* * * The necessity for a vaccination-officer is patent: as we have explained, however, irregularities of the kind complained of should be reported to the Local Government Board; and no doubt it is also serviceable that they should be publicly ventilated in the medical press.

MILITARY AND NAVAL MEDICAL SERVICES.

THE VACANCY IN THE GUARDS.

By the retirement of Dr. Logie from the regiment of Horse Guards, and owing to the brigade system of promotion of medical officers holding good in the cavalry as in the infantry brigade, other changes must take place. It is rumoured that the medical officer next for promotion will not accept the vacancy, as it would entail his withdrawal from his own regiment; and therefore, if it be filled up by the officer next senior in the brigade, the vacancy for a junior will occur in the 2nd Life Guards.

KNIGHTSBRIDGE BARRACKS.

THESE barracks have begun to give practical force to the argument of those who would desire their demolition, by showing very evident signs of decay, the walls of one portion having so given way that it has been found necessary to remove the men and horses of two troops from it. This calls to mind the state of dilapidation into which the Portman Street Barracks had passed before their demolition, when one wall of the officers' quarters leant inwards to such an extent that the handle of the bell-ropes hung more than a foot away from it, to the great surprise of a casual observer. The time cannot be, therefore, far distant, when the Knightsbridge Barracks must also be razed to the

ground, notwithstanding the apparent difficulty in finding a more suitable locality. Though many good reasons have been adduced for their removal to a new site, we do not look upon this as such an absolute necessity; for if, in their reconstruction on the same ground, they were made a storey higher, the accommodation would then be sufficient, and we should retain near the centre of London one of our most valuable aids in the preservation of law and order in times of emergency.

THE MEDICAL DEPARTMENT AND THE RECENT EXPEDITION AGAINST THE CONGO PIRATES.

COMMODORE SIR WILLIAM HEWETT, K.C.B., in his despatch, published on the 2nd instant, describing the results of the recent expedition against the pirates of the Congo River, thus refers to the professional services of Fleet-Surgeon Fegan, C.B., the principal medical officer of the Forces under his command.

"The uninterrupted health of the squadron during the time it has been employed in this unhealthy river may be attributed to the care with which Fleet-Surgeon Henry Fegan, C.B., considered the precautions that should be adopted to secure its preservation, and I have to acknowledge the many valuable suggestions he has submitted to me."

Considering the large proportion in which rewards and promotions were conferred on the combatant officers after the Ashantee War, and the comparatively small number of similar distinctions which were bestowed on the medical officers who did so much to preserve the health of the troops engaged in the unhealthy climate of the Gold Coast on that occasion (not to mention their equally sharing the fatigues and risks of the bush with the combatants), we were pleased to observe that the leading journal thought right to comment on this part of Commodore Hewett's despatch. The following remarks appeared in the *Times* on the same day as the publication of the despatches.

"We are happy to see, moreover, that he calls the attention of the Admiralty to the valuable assistance afforded him by the preparations of the medical officer. The doctors seldom have their services duly recognised on these occasions; but it is not too much to say that it is medical science which alone renders these African expeditions practicable. Not many years ago, our ignorance of the real nature and cause of the fevers which render the African coast so pestilential would have exposed a force to insuperable dangers either in such a slight expedition as the present or in such an undertaking as the Ashantee War; and there is no occasion on which the arts of preventive medicine become of greater value. It is possible now to avoid dangers which would formerly have been unconsciously encountered, but would have been absolutely fatal; and, though the climate of the Coast must always be pregnant with peril, it can be endured for a sufficient space of time."

UNIVERSITY INTELLIGENCE.

UNIVERSITY OF CAMBRIDGE.

EXAMINATIONS IN STATE MEDICINE.—The following is the first annual report to the Senate of the Syndicate appointed to superintend the examinations in State Medicine.—The first examination in State Medicine under the regulations confirmed by grace of the Senate, February 4th, 1875, was held on October 5th and three following days. Twenty-eight candidates entered, of whom twenty-six presented themselves for examination. Four offered themselves in Part 1 only, of whom one was approved. The remaining twenty-two were examined in both parts, and nineteen of them were approved. Two days were devoted to each part of the examination. Part 1 comprised Physics and Chemistry, and their applications to sanitary matters. Part 2 comprised the remaining subjects specified in the regulations; viz., the causes and prevention of epidemic and infectious diseases, the circumstances and conditions of life which are injurious to health, and the laws of the realm which relate to Public Health. In each part, two papers of questions, each of which had been submitted to all four examiners, were set, to which written answers were required. In each part, the candidates were also questioned orally by two of the examiners sitting together; and in each part the candidates were tested by practical work. The examiners report that the answering was generally good, some of it excellent, more especially in questions relating immediately to the actual duties of officers of health. This remark applies emphatically to the reports on the sanitary condition of some of the small courts and other places in Cambridge, which the candidates were directed to visit for the purpose of inspection, each candidate having a different locality assigned to him. The examiners are of opinion that the number and character of the candidates are evidence

that the examination supplies a public want, and may be of real service in the advancement of sanitary improvements. Such a knowledge of sanitary science as has been shown by the successful candidates proves them to be entitled to some trustworthy voucher for their acquirements. The University certificate, granted after a careful and thorough examination, will be such, and may serve to assist the judgment of those public bodies in which the choice of officers of health has been invested by the law. Every candidate was required to pay a fee of four guineas before admission to each part of the examination, and it has been found that this has been sufficient to defray all the expenses incident to the examination. The certificate is granted to those who have passed both parts of the examination without further fee. The Syndicate considers it convenient that the holders of the certificate should be designated in an uniform manner, and recommends that their designation be "Holders of the Certificate in Sanitary Science", or abbreviated, "S. Sc. Cert. Camb." The Syndicate has arranged that the next examination shall begin on June 13th, 1876, and considers it desirable to hold a second examination next year at the beginning of October. These times seem as convenient as any for the University, and are likely to suit medical men engaged in the practice of their profession. Whether it will be advisable to hold two examinations in any future year must be decided by the experience gained as to the probable number of candidates, and by other considerations. (Signed) H. W. Cookson, G. E. Paget, G. M. Humphry, P. W. Latham, G. D. Livinge.

