me with their experience, and it is chiefly in the expectation of drawing from a larger circle some additional and more valuable materials for a scientific induction, that I venture to place before the Section the present narrative of facts.

As I wish to be brief, I will abstain from reading *in extenso* the notes prepared for me by my friend, on the basis of pencil jottings made by myself in presence of the patient and her immediate relatives. These notes comprise a history carried over more than three years of observation of various phases of the disorder; and as these different phases are a little perplexing to follow, I will now endeavour, without adopting a strict chronological order of narrative, to bring before you two distinct groups of abnormal phenomena as mainly constituting the peculiar manifestations of the disease after it had assumed its present form. One of these groups of associated phenomena is a disorder of the muscular movements somewhat resembling *chorea*; the other is a disposition to sleep, occurring under circumstances, and to a degree wholly unusual, and suggestive (though with marked differences) of the rare pathological conditions which have been duly labelled and classified under the heads of catalepsy, ecstasy, lethargy, etc. Indeed, the association in one and the same case of abnormal muscular movements, with a temporarily suspended state of the consciousness resembling sleep, is so directly suggestive of the states above-mentioned, that perhaps the surest way to give a clear idea of the present case will be through a series of negatives, indicating the contrasts that occurred to me in witnessing the phenomena that may be even now daily, and almost constantly observed in the case of M. T.

This young girl of eighteen is, then, not a *cataleptic* according to any of the current descriptions of that rare condition. Her muscular movements have no resemblance whatever to the peculiar rigidity of *catalepsy*, and besides this difference in their character, these movements differ from those described in *cataleptic* subjects, while they approach the well-known jerks or jactitations of *chorea*, in the fact of their *alternating* with the state of suspended consciousness, instead of being an accompaniment, or rather an essential element of the unconscious or quasi-comatose state. In other words, while this young lady sleeps, she is for the most part still and tranquil; when she is awake, she is, almost without intermission, a prey to involuntary muscular movements. Indeed, with certain exceptions to be noticed by-and-by, there are absolutely no movements during the sleep that would be regarded as out of place during deep natural sleep.

Further, this girl is certainly not subject to any of those conditions allied to *catalepsy*, and, like it, among the more rare phenomena of disordered innervation, but still apparently faithfully described in some instances—conditions usually arising out of disordered emotion, and

ending in more or less complete unconsciousness with or without muscular disturbed movements of an irregular kind. It is impossible, in viewing the attacks of somnolency in the case of M. T., to confound them even for an instant with *hysterical coma*, or with the cases described under the names of *ecstasy*, or *trance*. There is, in fact, in my patient, no highly wrought emotional state whatever; and any hysterical appearances, properly so called, have been purely accidental and transitory, in the earlier part of her illness only, and scarcely to a greater degree than might have been expected from the moral effect of so singular a disease affecting an ordinarily sensitive subject. She has menstruated regularly throughout; has been subject to no known cause of hysterical derangement; has never sought to attract attention, or been in any way made an exhibition of, either in public or in private; she is, within the limits of her waking movements, cheerful and even lively, presenting no trace of exaggerated self-consciousness, and no dramatic or imitative faculty; she has no religious or metaphysical prepossessions connected with her disorder; enjoys on the whole fair bodily health, and is altogether what one would call a normal person of her years, apart from the peculiarities to be stated in this communication.

An equally broad line of demarcation is to be drawn between the present case and all of those characterised by the term *somnambulism*. In the case of M. T., there is no disposition whatever to *somnambulise*, or to perform any function of the waking state during the sleep; on the contrary, the periods when consciousness is withdrawn are, if possible, more distinctly and sharply divided from the waking periods than in the case of natural sleep, and are, so far as can be clearly ascertained, undisturbed even by dreams. There is also an entire absence, in the case now under consideration, of any of those phenomena of disordered or externally controlled will witnessed in the subjects of the so-called *mesmeric coma*, or *hypnotism*; and, *à fortiori*, no kind or manner of resemblance to cases, genuine or other, of *clairvoyance*.

The nearest approach, perhaps, to a classification of the case of M. T. among the *comata* of Sauvages and other systematic writers, would be under the designation of *Cataphora*, or *Coma somnolentum*. But little is gained when that name is conferred on the present case, beyond the recognition of the fact that abnormal or excessive sleep has been in other cases described as a form of diseased function.

There remains only one hypothesis to be negatively dealt with in advance; and no doubt it will have occurred to many as having been already in view in some of the diagnostic indications previously submitted. A sceptic might be disposed to ask, Is this girl a malingerer? If the preceding remarks are not a sufficient answer to this question, I can only appeal to the strong, indeed irresistible, moral impression produced by personal observation of the case, and by strict inquiry into all its incidents and surroundings, to justify an emphatic negative to the suggestion. I can, moreover say, that anything like premeditated deception or scheming, acted out consistently for so long a period as in this case, would imply *powers*, as well as *motives*, for deception, which seem to be wholly absent. And although, in criminal cases before the courts of law, the absence of apparent motive is properly not allowed to prejudice the direct or circumstantial evidence of a crime actually committed; yet, in a scientific inquiry, the absence of motive, and the presence of every conceivable guarantee of truthfulness, together with the almost physical impossibility of a sustained self-consistent imposture under the circumstances, must be allowed great weight in determining the mental constituents (so to speak) of a case of what appears to be purely physical disease. To proceed, then, with the description of the positive facts apart altogether from hypothesis.

1. The *chorea-like movements* in M. T. were among the earliest, and have been the most persistent, of her symptoms; indeed, before the peculiar somnolence, afterwards to be described, occurred, there was perhaps not very much in the character of these movements to distinguish them from ordinary *chorea*. As already remarked, they have, at all periods of the case, been characterised by a nearly complete intermission during sleep; and this remark applies to the natural and periodic as well as to the abnormal sleep. Further, the movements are in themselves painless, however disturbing; and they belong mostly to the series of the *clonic* spasms, or involuntary jerking movements. By far the most considerable, and certainly the most characteristic of these movements, is a slight, but rapid, oscillation or rotation of the head, precisely similar to that of a person who should wish to express, more or less emphatically by signs, his dissent from some assertion or argument; three or four such successive quick shakes of the head being followed by a brief interval of rest, and then by renewed shakings. There is never any nodding movement (as of affirmation); and the rotatory or shaking movement is wholly devoid of any dramatic

* Read before the Medical Section at the Annual Meeting of the British Medical Association in Edinburgh, August 1875.

character or apparent significance, *i.e.*, wholly involuntary and purposeless; it is also quite distinct from the tremor of paralytic agitans or of mercurial poisoning. It is, to a certain extent, increased by mental emotion (as when she is watched), but never is wholly absent at any waking moment, and yet is instantly and completely suspended during sleep. I have satisfied myself that this oscillation of the head, although, as above stated, not uninfluenced by her mental condition, is nevertheless to a considerable extent beyond the control of the will, judging by all the tests usually applied in the case of choreic movements. This peculiar movement is not, however, like the jerkings in many mild cases of chorea, determined simultaneously with, and apparently in direct relation to, a voluntary effort; on the contrary, it is capable of being considerably restrained for very limited periods, and is habitually either kept in abeyance, or at least minimised, during all positive and voluntarily directed movements of the body, but always recurs when no such positive movements are taking place. A similar effect, in temporarily restraining the involuntary movements, is produced by anything that for the moment fixes her attention, as in looking or listening intently, etc.

Associated with the rotatory movements of the head, are certain twitching movements of the left side of the face, especially of the angle of the mouth, exactly similar to the jerkings or twitchings of chorea. The same remark applies to occasional, but by no means very frequent, jerkings of the right arm. It is curious that these jerkings or twitchings, first of the left side of the face, and afterwards of the right arm, preceded in point of time the rotatory movements of the head, and also all the other local and general symptoms now present; so that the resemblance of the case at its first origin to one of ordinary chorea appears to have been very complete. When at the worst (about May 1873) the head-shaking and associated jerking movements were so constant, and so utterly uncontrollable and violent, as to be (according to the medical description) "fearful to look at". Even at this period, however, sleep, whether naturally or artificially induced, completely abolished these abnormal movements, and was practically undisturbed.

Certain abnormal muscular states, either associated with the sleep or of a more permanent character, will be mentioned immediately.

2. The *somnolence*, or abnormal disposition to sleep, in M. T., may be, as to its main characters, very easily described; it is, in fact, in most of its apparent external manifestations, nothing more than very deep and sound natural sleep, occurring at abnormal intervals, and in a very frequently recurring manner, without previous fatigue or exhaustion. In one respect it differs from this description; the patient usually cannot be roused by agitation or concussion, or even by ordinary noises; but is, on the other hand, usually readily enough awakened by calling out her name pretty loudly, and close to her ear. The most marvellous, and, to my mind, unexampled feature in the case, is the sudden transition from waking to sleep, and *vice versa*. In almost all the described cases of lethargic or comatose affections, there has been a kind of gradual transition between deep sleep or coma and thorough waking or consciousness; but in this case there is almost no such intermediate condition. Many times in the course of an hour, nay, several times within a few minutes, the patient may pass from the most perfect wakefulness into the most profound sleep, or from the latter into the former; and (with certain occasional exceptions, presently to be stated) no yawning, or stretchings, or mutterings, as in dreams, or any other of the familiar appearances of the half-asleep state, attend the transition. So uniform and so irresistible is the tendency to sleep, that the patient will inevitably be found to yield to it in a few minutes when conversing, or knitting, or performing any other habitual and mechanical operation, unless she is constantly roused and stimulated by some extraneous impulse towards voluntary and non-automatic movement. Given such impulses from without, at frequent intervals, she can be kept awake indefinitely; but in the absence of positive external impulses she is sure to pass into deep slumber, and that with a suddenness that is almost incredible, except on witnessing the fact. After a few seconds only of agitation the head drops upon the breast, and she is at once in a state of torpor from which nothing will arouse her but the familiar sound of her name spoken into her ear. And the moment that is done, she is awake again, and fully awake; the act of waking having something like the effect of a shock or concussion, and being immediately announced by a renewal of the head-shaking and other jerking and involuntary movements. So great is the tendency to fall asleep, that she has been frequently known to drop suddenly asleep when, in the course of walking about, she has stood still even for a few moments; her limbs then becoming relaxed, so that she would have fallen to the ground if not supported. And yet so completely is any permanent or enduring torpor or lethargy absent, that, if she be only kept awake, she will converse without any apparent sense of fatigue, will read a newspaper or a novel, will do any ordinary women's work, and will show

entire self-possession, a fairly good memory, and no deficiency of cheerfulness or of ordinary intelligence. If she be allowed to fall asleep, and then again suddenly reawakened (in the manner before mentioned), were it even many times in the course of half an hour, she still shows no want of self-possession, but resumes conversation, or her ordinary occupations, exactly at the point at which she left off. Such, in fact, has been the habitual course of her uneventful life, ever since her first period of abnormal sleep in March 1873.

To this general statement, however, there fall to be recorded several exceptions, which I shall now proceed briefly to detail. In the first place, the passage from the waking state into the sleep is not always perfectly tranquil, though always nearly instantaneous. It appeared to me, on several occasions, to be attended by spasmodic movements of a quite different kind from those observed in the waking moments; movements, especially of the hands, more or less similar to the carpopedal spasms of infancy, and with a considerable degree of tonic rigidity, though of brief duration; also a kind of unconscious *hand-washing* movement and convulsive spasms of the lips, all of which conveyed to a skilled observer a hint or suggestion of the earliest stages of certain paroxysms of epilepsy, without, however, the least degree of lividity, or pallor, or change in the character of the pulse, and without any ultimate development in the direction of a characteristic fit, either of epilepsy or apoplexy. A degree of moaning and restlessness, also, very commonly attends the first moments of the sleep; and similar manifestations are occasionally presented during its course, but without any apparent consciousness of them on the part of the patient, either at the time or afterwards. The nearest approach that has hitherto been realised to a half-asleep state, or to dreaming, has been an obscure impression of consciousness of words spoken to her in sleep; but opinions upon this point vary. It is agreed that even loud and unusual sounds, such as thunder, have often failed to awaken her, although apparently making her uneasy and restless. It is also agreed that all the usual sensations connected with the evacuations are powerless to awaken her, though giving rise to symptoms of distress, which have always made it expedient for her kind friends and nurses, by whom she is most carefully watched, to awaken her artificially; and, perhaps, one of the strangest (yet apparently well-attested) parts of the history is that she has never had any involuntary evacuations, even in her deepest somnolence. It is the decided conviction of her friends (founded, so far, upon actual experience) that she would never awake spontaneously, however long she might be left undisturbed; that neither the sense of starvation, nor the pressing necessity of evacuation, nor the weariness of an unvaried posture, nor any other naturally arising impression, would put an end to the somnolence. This impression must be taken as partly confirmed, partly to be corrected, by the observation that, in June, and again in December, 1873, she actually was submitted to a kind of unintentional experiment. On these occasions, she is said to have passed many days continuously in a state of profound and unbroken slumber, without either spontaneous evacuations or food artificially given. The longest period so passed on either occasion (as reported) was eight days. On these occasions, however, she did, at last, awake spontaneously and suddenly; so that it is not altogether certain that the experiment, if it could now be carried out with propriety, or even without danger, would not end in a similar way. But, on the other hand, it is the impression of her friends that artificial awakening is now more difficult than it was at first, requiring both more decided and loud noises, and closer to her ear than formerly. When she awoke spontaneously after an eight days' sleep, she had no conception of having slept more than a single night. She is able to dress herself, to take all her meals herself, to play the piano, and in many ways to enjoy life, and keep herself in occupation. But, in every instance, she requires to be constantly watched if anything of importance has to be done, otherwise she would be almost sure to fall asleep in the doing of it. This applies even to the ordinary evacuations as performed during her waking intervals. On the other hand, all the truly involuntary functions are perfectly maintained during the deepest sleep; the pulse never fails, the respiration is perfectly and naturally maintained, without much stertor; the feet and hands, however, tend to be cold, without any positive sense of chill.

There has never been any fever, or any severe or formidable local pain, but one of the most apparently persistent symptoms—one, indeed, present almost from the first—has been a certain amount of dull pain or uneasiness in the left temple; and she observed, at an early period, that, when this sensation was at the worst, the twitchings were also aggravated. An appreciable amount of halting in the right leg, and comparative weakness of the right arm, have been observed at times, especially by the patient herself; but there has been no permanent, nor even any unequivocal, paralysis at any time, or in any part of the body.

The following note of ophthalmoscopic observations in this case has been kindly furnished by Dr. Thomas Reid, of the Glasgow Eye Infirmary.

Ophthalmoscopic Examination in Case of M. T.

On account of the rapid and incessant lateral movements of the head, it was impossible to make the examination in the waking state. She was accordingly allowed to fall asleep, which she did quickly in the usual way. The pupils, previously normally dilated, remained so during sleep, except occasionally when, either from the stimulus of the light thrown into the eye or from involuntary muscular contraction, the pupil contracted slightly, and this was always accompanied by the associated act of accommodation for near objects. The left eye was slightly hypermetropic, and a good view of the fundus oculi was got both by the direct and the indirect method. The optic disc was oval-shaped, the major axis being vertical. The retinal veins were congested and rather tortuous; the arteries diminished in calibre, and barely visible. The right eye was slightly myopic, the optic disc ill-defined, contracted, rather pale, and slightly depressed in the centre. The veins and arteries were nearly as in the left eye. On being roused, an attempt was again made to see the fundus, in order, if possible, to compare the state of the circulation in the two conditions; but, with the exception of an apparent slight increase of the circulation indicated by the greater intensity of the reddish reflection of the fundus (which was all that could be observed under the circumstances), the condition in both states appeared to be much the same. The oval shape of the left disc was probably congenital. The atrophy of the right was probably associated with some intracranial degeneration. The appearance presented by the vessels might be accounted for by some local constriction at the optic nerve-entrance. There was no trace of hæmorrhage or exudation throughout the fundi.

Details of Case as referred to above.

M. T., a strong, well-formed, and well-coloured girl of fifteen years of age, of previous good health, and with no particular family history of any nervous disease, while sitting in an omnibus on her way home from school, in the beginning of May 1872, was suddenly seized with sickness, a feeling of fainting, and a peculiar spasmodic twitching of the muscles of the left side of the face. The sickness soon passed off, but the twitching remained: the spasmodic movements ceased during sleep. When this twitching had continued for a month or so, it was observed that her right arm began to twitch in like manner, and her head also began to jerk towards the left side. The case had at this time all the appearance of being one of chorea. In conveying food to the mouth, or otherwise using her right hand, she seemed to have little control over its movements, and it occasionally missed what it was intended to do. She continued in this state for some months with little or no change. She was able to go about, and even to go from home for change of air. About this time, she first complained of a dull heavy pain in the left temple, at the junction of the frontal and parietal bones, sometimes better and sometimes worse, but of no extreme character. This pain has been very persistent; and she has observed that when it is most severe, the twitchings are more marked than at other times. Latterly, she noticed that every second night the spasmodic twitchings of the face and the erratic movements of the head and arm were very much aggravated, so much so that she remarked that she had only one pleasant day out of the two: she dreaded the periodic return of the spasms. During this period she had a few hysterical fits.

In March 1873, she suddenly became unconscious, and lay for about a fortnight with her eyes wide open and pupils dilated. She talked nonsense in a stammering manner, sang songs and hymns, had optical delusions (*e.g.*, saw wild beasts, etc.), and did not know her friends. During this time, the spasmodic twitchings and the shaking of the head ceased. When she recovered from the unconscious state, the twitchings and the head-shaking began again in the most violent manner; and towards the end of May 1873, her state was something fearful to look at: the head rocked to and fro on the pillow in a semirotaory motion, and very rapidly; it could not be controlled, even by exerting considerable force and holding her head firmly with both hands. These violent movements ceased, however, during sleep; and in order to procure rest, the hypodermic injection of morphia was had recourse to. In performing this operation, it was remarked that at first, on the insertion of the needle, before the morphia was injected, the head ceased moving, and she fell into a sleep, the sleep being pretty much as is usual under morphia: latterly, however, she did not fall asleep till morphia had had time to act.

This violent semirotaory motion of the head continued without abatement till towards the end of June 1873, when one day she complained of feeling very wearied, and almost immediately thereafter she fell into a deep sleep, and slept continuously for two days (all the spasmodic

movements ceased). At the end of this time, she awoke for a few minutes, made a remark or so, and again fell asleep, continuing in this sleep for eight days. No amount of pinching or shaking her, however severe, could awaken her. Strong ammonia applied to the nostrils caused her uneasiness, but did not awaken her. At the end of eight days she awoke suddenly and spontaneously, her first remark being, "Is it true that my head has stopped shaking?" The head had stopped shaking, though there remained a slight, almost imperceptible, twitch of the face. During her sleep, she took no nourishment but a little wine and water, and beef-tea poured into her mouth with a teaspoon, and with difficulty swallowed (*i.e.*, swallowed mechanically). The bowels never acted, nor was her urine passed, nor did any necessity appear for the use of the catheter, there being no perceptible accumulation.

For the next five months, she kept pretty well in health, though there was always a perceptible twitching of the left side of the face (but very slight), and she complained of weakness of the right arm and right leg. In walking, it was noticed that she had a slight halt, and she dragged the right leg. She took her food well, and her health and strength visibly improved, so that she was able to go about, take walks, do fancy work, knit, sew, etc.

Towards the end of December 1873, she again suddenly fell asleep, and slept for eight days without awaking. Twitching ceased as usual during sleep, and she lay in a state similar to that in which she was in the June previous. At the end of the eight days, she awoke as suddenly as she had fallen asleep, got up and moved about as usual, seemingly unaware that she had slept more than one night; and then began the curious state in which she is at the present time. When she goes to bed, she falls asleep at once, and never awakes spontaneously, until she is awakened by her friends in the morning: she then gets up at once and dresses herself, but requires to keep always moving and active, for, if she were to sit down or stand still an instant, she would certainly fall asleep. She falls asleep at her meals, in the act of conveying food to her mouth, in the middle of a sentence, while carrying on an animated conversation, in playing the piano, or in reading or sewing. The only way she can prevent herself from falling asleep is by keeping herself in a state of activity by walking about. If she wish to read, or sew, or knit, she must keep moving; if she stand still, she falls asleep, and falls to the ground; and if she sit down, she sleeps almost immediately, and often falls off her chair, so that she has constantly to be under the supervision of her friends. During her sleep, she seems to have a sort of consciousness of some sensations, for when she has taken purgative medicine, about the time the bowels are going to act, her friends notice her getting uneasy; she moans and tosses about, and appears unhappy, and, on being awakened, she has an urgent call to stool, and asks why they did not awaken her sooner. She also appears to have a consciousness of noises, but never awakes, only gets restless and uneasy in her sleep.

At first, she used to fall asleep more easily, and was more easily awakened than she is now. She may sit now for five or ten minutes conversing before she drops off asleep, whereas at first she used to sleep the moment she sat down; now she can only be awakened by shouting her name close into her ear, whereas at first she could easily be awakened by making a noise at a distance from her, by whistling, or clapping of the hands.

Detailed Account of Waking State.—Constant lateral vibration of the head is observed, with quick movements of rotation, only stopping for a few moments when her attention is fixed, as in looking or listening intently, with slighter and less constant chorea-like twitching of the angle of the mouth on the left side; slight twitchings of the right arm are markedly observed, though not so much of late. There is a slight halt of the right leg, but no irregular movements. Washing and graspings of the hands are observed, evidently due to nervousness in the presence of strangers; they are not usual. She speaks intelligently, answers questions correctly, and is very observant.

The sleeping state is in the main a deep sleep, with body and limbs quite quiescent. This applies at least to the greater part of the duration of sleep, say during the night; and at first this was the usual condition of sleep at all times. In falling into sleep, her head drops on her breast, and she moans. At first, there was almost always more or less of spasms, twitchings, and quasi-convulsive movements of the hands and arms, and also of the face; but of late there have been decided rigid convulsions of the hands and forearms, very like the carpo-pedal spasms of infants. The hands are strongly flexed on the wrists, and the fingers bent into the palms of the hands, so strongly that they cannot be unclapsed. The head is observed at times to be turned round to the right shoulder in a strong spasm; this occurs sometimes in the middle of the sleep. These spasms are sometimes increased in intensity when she has been excited. There are also

chorea-like movements of the shoulders, and rather extreme convulsive jerking of the left angle of the mouth in falling into sleep, also deep sighing and moaning: this has been more observed of late. She never awakes spontaneously, nor is she ever awakened by any ordinary disturbance, or even by severe concussion, or painfully pinching or pricking within limits. She has been lifted off her chair and roughly shaken without being awakened. The only thing that can be counted on to awake her is to speak her name into her ear, or make a loud noise or whistle close to her ear. She used to be more easily awakened than now: a loud sound at a distance, as whistling or clapping of the hands, succeeded at first in arousing her, but not now. Loud sounds disturb her sleep, but do not awake her; even thunder, which is very disturbing in its effects on her when awake, does not disturb her sleep. When she is awakened, she looks up startled and confused, and looks about for an instant as if collecting herself. She is not conscious of anything during sleep, but has been suspected of being conscious of words spoken by others during her sleep; but this has not been verified. Frequent slight whinings and restlessness occur during sleep, as if unhappy, but she appears unconscious of them, or of any impression to cause them. In sleep, the pupils are widely dilated, the pulse is not affected by sleeping or waking, breathing is perfectly calm, and her colour does not change.

From the beginning of her illness up to the present time, she has always been perfectly intelligent, and can carry on a conversation with spirit; occasionally reads books and the newspapers, writes letters, and does fancy work. Her memory is not impaired; remembers what she reads perfectly well. In her disposition she is amiable, good-tempered, equably minded; has never any paroxysms of grief or anger; feels her position keenly; is easily excited; is rather sensitive, and does not like being seen by strangers; has not had hysterical symptoms for at least two years.

Her bodily health has been pretty fair all through her illness. At first, she was stout and of good complexion, but latterly she has lost flesh, is paler, and not so strong; walks with a halt, and prefers to lean on a person's arm when walking. Pulse 90 to 100. The bowels are costive; never moved except by medicine. The urine has never passed involuntarily; it has never required to be drawn off, but accumulates during sleep; never awakens her by necessity of discharge, but gives rise to symptoms of distress. Menstruation has been regular all through her illness; no uterine derangement; appetite poor; food is not taken heartily, but not refused or vomited; no gastric derangement; tongue white, and breath mawkish; no fever at any time; extremities always cold, but no sensation of chill or shivering; she has had occasionally, however, a feeling of a creeping sensation up the back, apparently fornication.

As regards remedies used, the disease assumed so many different phases that the treatment had to be changed from time to time. At the beginning, the remedies given were such as are usually administered for chorea: notably bromide of potassium, oxide of zinc, valerianate of zinc, ammonia, quinine, strychnia, and several preparations of iron. Antispasmodics were given for the hysterical symptoms while they existed, with alteratives and purgatives. To produce sleep and give rest, and so stop the constant vibration, chloral hydrate was administered, also opiates and the hypodermic injection of morphia. Blisters were applied to the nape of the neck and down the spine; the head was shaved, and blistered over the seat of pain. The bromide of potassium was given at several times—at one time in very large doses, either alone or combined with strychnine; but its use had to be stopped, owing to misgivings as to its effect on her health. Iodide of potassium and phosphorus were also administered. Tonics of quinine, strychnine, and iron, mineral acids, with bitter infusions, have been had recourse to of late in order to restore her strength.

CASE OF AORTIC ANEURISM SUCCESSFULLY TREATED BY THE DISTAL LIGATURE.

By THOMAS ANNANDALE, F.R.S.E.,

Surgeon to the Edinburgh Infirmary, and Lecturer on Clinical Surgery.

R. B., AGED 62, was first admitted under my care in August 1874, on the recommendation of Dr. Wilson of Motherwell. The patient had suffered from symptoms of thoracic aneurism for about six months; and, as these were steadily increasing in severity, he was advised to come into the Infirmary.

On admission, there was a distinct aneurismal tumour, pulsating strongly, and passing up from behind the clavicle and sterno-clavicular articulation into the neck, as far as the cricoid cartilage. The trachea was displaced towards the left side by the tumour, and the inner half

of the clavicle and its articulation with the sternum were pushed forward by the portion of the tumour under them. There was a well-marked *bruit* to be heard on all sides of the swelling, and there was dulness on percussion over a considerable area, corresponding to the situation of the thoracic part of the tumour. In addition to these symptoms, the patient had a constant irritating cough, pains shooting up into the head, want of sleep, and he was losing flesh markedly. He was ordered to keep in bed; and iodide of potassium, in twenty-grain doses, was given three times a day. After one month of this treatment, he left the hospital with his symptoms somewhat relieved, and he was advised to continue the iodide of potassium.

On February 8th, 1875, he was again admitted into my wards, as his symptoms had returned and become more troublesome. He had been unable to continue the iodide regularly, owing to the expense of it. An examination of the tumour showed an increase in its cervical portions. It had not only spread higher up, but it had also spread laterally so as to overlap the site of the subclavian artery. The upper portion of the tumour felt softer; and it was this portion which seemed to be increasing most rapidly. After carefully considering the circumstances of the case, and determining that pressure on the right carotid artery, immediately above the cervical portion of the tumour, very much diminished the aneurismal pulsation, it seemed to me a favourable opportunity for practising the distal ligature. The position of the tumour did not permit the subclavian artery to be ligatured; but there was just sufficient room to secure the common carotid above the cervical portion of the aneurism.

The patient having given his consent, I, on the 2nd of March, ligatured the common carotid immediately under the omo-hyoid muscle, which was drawn upwards, so as to reach the vessel. The internal jugular vein was unusually large and dilated; and some care was necessary to avoid injuring it, as it completely overlapped the artery. The operation was performed under the carbolic spray, and the ligature used was prepared catgut. The immediate effect of the ligature was to almost stop the aneurismal pulsation, and to convert the strong pulsation into a kind of quivering motion. Not the slightest local or constitutional disturbance followed the operation; and the wound was healed on the 17th. A week afterwards, the patient was out of bed. The day after the operation, the patient expressed himself as greatly relieved. He no longer himself felt the pulsation in the tumour, and the pains in his head and neck had disappeared. The pulsation in the aneurism was felt to be very feeble, and the tumour itself was decidedly smaller.

The patient left the hospital a few weeks afterwards, his symptoms continuing in the same improved condition, and the tumour gradually becoming firmer to the feel.

From time to time, the patient returned from the country to show himself, and his state on September 27th was as follows. His general health was good, and he had no pain or other uneasiness. He could stoop freely without giddiness, and could go up and downstairs easily. The tumour had continued to diminish in size, and its cervical portion was fully half an inch lower in level than before the operation. The whole tumour had become much flatter, and also firmer to the touch. On placing the hand over it, only a very feeble pulsation could be felt, but the pulsation was slightly stronger over the upper part of the cervical portion. A *bruit* could still be heard on all sides of the tumour, but it was not nearly so loud as formerly.

REMARKS.—Although it cannot be said that the aneurism in the case reported was completely cured, there can be no doubt as to the great relief which followed the operation. The case, therefore, appears to me to furnish additional evidence in favour of the distal ligature in suitable examples of otherwise incurable aneurisms, and it also tends to confirm the opinions of Mr. Holmes* and Mr. C. Heath,† who have so ably written on the subject.

From my experience in other cases of thoracic and cervical aneurism, and from an observation of cases treated by my friend and colleague Dr. G. Balfour, I can testify to the value of iodide of potassium in relieving the symptoms and promoting coagulation in this disease; but I am inclined to express the opinion that, should a fair trial of this drug fail to give complete relief to the symptoms, the distal ligature of the carotid should be employed, provided the case be a suitable one for the operation. The test of the suitability of the case for operation being the effect which temporary pressure on the distal portion of the carotid has on the aneurismal pulsation. If such pressure diminish the aneurismal pulsation, and should there be sufficient space to ligature the common carotid above the tumour, then I think the case is a proper one for operative interference. I also think with Mr. Holmes that operative interference

* *Lancet*, July 13th and August 31st, 1872.

† *On the Treatment of Intrathoracic Aneurism by the Distal Ligature.*

should, in the first instance, be confined to ligature of the carotid, ligature of the third part of the subclavian being resorted to if advisable at a future stage in the progress of the case.

The case reported further illustrates the value of the antiseptic catgut ligature and other antiseptic precautions, the combined use of which has, in my opinion, removed all the most serious risks in connection with the ligature of arteries.

ON LIGATURE OF THE COMMON FEMORAL ARTERY; AND ESPECIALLY ON LIGATURE BY AN ANTISEPTIC MATERIAL.*

By OLIVER PEMBERTON, F.R.C.S.Ed.,

Surgeon to the General Hospital, and Professor of Surgery in Queen's College, Birmingham.

THREE years since, when I had the honour to deliver the Address in Surgery at our Birmingham meeting, I mentioned a case of aneurism in Scarpa's space, in which, in preference to applying a ligature to the external iliac, I tied what I presumed to be the common femoral an inch below Poupart's ligament. I did this with an ordinary hempen ligature, and left the wound completely open.

So far as the treatment of the aneurism was concerned, the case did perfectly well; but, when I came to dissect the arteries involved—death having taken place from causes wholly removed from the aneurism—I found the circumflex ilii, epigastric, and profunda femoris given off together; that is, at opposite points of a line drawn from the main trunk a little above Poupart's ligament; the point of the ligature being five-eighths of an inch below these vessels, and the tube of the artery intervening being firmly plugged.

Now, although it is obvious that I really tied here the superficial, not the common femoral, owing to the abnormal origin of the profunda, yet the case affords an overwhelming proof of the fact that an abiding coagulum can form in the immediate vicinity of almost any number of branches on the proximal side of a ligature. If this be so, the chief ground for discarding the operation of ligature of the common femoral disappears.

I wish, however, to show that it is the duty of the surgeon to choose this proceeding in preference to tying the external iliac: a duty that becomes imperative when it is based on the knowledge that he submits his patient to less risk of danger to life from the mere operation; and, what is of equal importance, that he has yet a favourable artery to tie in case of failure. I am fully aware that no mean surgical authority—Mr. Erichsen—lays down the rule of surgery, "That in all cases of aneurism above the middle of the thigh, and in which sufficient space does not intervene between the giving off of the deep femoral and the upper part of the sac for the application of a ligature to the superficial femoral, the external iliac should be tied, unless compression can be successfully employed". From this I dissent, and, as I have already said, because the very reason Mr. Erichsen assigns for his judgment—namely, that the liability to secondary hæmorrhage is almost a necessary consequence of the operation, the shortness of the trunk rendering it necessary to tie the artery in close proximity to such large collateral branches that the arterial coagulum will not readily form—does not, in my opinion, constitute a sufficiently valid reason.

And now I will ask to place on one side for a moment the case I have submitted, and inquire whether this source of danger is not diminished, or even entirely removed, by the use of a ligature composed of antiseptic materials.

CASE.—A strongly built Indian soldier, aged 33, non-syphilitic, came under my notice at the General Hospital, Birmingham, in May 1874, with a rapidly increasing aneurism of the left superficial femoral artery. Of very slow growth in its early history, its character was now changed. Reaching to within three to four inches distance from Poupart's ligament, it compassed a space of six inches in extent, was largely raised above the surrounding parts, and was accompanied by strong visible pulsation, by œdema, and severe pain.

After a few days of carefully applied pressure at the arch had proved of no avail, on May 26th I tied the main artery and what should be the common femoral, an inch below Poupart's ligament. I used an ordinary antiseptically prepared catgut ligature, tying the vessel by a single loop, and finishing by a double one. The ends were cut off short, and the wound closed. The contents of the aneurismal sac remained fluid for a long time; and it was not until nearly three months had elapsed that everything was absorbed and the limb restored.

Now, neither at the operation nor subsequently did I follow out the antiseptic method of treating the wound; that healed in the ordinary way by suppuration and gradual repair. I simply desired to permanently close the artery at a given point without cutting it through; and this, I submit, was effectually and safely accomplished, even in the midst of suppuration.

I am not aware of any previous instance in which an animal ligature has been applied to the common femoral, with the exception of Professor Lister's case referred to by him in his Address to the British Medical Association at Plymouth (August 1871), where, in the face of a diffused popliteal aneurism, he tied what he expected to be the common femoral with a catgut ligature. The vessel, at any rate, as he informs me, was ligatured about the most frequent situation of the origin of the profunda—making the case all the more striking, as the only result he would expect from the application of a silk ligature in such a situation would be secondary hæmorrhage.

The principle involved in tying arteries in their continuity by means of animal ligatures may be still on its trial; but I will be bold enough to assert "that the fate or behaviour of a given antiseptic catgut ligature, applied to the continuity of an artery", will yet be foretold with confidence as to the favourable result. And in this I appear to be more sanguine than Mr. Maunder states himself to be in his recent Lettsomian Lectures on the *Surgery of the Arteries*.

It is, I think, to be regretted, that I was unable to place my recent experience in Mr. Holmes's hands before he summed up his views on ligature of the common femoral in his lectures at the Royal College of Surgeons last year, as I intended doing, thereby strengthening the conclusion at which he arrived: that there was no just cause to banish this operation from surgical practice. The cases of Ramsden, of Mott, of Porter, Macnamara, Colles, and myself, led him to this view with the use of the hempen ligature. Surely the consideration of Professor Lister's case, and the one I now for the first time lay before the profession, should remove from his mind his remaining objection, based on the uncertainty of the place of origin of the profunda: a circumstance, I venture to think, of no real importance, when the canal of the artery is not cut through.

TWO CASES OF ANEURISM, ONE OF THE CAROTID AND ONE OF THE FEMORAL ARTERY, SUCCESSFULLY TREATED BY THE WIRE COMPRESS.

By JOHN DIX, M.R.C.S., Hull.

THE wire compress, a substitute for the ligature, was first used by me in September 1860, just fifteen years ago, and was brought before the profession by a paper read at the Royal Medical and Chirurgical Society, January 13th, 1863. An abstract of this paper, with the discussion thereon, appeared in the weekly medical journals: it was published *in extenso* in the *Edinburgh Medical Journal* of September 1864, and reproduced in Braithwaite's *Retrospect*. The procedure was then looked upon as a novelty, and there was the usual dispute about priority of invention. The late Sir James Simpson afterwards settled this question for us by showing that the idea and the practice were more than three hundred years old—older, in fact, than the ligature—and that the only change from the method of the surgeons of the fifteenth century, was the substitution of wire for the thread of hemp or silk used by them. So true is the saying of Liston, that "young surgeons meet with many anomalous cases; they also rediscover many things".

It seems that this practice was superseded by the ligature, which was invented by Ambrose Paré about the year 1564; yet it was not altogether forgotten or laid aside, as mention of it crops up here and there in the surgical writings of various old authors, both English and foreign. Its revival in modern surgery is clearly due to the impetus given to surgical ingenuity by the introduction of acupuncture by Sir James Simpson and his writings thereon, which so rudely shocked the faith of surgeons as to the perfection of the time honoured ligature.

But the long needles as at first used were by no means pretty, and many who thus made trial of acupuncture, while recognising the soundness of its principle, could not shut their eyes to its defects, and so cast about for other methods of applying it. Hence we soon had before us various kinds of needles and varying modes of using them. Hence, also, arose this process, which I have called the "wire com-

* Read before the Surgical Section at the Annual Meeting of the British Medical Association in Edinburgh, August 1875.

press", which seems to have occurred to many minds, independently and almost simultaneously. I may mention Langenbeck of Berlin, Nendorfer of Prague, Mr. Hilliard of Glasgow, Dr. Pollock* of Pittsburg, as well as myself. So far as I know, I was the first in this kingdom to use it in actual surgery, and the first to write thereon in the paper to which I have already referred. This paper attracted considerable attention; many surgeons expressed themselves pleased with the device, and proffered to try it, though I know of no one who really gave it a serious trial except Mr. Teale of Leeds. It found a place in the next published edition of Druitt's *Vade-Mecum*; and a long chapter on the whole subject, under the title of "Filopressure", may be read in Simpson's book on *Acupressure*.

Meanwhile, out of this crusade, or revolt as it were, against the ligature, sprang the revival of another ancient and long defunct process, viz., torsion, by Professor Syme; and, also, the *carbolicised catgut* ligature of Professor Lister, which differs so much in its effect and action from the silk ligature that, but for bearing the same name, it would never be classed in the same order of appliances. These two processes have been so strenuously advocated, and been found so practically successful, that they are now the popular, and in some schools the almost exclusive, methods of arresting bleeding; and the "wire compress" has died out, and, except by myself, has been well nigh forgotten.

Yet it has never failed or disappointed me. Since I first wrote on the subject, I have scarcely ever used any other hæmstatic. I had then had but five cases. I have since employed it in many and various operations; amputation of limbs, breasts, testicles, and for various arteries accidentally wounded, and with most satisfactory results. Thus I have had, of secondary hæmorrhage, never an instance; of suppuration, a minimum; and not unfrequently complete primary union even in large wounds, and that without any antiseptic precautions. I will mention but two illustrations.

For the removal of a breast, the incision was nine inches long; three arteries were secured by the wire. On the fourth day, the only trace of the operation was a firm linear cicatrix and the suture marks. There was not a drop of pus nor exudation of any kind whatever.

About eight weeks ago, I amputated the leg of a feeble old man for acute destruction of the tarsal and ankle bones. Here again there was perfect primary union. On the sixth day, the stump was firmly healed, needing only the support of a strip of plaster. With such results, is it to be wondered at that I still have faith in this procedure and continue to employ it?

I pass now to the more immediate object of this paper, viz., to relate to you two cases of aneurism treated by this same "wire compress". In the essay to which I have already referred, I spoke of the *applicability* of this method to arteries in their continuity, and demonstrated the process by this rude model which I here again exhibit, and which, by a stretch of imagination, may be taken to represent a femoral artery, secured by the wire for an imaginary popliteal aneurism. It was two years afterwards that I first had the opportunity of bringing the idea to the test of actual practice, when the following case fell into my hands at the Sealcoates Union Workhouse, to which institution I have the distinguished honour of being surgeon.

William Gardner, aged 50, formerly a man-of-war's man, lately a lighterman, had met with much rough usage in his vocation, and also in the battles of Venus. He had aneurism of the left carotid, first observed "about the size of a hazel-nut", six weeks ago. It was now somewhat larger than a duck's-egg, occupying the anterior triangle of the neck, pushing the larynx from the medium line.

November 29th, 1865. The artery, which was very large, was exposed below the omo-hyoid, and an aneurism-needle passed under it in the usual way. A piece of surgical iron wire was threaded through the eye of the aneurism-needle and conveyed beneath the artery by the withdrawal of the needle, which was then detached from the wire. To each end of the wire a straight needle was next attached, and the two needles were passed through the tissues, on the outer side of the incision, being about half an inch apart at the surface of the skin, and the same distance from the edge of the wound; the wire being drawn through and thus looped over the artery, the needles were detached. The half of a vial-cork was placed, the flat side downwards, between the ends of the wire, and firmly pressed down along the course of the artery; the wire was tightly twisted over the cork, stopping at once the current through the artery and the pulsation of the aneurism. The superfluous ends of the wire were cut off, and the wound was united

by wire sutures. The man was then in a state of extreme collapse from chloroform; in fact, he was to all appearance dead, and was only resuscitated by the strenuous and persevering exertions of my assisting friends. With the recovery of the circulation, there was also a recurrence of feeble pulsation in the tumour. This was allowed to go on till the third day, when the compress was thus tightened. The cork being firmly pressed down upon the artery, and the wire drawn outwards by gentle traction on the twisted end, two small wooden wedges—portions of lincifer matches in fact they were—were pushed in between the cork and the wire; and now, for the first time, the circulation was entirely arrested, and all pulsation and *bruit* ceased. Two hours afterwards, there was again a feeble thrill; so next day, the fourth after the operation, another little wedge was inserted. After that, there was no more pulsation.—Fifth day. No pulsation; the tumour was evidently consolidating, and perceptibly diminished in size. One wedge was removed to lessen the tension.—Sixth day. The other two wedges were withdrawn in the morning, and, in the afternoon, the cork was also removed. The tumour was considerably smaller, and, on the seventh day, the wire was withdrawn without difficulty and without blood. Some pus exuded from the track of the wire, and there was moderate suppuration in the wound.—Tenth day. It is noted that "the tumour is nearly gone". There was pulsation in the artery up to the aneurism beyond the site of the application of the wire, showing that no damage was done to the coats of the vessels. This only continued for a few days, for, as it led to nowhere, the artery was soon obliterated, and, when the man died seven years afterwards, a fibrous cord was all that remained either of the artery or of the disease. In a fortnight, the wound had healed, and the patient was cured.

I related this case and exhibited the patient at a meeting of the East York and North Lincoln Branch of our Association, May 23rd, 1863; but it was not published, nor alluded to in print, except by a brief note in the *JOURNAL*, and in the *Medical Times and Gazette* of December 16th, 1865, in reply to Mr. Syme's strictures "On Acupressure and other Nonsensical Contrivances for the Suppression of Hæmorrhage". It is also alluded to in a paper by Mr. Teale in the *Lancet* of January 5th, 1867, on a case which he treated by this method.

On January 24th of the present year, my partner Mr. Rudd was called in to one John Hull, and, on his return, reported the case to me as one of femoral aneurism. I saw the man with him the next day. He also was a waterman, twenty-five years old, short, florid, and very fat. There was a pulsating tumour of large size at the lower part of the right thigh on its inner aspect, which was first observed about nine weeks before. It now measured quite four inches and a half in length and four inches across, and was clearly an aneurism of the femoral artery protruding from the edge of Hunter's canal. The whole limb was much swollen. Not to weary you with minute details, I would briefly state that pressure was tried for four days without benefit; and it was, therefore, determined to secure the artery by the wire compress, which was done on February 2nd, at noon. The superficial femoral was exposed in Scarpa's triangle, by an incision five inches long and at least an inch and a half deep. A wire was carried under it by an aneurism-needle, as in the previous case, brought out to the surface of the skin about half an inch on the outer side of the incision, and there twisted over the cork—which was firmly pressed down over the track of the vessel—till the pulsation was arrested. The wound was closed by wire sutures, supported by a large pad of lint on each side, and long strips of plaster over them. The limb was already bandaged with flannel during the application of pressure, and so it was left. At 3 P.M., there was pulsation in the aneurism. At 9 P.M., there was none. The pain, which had been great, had entirely left him. Next day, at 11 A.M., there was again pulsation. Two wedges were inserted between the cork and the wire; and at 9 P.M. there was no pulsation.—Third day; at 11 A.M.: the limb was readjusted on the pillows, and his position made less irksome. There was then no pulsation. At 9 P.M., there was a feeble thrill.—Fourth day. Slight pulsation; two more wedges were inserted, and the pulsation ceased, to return no more.—Fifth day. The limb was diminishing, causing the tumour to seem more prominent. The limb retained its warmth, and there was no constitutional disturbance whatever. He complained only of being worried by fleas.—Sixth day. Tumour less, quite solid. Wedges removed.—Seventh day. The cork was taken away, and the wire loosened. It moved in consonance with the pulse.—Eighth day. Wire removed without difficulty, followed by one single drop of pus and one of blood.—Ninth day. Plasters and sutures removed. The wound was entirely and completely healed. From the time it was closed, there was never the least exudation. The tumour was solid, and much diminished; in fact, the patient was cured. It was some weeks before the tumour was entirely absorbed and the limb regained its strength; but it is now some time since he returned to his laborious occupation, and the only

* Dr. Pollock, in a pamphlet which he has kindly sent me, relates twenty-six cases of amputation and one of aneurism (popliteal) treated by this method—which he calls "the wire-loop"—with excellent results. When it comes back to England as an "American" invention, it will probably attract more attention than it has done as an indigenous product.

difference between this leg and the other is the large cicatrix and a greatly increased growth of long thick hair.

I think it will not be denied that these cases prove that this is a safe and efficient mode of treating an aneurism. We may, therefore, now proceed to estimate its relative merits, as compared with other methods.

Into this competition certain of the hæmostatic agents do not enter. Torsion, for instance, is not applicable to aneurism; at least, I have not yet heard of any proposal to sever the artery and twist both ends in the wound, though my friend Mr. Maunder has lately suggested the division of the vessel, and the application of a catgut ligature to each end. I trust he will not practise it.

Acupressure, too, has been tried by Dr. Heron Watson and others; a needle being passed under the artery, and a wire twisted over it. I believe the result was not satisfactory, and I have lately heard nothing of the method.

Quite recently, Dr. McGill of Leeds has published a case in which he applied temporary compression to an artery by means of a pair of forceps sticking out of the wound: a method suggested to me many years ago by my friend Dr. John Lowe of Lynn. Surely this is an ugly-looking appliance, and, so far as I see, offers no advantages over the wire, whilst, as I shall presently show, it lacks one of the chief merits of my compress.

There remain, then, to be considered but the old-fashioned silk ligature and the carbonised catgut. As I have already remarked, these differ so materially in their action and effect, that it is a pity they are confounded together by bearing the same name, which only leads to a confusion of ideas.

I was once taken to task by a very great surgeon for abusing the ligature, "one of the grandest things in surgery". I do not forget that the abuse of the ligature adds nothing to the merits of my substitute; but neither will praise of the old friend detract anything from the new one; and, spite of previous warning, I cannot hesitate to protest that the ligature is but a clumsy unscientific appliance in the treatment of aneurism. Let us fairly, and without prejudice, trace its course and action.

For the cure of aneurism either by the coagulation of blood, or by the deposition of lymph in layers, or by these two processes combined—as I suppose mostly happens—the one thing needful is to obstruct the flow of blood into the sac, either partially or totally. Opinions differ as to which is preferable. Of course, the ligature acts only by sudden and abrupt exclusion; whenupon arises one of the special and greatest dangers of the operation—gangrene, to wit. Nevertheless, this risk must be run; so you cut down on the artery, and tie tightly round it a piece of silk or hempen cord, which is left dangling from the wound. And what have you done by this? You have made a contused and lacerated wound of the coats of the artery. This is said to be a good thing, essential to the process of repair, and to the ultimate detachment and withdrawal of the ligature; yet surely it is a violation of the first principles of surgery, which teach us that contusion and laceration are not favourable to healing. Well, but, at any rate, you have effected your primary object, and have cut off the current of blood from the aneurism. In two or three days, consolidation has taken place; and, if you could now get rid of your ligature, all would be well. But this you cannot do. Though the ligature has answered its purpose, and is now naught but a nuisance in the wound, yet the surgeon is, so to speak, at the mercy of his own weapons; he must bide his time, awaiting the slow bungling processes of nature to cast off the foreign body. Meanwhile, what is your ligature doing? First, it is setting up suppuration in the wound; surely a thing to be avoided, if possible. Next, it is producing ulceration through the artery itself. Who will maintain that *this* is not an evil? And when, after many tedious days or weeks, it is at length detached, what guarantee have you that the needful closure of both ends of the divided artery has taken place, and that bleeding will not ensue? On the contrary, do we not know by fatal experience that often and often hæmorrhage does occur; and, even when it does not happen, no one can deny that there has been the risk of it, and that the patient escapes more by good luck than by the skill and science of the operator.