EXAMINERS FOR DEGREES IN MEDICINE AND SURGERY.—At a congregation on October 14th, the following gentlemen were appointed Examiners in Medicine and Surgery:—First M.B. Examination: R. Apjohn, Caius; J. W. Hicks, Sidney. Second M.B. Examination: Henry Power; J. N. C. Davies-Colley, Trinity. Third M.B. Examination: Dr. Barclay; Dr. Bradbury. Master in Surgery Degree: Timothy Holmes and Christopher Heath. Dr. J. W. Ogle was appointed Assessor to the Regius Professor of Physic.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen were admitted Fellows on October 28th, 1875.

Adey, Charles Augustus, M.D. Edinburgh, St. Leonard's
Burder, George Foster, M.D. Aberdeon, Clifton
Coifield, William Henry, M.D. Oxford, Bolton Row
Falls, William Stewart, M.D. St. Andrew's, Bournemouth
Fearnside, Henry, M.B. London, Preston
Matterson, William, M.D. St. Andrew's, York
Monckton, Stephen, M.D. London, Maidstone
Montgomery, James Barclay, M.D. Glasgow, Penzance
Ord, William Miller, M.B. London, Brook Street
Semple, Robert Hunter, M.D. St. Andrew's, Torrington Square
Shepherd, Augustus Burke, M.B. Oxford, Seymour Street
Thorne, Richard Thorne, M.B. London, Inverness Terrace
Tuke, Daniel Hack, M.D. Heidelberg, Falmouth

The following gentlemen were admitted Members.

Herman, George Ernest, Bethnal Green Infirmary
Leech, Daniel John, M.B. London, Manchester

The following gentlemen were admitted Licentiate.

Chapman, Paul Morgau, Camden Park Road
Dyte, David Hyman, Bury Street
Gibb, Robert Charles, Guy's Hospital
Harvey, Thomas Prickard, Pyrland Road
Herman, George Ernest, Bethnal Green Infirmary
Hobson, John Morrison, Guy's Hospital
Lancaster, Henry Francis, Amersham Park Villas
Randle, James Mayne, Guilford Street
Rawlings, Alfred, Newlands, Sberborne
Taylor, Henry Cumberland, Guy's Hospital
Weakley, Samuel Joseph John, Upton, Essex

The following candidate, having passed in Medicine and Midwifery, will receive the College License on obtaining a qualification in Surgery recognised by this College.

Pickford, John Kemble, Maiden Newton

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, October 28th, 1875.

Bark, John, Royal Infirmary, Liverpool
Harvey, Henry Frederick, Gower Street
Morcom, Augustus, Conistow, Lancashire
Taylor, James, Sikes Croft, Bristol
Williams, William, variables, Easingwold, Yorkshire

The following gentleman also on the same day passed his primary professional examination.

Capoo, Herbert, James, St. Bartholomew's Hosp

MEDICAL VACANCIES.

The following vacancies are announced:—

CRICKHOWELL UNION—Medical Officer and Public Vaccinator. Salary, £35 per annum, exclusive of extra medical fees and vaccination fees. Applications on or before the 13th instant.
DENBIGHSHIRE INFIRMARY—House-Surgeon. Salary, £85 per annum, with board, washing, and residence.
HASTINGS UNION, Sussex—Medical Officer for Third District. Salary, £90 per annum. Applications on or before the 14th instant.
HUDDERSFIELD INFIRMARY—Physician.
LIVERPOOL INFIRMARY FOR CHILDREN—House-Surgeon.
METROPOLITAN FREE HOSPITAL—Honorary Assistant-Physician. Applications on or before the 13th instant.
MIDLAND COUNTIES SUPPLEMENTARY HOSPITAL, Leamington—Physician and Surgeon. Salary of the former, 100 guineas; and of the latter, 50 guineas; with board and lodging. Applications before the 8th instant.
NORTH STAFFORDSHIRE INFIRMARY, Hartsill, Stoke-upon-Trent—House-Physician. Applications on or before the 16th instant.
PROVINCIAL HOSPITAL, Port Elizabeth, Cape of Good Hope—House-Surgeon and Dispenser. Applications to T. E. Fuller, Cape Emigration Agent, 15, Coleman Street, London, E.C.
RADCLIFFE INFIRMARY, Oxford—House-Physician. Salary, £105 per annum, with board and lodging. Applications on or before the 24th instant.
ROCHDALE INFIRMARY—House-Surgeon. Salary, £100 per annum, with board, lodging, and attendance. Applications on or before the 6th instant.
ROSS UNION—District Medical Officer and Public Vaccinator. Salary, £100 per annum. Applications on or before the 22nd instant.
TONGUE and FARR, District of, County of Sutherland—Medical Officer. Salary, £150 per annum, and house.
WEST KIDING PRISON, Wakefield—Resident Surgeon. Salary, £400 per annum, with house, coals, gas, and water. Applications before November 15th.
WORCESTER GENERAL INFIRMARY—Physician. Applications not later than the 17th instant.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

BARTON, John K., M.D., appointed Visiting-Surgeon to the Convalescent Home at Stillorgan, *vice* Arthur E. J. Baker, L.R.C.S.I.
FUSSELL, Edward F., M.D., appointed Physician to the Sussex County Hospital, Brighton, *vice* H. Moon, M.D., resigned.
HOLLIS, William A., M.D., appointed Assistant-Physician to the Sussex County Hospital, *vice* E. F. Fussell, M.D., promoted.
KINSEY, Robert H., M.R.C.S., appointed Medical Officer to the County Prison, Bedford, *vice* R. Couchman, M.R.C.S. Eng., resigned.
LAWRIE, John D., M.R.C.S. Eng., appointed Honorary Surgeon to the Bradford Infirmary, *vice* John R. McGee, L.K.Q.C.P., resigned.
MORRIS, Samuel, L.R.C.S., appointed House-Surgeon to the Stanley Hospital, Liverpool, *vice* J. Bark, L.K.Q.C.P., resigned.
***MORRIS, D. Williams, L.K.Q.C.P.**, appointed Medical Officer and Public Vaccinator to the Skenfrith District of the Monmouth Union; also, Medical Officer and Public Vaccinator to the Kitchurch District of the Dore Union, and Medical Officer to the Dore Union Workhouse, Herefordshire.
SARGENT, Arthur F., M.R.C.S. Eng., appointed Junior House-Surgeon to the Tunbridge Wells Infirmary.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the communication.

DEATH.

SMART.—On October 25th, aged 36 years, at the residence of her father, Celia Elizabeth, wife of Bath Charles Smart, M.D., 90, Great Ducie Street, Strangers, Manchester, and daughter of Daniel Gurteen, Esq., J.P., Haverhill, Suffolk.

GUY'S HOSPITAL.—The Entrance Scholarships in Classics, Mathematics, Modern Languages, and Science, have been awarded as follows:—L. C. Wooldridge, £60; W. H. White, £30; J. T. J. Morrison, honorary certificate.

PRESENTATION.—On October 14th, the *employés* of the General Infirmary, Chester, presented Dr. W. J. Fleetwood, on his resignation of the house-surgery to the institution, with a valuable box of surgical, amputating, and other instruments, as a mark of their esteem and regard.

REQUESTS.—Mr. William Creek, formerly of Worcester, has bequeathed to the Hertford Infirmary and the Worcester Infirmary £200 each; to the Royal United Hospital, Bath, and the Harrogate Hospital, £50 each.—Miss Sarah Godin, late of Maida Vale, has left (*inter alia*) to the Surrey Dispensary, the London Hospital, and St. Mary's Hospital (Paddington), £200 each, free of legacy duty.

KING'S COLLEGE.—Mr. Norman Dalton, Mr. Denis M'Donnell, and Mr. Frederic Harvey Norvill have obtained the Warneford Entrance Scholarships of £25 a-year each, tenable for three years: Mr. J. Frederic Silk, a new student, the Science Exhibition, given by the Clothworkers' Company, of £25 a-year, for two years; and Mr. T. Furze Clarke has obtained the First Warneford Prize of £20, and Mr. W. H. Bloomfield and Mr. E. A. Snell, Warneford Prizes of £10 each.

OPERATION DAYS AT THE HOSPITALS.

MONDAY	Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.
TUESDAY	Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.
WEDNESDAY	St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.
THURSDAY	St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 3 P.M.
FRIDAY	Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.
SATURDAY	St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M. and 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.—	Medical Society of London, 8.30 P.M. Mr. Jabez Hogg, "On Spinal Concussion"; Messrs. Carr Jackson and Spencer Watson, "A Patient on whom Excision of the Astragalus was performed for Complicated Injury to the Foot and Ankle".
TUESDAY.—	Royal Medical and Chirurgical Society, 8.30 P.M. Dr. Semple, "On Diphtheria and its relations to (so-called) Group".
WEDNESDAY.—	Epidemiological Society, 8 P.M. The President will deliver an Inaugural Address.—Hunterian Society. A Council Meeting at 7.30 P.M. At 8 P.M., Mr. J. E. Adams will exhibit a Case of Plastic Operation on the Face for Rodent Ulcer; and will read a paper on Jodide of Potassium Poisoning. Dr. Peacock will read a paper on a Case of Aortic Disease originating in Malformation; will exhibit specimens of Malformation as a cause of Valvular Disease.
FRIDAY.—	Clinical Society of London, 8.30 P.M. Mr. T. Holmes, "Case of Ligature of Femoral Artery with Carbolised Catgut"; Mr. W. Haward, "Case of Lymphadenoma"; Dr. Murchison, 1, "Case of Acute Cancer of the Liver, with Pyrexia, in a man aged 24"; 2, "Two Fatal Cases of Acute Pyelitis and Nephritis, apparently consequent on Gonorrhoea".

NOTICES TO CORRESPONDENTS.

- CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.
- PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.
- AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.
- CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.
- WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.
- COMMUNICATIONS respecting editorial matters, should be addressed to the Editor; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

TOTAL DESTRUCTION OF THE LUNG.

SIR,—In reply to Dr. Walter's remarks respecting my case of total destruction of the lung, I write to combat his doubts of its accuracy, to inform him that no such binding down of the lung, or compression or flattening against the vertebral column, existed, as he ventures to suggest.—I am, sir, yours, etc.,
Holloway Road, Oct. 30th, 1875. E. COTTEW.

BIBLIOPOLE will find an interesting account of the works of Albino in Atkinson's *Medical Bibliography*, and also of his celebrated engraver Waadelaar.

THE CONDUCT OF MEDICAL STUDENTS.

THE students of Guy's Hospital, convicted in the police-court of riotous conduct at a music hall, have been dismissed with a reprimand, on tendering a full apology in court. The whole proceeding, however, cannot fail to attract the attention of the Treasurer of Guy's Hospital, and we shall make no further comment on the subject till we hear his decision, after inquiry, as to the proper course to be pursued.

CONSULTATION WITH UNQUALIFIED PERSONS.

SIR,—Is a Consulting Physician—or, indeed, any practitioner—acting correctly, medico-ethically speaking, in meeting in frequent consultation an unqualified assistant whose employer has been dismissed from attendance on a case?
October 27th, 1875. I am, etc., PARSONS.
* * * Certainly not.