Now let us follow out in the same way the *modus operandi* and effects of the wire compress. What a contrast to the foregoing picture does it present! First, then, whilst it obstructs the circulation just as completely and effectually as the ligature, it affords the operator a choice of methods—the gradual or the sudden occlusion—according to his judgment. Surely this is an important and material point, one on which it behoves the surgeon to have a definite view. My own opinion—whatever that may be worth—is, that gradual obstruction *at first* is of immense advantage; that it is more favourable to the cure of the aneurism, by leading to the deposition of lymph; and also greatly diminishes the risk of gangrene by allowing time for the establishment of the collateral

circulation, which keeps the limb, or may be the brain, alive. If the limb were cold, and gangrene threatening, the compression could be relaxed or altogether removed, and so the impending mortification might be prevented; and although, in such a case, amputation might be the only resource, yet this operation would be done at less disadvantage than in a gangrenous limb.

If, on the other hand, all go on well, and in five or six days the pulsation have ceased, the surgeon has his appliance under his entire control. He first relaxes the pressure by withdrawing the cork, or untwisting the wire; feeling his way, as it were, and still keeping command of the artery in case of need, till, being assured that the desired consolidation has really taken place, he with confidence, aye, with certainty of success, withdraws the wire. Meanwhile, the wound has healed, or, at all events, has had the best chance of doing so, there being no foreign body to excite suppuration. The artery also is still intact, so that hæmorrhage is impossible, and the patient is cured; may we not triumphantly say, *fulva, sile, et juvenis!* (See *fulva* *et* *juvenis*.)

I ere let me remind you that, in both my cases, a moderate feeble circulation through the artery was allowed for three days, and in twenty-four hours after its *entire* obstruction consolidation was complete. Moreover, the secondary processes of absorption of the tumour, and restoration of power to the limb, were accomplished with unusual rapidity, dependent possibly on the more healthy condition and action of the parts which had not been excited and disturbed by adjacent inflammation and suppuration, or by the laceration and ulceration of the artery; the circulation through which is probably restored beyond the point of compression, even up to the seat of the now consolidated aneurism; it certainly was so in my carotid case. Again, out of this perfect immunity from bleeding, the surgeon gains another advantage in a wider choice as to the point of election in operation. Thus, for hæmorrhagic reasons, it is thought specially dangerous to tie the common femoral; so much so, that some think it ought never to be done, though otherwise it would often be a desirable situation for a ligature. The use of the wire entirely obviates this objection. So with the external carotid, which is rarely or never tied because of its numerous branches, and, consequent proclivity to bleed; for this reason, the common carotid is selected, though the lesser operation might suffice, *quoad* the cure of the disease. Why, for instance, should you cut off half the circulation from a man's brain to cure a vascular tumour outside his skull?

So much for comparison with the silk ligature.

I have still to deal with the antiseptic catgut.

This appears to have been uniformly successful in the five cases in which it has been used by its inventor, Mr. Lister, but, as often happens, it has been far otherwise in the hands of others. Thus, Mr. E. Watson relates a disastrous case of popliteal aneurism, in which this appliance on the femoral artery failed to arrest pulsation, apparently by reason of the early yielding of the catgut. The same thing again happened when the iliac was subsequently tied, to remedy the failure of the previous operation; and so, after amputation, the patient died.

In Mr. Spence's case of ligature of the carotid, the patient, on the second day, became comatose and paralysed from embolism of the middle cerebral artery, caused "By a fragment of clot, which had become detached from the site of operation, in consequence of the too speedy softening and relaxation of the catgut, and so carried into the circulation by the current of blood". He also says that he has known hæmorrhage to occur after amputation, from the ligature softening and losing its constricting power. From this cause also, Mr. Holden affirms that fatal bleeding occurred in a case in which the femoral artery had been tied.

My friend Mr. Maunder (from whose lecture, in the *Lancet* of April 17th, I have gleaned these cases) expresses his opinion, founded thereon, that "The catgut may melt away before repair has taken place", but he says, "for the surgeon distrustful of the catgut there is yet one resource, viz., the antiseptic *silk* ligature cut short". I hereby offer him another and a better resource, viz., the wire compress. Farther on, he quaintly remarks that, "After mature consideration, he has arrived at the conclusion that the fate or behaviour of a given antiseptic catgut ligature, applied to the continuity of an artery cannot be foretold." I can confidently foretell both the fate and behaviour of the wire. Its behaviour is simply to control the circulation through the artery so long as is needful for the cure of an aneurism; and its fate is to be then withdrawn, and perhaps exhibited at a meeting of surgeons. Here is the piece of wire which so "behaved" in the case of my patient John Hall.

It seems, then, that the catgut may fail from softening and yielding too soon; a special and peculiar danger superadded, as it were, to the ordinary risks of the silk ligature; that it cuts the artery, and so gives rise to the risk of bleeding, and, of course, it can act only by

peremptory stoppage of the circulation. The wire compress is free from each and all of these objections.

This, then, is a fair summing up of the case as it appears to me :

The wire compress does not damage the coats of the artery as the ligature does.

It is not a foreign body in the wound, as the ligature is.

Therefore it does not excite suppuration and impede healing, as the ligature does.

It is not a fixture upon the artery, as the ligature is ; but it can be removed, or relaxed at any time, which the ligature cannot.

It does not ulcerate through the artery, and open the blood channel, as the ligature does ; therefore, bleeding is impossible : with the ligature there is always the risk, and not seldom the occurrence, of bleeding.

It causes a retarded circulation and gradual occlusion of the artery, so diminishing the risk of gangrene ; the ligature causes sudden obstruction, hence gangrene often follows.

Ultimately, or even at once, if desired, it entirely obstructs the current of blood, so curing the aneurism, as effectually and as completely as the ligature does.

It affords a wider choice of locality for operation than the ligature does, and is applicable to all arteries alike, which the ligature is not.

As compared with the catgut :

It is not liable to become relaxed or detached too soon, as the catgut is ; it does not cut the coats of the artery, as the catgut does.

Thus it confers absolute immunity from hæmorrhage, which the catgut does not ; it causes gradual occlusion, which the catgut cannot do.

I ask you, as surgeons, are these mere fanciful imaginary advantages, or have I, as I steadfastly believe, introduced to you a real improvement in surgery ?

POST PARTUM HÆMORRHAGE TREATED BY SOLUTION OF PERCHLORIDE OF IRON.*

By J. C. CLARK, M.R.C.S. and L.S.A., Medical Officer of the Gildersome District.

THE patient whose case I have the honour of bringing before you was, in several respects, unfavourably placed—mentally, physically, and sanitarily : *mentally*, for she was impressed with the idea that she was doomed to die in her confinement—a by no means uncommon idea in pregnant women ; yet, in her case, it was deepened by the fact that her mother had died from some pelvic mischief, which had parturition as its starting point ; and her aunt, her mother's sister, had died from flooding : *physically*, for she had a contracted pelvis, instrumental aid being required for her delivery ; and *sanitarily*, because the room in which she was confined was very small, damp, and cold, there being no fireplace and no ventilation ; and, just before delivering her, I was compelled to visit a patient suffering from pneumonia, with severe erysipelas of the face and head.

Mrs. C., a primipara, aged 19 years, had been in labour several hours when I was summoned, at 3 o'clock in the morning of February 3rd, to attend her in her confinement. The patient was a small, fair-complexioned woman ; she looked somewhat exhausted, although her pulse was fair ; the pains, which were of a bearing-down character, were regular, with an interval of about five minutes. On making a vaginal examination, I was struck by the facility with which my finger touched the promontory of the sacrum, thus showing probable contraction of the brim. The os was expanded to about the extent of two inches, and was easily dilatable. The membranes were projecting through it, and the head lay in the first position at the brim. I remained with her about two hours and a half, during which time the pains were regular ; but, as I expected, no progress was made ; and, feeling convinced that instrumental aid would be required, I left her, telling her friends to let me know if any change took place. Hearing nothing from them, I returned at 9.30, accompanied by my brother, who is a qualified man. On my way down, I was entreated to visit a patient who was suffering from severe erysipelas of the face and head, complicated with pneumonia, and whom I had been attending for some days past, as his friends believed he was dying. After examining this patient, I washed my hands, brushing my nails with a tooth-brush. On arriving at the midwifery case, I again washed my hands in a solution of permanganate of potash ; and, on examining the woman, found that the liquor amnii had escaped, but not the slightest advance had been made. My brother agreed with me that, as

we had already given Nature a fair trial, and as the pulse was becoming accelerated, we had better at once put on Barnes's long forceps. Without giving chloroform, I, with comparative ease, applied them, my brother carefully steadying the uterus, whilst I made traction during the pains. With considerable effort, I brought the head on to the perineum, and then removed the forceps, so as to allow Nature to complete the delivery. During the passage of the head through the cavity of the pelvis, a considerable amount of blood escaped by the side of the head. When, after due time, the head was born, I did not hasten the birth of the remainder of the body, but rather retarded it, so as to allow the uterus gradually to contract on its contents, my brother keeping up steady pressure, both during and after the birth of the child, the right side of whose forehead was forced in ; and it had facial paralysis.

As soon as the child was born, flooding commenced. We at once gave a full dose of ergot ; and, the placenta being extruded from the uterus by pressure from without, I removed it from the vagina ; it was followed by an unusually large amount of membranes, which I was especially careful in removing. Notwithstanding the removal of the placenta and membranes, the hæmorrhage was very profuse, although the pulse was fairly good. We at once applied cold to the vulva and lower part of the abdomen, keeping a steady grasp on the uterus. The bleeding almost stopped, only a little oozing taking place from the vulva. In a minute or two afterwards, the uterus seemed to melt away from the grasp, and profuse hæmorrhage came on. I now passed my hand into the uterus, and cleared out the blood and clots, firm pressure being maintained on the abdomen. This did not arrest the hæmorrhage ; whereupon we injected cold water into the uterus, through a Higginson's syringe. This had no effect. By this time, the patient had become blanched, respiration sighing, and pulse rapid. I passed my hand into the uterus again and again, but it would not contract on it. The woman's condition was becoming so alarming, that we thought it advisable to sponge out the cavity of the uterus with a solution of perchloride of iron (1 to 4), but it failed to arrest the bleeding. The woman's condition now appeared to be truly desperate ; the pulse was not perceptible at the wrist, she became blind, and the respiration was gasping, but blood was still running from the vulva. I now passed my left hand into the uterus (my fingers resting against the fundus), and carried the vaginal tube of the syringe along its palmar surface. I then slowly injected about six ounces of the perchloride solution. The hæmorrhage at once completely ceased, and the patient gradually rallied.

On Feb. 4th, pulse 124.....	respirations 24.....	temp. 99.8.
„ 5th, „ 120.....	„ 24.....	had no pain.
„ 6th, „ 130.....	„ 30.....	temp. 102.2.
„ 7th, „ 134.....	„	„ 101.8.
„ 9th, „ 100 (good quality) „	„ 24.....	„ 98.8.

From the time of her delivery on February 3rd, till the 11th of the month, when I ceased to take note, she slept well, took support freely, had no pain ; there was a very scanty flow of the lochia ; and the bowels were not moved till the seventh day.

OBSTETRIC MEMORANDA.

ON INJECTION OF THE PERCHLORIDE OF IRON IN POST PARTUM HÆMORRHAGE.

THE fatal case furnished by Mr. Boddy, in the JOURNAL of the 16th instant, and Dr. Swayne's comments upon it in the last number, are, I venture to think, of great importance, believing as I do that Dr. Swayne's explanation of the cause of death (*viz.*, the passage of some of the iron solution through the Fallopian tubes, or one of them, into the peritoneum) is very likely to be the true one. Indeed, I may say that the fear of such an occurrence has to some extent prejudiced me in the use of intrauterine injections of irritant fluids, especially since the following case happened a few years ago. Hastily summoned to a woman, I found her on the bed suffering apparently with the most severe colic that I had ever met with. On inquiry, it transpired that she had been prescribed for at the public dispensary, and for some weeks had been using, for leucorrhœa, a strong solution of sulphate of zinc and alum, which she had injected by an eight-ounce elastic bottle having an elastic nozzle of about six inches in length. She was in the act of using this injection at the time of being suddenly seized with the fearful pain in her belly ; and, as she admitted that she had introduced the nozzle higher up the vagina than usual, I considered that she had chanced to inject the womb itself, and then a Fallopian tube and the peritoneum. The case proved to be a sharp but short-lived peritonitis ; for, under opium internally, and poultices of mixed

* Read before the Leeds and West Riding Medico-Chirurgical Society.

mustard and linseed, she was out of danger in two days. Probably only a little of the astringent solution found its way into the peritoneum; nevertheless, it produced such a shock as I can readily conceive a parturient woman, already reduced by hæmorrhage, might succumb to at once.

G. F. HODGSON, Brighton.

CLINICAL MEMORANDA.

A CASE OF POISONING BY EATING LABURNUM-PODS.

On the afternoon of September 13th last, I was urgently called upon to attend a girl about five years of age, who, as I was told, had eaten some fruit of a laburnum tree. Upon my arrival, I found the child pallid, with a low and feeble pulse. The pupils were slightly contracted. She was exhausted and vomiting, the vomited matter being mixed with half masticated pods and seeds of the laburnum. An emetic of mustard was administered, which caused free vomiting, bringing up more seeds. The vomiting was kept up till the stomach was completely cleared of its contents. The child was then put to bed, and a little brandy and water given; after which, the pulse gradually increased in strength and frequency. The child slept well during the night, and in the morning seemed nearly well.

JOHN AITKEN, Carlisle, N.B.

CASE OF HYSTERIA IN A CHILD AGED TEN YEARS.

S. T., AGED 10, was always healthy. Her mother and father and grand parents were living. I was first called in to see her in September 1874, when she complained of severe pain at the epigastrium; this increased, and the child appeared in the greatest agony and misery in spite of all treatment. When first I saw her, she was a rosy healthy-looking child, but soon became sallow, and had an "abdominal" aspect. Three months previously to my seeing her, she had complained of the same pain once or twice a week; it grew worse up to September. When I visited her first, she appeared well nourished, rested upon a couch, ate and drank, could not speak above a whisper; pulse and respirations quick. She grew worse and worse, and became quite unable to walk; the pain continuing the same, though I gave her tincture of opium, belladonna, hyoscyamus, bromide of potassium, chloral hydrate, mustard and linseed poultices, blisters, and, in fact, tried every means to relieve the pain without the least (apparent) effect. In February, she began to cough and hiccuped. This lasted until April 16th, remedies having no effect; then convulsions set in, and she used to scream after taking food, of which she scarcely took anything but water (so I was assured by the parents); these convulsive seizures lasted over a week. I believed that the child, young as she was, had hysteria. I went to see her again a few days afterwards, and told the parents I believed there was nothing serious the matter, although they had given her up as about to die many times before. I ordered them to take severe measures and make her get up and walk; and, in May, she was got upon her feet, and little by little improved, and is now able to walk with crutches, and, probably, by the aid of galvanism, will be soon set to rights. She is now away for the benefit of a change of air, and I heard that yesterday the people with whom she is staying have taken away one crutch, and will shortly do away with the other. I did not suggest crutches, and was only aware of her using them a few days ago.

WM. H. SPURGIN, Maryport.

WEST HERTS MEDICAL SOCIETY.—The fifty-fourth meeting of the above Society was held at the Clarendon Hotel, on the 20th instant, Dr. P. HOOD, the President, in the Chair. A paper was read by Dr. Charles Wotton, Surgeon to the West Herts Infirmary, on The Period of Incubation of Epidemic Diseases. Small-pox, measles, scarlet fever, whooping-cough, mumps, diphtheria, typhoid and typhus fevers, and puerperal fever. The paper was illustrated by cases. A paper was also read by Dr. Saunders of London, medical officer of health for the combined sanitary district of Middlesex and Hertfordshire, on Preventable Disease in its Social Aspect. Among many practical remarks, Dr. Saunders combated the common and ignorant opinion that the infantile epidemics must be suffered at some period of life. He thought that with proper precaution they might be averted. He also thought that it was very necessary that the medical officer of health should have early information of contagious disease. He also brought forward cases to prove the increase of health following improved sanitary work. In the discussion which followed, Messrs. Hood, Brett, Saunders, Ambler, Iles, Leman, Brodribb, and Prior, took part. The next paper will be read by Dr. Iles on The Administration of Iron in Acute Disease.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, OCTOBER 26TH, 1875.

SIR JAMES PAGET, Bart., D.C.L., LL.D., F.R.S., President,
in the Chair.

ON THE USE OF THE ACTUAL CAUTERY IN THE ENUCLEATION OF FIBROID TUMOURS OF THE UTERUS. BY ROBERT GREENHALGH, M.D.

THE author in this communication, after briefly alluding to the unfrequent use of the actual cautery in this country, as compared with its application on the Continent, stated that during the last twelve years he had used it frequently, and with more or less success, in chronic enlargement, with induration of the cervix uteri, due to inflammatory or fibroid disease; in epithelioma and cancer of the neck of the uterus, where the organ was movable; in some cases of vascular tumour of the meatus urinarius; in slight cases of recto-vaginal and vesico-vaginal fistula; in incontinence of urine, due to dilated urethral canal; and in certain cases of interstitial and intrauterine fibroid growths. It was to its use in the two latter classes of cases that he limited his present observations. He then gave the details of five cases, three of intramural, one of extramural, and one of intrauterine fibroid growths, with the plan adopted, and the results in each case. He expressed an opinion that diffused fibroid deposits of the uterus in the early stage were more amenable to treatment than was generally supposed. He observed that, although the large majority of cases needed no surgical interference, yet there were others which, through the large losses of blood to which they gave rise, or the mechanical effects they produced, imperatively demanded such aid. The author then drew attention to the occasional ill effects of dilatation and enucleation by the knife, and summed up the advantages of the actual cautery under the following heads. 1. It is easy of application. 2. It occasions but little pain. 3. It is rapid in its action. 4. It occasions no bleeding. 5. No plugging is needed. 6. The charred opening is not favourable to absorption. 7. There is no offensive discharge from the charred surface. 8. The opening is readily dilatible, and without bleeding. 9. It permits manipulation through the opening immediately after its use. 10. By its use, portions of the tumour may be rapidly destroyed, its size reduced, and its lower segments rendered conical; thereby facilitating dilatation of the opening and the subsequent detachment, expulsion, or removal of the morbid growth. He then remarked that spontaneous expulsive efforts shortly followed its use, and the density of the tumours appeared to be more or less reduced after its application. The author, in conclusion, drew especial attention to the three following points. Firstly, the advisability of the gradual detachment of the growth from its surrounding capsule, especially in cases where the tumour is of large size, or where the patient has been much reduced by previous hemorrhages, by which further losses of blood are avoided, and more perfect contraction of the investing tissues is secured, and the chances of pent-up offensive discharge is almost certainly prevented. Secondly, the removal of only so much of the tumour at each operation as is external to the opening, by which the opening is kept dilated, and all chance of its closure upon the remainder of the growth avoided. Thirdly, the speedy destruction by the cautery, or removal by the *Arseur* or hand, of the tumour, should sloughing ensue.

Dr. GREENHALGH read extracts from a letter from Mr. Marriott of Leicester, with reference to one of the cases described, stating that the subject had been lately delivered of a fine healthy child, and had in all respects done well.—Dr. ALFRED MEADOWS thought that the plan of treatment recommended by Dr. Greenhalgh was valuable, but there would be difficulty in selecting suitable cases. Tumours varied much with regard to their relation to the uterine fibres. Some lay in a loose bed of cellular tissue, and were readily enucleated; while in others the tissue of the tumour seemed to merge into that of the uterus, rendering enucleation impossible. He thought that the treatment would be applicable in cases of tumours having a good amount of uterine tissue above and on the peritoneal and mucous aspects, so that the uterus could assist in their expulsion. But, if the tumour were adherent to the peritoneal surface, enucleation was not applicable. Generally, however, the cases could not be distinguished—although some cases of sub-peritoneal tumour might be diagnosed easily enough. He could scarcely agree with Dr. Greenhalgh as to all the advantages which he alleged the cautery to possess over incision. In most of Dr. Greenhalgh's cases, the finger was introduced to break down the adhesions of the tumour; and here an element of danger was introduced. The application of the cautery was in itself, however, free from danger.—Dr.

BARNES agreed as to the difficulty of distinguishing the cases proper for operation. In some instances, the dangers of meddling had been illustrated, although there had been no means of knowing them beforehand. Tumours attached to the cervix uteri were readily treated by various means; but the case was very different when the tumour was situated in other parts of the uterus. Portions of a tumour might be cut away, and healing would follow for a time; and this might be repeated, until at last a low form of inflammation appeared, and probably metritis and subsequent septicæmia. If such a tumour could be enucleated, the patient might recover; but it was not always possible to tell what tumours could be enucleated; and he did not think that the cautery would obviate the danger. And, although the cautery gave increased security against hæmorrhage, he did not think that it would absolutely prevent it. The cases indicating treatment were those attended with much hæmorrhage and with blocking of the pelvis. The application of the cautery was painless and safe, as he had noticed many years ago in the practice of Jobert de Lamballe.—Dr. GREENHALGH said that he suggested the use of the cautery in exceptional cases only, not in sub-peritoneal fibroids. One further advantage of its use was, that the lining membrane of the uterus was not interfered with.

AN ORIGINAL VIEW OF THE LARYNGEAL MOVEMENTS, ACCOMPANIED BY A NEW MOVABLE MODEL. BY EDMUND J. SPITTA, M.R.C.S.

The model illustrated the present theory by exhibiting mechanically the two operations of the larynx under which all its movements might be included, viz., the tensing and relaxing the cords and the opening and closing the glottis. The new view principally concerned the last-named operation. The author held, in the first place, from the construction of the crico-arytenoid joints, that neither forward nor rotatory movements of the arytenoid cartilages are possible, and that these cartilages can only move laterally, but that by this very movement the interval between the vocal cords is horizontally increased and the glottis opened. He then described the laryngeal muscles, and how they effect the two operations abovenamed, giving them fresh names in accordance with their actions; the arytenoideus, for example, was called the occludens, and the posterior and lateral crico-arytenoid together the patefaciens. Lastly, according to the author, a remarkable, though totally unexpected, corroboration of the truth of his view was derived from the peculiarity in distribution of the laryngeal nerves.

Mr. C. BROOKE called attention to the fact that Mr. Spitta had not represented the membranous portion of the vocal cords. The late Professor Willis had shown that, unless the upper edges of the membrane were rendered parallel, vocal vibrations were not produced, although the glottis was closed.—Mr. NUNN remarked that the principal point was the articulation of the arytenoid cartilages.—Dr. WHIPHAM had never been able to satisfy himself of the rotation of the arytenoid cartilages.—Dr. SPITTA said that the membranous parts of the cords had been omitted on account of certain difficulties, especially that of obtaining a membrane to stretch equally.

CLINICAL SOCIETY OF LONDON.

FRIDAY, OCTOBER 22ND, 1875.

GEORGE W. CALLENDER, F.R.C.S., F.R.S., Vice-President, in the Chair.

Tumour of the Skull of Doubtful Nature.—Mr. JONATHAN HUTCHINSON exhibited a child with a congenital tumour of the head, probably due to arrested development of the bones of the skull. The child was brought to Mr. Hutchinson at the Moorfields Ophthalmic Hospital in October 1871, being then six months old. She was the younger of two children, the elder being reported healthy. When she came under observation, there was found to be a large hemispherical tumour in the middle line of the top of the skull and frontal region. The tumour was smooth and hard; its base measured 4 in. by 5 in., and in the middle line it reached just to the root of the nose. On each side, the base of the tumour reached nearly as far outwards as the outer angle of the corresponding orbit. The fontanelles were not quite closed. A hard ridge occupied the situation of the sagittal suture in its anterior half. Behind the tumour, and almost continuous with its base, were one or two nodules. The eyeballs were very prominent, and the lower part of the sclerotics much exposed. The child was lost sight of until April 1875, when she was again examined. She was then four years old, but would not be taken for more than two. She had but just learnt to walk. She was cheerful, good-tempered, and could talk well. The right hand was always colder than the other, and the whole upper extremity was believed to be weaker than the left. Just above the outer angle of the eyebrows, the skull narrowed, having on each side prominent ridges which marked the junction between the squamous and

parietal bones. Thus it would appear that the whole frontal bone was too small. The eyeballs were very prominent, almost the whole cornea being exposed and much of the sclerotic below it. In the middle of the top of the skull, beginning a little behind the coronal suture, and passing backwards along the whole length of the sagittal, was a soft swelling an inch and a half high and probably two inches across. A sort of ill-marked depression crossed the tumour about its middle, and near to this depression two plates of bone could be felt in its walls. At its margins, lips of bone passed upwards into its walls, where they gradually thinned off and were lost, a condition which suggested that the tumour had pushed its way from within outwards. The tumour was soft, and received impulse from the circulation and from the respiratory movements. Mr. Hutchinson stated that he believed that, owing to the want of development of the frontal and anterior parts of the parietal bones, the brain, in its growth, had caused absorption of bone and bulging in the position of the sagittal suture. He also thought it a question whether the capacity of the child's head was increased. He had no doubt the tumour was in part brain, and partly fluid. He had notes of two other cases, in which a bony ridge passed from the nose on to the tumour, but he did not know the final result in either of those cases.—Mr. CALLENDER was inclined to agree with Mr. Hutchinson in his opinion of the case. He had seen a similar case under the care of the late Mr. Stanley. That patient died at the age of twelve years of a soft cancerous growth, which had increased slowly, and had produced scarcely any symptoms until it spread down deeply into the brain-substance.—Mr. MORRIS thought Mr. Hutchinson's explanation of the case improbable, more especially when one looked at the child's protruding eyeballs. About eighteen months before, a very similar case had come under his care; the patient being a single woman, forty-five years of age. She had some months previously received a blow over the parietal and temporal bones, whereon a small tumour arose, and slowly grew until it became about five and a half inches in diameter in all directions. It pulsed everywhere, but there were also at two or three different parts of the tumour pulsations of another kind, which were, in fact, pulsations in vessels in the tumour. A hard bony ridge ran round the tumour, and pieces of detached bone or phleboliths could be felt in its substance. The tumour being punctured, a bloodstained fluid came away. No further operation was performed, and the patient left the Middlesex Hospital. The tumour had since increased, and the patient occasionally saw black specks before the eyes, but there were no other symptoms. Mr. MORRIS thought the growth was a soft cancer of the diploë. Mr. Couling, into whose care the case had subsequently passed at Brighton, had lately examined the body of a man dying with soft cancer of the clavicle, and had also found three or four unsuspected soft tumours of the diploë of the skull. In Markoe's book of the diseases of the bones, three or four cases were mentioned, in which the characters of the growth were like those in this patient. He would ask why these cancerous tumours were so slow in growing.—Mr. HOLMES was not quite sure that the medullary cancerous character of these growths was proved. He mentioned the case of a male patient in St. George's Hospital, in whom such a tumour lasted fifteen years. He was about sixty years old at the time of his death, and had no symptoms except an occasional epileptic attack, or one of mild delirium, during which he would say foolish things. He had a soft pulsating growth at the top of his head, which was now preserved in St. George's Hospital Museum, and was of a fibrous nature, covered by thickened pericranium externally, and dura mater within. It was certainly not cancerous, and did not lead to the patient's death. This kind of tumour was included by Louis in his fungating growths of the dura mater.—Mr. MORRIS explained why the diagnosis of his cases was correct.

Ulcer of the Tongue of a Doubtful Cancerous Nature.—Mr. HUTCHINSON exhibited a patient with an ulcer of the tongue of doubtful nature. He was first seen in April 1874, when he had noticed the ulcer for two months. He was then 59 years of age. There was no history of syphilis, and the binoiodide of mercury and other specifics had been given without any benefit. When first seen, the ulcer was quite clean, and had a hard border; it was about the size of a sixpence, and situated exactly in the middle of the dorsum of the tongue. The ulcer was freely cauterised with acid nitrate of mercury. When the patient was presented to the Society, eighteen months afterwards, there was an oval patch in the middle of his tongue about as large as the stone of a damson plum, a little raised in the middle, and with ill-defined borders. There was no ulceration; but at its posterior part was a little hollow overlung by smooth papillary growths. It appeared that, soon after the application of the caustic, the sore had healed, and that it had since caused him not the slightest inconvenience or pain until June of the present year, when another sore similar to the first formed behind it; and at the same time a gland under the lower jaw enlarged. The

gland softened, broke down, and discharged a thin sero-pus; and in September another gland followed the same course. There was no history of cancer in the family. Mr. Hutchinson said this was the quietest form of cancer of the tongue, if it were cancer, which he had ever seen. It was certainly a most puzzling case for diagnosis. He had not examined it microscopically.—Mr. LEE thought the history of the lymphatic glands important. A lymphatic gland affected with cancer or syphilis had no tendency to soften or discharge a serous fluid.—Mr. MAUNDER thought cancerous glands did soften, and did not suppurate. When iodide of potassium was given in cancerous disease of the lymphatic glands, there was at first an improvement, but when once the inflammatory thickening had been removed by the drug, it ceased to effect any further good.—Mr. CALLENDER thought the disease was cancer from the characters of the growth itself, the age of the patient, the implication of the glands, etc.

Renewed Discussion on the Antiseptic Treatment of Wounds.—Mr. PICK said that, at the last meeting of the Society, Mr. Callender had come to the conclusion that salicylic acid did not warrant the encomiums passed upon it; and he (Mr. Pick) had brought forward a case of wound of the knee-joint treated by carbolic acid dressings. It was proposed to discuss both those papers this evening. [Abstracts of the papers were published in the BRITISH MEDICAL JOURNAL for October 16th, page 510.] In his case of wounded knee-joint, pus was not prevented from forming, but it was always sweet and healthy, and never decomposed. The patient was exhibited; he had a good ankylosed joint, and was able to earn his own living. Mr. Pick thought carbolic acid prevented the decomposition of the pus, but that it did not prevent suppuration. He had been especially struck with its value in excision of joints. Since he had adopted Lister's method of treatment, he had not had a case of pyæmia or of erysipelas. A recent patient of his, fourteen days after amputation of the thigh, had only had the stump dressed three times. He was struck, on removing the dressing, to find that the discharge in the external layers of the dressing, where air could reach it, was most fetid; whilst farther in, at the wound itself, the pus was quite sweet. Every case treated by him at St. George's Hospital for the past two years had been dressed after Lister's method, except one, a case in which he had removed an enchondroma from the parotid. That patient died of pyæmia, and was the only one lost by that complication throughout the two years.—Mr. MAUNDER had only read the abstract of Mr. Pick's case in the medical journals, but thought the history there presented was very much the history of other cases of suppurating knee-joints not treated by carbolic acid. He had lately had three cases at one time in the London Hospital, and had asked the worst one of those cases to attend that night to show himself. That case was six months in hospital, had suppuration extending in all directions, had drainage-tubes introduced, had required stimulants in large quantity, and finally could exhibit as good result without carbolic acid as Mr. Pick had obtained with that special mode of dressing. But Mr. Maunder thought that Professor Lister did expect something more than the prevention of putrefaction of pus, viz., the prevention of suppuration altogether. Mr. Maunder had brought down also another patient treated by another method advocated by himself, viz., by ligation of the main artery of the limb. This patient had, eight years ago, a serious injury of the knee-joint, treated by ligation of the femoral artery; and the inflammation of the joint was immensely controlled by the method of treatment adopted. The man had now a good ankylosed joint. Still, Mr. Maunder did not mean to say that great credit was not due to antiseptic treatment.—Dr. MOXON would like to know if Mr. Pick had observed whether bacteria were present in the pus from the knee-joint.—Mr. HOLMES thought the value of the antiseptic system could not be determined by appeal to individual cases. A case of compound fracture into the knee should not, for instance, be compared with a wound of the knee. Surgeons should give their general impressions of both plans of treatment. The more he himself followed the method, the more did he value it. Its chief value was in the prevention of traumatic fever, especially from large abscesses. But, to adopt the method thoroughly, the case must be so treated from the very first. The great principles of the treatment were very valuable; one especially, viz., that the wound was largely preserved from the contact of foreign bodies, and that the surgeon had to dress it himself. This Mr. Holmes believed to be the principal part of the whole thing, more than the supposed absence of germs, etc. He had seen pyæmia occur in cases treated antiseptically. He had taken three years distinct from each other (1864, 1870, and 1874), and had examined the mortality books at St. George's Hospital during those years, with the result that he found pyæmia was fatal in very different proportions in different years. In 1874, there were eleven fatal cases of pyæmia, of which eight were after various diseases for which no operation was performed, one being puerperal, one from diffused periostitis, etc.; whilst three

followed surgical operations, one of which was for fistula, one for strangulated hernia, and one an excision of the hip. In 1870, there were nineteen deaths from pyæmia; eleven of which followed disease; whilst eight were after surgical operation. In 1864, eleven of the two hundred and forty-one deaths were from pyæmia, of which only one was after surgical operation. Thus, the prevalence of pyæmia in London hospitals was comparatively rare; and one could not say that carbolic acid abolished the disease, except after many years of trial.—Mr. DE MORGAN thought that most of the benefit which had resulted from the antiseptic treatment was due to the vast care exercised by the surgeon, especially as in the case of Mr. Callender at St. Bartholomew's Hospital. At the same time, he thought antiseptics of great value. Take empyema as an example. A small opening being made into the thorax, the pent-up pus in the pleura became most fetid; but, upon more air being admitted through another opening, within twenty-four hours the pus became quite sweet. In Professor Humphry's wards at Cambridge one might see wounds thoroughly exposed, and they did remarkably well. He thought there were some cases which did very well with antiseptics. He had recorded in the first volume of the *Transactions of the Clinical Society* the case of a girl, whose joint he opened, and rubbed the interior well with the strongest solution of chloride of zinc—forty grains to the ounce of water—and in whom a cure was speedily effected. He doubted very much if that would have taken place if the powerful antiseptic had not been used. Another child with inflamed knee-joint had the joint sponged, and was better at once. If one took care that all hygienic rules were carried out, one got rid, to a great extent, of the secondary surgical diseases, which were formerly the curse of the London hospitals. He believed Professor Lister had done much good by calling attention to the benefits which great care in dressing wounds would secure. He (Mr. De Morgan) used boracic acid, sulphurous acid, and all other antiseptics; but the greatest care was now exercised in dressing all cases.—Mr. BARWELL said that, in speaking of the value of antiseptics and of Lister's method, we were speaking of two different things. In Mr. Pick's case, the wound was made some hours before the patient was seen by the surgeon. Any treatment begun thus late was likely to have the same effect of not preventing suppuration. Some cases could be healed readily without the necessity of using carbolic acid, if great cleanliness were exercised. He was sceptical of the germ-theory, but it was highly advantageous to the patient to keep the atmosphere around him saturated with carbolic acid, and to dress wounds always beneath this atmosphere. On the Continent, the antiseptic treatment had been taken up most vigorously, and rigorously carried out according to Professor Lister's directions. Several operations had been mentioned as dressed according to the method in which the wound had healed without suppuration or inflammation of any sort, as the removal of loose cartilages, etc.; and Mr. Barwell did not think that could be done by any other method of treatment. He believed Professor Lister had done his cause much injury, by mixing up with it such an amount of fussiness as to render his method unattractive to surgeons in general.—Mr. HEATH had been to Edinburgh to see Professor Lister's wards, and the results attained there were certainly astonishing. Professor Lister attributed great importance to the *minutiae* of his method; and, if anything went wrong with the wound, it was always found that something had been omitted in the dressing. Mr. Heath would like to know with which of the details insisted upon by Professor Lister Mr. Holmes dispensed. Mr. Heath thought that it was because the details were fussy, and operations under the spray were annoying, that surgeons generally had refrained from adopting Lister's plan. At the same time, he had seen cases do quite as well without carbolic acid treatment; whilst he had witnessed elevation of temperature where the antiseptic method had been used. He would like to know whether Mr. Callender continued still as successful in his operations at St. Bartholomew's Hospital as at the date of his paper in the last volume of the Reports of that hospital: because, if so, the success was as great as that attained by Lister's method. He would also ask why, if Mr. Maunder was so fond of ligaturing the femoral artery for inflamed knee-joint, he had not adopted that plan of treatment in either of the three cases he had mentioned.—Mr. THOMAS SMITH desired to raise one protest; that if surgeons tried Lister's method, they must take it with all its inconveniences. Mr. Lister felt that. Persons tried it; and, by omitting certain details, did, as Lister had said, "court failure". In the middle of an operation, for instance, persons would take up a pair of forceps, just put them momentarily into carbolic acid, and then thrust them into the wound; whilst old germs, which a proper preparation and longer soaking in the acid would have destroyed, still remained in the teeth of the instrument. Surgeons had no right to try the method without using all the details. Mr. Smith did not think any evidence had been placed before the meeting upon which an authoritative opinion from

that Society upon the value of Lister's method could be based.—Mr. MAUNDER had not ligatured the femoral artery in either of the three cases he had mentioned, because two of those cases were never bad enough to warrant the operation; and he was deterred from doing it in the worst case (that of the man exhibited), because he feared that the arterial supply to the limb was, by reason of the inflammation, too fully established.—Mr. BRAMWELL explained that he thought there were only blemishes in Lister's method, and that an advocate would try to simplify it.—Mr. CROFT had visited Mr. Lister's wards years ago in Glasgow, and could now say much in favour of his method, having since then used it. Surgeons should look at the antiseptic method not only from the point of view of the patient operated upon, but also from that of other patients in the wards. The pure condition of the atmosphere had a good deal to do with the results in these other cases.—The discussion was again adjourned.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

THURSDAY, OCTOBER 14TH, 1875.

S. W. BROADBENT, M.R.C.S., President, in the Chair.

Prevalent Diseases of the District.—Mr. I. E. ARMSTRONG, Medical Officer of Health for Newcastle-upon-Tyne, presented a "Return of Admissions to, and Deaths at, the Newcastle Fever Hospital, from March to September 1875, inclusive". The total number of cases admitted was 73. There were 49 cases of typhus, 11 of enteric fever. Of the typhus cases, 21 were admitted in March, 5 in April, 11 in May, 5 in June, 4 in July, 1 in August, 2 in September. Ten of the typhus cases were fatal. Mr. Armstrong, after making some remarks on individual cases, stated that the sanitary condition of the town was at present good.

Sacculated Abdominal Aneurism.—Dr. PAGE showed a specimen. The aneurism was about the size of an orange. It sprang from the commencement of the vessel, involving the celiac axis and both renal arteries. The patient was a clerk, thirty-two years of age. He denied having had syphilis, but had led a dissipated life. The origin of the disease was referred to strain. The sac ruptured behind the peritoneum. Death was preceded by convulsions.

Amyloid Degeneration of Kidneys and Spleen with Mitral Disease.—Dr. PHILIPSON showed specimens. The combined weight of the kidneys was 1 lb. 8½ ozs. The mitral valve and a large portion of the interior of the left auricle were coated with dense vegetations.

Calcareous Deposit in Mitral Valve.—Dr. PHILIPSON showed a specimen.

Aneurism of Thoracic Aorta.—Dr. PHILIPSON showed a specimen. The aneurism was of the size of a small melon. It sprang from the ascending portion of the arch. The superior vena cava was adherent to the outer wall of the sac. It was compressed by the tumour. During life, there was œdema of the face, upper extremities, and upper part of the chest.

Malignant Ulcer of the Hand.—Dr. BEATSON showed a specimen. He had, with the permission of Mr. Russell, amputated the hand under antiseptic precautions. The wound was healed in ten days, without a drop of pus, and without the slightest constitutional disturbance. The patient was seventy-five years of age.

Scirrhous of the Breast.—Dr. MURPHY showed a specimen. The tumour was a very large one. The breast was removed under the antiseptic method. The wound healed without a trace of pus. The operation was not followed by any constitutional disturbance.

Diseased Vertebra.—Dr. BYROM BRAMWELL showed a specimen. The disease was very extensive. The spinal canal was opened. The membranes were partly destroyed. The spinal cord ran through the middle of a fetid abscess. There was no paralysis.

Tumour of the Heart.—Dr. BYROM BRAMWELL showed a specimen. The tumour was of the size of a hen's egg. It was situated on the exterior of the left heart, at the junction of the auricle with the ventricle. On microscopic examination, it was found to consist of small cells, irregular in shape, containing many nuclei and nucleoli. The patient died very suddenly. Death was apparently due to cardiac syncope.

Hydatid Cyst of Liver.—Dr. BYROM BRAMWELL showed a specimen; also several drawings, and a series of microscopical preparations, illustrating its minute structure. In some of the scolices, the so-called calcareous particles were deeply stained by Beale's solution of carmine.

Hydatidous Mole.—Mr. GOWANS showed a specimen. The mass was expelled at the tenth week of utero-gestation. It was noted that the uterine tumour was larger than normal, extending to a point two inches above the umbilicus.

Progressive Muscular Atrophy.—Dr. BYROM BRAMWELL showed two cases. The first was a pitman, aged 22. Eighteen months ago, he first noticed a weakness in his left hand. A pail of water, which he was in the habit of carrying, slipped every now and again out of his hand. "Cold made the fingers curl up." The right hand became affected a year ago. The patient's general health was very good. The muscles of the body generally were well developed, the biceps remarkably so. The muscles of the left thumb and hand were completely atrophied. The muscles of the right hand were affected, though to a less degree. The muscles of the left forearm were beginning to be atrophied. The second patient was also a pitman. He was twenty-eight years of age. He was admitted to the Newcastle Infirmary some weeks ago, under Dr. Embleton, by whose kind permission Dr. Bramwell was enabled to exhibit the patient. In this case, the disease was in a very advanced stage. The man was unable to rise from his seat. He could not raise his hand to his head. The muscles of the arms and thighs were most affected. The disease had commenced only seven months ago, in the ball of the left thumb. It had rapidly spread to other muscles. The atrophied muscles still responded to galvanism. This patient stated that, when sitting, he felt perfectly well. Vision was somewhat dim. On ophthalmoscopic examination, commencing grey atrophy was seen to be present. This fact favoured the nervous origin of the disease.

Empyema treated by a Free Opening and Drainage-tube under Antiseptic Precautions.—Dr. BYROM BRAMWELL showed a case. The right chest had been twice tapped, and ninety-eight ounces of pus withdrawn by means of Weiss's aspirator. The cavity having again filled, a free opening was made, and a drainage-tube inserted under the spray, etc. The operation was performed by Dr. Mickle, junior house-surgeon to the Newcastle Infirmary, on August 30th. The dressing was changed daily. The operation had been followed by marked relief. The pulse and temperature had since been normal. Cough and expectoration had diminished. The patient had gained 8¼ lbs. in weight. There was still a daily discharge of about half an ounce. The dressing was removed for the inspection of members.

Staphyloraphy.—Dr. ARNISON exhibited a boy on whom he had operated on October 5th. The patient was only five years of age. The cleft was not complete, and did not include the alveolar process. The operation was designed to close only the posterior part of the cleft, and had been perfectly successful, union having taken place to the very tip of the uvula. Dr. Arnison stated that he had had better success by this method of procedure than by closing the whole cleft at a single sitting. He attributed the good result to the nervous and vascular supply of the parts being less interfered with.

Papers.—Mr. T. F. HOPGOOD read a paper entitled Strapping the Chest in Abscess after Pleurisy. The history of a case in which marked benefit from this mode of treatment had resulted was given.—Dr. BYROM BRAMWELL read a Report of a Case of Hydatids of the Liver treated by a free opening under Antiseptic Precautions. The patient was exhibited, and a large portion of cyst-wall discharged through the drainage-tube was shown.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

MICROSCOPIC SLIDES.

WE have just had an opportunity of inspecting a series of microscopic slides prepared by Arthur C. Cole and Son of Liverpool. These slides illustrated both healthy and morbid tissues, and the sections brought out well the different structures, and were chosen from good specimens. As to the mounting, it was all that could be desired, and the sections, in size and amount of surface, exceed anything we have hitherto seen. The staining is done by a process peculiar to Messrs. Cole, and is far superior to any in use elsewhere. Taken altogether, they are the most perfect and beautiful things of the kind ever offered for public sale. This is not only our own opinion but that of some of the most expert microscopists of the day, who have testified to the excellence of these slides. For teachers wishing illustrations for their class-teaching, they will be found very acceptable; while to students commencing their histological researches, they will be invaluable, not only for their demonstrating power, but as models to be aimed at as the students themselves become experts in the art.

BRITISH MEDICAL ASSOCIATION:
SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, OCTOBER 30TH, 1875.

A DUBIOUS VERDICT.

A CASE of some importance in a medico-legal point of view has lately occurred at Yeovil. We allude to that of Mr. Turberville, a gentleman of property, who died rather suddenly while staying at an hotel in the town. An inquest has been held and a verdict returned, but this does not appear to have given satisfaction, and, as usual, the local papers have been filled with letters setting forth conflicting views on the cause of death.

But for the fact that the deceased was possessed of considerable property, and had disposed of it in different quarters by several wills, the public would not probably have heard of this case. Under these circumstances, the medical evidence received at a coroner's inquest is in general closely scanned and severely criticised.

The deceased was a man about fifty years of age, unmarried; somewhat eccentric in his habits, of average good health, and showing throughout life a capacity to manage his affairs. A desire for will-making appears to have been one of his eccentricities; for we learn that he left behind him no fewer than seven different wills. By one of these, the last which he made, he left a large sum to the daughter of a druggist at Yeovil of the name of Maggs, whose acquaintance he had first made about three months previously. It is also stated that he had made propositions to this lady, and, at the time of his death, was under an engagement to marry her. By another will made shortly before this, he had bequeathed the whole of his property to a Mr. Bradlaugh, to be applied by him to the advancement of socialist and atheistical principles! There is a brother who has a claim on the estate, the legality of which would appear to depend upon these wills being set aside on the ground of eccentricity or insanity. We believe, also, that a question of the validity of a life-insurance is likely to arise. The medico-legal questions which present themselves in this case, are: What was the cause of death, poison or disease? If poison, as alleged in the verdict of the jury, what was the nature of the poison? Was it taken voluntarily for the purpose of suicide, or administered accidentally? Lastly, although this was not a question for a coroner's jury to decide, what was the mental condition of the deceased when the wills were made? and, on the assumption of suicide, when was the poison taken?

According to the evidence, it appears that the deceased arrived at the hotel at Yeovil on Thursday, August 12th. On the two following days, he was chiefly at the house of Mr. Maggs, the druggist, to whose daughter he was engaged; and, up to that time, he was well in health. On Sunday, the 15th, he complained of a pain in his leg, apparently arising from an attack of sciatica. He kept his bed on that day, and took a mixture containing iodide of potassium from a prescription which he had been in the habit of using for these attacks. This was dispensed by one of Mr. Maggs's assistants. He also had some calomel and colocynth pills. The deceased afterwards applied for chloroform, and Mr. Maggs sent him one drachm. On the following day (Monday) deceased was seen by a medical man, Dr. Aldridge, in company with Mr. Maggs. He was then in great pain, and is described by both as being like a "raving lunatic". He called for more chloroform, and Mr. Maggs left him in order to procure it. During his

absence, the deceased requested Dr. Aldridge to leave the room. In three or four minutes Dr. Aldridge returned, and found deceased still raving and calling for chloroform. He was in the act of administering the vapour from a few drops which he had sprinkled on a handkerchief, when he saw a whitish fluid escaping from the deceased's mouth, and with this a lump of a white substance, which, from the smell, Mr. Maggs pronounced to be cyanide of potassium. He subsequently ejected another portion. An emetic of sulphate of zinc was then given to him, which caused free vomiting. The mouth, gums, and tongue were burnt, (? corroded), with the poison. Three drachms of chloroform (in vapour?) were given to him. This produced sleep. Subsequently, on two occasions, three and four drachms of chloroform were administered in vapour, and with these small doses of morphia. He became more quiet, but showed no signs of recovery. He was conscious that he was dying, and complained only of pain in his leg. He died at ten o'clock P.M. on Tuesday, August 17th, *i. e.*, three days after the first attack of illness.

On an inspection of the body, the lungs were found in a healthy state. The heart was quite empty and flaccid. The mouth and tongue presented marks of corrosion. The stomach contained half-a-pint of dark-coloured fluid, but the intestines were empty. The stomach was examined by Dr. A. Bernays. Its mucous surface was pale and white, except towards the intestinal end, where there was a slight redness. The surface was covered with a slimy liquid. There was some decomposition. The liver and kidneys were bloodless.