ST. MARY'S.—The first or primary examination for the diploma of membership of the College this session will take place this day (Saturday).

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

MANCHESTER PROVIDENT DISPENSARIES' ASSOCIATION.

SIR,—Your issue of the 16th instant contains a communication with reference to the Manchester and Salford Provident Dispensaries' Association, which is calculated, though quite unintentionally, I am sure, to produce an erroneous impression upon the minds of your readers. Your correspondent charges the Association with violating the rules upon which it has been founded, by admitting friendly societies into connection with the dispensaries. The facts are as follows. A number of these friendly societies applied for permission to become connected with the Association, but they were informed that, as the income of some of their members would, no doubt, exceed the limit fixed by the rules, their request could not be granted. The General Council felt, however, that the subject was one which should not be hastily dismissed, and ultimately resolved to summon an extraordinary general meeting to decide whether it would be wise to make the necessary alterations in the scheme. At such a meeting, the committees of all the provident dispensaries and free charities, and the subscribers to the guarantee fund, are entitled to attend and vote. Each dispensary committee is composed of four doctors, elected by the medical staff as their representatives, four ordinary and four honorary members. The rules provide that when such a meeting is to be held, notice shall be given some weeks previously, in the three daily papers, stating its object, and that the committees of such free charity and dispensary shall receive a letter containing the same information, with an invitation to attend. All these steps were taken; and the chief mover in the present opposition to the Association was present at the meeting of his dispensary, and agreed without the slightest demur to the proposed alterations in the rules. The extraordinary general meeting took place; only three out of over twenty doctors were present; and resolutions were passed, and afterwards published in the papers, declaring the conditions upon which the friendly societies could be admitted to membership of the dispensaries. About a week afterwards, a protest was received from a number of the medical men against the arrangement, stating that it would not be accepted by them; but not a single reason was advanced to show that the Council were acting unfairly to the members of the medical staff. The subject was again fully discussed by the Council; and on the recommendation of two of our leading medical men, managers of the two largest hospitals in the city, it was decided that as the question had been fully considered at a meeting duly convened for the purpose, and as not a single reason had been advanced in the protest to show that the decision arrived at was an improper one, it could not be rescinded. I fail to see that there has been in this any "violation" of the original scheme. A violation can only mean that its rules have not been observed. I challenge your correspondent to show which of them has been broken. A great amount of pressure was then brought to bear by a few of the medical staff, instigated chiefly by a number of club-doctors, upon their fellow-members. The movement became a sort of trades-union one, and ultimately a large number of those connected with the dispensaries yielded to the pressure, and gave notice of their intention to resign. The Council then asked all the members of the medical staff to meet them to talk the matter over; but those who were dissatisfied met together and decided to decline the invitation. A feeling of extreme regret was expressed by the Council at the decision at which the doctors had arrived, especially as it became apparent that it would now be more difficult to carry on the dispensaries unless radical alterations were made in the conditions upon which medical men may become connected with them. The Council has always shown the greatest consideration for the interests of the profession; its conduct has always been guided mainly by its medical members, and it would have yielded at once in the present dispute, had there appeared any reasons for supposing that it was acting in opposition to the just interests of the profession.

But it may be said that the arrangement made with the friendly societies is an unfair one to the medical men now connected with them or with the dispensaries. It will be seen, however, that it is not so. The annual payment to a club doctor ranges from 2s. 6d. to 3s. per member; and for this he contracts to visit the members whenever required, to provide drugs, and make up the prescriptions. He is elected by a committee of working men, and is responsible to them for his conduct. The members may be spread over the whole area of Manchester and Salford; and, as an inevitable consequence, delay and annoyance are of frequent occurrence. [In many cases, the doctors do not personally attend the members, but send *unqualified* assistants.] It may be expected this system is not at all popular, either amongst the societies or the medical men; and few of any standing in the profession will become connected with it. The arrangement made by the Council is this: that each lodge of a society shall join collectively, the members attaching themselves to the dispensary of the district in which they may reside, and each paying at the rate of 3s. 6d. *per annum*. Of this sum, 2s. 2d. will be received by the doctor chosen by the member, and the balance will be employed in the payment of the expenses of management; but the surplus, after defraying these expenses, is to be received by the medical men. In a very short time, at the present rate of progress, this surplus will amount to a considerable sum; and the actual payment to the doctors for each friendly society member will be as much as, if not more than, that received under the existing club-system. At one of the dispensaries, it is now 2s. 9d. It is pretty certain that, were all the friendly societies to join the dispensaries, the total amount received from them by medical men would be increased; but, at the same time, the doctors would possess these advantages: that they would not have to find medicines or make up prescriptions; that they would not be elected by a committee of working men, or be obliged to retain unreasonable patients without having a fair court of appeal; and that their labours would be minimised by having to attend only upon those patients who may live in their own district, instead of being obliged to visit those who may reside in parts of the city widely separated from each other. In this arrangement, I fail to see how "the interests of the profession have been injured".

Your correspondent further states that the system affords a "miserable remuneration for an extensive and increasing expenditure of time and labour". I do not know who your correspondent is; and leave you to decide from what I have already stated whether or not he is an unprejudiced witness. This, however, I do know; that many members of the medical staff have expressed their entire satisfaction with the financial results of the system. One doctor says that "his private practice has doubled since he joined the dispensary"; another, that "his dispensary work is as well paid as any work in connection with a practice amongst the poor"; another is in receipt of £250 a year from his dispensary alone, although he joined but three or four months ago, and, I believe, had not been in practice before.

This fact is becoming more and more prominent, that the Manchester Provident Dispensary system, when fairly established, will well recompense the medical men who give it a fair trial. There are some in the profession who have disliked it from the first, and who would wish to make it a failure; to these, the results may not have been very satisfactory.