The chemical analysis was made by Dr. Bernays. The contents of the stomach were alkaline. There was some farinaceous food in them. There were no indications of cyanide of potassium; but some traces of antimony were found in the tissues of the stomach, as also in the kidneys and liver. There was no trace of morphia in the stomach or its contents. More than a week had elapsed after death before these analyses were made.

Upon this evidence, the jury returned a verdict to the effect, "That deceased, while in an unsound state of mind, took cyanide of potassium, which accelerated previous exhaustion, and resulted in death."

We cannot accept this verdict, nor can we perceive any reasonable grounds upon which such a verdict could be based. It is clear from the evidence, that the deceased was labouring under great cerebral excitement before any medicines were administered to him. It is probable that there was a diseased condition of the brain to account for this sudden attack; but unfortunately this organ was not examined, so that the existence of cerebral disease, adequate to destroy life in two or three days, must be a matter of speculation.

During his short illness, the deceased had taken three drugs, all capable of causing death—morphia, chloroform, and cyanide of potassium: the two former prescribed for him, the latter secretly taken by himself. The doses of morphia were small, given at sufficient intervals to prevent any poisonous effects from absorption, and there is no evidence to show that any symptoms of poisoning with morphia were at any time apparent. In reference to that formidable poison, cyanide of potassium, the evidence, whether physiological or chemical, fails to show that it operated in any way to accelerate death. According to legal decisions, what accelerates causes; and we are bound to look with great care to all the medical circumstances of this remarkable case before we assent to the verdict of the jury.

The deceased had clearly cyanide of potassium in his possession, and when taxed with placing some of this mineral in his mouth, he did not deny it. There is no chemical evidence of what the two white lumps which fell from his mouth consisted. Mr. Maggs states that the *smell* alone proved to him that they were lumps of cyanide of potassium, but they were neither weighed nor analysed. That the substance had a corrosive property is apparent from the condition of the mucous membrane of the mouth. So far, the theory is supported that deceased may have put some of the cyanide into his mouth during the temporary absence from his room of Dr. Aldridge and Mr. Maggs. It also follows that the substance was long enough in his mouth to pro-

duce a well-marked chemical action on the mucous membrane of the gums and tongue. It may also be inferred from the evidence, that the interval between the ejections of the two portions, was at least five minutes. One of the medical witnesses, who gave an opinion that cyanide of potassium was *not* the cause of death, stated that the quantity of this mineral which deceased had put into his mouth was about *ninety grains*! The corroded parts of the mouth were not chemically examined. The evidence of Dr. Bernays clearly shows that there was no cyanide of potassium in the stomach or its contents, nor any indications, such as are usually found, of a corroded state of the mucous membrane of the œsophagus and stomach.

Assuming that deceased had put so large a quantity as ninety grains of this mineral into his mouth and kept it there for five minutes without swallowing any portion of it, and that it was retained long enough to corrode the mucous membrane, we can only draw the inference that it must have been during that time absorbed and carried into the blood. The operation of this poison is generally rapid and well marked. The symptoms, indicated by unconsciousness, spasmodic breathing, and tetanic convulsions, come on in a few minutes, and a dose of a few grains may destroy life in from a quarter to half an hour. The interior of the stomach was not extensively reddened or corroded; and this is in accordance with the chemical result that no cyanide was there present.

In the absence of any symptom or appearance of the action of cyanide of potassium on the body, it is impossible to adopt the conclusion of the jury that this mineral in any way operated as a cause, or an accelerator of death.

The difficulty about the quantity put into the mouth and the long time which the deceased retained it there without swallowing it, in spite of its great solubility in the saliva, which would probably be more copiously secreted, still remains. It admits no explanation according to past experience. The suggestion made by Dr. Bernays, that the sample of cyanide found in the possession of deceased consisted of one-fourth of carbonate of potash, and therefore was a comparatively weak preparation, is not applicable to this case; for the ninety grains would be thereby reduced to sixty-eight grains of a poison, of which *five grains* have sufficed to destroy life.

The only conclusion which the medical and other evidence appears to us to justify, is that the deceased died from disease of the brain, probably accelerated by the frequent administrations of chloroform. The condition of the heart and the dark colour and fluidity of the blood (although decomposition may also account for these appearances), are consistent with the fatal effects of chloroform in cases of latent cerebral disease. Chloroform has not hitherto been discovered in the fluids and solids of a dead body after so long a period as a week. Had the blood and tissues been examined for chloroform soon after death, traces of this narcotic vapour might have been found in them.

There are some reports that there is likely to be a *renire de novo* in this case; that an application has been made to the Secretary of State for power to exhume and re-examine the body. We do not see what good purpose, either of a public or private nature, could be obtained by this procedure. It might include a second chemical analysis of parts not examined; but, in our view, this branch of the scientific evidence has been exhausted by Dr. Bernays. He found traces of antimony of old standing. There were no traces of morphia or cyanide of potassium, and it would be absurd to suppose that any traces of chloroform still remain in the decomposed body.

We have here professed to deal only with the cause of death. The deceased did not die from the effects of poison, but from natural disease. It may have been here, as it frequently happens under latent disease of the heart or brain, that the chloroform-vapour operated to accelerate death. It was certainly not caused or accelerated by the cyanide of potassium. In these remarks, we have confined ourselves chiefly to only one of the medico-legal questions arising out of this remarkable case; namely, the *cause of death*. In the conclusion which we have drawn, we have had

no intention to cast blame on the medical gentleman who thought himself justified in administering full doses of chloroform on several occasions, for the purpose of alleviating the cerebral excitement under which the deceased was labouring. It is well known that this vapour has, even in experienced hands, accumulated in the blood, and either caused or accelerated death from latent natural disease. This has happened in many cases in which the fatal results could not be foreseen.

In reference to the other questions, bearing on life-insurance and testamentary capacity, but a few additional observations are required. If the deceased put lumps of cyanide of potassium into his mouth, it is clear that he did not swallow any of it, and that he did not die from the effects. He would hardly have survived for twenty-four hours the effects produced by this poison in a few minutes, as a result of absorption. There is no ground to impute suicide; and an attempt at suicide does not legally invalidate a life-insurance. The cause of death can hardly affect the question of the validity of the two wills; one bequeathing £20,000 to the daughter of the druggist to whom deceased was engaged; and the other directing the whole of his property to be devoted to the diffusion of atheism and socialism. A testamentary act of this latter kind might be taken as an indication of eccentricity or insanity! The date of the documents, and the circumstances under which they were executed, will show whether the deceased had or had not a proper disposing capacity at the time when they were made. No question arising out of his last illness and death can at all affect the rights of these claimants, and they require no consideration in this place.

THE QUEEN'S HOSPITAL, BIRMINGHAM.

ON Monday next, an adjourned meeting of the governors of this institution will be held in the Board-Room, to decide what course shall be taken with reference to a report of a subcommittee on the income and expenditure of the hospital, which report was approved by the General Committee in June last. It will further be proposed that the ticket system, which has been in force since the establishment of the hospital in 1840, shall be abolished; and that the Committee shall be empowered to make such changes in the management of the hospital for the admission of patients as may be necessary to give effect to the proposed abolition of tickets.

We have been induced to call attention to this report, and to the points which will be fully discussed by the meeting on Monday, because the issues raised are important, not only to the supporters of the hospital immediately concerned, but to all hospital managers in these days of hospital abuse.

The working men, chiefly members of the Hospital Saturday Committee, led by their champion Mr. Sampson Gamgee, objected to the abolition of tickets, because they feared a system of espionage would be instituted which would be distasteful to the working men as a body. So strong and decided was the opposition to the scheme at the meeting in July, that the supporters of it, in the interests of the hospital, thought it best not to push matters to a division, but to adjourn the meeting until November 1st. With reference to the objections raised by the working men, we again express our opinion that Hospital Saturday has been a mistake from the first; as it has led the working classes, who are already too fond of availing themselves of the advantages hospitals offer to them of obtaining free medical attendance, whether they can afford to pay a medical man or not, to look upon these charities as institutions formed more for their own benefit than for the necessitous poor. We regret to learn that the Committee will probably offer, as a compromise to the working classes, to let the adoption of a system of careful and efficient inquiry into the fitness of the patients applying for relief stand in abeyance for the present; and to institute for it a registration fee of one shilling, which sum will be exacted from all applicants, however long under treatment. We urge the Committee to pause before they agree to any such compromise as this; because the experience of all hospitals which have tried the registration fee is, that it tends rather to increase than diminish the number of patients, and only ex-

Experiment 10. Dog weighing 11 kilogrammes.—12.2 cc. of bile injected into the duodenum (*b*, Fig. 10). Unfortunately, there is a hiatus in the curve immediately before the injection, owing to a loss of the bile; nevertheless, it is evident that increased bile-secretion followed the injection when the biliary flow had become fairly constant. Nine grains of podophylline, triturated in a mortar with 12 cc. of bile, were injected into the duodenum (*p*). A rapid increase in the bile-secretion ensued; but soon it diminished, and three hours after the injection it was lower than it had ever been. In this remarkable experiment, therefore, the *diminution* of bile-secretion after podophylline was far more remarkable than its increase; indeed, the increase might possibly have been owing to the injected bile, and not to the podophylline. Towards the close of the experiment, the pulse became weak, but not excessively so.

AUTOPSY.—The mucous membrane of stomach and whole length of small intestine were intensely red. The small intestine contained a large quantity of fluid. The large intestine contained a considerable quantity of liquid faecal matters. There was, therefore, abundant evidence that excessive purgation was imminent.

Fig. 10.

Fig. 12.

Fig. 11.

- Fig. 10.—Secretion of bile in a dog that had fasted eighteen hours. *b*, 12.2 cc. of bile; *p*, nine grains of podophylline in 12 cc. of bile injected into duodenum.
 Fig. 11.—Secretion of bile in a dog that had fasted nineteen hours. 6 cc. of bile and 6 cc. of water injected into duodenum at *b* and *b'*. Four grains of podophylline in 6 cc. of bile and 6 cc. of water injected at *p*.
 Fig. 12.—Secretion of bile in a dog that had fasted eighteen hours. 0.5 cc. of bile and 2.5 cc. of water injected into duodenum at *b*; the same, together with one grain of podophylline, injected at *p*, *p'*, and *p''*.

In this experiment, the intestinal irritation and the purgative effect were far greater than they were in any of the previous experiments with podophylline, and it is evident that the principal change in the bile-secretion was *diminution*. It therefore ap-

peared that, with a powerful solvent such as the bile, nine grains of podophylline produced a too violent effect upon the alimentary canal. The previous experiments having shown that, with a slighter action on the intestine, there was a more powerful action on the liver, suggested that, with a smaller dose of podophylline given in the biliary solvent, an action on the liver would be evident, and that this would follow the injection more speedily than it had done in the experiments where the podophylline was not given in a state of solution. The next experiment realised this anticipation in a very striking manner.

Experiment 11. Dog weighing 17.1 kilogrammes.—The bile-secretion was about 2 cc. per fifteen minutes before injection into the duodenum of 6 cc. of bile and 6 cc. of water (*b*, Fig. 11). The subsequent increase of secretion was trivial. An hour after this, four grains of podophylline, in the same quantity of bile and water, were injected (*p*). About half an hour afterwards, a great acceleration of the biliary flow began, and lasted about an hour. In one of the periods of fifteen minutes, no less than 5 cc. of bile were secreted; a quantity never noticed in any other experiment, even on larger dogs. When this great hepatic excitement had disappeared, 6 cc. of bile and 6 cc. of water were again injected (*b'*), as in the first instance. The fall in the secretion was for a time arrested; but within three hours after the administration of the podophylline, the action of the liver had almost entirely ceased. The pulse was weak, but not extremely so.

AUTOPSY.—The mucous membrane of the duodenum was intensely vascular, but that of the remainder of the small intestine did not show an increased vascularity nearly so great as in the previous experiment. The upper three-fourths of the small intestine contained very decided evidence of purgative effect. The gastric mucous membrane had a dull red appearance.

Experiment 12. Dog weighing 7.9 kilogrammes.—In this case, 0.5 cc. of bile and 2.5 cc. of water were injected into the duodenum (*b*, Fig. 12), without producing any noteworthy effect. The same quantity of bile and water, containing one grain of podophylline, was then injected, and the dose was twice repeated (*p*, *p'*, *p''*). After the first dose, an increase in the biliary secretion was perceptible in half-an-hour; it never became very marked, and it lasted only about an hour. The second, but especially the third dose, was followed by a fall in secretion, probably owing to purgative action taking place.

AUTOPSY.—There was evidence of severe irritation of the mucous membrane of the upper half of the small intestine; and a decided evidence of purgation in this portion of intestine. The lower part of the small intestine was almost quite empty and dry.

Composition of Bile before and after Podophylline.—The next question to be answered was evidently this, Is the increase in the quantity of bile after podophylline merely due to an increase of water, or are the bile-solids also increased? The bile secreted by dog 11, between the second hour and a half and the third hour, and that secreted an hour and a quarter after the administration of podophylline, were analysed with the following results. (Table II.)

TABLE II. - Podophylline.

Experiment 11.	Before.	After.
Water	90.83	91.07
Bile-acids, pigments, cholesterine, fats	7.75	7.84
Mucus	1.00	0.60
Ash	0.42	0.49
	100.00	100.00
Velocity of secretion per half-hour	4.6 cc.	9.6 cc.

It thus appears that, notwithstanding the great velocity of bile-formation, the special bile-solids were not diminished; the only noteworthy diminution being in the amount of mucus. This remarkable result was confirmed by the following analysis of the bile in Experiment 12. The table shows the composition of the bile secreted before and during the increase of the secretion after the podophylline was given.

TABLE III.—Podophylline.

Experiment 12.	Before.	After.
Water	94.26	94.28
Bile-acids, pigments, fats, cholesterine	4.66	4.68
Mucus	0.73	0.70
Ash	0.35	0.34
	100.00	100.00
Velocity of secretion per half-hour	1.86 cc.	2.47 cc.

Results of the Experiments with Podophylline.—1. Podophylline, when injected into the duodenum of a fasting dog, increases the secretion of bile. It is inferred that the increased biliary flow in the preceding experiments was due to increased secretion, and not merely to expulsion, because the gall-bladder had been wellnigh emptied by compression, and the cystic duct had been clamped: moreover, the increased flow was far too prolonged in some of the experiments to be attributable to spasm of the larger bile-duets; therefore, an increase in secretion must have been the cause. 2. When the bile is prevented from entering

the intestine, podophylline acts less powerfully and less quickly than when bile is introduced. 3. Augmentation of the biliary secretion is most marked when the purgative effect is not severe; indeed, if the purgative effect be very decided (*Experiment 11*), diminution and not augmentation of the biliary secretion may be the chief result. 4. Podophylline purgation is apparently due to a local action, for the irritation of the intestinal mucous membrane extends gradually from above downwards. 5. The bile secreted under the influence of podophylline, although it may be in increased quantity, contains as much of the special biliary matter as bile secreted under normal conditions.

ACTION OF ALOES.

Although aloes has been found by Röhrig to accelerate the biliary secretion, we were anxious to compare its action, as ascertained by our method, with that of other substances; and we also desired to know the composition of the bile secreted before and after its administration.

Experiment 13. Dog weighing 8.6 kilogrammes.—Sixty grains of aqueous extract of Socotrine aloes in 12 cc. of water were injected into the duodenum (*a*, Fig. 13). A decided increase in the biliary secretion was perceptible within half-an-hour thereafter. After attaining a maximum about an hour and a half after the administration of the drug, the secretion gradually fell; but although the experiment was continued for seven hours after the aloes was given, the effect had not disappeared.

Fig. 13.

Fig. 13.—Secretion of bile in a dog that had fasted eighteen hours. Sixty grains ext. aloes Soc. in 12 cc. water injected into duodenum at *a*.

AUTOPSY.—The aloes had extended along two-thirds of the small intestine, which contained about an ounce and a half of viscous fluid as the only evidence of purgation. There was a decided increase in the vascularity of the mucous membrane in this part of the intestine. The stomach contained a little mucus. Its mucous membrane was pale.

Experiment 14. Dog weighing 5 kilogrammes.—Sixty grains of extract of Socotrine aloes in 12 cc. of water were injected into the duodenum (*a*, Fig. 14). As in the previous experiment, the subsequent increase in the biliary secretion was decided within half an hour, and became very strongly marked.

AUTOPSY.—The aloes had extended half way down the small intestine. This portion of intestine contained about two ounces of viscous fluid; and its mucous membrane, together with that of the stomach, was intensely red.

Experiment 15. Dog weighing 9.5 kilogrammes.—In this experiment, it was proposed to test the effect of aloes on the liver when wellnigh exhausted: accordingly, at the sixth hour of an experiment on a dog that had fasted the usual period of eighteen hours, twenty grains extract of Socotrine aloes in 5 cc. of water were injected into the duodenum (*a*, Fig. 15), and this dose was repeated in half-an-hour. The secretion of bile was increased, but the effect was not very marked; nevertheless, the result is noteworthy, seeing that in this case there was a great secretion of bile during the first four hours of the experiment. (Fig. 15.)

Fig. 14.

Fig. 15.

Fig. 14.—Secretion of bile in a dog that had fasted eighteen hours. Sixty grains of Extract of Socotrine Aloes in 12 cc. of water injected into duodenum at *a*.

Fig. 15.—Secretion of bile in a dog that had fasted 18 hours. Twenty grains of Extract of Socotrine Aloes in 5 cc. of water injected at *a* and at *a'*. (The curve during the first three hours is omitted.)

Composition of the Bile before and after Aloes.—Table IV shows the results of the analysis of the bile in Experiment 13, secreted before and during the first two hours after the administration of the aloes.

TABLE IV.—*Aloes.*

Experiment 13.	Before.	After.
Water	84.11	91.44
Bile-acids, pigments, cholesterine, fat	12.45	7.53
Mucus	1.77	0.38
Ash	1.67	0.65
	100.00	100.00
Velocity of secretion per half-hour	1.5 cc.	2.65 cc.

Table v gives the result of the analysis of the bile before and after the administration of aloes in Experiment 14.

TABLE V.—*Aloes.*

Experiment 14.	Before.	After.
Water	83.93	86.75
Bile-acids, pigments, cholesterine, fat	12.30	10.79
Mucus	2.74	1.49
Ash	1.03	0.97
	100.00	100.00
Velocity of secretion per half-hour	0.66 cc.	2.2 cc.

It is evident from Tables IV and V, that, under the influence of aloes, the bile became more watery; nevertheless, the amount of bile-solids secreted per unit of time increased.

Results of Experiments with Aloes.—1. Sixty grains of the extract of Socotrine aloes, when placed in the duodenum, powerfully stimulated the liver. 2. Under its influence, the liver excreted a greater quantity of biliary matter in a given time, although the bile was rendered more watery. 3. Coincident with the marked action on the liver, there was only a slight purgative action.

ACTION OF RHUBARB.

The following experiments show that rhubarb is also a very remarkable hepatic stimulant. The ordinary infusion of the *British Pharmacopœia* was made with Indian rhubarb; it was then filtered and concentrated until 5 cc. contained the active part of seventeen grains of rhubarb. This was the dose employed.

Experiment 16. Dog weighing 22.2 kilogrammes.—5 cc. of the above infusion of rhubarb were injected into the duodenum four times in succession (r, r', r'', r''' , Fig. 16). Within half-an-hour after every dose, there was an increase in the biliary secretion.

Fig. 16.

Fig. 17.

Fig. 16.—Secretion of bile in a dog that had fasted fifteen hours. 5 cc. of a concentrated infusion of rhubarb injected into duodenum at $r, r', r'',$ and r''' .

Fig. 17.—Secretion of bile in a dog that had fasted eighteen hours. Respiration improved at a . 5 cc. concentrated infusion of rhubarb injected into duodenum at $r, r',$ and r'' .

cludes the pauper class, who, as we showed last week, do not form an appreciable number of the cases attended at the Queen's Hospital. If the Committee have felt it difficult to meet the expenses incidental to the treatment of the cases for which they have to provide under the ticket system, we are certain that a few months' experience of the working of the registration fee will convince them that it will be impossible to meet the demands made on their resources; and, what is far worse, without a proper system of inquiry, the adoption of such a course will be one more retrograde step in the march of hospital abuse; for directly those unscrupulous people who already frequent our hospitals in large numbers, find the doors of a great general hospital open to them without check or fear of inquiry, they will readily avail themselves of the opportunity the small registration-fee will afford to obtain the medical attendance they need without incurring the expense of a doctor's bill.

We are at a loss to understand why the Committee of the Queen's Hospital, which was the first in the United Kingdom to institute a searching inquiry into the circumstances of the patients attending the out-patient department, by means of the Charity Organisation and Mendicity Society, should so forget the sound principles of hospital management which formerly made their institution popular, as for the moment to entertain the idea of consenting to the adoption of a course which will make their hospital, we are convinced, more abused than any charity of the kind in the whole country.

Once more, we earnestly beg the Committee to be firm in the course they had decided to take in July; to adopt the free system by all means; to establish, if they think it desirable, a registration-fee—though we doubt the wisdom of this; and, above all, to insist upon the necessity of at once securing a careful and efficient system of inquiry into the fitness of all applicants for relief by means of the Charity Organisation Society, or some other body equally capable of conducting such an investigation with tact, discretion, and a due regard to the feelings and interests of the really deserving poor. If they pursue this course, they will earn the thanks of all who are interested in the great question of hospital reform; and, in addition, we are convinced they will insure for their institution that full measure of public support it at present so greatly needs.

THE DISPOSAL OF THE DEAD BODIES OF INFANTS.

THE recent discovery at an undertaker's premises in Southampton of the bodies of thirteen infants brings forward again a matter which has often been discussed, but still remains wholly unsettled. Similar discoveries, only differing in the number of bodies being smaller, have from time to time occurred with various results. Sometimes an inquest has been held, as in the case which occurred at the Bethnal Green Workhouse, where the bodies of four infants were by the merest accident discovered in a coffin supposed to contain only the body of a woman. In this case, the undertaker was severely censured by the coroner's jury; but, beyond this and the loss of a contract, which was probably not of much consequence to him, nothing more was done, for the simple reason that, legally, there was at the time no offence. Were such a discovery to be made now, and it were proved that the undertaker fully intended to conceal the fact of there being more than one body in the coffin, he could be proceeded against under Clause 19 of the Births and Deaths Registration Act, 1874, and fined £10 for the concealment alone. If, in addition to this, he attempted to bury a body without the usual certificates, he would be liable to another penalty of £10.

But, in the case before us, as in previous cases more closely resembling it, another difficulty arises. Is it an offence to bury the body of a child elsewhere than in a public burial-ground? That it is an offence against order and decency is undeniable, and that its general adoption would be attended with the greatest inconvenience and even danger, is equally plain. But is it an indictable offence to bury a child's body in a garden, field, or under a shop or dwelling-house? To answer this, we had better examine the laws which seem to bear upon the subject.

By the 24 and 25 Vict., cap. 100, sec. 60, it is enacted that, "If any woman shall be delivered of a child, every person who shall by any secret disposition of the dead body of the said child, whether such child died before, at, or after its birth, endeavour to conceal the birth thereof, shall be guilty of a misdemeanour, and, being convicted thereof, shall be liable, at the discretion of the Court, to be imprisoned for any term not exceeding two years, with or without hard labour". Dr. Alfred Taylor, in his *Principles and Practice of Medical Jurisprudence*, remarks on this:—"Various interpretations have been put upon the terms 'concealment' or 'secret disposition' of the body. . . . It will rest with the judge to determine whether the body has been so disposed of as to constitute legally a misdemeanour." It is difficult, if not impossible, to separate the disposal of the body from the concealment of birth, which may not have been the case with any of the thirteen bodies discovered at Southampton. Still there was undoubtedly a wilful concealment on the part of the undertaker's wife, who admitted the presence of only one "little still-born baby" on the premises, and added that there were no other dead children there. But let us now look at the recent Act already referred to (37 and 38 Vict., cap. 88), and see whether the most recently passed measure contains any regulations which may guide us. By Clause 17, every person who "buries" a body must either receive a burial certificate or notice from the undertaker, or must, within seven days after burial, send the registrar notice of such burial. By Clause 18, the person who has control over or ordinarily buries bodies in any burial-ground is not permitted to bury as "still-born" the body of any child without a certificate or declaration (the former from a medical practitioner, the latter from an authorised informant) or the coroner's order. The burial of a child which has lived for however short a time as a still-birth would expose the parents or custodians of the child to a penalty of forty shillings for failing to give notice of the birth, and a similar sum for not reporting the death.

As we have already seen, the undertaker, who smuggled the body into another coffin, would, on discovery, be liable to a penalty of £10, as would also the person wilfully burying the body under such circumstances. Again: making, giving, or using a false certificate of still-birth is punishable by imprisonment with hard labour, or even penal servitude. Thus it would seem as if recent laws had effectually guarded against the possibility of fraud or unfair play.

But, as has been frequently pointed out, the facilities for the disposal of the bodies of infants are so great, that detection is, and must be, a matter of difficulty. Their small size, the narrow line drawn between still and live birth, the difficulty of proving wilful concealment or false pretence—these and a host of other circumstances surround the matter with almost insurmountable difficulties. To give only one more; that much abused individual the undertaker, whose functions the recent Church Congress would supersede altogether, has been only too often willing to "undertake", amidst other offices, unsanitary if not unlawful ones. What led to the detection of the Southampton case was the effluvia arising from the decomposition of these thirteen bodies. How many similar cases may have occurred and escaped notice! It has been repeatedly suggested, and with great justification, that the State should take charge of all burial arrangements. If this were done, all such irregularities being punished with dismissal, and burial except by the State officials being illegal, it would not be worth anyone's while to offend. But, as this must be yet in the future, it becomes necessary to inquire, firstly, whether any hardship is inflicted by the present burial arrangements on the lower classes; and, secondly, whether there be a remedy. To the first question we must answer in the affirmative.

Take the case of the wife of a working man, to whom pence, to say nothing of shillings, are a matter of serious import. She is delivered of a child which just survives its birth, living a few minutes, or even drawing one feeble breath. She is attended by a medical man or midwife, who conscientiously tells what ought to be done, viz., inform the registrar, have the birth and death registered, and the body buried accordingly. It simply means that, whereas as a still-birth the

body might have been buried for half-a-crown or less, an expense varying from four to ten shillings must be incurred. That this is no imaginary case, every obstetric practitioner must admit. In one case which came to our knowledge, where a child was delivered by the forceps, only to breathe and die, the medical attendant was bitterly reproached by the mother for not giving her a false certificate, and saving, to use her own words, "all that expense". Again, a delicate matter is involved, which, however, must be faced, and that is the subject of baptism and funeral rites. It is simply preposterous to expect a working man (be his religion what it may) to see the justice of burying with funeral rites, and at the loss of half-a-day's work, an infant that has merely gasped; while he knows well that, but for what he would probably term a "snake", he might have been saved all that trouble and expense. It cannot be denied that such considerations as these are most probably at the bottom of such disclosures as the recent one at Southampton.

But is there a remedy? We think there is, and it is this. In every parish there ought to be a mortuary, which, besides affording shelter for all bodies found in the streets or elsewhere, should be a receptacle for the bodies of infants awaiting burial. These might be removed periodically to the cemetery or burial-ground. The burial fees ought to be uniform throughout the kingdom, and all infants under a certain age, say seven days, should be buried for the same fee as a still-birth. By thus affording people facilities for removing from their wretched homes, which often consist of one room only, the body of an infant, till such time as they can raise means for its burial, and removing this utterly senseless pecuniary distinction between burying still-births and dead infants, which are seldom larger, and often much smaller, the principal inducement to fraudulent and secret burial would be removed.

It should be made a misdemeanour to bury any body, whether of a still-birth, deceased child, or adult, in any but a public burial ground. Possibly the undertaker at Southampton may have been guilty of obtaining money under false pretences, but if so, this is an accidental circumstance, and quite apart from the irregular and indecent disposal of these bodies under the floor of his shop, for which there is only too much reason to fear that there is no penalty.

MR. CORDER, of Earl's Court Road, Brompton, has just published a most interesting series of views of the house and grounds formerly occupied by the immortal Hunter.

THE attacks of cholera in Delhi and the surrounding districts have disappeared. Fifty-one deaths from cholera were reported from the city of Lucknow in a week.

IN the case of alleged libel by William Kenny on Captain Charles Mercier, of the Hospital Saturday Fund, an application for postponement till the next sessions was made at the Old Bailey on the defendant's behalf, and, being unopposed, was agreed to.

THE Royal Commission to inquire into the practice of subjecting live animals to experiments for scientific purposes has held several sittings during the past week, for the examination of witnesses on both sides of the question. All the commissioners have been present.

MR. IRVING, assistant to Dr. Ryott, of Thirsk, Yorkshire, while riding, at about half-past one o'clock on Sunday morning, along the high road leading to the village of Kilvington, was stabbed twice by some unknown assailant, but fortunately received only very trifling injury.

IT will be observed that Sir Trevor Lawrence, Bart., son of the late Sir William Lawrence, the eminent Surgeon of St. Bartholomew's Hospital, is a candidate for the parliamentary representation of Mid-Surrey in the Conservative interest. Sir Trevor Lawrence was formerly a Surgeon in the Indian Army, and may be expected to take a warm and intelligent interest in medical and sanitary affairs.

IN the course of his report to the Chairman and Committee of the Royal Humane Society for the year 1873, Mr. Archer Farr alludes to the necessity of providing, if possible, on additional parts of the Thames, similar accommodation to that afforded by the receiving-house at Waterloo Bridge, of which he is medical officer.

WE regret to have to announce the death of M. Lorain, Professor of Medical History to the Faculty of Medicine in Paris. M. Lorain, who was only fifty years of age, died very suddenly of what is believed to have been an attack of meningeal apoplexy. He succeeded the late M. Daremberg in the professorship about two years ago.

MR. HUMPHREYS, Coroner for East Middlesex, held an inquest this week, relative to the death of Mr. Robert Stewart, aged twenty-nine years, surgeon, who died from injuries received through being crushed between the train and platform at the Bow Station on last Thursday night. The jury returned a verdict of accidental death, with a recommendation that something be placed at each staircase to prevent passengers from proceeding on the platform while a train was in motion.

THE attention of the Council of the Royal College of Surgeons having recently been drawn to the order issued by the Local Government Board, whereby a Fellow or Member of the College, unless he possessed a registerable *medical* qualification, was disqualified from advising whether or not a medical officer under this Board was justified in performing an amputation, the Council of the College requested the President, Sir James Paget, and the Vice-Presidents, Messrs. Hewett and Birkett, to make such representations on the subject of this order as they might think proper to the President of the Local Government Board. The result was communicated to the Council at the last meeting in a letter from Mr. Fletcher, the Assistant-Secretary, stating that an early opportunity would be taken by his Board to amend Article II of the General Order, relating to the qualification of those entitled to give certificates authorising Poor-law medical officers to perform amputations. The surprise is, that such an extraordinary "order" should ever have been passed, as by its operation it would exclude the most distinguished and competent Fellows of the College from giving the necessary surgical opinion in favour of an operation.

PROVIDENT DISPENSARIES AND THE HOSPITAL SUNDAY FUND. CONSIDERABLE dissatisfaction is expressed as to the manner in which the provident dispensaries are affected by the Hospital Sunday collection. In the Report of the Royal Pimlico (Provident) Dispensary, it is said:

"The question has been raised in the public mind, whether provident dispensaries have received a fair proportion in the distribution of the Metropolitan Hospital Sunday Fund. With reference to this question, it may be mentioned that the clergy of the district served by the Royal Pimlico Dispensary during the past year sent above £1,100 as the result of the sermons preached by them. The amount of the share received by this institution was £93:15:9, whereas one sermon preached in aid of the dispensary alone would probably have produced from £150 to £200. Therefore the Committee, seeing the deficiency in their receipts, cannot but feel the absolute necessity that local charities should be fully provided for before money is remitted for general metropolitan purposes."

The managers of the Haverstock Hill Provident Dispensary have also had the same subject under their consideration. Being dissatisfied with the award which they received last year (£12:15:6) they asked the local clergy for special grants from their Hospital Sunday collections. These amounted to £70, a sum which gives a better indication of the value of this institution (which has now four thousand enrolled members) than the trifling grant from the Hospital Sunday Fund. We have before pointed out that this is one of the difficulties with which the Hospital Sunday has to grapple. Wherever institutions are characterised by special features which recommend them to the liberality of the district in which they are situated, they will find their advantage in appealing to their neighbours, and not to a general fund.

The provident dispensaries present such a special feature, and one which is just now attracting a great deal of public attention; and it is not surprising that the managers should wish to reap some benefit from the efforts they have made to bring about a much needed reform. They are trying to *unpauperise* the working classes (if we may be allowed the word). Many of the more intelligent of the clergy are well aware of this, and are willing to give them their aid. Why, then, should they forego an advantage which seems to be justly their due?

THE "CORNWALL" OUTBREAK OF TYPHOID.

MANY fresh cases of typhoid have occurred on board the *Cornwall* school-ship during the week, and one death has taken place. Eight cases have been admitted to the Seamen's Hospital, Greenwich, making in all thirty-four received by this institution. Six have been taken to St. Bartholomew's. The total number of sick since the commencement of the outbreak is nearly eighty. Owing to increasing numbers, it was found necessary, in addition to the boat-house and small permanent hospital, to erect a tent, which, as an extra protection from wet, has a flooring of boards laid over gratings. As regards means of prevention, we are glad to find that the mode of water-transit has been altered, and that the supply is derived from a pipe laid down directly from the shore to the ship: an arrangement similar to that formerly in use on the *Dreadnaught*. The water-tanks have also undergone cleaning and whitewashing, the good results of which, it is to be hoped, will shortly become apparent. A further step has been taken by the Committee of the *Cornwall*, in making arrangements with the port sanitary authority for the use of the *Rhin*, a vessel stationed at Gravesend, belonging to the said authority, to which thirty-five cases have already been sent in a steamer hired for the purpose; and we may, therefore, hope that the weatherbeaten temporary hospitals at Purfleet will be shortly relieved of their occupants.

MORTUARIES IN THE METROPOLIS.

We believe it is now universally recognised by all sanitary authorities that, if the moral and physical health of the poorer classes is to be preserved, it is necessary that some provision should be made in the crowded parts of the metropolis, and especially among those who occupy one or at most two rooms, for the temporary accommodation of the dead in the interval that elapses between the death and burial. In the Sanitary Act, 1866, clauses were introduced giving power to the local authority to construct mortuaries, and to provide places for *post mortem* examinations, etc.; but, such clauses being permissive only, such mortuaries have not been very extensively established. This doubtless has arisen from two or three causes: first, unquestionably, from the ignorance on the part of the sanitary authorities of the value of such provision, and probably also from their indifference; but in many instances it has also occurred that the local authority has been hindered by the great difficulty which exists in procuring suitable sites; and, as the various vestries and boards of works possess no power of compulsory purchase, it has happened that, after three or four attempts to agree upon a locality, the subject has been abandoned altogether. Certain scandals arising from the want of such accommodation having occurred in some of the smaller parishes which go to make up the Strand Board of Works, a resolution, on the motion of Dr. Joseph Rogers, was unanimously carried, to memorialise the Metropolitan Board, praying that Board "to seek from Parliament, in the ensuing session, authority to construct mortuary buildings in the metropolis in such situations as the requirements of the neighbourhood may render requisite, together with compulsory powers for the acquisition of the necessary sites". We regret, however, to note that the Metropolitan Board has declined to take up the subject, although it would appear that Mr. Richardson, in bringing up the report of the Works Committee, to whom the memorial had been referred, and in moving its adoption, stated "that the mortuary question was beset with difficulties in London. Local boards had no power to purchase land for the erection of mortuaries. Objections were also raised to the erection of mortuaries by the inhabitants; and, even supposing that a mortuary

was erected in conjunction with several parishes, by the existing law it was illegal to convey a dead body from one parish to another. Individually, the Board did not oppose mortuaries, and would be glad to see them erected; but it was a matter which should be dealt with by the local boards, and not by the Metropolitan Board." We should have imagined that the statement which we have quoted would have carried conviction to the Metropolitan Board of the propriety of the course adopted by the Strand Board in requesting them to deal with this subject; for what body could be so well fitted as that which possesses the power of surveying the metropolis as a whole? Again, the Central Board, without incurring unnecessary expense, could have secured from Parliament powers of compulsory purchase; but now, by its decision, it throws on each of the several boards of works the onus of obtaining such powers for themselves; that is, if they be so minded. It is impossible, however, for the subject to remain where it is. The opportunity has been offered to the Metropolitan Board to deal with a great sanitary evil; and, with a full knowledge of its existence, it has been deliberately ignored. We look, therefore, to the Home Office, or to the Local Government Board, to make such alterations in the law in the coming session of Parliament as will effectually deal with the question.

IMPROVED DWELLINGS.

LAST week, an extraordinary general meeting of the members of the Improved Industrial Dwellings Company (Limited) was held at the Mansion House, to consider a special report of the Directors recommending the creation of additional capital to the amount of £250,000, by the issue of 25,000 shares of £10 each. The present capital is £250,000, of which £212,500 has been paid up. £84,000 has been borrowed from the Public Works Loan Commissioners, repayable by eighty half-yearly instalments; and £22,721 has been paid by shareholders in advance of calls. £323,068 has been expended on land and buildings. The reserve fund for equalisation of dividends is £17,000, and for other purposes about £9,000. From the company's formation, a dividend of 5 per cent. has been paid. The company had now 2,199 tenements in different parts of London, accommodating 12,150 persons. The rate of mortality for the nine years last past had been 16 per 1,000 in the company's dwellings, against 23.6 per 1,000 in the whole metropolis. The density of population in the metropolis averaged 42 per acre, but in the company's dwellings it was 750 per acre; yet the death-rate of persons over a year old was 17 in the metropolis, and only 10.35 in the dwellings. The birth-rate was proportionately excessive in the dwellings; but, in comparison with the rest of the metropolis, the death-rate of infants was only 1.7 per 1,000 higher. The chairman (Sir Sydney Waterlow, M.P.) moved the adoption of the report, which was seconded by Mr. Alderman Finnis, and carried unanimously. This most admirable company, unlike many pseudo-philanthropic building societies—which are largely jobbed—is a model of economy and efficiency. Its financial management is sound, and it is in all respects a most valuable association.

A HOSPITAL SOLD.

WE regret to observe that the Royal Albert Infirmary, at Bishop's Waltham, in the county of Hampshire, which has remained unoccupied since its inauguration and the unveiling of the statue of the late Prince Consort (to whom the building was dedicated), which stands over the principal entrance, the statue being the gift of one of the present members for Southampton, Sir Frederick Perkins, was sold by auction on Tuesday last by Mr. Richard Austin, together with the greater part of the property, consisting of about 1,280 acres of land, which formed the estate of the late Sir Arthur Helps, K.C.B. The foundation stone of the proposed infirmary was laid by Prince Leopold, accompanied by Prince Louis of Hesse and Earl Granville, on August 4th, 1864; and the ceremony of inauguration was held in the presence of the Princesses Helena and Louise in November, 1855. The building is of the best materials and workmanship, standing high and dry

on an eminence facing the ruins of the old Bishop's Waltham Palace. The surrounding scenery is very pretty, the locality being one of the prettiest in the county of Hampshire. Some thousands of pounds have been expended upon the hospital. It has now been sold for £1000, to clear off the expenses of the building, and consequently the object for which it was intended has not been carried into effect. General regret is felt in the neighbourhood that such a noble edifice, erected for charitable purposes, inaugurated under Royal auspices, and founded by so notable a man as Sir Arthur Helps, should be allowed to pass into the market. The sale created much interest, and was largely attended.

VACCINATION IN ENGLAND.

DR. SEATON reports, in the first annual report of the working of the Vaccination Act, 1871, that if, from the 617 extra metropolitan unions, 39 unions in which there was an exceptional proportion of cases unaccounted for, and in regard of which the Local Government Board consequently remonstrated with the respective boards of guardians, be deducted, it will be found that of 653,811 births registered in the remaining 578 unions in 1872, all but 23,841, or 3.6 per cent., were finally accounted for in the vaccination registers at the time the returns were made. For the sake of comparison, it may be noted that in the same year in Scotland (where a system similar to that established in England under the Act of 1871 had been in operation for nine years with a success which the Registrar-General for Scotland has frequently reported as marvellous) the proportion of cases unaccounted for, including postponements, was 2.658 per cent. of the births. The much greater relative extent to which population is aggregated in large towns in England than in Scotland, must always make it a matter of greater difficulty to trace cases of neglect in the former than in the latter division of the United Kingdom.

DEATH OF PROFESSOR PORTA.

THE eminent Italian surgeon Luigi Porta, Professor of Clinical and Operative Surgery in the University of Pavia, died on September 10th, at the age of 75. His funeral was attended by deputations from almost all the Universities of Italy and from other scientific institutions. He has bequeathed the whole of his property, amounting to 250,000 *lire* (£10,000) to the University of Pavia; and has directed that, if it should be decided to place in the University a commemorative tablet, it shall bear an inscription of which the following is a translation: "Luigi Porta, Senator of the Kingdom, Professor for more than fifty years of Clinical and Operative Surgery in this University, a most loving citizen of Italy, member of national and foreign Academies, founder of the Porta Museum, author of many scientific works, in which, and in the instruction of Italian youth, he spent a life of seventy-five years, in dying bequeathed his property to the University, in testimony of affection and gratitude."

THE FEVER AT CROYDON.

THE Croydon Local Board are not out of their difficulties: typhoid continues to recur in waves, and one or two deaths are registered as occurring in the district every week. The Registrar-General draws attention to the fact, and points out to the public that sixty-two deaths have been registered as having taken place since the outbreak of the epidemic in February last. It appears, from the evidence which is published in the local journals, that the Board of Health are now taking active measures to keep up their constant supply of water, but will not adopt the measures that Dr. Carpenter advised; viz., that they should prevent the possibility of contamination by removing the openings by which contamination can arise. All manner of causes are put forth by various parties as reasons why the fever continues; but, whilst contamination of water-supply must take place whenever the supply is intermittent—and, from the report now before us, it appears that it is intermittent every other night for two or three hours—there is no necessity to go further for another surmised cause. We cannot understand how men elected to guard the public health can allow such a state of things to continue, and how they can think that digging a

new well and providing a new engine (which, the report before us informs us, is to be done) can do much towards staying the progress of the present epidemic. It appears that a year will elapse before the water-supply is effectually supplemented. In the meantime, the germs of disease continue to be spread, and cases arise, to the serious injury of the district in which they occur.

THE DEATH-RATE OF HULL.

THE high death-rate of Hull seems to have thoroughly aroused the inhabitants and local press in that town, and not before time; for, when a town which at one time ranked as one of the healthiest amongst the eighteen large ones reported on by the Registrar-General, becomes one of the lowest, there must be some grave negligence on the part of the sanitary authorities to account for the change. The negligence and defects which have led to this result may apparently be ranged under the following heads. 1. The authorities have evaded the spirit of the Public Health Act, by retaining a medical man at the paltry fee of £20 *per annum*, who can only act under the direction and with the sanction of the Sanitary Committee, which Committee is not composed of the most enlightened members of the Corporation. 2. Sewer-ventilation is neglected; there being, we believe, only one or two proper ventilating shafts for the whole town. Of course, man-holes cannot be counted as such, for it is well known that only the smallest quantity of foul air can escape from these places when closed. 3. The population has overgrown the power of the capillary drainage to carry the sewage into the main drains. The latter are good, no doubt, although not ventilated. 4. The Corporation has not yet adopted the Artisans' Dwellings Act, which would give them the power to destroy the fever-nests which exist, when they cannot be improved. 5. One of the principal defects is the want of a continuous water-supply direct from a pure source; and, if it must be stored for emergencies, the receptacles should be covered, so as to prevent vegetation, and any nuisance occurring near them immediately suppressed. 6. The house-drainage needs to be inspected, and the connections with the main drains made certain. In fact, when the local authorities have appointed a first-class medical officer of health, with a proper salary, so as to make him thoroughly independent, they will have made the first and one of the most important steps towards improving the health of the town. We think it is a case in which it would be the very best plan for the Local Government Board to send down an inspector, as then the causes of the unsatisfactory death-rate would be thoroughly investigated, and the best advice given as to the most approved means to be adopted for their removal.

PAYMENT FOR RETURNS.

DR. GIBBON, the Medical Officer of Health for Holborn, in presenting his Report on the sanitary condition of the district during the year ending Lady Day 1875, regrets that he is unable to set out as heretofore the full details of the birth-rate, death-rate, ages at death, and the causes of death, in the whole and in each subdivision of the district. The cause of this inability he states as follows.

"The Registrar-General in October last, without waiting for the completion of the year, suddenly declined any longer to let me as well as the other medical officers of health have the weekly returns of the births and deaths of the district, which he had regularly done for the previous eighteen years. These returns consisted of the local registrar's copies of the medical certificates of death, which, after being copied at the Central Register Office, the Registrar-General had regularly each week transmitted to the various district medical officers of health, and thus caused them to be utilised for the prevention of disease, instead of being treated as waste paper. The reason assigned by the Registrar-General for declining any longer to furnish me with these returns was, because he considered that the local registrars were entitled to receive additional pay for them from your Board, on the following grounds: first, because they were put to extra trouble; secondly, because, as the returns were put to a secondary use, they were entitled to extra payment for such use. On inquiry, however, it was found that the transmission of the returns to me entailed no additional trouble whatever on the local registrars; and, as the original death-certificates were sup-

plied gratuitously by the skill and labour of the medical profession, and merely copied by the district registrars, it was difficult to see how they could substantiate any claim to a 'copyright' in them. The only persons, as it appears to me, who have any copyright property in these death-certificates, and can fairly complain that they are put to a secondary use, are the doctors, whose skill and labour supply the information, which, after being appropriated by the State for Statistics, is used for the prevention of disease and in restraint of their own professional employment. The only persons put to extra trouble in transmitting the returns to me were the clerks in the General Register Office who posted them. After full consideration of the matter by a Committee, your Board did not deem it just that the ratepayers should be called upon to pay twice for one and the same copy of these death-certificates."

THE HOLBORN IMPROVEMENTS.

THE first fruit of the Artisans and Labourers' Dwellings Bill has made its appearance in the shape of a report presented to the Metropolitan Board of Works by Sir J. W. Bazalgette and Mr. Vulliamy. It gives particulars as to the proposed improvement of an unhealthy area adjoining Gray's Inn Road, containing ten acres and a half, nearly three-fourths of which is covered by a low class of houses, courts, and alleys "unfit for human habitation, owing to their closeness, narrowness, and bad condition". The report proposes to remove these houses, and to replace them by twenty-two blocks of buildings, surrounded by paved open spaces averaging thirty feet in width, and connected by streets and footways. Some difficulty has been experienced in ascertaining accurately the numbers of the present resident population; but it is believed that the labouring population living upon the area to be dealt with is 5,515, one-half of whom are adults and the other half children. They occupy 335 houses, averaging six rooms per house, or a total of 2,102 rooms; 981 rooms are let in single tenements to 981 families, numbering 3,218 persons, averaging 3.28 persons per room; 766 rooms are let in two-room tenements to 383 families, numbering 1,795 persons, averaging 2.34 persons per room; 355 rooms are let in three or more room tenements to 97 families, numbering 502 persons, averaging 1.4 persons per room, being a total of 2,102 rooms let to 1,461 families, numbering 5,515 persons, averaging 2.62 persons per room, with 132 empty rooms, making a total of 2,234. In addition to these, there are four registered lodging-houses, containing 43 rooms, and accommodating 144 persons. The cubic space per head varies from 284 to 900 cubic feet, and averages 540 cubic feet. This amount of house-room bears a favourable comparison with what has been provided by the various model lodging-houses constructed within the metropolis with very satisfactory results; so that, in fact, the miserable condition of the locality is not due to the overcrowding of the houses, but is attributable to the narrow courts and want of proper ventilation, cleanliness, and sanitary arrangements. It is proposed to deal with the 10½ acres included within the unhealthy area in the following manner:—2¼ acres of factories and other buildings mentioned in the scheme will remain undisturbed; one-third of an acre will be given up to the rebuilding of schools to be removed by this improvement scheme; one acre will be applied to the widening of Gray's Inn Road and the buildings facing it; 2¾ acres to the formation of new thoroughfares within the area to be dealt with; and two acres to be left in spaces for air and recreation between the new buildings, so that the open spaces over the whole area will amount to about 4¾, instead of the now existing open spaces of 2½ acres only. The new labourers' dwellings will cover an area of about two acres. It would doubtless be economy of space if the basement were converted into playgrounds for children in wet weather, and for the storage of the costermongers' barrows; but the difficulty of keeping such underground premises clean, and from being abused and used as receptacles for refuse, and thus converted into disease-breeding nuisances, has induced the framers of the scheme to forego this advantage, and they propose to provide for these requirements by roofs to be formed over a part of the otherwise open spaces. By the foregoing arrangements, a covered area for labourers' dwellings of about fifteen square feet per individual will be obtained, and not less than 500 cubic

feet of air per adult within the new buildings. It will, therefore, become necessary that each house should contain on the average five separate floors or flats, which will average about nine feet in height from floor to floor, and give a mean superficial area of about 150 square feet for living rooms and 100 square feet for bedrooms. The rooms may be divided into tenements of one, two, and three rooms each, probably in the following proportions:—1,000 of one room, or two smaller at one-room rents; 400 of two rooms; 100 of three rooms. The object at the present time, however, is to develop the practicability of effecting an efficient improvement scheme upon the area to be cleared in pursuance of the requirements of the new Act, and upon which to form an estimate of the cost, rather than definitely to determine the details of the improved buildings, which may hereafter, under certain general regulations to meet the requirements of the poor, be modified by those who shall undertake their erection. The rents now paid at Holborn for one room vary from 1s. 6d. to 4s. per week; for two rooms, from 3s. to 5s.; and for three rooms, from 7s. 6d.; giving an average of 2s. 11d. per room, and producing a total rent of £16,000 *per annum*. It would seem to be an essential feature of this project that the present rental should not be increased, and this standard has been adopted in framing the estimates. Under the Metropolitan Streets Improvements Act, 1872, the Board is about to provide spaces for the erection of dwellings for the artisans who will be displaced by the pulling down of the old houses. One of these spaces in Liquorpond Street is already cleared, and, being close to the Holborn area now under consideration, it would, if the new buildings were at once erected, be available for the reception of some of the persons who must be turned out for the present improvement scheme. But the Secretary of State is unable to sanction the building on this site until all the plots of land intended to be covered by artisans' dwellings have been actually acquired. It appears probable that it certainly cannot be less, and will probably be more, than a year before all these plots are actually obtained. The delay thus occasioned will to a very great extent defeat the object of the new buildings, which are to accommodate those artisans who have had to quit their dwellings. But, as those will have been driven to seek new homes at a distance from their old ones, and many of them will have found employment elsewhere and never return, the new houses will become inhabited by a fresh set of people. The writers of the report are of opinion, therefore, that, if it be possible, the difficulty should be removed, and these spaces should, as soon as practicable, be covered with such buildings, so that not only may the poorer classes who may have been displaced by the street improvement be provided with houses, but some at least of those who must be temporarily removed by the present improvement scheme may find accommodation there; and they recommend that not more than about one-fifth of the present population of the Holborn area should be displaced at one time, nor the remainder after the first fifth until the new accommodation has been provided for that fifth.

THE LONDON FEVER HOSPITAL.

WE have been compelled by pressure on our space to defer for the last few weeks notice of several important changes which have recently been effected in this very valuable institution, by which its usefulness has been much enhanced. A number of slips or side-wards, which were used for the isolation of refractory and other special patients, have been entirely removed, and the walls beside which they stood have had large windows placed in them, much to the improvement of the larger wards. New bath-rooms, closets, sculleries, etc., have also been added. There was last week a goodly number of patients suffering from scarlet fever in the wards occupied by such cases; but scarcely any typhoid fever patients were in the hospital. The Metropolitan Fever Asylums now take charge of paupers suffering from contagious fever, and the Fever Hospital is the only institution in the metropolis devoted exclusively to the treatment of fever occurring amongst classes higher than those in the social scale. It receives as patients working men and their families,

domestic servants, clerks, and *employés* in commercial houses. Special wards are also provided for private patients. Thus, the hospital may be used to limit the spread of contagious fever in families in good circumstances, or in schools, hotels, etc.; and medical men and anxious heads of families have found it of most essential use in cases of pressing emergency. Working men or their families are admitted at once without payment and without letter of recommendation, if they be not in receipt of parish relief. Domestic servants, *employés* in houses of business, etc., are admitted on the recommendation of a governor or annual subscriber of a guinea, or on payment of two guineas on admission, which payment, however, covers scarcely one-third of the actual cost attending the treatment of those cases. Special wards for private patients, fitted with every comfort and convenience, are also provided, in which a single patient, or two children of the same family or school, can be placed. The payment for one of these rooms, with the attendance of an experienced nurse and the care of the resident medical officer and visiting physicians, and including food and medicines, has been fixed at three guineas per week, which is very much below the cost of similar cases at home. Cases admitted into these private wards may be attended by the family medical attendant. A carriage for the conveyance of fever-patients is kept at the hospital, and is sent at once for cases requiring admission; the only payment asked being for horse-hire, which is usually about one shilling per mile. The object of the hospital authorities has been to prevent expense from being an obstacle to the removal of cases from places where they would spread contagion. In this way, the hospital certainly meets an urgent public requirement; and we feel assured that it is only necessary that the advantages of the institution should be known for them to be fully appreciated, and for medical men and the public to avail themselves very largely of the same.

RECENT URBAN MORTALITY.

DURING last week, 5,153 births and 3,636 deaths were registered in London and twenty other large towns of the United Kingdom. The general mortality was at the rate of 25 deaths annually in every 1,000 persons living, and in the different towns varied as follows: in Portsmouth it was 17; Sunderland, 19; Wolverhampton, 20; Dublin and Glasgow, 21; Edinburgh, 22; Sheffield, 23; Newcastle-upon-Tyne and London, 24; Norwich, Leicester, and Birmingham, 25; Oldham, 26; Liverpool, 27; Manchester and Bristol, 28; Hull, 30; Nottingham, Salford, and Leeds, 31; and Bradford, 32. The mortality from scarlet fever was proportionally greatest in Bristol, Nottingham, Bradford, Leicester, and Salford. The deaths referred to diarrhoea were excessive. In London, 2,222 births and 1,563 deaths were registered. The annual death-rate was 23.7. There were 34 deaths from measles, 127 from scarlet fever, 11 from diphtheria, 47 from whooping-cough, 26 from different forms of fever, 41 from diarrhoea, and not one from small-pox; in all, 286 deaths, or 23 above the average of the week from those diseases. The zymotic rate ranged from 3.5 in the central to 5.0 in the north groups of districts. The 127 deaths from scarlet fever exceeded the average by 35, and were equal to an annual rate of 1.9 per 1,000; a higher death-rate from that disease prevailed last week in five other of the eighteen large English towns, and in Bristol it was so high as 5.9 per 1,000. The Asylum District Fever and Small-Pox Hospitals at Homerton and Stockwell, contained 330 patients on the 23rd instant, of whom 64 were under treatment for fever, and 253 for scarlet fever. In outer London, 425 births and 248 deaths were registered, and the general and zymotic death-rates were 17.0 and 3.6 per 1,000 respectively, against 23.7 and 4.3 in inner London. At Greenwich, the mean reading of the barometer during the week was 29.44; the mean temperature of the air was 49.7, or 0.5 above the average of the week; the mean degree of humidity of the air was 90; the general direction of the wind was easterly; the horizontal movement of the air averaged 10.6 miles per hour; and rain fell on six days during the week to the amount of 2.16 inches. At Greenwich, 3.88 inches of rain were measured during the first 23

days of October; and, in the three weeks ending last Saturday, 5.68 inches were measured in Wolverhampton, 6.09 inches in Sheffield, and 6.33 inches in Birmingham. During the first nine months of this year, the average rainfall, derived from observations taken at various stations between 50 and 55 degs. of latitude, amounted to nearly 23 inches, against 29, 21, and 19 inches respectively in the same periods of the three years, 1872-3-4.

NINETEEN MORE COMPETING DIPLOMAS.

THE University of Cambridge is heartily to be congratulated on the success of her first open examination for certificates in State Medicine. It will be seen that the list includes several names of great eminence. We cannot, however, consider that the isolated action of competing Universities and examinations is a desirable method of supplying qualifications in State Medicine. The Cambridge certificate is strictly a fancy diploma. Any other medical examining body is, of course, at liberty to issue its own diploma; and we are thus threatened with a competition downwards, involving the same mischiefs as have accrued from the like unrestricted competition in medical diplomas. We should not be surprised if some examining bodies were willing to sell certificates of competency in State Medicine at a very low rate, scientifically and pecuniarily. There is nothing to prevent them from following the dictates of their own will. A statement on this subject has been addressed to the General Medical Council by the Committee of Council of the British Medical Association; and we trust that the distribution of certificates in State Medicine will by that body be considered, with a view to general organisation. Meanwhile, the University of Cambridge has acted with energy and liberality.

PATHOGENESIS OF ŒDEMA.

THE Société de Médecine et de Chirurgie de Bordeaux, being of opinion that the theories recently advanced, as well in France as in Germany, to explain the formation of œdema, are incomplete, and do not rest on bases sufficiently proved, has put forward the following question for its prize of a gold medal of £12 for 1876: "Explain the pathogeny of œdema. Essays to be sent, under the usual conditions, to M. Douand, Secretary General of the Society, Allée de Tourny, No. 10, before the 31st August, 1876."

HARVEIAN SOCIETY OF LONDON.

THE first meeting of the forty-fifth session of the Harveian Society took place on October 21st, and was attended by a very full muster of members and visitors. After some remarks by Dr. Wiltshire on Pruritus Vulvæ, Mr. Carr Jackson read a paper on Lateral Curvature of the Spine, in special relation to its early recognition and treatment. The symptoms attending the first or curable stage of the disease were minutely described; and, in laying down the general principles of treatment, Mr. Jackson entered a vigorous protest against the too often unnecessary use of cumbersome apparatus. Numerous applications for membership were received; and it is evident that this useful Society will derive fresh impulse from the establishment of the Harveian Lectures, and the happy selection of Dr. Sibson as first occupant of the chair.

CARELESS USE OF NARCOTICS.

THE *Philadelphia Medical Reporter* mentions that four deaths have occurred in the St. Louis Insane Asylum from careless administration of narcotics. The medicine administered was a mixture of fluid extract of conium, bromide of potassium, morphia, and atropia, as follows: R Fl. ext. conium (Squibb's), ℥xv; water, ℥iv; bromide of potassium, ℥iv; morphia, gr. xxiv; atropia, gr. ½. M. The four ounces of bromide of potassium would add two ounces to the volume of the mixture, making twenty-two ounces. If a teaspoonful (or one drachm) were given (and, from the testimony, we have reason to believe much larger doses were given than were ordered), it would contain forty-three minims of the conium, to say nothing of the other elements. The

lesson so dearly learned at this institution is, that forty-three minims of (Squibb's) fluid extract of conium is an unsafe dose, unless to those habituated to its use. In the present case, doubtless, the physician prescribing a teaspoonful believed his patients accustomed to its use (*as two gallons of fluid extract of conium had been used in the institution during the two months previous*); while the fact seems to be, that the article used was inert and worthless; hence his patients were not habituated to the use of conium.

THE SUPERINTENDENCE OF EMIGRANT SHIPS.

ATTENTION is called, in an Australian letter to the *Hour*, to the putting into Holmes's Bay of the *Star Queen*, bound for Maryborough, Queensland, with 320 emigrants on board. They had suffered considerable privations, although she had only been 110 days out. It is alleged that, had she been victualled according to law, she might have lasted another month without running short of provisions. A letter was written by the surgeon-superintendent to the *Argus*, in which he stated that "the biscuits were exhausted on the eighty-ninth day out, in longitude 65 degrees E., except three and a half bags reserved for the crew. On arrival at Melbourne, the *Star Queen* was without biscuits, preserved and fresh meat, potatoes, and molasses, and had only six days' supply of salt meat, and eight days' flour for passengers and crew."

SCOTLAND.

THE Police Board of Greenock have agreed to prosecute any manufacturer or other person who allows deleterious matter to flow into West Burn, a stream passing through the town.

DR. ANGUS MACDONALD was last week elected physician to the Hospital for Sick Children, Edinburgh, in the place of Dr. Stephenson, professor of midwifery in Aberdeen.

WE understand that the Obstetrical Society of Edinburgh are about to issue shortly a third volume of *Transactions*, embracing the three sessions, 1871-72, 1872-73, and 1873-74. It is now in the printer's hands, and will appear very soon.

IN the proposed Edinburgh Police Bill, a clause is inserted requiring that medical men shall report every case of infectious disease under their care to the medical officer of health under penalty of a fine. A remuneration of 2s. 6d. is to be given for each such report.

AT the annual general meeting of the Royal College of Surgeons of Edinburgh, held last week, Dr. Littlejohn was elected President of the College, in the place of Dr. James Simson, whose term of office has expired.

WE regret to learn that the fine steamship *Britannia*, which was handsomely put at the service of the Association for the excursion to the Bass Rock during its meeting in Edinburgh, went ashore on the Ridge Rocks, Holy Island, during the recent gales, and has become a total wreck.

SEWAGE OF FORFAR.

AT a meeting of the Forfar Police Commissioners last week, a letter was read from the agents of the Earl of Strathmore, stating that the nuisance caused by the sewage of the town being allowed to flow into the Loch of Forfar had become absolutely intolerable. They wished to know if any measures were contemplated for remedying the evil, otherwise they would, without further notice, commence legal proceedings. A committee was appointed, and a letter was sent to the Earl, requesting his forbearance until the result of the Royal Commission on the sewage question was ascertained.

LADYBANK WATER-SUPPLY AND DRAINAGE.

AT a special meeting of the local authority of Colleslie, it was resolved that, with a view to abate the evils arising from want of drainage and from unwholesome water, a part of the district, including Ladybank and Monkstown, be formed into a special drainage and water-supply district. The above resolution has been come to in consequence of results of an analysis made by Dr. Stevenson Macadam of six samples of water from the wells of the village, which were all found to be contaminated by organic matter and nitrates.

HOSPITAL FOR CRIEFF.

THE chief magistrate of Crieff has received the following letter from Lord Aveland.—"Dear sir,—I am requested by Lady Willoughby to write to you and suggest whether it would not be desirable to establish a cottage hospital in Crieff. Should such a scheme be acceptable, Lady Willoughby will be happy to send £400 towards the building fund, £10 annual subscription, and grant a piece of land at a low feu-duty for the erection of the hospital. I shall be happy to give £100 donation and £5 annual subscription towards the same purpose.—I remain, yours faithfully, AVELAND."

NEW LUNATIC ASYLUM NEAR GLASGOW.

THE new lunatic asylum at Woodilee Lenzie, near Glasgow, erected by the Barony Parish, Glasgow, at a cost of £140,000, was formally opened on Friday last. The buildings, which are Elizabethan in style are 700 feet in length and 400 in breadth, and they cover about seven acres of ground. The internal arrangements are most complete. The asylum will accommodate about 1,000 patients. Several of the local members of Parliament, including Dr. Cameron, member for Glasgow, attended the banquet which took place in connection with the proceedings.

DEATHS IN EDINBURGH.

IN the weekly health report of the city of Edinburgh for last week, it is noticeable that all the deaths from zymotic disease (22 in number, out of a total death list of 89) are from scarlet fever, except one from whooping-cough. They are nearly equally distributed between the old town and the new. The week's mortality is equivalent to an annual mortality of 23 per 1,000.

IRELAND.

DR. AQUILLA SMITH has been re-elected Representative of the King and Queen's College of Physicians in the General Medical Council.

THE annual collections on Dublin Hospital Sunday have been arranged to take place on November 14th.

SEVENTY candidates have just been examined for matriculation at the Queen's College, Galway. This is the largest number since the opening of the College.

AT a special meeting of the Governors of the Cork Lunatic Asylum, held on the 22nd inst., three of the attendants were dismissed for ill-treating one of the patients of that institution. It is intended also, we understand, to prosecute one of the attendants thus discharged for assault.

MEDICAL RELIEF AND VACCINATION.

FROM a Parliamentary paper lately published, we learn that the amount of medical relief in Ireland during the decade of 1864-74 has decreased from 888,835 cases to 687,165, being a decrease of 201,670. There has been an increase, however, in the cost of medical charity, the amount expended in 1874 being £140,922, against £117,048, or an increase of £23,874; during the same period, the vaccination increased from 131,426 to 139,587 cases.

THE SCIENTIFIC GRANTS COMMITTEE.

THE Scientific Grants Committee of the British Medical Association have this year received £300 for allotment amongst those who desire assistance in original researches in medical and the allied sciences. The following grants have already been made, and the Committee are prepared to allot the balance of £170. Applications, which must be made not later than the 29th of December next, should be sent in at as early a date as possible to the General Secretary of the Association, 36, Great Queen Street, W.C.

Dr. Braidwood and Mr. Vacher, on the Life-History of Contagion, £25; Professor Rutherford, Researches on Biliary Secretion, £20; Dr. Crichton Browne, on the Antagonism of Medicines, £10; Dr. McKendrick and Professor Dewar, on Physiological Action of Chinoline and Pyridine Compounds, £25; Dr. Mahomed, the Pathology of Albuminuria, £15; Dr. Munro, Cupar Fife, an Antidote for Chloroform, £3; Dr. Caton, on the Electric Currents of the Brain, £15; Dr. Fothergill, the Effect of Certain Agents on the Circulation, £10; Dr. Spencer, Clifton, the Action of Uranium Salts on Diabetes, £10.

In addition to the scientific grants, Mr. Samuel Wood of Shrewsbury has generously presented £25, to be given for the best essay on Pyæmia; and there is also the Hastings Prize Medal of twenty guineas, offered for the best paper on Diphtheria, its Pathology, Diagnosis, and Treatment. Papers for the Wood Grant and Hastings Medal should be sent in, addressed to the General Secretary, 36, Great Queen Street, on or before the 1st of May next.

ASSOCIATION INTELLIGENCE.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT MEETINGS.

THE next meeting of the above District will be held in the Library of the County Hospital, Canterbury, on Thursday, November 11th, 1875, at 3 o'clock; FRANK WACHER, Esq., in the Chair.

Dinner at the Fleur-de-Lis Hotel at 5 o'clock precisely. Charge, 6s. 6d., exclusive of wine.

Gentlemen who wish to make communications to the meeting are requested to inform me at once, in order that a notice thereof may be included in the circular convening the meeting.

EDWARD WHITFIELD THURSTON, *Honorary Secretary*.
Ashford, October 27th, 1875.

SOUTH OF IRELAND BRANCH.

A MEETING of Council was held on October 20th, and it was arranged to hold the general annual meeting of the Branch on November 9th, 1875.

At this meeting, officers for the ensuing year will be elected, and the Council's report read.

It was also resolved that a dinner be provided, and that the members dine together on the day of the annual meeting.

Further particulars of the business to be transacted at the general meeting will be announced after the next meeting of Council.

SOUTHERN BRANCH: DORSET DISTRICT MEETING.

A MEETING of the Dorset District of the Southern Branch was held in the Board-room of the County Hospital, Dorchester, on Wednesday, October 20th, at 4 P.M.: Dr. ALDRIDGE, President, in the Chair.

THE PRESIDENT read a letter from Dr. Lush of Weymouth, regretting his absence from domestic affliction. A letter of condolence was voted to Dr. Lush.

Officers.—The meeting proceeded to elect the following officers for the ensuing year. *President:* F. J. Parsons, L.R.C.P.Ed., Portland. *Vice-Presidents:* R. G. Long, Esq., of Stalbridge, and R. M. Rendall, Esq., of Maiden-Newton. Dr. W. Vawdrey Lush of Weymouth, and Mr. C. H. Watts Parkinson of Wimborne-Minster, were re-elected Joint Secretaries and Treasurers, and a vote of thanks given them for past services.

The *Thanks* of the meeting were given to Dr. Aldridge, President, for the able manner in which he had filled the duties of the office during the year.

The *Next Meeting* was arranged to take place at Portland.

New Members.—Dr. G. Leworthy Thorne of Swauage, and Dr. R.

T. Hearne of the Dorset County Hospital, were unanimously elected members of the Branch and District.

Papers, etc.—Dr. ALDRIDGE then read an interesting address on the Hygienic Treatment of Disease, and congratulated the members on the formation of the Dorset District.

2. Mr. EWENS of Cerne-Ablas, Vice-President, read an account of a Case of Hypospadias, on which he had operated with success.

After some little discussion, the meeting terminated after votes of thanks to Dr. Aldridge and Mr. Ewens for their papers, and to the Committee of the County Hospital, for their kindness in granting the use of their Board-room.

YORKSHIRE AND EAST YORK AND NORTH LINCOLN BRANCHES: CONJOINED MEETING.

A CONJOINED meeting of these Branches was held in the Museum, York, on October 13th.

Communications.—The following communications were made.

Mr. DIX: Cases of Aneurism treated by the wire compress.

Mr. Jalland: Fracture of the Upper End of the Tibia, from indirect violence.

Dr. Kelburn King: Case of Congenital Hard Cancer treated by Amputation, four years ago, with no return up to this date.

Dr. HIME: Cases of Ovariotomy.

Mr. Nicholson: Removal of Nine False Teeth with Metal Plate, from behind the Larynx.

Mr. Haxworth: Remarks on the Treatment of Dipsomania by Capsicum.

Dr. Lunn: Cases of Laryngotomy.

Dr. Elliott: Treatment of Enteric Fever.

Dr. Shann: Case of Fracture of the Petrous Portion of the Temporal Bone.

Dinner.—After the meeting, thirty-six members dined at Harker's Hotel.

SHROPSHIRE SCIENTIFIC BRANCH: ANNUAL MEETING.

THE annual meeting of the Shropshire Scientific Branch was held in the Natural History and Antiquarian Museum, Shrewsbury, on Wednesday, September 22nd; WILLIAM MATTHEWS, Esq., of Nantwich, President, in the Chair.

Address.—THE PRESIDENT opened the proceedings by an address on puerperal fever and pelvic abscess, and the history of several patients, and the treatment he had adopted in his practice. A prolonged and animated discussion followed.

Papers.—Dr. ALFRED EDDOWES read a paper on a Case of Apoplexy of the Heart, and exhibited the preparation he had made, showing the degeneration of the muscular fibre, the ruptured vessel, and the infiltration into the walls of the heart.—Mr. WOOD read a paper on Chorea.

Dinner.—The members afterwards sat down to an excellent dinner at the George Hotel. There were twenty-five guests.

WEST SOMERSET BRANCH: AUTUMNAL MEETING.

THE autumnal meeting of this Branch was held at the Railway Hotel, Taunton, on Thursday, October 14th, at 5 P.M., GEORGE CORDWENT, M.D., President, in the Chair. Twelve members were present.

The Secretary produced letters of regret from several members who were unavoidably prevented from attending.

Paper.—Dr. CORDWENT read a paper on Tissue Change in Fever. A discussion followed. It was proposed that the thanks of the meeting be given to Dr. Cordwent for his paper, and that he be asked to have it printed. The proposal was supported by several speakers, and carried with acclamation. Dr. Cordwent declined, for reasons assigned, to allow his paper to be printed.

Blood-letting in Disease.—The question of the evening, viz., "Is the disuse of Blood-letting in the Treatment of Disease in accordance with the principles of Pathology?" was put from the chair, and answered by all present, the discussion being very full and animated. An unanimous and emphatic expression of opinion as to the value of blood-letting, and of its disuse not being in accordance with the principles of pathology, was elicited.

Habitual Drunkards.—Petitions to the Legislature on the subject of habitual drunkenness, which Mr. Randolph had ready for signature, were signed at the conclusion of the above business; and the meeting broke up at half-past eight o'clock.

CORRESPONDENCE.

THE ORIGINATOR OF CRÈCHES.

SIR,—In the JOURNAL of October 23rd, I see noticed the death of M. Marbœuf, "the originator of crèches, or infant nurseries".

The following quotation is from the curious *Budget of Paradoxes*, by my late brother. "At Amiens, at the end of the last century, an institution was endowed by a M. de Morgan, to whom I hope I am of kin, but I cannot trace it: the name is common at Amiens. It was the first of the kind I ever heard of. It is a salle d'asyle for children, who are taught and washed and taken care of during the hours in which their parents must be at work. The founder was a large whole sale grocer and colonial importer, who was made a Baron by Napoleon I for his commercial success and his charities." Here, I take it, we have the first introduction of the principle of the infant nursery.

Yours obediently, etc., C. DE MORGAN.

London, October 23rd, 1875.

VIVISECTION.

SIR,—Sir Charles Bell has left on record an express declaration that his great discovery was due not to experiment, but to observation. A few experiments were afterwards made, not for his own conviction, but for the satisfaction of others. He, therefore, protested against the statement of a foreign reviewer, that the results were in favour of vivisection. "They are, on the contrary", he said, "deductions from anatomy"; adding that "experiments on living animals have done more to perpetuate error than to enforce the just views taken from anatomy and the natural sciences". Certain it is that this method of research is subject to many fallacies, and that its advantages have been greatly exaggerated. Dr. Prichard, in reviewing the researches of Flourens, Serres, Bouillaud, and other experimenters, says:—"The results thus obtained not only differ in essential respects from each other, but are completely opposed to conclusions deduced from minute and careful observation of pathological facts." A more recent French physiologist, M. Colin, admits this uncertainty of results. "Often the same experiment repeated twenty times gives twenty different results, even when the animals are placed apparently in the same conditions. It may even happen that the same experiment gives contradictory results." To the same effect, Legallois had formerly said:—"I had almost as many results as experiments, and at length resolved to abandon this method of inquiry, not without regret at having sacrificed a vast number of animals and lost much time." It is not surprising, therefore, that Dr. Carpenter says:—"Almost all our knowledge of the laws of life must be derived from observation only. Experimentation can conduct us very little farther in this inquiry." And again: "On such subjects as the functions of the different parts of the encephalon, I do not believe that experiment can give trustworthy results, since violence to one part cannot be put in practice without functional disturbance of the rest. Here I consider that a careful anatomical examination of the progressively complicated forms of the encephalon, from fishes up to man—experiments, as Cuvier calls them, ready prepared by nature—is far more likely than any number of experiments to elucidate the problem." Still there are found men, impelled by scientific zeal and ambition, who renew the Sisyphæan labour, hoping to solve the mysteries that have baffled their predecessors. Let such men hear the words of the old Roman Celsus:—"It is alike unprofitable and cruel to experiment with the knife on living bodies, so that the art which is designed for the protection and relief of suffering is made to inflict injury, and that of the most atrocious nature. Of the things sought for by these cruel practices, some are altogether beyond the reach of human knowledge, and others could be ascertained without the aid of such nefarious means. The appearances and conditions of the parts of a living body thus examined must be very different from what they are in their natural state. If, in the entire and uninjured body, we can often, by external observation, perceive remarkable changes produced from fear, pain, hunger, weariness, and a thousand other affections, how much greater must be the changes induced by the dreadful wounds and cruel mangling of the dissector in internal parts whose structure is far more delicate, and which are placed in circumstances altogether unnatural." The vivisectors of those days had human subjects to operate upon, condemned malefactors being given over to them, especially in the school of Alexandria. The differences of structure and function in the lower animals must give the less chance of light being thrown on human physiology.

These introductory remarks I make not as an opponent of experi-

ment, but to remind those who have not closely studied the question of the fallacies of this mode of inquiry. That some discoveries are due to experimental physiology no one will deny; but the number and importance of these discoveries are grossly exaggerated. In an early number of the BRITISH MEDICAL JOURNAL for 1875, a list was given of "discoveries due to vivisection". Not one in ten of these alleged discoveries can be truly affirmed to be due to experiment alone. By far the largest number are equally due to observation, either by anatomical research, as in the case of Sir Charles Bell, or in the ordinary way of clinical and pathological study.

But it is not the object of this letter to discuss with physiologists the precise number or importance of discoveries thus made. Granting at present all that can be said in favour of vivisection as a legitimate and useful mode of inquiry, I wish to appeal to the profession on the subject of abuses of very recent growth. Ten years ago, when Dr. Markham of St. Mary's Hospital published his prize essay, he said that "experiments performed before students, in classes or otherwise, for the purpose of demonstrating known facts in physiology or therapeutics, are unjustifiable". Dr. Markham says of such operations:—"They are needless and cruel; needless, because they demonstrate that which is already acquired to science; and especially cruel because, if admitted as a recognised part of students' instruction, their constant repetition through all time would be required." Then, in parenthesis, he adds:—"I need hardly say that courses of experimental physiology are nowhere given in this country; and that these remarks apply only to those schools in France and elsewhere where such demonstrations are delivered."

What is the state of matters now? and to what length could the imitators and pupils of foreign vivisectors have gone but for the protest of public opinion, which has given origin to the Royal Commission? It may be said:—"Let us wait to hear the report of the Commission." The publication of that report will begin rather than end this controversy. It is difficult to obtain direct evidence of what is done, and those who used to be boastful among their brethren of the number of their experiments are now cautious and reticent. But the publication of such a book as the *Handbook for the Physiological Laboratory* suffices to show the nature and extent of the evils against which the public voice has been raised.

That any legislation should be the result of the Commission is the last thing to be desired. It would be a disgrace to science if schools of physiology were to be registered, and licensed, and inspected, like slaughter-houses. The appeal against the abuse of vivisection must be made to the medical profession itself, either to the members individually or to the Medical Councils and official bodies. It is not a question of science against sentiment; true science is on the side of humanity on this point. Professor Owen has thus recorded his views: "I reprobate the performance of experiments to show the students what such experiments have taught the master; whilst the arguments for learning to experiment by repeating experiments on living animals are as futile as those for so learning to operate chirurgically." Professor George Wilson, in his *Life of Dr. John Reid*, says that, to encourage students to engage in such researches, is "putting a premium upon animal torture and animal murder". Sir Robert Christison objects to all public demonstrations by experiment on living animals, and has always done so. These exhibitions are, therefore, against the highest scientific opinions, and are justly characterised as wanton and cruel.

I do not think that the depth and strength of popular feeling as to the abuses of vivisection are sufficiently known to the medical profession. Foolish things may have been said, and extreme opinions urged by those who advocate the total abolition of vivisection. But, apart from this popular and sometimes ignorant clamour, there is a public opinion not to be despised. Sir Arthur Helps gave expression to the feeling prevalent among men of culture in all professions when he said that "any man known to have practised needless cruelties on animals should be placed under a social ban". It is very certain that the whole tone and standing of the profession may be lowered from being associated in the public mind with these horrors. It was not by mere technical knowledge and skill that the medical profession obtained and kept the high place that it holds in English life and history. There has been always a succession of men of high standing, scholars and gentlemen, men also as conspicuous for their generous and humane character as for professional acquirements. It was when the associate of such men that Dr. Samuel Johnson wrote his celebrated paper on Vivisection (No. 17 of the *Idler*), describing "a race of wretches among the inferior professors of medical knowledge", who, by knife, fire, and poison, sought the advancement of knowledge: He would not have written thus if the higher grades of the profession approved such practices. There has been always in the Provinces also a succession of

medical men, high in character as well as attainments—men like Cotton of St. Alban's, Hey of Leeds, Bardsley of Manchester, and others—whose names are yet held in honour. These men gave tone to the whole profession in the spheres of their influence. There are men of the same stamp now in all parts of England, who could maintain the same high tone in our provincial medical associations. To them this appeal is made to resist the influence of those who would hold up as the great lights and ornaments of the profession men like Magendie and Schiff, instead of men like Haller and Heberden, Bell and Abercrombie. If a new epoch of medical history in England is to be begun, let it at least not be without a protest being heard.

I am, etc., JAMES MACAULAY, M.D., F.R.C.S.E.

THE USE OF "SOOTHING SYRUPS".

SIR,—There are few medical men in general practice who cannot call to mind numerous instances of children who have from time to time come under their care in an emaciated helpless condition, brought about by the constant pernicious use of quack medicines, known as "soothing syrups". Nor can we wonder that poor ignorant mothers should have recourse to such baneful remedies, when the proprietors of these patent drugs can find qualified medical men ready to eulogise the vendors by flaming testimonials of the marvellous efficacy of the nostrum in any and every disease, and will even stand by them in open court when the wholesale use of such medicines is called in question. It is much to be deplored, that our medical governing bodies have not the power or the inclination to deal with this subject.

The following is a brief sketch of a case of a death from an overdose of soothing syrup which has lately come under my care.

On the morning of September 14th, I was called to see two children, twins, who, from the report brought to me by the father of the children, were dying from "a dose of a bottle" given to them by the mother. On my arrival, I found the twins, eight weeks old, in a helpless, lifeless condition. I learnt from the mother that, in making some purchases in the town the Saturday previous, a pamphlet was placed in her hands by a chemist, which set forth in powerful language the wonderful efficacy of "Harrop's Soothing Syrup in every imaginable disease". The woman carefully perused the book, which stated among other things, that "Harrop's Soothing Syrup is a safe remedy in all infantile diseases"; that "it is a safe, harmless, and innocuous remedy"; and that "it neither stupefies nor sleeps the child". And having satisfied herself that this harmless syrup was so efficacious, she, on the first occasion that the children showed any uneasiness or became restless, gave each a teaspoonful of the syrup. It would appear that the woman, being fully convinced after reading the pamphlet that the syrup was harmless, did not take the trouble to take off the paper in which the bottle was folded, and consequently did not see the label which gave directions as to the doses to be given to children; not one word, however, is mentioned in the pamphlet as to the dose to be given, nor does it even guard the reader by referring him to the label on the bottle, but leaves (as it did in this case) the impression that the dose of so harmless a remedy need not require a consideration.

On examining the children, I was fully satisfied that they were both under the influence of some powerful narcotic. They appeared to be in a deep sleep; violent agitation failed to bring about the slightest movement in either of them. The skin was markedly livid; the pupils were firmly contracted almost to a pin's point; frothy mucus flowed from their mouths; pulse and breathing were scarcely perceptible; and in this condition they remained for eight hours, when one died; the other, the stronger child of the two, by powerful stimulation, violent jactitations, and the use of cold douche, gradually but very slowly recovered. The *post mortem* appearances fully confirmed the view that I had entertained, that the child had died from an overdose of an opiate. The skin was so livid as to be almost black, and conveyed the impression to those who assisted me in my examination that the child's parents were negroes. The vessels of the pia mater were immensely distended, and on the surface of the brain two large clots of blood were deposited. The substance of the brain was much congested, the ventricles containing a quantity of serum. The heart was firmly contracted and empty. The stomach, intestines, and other organs of the body were normal and healthy.

By the order of the Coroner, the contents of the bottle from which the doses were taken were analysed, and were found to contain morphia; and, from the statement of the proprietor of the syrup, that each pint contained one grain of morphia, supposing the evidence of the mother to be correct, the dose of morphia which proved fatal in this case was one-sixtieth of a grain, a dose sufficient to cause death when the age and the condition of the child are taken into account, it being a twin and in a weak emaciated condition. I am of opinion that morphia should

not be given to children of such tender age under any circumstances, so susceptible are they to its influence. May not the use of these syrups so frequent in the present day account for many of the deaths in children on whom inquests are held, and where the deaths are returned as convulsions, etc.?

This case fully illustrates the necessity for the Government to make an order that no patent shall be granted for the sale of any medicines unless the contents are specified, and then the sale of those containing narcotics or other powerful remedies should be strictly prohibited.

I am, sir, yours truly, JOSEPH MORRIS, M.D., etc.
Barnsley, October 22nd, 1875.

COMPULSORY REGISTRATION OF DENTISTS.

SIR,—Will you kindly permit me to make a few remarks concerning a recent provincial meeting which was convened with the object of obtaining aid from Parliament to ensure the compulsory registration of dentists?

I most thoroughly agree with the intelligent criticism upon this subject which recently appeared in your JOURNAL.

The conclave was composed, with few exceptions, of unqualified members of the profession; and, although it is satisfactory to find that all ranks are being aroused to the necessity of improving the status of their calling, I fear that the result of this meeting may not be that speedy success which its promoters anticipate. Moreover, it is to be regretted that the means employed to enlist the sympathies of those taking the highest rank in the profession are not by any means the best calculated to attain that end, inasmuch as I have just received a paper giving a notice of the above mentioned meeting, in which is enclosed a thin tablet of cork of cunning workmanship, on which is imprinted an advertisement recommending certain "plastic fillings" to be obtained of one who took a prominent part in this movement for the promotion of dental reform. Now, although this can only be looked upon in the light of a trade circular, still it is certainly a paradox to see it enclosed with a scheme for "dental reform".

The only true reform must consist in higher and more perfect education; and there need be no fear lest dental surgery should not take its legitimate position immediately a majority of those who practise the specialty become fully qualified practitioners. You still insist upon the necessity of separating the mechanical from the more purely surgical part of dental practice, and, at the risk of giving offence to some less liberal members of the profession, I frankly confess that I think that such a consummation is devoutly to be wished; for I am convinced that it is this connection which has brought much that is undesirable into our ranks, though I cannot see that the union of the two branches converts a profession into a business more than the retailing of drugs by the general practitioner who compounds his own prescription.

The manufacture of mechanical substitutes for the natural denture I would gladly relegate to a body of skilled mechanics, who should hold a similar position to that of the ordinary manufacturer of surgical appliances; the instruments being made and adjusted subject to the supervision of the surgeon, who, especially in dental practice, ought to have a competent knowledge of mechanics, as a mere mechanist might fail in that æsthetic, artistic, and anatomical perception which is necessary in cases of deformity like those alluded to here.

But this division will not achieve all that which is to be desired; for those who are ambitious of the highest professional and social position must enter their profession through a portal, the entrance to which should imply a liberal education, both general and special; and this is to be found in the diploma of Member of the Royal College of Surgeons, to which it is to be regretted that the special degree in dental surgery was not primarily appended. One of our most distinguished and celebrated surgeons lately said, whilst speaking authoritatively in the name of the Royal College of Surgeons, that that body would be only too glad to receive the best men of that specialty into its fold; and I likewise believe that those men would infinitely prefer that connection to any other. Speaking for myself, and I believe for some others, I desire no other position than that which I have as a qualified surgeon. I trust that ere long every general hospital will have a special department for instruction in dental diseases, as for those of the eye, throat, or ear; for I am certain that the attempt to separate the profession of dental surgery from that of general surgery would be a great mistake. Had the diploma of Licentiate of Dental Surgery been only conferred as a pendant to that of M.R.C.S., the coveted means of registration would have been thereby obtained at once. Still, although it is to be feared that a special registration would have a tendency towards the separation of the general and special branches, yet, on the principle of choosing the least of two evils, I believe that, if that registration could be made to depend upon the possession of the diploma of L.D.S., so that none

should practise without this *minimum* degree, the profession would be purged of much that is unclean and unhealthy in its ranks; above all, of that advertising class which makes a sensitive man occasionally blush for the name of his profession. To such a project I would give support, though I should esteem it a matter of regret if this should lead to such a separation as that to which I have referred. In America, such a mistake has been made, and we find that the children are now seeking a connection which the parent justly disclaims, save on the condition that they educate themselves as fully qualified practitioners. Let us take warning from that example, and determine to ally ourselves with those from whom to be divided would be a loss of honour in a professional as well as in a social point of view.

Finally, if specialists are ambitious of the status granted to their medical *confères*, they have only to educate themselves as they are educated. Let them take a larger and more liberal view of their calling, banishing all petty jealousies and intestine bickerings. Let them advance schemes for the common weal, apart from mere personal interest and the gratification of individual ambition, and there would then be no difficulty about special registration, whilst men who now hold aloof from special politics, and the general body of those practising the specialty they have adopted, would join the van of those who love the good name and support the fair fame of their profession in word and action.—Believe me, sir, yours faithfully,

S. HAMILTON CARTWRIGHT, Professor of Dental Surgery at King's College, and Lecturer at the London School of Dental Surgery.

London, October 25th, 1875.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

NOTTINGHAM SEWERAGE WORKS.

CONSIDERABLE improvements in the sewerage of the town and neighbourhood of Nottingham have recently been carried out. The town contains about 100,000 inhabitants, and is surrounded by numerous populous suburbs, all of which, with the town, lie more or less upon the banks of the River Trent and its tributary the Leen. The Trent has a total watershed of 4,076 square miles, of which 2,900 lie above the town. As a rule, towns and villages become involved in unnecessary expense, because their sewerage works are carried out quite independently of their neighbours. This, however, the Town Council of Nottingham, who have the credit of holding advanced views on many sanitary questions, determined, if possible, to avoid; and, in view of the pollutions to which the Trent and its tributaries were subjected, they felt that, sooner or later, the various offending places would be dealt with in Chancery by the riparian owners; each place would in turn proceed against its higher neighbour; and so the various authorities in the neighbourhood would gradually become immersed in a sea of litigation and strife, and the evils complained of would in all probability remain long unabated. Under these circumstances, a delegation was invited from each of the interested localities to join a committee of inquiry, and each authority, that for Bulwell alone excepted, took up the matter with the earnestness it deserved. The result was a Bill known as the "Nottingham and Leen District Sewerage Act, 1872", which is stated to have received the hearty commendation of the Government before it became law. The sewerage district created under this Act included an area of twenty square miles, and a population of about 150,000; it contained a large manufacturing district, with the special pollutions of streams inseparable from such a neighbourhood. The first step adopted was the construction of a large intercepting sewer, about six miles in length, in the valley of the Leen, by which all polluting matter was taken out of the Leen, and so the purification of that river has been ensured. This sewer is so constructed that its whole length can be carefully examined, and its ventilating arrangements consist of open shafts, at intervals, connected with the manholes. Speaking of these ventilators, Mr. Tarbotton, the borough engineer, says:—"These are unobstructed by charcoal or any other deodorant; the principle relied upon has been thorough aëration of the interior and frequent points of exit" for the already diluted foul air. It is worth stating here that in Nottingham all the sewer-ventilators were formerly filled in with charcoal trays of various patterns; but it was found that charcoal really impeded sewer-ventilation, and hence its use was at last abandoned. Storm water-overflowers are also built along the course of the intercepting sewer, by which excessive rainfall can escape into the River Leen at convenient places. In one part, water-tight iron pipes

have been used as sewers, because the sewer passes through some thin limestone beds which are full of water. The next operation of the Board formed under this Act will be to determine how the sewage shall be purified, and probably utilised, before passing out at the outfall into the Trent. The present total daily volume of sewage to be treated at the outfall is about five millions of gallons; but prospective increase must, of course, be contemplated.

The Act gives the contributing districts ample powers to prevent the pollution of streams within the area described, and under it the various manufacturers will be compelled to resort to the sewer for the disposal of their refuse, and in some cases, as, for example, in bleaching and dyeing establishments, to modify their systems of discharging foul and surplus liquids from their works. The advantages of the Act may also be, under certain circumstances, extended to sanitary authorities without the district; and it is possible that before long Bulwell may see that it has gained no advantage in remaining inactive whilst all its neighbours are working to free themselves of filth.

The advantages of the action taken by the Town Council of Nottingham and some of its neighbours in this matter are very great; and it would be well if, in many other localities, the union of districts lying upon the same watershed were made compulsory for the purposes of outfall sewerage, and for the joint appropriation or distribution of sewage. Much disjunctive action, which is almost necessarily weak, costly, and socially unsatisfactory, would thus be avoided, and the extended area of local administration thus secured could hardly fail to result in a more intelligent representation of the interests concerned.

POOR-LAW MEDICAL SERVICE OF SCOTLAND.

THE Secretaries of the Aberdeen, Banff, and Kincardine Branch would be glad to receive from any members of the Branch information concerning any defects in the administration of parochial medical relief, and any suggestions for reforming the present Poor-law for Scotland.

Aberdeen, October 20th, 1875.

J. URQUHART.
ALEX. OGSTON

MILITARY AND NAVAL MEDICAL SERVICES.

AT the quarterly meeting of the directors of the Naval Medical Compassionate Fund, held on the 12th instant, Sir Edward Hilditch, Inspector-General, in the chair, the sum of £90 was distributed among the various claimants.

LAST Friday's *Gazette* contained the announcement that Surgeon-Major Sydney Alder had been placed on the half-pay list of his rank. Mr. Alder, who served in the Crimea and Ashantee campaigns, returned from the Gold Coast, suffering from severe mental aberration, and it will be recollected was recently acquitted from all blame in the melancholy circumstances attending the death of Lieutenant Wilson of the Royal Artillery at Cardiff.

THE appointment of medical officer to the Royal Horse Guards is vacant by the retirement of Dr. Cosmo Gordon Logie on half-pay, with the rank of Deputy Surgeon-General. Dr. Logie, who leaves to the regret of all ranks, joined the Medical Department of the Army as an Assistant-Surgeon in October, 1841, and has been connected with the "Blues" for over twenty-two years, joining the regiment as its surgeon in April, 1853, as the successor of Mr. George Gulliver, now on the half-pay list of army medical officers.

DRESS OF MEDICAL OFFICERS OF THE INDIAN ARMY.—The Viceroy of India, on August 30th, directed that the dress laid down in the dress regulations for the army, dated Horse Guards, War Office, 1st November, 1874, pages 68 to 72, for officers of the British Medical Department, with the modification stated in the following paragraph, shall be worn by officers of the Indian Medical Department, without reference to the branch of the Service to which they may be attached. The buttons shall bear the words Bengal (Madras or Bombay) Medical Staff. Two years from the date of the order are allowed for wearing out any uniform in possession.

OFFICIAL STATEMENTS.

SIR,—Will you kindly permit me, through the medium of your JOURNAL, to inquire of any of your readers, how it was that, in spite of the assertion made some time during the summer by Mr. Gathorne Hardy, that he did not object to the publication of the number of vacancies to be competed for at the examinations for medical officers in the home service, yet the advertisement in the *Times* referring to the last examination in August, was just as silent as ever on the matter?

Surgeons were wanted, and that was all. One other point I would wish to draw attention to. Mr. Ward Hunt, some time ago, in answer to a question from an Irish member, stated that rejected army candidates had never been received at the Admiralty. He spoke accurately, I believe; but he failed to state, that men who were qualified for the army, but who did not obtain a vacancy, were often offered the navy, and that several accepted it. I know myself of three instances.

I have the honour to be, Sir, your obedient servant,
Aberdeen. VIGILANT.

OUR MILITARY HOSPITALS.

THE court of inquiry convened to consider the case of Private Ban, of the 78th Highlanders, has now made its report, and the decision is, that henceforth soldiers suspected of being insane are to be sent for observation to the Royal Hospital at Netley. But the fact cannot be disguised, that the man ought to have been removed thither for treatment in the first instance, in accordance with instructions fully laid down in the Queen's regulations and arrangements specially made at that establishment for the purpose. Originally admitted for primary syphilis on February 1st, Ban's disease was subsequently altered in the returns to melancholia, the theory of those in attendance being that the symptoms of mental derangement from which he suffered were the result of the constitutional manifestation of the venereal poison. Ordinary precautions were taken to as great an extent as was possible in a hospital which is only a series of huts, and at all times unsuitable for such cases; but any effective arrangement was seriously impaired by the frequent change of surgeons in responsible charge, no fewer than seven successive signatures having been affixed to the diet-sheet during the month of July.

The Court animadverted strongly on this point, and called upon several medical officers to state what duties had been performed by them since their arrival at Aldershot: and their evidence showed the very multifarious variety of work they had been called upon to do, and the very frequent changes to which they had been subjected. The principal medical officer was then requested to explain whether such arrangements were necessary, and his answer was, that they were quite inseparable from the present system as put in operation at the camp. But it is perfectly clear that, with an undermanned department, such irregularities must continue, as there are not medical officers enough to secure effective trial of the present plan, and as the whole medical staff is now working at high pressure, and is quite inadequate to perform even the ordinary routine duties of peace time. Relaxation is only attainable by throwing additional work on an already highly taxed *confre*, and in the Army Hospital Corps things are worse, and confusion reigns supreme. Perhaps at no previous period did so much dissatisfaction prevail throughout the ranks of our military brethren, and we hope soon to return to this question, with the view of putting our readers in possession of a few more plain facts concerning the administration of our military hospitals.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, October 21st, 1875.

Blake, George Farncombe, Old Square, Birmingham
Parker, Alfred Charles, Worthington, Leicestershire
Thayer, Linus Orton, 71, Mildmay Park, N.
Tyrrell, Frederick, Harlington, Middlesex

The following gentlemen also on the same day passed their primary professional examination.

Bradford, Cordley, Queen's College, Birmingham
Davis, Arthur Randall, Middlesex Hospital
Mason, John Wallis Barron, Middlesex Hospital
Warner, James, London Hospital

MEDICAL VACANCIES.

THE following vacancies are announced:—

ADDENBROOKE'S HOSPITAL, Cambridge—House-Physician. Salary, £65 per annum. Applications on or before November 2nd.
BIRMINGHAM and MIDLAND FREE HOSPITAL FOR SICK CHILDREN—Acting Physician and Extra Acting Physician. The Extra Acting Physician will have to attend on three afternoons in each week, and will receive a salary of £60 per annum. Applications on or before November 3rd.
BROOKWOOD ASYLUM, near Woking—Second Assistant Medical Officer.
CHRISTCHURCH UNION—Medical Officer for the Eastern District. Salary, £100 per annum, and fees. Applications on or before November 6th.
COLCHESTER UNION—Medical Officer. Salary, £90 per annum. Applications before November 1st.