If any of your readers desire to receive further information about the provident dispensary system as established here, and the probability of medical men connected with it obtaining a fair recompense for their time and labour, I shall be glad to supply it. In some of the rapidly increasing districts of Manchester and Salford there is a great scarcity of medical men, those now established there being greatly overworked.—I am, sir, etc.,
WILLIAM O'HANLON.
October 1875.

J. F. R.—Attendance at the Sussex County Hospital, Brighton, will be recognised.

THE TWO SYSTEMS OF EDUCATION.

SIR,—Your leading article in the JOURNAL of October 2nd on the above subject suggests to me a promise which I made myself during the late meeting of the British Medical Association in Edinburgh—viz., to give you my personal experience of the respective merits of systematic lectures and practical instruction; since I believe that, after having listened to about fifteen hundred lectures on various subjects, I am quite as capable as any of the professors who teach to form an opinion on the matter. Before, however, making any assertions, I may observe that I am one of those men who never required any stimulus to work. I have always been a diligent student, and, though I have not become a great man, I can hold my own among my contemporaries. Many of the most able of my fellow-students are now scattered all over the world, and settled in obscurity; a very few have distinguished themselves in a sort of a way; some have "gone to the wall", and some of the most promising are dead. As I have no particular policy to pursue, no ambitious aims to gain from this communication, beyond a bare statement of facts, I hope my remarks will be taken as a simple unvarnished tale. It will be understood, of course, that I studied medicine at Edinburgh, as it is of that school that I desire to speak. Well, after an absence of sixteen years, I returned to attend the meeting of the British Medical Association last August, at the University, and the first thing that struck me was, the dingy appearance of the old lecture-rooms, and the melancholy aspect of the narrow winding stairs which led to those sepulchral-looking dens, which vividly recalled to my memory the days when I was a beardless boy, trudging along up and down, with a huge book under my arm, and engaged from 9 a.m. to 5 p.m. attending dry lectures, etc. This naturally led me to reflect how much I actually learned from attending these systematic lectures, from books, and from practical instruction; and I am bound to say that I have only a very hazy recollection of the lectures; in fact, I gained nothing at all by them; all my knowledge I have acquired from books, from dissection, and from clinical instruction; and, if I were beginning life over again, I would upon no account pay the slightest attention to these lectures.

I can vividly recall to memory the appearance of patients, and of morbid specimens, the attitude, language, and bearing of clinical teachers, but all the rest is chaos; all, in truth, was so much waste of time. A couple of hours a day receiving practical instruction at the infirmary, as many more attending a "grinder" (as "coaches" were termed in those days), would have been much better; the remainder might have been well spent in committing the pathology, symptoms, and treatment of diseases to memory in my own lodgings, or in investigating my constitution by taking long walks into the country.

If the object of the Medical Act be to relieve human suffering, all teaching should be clinical, all instruction should be practical. It is a pity, nevertheless it is a fact, that a knowledge of hydrostatics, physics, and all theologies, do not help us much in curing diseases. After exhibiting ourselves as scientific "ogres", fit to tackle anything, we come at last to acknowledge our utter helplessness; and it is then that we begin to think that what is called knowledge is not knowledge at all, but a heterogeneous conglomeration of opinions that live but for a few years. What is considered knowledge to-day will be scouted fifty years hence. How, then, can we dogmatise that the method of teaching in one particular school is better than that in all others? One session of pure practical instruction is worth a dozen of the present mixed sort. Old men appear to be incapable of comprehending this. What can be said of any theoretical teaching, university education, or otherwise, more than that it subjects the mind to more or less discipline? and what discipline can be better than bedside instruction? Men of mediocre talents, as well as the most brilliant, may, by dint of hard work, commit a great deal to memory from listening to dry lectures, but that will never make either philosophers or learned men of them; indeed, the most theoretical are often the most useless at the bedside when there is something really to be done. If the medical art were perfect, matters would be different; but as it is, and as it will be taught for some time, there is great room for improvement. Those who consider themselves authorities upon the subject of medical education, appear almost all to run into the same groove—viz., that four years should be sufficient to insure a complete and thorough medical education. This is the rock upon which they split. The time is too short. No man can acquire the thorough and profound knowledge required of him in such a short space of time. Hence the cause of there being so many sciolists amongst us. Specialists appear to forget that they either lecture or examine upon one, or at most two, subjects, and that whatever standard of proficiency they may meet with among some students, the result is always the same—viz., "got up for the occasion".

It appears to me, therefore, that for all those intended for the medical profession, instruction should be compulsory only in anatomy and physiology, the principles and practice of medicine (including the action and uses of drugs), surgery, and midwifery, as common sense and experience both teach us that whatever else is learned, is either forgotten or neglected the moment the tyro enters upon the "struggle for existence". This does not, of course, mean to exclude instruction in any of the other departments of human knowledge, which should be open to all comers, male or female, who may have an inclination or aptitude for such studies.

Any one who looks at the subject impartially, will find that the success of Edinburgh, as a seat of learning, is as much to be attributed to political considerations as to the wisdom and greatness of its professors. Once having got the lead, it was not very difficult in those days to keep it. If it had not been the capital of Scotland, it would never have been so famous as it is, and its system of teaching would have remained in obscurity. If any single circumstance could have contributed to its success, it must be put down to national character alone; and this ought not to be lost sight of by those wisecracks whose minds appear to be enveloped in a haze of "vested interests", and whose intellects are incapable of further expansion.—I have the honour to be, sir, your obedient servant,

Edinburgh, October 1875.

K. N. M.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, no later than Thursday, twelve o'clock.

INJECTION OF PERCHLORIDE OF IRON IN POST PARTUM HÆMORRHAGE.