COVENTRY and WARWICKSHIRE HOSPITAL—House-Surgeon and Dispenser. Salary, £100 per annum, with board, lodging, and attendance. Applications on or before November 1st.
DENBIGHSHIRE INFIRMARY—House-Surgeon. Salary, £85 per annum, with board, washing, and residence.
HUDDERSFIELD INFIRMARY—Physician.
LEICESTER AMALGAMATED FRIENDLY SOCIETIES MEDICAL ASSOCIATION—Resident Medical Officer. Salary, £175 per annum, with residence, coals, and gas. Applications on or before November 2nd.
LIVERPOOL INFIRMARY FOR CHILDREN—House-Surgeon.
METROPOLITAN FREE HOSPITAL—Honorary Assistant-Physician. Applications on or before November 6th.
MIDDLESEX HOSPITAL—Two Resident Physicians' Assistants, and One Resident Obstetric Assistant. Applications on or before the 30th instant.
NORTH SHIELDS AND TYNEMOUTH DISPENSARY—House-Surgeon and Dispenser. Salary, £120 per annum, with furnished house, gas, coals, etc. Applications to be made on or before November 1st.
NORTH WALES COUNTIES LUNATIC ASYLUM, Denbigh—Assistant Medical Officer. Salary, £100 per annum, with board, lodging, and washing. Applications before November 3rd.
PROVINCIAL HOSPITAL, Port Elizabeth, Cape of Good Hope—House-Surgeon and Dispenser. Applications to T. E. Fuller, Cape Emigration Agent, 15, Coleman Street, London, E.C.
ROXBALD INFIRMARY—House-Surgeon. Salary, £100 per annum, with board, lodging, and attendance. Applications on or before November 6th.
ST. GEORGE, HANOVER SQUARE, PROVIDENT DISPENSARY—Physician-Accoucheur. Applications to be made on or before November 3rd.
STROUD GENERAL HOSPITAL—House-Surgeon. Salary, £60 per annum, with board, furnished rooms, attendance, and washing.
TAWKESBURY RURAL HOSPITAL—Assistant-Surgeon.
TONGUE and FARR, District of, County of Sutherland—Medical Officer. Salary, £150 per annum, and house.
WEST RIDING PRISON, Wakefield—Resident Surgeon. Salary, £400 per annum, with house, coals, gas, and water. Applications before November 15th.
WORKSOP DISPENSARY—Resident Surgeon. Salary, £120 per annum, with furnished apartments, coal, gas, and attendance.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

***FOSTER**, Balthazar, M.D., F.R.C.P., appointed Honorary Consulting Physician to the Ear and Throat Infirmary, Birmingham, *vice* *Alexander Fleming, M.D., F.R.C.P., deceased.
***GRIMSHAW**, Thomas W., M.D., appointed Physician to the Coombe Hospital, Dublin.
***MOORE**, John W., M.D., appointed Physician to the Coombe Hospital, Dublin.
PEEL, Edward, L.K.Q.C.P.I., appointed Physician to the Coombe Hospital, Dublin.
SVKES, William, M.R.C.S. Eng., appointed House-Surgeon to the Doncaster General Infirmary and Dispensary, *vice* F. Wallis, M.R.C.S. Eng., resigned.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTH.

HEWITT.—On October 16th, at Winkfield, near Windsor, the wife of *T. Hewitt, M.D., of a daughter.

MARRIAGE.

CAREY-KAUNTZE.—On the 26th instant, at Uninn Chapel, Oxford Road, Manchester, by the Rev. Alexander McLaren, B.A., William Carey, M.B., eldest son of W. H. Carey, Esq., of Simla, India, to Rebecca Charlotte, second daughter of the late Captain Henry Kauntze, 11th Hussars.—No cards.

DEATHS.

***HEYGATE**, Thomas Nicholas, M.R.C.S. Eng., at Hanslope, Bucks, in the 65th year of his age, on October 12th. He had been in practice at that place upwards of forty years, and was brother of the late Dr. Heygate of Derby.
LUSH.—On October 18th, at Weymouth, Ann, wife of *William George Vawdrey Lush, M.D., for six years Sister Mary, and for twelve Sister Elizabeth, of St. Bartholomew's Hospital.

At Michaelmas Quarter Sessions, Dr. Joseph Wickham of Penrith qualified as Justice of the Peace for the County of Cumberland.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—Mr. H. W. Yate has obtained the Epsom Scholarship of £60 the first year, £25 the second, and £15 the third; Mr. R. N. Normasdjji the Scholarship, tenable for three years, of £60 the first year, £40 the second, and £20 the third; Mr. A. B. Prowse, the Scholarship of £20 in Anatomy; Mr. K. W. Millican, the Exhibition of £20 for one year.

TESTIMONIAL.—The Rev. Arthur G. Purchas, M.R.C.S. Eng., has been publicly presented with a purse of 137 sovereigns and an address at the Choral Hall, Onehunga, Auckland, New Zealand. The address was as follows:—"To the Rev. Arthur Guyon Purchas, M.R.C.S.E. As you are about to remove from the town of Onehunga, after an intimate connection with the place of more than twenty-eight years, we have been requested by your fellow-townsmen and others to ask your acceptance of the accompanying purse of sovereigns, as a small testimonial of the estimation in which you are held as a clergyman, medical man, and public-spirited citizen. We take leave to express the sincere regret which is felt at your removal from our midst, and, for the future wish it may 'be well with thee'."

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAYGuy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAY..St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

SATURDAY....St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M. and 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.—Medical Society of London, 8 P.M. General Meeting; Revision of Laws. Mr. Jabez Hogg, "On Concussion of the Spine, followed by Impairment on Loss of Vision"; Mr. Wm. Adams: "A Patient on whom he had operated for Obliteration of Depressed Cicatrices".

TUESDAY.—Pathological Society of London, 8.30 P.M. Mr. Heath: Calculi of Cystic Oxide. Mr. Heath: Epithelioma of Tongue and Jaw. Mr. Heath: Cancer of Rectum: Colotomy. Dr. Hilton Fagge: Carcinoma Lipomatousum. Dr. Hilton Fagge: Distended Diverticula of Intestine. Dr. Hilton Fagge: Pulmonary Embolism. Dr. Barlow: Tubercle of Pancreas. Mr. Marsh: Tumour in Upper Jaw. Mr. Wagstaffe: Double Cancer of Male Breast. Mr. Fairlie Clarke: Tubercular Lupus of Tongue and Palate. Mr. Maunier: Fatty Tumour in Male Breast. Dr. Goodhart: Abscess in the Heart. Mr. Pearce Gould: Syphilitic Heart. Dr. Greenfield: Syphilitic Pneumonia. Mr. Clement Lucas: Paris after Tracheotomy. Dr. Ralfe: Aneurism of Aorta. Dr. Dowse: Ilio-Sarcoma of Brain. Mr. Lennox Browne: Syphilitic Disease of Pharynx and Larynx.

WEDNESDAY.—Royal Microscopical Society, 8 P.M. Mr. H. C. Sorby, "On a New Method of Measuring the Position of Bands in Spectra".—Obstetrical Society of London, 8 P.M. Dr. George Roper, "On Prolapse of the Funis during Labour"; Dr. Swayne (Clifton), "On a New Form of Blunt Hook and Sling for assisting Delivery in Breech Presentations"; Mr. Lawson Tait, "Case of General Dropsy in a Fetus"; Mr. Lawson Tait, "Note on a Diseased Placenta"; Dr. Heywood Smith, "Notes of a Case of Ruptured Vagina during Labour, with Recovery"; Dr. Wiltshire, "Spontaneous Rupture of the Vagina: Recovery"; and other communications.

THURSDAY.—Harveian Society, 8 P.M. Council Meeting, 7.15 P.M. Dr. Alfred Meadows, "On the Diagnosis and Treatment of the Curable Forms of Fibroid Tumours of the Uterus".

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with Duplicate Copies.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

"MEDICAL STUDENTS."

WE are very sorry to see a police prosecution at Marlborough Street this week of some young men alleged to be "medical students", charged with rioting at a music hall, and raising a cry, "Guys to the rescue". It was alleged that "medical students had of late frequently misconducted themselves". We sincerely hope that these allegations may be groundless. If they prove to be true, we trust that the authorities at Guy's will take severe notice of such a course. Medical students in London have of late years deservedly earned a high reputation for gentlemanly conduct, and that character must not with impunity be injured by black sheep among them.

ERRATUM.—In the JOURNAL for October 16th, page 496, column 2, line 22, for "corpus callosum" read "corpus striatum".

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

MAUNSELL MEMORIAL FUND.

Amount already acknowledged in this JOURNAL, £168 13s. 0d.

The following subscriptions, in addition to those already acknowledged, have been received.

	£	s.	d.

TOTAL DESTRUCTION OF THE LUNG.

SIR,—In the case of "Rapid and Total Destruction of the Lung," described by Dr. Cottew in the JOURNAL of the 16th instant, I should very much doubt if any such destruction had occurred. I would venture to suggest that if he had pursued his investigations a little further, he would have found the lung bound down by adhesions, and compressed and flattened against the vertebral column.

I am, sir, yours, etc.,

J. WALTERS, M.B.

Reigate, October 23rd, 1875.

C. K. S.—Mr. Holthouse's temporary home for inebriates is at Falham.

W. G. K. (Gloucester) should address M. le Doyen de la Faculté de Médecine, Paris, asking for any further information which he may require.

THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH AND THE ADULTERATION OF DRUGS.

A CORRESPONDENT writes:—It may possibly astonish some of the physicians of the Royal College of Physicians of Edinburgh to find at the present time, when adulterations of every kind are being put down by Acts of Parliament, that they have been neglecting their duties (*sic*) as expressed in the charter granted to the College in 1685 (quoted by Hugo Arnot in *History of Edinburgh*, 1779, p. 322), as follows:—"The physicians of the Royal College shall at least twice a year visit all the apothecaries' shops within the city and liberties of Edinburgh, and destroy all insufficient and corrupted drugs." So it seems that adulteration of drugs was not quite unknown two centuries ago.

W. H. F.—Messrs. Hawkins of Savile Row, and Rouse of Wilton Street, are the honorary secretaries of the Hewett Testimonial, to either of whom subscriptions may be sent.

MR. WORTH.—The discussion is ended for the present, as we have no further space to give to it.

CLUB ELECTIONS.

SIR,—Having seen in the BRITISH MEDICAL JOURNAL several letters about medical men advertising, I beg to forward you the enclosed, which was exposed in the window of a public-house, and I think needs no comment.—Yours truly,

October 1875.

A MEMBER.

"Election will take place on Monday, November 15th, 1875.—L.A.I.O.O.F. Sick and Burial Fund.—Appointment of New Surgeon.—Vote for Dr. Axham, L.R.C.P.E., L.M., and M.R.C.S., London (Registered), 1, Brewer Street, Golden Square, Surgeon to the Hearts of Oak Benefit Society. The highest practical Testimonials.—Dr. Axham has had the pleasure of supplying medicine to, and acting for Dr. Reeve to, upwards of a hundred members of the above fund."

AN ASSOCIATE.—As to the authorities to be consulted in reference to the subject-matter of our leader of March 27th, on Pyrexia and Apyretics, the chief are: Leyden (*Deutsches Archiv*, vol. v, p. 273); Rosenthal (*Zur Kenntniss der Wärmeregulierung bei den Wärmeregulierenden Thieren*, Erlangen, 1873); Liebermeister (*"Zur Lehre von der Wärmeregulierung"*, Virchow's *Archiv*, vol. liii); Röhrig and Zuntz (*"Zur Theorie der Wärmeregulation und der Balneotherapie"*, Pflüger's *Archiv*, vol. iv); Winternitz (*"Beiträge zur Lehre von der Wärmeregulierung"*, Virchow's *Archiv*, 1872); Senator (*"Untersuchungen über Wärmebildung und der Stoffwechsel"*, Reichart and Du Bois Raymond's *Archiv*, 1872); Milner Foehrigill (*"The Depressants of the Circulation"*, BRITISH MEDICAL JOURNAL, January 1874); Wunderlich's *Medical Thermometry*; and H. C. Wood's excellent work on *Therapeutics and Materia Medica*, Lippincott and Co., Philadelphia, 1874.

LAHORE SCHOOL OF MEDICINE.

C. B. asks: "1. Is there a medical school at Lahore? 2. How many students are annually educated there? 3. Does it grant degrees? and are its degrees recognised in England? 4. Is it connected with the University of the Punjab?"

* * * 1. Yes. 2. From one hundred to one hundred and forty. 3. No. The degree of Licentiate in Medicine and Surgery is granted by the Punjab University College. 4. There is no "University of the Punjab". There is a "Punjab University College".

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

MRS. MONCKTON (Rugely) and Mr. NETTLESHIP (London) should have addressed the General Manager, 36, Great Queen Street, W.C.

THE PRODUCTION OF HYDROPHOBIA.

SIR,—Some years ago I read, in the library of the Athenæum Club, in a book or periodical, an account of some interesting experiments conducted for the purpose of ascertaining whether it were possible to produce hydrophobia in dogs by artificial means. The experiments, I remember, were made upon three dogs, who were treated in some respects differently, but were all exposed to a hot summer sun. I have since made repeated and wearisome attempts to find the passage. Can you or any of your readers help me? I should feel greatly obliged if any gentleman would send the information direct, to the address of "J. C., Athenæum Club, Pall Mall".—Your obedient servant,
J. C.

MR. J. C. LEACH, B.Sc.—1. No; the last Act adds little or nothing new. It is a digest mainly, and hardly affects the actual law; only rendering the various Acts easier of reference.—2. There are *The Sanitary Record* and *Public Health*: our correspondent had better form his own opinion.

MR. WIGG (Derby).—The letter has been forwarded.

MR. EDMUND OWEN.—The proof arrived too late.

INJECTION OF PERCHLORIDE OF IRON IN POST PARTUM HÆMORRHAGE.

SIR,—The case of *post partum* hæmorrhage reported in the JOURNAL to-day, and two cases (not fatal) in my practice lately, make me anxious to know from any of your readers who may have experience of galvanism in these cases, what success they have had, what battery has been found most useful and convenient, and how applied so as best to secure contraction of the uterus. There must, surely, be many who have tried it. Any information on the subject would much oblige yours, etc.,
A BUSY PRACTITIONER.

October 16th, 1875.

INQUIRER.—Should address Professor Liveing, University of Cambridge.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Bristol Daily Post; The Evening News; The Sheffield Post; The Metropolitan; The Blyth Weekly News; The Edinburgh Daily Review; The Glasgow Herald; The Western Daily Press; The Merthyr Telegraph; The Leighton Buzzard Observer; The Bristol Daily Times and Mirror; The Derby and Chesterfield Reporter; The Lincolnshire Herald; The Sunderland Daily Echo; The Co-operative and Financial Review; The South Wales Daily News; The Macclesfield Courier; The Melbourne Argus; The Southampton Times and Hampshire Express; The Jarrold Express; The Birmingham Daily Post; The League Journal; the Sheffield and Rotherham Independent; The Derbyshire High Peak News; The Liverpool Daily Courier; The National Food and Fuel Reformer; The Worcester Herald; The Norfolk News; The Worcester Chronicle; The North British Daily Mail; The Social Science Review; The Carlisle Express; The Sussex Daily News; The Royal Leamington Spa Courier; The Bethnal Green Times; etc.

* * * We shall be greatly obliged if correspondents forwarding newspapers will kindly mark the passages to which it is desired to direct attention.

COMMUNICATIONS, LETTERS, ETC., have been received from:—

Mr. Campbell De Morgan, London; Dr. Rutherford, Edinburgh; Dr. W. T. Gairdner, Glasgow; Mr. Nicholson, Hull; Mr. Steele, Bristol; Mr. Edmund Owen, London; Mr. Annandale, Edinburgh; Mr. Jonathan Hutchinson, London; Mr. Burdett, Greenwich; Mr. W. H. Spurgin, Maryport; Dr. Robert Barnes, London; Dr. Morris, Barnsley; Mr. F. W. Strugnell, London; Dr. Fox, Chelmsford; Mr. Jessett, Chatham; Dr. C. T. Williams, London; Mr. H. INTRODUCTORY LECTURE

ON THE

PAST AND FUTURE OF THE SCHOOL OF MEDICINE OF EDINBURGH.

Delivered to the Students of the Edinburgh School of Medicine, on November 1st, 1875.

By JOHN CHIENE, F.R.C.S.Ed., F.R.S.E.,

Lecturer on Surgery; Assistant-Surgeon, Edinburgh Infirmary; and Examiner in Anatomy in the University of Edinburgh.

GENTLEMEN,—A great deal has lately been said against the continuance of introductory addresses. Surely, on the present occasion, I might be justified in upholding that view. I might dyspeptically give an introductory on the uselessness of introductory lectures. I might, in still worse taste, dilate on the folly of choosing medicine as a profession. I am too proud of my profession to do so. Perhaps, however, it is only right to tell you that, if your object in this life is to make money, the sooner you try something else the better. You must remember that a life of continual endeavour to benefit your fellow man is worth some worldly sacrifice. On the other hand, if you work honestly, you will have money sufficient for your wants—a sufficiency with happiness, as distinguished from riches with its accompanying troubles.

Your teachers, in asking one of their number to begin the session today, are of opinion that some little good may follow an introductory address. However imperfectly I may fulfil my task, I have an inward feeling that there is a certain value in the custom. The few words that I have to address to you to-day, appear to me like the bugle-call to the regiment; before it sounds, the men are standing here and there—a crowd. After it has sounded, the men are the same, but, instead of a crowd, they are now a well-ordered mass of soldiers, willing and ready to obey the word of command: such, I hold, to be the use of an introductory lecture.

I address you as members of the Edinburgh School of Medicine in the widest acceptance of the term. Some would divide this School in its interests, in its usefulness, and in its power for good, into two divisions—the University and the Extra-Academical School. Its strength lies in their combination; the division is only in name. There are professors, there are teachers; they are all one body, whose sole object is your training as efficient members of the medical profession. The remarks I have to make are in your interests, and with an earnest desire for your welfare as students of a School which knows no divisions.

I would ask, why are you students of this School, with its old infirmary and its shabby class-rooms? In order to answer that question, I must ask another. To what is the success of the Edinburgh School due? Sir Robert Christison, in an instructive and interesting history of the University of Edinburgh, delivered at the meeting of the British Medical Association in this city in August last, directs attention to certain of the reasons of the continued success of the Edinburgh School. It may not here be out of place to point out to you other reasons for the fact, that the School to which you belong holds a pre-eminent position amongst the training establishments in this country.

I believe one of the greatest causes of our continued prosperity is, that alongside of the University there is an efficient teaching staff, which acts, so to speak, as a tonic to the University professors, encouraging a friendly rivalry, which is constantly spurring them on to continued effort, and by insisting that they perform their work in a thorough manner, directly advancing medical science. Competition is the greatest incentive to good manufacture. Free trade in commerce has increased the mercantile position of this country. Free trade in the teaching of medicine has brought students to Edinburgh, and has sent them away well educated and well prepared for the practice of their profession. The presence of an Extra-Academical School of Medicine is, in my opinion, the principal reason why the Faculty of Medicine is more prosperous and more famous than the other Faculties in our University. The establishment of an Extra-Academical School in Arts and Law, with the same privileges as we at present possess as medical teachers, would be an advance in the right direction, and would, I feel sure, be followed by greater efficiency in the teaching in these Faculties, and by a marked increase in the number of students.

It must be matter of regret to all interested in the Edinburgh School that our professors are not endowed. I hope that some rich person may see his way to leave his money for this purpose. An endowment of the Chairs of the Medical Professors would necessarily soon be followed by an abandonment of the privileges which they at present possess. Their present privileges are their endowment. These privileges are against the teachers outside the University walls; and it may with truth be said that the endowment comes at present directly out of the pockets of the extra-academical teachers. It would, undoubtedly, be for the benefit of the University if all restrictions could be removed. Endow the professorial chairs, give the lecturers equal privileges and equal rights with their seniors inside the University, and the result would certainly be a still further increase in the prosperity of this School. In the meantime, it is for the advantage of the lecturers that these privileges of the University should be maintained; because they—or their equivalent, an endowment—are necessary for the well-being of the University, on which the welfare of this School principally depends. Without the University in a flourishing condition, the School must go down. While this is true, it is necessary also to remember, more especially as, at the present time, there seems in the minds of some a tendency to consider the University as the Edinburgh School, that, without a powerful extra-academical school, the University influence would necessarily decline. Neither alone can draw the students to Edinburgh. Both working together, with a well-regulated infirmary in common, have now, for many years, stood the test of time, and have seen the rise of many powerful schools in London and the provinces, but have, in consequence of their inherent strength, suffered but little in the competition.

Another reason which has a very material bearing on our success lies in the fact that here each teacher is free to choose his subject. He begins early as a lecturer on some particular branch. Anyone can, after obtaining permission from the Royal College of Physicians or Surgeons, and from the University Court, commence teaching; and, if he have the ability, he will certainly draw to his class-room a proportion of the students. An early and special training in teaching is the only way to true success. As Captain Webb says, "to be a good swimmer, one must begin young"; to be a good teacher also requires years of special study. Speciality in practice may degenerate into quackery, speciality in teaching never can. A teacher is always subjected to a scientific cross-examination, a practitioner is not. In this way, the future occupants of our professorial chairs are being thoroughly educated. Teaching is like a trade: in trade, a lengthened apprenticeship fits a man to turn out good work; in teaching, an apprenticeship served as extra-academical teachers make successful professors, and enables our University to turn out good students. But this is not a training-school for our Alma Mater alone; it not unfrequently supplies our sister universities. In every Scotch university, there are now professors who were once efficient lecturers in the Extra-Academical School of Edinburgh. Since the delivery of the Introductory Lecture of 1874, two of our lecturers have thus been promoted. Dr. Pettigrew has been appointed Professor of Anatomy and Medicine in the ancient University of St. Andrew's, and the University of Aberdeen has chosen Dr. Stephenson as Professor of Midwifery. I need not tell you how honestly these gentlemen worked as teachers in this school. I feel sure that they will faithfully represent and uphold the character they have earned here. While we, teachers and students, regret the loss to ourselves, we rejoice in their promotion, and heartily wish them success. Their places will be filled by men who feel that they are fitted for the task. There is no surer road to success than a belief in self. It is this self-belief, this individuality, which this School fosters. Anyone is free to try the experiment; the result, if he fail, will be disastrous only to himself; he will know if he succeed, when he draws to his class-room a few earnest students, who can only be attracted by himself; their progress his encouragement; his earnestness their best example.

It was this earnestness that endeared John Goodsir to his pupils. The noisiest spirit was quiet when Goodsir taught. His truthfulness hushed to silence the largest class in the University. As a teacher, he led his men onwards to a victory over ignorance. They followed, because they believed in their leader. An earnest man searching after truth was the secret of Goodsir's power.

This essential feature of our method—to allow each to choose his place on our teaching staff—directly encourages the individuality of the teachers, and this in its turn encourages the individuality of the taught. Individuality means freedom. You are free to choose your teacher, and in most branches you have an abundant choice. You choose your teacher on account of his individual worth. He may have certain peculiarities; it is desirable that he should ventilate them. He may believe in his methods of conveying instruction; he can put them to a

practical test, and, if he be a true prophet, his labours will be followed by well merited success. Glasgow, I am glad to see, is beginning the good fight; all success to those gentlemen who have obtained permission to lecture in the Royal Infirmary of that city. The results to themselves will be self-improvement, the result to their University will, I feel sure, be an increase in its efficiency.

The self-additions to our teaching staff, on the principle just laid down, are this year comparatively few in number—Dr. Underhill as a teacher on Midwifery, Dr. Andrew Wilson as a teacher of Natural History. The former branch has already many votaries. To Dr. Wilson is due the credit of filling up a blank in our curriculum. Dr. Underhill has to compete with his seniors; he has to fight an uphill friendly battle. Dr. Wilson has an open field before him.

It is a subject of congratulation that Dr. Wyllie, one of our lecturers on pathology, has been appointed Pathologist to the Royal Infirmary. It is right that the science and practice of pathology should be combined.

In order to true teaching, then, individuality and freedom must have the sway. In order to true learning, I believe the same rule holds good; to interfere with the individuality of a student appears to me the great mistake of the systems of the present day.

Carlyle, in his *Life of Schiller*, when describing the time Schiller spent at a school in Stuttgart, in consequence of a well intended act of patronage by the Duke of Württemberg, says:—"The Stuttgart system seems to have been formed on the principle, not of cherishing and correcting nature, but of rooting it out, and supplying its place with something better. . . . Everything went on by statute and ordinance; there was no scope for the exercise of free will, no allowance for the varieties of human structure. A scholar might possess what instincts or capacities he pleased; the regulations of the school took no account of this; he must fit himself to the common mould, which, like the old giant's bed, stood there, appointed by superior authority, to be filled alike by the great and the little."

The system of medical education of the present day has certain of these features. Rules, regulations, statutes, visitors of examinations, assessors, councils, are the order of the day. The result perhaps is a better training of the mass to mediocrity—a necessity, no doubt. Would that it could be attained without damaging and distorting the individuality and freedom of the student. There must undoubtedly be a certain amount of restraint, but let it be as little as possible. There must be examinations, but let them be more frequent and less formal. The student should be allowed to pass in any one subject, always supposing that he knows it thoroughly. To judge of this thoroughness, the standard the examiner has to remember is, that an extensive knowledge is not so much required as that the knowledge should be precise and accurate. A mistake is infinitely worse than an omission. The man who does not know has only to learn; the man who is in error has to unlearn and then to learn.

These remarks regarding the individuality and freedom of this School, cannot but recall to many present the recent death of perhaps one of the greatest of our teachers—John Hughes Bennett. The time has hardly come for a proper estimate of his character. His individuality was too marked, and the freedom with which he expressed his opinions too apparent, to enable us at present fully to estimate our loss. Professor Bennett was a teacher in the highest sense of the word; his love of his work, his natural talent for teaching, fostered by years of special study, the clearness of his lectures, the impress he made on the minds of his students, will not die. In our wards, where the essential features of his system of clinical instruction are almost universally adopted; in our laboratories for the teaching of practical physiology; in the privacy of our studies when at work with the microscope, Bennett still lives. His career of untiring industry, of ardent application to his professional work, were the characteristic features of his nature. Years will pass away before we can properly estimate the good work John Hughes Bennett did in the Edinburgh School.

I am now brought from the past to the future. What is the future of our School? To be successful we must go forwards. Our motto must be "Excelsior," and the new Infirmary and University buildings show that this is not forgotten. But in order that the new University buildings may bear proper fruit, we must soon have outside the University more appliances for the teaching of such subjects as anatomy and physiology. The efficient teaching of the so-called practical subjects, medicine, surgery, and midwifery, does not depend on appliances. A warm, comfortable class-room, with a self-made museum which no money can purchase, are the stock-in-trade of these lecturers. It is different with anatomy, physiology, pathology, and chemistry. For the well-being of any school, well paid demonstrators are required for these subjects. This is more especially true of anatomy. To teach physiology, it is absolutely necessary that there

should be a well equipped laboratory; so also with pathology and chemistry. These necessities cannot be attained in this building, and, in my opinion, the time has now arrived for building new class-rooms and laboratories for these subjects. But it is as reasonable to expect the professors to build their laboratories, as it is to ask our lecturers to build theirs. We cannot, I fear, expect the public to contribute. To whom, then, are we to apply? It appears to me that the Colleges of Physicians and Surgeons should undertake the work. There is a great deal of talk about the uselessness of such bodies, and there is at present a cry that their work should be taken from them. The result would be a feeble existence—a second childhood—reminding us of Paget's classical description of a natural decay. "For," he says, "it is natural to become feeble and infirm, to wither and shrivel, to have dry husky wrinkled skin, and greasy brittle bones, to have weak fatty hearts, blackened inelastic lungs, and dusky thin stomachs, and to have every function of life discharged feebly, and as it were wearily, and then, with powers gradually decreasing, to come to a time when all the functions of bodily life ceasing to be discharged, death without pain and distress ensues."

Such a picture is too painful to dwell upon—our relationship is too near. I will only say, that some apparent good done by these august bodies will be the best answer to their accusers. What could be more worthy of their existence than the strengthening of the School to which they belong, and on which, if the truth must be told, they live? The College of Surgeons started the Anatomical School, the College of Physicians the Royal Infirmary of this city. Let the same spirit now rule their councils, and let them see that before very long we owe to their joint efforts a well-equipped building, with well paid demonstrators, in which the scientific subjects may be taught with comfort to both teachers and taught. I lately visited the Medical Schools of Liverpool and Manchester, and the lesson I learned there is, that such Schools as these, with their splendid equipments for practical study, will, if we do not look to our appliances, dazzle and intercept many of our students. Lastly, am I asking the Colleges to run too great a risk? The College of Surgeons kindly built this class-room, I forget how many years ago, and they perhaps can give their sister College an idea of the interest they have received on their original outlay. A good rent, coupled with a good name, will, let us hope, ward off the evil day which, prophets say, is drawing nigh. In the name of the lecturers, and on behalf of the students, I ask this of the Colleges. I ask it in no spirit of rivalry to the University, for my firm belief is, that the better the appliances without, the greater will be the success within the walls of the University. I have not time to do more than mention certain other improvements which would, in my opinion, add to our efficiency.

We require a lectureship on Public Health—it is too important a subject to be tacked on to Medical Jurisprudence, thus injuriously curtailing the lectures on that important subject. I sincerely trust that some one will take up Professor Stephenson's mantle, and continue the lectureship on Diseases of Children. I would also wish to see the addition to our curriculum of a short summer course on Diseases of the Ear. Speciality in teaching is, as I have already said, a good thing. It is the only way to make thoroughly sound practitioners.

We are not now far distant from what must be to all of us an interesting event in the history of our School. We are soon to leave the old infirmary, which, for one hundred and fifty years, has done such signal service to medical science. A history of that institution would indeed be a record of medicine and surgery. It was at one time my intention to devote the time at my disposal to-day, to a short recapitulation of the important discoveries in medicine and the improvements in medical teaching, which have taken birth within its walls. I found, however, after considerable investigation, that, in the time at my disposal, even an abstract of the good work done was impossible. I trust that some one will undertake the task. A history of the Edinburgh Royal Infirmary will be a valuable work of reference in time to come.

If, however, I cannot even very hurriedly allude to the past, I may for a moment dip into the future. With new buildings, well-regulated wards, and clinical lecture-rooms, with increased facilities for clinical instruction, is there nothing that can be done still further to improve the bedside teaching?

Our managers are fully alive to the fact that the welfare of the patients and the well-being of the students are inseparably connected. The diagnosis and treatment of every case carefully sifted by a teacher in the presence of an intelligent, sharp-sighted, perhaps somewhat fault-finding audience, is the best guarantee for a judicious diagnosis and a careful treatment. There is no class of patients so carefully treated as the patients in any well-regulated infirmary attached to a large school of medicine. Take any hospital without students; go round

with the physician or surgeon; and the visit, instead of being a carefully performed duty, is generally a hurried run through the wards, and a general acquiescence in the treatment of the house-surgeon, on whose shoulders rests the greater part of the treatment. How different is the visit of the teaching physician or surgeon! With him, to teach is to learn; and the daily visit to his wards is to him both the most profitable and the most pleasant period in his daily work.

A studentless hospital reminds me of a private picture-gallery: splendid pictures, but no one to look at them. A hospital with students is like one of our national galleries, through which thousands yearly pass. The pictures sustain no harm from being looked at; and the chances are, that they are better cared for than even the most valuable private collection. Your interests, the interests of your teachers, the interests of the managers as representatives of the general public, are one—the welfare of the patients. The more thorough the system of medical instruction, the greater is the public fame of the Infirmary.

Is it right that, during three of the four years of your student-life, only one hour daily is given by the authorities to clinical study? The hours from twelve to two should be sacred to the hospital. The result, as the classes are at present arranged, is, that the student spends about three-quarters of an hour in the Infirmary. It will, I think, be generally allowed that this time is too short. By careful consultation between the University professors and the extra-academical teachers, the classes could be arranged in such a way as to meet this want. There are many ways in which the change could be made. This, however, is not the place to discuss the question.

Might not the out-patients be utilised more than they are at present for the teaching of the elements of medicine and surgery? There is surely a quantity of material running to waste, which might be made use of for the teaching of the junior students. Before visiting the wards of the surgical hospital, the junior student might learn the elements of practical surgery; so also, in the medical house, auscultation and percussion could be taught in the medical waiting-room. Such preliminary study would lighten materially the labours of the surgeons and physicians.

One of the weak points of our School is the small number of beds, as compared with the large number of students. Our wards are uncomfortably crowded. An organisation of the out-patient department would undoubtedly lessen the number of students attending the wards.

When the new Infirmary is opened, the Sick Children's Hospital and Chalmers's Hospital will be within easy reach. I sincerely trust that every encouragement will be afforded by these institutions for clinical study. Practically, at present, they are studentless hospitals. In this way, also, the crush of students would be relieved.

The appointment of a special professor of Clinical Medicine appears to me another improvement worthy of consideration. Glasgow has taken the lead in this matter. Surely it is an anomalous position to have a professor of Clinical Surgery and none of Clinical Medicine. The professor of Practice of Physic must have wards to illustrate his systematic lectures; but there should be one man who is the acknowledged head of clinical medical instruction. Such an appointment would, I believe, directly benefit our School.

I cannot help hoping that the managers will be able to allot special wards in the new buildings for the study of diseases of the throat, diseases of the ear, and skin-diseases. At present, our students have to go to the Continent for such special clinical instruction. It is also absolutely necessary that the department for the study of syphilis should be thoroughly equipped.

I think that the time has now arrived when these points should be discussed. My wish is your good, as long as it does not interfere with the welfare of the sick poor. I have tried to show that your interests and theirs are inseparably connected. These remarks regarding certain changes which might, in my opinion, be advantageous to our Infirmary, are made in no complaining spirit. We are governed by an enlightened board of management; we are proud of our hospital, proud of our clinical teaching; but I feel that, to keep our place as the leading medical school in this country, we must not stand still. Progress in the right direction will result in greater fame, will directly benefit the patients, and will, if possible, still further widen the range of the grand motto laid down by the founders of our Infirmary—"This Hospital will be open to all the curable distressed, from whatever corner of the world they come, without restriction."

I have to-day avoided offering you advice regarding your duties and your studies. Any recommendations as regard your duty to yourselves and to your teachers are unnecessary to the great majority present. I am addressing men who have begun the business of life. For the few who, perhaps, require to be told their duty to themselves, any words spoken in general terms would, I feel, have little good effect. I could

not be particular enough. The advice given would not exactly fit each recipient, and the result would be an abandonment of what really was applicable. Instead of advice as to your general conduct, I might speak regarding the proper methods of study, the order in which you are to take your classes, your text-books, note taking, etc. The objections to this are that general advice is rarely followed. The student has to drop his individual sense, and merge into the common run of humanity. Such advice would directly interfere with what, in my opinion, is above everything else to be encouraged—your individuality. Any interference with this essential to your healthy existence would be as disastrous to our School as would be the loss of that essential amongst your teachers. All of you, perhaps, wish some point cleared up. To-morrow, meet your individual teachers as individuals, and explain your individual wants. More benefit will be derived by a few minutes' conversation than by listening to an introductory lecture teeming with generalities.

In conclusion, I have simply to bid you all welcome. We, as teachers, will try to do our duty; we expect you to try to do yours. Our sincere wish for you all is happy honest work. The teacher is your steersman; you are the rowers. Remember that a single bad oar spoils the whole boat.

Junior students, you have chosen a School with a name and a fame, with a reputation for work. The maintenance of these qualities depends on you. You have in your seniors many bright examples of how that reputation is to be maintained. Follow in their steps, and be prepared to take their place when another introductory comes round.

To the senior students I say—Go on as you have begun; do not abate your efforts. More is expected of you, the more your opportunities. Be proud of your School; endeavour that your School may be proud of you; and when you leave us, may your chief pleasure be in the recollection that you were once Edinburgh students.

THE TREATMENT OF OBSTINATE VOMITING CONNECTED WITH PREGNANCY.

By EDWARD COPENAN, M.D., F.R.C.P.,
Senior Physician to the Norfolk and Norwich Hospital; Vice-President of the British Medical Association.

SINCE the publication in our JOURNAL of the few cases which suggested to me the novel treatment I advise for obstinate vomiting connected with pregnancy, with its attendant effects of depression, emaciation, and all the symptoms of starvation, I have received promises, both at home and from abroad, that such an apparently valuable means of relief shall have a fair trial, and that I shall be duly informed of the results.

My paper in the JOURNAL has elicited from Dr. Graily Hewitt some valuable observations on the subject in a more recent number, in some measure corroborating my own views, although only partially according with my present ideas as to the cause of the disease; and, still more recently, Dr. Henry Bennet has been sufficiently attracted by it to repeat in the JOURNAL the valuable suggestions he had previously offered to the profession in his own published works. My paper has also been translated in a masterly style by M. J. Lucas-Championnière of Paris, and published in the *Journal de Médecine*, of which he is the chief editor; and in a private letter he says he was so struck with the great importance of it, that he translated it for the benefit of the readers of his journal, adding that he himself, as well as several of his hospital colleagues, intend to apply the treatment when opportunities offer, and communicate the results to me. Also, in a letter from Dr. G. Pacchiotti of Turin, he says, referring to my method of treatment of obstinate vomiting in pregnancy: "It is so simple and so extraordinary, that it is astonishing that it has not been found before. As soon as an opportunity comes, I will try it and tell you what happens."

I have always felt throughout my professional life that increased practical knowledge in the treatment of disease should be the principal aim of the physician, and that all other collateral studies should be ancillary to this chief object of the practice of medicine. No kind of work in our profession earnestly entered upon and diligently carried out can fail of doing good in some way or other, and producing beneficial effects directly or indirectly to suffering humanity; but the cure of disease is not only one of our primary objects, but one which has not been so carefully studied and worked out as its importance demands compared with some other branches of medical science.

Several different conditions of the uterus have been referred to as causes of sickness during pregnancy; for instance, Dr. Graily Hewitt

attributes it to version of the cervix, producing constriction of the inner os, and states that the rectification of these displacements will cure it. Dr. H. Bennet looks upon inflammation and ulcerations of the os and cervix as the cause, and the use of the proper remedies for these affections the cure. M. de Saint-Germain has related a case in which he used M. Tarnier's dilator for the purpose of producing abortion, and immediately afterwards the vomiting ceased and did not recur, although the expulsion of the ovum did not happen for many weeks after the sickness had subsided. My own opinions as to the cause or causes of this complication of pregnancy are not yet sufficiently matured to enable me with certainty to afford any positive explanation; but I am inclined to believe that in such cases there is always some irritating condition present which induces a strain upon the neck of the uterus, or perhaps also on other parts of the uterus, exciting that organ to a disposition, so to speak, to get rid of its contents. After further investigation of the subject, I shall hope to give my views more particularly, and meanwhile I will content myself with what further evidence I have had with reference to the value and certainty of the treatment.

Whilst I was waiting in the reception-room previously to the public dinner of the British Medical Association in Edinburgh, a gentleman introduced himself to me that he might relate a case of almost fatal vomiting during pregnancy which had recently occurred to him. He told me the case was an extreme one, that he thought himself that nothing but emptying the uterus would save the patient's life, and that her husband utterly despaired of her living many days. He then added: "I had recently seen your paper in the JOURNAL, and, in order to calm the utter despondency of the husband, I ventured, *solely on the strength of your published experience*, to promise him that, after a certain operation, his wife's life would not only be saved, but that she would be well in a few days. I dilated the os uteri as you recommend; her sickness immediately stopped; and, to the astonishment of the husband and to my own amazement, she went steadily on to recovery." This gentleman, whose name I forget, but think he lives at Swansea, promised to publish the case, and any others he might have; and, in our short conversation, I had not time to make out particulars as to age, duration of pregnancy, etc., but I hope they will appear in due time in the JOURNAL.

On my return home from Scotland, I found a letter awaiting me from Mr. Atkinson of Ripponden, near Halifax, to the following effect. "Dear Sir,—I think I have had a case during the last three days, the treatment of which carries out the idea of the good results of such procedure. It was a case of vomiting in a woman who has had eight children; and, during the last three days, had a fright from a sudden death occurring next door to her. I attributed the vomiting at first more to a bilious attack, and gave her the usual effervescent saline, with a dose of calomel, but the vomiting continued just the same. Forty-eight hours afterwards, I dilated the os with my fingers, left, and ordered a mixture of carbonate of soda, nitrate of potass, and dilute hydrocyanic acid. She has had no return; and now, two days afterwards, wants to get up. I may also state that she has never been troubled with vomiting before in her pregnancies, and has got up the day after her confinement. She had eight years ago two miscarriages; none since; and is now six months advanced. I do not attribute the allaying of the vomiting to the alteration of medicine so much as the manipulating the os, and I thought I would just mention it to you. I have no doubt it is a procedure which may be carried out without danger to the woman, and seems to be a remarkable antidote to vomiting occurring in pregnancy, primipara or multipara. Of course, this is only one case; but I am sure it may be put down to this treatment as being the means of relieving the vomiting."

I have recently had a case bearing strongly upon the subject in question. A lady, five months gone in her second pregnancy, caught a cold, had a chill, and was attacked with severe frontal neuralgia; at the same time, she became unable to retain her food, and for several days vomited everything she took. She is of a delicate, excitable habit, and had for some weeks previously been taking a great deal of exercise, rowing, etc. Latterly, she had been feeling her dress rather tight, but had not hitherto let it out, and remarked to me that no one would have known she was pregnant from her appearance. For her attack of neuralgia, she had taken aperients and quinine, which latter did not, as she said, agree with her; and she had had local applications over the brow of belladonna, aconite, and chloroform, none of which had relieved her. Hypodermic injection of morphia had been suggested, and, from the severity of the pain, I thought it very proper treatment in default of other remedies. I found the neuralgic pain intolerable, the left eye watering, and she was unable to bear even the pressure of the pillow upon the part. No local application appeared to relieve her. The constant vomiting after food (not a necessary result of neuralgia), coupled with what she described as a "riotous

motion of the child", led me to think the whole case might have an uterine origin. Perhaps the child was dying; but, on examination, I heard the foetal heart distinctly, and could mark out the position of the placenta by the peculiar *bruit*. I then examined *per vaginam*, and found the head low down in front, and the os uteri corresponding with the promontory of the sacrum; the pelvis was capacious; and it seemed to me that the uterus was anteverted, so as to allow the head to be felt below the level of the os uteri. The os was slightly patent, but there was no discharge and no particular feeling of bearing down, only a frequent desire to pass urine. By gentle continued pressure, I raised the protruding portion of the uterus with the head of the child out of the lower pelvis, and restored the os uteri to a more natural position; after which, I was bold enough to prognosticate that no further vomiting would occur. Some hours afterwards, I had a message to say that no further sickness had occurred, but that the pain in the brow was as bad as ever. On my visit the next morning, I found there had been no return of vomiting, that she had slept well during the night, and there was no pain, "only a feeling of having been bruised", as she expressed it, in the forehead. She had taken no medicine, neither had she used any local application, except warm water, since my visit the day before. She had taken simple nourishment and a little champagne to relieve the faintness which the excessive pain had occasioned. On visiting her the next morning, I found she had slept soundly all night, had neither sickness nor pain, had taken nourishment, partridge, etc., without any feeling even of nausea, and really appeared well, with a good pulse, healthy skin, clean tongue, and cheerful happy expression of countenance. After one day's interval, I have seen this patient again to-day (October 5th), and found her in every respect perfectly well and contemplating a journey into Scotland in the middle of next week.

I do not think I have a theoretical mind, and I have no belief in any theory that is not based on facts. I have not as yet appended any special theory to the subject under consideration, but have no doubt, as facts multiply, there will be found good reasons, both anatomical and physiological, for the phenomena observed. I am very sanguine that much good will arise from the discovery of this "novel treatment", as it is called, and that lives not a few, of both mothers and children, may be saved by its adoption.

P.S.—I have since been informed that the contemplated journey took place; that the patient travelled all night, arriving at her destination at four o'clock in the afternoon, and was so little fatigued as to be able to join the party at dinner the same evening.

HYDATID DISEASE:

AS ILLUSTRATED BY SPECIMENS CONTAINED IN THE PATHOLOGICAL MUSEUMS OF THE METROPOLIS AND IN OTHERS ELSEWHERE.

By T. SPENCER COBBOLD, M.D., F.R.S., F.L.S.,
Correspondent of the Academy of Sciences of Philadelphia.

II.

THE museum connected with King's College contains at least a dozen good specimens of liver-hydatids, several of the cases being of special interest from a pathological point of view. There are two remarkably fine examples of hydatids contributed by Dr. Hooper; the parasites in one case affecting the spleen, and in the other involving the ovary and uterus. The spleen contained numerous encysted hydatids, whilst the uterine organs exhibited "an immense collection" of the same growths. In this place, also, I may refer to an hydatid-like entozoon, taken from a cyst in the ovary of a female who had been under the care of Dr. Johnson (December 15th, 1860). It is, apparently, a genuine example of the slender-necked hydatid (*Cysticercus tenuicollis*); and if so (as might be determined by dissection), is, so far as I am aware, the only specimen of the kind in existence from the human bearer. There is a renal hydatid (presented by Dr. Pass of Warwick) which was obtained from a lunatic, its presence being "quite unsuspected during life". Amongst the liver cases (the majority of which are from Dr. Hooper's collection), there is one enormous hydatid that was obtained from a young woman who had died during a fit of laughter. The tumour had pushed the diaphragm up to a level with the fourth rib; and it is stated that, on puncturing the cyst, the fluid contents were ejected "in a jet nearly two feet high". There is one case represented where numerous hydatids were expectorated after hepatitis, whence it was concluded that they were originally connected with the liver. There is a large solitary hydatid that was removed from a young female who died of phthisis, and in whom the consequent swelling had formed in the neighbourhood of the navel. Especially instructive, also, from

a clinical point of view, is a case of peritoneal hydatids where the tumours had been diagnosed to represent a case of extra-uterine foetation. It appears that there were two cysts, one of them being connected with the uterus. Two of the enormous hydatids taken from these cysts are preserved in the collection of the "Anatomy School of Oxford". Several of the preparations show to perfection the stages of natural cure produced by calcareous degeneration; and there is one liver showing three of these so-called ossified cysts. The disease in this case proved fatal.

Most of the entozoa displayed in the Charing Cross Hospital Museum have been contributed by Dr. Wiltshire; the series being particularly strong in tapeworms. There are four characteristic examples of hydatids of the liver, representing as many separate cases. Two were from abscesses of this organ. In one of these, Mr. Canton's case, the hydatid was, I believe, expelled after operation; but, in the other example (presented by Mr. Rose of Swaffham), the parasite was evacuated from an abscess which burst of itself, externally.

In the Museum at University College, I examined sixteen preparations of hydatid disease, representing almost as many distinct cases. One is a wax model. Eight of the specimens were from the liver, five from the abdomen (including those of the omentum and mesentery), two from the lungs, and one from the heart. The model displayed ordinary hydatids of the liver bursting into the lungs. The mesenteric example is particularly fine, whilst that from the omentum is undergoing calcareous degeneration. Probably the most interesting of all is the example showing an hydatid lodged in the septum of the heart. This was from a middle-aged female who died suddenly, whilst pursuing her ordinary domestic avocations.

The Museum of the Royal College of Surgeons contains a fine collection of parasites; its chief strength in this respect being due to the special series of entozoa. Were visitors to judge by the contents of the catalogue of this series (which I prepared some years ago at the instance of the Council of the College), they might be led to suppose that the hydatids were only feebly represented. Out of nine preparations of hydatids in this section, only six have come from the human body. However, scattered throughout the collection, I found that there were no fewer than thirty-five different preparations of hydatids belonging, apparently, to as many as thirty separate cases. Omitting, for the present, all mention of those derived from animals, I ascertained that, of the thirty human cases, thirteen were referable to the liver, four to the abdomen, three to the lungs (one of which was originally connected with the liver), and two to the brain. Five were of uncertain seat. With the abdominal cases, we may also include one case of hydatids of the spleen, and another where these organisms were found in the region of the bladder. There is a characteristic breast case. One of the original Hunterian cases (in which "a prodigious number of hydatids were found in the sac of the liver and dispersed throughout the cavity of the abdomen") appears, though it is not expressly so stated in the catalogue, to have been regarded as an ordinary example of abdominal dropsy. In one of the three lung cases, two small hydatids were separately expectorated at an interval of about a month. This occurred in a female.

I may here incidentally remark that many cases are on record where abdominal hydatids have been overlooked: the patient being supposed to be suffering from ascites. One such instance took place a few years ago at the Middlesex Hospital. I well remember, also, a case of supposed hydrothorax, where the *post mortem* examination revealed the presence of immense numbers of these formations occupying the right side of the chest. This last-mentioned case, however, occurred at the Norfolk and Norwich Hospital at the time when I was studying there, thirty or more years ago.

The pathological collection connected with St. George's Hospital displays several good hydatid preparations; the entire series representing at least twenty-two separate cases. Of these, fifteen are referable to the liver; that is, if we include Dr. Dickinson's case, already published, where hydatids were found within the hepatic duct. There are two renal cases; also one from the brain (Dr. Dickinson's case), and another where an hydatid was expectorated. Besides these, there are three other highly characteristic examples of echinococcus disease affecting the region of the neck, breast, and axilla respectively.

The Museum of the London Hospital Medical School contains a large collection of parasites. Out of fifty-seven preparations of entozoa, I found twenty-two referable to hydatids; and, so far as I could gather, all of them belonged to different cases. Only one case seems to have been published in detail. This, though a very old preparation, is a fine example of an hydatid, nearly three inches in length, occupying one of the cerebral hemispheres (*Edin. Med. Journ.*, vol. xv). There is a second brain case, where the vesicles were of small size, but very numerous. Of the other twenty cases, fourteen belong to the liver, two

to the spleen, one to the lung, one to the uterus; one being a very large hydatid of doubtful seat, and another being referable to the lumbar region, where it formed a tumour containing "a large number of small hydatids". Amongst the more remarkable specimens is that described in the MS. Catalogue as "a true hydatid cyst developed in connection with the broad ligament". This preparation, unique of its kind, shows no trace of the ovary, which, indeed, seems to have disappeared altogether. One of the liver cases should rather be classed as abdominal, since the large cyst is situated between the diaphragm and liver, pressing upon the latter organ below and also upon the lung above, but apparently not involving either of these viscera structurally. Another very striking case is that in which there is an external opening communicating with the cyst in the liver, and an internal opening through the diaphragm communicating with the lungs and bronchial tubes. The patient had actually coughed up liver hydatids by the mouth, and had passed others through the right wall of his abdomen. There is another liver case in which the hydatids, in place of escaping externally, had gained access to the inferior vena; and, if I understand the MS. record rightly, in the same patient, a second hydatid communicated with the portal vein, and a third with the hepatic vein. Lastly, I must add that there is yet another fine preparation of liver-hydatids, occurring in a lad nineteen years of age. He had, it seems, met with "a slight accident, and died with obscure head-symptoms"; but the odd part of the case is that, at the *post mortem* examination, there was positively nothing found that could explain the patient's death. He was under the care of Mr. Luke (1834).

FAILURES OF MEDICINE.*

By T. COLE, M.D., Physician to the Royal United Hospital, Bath.

It is acknowledged on all hands, and with some degree of justice, that medical science has of late made most wonderful progress. Never were her prospects brighter; never was her power of doing good and preventing evil more extended; never were her votaries more ardent, able, and illustrious. Her torch shines with unequalled brilliancy, and its healing rays illumine the darkest corners of misery and desolation. Her children are full of mutual congratulations, and those whom she benefits are not backward in their praise. The picture is pleasing, and we naturally view it with a sense of satisfaction and delight. We revel in all its bright touches, and, charmed with the general aspect of pleasure which it presents to us, forget the dark shadows which, equally with these touches, go to make up the whole. It suits us ill to compare them, when, by serious contrast, the shadows deepen and blacken; and we are forced conscientiously to confess, too, that the gay and splendid tints must, and do,

"Take a sober colouring, from an eye
That hath kept watch o'er man's mortality."

It is our business to keep watch "o'er man's mortality", and it is, therefore, our duty to allow nothing to interfere with that business; to permit no dazzling pictures to pervert our vision; to hinder every soft illusion from lulling us into a false and injurious repose. I willingly admit that our art has made much sure and steady progress in the past, and that it affords legitimate reason for rejoicing among the members of our profession. But are we not in danger of overestimating the degree of that progress, and of losing sight of our failures and retrogressions? Do we not pride ourselves too much on our advances in physiology, pathology, and therapeutics, and think too little of those ever-recurring scenes of agony which every death-bed furnishes, and which tell us, in terrible language, how ineffectual oftentimes are our best efforts, how feeble the weapons we employ? Should we not the rather calmly and seriously consider the reasons why our science proceeds with such slow and halting steps, and endeavour to find out how they may be quickened, and a more solid triumph ensured? The deep conviction that we are prone to lose sight of this, the graver aspect of the question, and a strong desire to obtain the matured opinions of those present upon it, must be my apology for intruding upon your time and patience to-night.

With your permission, I will briefly allude to a few of the more important causes which influence our failures. To understand the obstacles which impede our pathway, and the manner of surmounting them, is halfway to the end of our journey. Those which obstruct the road along which medicine travels are probably more numerous and difficult than any which lie in the course of other sciences. Some are peculiar to herself; others she shares with them. Moreover, her path runs close by and parallel with theirs. And, unfortunately, so scantily

* Read before the Bath and Bristol Branch.

furnished is hers with intelligible directing-posts, that she is often compelled to use those which they have furnished for themselves. But they speak their own languages, which she has to learn before she can advance; and even when learnt, they often lead astray, or give no information at all. She is obliged to employ the same methods of observation, yet has far more difficulty in escaping from the fallacies which surround every logical process; and has to rely for a great portion of her knowledge upon these very sciences. Frequently she has to accept on trust their theories and deductions, and build upon them. Not seldom these are false, and she builds in vain. This affords ample explanation why she has adopted so many systems of practice, and why each in its turn has blazed upwards to the zenith, and then fallen for ever to the nadir of oblivion. When it is thus considered that medical science is dependent to such a degree upon other sciences, it should excite no surprise that she lags so far behind. Some would even deny her the right of assuming the title at all, so imperfect are her claims to it. But astronomy, at the dawn of celestial discovery, was far less developed than our branch of knowledge now is. Besides, we can never attain to the exactitude and perfection of which the students of other sciences make boast. They work in the glorious fields of nature, comparatively unimpeded by the thistles and briars of abnormality that infest our toil. We labour in antinature. Although a curse has gone forth, at all events, over our little planet, yet stars, rocks, beasts, and birds, and flowers have, to a great extent, escaped its influence. But we, with all our race, the objects of the sad science of physic, are rendered so by the introduction of conditions antagonistic to our natural state, and, therefore, to our well-being. However, not only is medicine dependent upon and intertwined with other sciences, but it is also, in a certain sense, independent and isolated. With the exception perhaps of some portions of the moral sciences, it alone deals with conditions of disease. Whatever light physiology may throw upon the functions of the healthy tissues and organs of our bodies, however great an insight organic chemistry gives us into the changes which take place in them during their normal exercise, our study alone can inform us of the alterations which disease produces in our system, and of the laws by which its processes are regulated and controlled. Not but that it is absolutely necessary for us to know the mechanism of the machine and its purposes before we can repair any injury to it. But it is equally essential to understand the injury itself before we can remove it. This brings before us the question, What is disease? Errors on this important point are so many *ignes fatui*, drawing us away from the true path of progress. Is, then, disease simply a derangement of the animal machine, or is it something superadded thereto which we can think and talk about, and work against, in the human economy?

First, let me remark that many conditions dignified as diseases, and named accordingly, are not so at all; for example, jaundice, paralysis, vertigo, and a host of others. Accurately speaking, they are only evidences or symptoms of widely varying diseases. As terms, we find them useful, serving as they do for cloaks to our ignorance of the real morbid states upon which they depend. Further, many conditions that have a more legitimate claim to the title are only effects of other complaints, and really stand in the relation of symptoms to them, and are not, as a rule, amenable except to treatment appropriate to the complaints themselves; for instance, gouty and syphilitic bronchitis, or epilepsy from an intracranial tumour. Of course, we are often compelled to treat symptoms for their own sake. Thus bromide of potassium might control the convulsions due to a syphilitic tumour in the brain or its membranes; but the only way in which we should hope to cure them would be by curing the tumour, as by iodide of potassium. If we thus eliminate such conditions as I have alluded to, we shall be in a better position to determine this important matter. Is, then, disease an entity which we can imagine as apart from the body that is the seat of its phenomena? The answer, I think, must be emphatically "No". Nevertheless, the definiteness and invariableness of the characters of the various diseases entitle them to an individuality no less real than that claimed by the objects of all other sciences. We cannot delineate them with such precision, it is true, as we can the subjects of the physical and more exact departments of knowledge. But this arises from the much greater intricacy in the chain of events, and our ignorance of factors too subtle and complicated for our present means of research. Were our powers of observation more extended, we should probably analyse the maladies already known to us into an infinity of clearly defined groups. However this may be, there is good reason to assume that the phenomena of properly defined maladies are constant enough to warrant the supposition of their dependence, in each given case, upon a certain physio-logic-pathological process. Physical diagnosis lends additional countenance to this view, although we are in danger of looking too much at

the physical characters of diseases, and too little at the vitalistic phenomena which are equally essential to them. And, if there be any drawback to the utility of the various scopes and other instruments which modern science has invented, it is the tendency we all have, more or less, to treat what we hear, and see, and feel, rather than the particular departures from health, in their widest sense, that these signs only serve to indicate.

But however clear to us may be the fact that each disease, properly so-called, is distinct from every other disease, and is capable of definition, so far as the progress of our science permits, it must be confessed that the routine practice which follows too close an embrace of this doctrine is most illogical and pernicious. It is just as absurd to treat the disease and not the patient as it is to treat the patient and not the disease. Both ought to be the subjects of treatment: the disease in the patient. Nor ought we to lose sight of the causes of ill-health, which may fitly, in many instances, be called entities, and by their quality impart a specific element to most maladies of the utmost importance in regard to treatment. Thus, taking into consideration the varied causes of the diseases which attack us, as well as all the modifications they undergo in their different subjects from peculiarities of temperament, time, place, and other perturbing influences, we can institute a plan of treatment calculated either to remove the disease or restore the patient. Very important is it to determine which of the two we can attempt in each case. Sometimes we can remove the disease, as ague by quinine; more often, as in the continued fevers, we are obliged to be content with the humbler alternative of relieving symptoms, and tiding the patient over a certain period till the course of the disease has been brought to a natural termination. By this means, we shall avoid those false methods of treatment, such as homoeopathy and many others, which have had their origin in the fallacy that disease is an entity, a positive existence, to be sought out, fought against, and driven from the system. Granted that we have determined the nature of disease, an almost insuperable difficulty meets us in the subject of it. It is not merely a machine, of which we thoroughly understand the mechanism, that engages our attention; but it is a highly organised being, about whose structure and functions we know very little indeed, and whose body is not only under the control of the mind and higher faculties, but also reacts upon them. It requires all our ingenuity and skill to estimate the share taken by each of these in the production of disease; and we are often baffled altogether. There are thus causes at work so complex and obscure as to defy all our methods of research and calculation. A thousand refined influences, moral, mental, and emotional, are sufficient to perturb our analytical scrutiny. "What medicine can minister to a mind diseased?" expresses but one side of the truth. How little can medicines avail in diseases of the body, over which the mind and passions hold sway. Under ordinary circumstances, the intricacy of the matter is great enough; but, when we add to it idiosyncrasies of mind and body, we become more and more entangled in its meshes. We all meet with mental and moral idiosyncrasies. And, to touch upon bodily ones, how can we explain the fact that one person may be salivated by a grain of calomel and another cinchonised by a grain of quinine? On the other hand, we all of us know that some persons can take enormous doses of poisonous medicines with impunity. The laws that govern these uncertainties have not yet been elucidated, and, until they are, idiosyncrasy will ever be a stumbling-block in our way. The imperfect state of our physiological knowledge is another barrier to the advance of medicine. Great strides have been made in this direction; but as yet we are only on the threshold of the subject. The subtle working of the brain and central nervous system, and their mysterious influence over the functions of the different bodily organs, have scarcely been interrogated. But few of the outworks of this great citadel, which towers majestically above all our puny endeavours to capture it, have as yet been taken, and the fortress itself would seem to be well-nigh impregnable. The few brilliant discoveries which have been made only heighten the gloom with which our ignorance enshrouds this grand object of our contemplation. Yet hidden behind the laws which preside over the functions of these portions of our organism lies the explanation of innumerable phenomena of health and disease, which at present are utterly inexplicable. It is probable that the nervous system is the theatre of most of the diseases which afflict us.

This point deserves much more consideration than it has received. I believe a thorough understanding of it would elucidate the nature of nearly every morbid process. Glancing over the other structures of the body, how little is known of the work of the spleen, suprarenal capsules and other ductless glands, and even of the liver and the skin. That wondrous fluid the blood, ever flowing through the lanes and alleys of the body, requires profounder investigation than has been bestowed upon it. Conveying health and sustenance to every organ, how often is it compelled at the same time to carry destruction and

death. Poisons we introduce of our own accord, or which pass into us unobserved, wander in its rapid stream, polluting and destroying the fair fabrics with which they meet. Surely much more needs to be known about this life-liquid. I believe spectrum-analysis would be a great source of knowledge in this direction. Physiology must indeed be wonderfully improved before medicine can obtain from her that aid which is necessary for the scientific treatment of disease. One word with regard to diagnosis, probably the most advanced department of our art; yet how far from perfect it is. Take skin-diseases as an example. It is very easy to say this is eczema, this psoriasis, and so on; but that is a very superficial distinction. Look at herpes. To say a person has herpes zoster is no diagnosis at all. We must unravel the mystery of the complaint, and discover its seat in the nervous system, and the peculiar change there, before we can diagnose the disease satisfactorily. Why the affection of the eye in herpes frontalis? why the lingering agony after an attack of zona? Here is a remarkable case. A lad has a large crop of herpes labialis on the left side of the lower lip, great darting pain in the lower part of the left cheek, and intense inflammation of the left tonsil. Will any gentleman interpret this for me? All came together, and gradually subsided together, and were doubtless connected pathologically. An accurate system of diagnosis means a thorough revision of the groups of diseases: a thing impossible at the present stage of pathology, about which I will now say a few words.

No branch of medicine is more important. It forms the rational basis of all treatment. The nature of a disease is the key-note to its management. If we have but a small insight into the laws which govern any pathological process, small indeed will be our power to arrest it, or render it harmless to the subject in whom it occurs. The only exceptions to this rule are the merely empirical means which experience has taught us to be useful in a few diseases, as quinine in ague, iodide of potassium in certain stages of syphilis, and arsenic in psoriasis. Of course, we indulge in a vague kind of way of combating all manner of complaints, and use for this purpose all manner of remedies, and we frame hypotheses to enable us to do so. But such is the state of pathological science, that it would be difficult to prove any or very few of these to be true. The inherent difficulties of the subject are very great. The simple determination of the gross anatomical features often defies us. Still more do the minute changes which take place in the affected tissues. Sometimes we are able to enumerate the microscopical characters of a diseased part with tolerable precision; but, having done this, how seldom can we arrange the tiny links thus presented to us into a well ordered chain of sequences, and so discern what are causes, what effects; from what source the disease sprang, and what are the ravages resulting from its destructive working. The structure of cancer and tubercle is fairly made out; but we have only to refer to the discussions on their nature at the London Pathological Society's meetings to find how imperfect is our knowledge of these diseases. Are they constitutional or local in their origin? What is meant by the former? Does it imply a general predisposition in the system to any special departure from health, or a mere tendency to special local change arising from some hereditary or acquired defect in the particular tissue or organ? Each speaker seemed to have his own pet theory, the product of his imagination rather than a true deduction from the bare facts at present known to us. These discussions, admirable in themselves, appeared especially able in rendering confusion worse confounded. But the light the microscope furnishes fails us when we have most need to long for its glimmering assistance. What is the pathology of hydrophobia, cholera, syphilis, and a host of others? It affords no real answer here. Who can furnish a rational explanation of the phenomena of acute rheumatism? One says it is a neurosis, whatever that may mean; another that it essentially consists in the presence of lactic acid in the blood. If we had to choose between these two hypotheses, we should be comparatively happy. But the speculative habit will not let us off so easily, and generates a profusion of smaller ones to plague us. Not much harm would result were our treatment uninfluenced by these theories; but built upon them are the quinine, the alkaline, the blister, and peppermint-water plans advocated with such energy. Do we know more of the "nova cohors februm" than we did years ago? The beneficent fact that small-pox, the most virulent of the band, has the poison of its sting destroyed by previously tainting those who may be exposed to its malignant power with a mild dose of that poison is a wondrous discovery; yet we cannot explain it, and seem almost as far off as ever from an accurate theory of the fevers as a class. Do they ever arise *ab initio* in the body, or always attack it *ab extra*? If the latter, does the poison act principally on the blood, or nervous system through the blood? Does it propagate fresh poison while in the system? Does it seek to pass out of the body by the various natural outlets, thus causing the changes in the skin, lungs, kidneys, and intestines, till all

has escaped, to begin anew its evil work, or are all the symptoms mere results of the poison, which, having immediately affected the system, is at once powerless for further mischief there, though still powerful to affect another? These and a thousand other questions must be answered before we can attempt to write a true account of the nature of these diseases. How subtle are the alterations in the brain and nervous system which constitute their different maladies. Some we recognise, others are quite beyond our ken, and probably ever will be. Look at the different changes found in fatal cases of epilepsy; why, they are all found in other cases of brain-disease which we believe to be totally different from epilepsy. Therefore, they cannot be essential to its existence, but are probably only results produced by the special disturbance from which the disease arises.

Time will not let me do more, however, than indicate in this imperfect manner the comparative failure of this branch of medicine. The great aim and object of our profession is the rightful use of medicines, and thereby the control and cure of disease. It must be confessed that therapeutics is in a very unsatisfactory condition. An army may be in the highest state of discipline, led by the most prudent and experienced generals, and brave to a degree; but without weapons it would be useless. The medical army is certainly not weaponless, but its armoury contains many implements of warfare which have become rusty and neglected, not a few of questionable utility, and some of very modern design and pattern scarcely tested as yet. There are fashions in drugs, as in everything else, and we are not philosophical enough to escape the contagion. Therapeutical Sniders are constantly being invented, warranted to slay every disease at which they are aimed; but how often they disappoint by hitting wide of the mark, or by bursting after being used a few times. Sometimes they are so unskillfully handled as to kill either the reputation of the medical man or the unfortunate patient himself. Take bromide of potassium for example. In what diseases has it not been used, and with signal success, too, according to its advocates? Some time ago, I collected notes on this drug, and was astonished to find what a panacea it was. I almost felt we had found something as valuable as potable gold; but I also discovered that its many virtues were denied by very competent persons, and my heart melted within me, and the golden dream vanished. The fact is, we do not appreciate the various fallacies which surround observations on the action of remedies. Experiments with drugs require a peculiarly philosophical mind in the investigator. Too severe a scepticism, on the one hand, and too eager a belief, on the other, have to be avoided. A calm and judicious summing up of the most intricate and dubious evidence must be made. Idiosyncracies must be remembered. How difficult is it to find cases identical in all their important particulars from which to draw reliable conclusions.

Diseases vary in severity and type. Climate, season, the presence of other diseases must be considered. The drugs should always be introduced with the same rapidity into the system, and equally transmitted. An antagonist, of whose existence we are unaware, may neutralise the remedy, or it may be impure. The time of administration, the doses, and the intervals between them must be taken into account. Then, what is Nature doing all the time? How can we estimate her share in the result? Our knowledge of the natural history of diseases is very defective. We are afraid to give up any case to Nature's care; and are, therefore, incapable of judging how far she would be equal to the task. Some are bold enough, it is true, to suppress all artificial aid and watch what will happen, and a few are thorough champions of the so-called expectant plan. But life is so valuable, and the medical adviser's responsibility so great, that most men shrink from relying solely on Nature's power; but bring to her assistance the various means which theory or experience prompts them to adopt. This inability to estimate the part which Nature takes in the cure of disease is a great source of error in experimental inquiries into the action of remedies, and seriously retards the development of therapeutical science. It renders it almost impossible for us to use any of the ordinary methods of research. The composition of causes introduces the greatest intricacy into the investigation; and this is increased by the intermixture of effects. We cannot eliminate conditions, of the existence of which we are ignorant; and there are many which we recognise, but which are so essential to life that we could not suspend them without frustrating the design of the experiment altogether. Conclusive as the following instance seems to be, and well nigh approaching the accuracy of the logical method of difference, yet, without a number of confirmatory instances, it scarcely passes beyond the range of the probable. Subacute nephritis, with great hæmaturia, continued for many weeks in a lad who had suffered from the acute form after scarlet fever. The hæmorrhage resisted all kinds of treatment. In despair, I tried oxide of silver, which I had found valuable in other hæmorrhages. Three half-grain doses stopped the bleeding; and it never returned. I am morally sure of it.

But how seldom can we find a case so favourable even as this as an experiment. So seldom that, according to Mr. Mill, the experimental methods of investigation are but little worthy of attention in this line of research. We are thus compelled to fall back on the deductive method. Even this is not available, except to a very limited extent. For every deduction must start from a previous one, or some induction. If we wish to find out under this method whether any particular medicine is useful in a certain malady, we must discover first of all the laws of all the causes implicated in the result. We must clearly determine the properties of the drug. These, of course, include its physiological action. This part of the process is beset with a thousand fallacies. We must then determine the pathological laws which govern the said malady; and who could assert that he thoroughly understood the natural history of any malady at all? Take croupous pneumonia. The physical signs and peculiar pulmonary changes are well known. But, why should the disease commence sometimes with acute gastro-enteric catarrh? What is the significance of the little crop of labial herpes so often accompanying it? Why should the general symptoms abate so remarkably just when the lung becomes solidified? Why should the chlorides desert the urine. These are but a few of the queries which must be answered before we know what pneumonia really means. And when all this is done, and we have become fully acquainted with all the particulars essential to the elucidation of the subject, and are in a position to draw our deduction as to the value of our drug, we must verify it by past experience or by some other evidence. Mr. Mill ably discusses this matter, and justly points out the small amount of success likely to be obtained in such intricate investigations. Suppose we took a case of chorea and made a series of inductions with regard to the causes of the disease, we should find some cases induced by fright, etc., some in connection with rheumatism, and many other apparent causes. But how difficult to connect the causation with the disease. If rheumatism be concerned, some will say it is the rheumatic element; some that it is an embolic state of certain parts of the brain, from detached valvular vegetations; some that the rheumatism is a mere coincidence. These are only hypotheses, of but little value till proved true. Take the various drugs used in this disease, we know little more about them than that they are so-called nerve tonics mostly. Bring them to the test, they fail as often as they succeed. One vaunts arsenic, another praises zinc, a third juice of conium. Some cases resist all. I remember a boy, on whom bark and ammonia acted like magic, when all other means had been tried in vain. Another case of very severe unilateral chorea in a girl, with anæmia and valvular mischief, resisted iron and arsenic, with chloral at bedtime. The patient was very sleepless; and, at the end of three or four days, was quite worn out. Three or four one-scruple doses of chloral at two hours intervals sent her to sleep, and she awoke well. The next case I had derived no benefit from chloral. Can we generalise from such facts as these. The results, perhaps, depend on the varying causes or the different conditions of the patients. But the general conclusion must be that none of the drugs mentioned are *bona fide* cures of, or at all events specifics against, chorea. Want of success depends in many cases, no doubt, upon our ignorance of certain essential conditions in them, and thus our want of skill in combating these. Time would fail if I were to touch upon general principles of treatment, such as the use of bleeding, counterirritation, and a host of others; and I must pass by many minor impediments, such as the inaccuracy of names and classifications, and the fallacies of statistics and averages as guides to treatment.

I will allude very briefly to two other points. 1. There can be no doubt that we are too prone to slight the labours of those who have gone before us. We despise their antiquated notions, in which lie concealed from our superficial notice truths of the greatest value. Our brethren in all ages have performed their part in leaving us rich legacies of knowledge. But we are not willing to claim or make use of them, because they are encumbered with much that is absurd, useless, and untrue. Each generation, instead of adding to the great fabric whose foundations were laid thousands of years ago, prefers to pull the edifice to pieces and rebuild it after its own fashion. There is thus a perpetual change in theory and practice by no means conducive to progress. 2. Valuable stores of knowledge, accumulated by individual thought and experience, often perish with those who possessed them. How many have amassed most useful materials during their years of practice, and never given them the publicity they deserved. The consequence is that hundreds of able cultivators of our art leave the world without contributing in the least degree to the advancement of their science. Certainly much more is done than heretofore in this direction. But a great Association like ours ought to develop some plan, by which this most important means of spreading medical knowledge could be more successfully carried out than at present.

Having sketched very roughly and imperfectly the main causes of

the backwardness of medicine, I will say one word in conclusion on her future. It were idle to imagine, so long as the state of the world and men's passions and frailties exist, as at present, that diseases will cease from off the earth. Some may disappear; but their place will probably be taken by others. The pangs and terrors of most will very likely be mitigated. But there will ever be the need of the labours of men like ourselves. The dreams of the optimist are worse than useless. Let us, then, note down every fact, however trivial; sift every piece of evidence, however insignificant; and test every theory by the most scrutinising experience; thus furnishing broad and sure bases for greater deductions than even the brilliant discoveries of Jenner, Marshall Hall, and other worthies; deductions which will throw clearer floods of light upon the nature of disease, and therefore upon the treatment of it. It falls to the lot of but few

"To leave a name,
A light, a landmark on the hills of fame";

but we can, at least, hand down to another generation the torch, dimmed by no want of care or zeal, but burning more strongly and brightly in the cause of humanity.

ON INTRAUTERINE INJECTIONS.

By ROBERT BARNES, M.D.,
Obstetric Physician to St. George's Hospital.

THE cases of injection of perchloride of iron to restrain *post partum* flooding, recorded in recent numbers of the BRITISH MEDICAL JOURNAL by Mr. Boddy and Mr. J. C. Clark, together with the comments of Dr. Swayne and Mr. G. F. Hodgson, induce me to offer a few observations upon the subject.

In Mr. Boddy's case, the injection was followed by death. The severity of the hæmorrhage and the reduced state of the patient are attested by the fact that "several large doses of ergot and two injections of cold water into the uterus" produced only a "temporary good effect". Under such conditions, reflex action failing, the resort to styptic injection is, in my experience, generally indicated. I cannot doubt that Mr. Boddy was justified in using it in this case. But the mode in which he used it seems to be open to some objection. The instrument employed was an "ordinary enema-syringe"; the styptic consisted of "four ounces of liquor ferri perchloridi fortior to twelve of water. The nurse worked the syringe. . . . The hæmorrhage ceased immediately on the injection of the solution; and, during the first part of the process, the patient made no complaint, and the uterus began to firmly contract. But, during the latter part of the process she began to be uneasy, complained of pains in the belly; then severe cramps of the flexors of the legs occurred; next she gave a shriek, crying out 'Oh my belly'; a general convulsion took place, the skin became blue, the pulse ceased, and she expired. All this took place during the last two or three strokes of the enema-syringe. The uterus was firmly contracted round the injection-tube, some little force being required for its withdrawal."

I do not question the correctness of Mr. Boddy's conclusion "that the injection of the perchloride of iron was the immediate exciting cause of death". But his opinion that "the hæmorrhage could not be the cause, because the injection was used before the loss of blood had begun to affect the nervous system" is at variance with his previous statement "that ergot and injections of cold water failed to induce active uterine contraction". When the reflex function is impaired to the degree indicated by this test, a very serious effect has been produced upon the nervous system, under which it is peculiarly susceptible to the influence of shock. Shock was caused by the iron injection; and from the narrative it may be concluded that it was mainly due to the mode in which the injection was made. Mr. Boddy misunderstood my directions, if he thought that the whole quantity of sixteen ounces must be injected; and the use of an enema-syringe worked by a nurse is no part of my instructions.

At page 472 (*Obstetrical Operations*, second edition) are the following directions: "You have the Higginson's syringe, adapted with an uterine-tube, eight or nine inches long. Into a deep basin or shallow jug pour a mixture of four ounces of the liquor ferri perchloridi fortior of the *British Pharmacopœia* and twelve ounces of water. Pump through the delivery-tube two or three times to expel air, and insure the filling of the apparatus with the fluid before passing the uterine-tube into the uterus. This, guided by the finger of the left hand in the os uteri, should be passed quite up to the fundus. Then inject slowly and steadily."

Without insisting unduly upon the probability that a nurse under exciting circumstances cannot be trusted to pump slowly and steadily,

I must insist that this part of the operation should be done by the surgeon himself, and that an enema-syringe is calculated to pump the fluid into the uterus with unnecessary and even dangerous force. From this risk the Higginson's syringe is comparatively free. The propelling force, even when the ball is firmly compressed, is small.

Further, if the finger guiding the injection-tube be kept in the os uteri, information is given as to the effect produced in checking the bleeding, and the closure of the os upon the tube is obviated. As I have explained in my work on the *Diseases of Women*, when the os uteri is closed, the uterus, contracting concentrically upon fluid contents, tends to drive the fluid along the Fallopian tubes. Dr. Swayne's comment to this effect is perfectly in accordance with observation. It is an imperative condition to preserve patency of the cervix for the outflow of the injected fluid. In the work referred to, and in the third edition of the *Obstetrical Operations*, which will shortly be published, I have discussed with some care the subject of intrauterine injections in the puerperal and non-pregnant woman. In the first work, I have given an example similar to that of Mr. Hodgson of severe collapse, following an ordinary vaginal injection of sulphate of zinc in a non-pregnant woman suffering from prolapse, with patency of the cervix uteri.

Mr. Clark's case is an excellent illustration of the beneficial use of iron-injection in *post partum* flooding. Here again, as in many other cases, it acted after the failure of grasping, ergot, firm pressure on the abdomen, and the injection of cold water. It is not unworthy of remark, that Mr. Clark had previously injected a solution of permanganate of potash. It did no good; although, had the uterus been excitable, the cold might have been expected to act. I have recently been informed by an excellent provincial practitioner that, in a case where previous experience had led him to anticipate flooding, when he had consequently given ergot and used all other means of prophylaxis, hæmorrhage occurring, he injected permanganate solution with apparent advantage. But the uterus relaxed again, filled with blood, and death ensued. He has since trusted to the iron-injection in similar cases, and always successfully. He believes that, had he not been deterred from using it in the case described, the woman would have been saved.

ON THE CAUSE OF DEATH AFTER USING PERCHLORIDE UTERINE INJECTIONS FOR *POST PARTUM* HÆMORRHAGE.

By EDWARD JOHN TILT, M.D.

UNDER the head of "Obstetrical Memoranda", in last week's JOURNAL, Mr. Hodgson of Brighton relates how, while making a vaginal injection, a patient of his passed the tube into the cervix, and thereby caused a solution of zinc to flow from the womb through the Fallopian tubes into the peritoneum, thereby producing what he calls "short-lived peritonitis". I doubt this explanation, unless Mr. Hodgson ascertained that, in this patient, the cervical canal was sufficiently patulous to freely admit the tube of the instrument.

I should not presume to doubt the validity of his explanation, had I not met with half a dozen cases during the last thirty years, in which the use of a vaginal injection was suddenly followed by pelvic symptoms sufficiently acute to suggest peritonitis; symptoms yielding to appropriate treatment in one, two, or three days. In these cases, I had found more or less trouble to introduce the uterine sound, so I cannot suppose that my patients could have possibly passed into the cervix an elastic tube ten times the size of the uterine sound. I should add that, in these cases, the liquid injected was a weak solution of acetate of lead, and that the women had been in the habit of using injections. I submit that a better way of accounting for such cases is to admit that the patients have been awkward, and roughly jammed the extremity of the tube against the sore extremity of the cervix, the concussion being sometimes intensified by the patient, in her fright, pressing the instrument farther in, instead of withdrawing it. Those who so frequently explain the sudden advent of formidable symptoms in disease of the unimpregnated womb, by the passing of a fluid through the Fallopian tubes into the peritoneum, should remember that any surgical treatment of the womb, or even the rough use of the uterine sound, may cause the most formidable pelvic symptoms, and leave traces of pelvic peritonitis even if these symptoms soon abate. They should also bear in mind that Dr. Fontanes has published an account of various experiments in which he found it impossible, by distending the dead womb, to make fluids pass through the Fallopian tubes into the peritoneum. Neither should it be forgotten that the unimpregnated womb has often been injected with various fluids; that the patients have sometimes died and been examined; and that, as far as I am aware, in no case has the fluid in-

jected into the womb been found outside the fimbriated extremities of the Fallopian tubes, except in two cases mentioned in the discussion of my paper on Pelvic Lymphangitis, at the Obstetrical Society of London; one by Mr. Ross Jordan of Birmingham, the other by Dr. Palfrey—cases which have not been published, I believe. It would be singularly illogical to let these occasional untoward results of using injections weigh against their great value in the treatment of diseases of the sexual organs; the more so as these accidents can be prevented by telling the patients to use a flexible tube, and by showing them how to bend it, and how to introduce it into the vagina so that the nozzle of the tube may not run any risk of touching the os uteri.

Dr. Swayne of Bristol has lately explained a death that occurred after the injection of a solution of perchloride of iron into the womb to check *post partum* hæmorrhage by supposing that the solution had passed into the peritoneum. I am not aware that this explanation is warranted by the finding of the perchloride outside the fimbria in similar cases when the bodies have been opened. During the last few years, in the Paris hospitals, a solution of carbolic acid has been often injected into the womb soon after parturition. Many of these patients have died and been examined; but it was not found that the carbolic acid had passed through the Fallopian tubes into the peritoneum. I do not, therefore, think the fear of such an occurrence should bar the use of Dr. Barnes's method of checking incoercible *post partum* hæmorrhage; but I think it would be advisable to use tincture of iodine instead of the perchloride of iron, for reasons that I have given elsewhere.

A CASE OF GENERAL EXFOLIATIVE DERMATITIS (PITYRIASIS RUBRA), ACCOMPANIED WITH FEVER AND GENERAL PROSTRATION.

By EDWARD I. SPARKS, M.A., M.B. (Oxon.), M.R.C.P.,
Physician for Diseases of the Skin in Charing Cross Hospital, etc.

THE report in the BRITISH MEDICAL JOURNAL of March 13th, 1875, page 359, of a case of pityriasis rubra exhibited to the Glasgow Pathological and Clinical Society by Dr. Gairdner, has induced me to publish an account of a case in which the temperature was also elevated, which was under my care in 1873, and to which I had previously been unable to find a parallel. The history is as follows.

M. A. D., aged 48, was admitted into Charing Cross Hospital, under my care, on August 9th, 1873. She was brought in a cab, and was too ill to walk. All that could be discovered about her previous history was, that she had for some years been subject to rheumatic attacks. She was in Guy's Hospital twelve years ago with rheumatic fever, and, five years ago, was laid up with another attack for nearly five months. She had had eight living children, the youngest now four years old. Her husband was a strong healthy man. She had lived at Woolwich several years; but, two months ago (June 13th), she moved to New Cross, and had not been well since. She had ailed all the year, and had pains in her elbows and knees, and her joints had been swollen sometimes, but not so much as to prevent her from getting about. Her skin had been for some time rough and dry, but without scaldiness, until about two months ago, when it became somewhat redder than natural, and inclined to peel in the bends of the elbows and in the axillæ. About a month ago, her hands were rough and scaly, and she believed that the redness and roughness of her body became much worse about a week before her admission. For some time, she had slept badly, and been thirsty and scarcely able to satisfy her thirst. Her bowels had been much confined; her appetite had been bad for some time. The remainder of the history will be given *verbatim* from the daily notes.

State on Admission, August 9th.—She complains of pains in her knees and shoulders on movement; but the joints are not swollen nor tender. Tongue very white on the dorsum, with red edges. Pulse, 120; temperature, 102.5 deg. Fahr. (4 P.M.). The most striking thing about her is the condition of her skin. There is a diffused redness of the chest and arms; but the legs are less affected, except the inner parts of the thighs, which are of a very deep red colour, and at first sight suggest the idea of scarlet fever. The skin is at the same time considerably thickened and dry, especially below the clavicles and over the front of the chest, and there is a large amount of scaly desquamation about the popliteal spaces, outer sides of the hips, both shoulders, and the front of the chest. The face is unaffected, except that there is a slight patch of redness inclined to scale on the left of the nose. The hands, to the tips of the fingers, are red, dry, and shiny, and there is desquamation in the flexures of the finger-joints. There are three or four flat pustules, of the size of small peas, over the lower end of the sternum. The patient is very weak, and unable to sit up—

right. Her heart and lungs are perfectly healthy. Bowels confined. Ordered a saline mixture (one ounce) every four hours, and spoon diet.

August 11th. The skin is in much the same state as on the 9th, but perhaps a little less red. Morning temperature, 101 deg. Fahr.; and the evening, 102.5 deg. Fahr.; pulse, 120; tongue dry. She is very thirsty, and is continually wanting to drink. She sleeps very badly. The abdomen is not tender. She still complains of pains in the shoulders when she moves.

August 12th.—The evening temperature to-day reached 102.6 deg. (its highest point), and her urine contained a trace of albumen. Her lungs and heart were again carefully examined, and found healthy.

August 13th. The skin is peeling freely; the redness is decidedly less. The urine is passed involuntarily. Pulse, 116, full and soft, very weak; lips dry; tongue fairly moist; no sore-throat.

August 14th. The temperature is still high; it has not been below 101 deg. Pulse, 120; tongue dry and brownish; but her general aspect is somewhat improved. She rambled a good deal last night. The abdomen is not tender anywhere; there is no tympanites, no enlargement of the spleen. The bowels are very confined. She was ordered to have an enema of warm water, and to omit the saline mixture; to have six ounces of wine, and a draught containing four grains of sulphate of quinine every six hours. The skin is less red, but just as scaly. The pustules on the sternum have died away. A curious appearance was noticed at this time on her tongue, for the description of which I am indebted to the notes of my friend and colleague Dr. Bruce, then medical registrar. He says: "On the left border, about one inch from the tip, is a very peculiar group of white bodies. They are in three masses; one is single and circular in outline, and smallest; the second and third apparently compound (each of two), and more irregular. In colour they are almost pure white; they are distinctly raised above the general surface, and so appear as boldly defined tubercles of about the size of a split pea. They are firm and resisting to the finger, and are not to be removed by scraping. No other similar tubercles on the mucous membrane of the mouth are to be seen. They are somewhat painful."

August 16th. Temperature at 2 P.M., 101.2 deg. She seems decidedly better. She can turn on her side, and has not passed her urine under her since yesterday. She is quite sensible, and has slept much better the last two nights. The skin over the chest is still pale red, dry, and desquamating. The back is nearly free from scabiness, except over the sacrum and buttocks. She has been for several days on a water-mattress, in consequence of a tendency to bed-sore.

August 19th. The skin of the legs is now only dry and rough, thickened and parchment-like, and there is only slight desquamation in the popliteal spaces; the greatest amount of scabiness occurring about the hips. The whole of the trunk and arms are dry and thickened. Desquamation is going on about the axillæ and shoulders. The skin of the face is slightly thickened. The colour of the skin is deepest over the chest; but even there it is much less than when she was admitted. Temperature—morning, 101.2 deg.; evening, 102 deg. During the last three days, a crop of papules and pustules has been coming out on the front and back of the left forearm and on the back of the arm, as well as on the back below the level of the scapula; there are also a few on the face. They begin as slightly raised red elevations about the size of a small pea, and, while some never go beyond this stage, others become converted into flat pustules. There are none on the right arm or on either hand, and they are of the same character as those which she had on the sternum when admitted. The quinine is reduced to two grains three times a day, and the enema is to be repeated, as her bowels are very confined. The skin is to be washed with soap and water every day, and well greased afterwards.

August 21st. Temperature, 100 deg.; pulse, 90; tongue quite moist, but covered with white fur. She still has pains on movement in the shoulders; but the joints are not swollen. The pustules are more numerous to-day on the back and face, but their characters are the same. The skin generally seems more thickened to-day, and there is a good deal of redness and desquamation in the bend of the elbows.

August 22nd. Temperature, 98.6 deg., morning; 100 deg., evening. There are no fresh pustules anywhere except on the face; there are none on the scalp or inside the mouth, and there have been none on the lower extremities. The patient's appetite is better.

From the time when this note was taken, she continued to improve; the pustules dried up, leaving a red stain, without scabbing, and the tongue began to clean and the appetite returned. Desquamation was free over the sacrum in large flakes, and also about the root of the neck, the shoulders and the forearms, and on the latter patches of smooth normal skin began to be visible as the scales fell off.

August 27th. The quinine was discontinued, and she was ordered fifteen minims of tincture of perchloride of iron three times a day.

August 30th. Pulse, 84; temperature, 99 deg. The face is now nearly clear of scales, and there are three or four hard red papules on the brow and cheeks, and one pustule on the brow. The skin of the chest and back, and of the arms above the elbow, as well as that of both legs, is dry and shining, parchment-like and tough to the feel. It is slightly thickened, and, especially on the back and chest, is thrown into creases and wrinkles, the edges of which on the back are reddened, so that it is crossed by raised red lines. There is considerable desquamation, in papery flakes of the size of the finger-nail, on the forearms. The skin of the legs below the knee seems more thickened and wrinkled than before, and desquamation is going on over the back of the toes and the dorsal surface of the feet to a considerable extent. The colour of the skin is deepest in the bends of the elbows. The patient is in rather a stupid state, but is quite sensible if roused. Her temperature is normal, and her appetite improving.

September 4th. The skin of the forearms has almost regained its natural colour. There are a few very thin scales on the palms of her hands. The amount of general desquamation is considerable; so much so, that the nurse talks of the scales in the bed as "a nuisance". The back and front of the chest are dry and wrinkled, "like a hide". The patient can now raise herself in bed and sit up without help, and she is more cheerful. There are still a few indolent pustules and papules on the forehead.

From this time, no special note was taken, as I was away for my autumn holiday; but I was informed that she steadily improved, though desquamation continued very abundantly for some time, so that, as the nurse expressed it when I saw the patient again on October 2nd, "she peeled all over again in the last three weeks". At this date, however, she appeared to have almost entirely recovered, and the notes state that "she eats and sleeps well, and her bowels, which, during her illness, were obstinately confined, are now regular. The skin of her whole body is now normal, and of natural colour and texture, and all thickening has disappeared. Her hair is coming out rather freely, especially in the middle of the scalp. She still has a few stains where the pustules were, on the left forearm; but there is no trace of scars. The patient has taken no medicine except the iron mixture for more than a month." She left the hospital the same day.

On October 14th, she came up again to show herself, looking much fuller in the face and generally more healthy than when she went out. She still felt rather weak, and was easily knocked up by her household work. She complained of "crampy pains" in the right shoulder and arm in the mornings, and of stiffness in the hip-joints, so that she could not stoop well. The skin was quite normal, and entirely free from scabiness or thickening; but her hair was coming out in large quantities. She volunteered the statement that "she did not remember anything about herself in the first fortnight she was in the hospital". She did not come up again until April 30th, 1874. She had then had no return of the eruption, and was looking healthy and well. As she was suffering from dyspepsia, the result of mental shock caused by the attempted suicide of her husband a few days before, she was transferred to my colleague Dr. Green. In March of the present year, in answer to my inquiries, she wrote me that she had had no return of the skin-affection since she saw me.

REMARKS.—I have called the disease above described exfoliative dermatitis (pityriasis rubra), because that is the only subacute affection of the skin which corresponds with the phenomena observed. It is the only disease in which the whole surface of the body is affected with simultaneous redness and desquamation in flakes. That the disease was not eczema, was proved by the absence throughout of any kind of moist discharge, of crusting, or of pruritic irritation; besides which, as Devergie has pointed out, eczema never involves the whole skin at once. That we had not to deal with one of those cases of general psoriasis which had assumed the aspect of an exfoliative dermatitis such as have been described by three or four observers, is at once clear from the patient's history, as she had never had any of the characteristic patches of psoriasis on the knees and elbows, or on other parts of the body, previously to the general eruption. No two observers have given an exactly similar description of the symptoms of exfoliative dermatitis; and the present case differs in one or two important points from others which I have found recorded. The high temperature and the severity of the general symptoms (dry, brown tongue, mild delirium, and incontinence of urine) made me at first suspect that the skin-affection was not the essential feature of the disease, but that there was some other abnormal process underlying it, and perhaps independent of it. The pains in the joints, however, which at first suggested the presence of rheumatic fever, were found to partake more of the character of chronic rheumatism than of the acute form. There was no implication of the smaller joints, no shifting of the pain from one joint to another; tenderness on pressure was completely absent; nor was there the slightest

swelling in the right shoulder-joint, which was the most painful. Typhoid fever could be excluded, after a few days' observation, by the absence of splenic enlargement, tympanites, and diarrhoea; and no disease could be detected in the other organs of the body after repeated examinations. The course of the disease further showed a close relation between the general symptoms (temperature, pulse, etc.) and the hyperæmia and desquamation of the skin, both appearing to reach their height and to subside *pari passu*. I may also say that the diagnosis of exfoliative dermatitis or pityriasis rubra was acquiesced in by others who saw the case. The most remarkable features in Mrs. D.'s illness were the attendant fever and the extreme prostration in the first two weeks, accompanied by blunted condition of intellect and other nervous symptoms. The maximum temperature did not reach quite as high a point as in Dr. Gairdner's case (103.8 deg. Fahr.); but the morning temperatures were much higher, never falling below 101 deg. for seven successive days after admission; while the evening temperatures ranged from 102.2 to 102.5 deg. from the 7th to the 16th of August. On the 17th, the morning temperature was 100.2 deg., and that in the evening 101.2 deg.; and, on the 18th, there was a further fall, the morning temperature being 99 deg., and the evening 100 deg.; and this range continued pretty uniformly until the 24th, when the evening temperature reached 99.2 to 99.5 deg., with a nearly normal morning temperature, until September 9th, when the thermometer was no longer used.

Dr. Gairdner's is the only other case (but see Postscript) which I have found reported, in which any special mention is made of the temperature in connection with exfoliative dermatitis. Hebra (*Lehrbuch der Hautkrankheiten*, zweite Aufl., 1874, erster Band, s. 399, article Pityriasis Rubra) merely says: "The temperature of the affected skin is somewhat raised." Devergie (*Traité pratique des Maladies de la Peau*, 1857, p. 443) only seems to speak of the patient's own sensations when he says "dans la période d'acuité, le malade brûle dans son lit, il ne peut supporter qu'un drap même en hiver". There can be little doubt that in the chronic cases, such as Hebra and Professor Wilson describe, fever, if present at all, is so extremely slight as to pass unnoticed; in the present case, as in Dr. Gairdner's, this symptom seems attributable to the rapid onset of the inflammation of the skin, for we can understand that an acute interference with the functions of so large an area of skin would be, *à priori*, more likely to be followed by constitutional symptoms than a chronic one; for example, a diffused psoriasis, which, as we know, may be associated with perfect health. I hope that, now attention has been called to this point, all those under whose care any example of this rare disease may come will make as careful observations of the temperature as they are able, and publish the results. In this way, we may be able eventually to deduce the law followed by the fever in exfoliative dermatitis, and to prepare a typical tracing.

I am unable to explain the development of crops of indolent pustules on various parts of the arms and body, unless they were due in some way to obstruction of the ducts of the sebaceous or the sweat-glands by the inflammatory process around them. They have not been noticed, however, by other observers. Those on the face had, in their early stage, a great resemblance to the shotty papules of small-pox; but there the resemblance ceased, for the resulting pustules had no definite duration, were always flat, and non-umbilicated, and dried up without crusting, and there was no relation between their appearance and the general condition of the patient.

I question whether the treatment adopted had much, or any, influence over the disease, except in so far as it tended to maintain the patient's strength. She got quite well without any specific remedy, such as arsenic, with the simple use of tonic remedies; no external application was made to the skin, except soap and water and simple ointment.

POSTSCRIPT.—Since the above was written and ready for publication, my attention has been called by a notice in the *Gazette Médicomadaire*, No. 12, 1875, to an essay, entitled *Dermatite Exfoliatrice Generalisée* (Thèse Inaugurale, Paris, 1875), by Dr. E. Percheron, in which nearly all the recorded cases of exfoliative dermatitis, or pityriasis rubra, are collected and commented on in a very careful and lucid manner. To me, Dr. Percheron's essay has a special interest; for in it he describes a case in which a considerable amount of fever existed for several weeks, and the temperature (a chart of which he appends) was accurately taken. It is curious that, like Dr. Gairdner and myself, he was under the impression that his was the only case in which the thermometer had been used. The highest temperature noted was 40.4 deg. cent. (104.7 deg. Fahr.), and there was often a difference of from 2 to 3 deg. cent. (3.6 to 5.4 deg. Fahr.) between the morning and evening temperatures, owing to considerable morning remissions. The trace also shows the existence of short periods of several days characterised by a gradual rise in the evening temperatures, and which corresponded to the presence of complications (endocarditis, bed-sores, etc.); but, as Dr. Percheron re-

marks, there is no indication of a cyclical course, such as we find in pneumonia and the specific fevers.