SIR,—I read with great interest the account of Mr. Boddy's case of *post partum hæmorrhage* treated by the injection of a solution of perchloride of iron, as recommended by Dr. Barnes, which appeared in your JOURNAL of the 16th instant, and was somewhat surprised at the author's conclusion as to the immediate cause of death; and I wish, therefore, to submit to your readers what appears to me to have been the direct cause of death in this case, with the hope that, should my theory be fallacious, it may be corrected. First, let us consider the salt from a therapeutic point of view. What are its direct actions? Three; viz., styptic, astringent, and irritant; and, keeping these in view, I think we have the key to the pathology of the case. When the solution is first injected, the hæmorrhage ceases. How? By plugging of the mouths of the uterine vessels. But does this thrombotic process end here? I fear not; but, extending to the vessels forming the uterine plexuses, perchance a portion of a thrombus is broken off and washed into the general circulation, and not arrested until it reaches the bifurcation of the pulmonary artery, and here, cutting off the supply of blood to both lungs, death is the result, accompanied by convulsion and blueness of the cutaneous surface. With regard to its second and third actions—viz., those of astringent and irritant—I need say nothing, as we know that the uterine mucous membrane is corrugated, and the muscular tissue caused to contract by reflex action, as shown by Mr. Boddy, accounting for the abdominal and sural pains. Now, to me this points out a practical lesson, that the solution should be of such strength and in such quantity as just to plug the mouths of the torn vessels and cause uterine contraction; and I presume less than twelve ounces, especially of such a strength as that used in this case, would accomplish this end.

I may add, that, had a necropsy been performed, a valuable addition might have been made to obstetric science, as I believe Dr. Barnes does not notice such a case as this in his valuable work on obstetric operations.—I am, etc.,
J. G. B.

A METROPOLITAN TEACHER.—The delay in making the return to Dr. Ogle has been caused by the Newcastle School not having seat in the number of students entered there this session.

TREATMENT OF ENURESIS.

SIR,—Could any reader of your valuable and widely circulated JOURNAL assist me under the following circumstances? I have a case of enuresis, in which I have tried a variety of remedies; amongst others, tonics, cantharides, vermifuge medicines, and specifics of various kinds, all apparently without any success. The boy is now about thirteen years of age, and has been afflicted with the disgusting habit of wetting his bed almost every night, except when taken up, and even then occasionally, yet in the day-time he does not appear to require to micturate unusually often. He is a heavy sleeper, and his health in all other respects seems excellent. I may mention, also, that he feels acutely his lamentable condition.

If any of your correspondents or readers will aid me in this matter, they would be doing a good and valuable service to many a family, and confer a favour on
Dublin, Nov. 3rd, 1875. A COUNTRY PRACTITIONER.

DOSAGE OF ESERINE.

SIR,—I read in your estimable paper of September 25th, which I have just seen only now, a note by Dr. Munro on Eserine Discs in Tic; this article troubles me a great deal. May I ask one of the three gentlemen—Dr. Munro, Mr. Squire, or M. Duquesnel—to explain me the weights they give? Dr. Munro says he has given the eserine, "1-25th of a kilogramme" for a dose, which means 40 grammes. May I ask him if his patient is still alive? A gramme in your English *Pharmacopœia* equals 15.432 grains; but the doctor makes it so that forty of these grammes equal .0006 of a grain. Perhaps your system of weights is different from ours. Besides, the discs contain .0006 of a grain; and the doctor says that 1-3200 is a proper dose. May I ask him again how he manages this? I tried to divide 32 by 6, but I could not possibly get whole numbers. Shall I cut a disk? Give me kindly a good explanation, or else I shall be obliged to come back to my own system of weights, which seems to me to be more easy and natural than your English.

Agree, Monsieur le Rédacteur, my distinguished salutation. KILOGRAMME.
Paris, October 25th, 1875.

* * It is not surprising that our correspondent should ask if the patient is alive, after taking one-twenty-fifth of a kilogramme of eserine. The word *kilogramme* was put by error for *milligramme*; and our correspondent will readily see that one-twenty-fifth of a milligramme is about .0006 grain. As regards the dose being 1-3200 of a grain, it will be observed that Dr. Munro says that half a disc is sufficient as a rule; therefore, .0006 x .5 = .0003 grain = 3-10000 of a disc = 1-3200th of a grain nearly, or more accurately 1-3333.

"DENS SAP."—Mr. Hancock has resigned his seat at the Dental Board of Examiners of the Royal College of Surgeons. His successor will be appointed on the 11th instant.

THE INDIAN MEDICAL SERVICE.

SIR,—Does the Indian Army (medical) offer a good position to a young surgeon at the end of twenty-five years? Would it be preferred in point of position, rank, and pay, to a partnership in an English county, never exceeding £700 for some time, to one who will remain unmarried?—Yours obediently,
F.R.C.S.

* * The best reply we can give to F.R.C.S. is to ask him to apply at the India Office for a copy, to be had for the asking, of the terms offered to candidates for the Medical Service of India. There he will see at a glance the pay, rank, and pension given in detail. We have only to add, that Her Majesty's India Medical Service is still the best in the world, and that it commands the best men in the market. Like every other public service, its members have "grievances"; but if the young surgeon, to whose welfare he takes an interest, elects to go into private practice, he will find "grievances" in the course of his career to be "as plentiful as blackberries".

SEVENTY SNAILS IN THE RECTUM.—Dr. Jules Boeckel of Strasburg has communicated (*Gazette Médicale de Strasbourg*) to the Medical Society of that city a note of a case in which a man, admitted for severe pain in the lower part of the abdomen, stated that one of his friends, five or six days previously, taking advantage of his drunkenness, had introduced a number of snails into his rectum. By exploration, there were removed fifty-two snails, and others followed the use of an enema. In all, seventy were removed. The snails, nearly dead, appeared not to have undergone any degree of maceration or digestion.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

LUNACY IN SCOTLAND.