Dr. Percheron finds, from a view of the literature, that it is not, as Dr. Gairdner seems to think, the exception, but the rule for the nails to be affected. He says the hair and nails are generally lost; the latter are raised by an accumulation of epidermic scales beneath them, so that the finger-tips are surmounted by a kind of coarse shell (*carapace grossière*). I did not observe any alteration of the nails in Mrs. D.'s case, but her hair came out in great quantity towards the end of her attack.

The curious spots which formed beneath her tongue are paralleled, to some extent, by two cases to which Dr. Percheron alludes, in one of which "plaques diphtheroides" occurred on the lips and the mucous membrane of the cheeks; and in the other "the papillæ and tongue seemed quite destroyed, and the surface had a varnished look".

Without entering into any further account of Dr. Percheron's essay, the perusal of which I can strongly recommend to anyone interested in the subject, I will make one observation, in conclusion, on the title which he gives to the disease under consideration, namely "generalised exfoliative dermatitis". Most writers—Devergie who first described it, Hebra, Dr. Tilbury Fox, and others—call it pityriasis rubra, a name which has the advantage of brevity, but which is nevertheless inaccurate. The objection may seem pedantic; but, considering how dermatology is already overlaid with unmeaning terms (lichen, sycosis, herpes, etc.) when new ones have to be coined, it is as well to select a correct title. Pityriasis (*πίτυρις*) implies that the scales thrown off are small like bran; whereas, in "pityriasis rubra", a striking feature is their size and abundance. For this special reason, I agree with Dr. Percheron, that Professor Erasmus Wilson's name "general exfoliative dermatitis", although somewhat long and cumbersome, is preferable for scientific purposes to that of "pityriasis rubra".

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN.

LONDON HOSPITAL.

FRACTURED PATELLA: ANKYLOSIS OF KNEE-JOINT: SUBCUTANEOUS OPERATION: GOOD RESULT.

(Under the care of Mr. MAUNDER.)

[Reported by Mr. BRAMWELL.]

GEORGE W., aged 33, was admitted into the London Hospital on May 12th, 1875. The patient stated that rather more than three years ago he fell and broke his right patella into three pieces. He was taken to a metropolitan hospital, and remained in bed upwards of three weeks. He was soon discharged, wearing a plaster of Paris bandage. He wore this bandage for some weeks, when it was replaced by a leathern knee-cap. The joint remained stiff ever since this accident. On two other occasions he sustained an injury to this joint, and on both he went into hospital.

Amputation had been suggested, but this not according with the patient's views, he came to the London Hospital for relief.

On admission, the patient was found to walk like a man with a wooden leg, swinging the limb in a half circle as he progressed. The right knee-joint was the seat of fibrous ankylosis; it was extended and stiff. The slightest possible passive flexion of the leg could be made, but not without causing pain. The patella was in three pieces, having been fractured transversely. These fragments seemed to be connected by a fibrous band, which was drawn backwards into the joint. Mr. Maunder believed that the synovial and cartilaginous constituents of the joint had been more or less destroyed, and a false ankylosis had resulted. To overcome this, it was determined to try the effect of forcible flexion.

May 19th. The patient being under the influence of chloroform, Mr. Maunder slowly bent the leg, and the adhesions broke down audibly. There was considerable swelling at once, and ecchymosis soon followed. This attempt having failed, Mr. Maunder determined to try another plan.

June 2nd. The patient being again under the influence of chloroform, the blade of a strong tenotomy-knife was entered just above the inner side of the superior fragment of the patella, and, having been insinuated between this and the femur, was made to divide subcutaneously the fibrous tissue which united the fragments of the patella and their bond

of union on the one hand, with the femur and the fibrous tissue in the recesses of the joint on the other hand. About a dessertspoonful of blood was lost; and, the knife having been withdrawn, the wound was closed, as after tenotomy, by a compress and strapping. The limb was now forcibly bent to a right angle, and then secured in the extended position by a back splint. Ice-bags were applied to the knee.

June 6th. The wound had healed by primary union, and there was very little pain about the knee. The splint was removed, and passive movements were commenced. The patient was desired to move the limb occasionally as he lay in bed.

June 10th. The patient was ordered to get up and to make repeated efforts to extend and flex the leg.

July 20th. The patient had daily exercised his leg, gradually increasing both the angle of flexion and power of extension. When standing, he could raise the foot and bring the leg to an angle of about 107 degrees with the thigh. When he was seated in a chair, no difference could be perceived in the two limbs, as each knee was flexed to an angle of about 95 degrees. On extending the leg, the atrophied quadriceps could be felt, by the hand placed upon it, to contract. The upper patellar fragment could be moved laterally, and could also be felt to move when the patient bent his leg. He walked with a scarcely perceptible halt. He was greatly pleased with the result of the operation, and confident of still further improvement.

In undertaking the operation, Mr. Maunder said that he had very little anxiety with regard to any possible injurious consequences, because it must be remembered that he proposed to introduce a knife and divide certain structures, in the site of a joint it is true, but which joint, with its usual susceptibilities to inflammation, no longer existed. He was uncertain as to the result, and had explained this to the patient. Success had exceeded his anticipation.

ROYAL PORTSMOUTH, PORTSEA, AND GOSPORT HOSPITAL.

DISEASE OF RIGHT KNEE-JOINT: OLD AND RECENT SYNOVIAL MISCHIEF: CHRONIC OSTITIS: ULCERATION OF CARTILAGES: EXCISION: RECOVERY.

(Under the care of Dr. J. WARD COUSINS.)

G. S., AGED 11, six years ago, had an attack of measles. Soon afterwards, his right knee became painful and swollen, and for those symptoms he was admitted to the Royal Portsmouth Hospital. He was re-admitted on May 10th, 1874. His mother then stated that his leg had been much worse for six months. The boy looked pale and delicate, and had recently lost flesh. The leg was useless. The knee was enlarged and tender. It was flexed at an angle of 90 deg., and any attempt to straighten it caused much suffering. The patella was fixed, and tender when pressed against the joint. His nights were often disturbed. The condyles of the femur were much enlarged, and likewise the head of the tibia, but the enlargement of this bone was not so marked.

Excision was performed on May 23rd; and, after the operation, the limb was securely fixed in a Liston's splint. The joint contained a few teaspoonfuls of thin pus. The synovial membrane was universally thickened and vascular, and overlapped the articular surfaces. The adhesions between the bones were readily broken down. The greater part of the cartilages had disappeared, and several worm-eaten spots were visible in them. Some old ulcerations which allowed the probe to pass to soft bone were found at the intercondylar notch and in the outer condyle. The patella was extensively softened; and it was, therefore, entirely removed. About an inch-and-a-half of bone was taken off the femur, and three-quarters of an inch from the head of the tibia. At the time of resection, the cancellous tissue, especially that of the femur, was so soft and fatty that it could be broken down with slight pressure with the finger, and this raised a reasonable doubt as to the possibility of recovery.

Very little constitutional disturbance followed the operation. The process of repair favourably progressed: firm fibrous union was at length established, the swelling of the joint subsided, and the wound healed.

He was discharged on November 24th, 1874, with a very useful limb. August 31st, 1875. The patient continued well, and could walk several miles at a stretch with ease. He still wore a back leather splint. Some movement existed at the joint, and the limb was shortened about three quarters of an inch.

REMARKS.—The case was interesting, because, at the time of resection, the cancellous structure of the bones was soft and unhealthy; still the progress of the case was very satisfactory. Cases have been reported in which the bones presented the same vascular and unfavour-

able appearance, and yet very favourable results were obtained by resection. The free division of the osseous tissues seemed to arrest the inflammatory process within the cancellous structure, and to promote induration and repair. In the treatment of diseases of the knee-joint, it is often an anxious question for the surgeon to decide between amputation and excision. The above case in every respect appeared favourable for the latter procedure. The disease was essentially chronic, with hopeless destruction of the joint, malposition, and fibrous ankylosis; at the same time, the constitutional powers of the patient were tolerably good. He was not worn down with suppuration and irritation. He looked able to bear the shock of the operation, and to submit to the tedious after-treatment, which, under the most favourable conditions, is generally prolonged through many months.

REVIEWS AND NOTICES.

ZOOLOGY FOR STUDENTS. By C. CARTER BLAKE, D.Sc. Daldy, Isbister, and Co. 1875.

THE long solitary reign of Rymer Jones's *Animal Kingdom* has been succeeded by the struggle for existence of a variety of zoological handbooks of very different degrees of merit. The youngest of these, by Dr. CARTER BLAKE, is very modest in its claims, and avowedly intended for mere students only. The book comes out with Professor Owen's *imprimatur*: a fact which will recommend it strongly in the eyes of the majority, though it will evoke no little hostility amongst some of an opposite school. Feeling, as we do, that deference and respect are due to Professor Owen's judgment now, as well as gratitude for his many labours in the past, we avow ourselves as belonging to the former category. The author tells us in his preface: "I have been careful to exclude from a manual intended for the student all unproved facts or problematical classifications"; and, in so doing, we think he has done wisely.

Of the whole book, 228 pages are devoted to the Vertebrata, and 154 to the Invertebrata. In such a space, of course, so vast a subject as the zoology and structure of the lower animals can be treated of in a fragmentary manner only. Nevertheless, the student who reads them carefully will acquire a mass of information, and will find the task a pleasant one, calculated to whet his appetite for the acquisition of more special knowledge than the handbook itself pretends to furnish. The classification adopted by the author is mainly that of Professor Owen, and therefore diverges from that which has become more generally adopted. There are some omissions we see with regret in a work having so many merits. Thus the little group of *Rhinocephala* is passed over in silence. A more serious defect is the omission of an index: a want likely to be specially felt by the student who has not yet formed acquaintance with the zoological terms of the table of contents. For all this, however, we can cordially commend Dr. Blake's *Zoology* as a work containing a mass of useful information conveyed in an agreeable and attractive form.

NEW BOOKS AND NEW EDITIONS.

The Royal London Ophthalmic Hospital Reports for September contain some important papers. Mr. Hulke gives a summary of 192 cases of Astigmatism. Mr. Jonathan Hutchinson's continuation of his report on the Forms of Eye-Disease which occur in connection with rheumatism and Gout contains the results of much careful observation. Some peculiar cases of eye-disease are contributed by Messrs. Swanzy, Henry Wilson, and Priestley Smith. The Curator's Pathological Report, contributed by Mr. Brailey, and the copious Periscope, add to the varied interest of this well-conducted periodical.

A second, revised, and cheaper edition of Dr. LEISITMAN'S *System of Midwifery* (Maclehose, Glasgow) shows that professional appreciation of this handbook has been even more active in exhausting the first issue than could have been expected.

Dr. LEARED'S little monograph on *Imperfect Digestion* (Churchill) has reached its sixth thousand. It is pleasantly written, and, though devoid of striking novelty, there are few who can read it without "getting a wrinkle" likely to be useful.

BRITISH MEDICAL ASSOCIATION:
SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, NOVEMBER 6TH, 1875.

THE VALUE TO MEDICINE OF EXPERIMENTAL
OBSERVATION.

IN an excellent address delivered at the opening of the session to the students of the Edinburgh Royal Veterinary College, Dr. McKendrick, himself a distinguished worker at the progress of the fundamental processes by which the medical art is advanced, dwelt with emphasis on the importance of experimental investigation. An abstract of his remarks will at this juncture be especially interesting. He pointed out that nearly all the knowledge which we at present possess regarding many of the processes occurring in the living body has been obtained by observation on the lower animals. Without the frog, the pigeon, the rabbit, and the dog, we would have known very little indeed regarding the functions of our own bodies. Observations made on these humbler animals have given us information regarding the functions of almost every organ of the body, and of the muscular and nervous systems. Knowledge of this kind is the foundation of the medical art; without it, we could have no right conception of many of the phenomena of disease. Disease is simply a disturbance of the normal functions of the various tissues and organs which form the body. It is impossible to understand these disturbances until we have ascertained what the normal functions are; and this knowledge has been derived from many of the humbler animals. It may be safely said that nine-tenths of the facts taught in a course of lectures on the physiology of the human being have been thus acquired. So much as regards physiology. He proceeded to inquire how the matter stands with reference to pathology.

He observed that the changes occurring in organs and tissues, visible to the naked eye or by means of the microscope, constitute what is usually known as pathological anatomy. Pathology, again, is the department of medical science which describes the phenomena occurring in living tissues and organs which are the seat of disease. Its province, strictly speaking, is not to tell how the organs look to the naked eye after death, or even what is revealed by the microscope, but to describe the changes in function which produce these appearances which we say are diseased. Pathological anatomy is now a department of knowledge possessing an immense number of well ascertained facts. Many thousands of *post mortem* examinations have been made in our public hospitals by skillful persons and under the eyes of critical observers; and the size, form, naked-eye appearances, and even the microscopical structure of diseased organs, have been carefully recorded. It may, he thinks, be confidently asserted that little more, except with regard to microscopical structure, has to be done in this direction. With regard, however, to the causes of these morbid appearances, and the history of the processes which precede these pathological effects, comparatively little has been ascertained. The human pathologist usually sees the organ after disease has done its worst; but he has rarely any opportunity of watching the processes by which the organ has been impaired or destroyed. Here, of course, he alluded to the graver diseases which tend to destroy life. There are numerous minor ailments, both in man and in the domestic animals, which occupy the attention of practitioners in the daily routine of their professional life. In these, pain

may be relieved or recovery accelerated, but they tend to recovery without the use of any remedies. It is not, therefore, a matter of such importance to investigate these thoroughly. It is true that, in the wards of the public hospital, the patient labouring under a serious malady may have been under the care of a skillful physician who has recorded all the signs and symptoms of the disease; but even he often sees the disease after it has passed into a stage when little can be done, except to alleviate the sufferings of the patient. Regarding the earlier stages of the disease, during which only minute alterations of the tissues are taking place, we know little. The reason of this is quite obvious. Men rarely apply to the physician for assistance until graver diseases have been well established. This is especially true of those who enter our hospitals or infirmaries. Not infrequently diseases originate without the manifestation of symptoms calculated to arouse feelings of anxiety; consequently the patient does not present himself until morbid changes have occurred which are almost, in the present state of knowledge, beyond the powers of the healing art.

A very slight consideration, he said, will show that a knowledge of the preliminary stages of diseased action is necessary to carry out any mode of treatment by which we may hope absolutely to cure the disease. It is almost impossible to expect this kind of knowledge from observations on the human being in our present state of civilisation. For example, how little do we know regarding the origin of tubercle or of cancer, or of the mode of action of those poisons which produce the various fevers. It is true there is an enormous amount of information regarding each of these scourges of the human race; but the essential nature and properties of the predisposition or virus which causes each are still in the region of dim uncertainty and speculation. While this is the case, so far as remedial treatment is concerned, the efforts of the physician are directed towards the prolongation of life and the relief of suffering.

Our knowledge of the influence of drugs in the treatment of disease is also unsatisfactory. Many alter symptoms and relieve suffering, and so far have a curative effect; but the exact action of any one remedy, more especially in diseased conditions, has by no means been accurately ascertained. It is next to impossible for the practitioner in human medicine to ascertain precisely the action of various remedies. Hereditary predisposition, social influences, and even personal considerations, may often prevent him from arriving at the exact value of any supposed remedy which he may administer. It is impossible for him also to vary the conditions both of the disease and of the remedy without subjecting the patient to discomfort or inconvenience, and consequently of risking his own professional reputation. Dr. McKendrick did not forget that valuable therapeutic inquiries may be made on large numbers of men in as nearly as possible the same conditions; but these must be preceded by careful preliminary researches on animals.

During the last few years, a department of inquiry, termed experimental pathology, has been established in various parts of the Continent. The object is artificially to establish diseased actions, and to observe these under various conditions. By this method, we may hope to obtain an insight into the origin of such diseases as pulmonary consumption, of cancer, and of the various fevers, which destroy in Great Britain alone more than half a million of people annually. Diseases of the same class, more especially those of the latter group, cut off tens of thousands of our domestic animals. Surely it is worth sacrificing many animals, if by this means some knowledge could be attained by which we may arrest the ravages of these fearful maladies. By the mere observance of cases of disease, by the most elaborate *post mortem* and microscopical examinations, little more can be done than to arrive at a knowledge of a physiological explanation of symptoms and of the effects seen after death. Only by careful experimental inquiry, conducted on the same principles as in any other objective science, conjoined with the results arrived at by observations of diseased animals and the facts ascertained by careful *post mortem* examinations, can we hope to gain a knowledge of the cause and earlier stages of these maladies; and only when we have done so can we found any rational

treatment which may either prevent them or quickly arrest their progress.

As an example of the kind of investigations which might be carried on in connection with a veterinary college, Dr. McKendrick alluded to the systematic study of the intimate pathology of the morbid infections now being carried on at the Brown Institute, London, under the superintendence of Professor Burdon Sanderson. This Institution is for the cure of diseased animals, and for the furtherance of any work having this end in view. The results have been embodied in a series of papers, published in the reports of the medical officer of the Privy Council. As is well known, certain diseases are remarkably contagious. No better example of this could be given than what is termed foot-and-mouth disease, now very prevalent in this country. Contagion has always been supposed to consist of matter of some kind or other capable of being communicated through the air or by direct contact. It is evident that the identification of the infective matter peculiar to each contagious disease, and the changes which it effects when introduced into the living body, would be valuable both for the prevention and for the probable cure of the disease.

The first distinct information regarding the identification of contagia was recorded by Dr. Lionel Beale of London so recently as 1865, when he drew attention to the existence in the fluids and tissues of animals which had died of rinderpest, of innumerable minute organic particles. These particles Dr. Burdon Sanderson soon afterwards showed to be the true matters of contagium. He pointed out that the animal juices might be separated from them, and thus rendered non-infective. Professor Chauveau, of the Veterinary School, Lyons (one of the ablest physiologists of the present day), demonstrated the existence of similar particles in vaccine lymph, and showed that on the introduction of these successful vaccination depended. About the same time, Hallier, Professor of Botany in Jena, announced the discovery of numerous varieties of minute organisms in various kinds of disease. The appearance of Hallier's communications excited great attention among men of science, and not a few of his statements have been refuted. The particles discovered in various diseases are found to be living organisms, capable of multiplying with enormous rapidity, and of exciting changes in living tissues. They resemble some of those which are engaged in the ordinary processes of fermentation and putrefaction.

Following up this line of research, Dr. Burdon Sanderson has recently made important contributions to a history of the contagia and morbid processes of diphtheria, erysipelas, relapsing fever, and of the splenic fever (*Milzbrand* of the Germans); while Dr. Klein, the assistant professor at the Brown Institute, has identified and described the effects of the contagium-particles of the *variola vaccina* or sheep-pox.

It appears to Dr. McKendrick that these researches indicate a line of inquiry likely to lead to great results. It is work which ought to be prosecuted with all diligence. Every contagious disease among the domestic animals must be thoroughly examined. Where can this be better done than in connection with a veterinary college, provided with proper arrangements for keeping diseased animals, on which both before and after death careful observations may be made? No doubt there are practical difficulties to be met and overcome. Animals suffering from contagious maladies cannot be brought to the building of the College, but it would not be difficult to maintain suitable accommodation for them in an isolated building beyond the confines of the city. Here the investigator might work with all needful appliances. Certainly such a scheme would involve expenditure of money; but it would be well expended by the discovery of facts in the history of disease of the highest practical importance. We can never hope to take efficient action regarding the prevention or the cure of contagious diseases until more is known regarding their intimate nature. When accurate knowledge of this kind has been arrived at, precautions may be taken which will effectually stamp out the disease. Many will probably consider such a state of matters to be Utopian, but the march of scientific discovery is bringing us daily nearer to it.

THE QUEEN'S HOSPITAL, BIRMINGHAM.

ON Monday was held the adjourned meeting of Governors of the Queen's Hospital, Birmingham, to which we last week referred, to consider a report which recommended the abolition of the privileged system of admissions.

Mr. Muntz proposed an amendment, which, however, admitted substantially the principles of free admission, and registration fee, and inquiry, but was directed especially towards mollifying objections on the last point. It proposed "that this inquiry shall be regulated on the basis of the principle usually adopted by the sick societies of working men to ascertain the fitness of members to receive club benefit"; also, "that printed forms of 'certificates of fitness' be supplied in any number to any subscriber who may desire to recommend cases for consideration".

Certain gentlemen, who would probably have advocated other views, and certainly objected to the "registration fee", were held by the Chairman (in accordance with the custom of the House of Commons) to be disqualified from speaking on this occasion, as they had already spoken at the previous meeting; some differences of opinion were expressed, though but little supported by the meeting, which was a large and influential one. Mr. Bunce, Chairman of the Subcommittee, ably summarised the general principles involved in the change, and the following resolution was ultimately carried by a majority in the ratio of at least 4 to 1.

"That this meeting approves generally of the recommendations of the Subcommittee's report, and instructs the Committee to consider and decide on the mode and time in and at which such recommendation shall be carried out."

It may be worth while to quote a portion of the report thus approved—an able document. In order to equalise income and expenditure, it propounds three alternatives.

"1. The closing of some of the wards.

"2. Raising the price of the tickets.

"3. The abolition of the privileged system, the cessation of notes, and the working of the hospital on the basis of free admission—regulated solely by the needs and fitness of the applicants, and by the means at the disposal of the charity. This is the method which the Committee unanimously recommend for adoption by the Board, and for submission to a special meeting of Governors. They propose, in conjunction with it, the adoption, in the case of all patients excepting accidents and urgent cases, of a registration fee of one shilling for each patient, such fee to be renewed at the expiration of a month. A registration fee is already required at the Children's Hospital and the Women's Hospital, where it is found to work satisfactorily, and the Committee believe that, at the Queen's Hospital, it will constitute a large and steady source of income.

"If this plan be adopted, it will be necessary to arrange a careful and efficient system of inquiry into the fitness of patients, in order to prevent the hospital from being, on the one hand, burdened by those who should properly be treated at the parish infirmary, and, on the other, to prevent imposition by those who can afford to pay for medical attendance, and who, therefore, are not fit objects of benevolence.

"It may also be necessary to deal with the number of new admissions by fixing a limit for each day, excepting as regards accidents and urgent cases. This is a subject which should be referred to the Medical Board for their consideration and advice.

"The Committee do not think it necessary in this report to discuss the arguments in favour of a free system. They may, however, point out that it has two great merits: it gives absolute freedom to the medical staff in deciding as to the medical fitness of applicants for relief; and, at the same time, it gives absolute power of control to the Board as to the number of patients to be received, and the amount of expenditure to be incurred. Under a ticket system, no such power exists, because it is part of the implied contract with the subscribers that, accidents, etc., excepted, applicants presenting tickets shall have priority over those who apply without them.

"The Committee do not believe that any loss of income from subscriptions at all worth considering will result from the adoption of the free system; and whatever loss will be temporarily incurred will, in their opinion, be very largely exceeded by the produce of the registration fee. They also believe that it will be possible to appeal with con-

AUTOPSY.—The rhubarb had extended along about a third of the small intestine. There was no unusual redness of the mucous membrane, and there was only slight evidence of purgative action.

Experiment 17. Dog weighing 13.4 kilogrammes.—The artificial respiration, which was deficient at the commencement of this experiment, was improved at *a*, Fig. 17. This was followed by an increase in the secretion of short duration: 5 cc. of the same infusion of rhubarb as that used in the previous experiment were injected into the duodenum three times in succession (*r*, *r'*, *r''*, Fig. 17). The biliary secretion was augmented within half-an-hour after each injection.

AUTOPSY.—The rhubarb had extended along four-fifths of the small intestine. There was no unusual redness of the mucous membrane. The portion of intestine through which the rhubarb had extended contained 120 cc. of a thick yellowish fluid: there was, therefore, decided evidence of purgative action.

Experiment 18. Dog weighing 22.7 kilogrammes.—In this experiment, it was proposed to test the action of rhubarb upon the exhausted liver. The artificial respiration being defective at the commencement of the experiment, was improved at *a*, Fig. 18. At the middle of the fourth hour, a remarkable increase of secretion took place, and lasted for two hours. The cause of this was not apparent until it was observed that a warm July sun shone full upon the abdomen, from the middle of the fourth

Fig. 18.—Secretion of bile in a dog that had fasted eighteen hours. Respiration improved at *a*. 10 cc. of the concentrated infusion of rhubarb injected into duodenum at *r*; and 5 cc. at *r'* and *r''*.

to the middle of the sixth hours of the experiment: the increase in the secretion was, therefore, probably due to a rise of temperature: 5 cc. of the concentrated infusion of rhubarb, given in the previous experiment, were injected into the duodenum three times in succession (*r*, *r'*, *r''*), and, notwithstanding the very high secretion shortly beforehand, the rhubarb increased it still further.

AUTOPSY.—The rhubarb had extended along two-thirds of the small intestine. There was no unusual vascularity of the mucous membrane. The upper portion of the intestine contained 87 cc. of a yellowish-green liquid, whereas only 20 cc. of water had been injected. Purgation had, therefore, evidently been produced.

In these three experiments, it appears that an infusion of seventeen grains of rhubarb was given nine times, and on one occasion twice this quantity, and that none of these doses ever failed to increase the biliary secretion within half-an-hour after administration. The amount of water given was so trivial that its effect may be entirely disregarded. It is to be noted, that the excitement of the liver produced by rhubarb was accompanied by far less intestinal irritation than was the case with podophylline and aloes.

Composition of the Bile before and after Rhubarb.—The bile secreted before and after the administration of rhubarb in all the three experiments was analysed. Tables VI, VII, and VIII show the result.

TABLE VI.—*Rhubarb.*

Experiment 16.	Before.	After the second dose.	At the close of the Experiment.
Water	88.80	89.28	88.98
Bile-acids, pigments, cholesterine, and fat	9.60	9.60	9.60
Mucus	1.00	0.60	0.80
Ash	0.60	0.52	0.62
	100.00	100.00	100.00
Velocity of bile-secretion per half-hour	1.9 cc.	2.95 cc.	2.55 cc.

From the foregoing analysis, it appears that the percentage amount of the special biliary matter was not diminished by the action of rhubarb, although there was so great an increase in the amount of bile. This result, which corresponds to that observed in the case of podophylline, is confirmed by the following analyses.

TABLE VII.—*Rhubarb.*

Experiment 17.	Before.	After.
Water	85.47	86.23
Bile-acids, pigments, cholesterine, fat	11.59	11.03
Mucus	1.87	1.72
Ash	1.07	1.02
	100.00	100.00
Velocity of bile-secretion per half-hour	1.45 cc.	3.95 cc.

TABLE VIII.—*Rhubarb.*

Experiment 18.	Before.	After.
Water	85.35	85.52
Bile-acids, pigments, cholesterine, fat	12.07	11.98
Mucus	1.53	1.49
Ash	1.05	1.01
	100.00	100.00
Velocity of bile-secretion per half-hour	4.32 cc.	5.37 cc.

It therefore appears that rhubarb, like podophylline, excites the liver to secrete bile, having a composition similar to that secreted under normal conditions.

Results of Experiments with Rhubarb.—1. An infusion of seventeen grains of Indian rhubarb, when placed in the duodenum, never failed to increase the secretion of bile. 2. The bile, although secreted in increased quantity, had the composition of normal bile as regards the biliary constituents proper. 3. The doses which so powerfully excited the liver had in one case no marked purgative effect, but in other two cases the purgative effect was considerable.

ACTION OF SENNA.

Senna excites the liver, but not so powerfully as rhubarb. The ordinary infusion of senna of the *British Pharmacopæia* was prepared and concentrated until 5 cc. contained the active part of forty-five grains of senna; a small dose for a man.

Experiment 19. Dog weighing 22.3 kilogrammes.—5 cc. of the concentrated infusion of senna, prepared as above, were injected into the duodenum twice in succession (*s* and *s'*, Fig. 19). After the second dose the secretion rose rapidly, but, unhappily, the animal died from asphyxia, owing to the accidental closure of the expiration aperture of the bellows-tube.

Fig. 19.—Secretion of bile in a dog that had fasted fifteen hours. 5 cc. concentrated infusion of senna injected into duodenum at *s* and *s'*.

Fig. 20.—Secretion of bile in a dog that had fasted nineteen hours. 5 cc. concentrated infusion of senna injected into duodenum at *s*, *s'*, *s''*, *s'''*, *s'iv*.

Fig. 21.—Secretion of bile in a dog that had fasted eighteen hours. 7 cc. concentrated infusion of senna injected into duodenum at *s* and *s'*.

Experiment 20. Dog weighing 8 kilogrammes.—5 cc. of the above-mentioned concentrated infusion of senna were injected into the duodenum five times in succession (*s*, *s'*, *s''*, *s'''*, *s'iv*, Fig. 20). The secretion of bile rose rapidly after the second dose, as in the previous experiment, but it soon fell again; and the third, fourth, and fifth doses did not increase it.

AUTOPSY.—The senna had extended along three-fourths of the small intestine, which contained 80 cc. of liquid. Seeing that the amount of fluid injected was 25 cc., considerable purgation had been produced. There was a considerable increase in the vascularity of the duodenal mucous membrane, but elsewhere there was no unusual redness.

It appears from this experiment that, although the amount of senna given was sufficient to distinctly act on the intestine, it did not produce any very marked effect on the liver. The purgative effect was greater than in the case of rhubarb, in Experiment 16, but less than in Experiments 17 and 18. However, the effect on the liver was less than in all the rhubarb experiments.

Experiment 21. Dog weighing 5 kilogrammes.—In this case it was proposed to test the action of senna on the exhausted liver. Accordingly, at the middle of the eighth hour of an experiment on an animal that had fasted for the usual period of eighteen hours, 7 cc. of a concentrated infusion, containing the active part of ninety grains of senna, were injected into the duodenum twice in succession (*s* and *s'*, Fig. 21). No noteworthy effect on the biliary secretion ensued.

AUTOPSY.—The senna had extended half-way along the small intestine, which contained about an ounce of viscous fluid, thus affording slight evidence of purgative action.

Röhrig, from some experiments with rhubarb and senna (*lib. cit.*, p. 253), concluded that in their activity as cholagogues they stand much on the same level; and, although far inferior in power to aloes, their infusions are nevertheless more powerful than water. The defective method of experiment employed by him is the probable cause of this statement. The estimate of the action of senna is indeed correct; but the foregoing experiments show that rhubarb holds a much more important rank as a hepatic stimulant than senna, and this is still further seen when we compare the analysis of the bile before and after senna with that of the bile before and after rhubarb.

TABLE IX.—Composition of Bile before and after Senna.

Experiment 20.	Before.	After.
Water	90.63	91.31
Bile-acids, pigments, cholesterine, fat	7.20	6.75
Mucus	1.30	1.20
Ash	0.87	0.74
	100.00	100.00
Velocity of secretion per half-hour	0.82 cc.	1.136 cc.

It appears from this analysis, and from the velocity of secretion, that although senna causes the liver to excrete more biliary matter, its power is far below that of rhubarb.

Results of the Experiments with Senna.—1. Senna is a hepatic stimulant of feeble power. 2. It renders the bile more watery.

ACTION OF COLCHICUM.

Colchicum has been recommended as a cholagogue in cases of gout, but its action on the liver has not hitherto been tested by direct experiment.

Experiment 22. Dog weighing 23.5 kilogrammes.—Sixty grains of the aqueous extract of colchicum of the *British Phar-*

Fig. 22.

Fig. 23.

Fig. 24.

- Fig. 22.—Secretion of bile in a dog that had fasted sixteen hours. Sixty grains of aqueous extract of colchicum in 10 cc. of water injected into duodenum at *c*.
- Fig. 23.—Secretion of bile in a dog that had fasted twenty hours. Twenty grains of aqueous extract of colchicum in 5 cc. of water injected into duodenum at *c*.
- Fig. 24.—Secretion of bile in a dog fed on liver fifteen hours before the experiment began, but food was still found in the stomach at the close. Forty grains of aqueous extract of colchicum in 8 cc. of water injected into duodenum at *c*.

macoptia in 10 cc. of water were injected into the duodenum (c, Fig. 22). In an hour the biliary secretion began to increase, and five hours after the injection it was nearly five times more than before the drug was given. The secretion then fell, and just at the close of the experiment a large quantity of liquid feces was discharged.

AUTOPSY.—There was great vascularity of the upper four-fifths of the mucous membrane of the small intestine. The vascularity of the duodenum was intense. The mucous membrane of the large intestine was also unusually vascular. The gastric mucous membrane was pale. There was evidence of considerable hydrocatharsis in the small intestine. The large intestine was empty, owing to the recent discharge of fecal matter.

Experiment 23. A somewhat weak dog, weighing 7 kilogrammes.—Twenty grains of aqueous extract of colchicum in 5 cc. of water were injected into the duodenum (c, Fig. 23). The effect on the biliary secretion was evident at the end of an hour; but throughout the whole experiment the animal secreted only a small quantity of bile, and by the fifth hour the pulse was so weak that the experiment was closed.

AUTOPSY.—There was somewhat increased vascularity of the mucous membrane in the upper fourth of the small intestine. There was no distinct evidence of purgative action.

Experiment 24. Dog weighing 9.9 kilogrammes.—Forty grains of aqueous extract of colchicum in 8 cc. of water were injected into the duodenum (c, Fig. 24). The effect on the bile-secretion was not very marked; for although, after the lapse of an hour, the falling of the secretion was arrested, it did not, under the influence of the colchicum, rise to any very notable height. At the close of the experiment, a quantity of partially digested food was found in the stomach. On this account, it was impossible to be sure whether or not a small amount of fluid in the upper part of the small intestine was due to cathartic action. The mucous membrane of the duodenum was intensely red.

Experiment 25. Dog weighing 23.6 kilogrammes.—Sixty grains of aqueous extract of colchicum in 10 cc. of water were injected into the duodenum (c, Fig. 25). Although the biliary flow thereafter varied much, a decided increase was evident an hour and a half after the administration of the drug. The increase lasted about four hours, after which the secretion gradually fell.

Fig. 25.—Secretion of bile in a dog that had fasted eighteen hours. Sixty grains of aqueous extract of colchicum in 10 cc. of water injected into duodenum at c.

AUTOPSY.—There was increased vascularity of the mucous membrane of the upper three-fourths of the small intestine. The whole small intestine contained evidence of powerful cathartic action.

These experiments show that the aqueous extract of colchicum in large doses increases the biliary secretion.

TABLE X.—Composition of the Bile before and after Colchicum.

Experiment 25.	Before.	After.
Water	88.434	90.63
Organic Bile-solids	10.616	8.75
Ash	0.950	0.62
	100.00	100.00
Velocity of bile-secretion per half-hour	1.2 cc.	2.24 cc.

It appears from the above analysis, that colchicum rendered the bile more watery; nevertheless, owing to the increased velocity of secretion, more biliary matter is excreted by the liver under its influence.

Results of Experiments with Colchicum.—1. Sixty grains of the aqueous extract of colchicum powerfully excited the liver, and produced hydrocatharsis; forty, and even twenty grains, also increased the biliary secretion, though less powerfully. 2. Colchicum, while it increases the amount of biliary matter excreted by the liver, renders the bile more watery.

fidence to the public on the simple basis of the work done by the hospital, and to appeal especially to those persons who might be disposed to give small subscriptions, but who do not now give them, because such subscriptions carry no privileges.

"Even as it is, the hospital is, to a very great extent, a free institution, so that it endures all the restraints and satisfies many of the claims of that system, without possessing the control insured by the complete adoption of it.

"At the end of 1873, there were 135 patients in the wards. During the year 1874, 1,683 were admitted; and of these, 345 were admitted by ticket, and 1,338 were admitted free. Of the out-patients—a total of 15,259—8,169 were admitted by ticket, and 5,535 were admitted free, to which must be added 773 in the obstetric department, 330 ophthalmic cases, and 459 dental cases; thus making the free admissions 7,090, or nearly one-half, in the out-patient department, while in the in-patient department they were two-thirds.

"That the majority of the Governors do not very keenly value the advantages of the ticket system is evident from a return laid before the Committee, which shows that 141 life Governors, entitled to 186 in-patient notes, used only 74 of them; and that 728 subscribers of £2 2s. and upwards, entitled to 844 in-patient notes, used only 271, in addition to which 181 in-patient notes were exchanged for out-patient tickets.

"The Committee believe, therefore, that the assent of the Governors would readily be given to the proposed change; they believe that it would increase the confidence of the public in the charity; that it would tend to the reception only of the cases fittest for relief; that it would give a larger means of income, and a power of control now deficient; and, therefore, they recommend it for general adoption."

The collection of Hospital Sunday (October 31st), which was made this year in due course for the benefit of the Queen's Hospital, and which amounted to the very handsome sum of £3,200, may fairly be taken as evidence of the interest and of the confidence of the public in the abovementioned scheme and in the present management of the hospital.

THE Medical Society of London will henceforth meet on Mondays at 8.30, instead of 8 o'clock.

A MEETING of the Executive Committee of the General Medical Council was held last week. The business was principally of a private character, without any special public interest.

DR. GUSSENBAUER, the able clinical assistant of Professor Billroth in Vienna, has been appointed Professor of Clinical Surgery in the University of Liège in Belgium.

AT the meeting of the British Medical Association at Brighton in August 1876, the Address in Medicine will be delivered by Dr. Sieveking; the Address in Surgery, by Mr. Wheelhouse of Leeds; and the Address in Public Health (State Medicine), by Dr. Carpenter of Croydon.

It is announced that Dr. Irving, who recently stated that he had been stabbed on the road between Thirsk and Kilvington, was found dead in his bed, having died suddenly. An inquest was held; when it appeared from the evidence that he had committed suicide by taking prussic acid.

MR. H. R. FOX BOURNE, it is announced, is about to publish a new life of the illustrious John Locke, to which will be prefixed a curious collection of medical memoirs and notes, showing how extensive were his studies and practice as a physician, and connecting him as a joint-worker with Thomas Sydenham, "the father of English medicine".

DR. PARKES will give the Harveian Address at the Royal College of Physicians, London, next year; Dr. Habershon, the Croonian Lectures; Dr. Dickinson, the Lumsian Lectures; Dr. Shepherd, the Goulstonian Lectures. We hope to be able, by arrangement with the lecturers, to publish these lectures *in extenso* in the pages of the BRITISH MEDICAL JOURNAL.

WE shall also have the pleasure of publishing Dr. Sibson's forthcoming lectures on Bright's Disease and its Treatment at the Harveian Society of London.

MR. MACNAMARA has been elected Surgeon to the Westminster Hospital by a large majority of votes. Looking to the high reputation which Mr. Macnamara earned in India, and the favour with which his surgical writings have been considered in this country, we cannot but consider this a very judicious choice, and one which is likely to add to the reputation and usefulness of the Westminster Hospital. A good deal of warmth had been imparted to the contest, owing to the fact that Mr. Cooke, the senior assistant-surgeon of Westminster Hospital, resented Mr. Macnamara's candidature as an infringement on his natural right of promotion. No such natural right, however, exists: many precedents in the best hospitals exist for importing external surgeons and physicians of capacity to fill vacancies, where it is thought that their assistance will give desirable *prestige* and value to the hospital service. Recent instances at University College, St. George's, and St. Thomas's Hospitals are quite in point. Conceiving himself otherwise affronted by the action of his colleagues, Mr. Cooke has shown a very unnecessary and undesirable vigour in the discussion of purely personal topics. He must be warned that such a course rarely fails to affect injuriously the reputation of any one who employs it. He has at a comparatively early age achieved an honourable position as the senior assistant-surgeon at a great metropolitan hospital; he has many years before him in which to vindicate his professional fitness for yet higher appointments; and he has also, we believe, the capacity to do it. The first element in such success is deference to the feelings of colleagues, and the power and the will to work harmoniously with them. There is, in the record of the proceedings, some evidence of a tendency of the staff to form a "cabal" against one member; and of this we think Mr. Cooke, as the probable victim, had reason to complain. The policy of suppressing and professionally tabooing some one member of their body, with whom they do not agree, is a very objectionable one; and we are not altogether sorry that Mr. Cooke's very vigorous proceedings have shown the staff that individuals have rights and claims which must not be lightly disregarded. Each party has, we hope, received a lesson; and we trust that all will now work in amity and for the good of the hospital and school; and that we shall hear no more of discord at the Westminster, or of any attempt to get rid of individuals by the action of cliques.

THE Royal Commission to inquire into the practice of subjecting live animals to experiments for scientific purposes have again held daily meetings during the week. Nearly all the more eminent persons having cognisance of the subject from any point of view have now been examined, and we believe that the meetings of the Commission for the collection of evidence will shortly come to an end.

IS COWPOX PREVENTIVE OF FOOT-AND-MOUTH DISEASE?

M. FELIZET of Elbeuf has observed that, while epidemics of cowpox and foot-and-mouth disease have been prevalent simultaneously in his vicinity, no beast affected with cowpox has, up to this date, been attacked by foot-and-mouth disease. Following out this observation, M. Felizet has during the last four months vaccinated thirty oxen, and not one of the twenty-five beasts effectually inoculated has, up to this date, shown any sign of foot-and-mouth disease, although living among animals largely infected with it. M. Felizet communicates this observation to the *Recueil de Médecine Vétérinaire*. The editor, M. Bouley, suggests with reason that, in order to ascertain if cowpox is preservative against foot-and-mouth disease, the experiment should be reversed, and animals which have had the foot-and-mouth disease should be vaccinated; for foot-and-mouth disease ought, conversely, to be prophylactic of cowpox. If a beast which has had foot-and-mouth be still vaccinable, the question is settled against M. Felizet. It is certainly a question very well worth investigation.

A MEDICAL NIGHT SERVICE.

PARIS will probably soon have a medical night-service, from which possibly we in this country may take a hint, and such as we have already described as existing at St. Petersburg. The *Préfet de Police*, in his memorandum on the budget of 1876, expresses himself thus.

"*Public Succour*.—We arrive at a question often discussed: that of medical succour to persons attacked during the night by sudden accidents or ailments. The cases in which the absence of this help has been fatal to sick persons are happily rare; but one painful occurrence (often, moreover, exaggerated) suffices to give rise to recriminations against the medical body, which, however, taken as a whole, holds cheaply enough its repose, its health, and, yet more so, its interests. The strength of medical men is not without limits, and their fatiguing and perilous profession makes repose at certain hours an imperious necessity for them. On the other hand, the exaggerated disquietudes of patients and their families often lead to useless summonses. Finally, more than once, under pretext of an urgent visit, physicians have been led into ambushes, not to speak of ungrateful and dishonest clients, who refuse the legitimate remuneration due to the service rendered."

To remove these inconveniences for the benefit of the public, the *Préfet de Police* recommends the following arrangements, which will necessitate the inscription on the budget of the city of a sum of only 10,000 francs (£400). In every quarter, medical men will be invited to declare whether they are disposed to attend to requisitions addressed to them in the night. The names and domiciles of those who may be willing will be inscribed on an official list posted in the police-stations of the quarter. The person who may require a doctor will go to the neighbouring police-station, and will select from the list the practitioner whose aid he desires. A police-officer from the station will accompany him to the house of the medical man, will follow the latter to the house of the patient, and will, when the visit is over, reconduct him home. On leaving him, he will give him an order on the police treasury for ten francs. According to the pecuniary position of the patient, the administration will reclaim the fees paid, or will assume the cost of them.

ARSENICAL POISONING BY A GREEN LAMP-SHADE.

At a recent meeting of the Medical Society in Bonn, Professor Zuntz brought forward a case, in which a gentleman who had for several years been subject to migraine observed that for some days he had headache late in the evening, which, without interfering with sleep, continued in the morning, and was accompanied with loss of appetite and *malaise*. In about a fortnight, the symptoms became more severe, and lasted the whole day. At the same time, similar symptoms, but much less severe, appeared in two students who sat at the same table in the evening. The green shade of the petroleum lamp was suspected to be the cause of the mischief; and, on chemical examination, it was found to contain arsenic. Its use being discontinued, all the symptoms ceased in the three individuals. It was evident that the heat of the lamp had set free the arsenic; and the greater severity of the symptoms in the first mentioned individual was due to the fact that he was near-sighted, and therefore sat nearer the lamp than the others did. Professor Zuntz said that he himself was some years affected in a similar way, though less severely, while using a green lamp-shade, in which arsenic was found.

MANCHESTER PROVIDENT DISPENSARY ASSOCIATION.

IN another part of our columns will be found a letter from Mr. O'Hanlon, the Honorary Secretary of the Manchester Provident Dispensary Association, in answer to some statements made by a correspondent on October 16th. It was said that friendly societies had been admitted to the benefits of the provident dispensaries, and that this was "a direct violation of the terms of the original scheme". Mr. O'Hanlon replies, that the resolution to admit friendly societies was passed with strict regularity, after full consideration; and that the medical men connected with the Association had ample opportunities of expressing their opinions upon it. Again: our correspondent stated that the dispensaries offered "a miserable remuneration for an eminently extensive and unceasing expenditure of time and labour". But Mr. O'Han-

lon shows that the work done under the Association is at least as well paid as any practice among the same class of people, and that the rules laid down are such as to minimise the doctor's labour. The whole of Mr. O'Hanlon's letter is well worthy of the careful study of all who are interested in this important question, and the temperate reply which he makes to our correspondent cannot fail to carry great weight. The experiment which is being made at Manchester is the most important practical reform which has been introduced into our profession for many a year. That it cannot be carried out without exciting some opposition and disturbing some vested interests, we can well believe; but it seems to us so certain that, when once fully established, it will be beneficial both for the working classes and also for the medical profession, that we wish it all success.

THE BRITISH MEDICAL DEFENCE ASSOCIATION.

THE East London Branch of the British Medical Defence Association recovered last week another penalty of £20 and costs from a person who was illegally practising at the East End of London. As in the two recent cases in which like penalties were recovered, so in the present instance, registered medical men endeavoured to shield the defendant in his practice. The Provisional Committee have decided to call a general meeting of medical practitioners for the 30th instant. The time and place of meeting will be duly advertised in the medical papers.

THE UNIVERSITY OF VIENNA.

FROM a report on the condition of the University of Vienna just issued by a committee of professors appointed in the beginning of the present year, it appears that the teaching staff in the faculty of medicine consists of 111 persons; viz., 22 ordinary and 32 extraordinary professors, and 57 private teachers (*privat-docenten*). Of the 111 individuals, 24 are Bohemians, 18 Viennese, 17 Hungarians, 9 Moravians, 6 Lower Austrians, etc. The only two professors who are foreigners are Brücke and Billoth. It is indeed true that Professor Meynert is a native of Dresden, Dr. Monti of Italy, and Dr. Lott of Göttingen; but all three came to Austria in very early life, and studied and obtained their diplomas in Vienna. The report refers to the abundance of clinical material, and points out that in the means of teaching, the University is behind the demands of the times, and recommends the building of the honorary institutions for teaching of the several departments of science. There are in the four German Universities of Austria five chairs of Anatomy, and four each of Physiology, Pharmacology, Pathological Anatomy, and Forensic Medicine; and the aspirant to each of these chairs—who, moreover, gets very little practice—is obliged to abandon his pursuit after some years, or to wait fifteen or twenty years for a professorship, unless he find a post in some foreign state. The reporters recommend: 1. An increase of the German medical professorships in Austria; 2. An increase in the number of assistantships in the various institutions, so that the persons appointed may be able to remain longer and do more work. They further observe that, "If so great a medical faculty as that of Vienna is to keep its place in the first rank, it must keep the whole nation in view so as to be able to place the best men in the first places when vacancies occur. Such men can be found and obtained, if the government and the faculties consult together and treat each other with mutual confidence." The statistical view of the attendance of students shows a steady decrease since 1870, while from 1865 to 1870 there was as steady an increase. From 708 students in the winter of 1864-65, the numbers rose to 1,470 in 1869-70, and then fell to 877 in the winter session 1874-75. The number of first year medical students also shows a falling off; being 155 in 1864-65, 246 in 1869-70, and 133 in 1874-75. In the medical faculty, 171 students have stipends amounting to about 35,000 florins (about £3,645 yearly). In the winter session 1873-74, 44 students applied to be relieved from payment of college fees; these were entirely remitted to 13, and half to 11. In 1874-75, of 40 applications, 20 were successful.

THE "CORNWALL" OUTBREAK OF TYPHOID.

A FEW more cases of typhoid have occurred during the week on board the *Cornwall*—making, we believe, a total of 89 out of 235 boys in the ship. Of these, 37 have been sent to the *Rhin* at Gravesend; 9 remain at Purfleet, being unfit for removal at present; 9 others are at St. Bartholomew's; and 24 out of the original 34 are still under treatment at the Seamen's Hospital, Greenwich, the remainder having been discharged convalescent. The virulence of the outbreak has greatly diminished; and strong hope is entertained that it will be speedily brought under control. We understand that a considerable proportion of the cases in the *Rhin* are of a very mild description; and that some of those at St. Bartholomew's are of a doubtful kind. At the Seamen's Hospital, as we before stated, the majority have been of a pronounced, and several of a severe, character.