SIR,—I perused with great interest and approval the able leading article on Lunacy in Scotland, which appeared in the JOURNAL of the 16th instant. The article is so moderate and full of common sense, that it must, I think, commend itself to those engaged in the treatment of the insane, and practically acquainted with the subject. I am glad to see that your powerful pen has been taken up in such a cause, for I believe it is high time to place some check upon the vagaries of the Scotch Lunacy Board, their extreme views, and mischievous attempts to mislead, which are calculated to shake the confidence of the public in our present asylum system, and in the medical officers having charge of asylums in Scotland, who require to be protected from the tyranny of the Board, but who, with two or three exceptions, do not appear to have the courage to speak out, or to defend themselves. The extreme views and absurd crochets of the Scotch Lunacy Commissioners may be gathered from their annual reports, and are set forth in a review of Dr. Wynter's book *On the Borderlands of Insanity* (probably emanating from a member of the Lunacy Board), which appeared in the *Scotsman* on September 6th last. This review contains views hostile to Scotch asylums and their medical officers, who, as a body, are treated with scant courtesy and with marked contempt by the Lunacy Board. No wonder, then, that the Board is not held in much respect. It is not composed of practical men; it indulges in theories; it does not look at insanity as it exists in our midst, but imagines that Gheel-like colonies and Kennaway boarding-out villages could meet the requirements of the pauper insane, and eventually that education is to prevent madness, and clear it off the face of the earth. Although insane colonies like Gheel could be established in this country, there would still be a necessity for asylums, which have done, and are still doing, great good, not only as curative hospitals, but as homes for those who are dangerous to society and to themselves.

The matter and spirit contained in the Commissioners' official reports of the various asylums inspected by them do not tend to inspire one with respect for their wisdom or impartiality. As you truly remark in your leading article referred to, they have too much leisure on their hands, which they devote to free indulgence in statistics, theories, and crochets, with occasional abuse of the institutions they are supposed to improve and control.—I am, yours, etc.,

October 25th, 1875.

COLONIAL DEGREES.

SIR,—I have read the several letters in the BRITISH MEDICAL JOURNAL relating to the registration of foreign degrees, and certainly think the Medical Council should carefully ascertain by unmistakable evidence that such degrees have been obtained after a due course of study, by attendance on lectures and hospital practice, as well as after due examination, otherwise it would be most unfair towards those British graduates who have spent both time and money in obtaining their degrees. There is a pushing holder of a colonial degree in my immediate neighbourhood whose education is such that he cannot spell ordinary English words correctly, while his Latin is something ludicrous; e.g., "occasionally," "I new a person," etc.; and his prescriptions are written in the same style; thus, "Acid plumbi, zinci valerianis, pot becarb, vin quinine inf, glyceryza, ft. gargil", and others too numerous to mention; yet, strange to say, he has somehow managed to obtain a license in medicine and surgery from a British College, and his name appears on the *Medical Register*.—I remain, sir, yours truly,

October 20th, 1875.

A BRITISH GRADUATE.

RIGHT TO SUE FOR MEDICINES, ETC.

The *Solicitors' Journal* and *Weekly Reporter Digest* for 1875 contains the following note.

"*Medical Act, 1858, 21 and 22 Vict. c. 90, ss. 31, 32; Apothecaries' Act, 55 Geo. III, c. 194, s. 21: Right to Sue for Medicines and Medical Attendance.*—By the Apothecaries' Act, no apothecary (with an exception in favour of old practitioners not material to this report) can recover any charges unless he can prove at the trial that he has obtained a certificate from the Court of Examiners. By the Medical Act, 1858, no person is entitled to recover for medical or surgical charges unless he can prove upon the trial that he is registered under the Act. Held, that a practitioner cannot recover for medical services rendered before he obtained his certificate under the Apothecaries' Act, although at the trial he may prove that he has since obtained it, and been registered under the Medical Act.—*Leman v. Housley, Q.B.*"

This will reply to several queries which we have lately received.

ORGANISATION OF OUT-PATIENT DEPARTMENTS.

THE Children's Hospital, Great Ormond Street, with great wisdom, has employed, as our readers are aware, the services of the Charity Organisation Society in investigating the new applications for medical relief at its out-patient department. At the last meeting of the Council of the Society, the secretary read a statement which he had received from the Children's Hospital, with reference to the number of out-patients during the quarter ending September 30th. There had been 4,115 new applicants. Of these, 47 had been summarily rejected at the hospital, on account of over-age, or the infectious nature of their complaints; 439 had received "casual papers," and had been seen once, their ailments being so slight as to make it unnecessary for them to attend again; 131, whose fathers or mothers were receiving more than 30s. a week, also received "casual papers," and were seen once, on the ground of their requiring good advice, and being unable to pay a consultation-fee; 3,498 were furnished with letters and referred to the committees of the Charity Organisation Society, after being seen once, that these letters might be stamped by them, if the statements made by the applicants at the hospital proved to be substantially true; 122 letters had been returned to the hospital unstamped, for various reasons; but the committees had not in all cases sent information about rejected cases, and the hospital authorities were unable to say how many of the 3,498 had returned, as they did not enter second attendances. He was informed that there had been 400 fewer applicants than during the corresponding quarter of last year, whilst the opening of the new buildings might have been expected to increase the number. The district committees would be able to say how many letters had been brought to them during the quarter, and how many they had stamped.

MEDICAL APPRENTICESHIPS.