THE BROWN INSTITUTION.

It is most gratifying to hear that some arrangement is likely to be made between the Royal Agricultural Society and the Brown Institution for investigating the very serious diseases to which cattle are now subject in almost all the agricultural districts of England. Of course, such an inquiry could not be placed in better hands than those of the Professor Superintendent of the Brown Institution, who did so much for the investigation of the cattle-plague.

PUBLIC HEALTH APPOINTMENTS.

THE faith of the public and of the legislature in the desire of local boards to elect their medical officers of health from a pure regard to their special qualifications, will not be strengthened by what has just occurred in the parish of St. Giles. The board has recently lost the services of a most able and accomplished sanitarian, Dr. Ross, whose premature and sudden death is the subject of universal regret. The filling of his office unquestionably involved a serious responsibility, for it is hardly possible to name a district which stands in greater need of the services of an experienced and highly informed sanitarian at the present juncture than the parish of St. Giles. There were many highly qualified candidates, men who had won their spurs in public sanitary work, graduates of the great universities, and others of eminence. From the list of thirty candidates the board has selected a gentleman of whom, however capable he may be otherwise, it can only be said in this relation that his special recommendation appears to have been, that he was a member of the local board which elected him. Occurrences such as this are to be regretted, not only for the sake of those specially concerned, but for the example which they set.

METROPOLITAN MORTUARIES.

EVERY week makes more evident the necessity for the provision in all the districts of London of mortuaries to which may be removed from the crowded habitations of the poor the dead who have fallen victims to infectious disease. We are glad to learn that the Strand Board of Works will not quietly acquiesce in the recent extraordinary decision of the Metropolitan Board of Works declining to entertain the consideration of measures necessary for facilitating the erection of such mortuaries. A notice to the following effect has been placed on the minutes of the Strand Board by Dr. Rogers, for the next meeting:—That this Board has learned with astonishment and regret that the Metropolitan Board of Works has declined to accede to the prayer of a memorial of this Board on the question of the establishment of mortuaries in the metropolis, although the Chairman of the Works Committee of the Metropolitan Board, in bringing up the report on the memorial, acknowledged the validity of the facts set forth in the memorial indicating the necessity of such mortuaries, and the difficulty experienced by district boards in providing them. That the Strand Board do, therefore, direct their clerk to write to the President of the Local Government Board, requesting an interview, with the object of pressing upon him the desirability of introducing a Government measure next session or the provision of such accommodation in the metropolis. In the

event of this resolution being adopted, that the clerk be directed to write to Sir C. Russell, M.P., and Mr. W. H. Smith, M.P., members for the borough of Westminster, asking them to attend, and to introduce and support the views of the deputation. There is, we hope, little doubt that this resolution will be carried and acted upon. This is unquestionably a subject which may desirably occupy the early attention of the Government.

A PHYSIOLOGICAL TEST OF CHEMICAL PROPERTIES.

AT a meeting of the Californian Academy of Sciences, August 2nd, reported in *Nature*, Dr. Blake referred to some physiological experiments he had performed to determine the molecular relations of beryllium. Neither the specific heat of the metal, nor the vapour density of its chloride had been determined, and chemists were undecided as to whether it was a bivalent or quadrivalent element. Its physiological reactions, when introduced directly into the blood of living animals, so closely resembled those of alumina, that there can be no doubt that it belongs to the same isomorphous group, and that it is a quadrivalent element. There is also a close relation between the intensity of physiological action of this substance and its atomic weight. When compared with aluminium, as in a series of experiments conducted expressly to determine this point, the quantities of Be_2O_3 , under the form of sulphate, required to kill a rabbit weighing 2,270 grammes, when injected into the veins in divided doses (three injections), were .059, .061, .050; the quantities of Al_2O_3 , introduced into the veins under the same conditions, were .021, .023, .022; and the smallest quantity required to kill, when introduced in one injection, was, of Al_2O_3 , .016, and of Be_2O_3 , .038, showing a marked increase in the physiological action of these substances with an increase in the atomic weights, the atomic weight of aluminium being 27.4, and of beryllium 14. This, the author believes, is the first occasion on which physiological reactions have been used to determine the chemical properties of a substance. Should, however, the carbon compounds follow the same laws in their physiological reactions as the inorganic elements, living matter must offer a valuable reagent in investigating their molecular properties. The interesting experiments of Messrs. McKendrick and Dewar, published in the twenty-third volume of the *Proceedings of the Royal Society*, would indicate that such may be the case, as these gentlemen found, in experimenting with the compounds of the chinolin and pyridin groups, that the physiological actions became stronger in going from the lower to the higher members of the series. They also observed that in the pyridin group, when the base became doubled by condensation, not only was the physiological action more intense, but its character was completely altered, agreeing in these respects with the salts of iron with which analogous changes take place, both in the character and intensity of their physiological action, when the molecule is doubled in the change from ferrous to ferric salts, as Dr. Blake has shown in the *Journal of Anatomy and Physiology*, vol. iii, p. 24.

ST. ANDREW'S GRADUATES' ASSOCIATION.

UNDER this name, the St. Andrew's Medical Graduates' Association has been reconstituted. The Council of the Association is actively engaged in promoting the re-election of Dr. Richardson, F.R.S., as assessor of General Council in the University Court of St. Andrew's; an office which has fallen vacant by the resignation of Patrick Anderson, Esq. Dr. Paul is Honorary Treasurer, and Dr. Sedgwick Honorary Secretary. Dr. A. Watson Wemyss has also been a candidate for some weeks for the appointment. He grounds his candidature on "the great interest he entertains for the prosperity of the University, together with the experience he acquired as one of the patrons of the Edinburgh University before the passing of the late Parliamentary Act, and on his connection with the Medical School of Edinburgh". On these grounds, and on the ground that "he has at all times done what lay in his power to aid the medical profession and for the advantage of the public", he claims the support of the graduates in England as well as in Scotland.

THE HOSPITAL FOR SICK CHILDREN.

THE new building in Great Ormond Street is now nearly ready for the reception of patients, and will be opened at the end of the third week of this present month. In consequence of the increased accommodation for patients which will be afforded, it has been found necessary to appoint a third physician; and we are pleased to learn that Dr. Cheadle, who has held the office of assistant-physician for eight years, has been promoted to the higher post. The vacancy thus created in the junior staff has been filled by the appointment of Dr. Lees, a graduate of Cambridge, where he was a scholar of Trinity College, and a wrangler in the mathematical tripos of his year.

ACCIDENTAL POISONING BY A DISINFECTANT.

THE great increase of these cases of late will inevitably necessitate some legislative enactment compelling the manufacturers to put disinfectants up in bottles of such a distinctive shape and colour as to at once proclaim the nature of their contents, or the invention and use of some disinfectants devoid of poisonous qualities. The last death reported from swallowing carbolic acid was at Bolton, where a char-woman drank some carbolic acid in the cellar of a hotel where she was employed, thinking it was some other liquid. Shortly afterwards, she became unconscious, and died in half an hour.

WORCESTER INFIRMARY.

AT a special meeting of the governors held at the Infirmary on October 29th, Alderman Webb proposed, as an addition to rule 59: "But in case of the unavoidable absence of the honorary medical officer and of his substitute, the house-surgeon shall attend to the patients of such absent officer, and shall record the fact of his having done so in a book to be laid before the Executive Committee; and the honorary medical officer, when called upon to do so, shall furnish such explanations, not in violation of professional confidence, as the Executive Committee may require." Sir E. Lechmere seconded the motion, which, he said, would promote that cordial co-operation between the governing body and the medical staff which was essential to the successful working of the institution. In answer to the Rev. W. Thorne, Dr. Strange said the medical staff would cordially accept the motion. The motion was carried unanimously. We understand that the present staff acquiesce in the resolution, which accords with the practice of most of the metropolitan hospitals.

HOSPITAL SUNDAY FUND.

ON Monday, the 1st inst., a meeting of the Council of the Hospital Sunday Fund was held at the Mansion House, for the purpose of receiving and considering the Report and awards of the Committee of Distribution for the present year. The report stated that the applications had been 13 in excess of those which were accepted in 1874. The Committee recommended that £22,945 12s. 11d. should be granted to 70 general and special hospitals and 4 institutions, and £2,531 0s. 2d. to 47 dispensaries. Two claims were altogether disallowed; and in 27 instances, conferences were held with the managers of charities before the awards were finally fixed. These conferences arose out of the conditions under which the Committee worked this year: for they were not empowered to give any institution less than its arithmetical basis without previously holding a conference with the managing body in regard to the points upon which it was open to criticism. This is an excellent rule. It gives managers an opportunity of pleading their own cause; and it gives the Committee a means of bringing into the light any circumstances which they consider unsatisfactory. The result of the conferences this year was that, in some cases, the arithmetical basis was allowed to stand; but in others, and they formed the majority, it was reduced. Some discussion arose at the meeting as to whether the awards of the Distribution Committee were to be regarded as final, or whether the hospitals and dispensaries should have a right of appeal to the Council. If (as appears to have been the case) no draft of the report was circulated among the members of the Council, and if there was no appeal to them, the Council were only called together to dis-

charge a perfunctory duty, to pass a vote of confidence in the discretion and justice of the Committee. After some conversation upon this subject, the report was adopted, with the understanding that, in future, documents of such importance should be circulated among the members of Council a week before the meeting. The awards were then ordered to be paid. We observe that, as last year, the London Hospital heads the list, with a grant of £2,404 13s. 4d., followed by St. George's with £2,175, and the Middlesex with £1,741 1s. 8d. These sums are considerably smaller than those which were received by the same institutions last year.

CONTEMPT OF THE CORONER'S COURT.

WE are able to give a very simple and satisfactory explanation of the paragraph with the above heading which appeared in the daily papers on Thursday. So far from having "refused to give evidence", Mr. Collyns, the house-surgeon referred to, never received the slightest intimation that an inquest was about to be held. The coroner's beadle left a verbal message in the morning with the hall-porter, who unfortunately forgot to deliver it; and Mr. Collyns heard nothing on the subject until he returned from his walk, and found that, to use Mr. Samuel Weller's expression, he had been accused of "making the coroner's court contemptible". The beadle's remarks, also, about the fees, were altogether untrue; it is perfectly well understood that no fees can be claimed in the case of a patient who dies in the hospital; and although the law has always been considered somewhat hard on hospital officers, it has long been quietly acquiesced in, and there has been no recent agitation respecting it.

THE CONJOINT SCHEME.

THERE appears to be a probability that the negotiations which have so long delayed the settlement of the conjoint scheme are at length likely to end in a successful realisation of the wishes of its supporters. It will be remembered that the members of the Apothecaries' Company were prevented, by the peculiarities incidental to their Act of Parliament, from giving their adhesion to the scheme; but by their Enabling Act, passed last session, they are now no longer prevented from a general acceptance of the terms. Another serious difficulty in the completion of the scheme arose with respect to the appointment of examiners, notably of those in surgery. We are pleased, therefore, to know that the President of the Royal College of Surgeons has now invited the various medical examining boards in England to send each two delegates to a conference. The College of Physicians, at a meeting of the Fellows last week, appointed the President, Sir George Burrows, and the Registrar, Dr. Pitman, to represent its interests at such conference. The University of Oxford has appointed Drs. Acland and Rolleston to be its delegates; and the University of London has nominated Drs. Quain and Storrar for the same purpose. We have not yet heard who will represent the other examining bodies. It may be hoped, therefore, that, before the commencement of another session, this valuable project will be in complete operation.

WINTER QUARTERS IN ALGIERS.

A CORRESPONDENT writes to us from Algiers:—"I send you a few short remarks upon Algiers, with regard to the means of transit there, and the accommodation there, in the hope that it may prove of service, as I find that there are many who look upon Algiers as a sort of *Ultima Thule*. There are two excellent lines of steamers which cross twice a week from Marseilles, the average passage being thirty-six hours. These steamers are most comfortably fitted up, and the table is good. They carry the mails, which come with the utmost regularity, so that one can reckon on having the London newspapers of Friday in Algiers on Monday morning. The hotel accommodation is very fair (if not with all the comforts of home), quite equal to that of the hotels of Cannes, Nice, and Mentone. There are three large hotels in the town, which are all pretty equal in merit, though they differ slightly in prices. The latter naturally depend on the size and exposure of the rooms required. Speaking roughly, a

single man can live very well at the rate of from ten shillings a day upwards. For those who do not care to reside in the town, there is a small hotel kept by a Maltese out in the suburb of Mustapha Supérieur. In this latter quarter are the numerous villas of the richer citizens of Algiers; who, however, only reside in them during the summer, and let them during the winter season, at prices varying from 2,000 to 8,000 francs (£80-£320) for the season of six months, which may be reckoned as lasting from the beginning of November till the end of April; though up to the end of May it is quite possible to remain at Algiers, and, indeed, it is more enjoyable and beautiful at that time than at any other. The weather here during the last fortnight has been most perfect: a cloudless sky and warm sun, but still with enough air to prevent the heat being oppressive. The thermometer has marked 75 deg. in the shade pretty constantly every day, and has never fallen below 58 deg. at night. Of course, it will not remain so high long; but at present it shows no sign of change. The country is much in want of rain, hardly any having fallen since April. Very few English have as yet arrived, except those who own villas and reside here every winter. One of the objections hitherto with regard to Algiers has been the absence of any resident English physician here. This deficiency has been remedied this winter, as Dr. W. Thomson of Edinburgh has now settled here. With regard to the climate of Algiers, I hope to be able to send you a few notes on it from time to time."

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

THE usual general meeting of the Society was held on the evening of Friday, the 29th ult., by the liberality of the Fellows of the Royal Medical and Chirurgical Society, in their library. Sir George Burrows, Bart., President, occupied the chair. The attendance was very limited; out of more than four hundred members, only ten were present to support the President; and, of the ten, four were officers of the Society. Although it may be very complimentary to the officers, as showing how satisfied the members are with the management, still it would be more gratifying to them if the members would attend at the general meetings, and manifest an interest in the working of the Society. From the half-yearly statement of accounts read, it appeared that, during the last half year, 58 widows and 20 children had received grants amounting in the aggregate to £1,236 10s.; the expenses had been £130 11s. 5d., which sum included the cost of the circular sent in the beginning of the year to all members of the profession eligible to become members of the Society. The total receipts of the half year available for payments had been £1,598 10s., and the payments £1,367 1s., leaving a balance of more than £200. A legacy of £1,500, less duty, had been received from the executors of Alexander Barker, Esq., and a legacy of £100, less duty, from the executors of T. F. Chilver, Esq., a member of the Society; and another legacy of £1,000, duty free, was reported from the Rev. H. C. Morgan. Sir Thomas Watson, Bart., and Dr. Billing, were elected vice-presidents in the places of Dr. Latham and Sir Charles Locock, Bart., both deceased; and Mr. Streatfield was elected a director in the place of the late Mr. Sercombe. It was announced at the meeting that the directors intended, out of the balance in hand, to make a present at Christmas of £4 to each widow, £1 10s. to each child, and £4 to each of the recipients from the Copeland Fund. The meeting closed, at about half-past nine o'clock, by a vote of thanks to the President for his attendance at the meeting. It is much to be regretted that the members of the profession who are eligible for membership, and who comprise the four thousand medical men resident in the London Postal District and the extra-metropolitan parts of Middlesex, do not more fully avail themselves of the very great advantages which this society offers. For an annual subscription of two guineas only, a young man may secure to his wife and children after his death a sufficiency to keep the wolf from the door. But, as appeals are being continually made to assist the widows and orphans of our professional brethren who are in absolute penury, nothing but reckless improvidence can explain that state

of things, for which the above society offers a complete remedy. The funded property standing in the names of the trustees—the results of legacies, donations, etc.—amounts to more than £70,000, the interest on which (about £2,500) is added to the yearly subscriptions of the members (about £500 only) for distribution to the widows and orphans of deceased members. Last year, £2,930 were thus distributed in grants, whilst the working expenses did not exceed £250. The Secretary, Mr. J. B. Blackett, attends at the office, 53, Berners Street, every Wednesday and Friday, from 4 to 5 P.M., from whom all required information, with prospectuses, etc., may be obtained.

SCOTLAND.

DR. JOHN WYLLIE has been elected Pathologist to the Royal Infirmary, Edinburgh, *vice* Dr. Bell Pettigrew, appointed to the Chair of Anatomy and Medicine at St. Andrew's.

THE mortality of Glasgow has now remained for a month at the low rate of twenty-one. We believe that there is no record of such a long continuance of such a low rate in Glasgow; but, with the coming-in of cold weather, doubtless there will soon be a rise.

THE winter session commenced in Edinburgh on Monday last, on which day inaugural addresses were delivered, the one at the University by Sir Alexander Grant to the whole body of students; that at the extra-academical school by Mr. Chiene. We publish it on another page.

GLASGOW MEDICAL SCHOOL.

THE medical classes in connection with the Glasgow University were opened on the 27th, when the usual opening address was delivered by Professor Buchanan. It was devoted principally to advice to the students as to their general conduct in and out of the lecture room. Regular and constant attendance on the lectures was advocated as the best means of utilising the opportunities afforded of acquiring knowledge. The session at the Andersonian University commenced on the day following, Dr. Alexander Lindsay being the lecturer.

POISONING BY GAS.

ANOTHER poisoning by gas has occurred recently. A tinsmith, named McLeish, and his two children, who all occupied the same room in a small house in Arbroath, were found suffocated in bed on Friday morning; the children were dead, but the man was still living, though unconscious. The room in which they were sleeping was about twelve feet square; the gas had escaped from the lead-hole of the meter, the temporary plug which had been inserted into it having fallen out. Every effort was made by the medical men of the town, several of whom saw McLeish, to restore him to consciousness, but without avail; and he died in the course of the following night.

UNIVERSITY AFFAIRS.

AT the meeting of the Edinburgh University Court on the 27th ult., besides other business, the court adhered to their objections to the alterations proposed by the University of Aberdeen with reference to additional examiners in medicine. It was also proposed some time since, by the same University, that Greek should be made an optional subject for the M.D. degree; that the examination in clinical surgery should be taken at the end of the third year of study, with some further changes. The Edinburgh court had already sent in answers objecting to these changes; and now a committee was appointed to prepare and send in a further answer. Mr. Andrew Wilson was recognised as a lecturer on natural history in Edinburgh, whose lectures should qualify for graduation in medicine in the University; and Mr. Millen Coughtrey, Professor of Anatomy, University of Otago, New Zealand, was recognised as a lecturer whose lectures should qualify for graduation in medicine in the University.

FAREWELL DINNER TO PROFESSOR DEWAR.

ON the 27th, Professor James Dewar was entertained at dinner by a number of scientific and other friends on the occasion of his leaving Edinburgh to fill the Jacksonian chair of Natural Philosophy in the University of Cambridge. Professor Crum Brown was in the chair; and was supported by Sir Robert Christison, Professor Tait, Dr. Matthews Duncan, Dr. McKendrick, and many others. In proposing Professor Dewar's health, the chairman referred to his distinguished career as a student, as assistant to Dr. Lyon Playfair, and as an original investigator in chemical science. The toast was very heartily responded to; and, after a number of other toasts, the evening was brought to a close by wishing Professor Dewar every success in his new position.

THE WATER-SUPPLY OF EDINBURGH.

FROM the usual returns of the state of the reservoirs, we learn that Loganlea remains empty; and that all the others have fallen more or less, except Clutterdean, which has risen a foot and a half; the stock of water now stands at 29,700,000 cubic feet, as compared with 56,000,000 at the corresponding date last year; the delivery continues at the rate of 26.24 gallons a head to a population of 275,000. The rainfall at Glencorse has been considerably less than at a corresponding period of last year or the year before.

THE NEW BLIND ASYLUM AT EDINBURGH.

THE directors of the Royal Blind Asylum held their first meeting in the new institution, Craigmillar Park, on the 26th. The chairman, Mr. Cowan, M.P., delivered a short address of congratulation on the progress and extent of the new buildings. The new asylum, he said, was built rather in excess of the present demands; but there was little doubt it would soon be fully occupied. He hoped that now that the new buildings were completed, the increase in the subscriptions of the friends of the blind would be considerable; but was glad to learn that the directors, in undertaking this important work, had not seriously burdened the existing funds of the asylum.

SCARLET FEVER IN EDINBURGH.

SCARLET fever continues to be very prevalent in Edinburgh; and, again, all the deaths from zymotic diseases (seventeen in number) which occurred last week in the city are, with one exception, due to that cause—the one excepted case being due to whooping-cough; apart from this, the general health is very good, the mortality, in spite of the number of scarlet fever cases, being at the rate of twenty in the thousand.

IRELAND.

DEATH OF DR. JOHN HAMILTON.

AFTER a painful illness of some months' duration, this gentleman died at his residence in Dublin on last Tuesday, in his sixty-seventh year. Dr. Hamilton was a surgeon of considerable eminence, and was much esteemed for his skill, combined with great courtesy and kindness of disposition. He was Vice-President of the Royal College of Surgeons in Ireland, Visiting Surgeon to Swift's Hospital for the Insane, Surgeon in Ordinary to the Queen, Ex-President of the Pathological Society of Dublin, and late Surgeon to the Richmond Hospital, etc. Dr. Hamilton had a very extensive practice, and was the author of some works on syphilitic affections.

DUBLIN MAIN DRAINAGE.

AT a special meeting of the Corporation of Dublin held on the 27th ult., the draft of a Bill intended to amend the Dublin Main Drainage Act was brought forward, and it was determined that the necessary steps should be taken for bringing forward the Bill in the ensuing session. During the sitting, a communication was read from the Lords of the Treasury, stating that they were not at present in a position to answer the question of the additional security that will be required for

the advances to be made for the main drainage of Dublin; and, looking to the large amount of public money which will be advanced for this work, as well as to the amount contributed out of public moneys, they consider it an imperative necessity that the Government should be represented on the Committee charged with the responsibility of carrying out the works, by two officers who should possess the same right to vote and take part in the proceedings of the Drainage Committee as every other member of that board. This decision of the Treasury has met with the approval of the citizens, but has much annoyed the Corporation and their friends.

HOW DISEASES ARE SPREAD.

IN the police-court at Cork, last week, one of the parties interested in a case was a woman who had a child in her arms affected with scarlatina, and almost in a dying condition. No punishment was awarded by the presiding magistrate, who merely made an order that no woman with a child in her arms should be admitted into the court for the future. The police-court at the time was densely crowded; and, consequently, it is to be expected that more than one of those present at the time may be affected with a disease so terribly infectious as scarlatina, by the imprudence of this woman.

AN ATTEMPTED NUISANCE.

THE Corporation of Dublin attempted lately to construct in one of the leading thoroughfares of Dublin a public latrine, and a few days since had several men excavating, as a preliminary for its formation, a hole in the centre of the street in question, which was to contain a trough fifteen feet long, to be filled with water, and the contents removed day by day. The residents bitterly complained of this unjust procedure, deteriorating as it would the value of property in the immediate vicinity, and also in a sanitary point of view against a nuisance of the kind. They waited upon the Corporation, who, at a meeting held last Monday, finally determined to stop the objectionable measure. One of the local papers in commenting upon this matter, said that they would dissuade the residents from having recourse to anything like Lynch law; yet it would be a fitting judgment to shut up the whole Committee who attempted to perpetuate the job in their own cloaca for twenty-four hours: a sentence from which few outside the Corporation would dissent.

SURGICAL SOCIETY OF IRELAND.

AT a meeting held on the 1st inst., the following gentlemen were selected by ballot members of Council for the ensuing year. *President:* Edward Hamilton. *Vice-President:* John Hamilton. *Council:* Charles Benson, M. Harry Stapleton, Philip Bevan, Richard G. Butcher, James H. Wharton, George H. Porter, J. Stannus Hughes, William Colles, Albert Walsh, Rawdon Macnamara, John Barker, Jolliffe Tufnell, John Morgan, Edward D. Mapother, Henry Gray Croly, Edward H. Bennett, Anthony Corley, William Stokes, Benjamin F. McDowell. *Honorary Secretaries:* Benjamin Wills Richardson, Humphrey Minchin.

ULSTER EYE, EAR, AND THROAT HOSPITAL, BELFAST.

THIS institution was opened in January 1871, and since then, the annual number of patients receiving benefit from it has increased so rapidly that the expenditure has been in excess of the income, and there is at present a debt on the hospital to the amount of £500. The building itself was a gift of the late Mr. Edward Benn, but the cost of the inmates has incurred this debt, the managers of the charity being desirous to meet the many pressing claims of the poor that applied for treatment. It is intended to raise the sum required by a bazaar, which will be held in a few months, and we trust its success will meet with the expectations of its promoters. The Ladies' Committee, in a circular lately issued, drew attention to the fact that fully one half of the patients in the intern department have been country people, but on looking over the reports, they find an entire absence of support from the country gentry.

MEDICAL ADVERTISING.

At the last meeting of the Bath and Bristol Branch of the British Medical Association, it was proposed by Dr. FALCONER, President of Council of the Association, seconded by Mr. MASON, and carried unanimously—

“That, in the opinion of this meeting, the practice of advertising medical books in the public newspapers is derogatory to the interests and dignity of the profession, and likely to occasion social inconvenience and annoyance, and should, therefore, be discontinued.”

At the annual meeting of the Shropshire Ethical Branch, on October 27th, the following resolution was adopted unanimously—

“That, in the opinion of the meeting, the system of advocating medical works in non-medical papers, is highly objectionable, and incompatible with the honour and dignity of the profession; alike reprehensible, also, is the practice of giving written testimony in favour of articles of commerce, and tacitly or otherwise sanctioning its publication.”

OUTBREAK OF TYPHOID FEVER IN THE
UPPINGHAM SCHOOL.

WE regret to put upon record particulars of a severe outbreak of fever at this school, under circumstances indicating grave neglect of ordinary sanitary precautions.

In June last, Lord Hawke's son was seized with enteric fever, and died on the 24th, just at the commencement of the Midsummer holidays. This was the first case. On September 21st, another boy was seized in the same house, that of the master of the lower school. This house is quite isolated, and has no connection with the general drainage of Uppingham; in fact, all the sewage is received into cesspits, which are close to the water-supply. The cisterns supplying the water-closets in nearly all the houses (infected) are supplied with lifts, from which the dormitories are supplied with water. After this second case, the fever began and continued to spread in other masters' houses in the neighbourhood of the lower school, the boys of which were in the habit of going from one house to another to take their lessons. Up to October 13th, no intimation whatever was given to the sanitary authority of the state of things within the masters' houses, and the fact that enteric fever was prevailing in these houses was quite accidentally made known in Liverpool on the 9th, where many parents of the boys reside. These parents met and telegraphed on the 11th to the head-master, and demanded that an investigation should be made. He replied, that action had been taken. It was, however, by the evening post of the 11th. The sanitary authority were made aware of this fever on October 13th; then there were over thirty boys down, and some expected to die. There have been no fresh cases. There have, however, been five deaths in all—four since October 13th, and one in June last.

The medical officer has been eight days investigating the cause of the outbreak, and has no doubt that it originated within the house of the lower school. At a meeting on October 27th, the medical officer of health read a preliminary report on the cause of the outbreak, and recommended that notices should at once be served on four of the masters to remove the nuisances caused by their cesspits. On the 3rd instant, another meeting took place, and the medical officer of health reported further; the result being, that the head-master and others were served with notices the same afternoon to remove nuisances arising from cesspits, etc. At the same meeting, a vote of censure was passed on the masters in whose houses the fever had occurred, for not having immediately communicated with the sanitary authority, instead of allowing the disease to increase as it did from September 21st to October 13th. The medical attendant (who is the only medical practitioner in the town allowed by the head-master to attend the boys) was also blamed for not attending a meeting of medical men of the town convened by the medical officer of health, and for withholding information from him.

The medical officer of health called in on Monday last Mr. Roger Field, C.E., to consult him as to some engineering difficulties connected with the drainage; and that gentleman was on the 3rd inst. appointed by an unanimous resolution to report on the sewers, etc., of the town, with the view of making the drainage-system, both public and private, as complete as possible.

Mr. Haviland, finding that the healthy boys were allowed by the head-master still to go to the infected houses, immediately wrote to

him, on his own responsibility, to prohibit the practice. A meeting of the trustees was called for the next day, last Friday; and it was decided that the school should be dismissed. The boys left for home on Tuesday, the 2nd. The boys in the hospital are doing well. One boy, however, is still seriously ill.

The house in which the outbreak took place is a splendid mansion; but the architect seems to have never entertained the idea of its being necessary to provide for the health of its inmates. Gigantic cesspools lie in close relation to the water-supply, and every arrangement is made for the pollution of the air by regurgitation of gases from them.

The school-register contains the names of about 375 boys.

EXAMINERS AT THE ROYAL COLLEGE OF
SURGEONS OF ENGLAND.

A MEETING of the Council of the College was held on the 1st instant to receive the report of the Committee appointed to consider and report on the best means of giving effect to the new Bye-laws relating to Examiners and Examinations in Anatomy and Physiology. It was found convenient by the Committee to arrange the subjects of which they treated under four heads. The following are the more important details.

I. With respect to the mode of appointment of the Examiners in Anatomy and Physiology, hereinafter called the Board of Examiners in Anatomy and Physiology, the Committee recommended to the Council the adoption of regulations for the formation of a Board of Examiners in Anatomy and Physiology for the Membership and Fellowship, of which the following are the more important. 1. The Board of Examiners in Anatomy and Physiology shall consist of nine Members to be appointed by the Council to conduct the Examinations in Anatomy and Physiology for the Membership and Fellowship of the College. 2. The Examiners shall be elected from the Fellows of the College. 3. One Member, at least, of the Board shall be a Member of the Court of Examiners, and shall act as Chairman of the Board. 4. The Examiners in Anatomy and Physiology shall be elected annually. 5. An Examiner in Anatomy and Physiology shall not hold office for more than five consecutive years; but, after an interval of one or more years, shall again be eligible for election. 10. Notice of intended elections to the Board of Examiners in Anatomy and Physiology shall be advertised in the medical journals not less than six weeks prior to the date of those elections; and Candidates shall be invited to send in their applications to the Secretary not less than one month prior to the date of election.

II. As regards the mode of payment of the Members of the Board of Examiners in Anatomy and Physiology and of the Members of the Court of Examiners for the Membership, the Committee adopted the principle that Examiners shall be paid according to work done, *i.e.*, by a capitation fee divisible between the Examiners present at each Examination; and from calculations based upon the receipt and expenditure of the last five years, recommended the Council to sanction the following regulations for payment of Examiners for the Membership, whereby each Examiner in Anatomy and Physiology will receive about £140 *per annum*, and each Member of the Court of Examiners about £200 *per annum*, *viz.*: 1. The Members of the Board of Examiners in Anatomy and Physiology for the Membership shall be paid by an equal division, amongst those present at each Examination, of £2 per Candidate. 2. The Members of the Court of Examiners shall be paid by an equal division, amongst those present at each Examination for the Membership, of £4 4s. per Candidate, the time occupied in the final Examination being twice as much as that allotted to the Examination in Anatomy and Physiology. 3. Each Member of the Court of Examiners shall, in accordance with the provisions of the Bye-laws, receive the fee of £1 1s. for each attendance at a meeting, over and above the sum received by him as his share of the Capitation Fee.

III. Regarding the mode of payment of the Members of the Board of Examiners in Anatomy and Physiology and of the Members of the Court of Examiners for the Fellowship, the Committee took into consideration the small amount now received from Candidates for the Fellowship, and the very inadequate payment to Examiners for the Examinations for the Fellowship; and, with a view to remedy this state of things, recommended to the Council that immediate steps be taken to obtain a Bye-law enabling the College, in accordance with the provisions of Section 7 of the Charter of the 7th Victoria, to require that a Candidate for the Fellowship by Examination shall pay a fee not exceeding Thirty Guineas over and besides any stamp-duty on his admittance or diploma. The Committee, in anticipation of such a Bye-law being obtained, recommended the Council to adopt regulations for the payment of the Examiners in Anatomy and Physiology and of the

Court of Examiners for the Fellowship, which, based upon calculations extending over the last five years, will give to each Member of the Board about £30 *per annum*, and to each Member of the Court (including his fee of £1 1s. for each attendance on a meeting of the Court) about £45 *per annum*, the time expended in the conduct of the final Examination of each Candidate for the Fellowship being rather more than three times longer than that employed for each Candidate in the Examination in Anatomy and Physiology for such Fellowship.

IV. With respect to the Degrees, Diplomas, Licenses, or Certificates to be recognised as exempting Candidates from the necessity of passing the Examinations in Anatomy and Physiology for the Membership and Fellowship respectively, the Committee had had under consideration this subject, together with Mr. Quain's letter of the 14th of January last, calling the attention of the Council to the existing regulations for the Membership of the College, as affecting the eligibility for admission to Examination of Graduates in Surgery of Scottish Universities, and suggesting to the Council whether it might not be expedient to grant greater facilities than they at present possess to Graduates in Medicine and Surgery of the British Universities desirous of obtaining the Diploma of this College. The Committee were not prepared to make any recommendation to the Council on this subject, but proposed to defer it for a future report.

The report having been agreed to, a meeting of the Council will be held on the 11th instant to confirm the same; and, as will be seen in our advertising columns, notice has been given that the Council will, in December next, proceed to the election of Examiners in Anatomy and Physiology; and Fellows of the College are invited to send in their applications for the appointments.

PROVINCIAL MEDICAL SCHOOLS.

THE official return of the number of gentlemen pursuing their professional studies at the eight recognised provincial hospitals, has just been made to Dr. J. W. Ogle, the Government inspector of the anatomical schools in connection with those hospitals, from which it will be seen that there is a considerable falling off from the number quoted last session.

	1875.	1874.	1873.
1. Manchester, Owens College	110	142	138
2. Liverpool Infirmary	63	72	84
3. Birmingham, Queen's College	59	72	79
4. Leeds School of Medicine	45	45	46
5. Cambridge University School	56	44	40
6. Durham University College	28	37	34
7. Bristol Old Park Medical School	31	26	24
8. Sheffield Medical Institution	17	15	10
Totals	398	453	455

It will be seen that there is an increase in the number of students at the two smallest schools. Leeds remains stationary, but at the large schools there are in some cases a considerable decrease. The gross numbers showing the diminution will be seen above.

The following comparative table will, no doubt, be read with considerable interest, not only by the metropolitan and provincial teachers, but by the profession generally, as showing the number of medical students in town and country respectively during the past decade.

Years.	Metropolitan.	Provincial.	Totals.
1865	1013	249	1262
1866	1027	258	1285
1867	1125	257	1382
1868	1194	281	1475
1869	1241	330	1571
1870	1298	357	1655
1871	1475	368	1843
1872	1496	402	1898
1873	1650	455	2105
1874	1745	453	2198
1875	1769	398	2167

It will therefore be seen that at our eleven recognised metropolitan schools there is an increase of twenty-four students over the number of last year, including dental students, and that this increase has been progressing since 1865, whereas there is a decrease of fifty-five students at the eight recognised provincial schools since last session.

* It will be seen that there is a slight increase in the number already published in this JOURNAL, of gentlemen pursuing their studies in this metropolis: this includes also five more new entries; viz., one each to the following schools—St. Bartholomew's, St. George's, University College, Middlesex, and the Westminster.

ASSOCIATION INTELLIGENCE.

SOUTH-EASTERN BRANCH: WEST KENT DISTRICT.

THE next meeting is appointed to be held at St. Bartholomew's Hospital, Rochester, on Wednesday, November 10th, at 4 P.M.: ROBERT ROSS BROWN, Esq., in the Chair.

Dinner will be provided at the Bull Hotel at 6 P.M. Papers on clinical subjects have been promised by the Surgeons of the Hospital.

FREDERICK J. BROWN, M.D., *Honorary Secretary.*
Rochester, November 1st, 1875.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT MEETINGS.

THE next meeting of the above District will be held in the Library of the County Hospital, Canterbury, on Thursday, November 11th, 1875, at 3 o'clock; FRANK WACHER, Esq., in the Chair.

Dinner will be provided at the Fleur-de-Lis Hotel at 5 o'clock precisely. Charge, 6s. 6d., exclusive of wine.

Notices have been received of the following communications to be read at the meeting.

1. The Report of the Ethical Committee will be submitted for adoption.
2. Mr. Clement Walter: A few remarks on Diabetes.
3. Mr. Rigden: The comparative Birth-rate and number of Conceptions at different periods of the year at Canterbury.
4. Mr. Rigden: A case of Shoulder-Presentation in which the arm had been prolapsed during fifteen hours.
5. Dr. Housby Wright: A case of Empyema treated by Aspiration. Gentlemen who intend to be present at the dinner are particularly requested to inform me on or before Tuesday, the 9th instant.

EDWARD WHITFIELD THURSTON, *Honorary Secretary.*
Ashford, November 3rd, 1875.

THAMES VALLEY BRANCH.

THE first meeting of the above Branch will take place at the Board Room of the Richmond Infirmary, on Wednesday, November 17th, at four o'clock.

Papers will be read by—

1. Dr. Milner Fothergill: On the use of Digitalis in Aortic Disease.
2. Dr. Donkin: On the Nomenclature of Bright's Disease, clinically considered.
3. Dr. Wiltshire: On the Pathology, Diagnosis, and Treatment of Uterine Polypi.
4. Dr. Fenn: On the Pathology and Treatment of Acute Rheumatism.

There will be a dinner afterwards at the Greyhound Hotel at six o'clock. Charge, 7s. 6d. each, exclusive of wine.

F. P. ATKINSON, M.D., *Hon. Sec.*
Kingston-on-Thames, November 2nd, 1875.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

THE next meeting will be held in the Council Room of the Midland Institute on Thursday, November 11th, 1875. The Chair will be taken by the President at 3 o'clock P.M. precisely.

The following papers will be read.

1. Mr. Furneaux Jordan: The Gradual Decrease of Operative Surgery.
2. Dr. Warden: On Contraction of the Meatus Auditorius Externus, and its treatment by a new form of Dilator. Members are invited to exhibit pathological specimens at the commencement of the meeting.

BALTHAZAR FOSTER, M.D. } *Honorary Secretaries.*
JAMES SAWYER, M.D. }
Birmingham, November 1875.

PROCEEDINGS OF THE COMMITTEE OF COUNCIL.

At a Meeting of the Committee of Council, held at the office of the Association, 36, Great Queen Street, London, on Tuesday, the 12th day of October, 1875. Present: Dr. Falconer, President of the Council, in the Chair; Mr. W. D. Husband (Treasurer), Dr. Clifford Allbutt, Mr. J. W. Baker (Derby), Mr. Callender, F.R.S., Dr. C. Chadwick, Dr. R. Farquharson, Mr. R. S. Fowler, Dr. E. L. Fox, Mr. R. Harrison,

Mr. G. F. Hodgson, Mr. F. E. Manby, Dr. Morris, Mr. R. II. B. Nicholson, Dr. C. Parsons, Dr. W. Procter, Dr. Sibson, F. R. S., Dr. W. F. Wade, Dr. Waters (Chester), Mr. C. G. Wheelhouse, Dr. E. Wilkinson, Mr. Samuel Wood.

The minutes of the last meeting were read and found correct.

Read letters of apology for non-attendance from Mr. Alfred Baker, Dr. E. Copeman, Dr. Alfred Carpenter, Dr. Matthews Duncan, and Dr. B. Foster.

Read list of candidates for election.

Resolved—That the twenty-one gentlemen whose names appear on the circular convening the meeting, be and they are hereby elected members of the Association.

Resolved—That the minutes of the JOURNAL and Finance Committee of this day's date be approved, and the recommendations carried into effect.

Mr. Hodgson then withdrew his motion of which he had given notice, relative to the annual meeting being held at Brighton in 1876.

Resolved—That the President-elect, the President of the Council, the Treasurer, Dr. Carpenter, Mr. Callender, F. R. S., Dr. Chadwick, Mr. Bramwell, Mr. Hodgson, Dr. Hall, Mr. Humphry, Dr. Holman, Dr. W. Moore, Dr. S. Monckton, Dr. Jardine Murray, Dr. Parsons, Dr. Sibson, F. R. S., Mr. Heckstall Smith (St. Mary Cray), Dr. Stedman, Mr. Salzmann, Dr. Wade, and Mr. Wheelhouse, be the Arrangement Committee, with power to add members of the South-Eastern Branch—the number not to exceed twenty-four.

Resolved—That there be three addresses, viz., one in Medicine, one in Surgery, and one in Public Medicine.

Resolved—That Dr. Sieveking be requested to give the address in Medicine.

Resolved—That Mr. C. G. Wheelhouse be requested to give the address in Surgery.

Resolved—That Dr. Alfred Carpenter be requested to give the address in Public Medicine.

Resolved—That the subject of the Hastings Prize Essay for 1876 be Diphtheria, its Pathology, Diagnosis, and Treatment.

Resolved—That it be referred to the Scientific Grants Committee to consider whether any other way of awarding the Hastings Medal would be more conducive to the interests of medical science, than the present one of awarding it for an essay on a specific subject.

Resolved—That advertisements be inserted in the medical journals that applications for grants may be made to the Scientific Grants Committee of the British Medical Association up to the 29th day of next December.

Resolved—That Messrs. Price and Co., be appointed Auditors for the year 1875 in accordance with By-Law 33.

CORRESPONDENCE.

CONTEMPT OF A CORONER'S COURT.

SIR,—With reference to a paragraph which has recently appeared in the daily press headed "Contempt of a Coroner's Court", the real facts of the case are as follows.

1. I had no notice, either verbal or written, that the inquest was going to be held.

2. I knew no fee was allowed in such cases, as I have given evidence several times before.

3. I have heard no complaint about fees from any member of the resident staff.

I am, sir, your obedient servant,

THE HOUSE-SURGEON, University College Hospital.

* * The Coroner's remarks appear to have been hasty and unfounded.

HOSPITAL ABUSE.

SIR,—Will you allow me to make a few remarks on the subject of Hospital Abuse, *à propos* of the recent article on Provident Institutions and Hospitals in the JOURNAL. Having given the subject much attention for now very many years, and feeling that it is one that deserves much more notice than it has had at the hands of the public, I naturally have read your remarks with great interest.

I hoped that, at the last annual meeting of the Association, the subject might have been brought prominently before the members by some one capable of doing it justice, and who would have obtained for it the consideration it deserves. Though I am disappointed, I will not despair that we shall soon discuss the question fully, and be able to offer efficient aid and advice on the subject to the public.

I gladly admit, with you, that in the last five years, hospital re-

form has made great progress, and believe that the necessity for it is all but universally admitted.

Still, though the lay authorities of some of the metropolitan hospitals have taken effective measures to ascertain the true state of things, with sincere desire to act on the information obtained, it is painfully evident that others are either unwilling or unable to do so. I can make all allowance for the amiable weakness that indisposes us to inquire whether it is one's duty to assist the poor in all their trials and with providing the ways and means of relieving all who will accept our help. It certainly alloys the pleasure of giving, to find that our alms are misapplied, or, perhaps, productive of injury, by destroying the *morale* of those who receive them. Can it be doubted that it is a characteristic of our times, that people in all grades of society scramble for the endowments that were intended for others?

The well-to-do are not ashamed to accept the provisions made for the poor scholar, the poor gentleman, the poor widow, the poor orphan.

Perversion surrounds us on all sides. It is almost, if not quite, impossible so to devise money that it will not be misapplied when intended for charitable purposes. What wonder, then, that hospitals are abundantly abused?

That they are abused by all classes is beyond controversy: by the subscriber who sends his dependants to them, by the prosperous tradesman, the well-paid clerk, the better paid artisan, by "the gentleman and lady of *limited* means" (a very large class when they are their own assessors).

Let the authorities of the London Hospital ask the medical men of the East End if the hospital is abused, instead of enacting the farce of "issuing a series of questions to each member of the honorary (and honourable) medical staff" (who know little or nothing of the social condition of their patients), if they really wish to know the truth and are not content with foregone conclusions. And I may state, with all deference, that, if the hospital is not much abused now, it certainly was during the many years I was officially connected with it; and I have yet to learn that any effectual steps have been taken to diminish the evil.

Of St. Mary's, University College, and Charing Cross, one can only conclude that the lay authorities are content to close their eyes and ears to unpleasant facts, and remain deluded.

It is certainly no part of the duty of the medical staff to consider the eligibility or ineligibility of their patients; but it is obviously the duty of the governors to see that only proper applicants are admitted as either in- or out-patients; and it is only just to the subscribers, the patients, and the medical officers, that every reasonable means should be employed to exclude improper objects.

Now, I maintain that usually no such care is taken at hospitals; it seems no one's business to ascertain the position of applicants, so, consequently, it happens that only now and then a flagrant case comes to light; the governors and medical staff alike are ignorant as to the rest.

To the honour, be it said, of the lay authorities of the Moorfields Hospital, effectual steps were taken some years ago to grapple with this social disorder, and six hundred applicants were refused in one year. Now, I am sure no one connected with that hospital would assert that all improper objects are detected and excluded; but, if six hundred cases were refused in a year, who can doubt the magnitude of the abuse? I may add that the number of ineligible patients constantly diminishes, probably in consequence of the publicity of the investigation, though many have learned to evade the Secretary's vigilance and scrutiny, and have even been detected in fraud.

But, in conclusion, sir, allow me to ask the opinion of the medical men engaged only in private practice, and I venture to predict such an overwhelming wave of testimony as would silence all cavillers and demand the public recognition of the immensity of hospital abuse.

I am, sir, faithfully yours,
J. C. WORDSWORTH, F. R. C. S.
London, October 1875.

COMPULSORY REGISTRATION OF DENTISTS.

SIR,—I shall esteem it a favour if you will permit me to state that I fully sympathise with Mr. S. Hamilton Cartwright's views, as expressed in his letter to you of the 30th ult. It is pretty generally known that I endeavoured, some years ago, to bring about the wholesome reform which he advocates; but I was forced to retire, because I found that I should have to fight the battle almost single-handed.

I regret that I am at present unable to take up in detail the various matters of which Mr. Cartwright's letter treats as, with your permission, I may possibly do at some future time; but it may be serviceable to the cause he advocates, to mention in the meantime that I have for some years past conducted my own practice upon the system which he would be glad to see extended, and have deputed to skilled me-

chianicians all work that may be defined as actually mechanical; and these execute my orders out of the house, and bring the results for my supervision and adjustment precisely in the same way that surgical instrument-makers carry out the instructions of an operating surgeon.

I remain, sir, faithfully yours,
WILLIAM DONALD NAPIER.
22, George Street, Hanover Square, Nov. 3rd, 1875.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

VACCINATION.—Mr. R. S. Hall of Ince, near Wigan, has received an extra grant amounting to £54:15, for the efficient state of vaccination in his district. He received a grant of £45 after the last inspection, two years ago.

THE ARTISANS' DWELLINGS ACT IN LIVERPOOL.—At a recent meeting of the Liverpool Health Committee, the engineer submitted a report for placing a district of the town, known as Nash Grove, under the operation of the Artisans' Dwellings Act. The area is situated off Scotland Road, one of the lowest parts of the town, and it contains about 22,487 superficial yards, 18,770 of which are covered by low-class dwellings, or yards, in use for trading purposes. Allowing for the removal of existing buildings, the engineer estimated the cost to the corporation of acquiring the site, sewerage, and paving at about £92,600. From this amount has to be deducted the value of the land for building purposes after the alteration, which is estimated at £30,746, leaving £62,254 as the actual cost of the improvement. After some discussion, the report was adopted.

POOR-LAW MEDICAL SERVICE OF SCOTLAND.

The Secretaries of the Aberdeen, Banff, and Kincardine Branch would be glad to receive from any members of the Branch information concerning any defects in the administration of parochial medical relief, and any suggestions for reforming the present Poor-law for Scotland.

Aberdeen, October 20th, 1875.

J. URQUHART.
ALEX. OGSTON.

VACCINATION OFFICERS.

SIR,—I am glad that Mr. Glissan called attention, in your issue of the 23rd instant, to what he very properly designates a "growing nuisance". In this parish, the public vaccinator does not (that I am aware of) send out cards, as in Mr. Glissan's case, but calls upon my patients and threatens them with a prosecution unless they have their children vaccinated by him, although in some cases the children have already been vaccinated by me. Unfortunately, few of the lower classes know that any registered medical man may vaccinate, consequently our public vaccinator often succeeds in doing me out of my half-crown. It is high time, I think, that the excessive zeal that some of these officers display in doing their duty (?) should be put a stop to. If we had no vaccination-officer, there might be less room for complaint.—Yours truly,

J. BAIN SINCOCK.

St. Agnes, Cornwall, October 25th, 1875.