SIR,—Permit a practitioner of nearly forty years' experience to protest most energetically against the opinion expressed by the Rev. Mr. Poulton, in his introductory address at Queen's College, Birmingham, on the subject of apprenticeships. There never was a greater mistake made in medical education than that which takes youths direct from their ordinary schools to medical lecture

rooms and hospital wards. The consequence is, that numbers of young men pass their scientific examination with credit, and yet are entirely ignorant of all those minor details of practical medicine which go to form the successful practitioner: nay, even as they become advanced in the profession, unpractical prescriptions too often betray to the chemist the total unacquaintance of the prescriber with ordinary pharmacy. No doubt the old apprenticeship of five years, chiefly occupied in compounding superfluous medicine, was an abuse; but now, custom has gone much too far the other way. There can be no better portal for a youth into our profession than a year or two of residence in the house of an intelligent gentleman in general practice in the country, more especially of one with union and club practice. In such a position he lives, as it were, in a medical atmosphere. He must acquire practical knowledge of pharmacy, such as he cannot get elsewhere; and the morning waiting-room cannot fail to bring before him those details of medical and surgical practice which make up by far the larger proportion of our daily work. The varicose ulcer, the fractured arm or dislocation, the abscess or the wound, all come in succession, varied with minor medical cases, whilst severer ones have to be visited with his master at their own homes.

In years gone by, when in active country practice, I have had various youths pass through my hands, and have been pleased to hear from them testimony as to the advantage they found, the knowledge acquired, during their pupillage, not only in practice, but in their student-life. Of course, I am presupposing that the master not only knows his profession, but is willing to take pains, as a conscientious duty, to teach it to his pupils, and to train them in every way to become gentlemen as well as medical men.

By all means educate youths intended for our profession thoroughly in general literature, but do not ignore that practical training for the every-day work of the profession, which, if not acquired during pupillage, must be afterwards more irksomely acquired, when such work should be over.—I remain, sir, faithfully yours,

October 27th, 1875.

F.R.C.S.—The subject was discussed at the last meeting of the Council of the College of Surgeons. Particulars relating to the appointment will be found in another column, and the official notice in our advertising pages.

REMARKS

ON

SOME PHYSIOLOGICO-PATHOLOGICAL PHENOMENA OF THE CIRCULATION IN PREGNANT WOMEN.*

BY ROBERT BARNES, M.D.,

Obstetric Physician to St. George's Hospital; President of the Metropolitan Counties Branch.

THE modifications wrought in the circulation under the influence of pregnancy are of great physiological and pathological interest. The phenomena by which these modifications are revealed throw a valuable light upon certain anxious clinical problems, and afford distinct indications in practice. These modifications may be classed under two heads: 1. Changes in the constitution of the blood; 2. Modifications in the dynamic conditions of the circulation. In every pregnant woman, changes easily discovered in both these conditions are present; but in some exceptional cases evidence of a special and more striking character shows itself. The right interpretation of these exceptional cases depends upon our knowledge of the general laws that govern the circulation in the pregnant woman. Unless they be rightly interpreted, we might be led into serious practical errors.

I need not do more than refer to the general facts established by Andral, Becquerel, and others, as to the alterations induced in the blood itself during pregnancy. They found increase of water, diminution of red corpuscles, increase of fibrine. These changes do not, perhaps, occur universally; but they are certainly frequent. Of late years, it has been recognised that leucocythæmia—that singular disease in which the white corpuscles acquire a remarkable preponderance—is especially liable to arise under the influence of pregnancy; and it is enough for the present purpose to call to mind the various empoisonments of the blood which arise from obstructed excretion, as when urea and uric acid or biliary matter accumulate in it, the kidneys or liver being overtaxed. It would lead me away from the path I propose to follow, were I to pursue this subject.

With regard to the dynamic changes, it is desirable to say a few words. Since the researches of Natalis Guillot, Larcher, Duroziez, and others, it is, I believe, admitted that there is a normal hypertrophy of the heart induced by pregnancy. I have myself made observations which satisfy me of the truth of this proposition in some cases; and visible evidence is occasionally obtained in the production of enlargement of the thyroid gland, and that prominence and brilliancy of the eyeballs known as Graves's disease. This exophthalmic goitre is sometimes induced by pregnancy. Here it must be regarded as an exaggerated expression of the physiological increase of the heart's force. Other evidence exists of this increased action. The pulse is usually somewhat quicker than in the non-pregnant state. There is strong ground for the conclusion that a greater volume of blood is flowing in the vessels. Two organisms have to be supplied; and, when the fetus is thrown off, a considerable quantity of blood, which may be regarded as surplus, is commonly discharged, without any obvious detriment to the mother. The sphygmograph supplies direct testimony to the increase of tension of the arterial system. Dr. Mahomed has ably illustrated this point in reference to the albuminuria of scarlatina, and incidentally with reference to the albuminuria of gestation (*Med.-Chir. Trans.*, vol. lxxv); and in a paper in the last volume of the *Obstetrical Transactions* by my son, Dr. Fancourt Barnes, are some interesting tracings showing this increase of tension. In my Lumleian Lectures (1874), I dwelt upon the increase of nervous irritability induced by pregnancy, showing that conditions which would not excite convulsion in the non-pregnant woman were sufficient to do so in the pregnant. Now, increased nervous tension can hardly exist without influencing the circulation dynamically; and that influence will be shown in increased vascular tension. Again, the new developmental nîsus set up in the uterus of necessity attracts a large supply of blood to this organ, and induces increased vascular activity analogous to that which Hunter described as taking place during the growth of the stag's horns.

Passing from these general facts, let me invite attention to the hæmorrhages, not alone the uterine, which occur during pregnancy. In the first place, we must take note of the remarkable hyperæmia

which is commonly seen in the skin and mucous membranes of pregnant women. In some women, this hyperæmia is general; but in most it is prominently marked in the veins of the breasts; and in the vagina, vulva, rectum, and inferior extremities, to such a degree as often to afford the best proof of pregnancy in the early months.

I will now offer a few clinical illustrations of the peculiar ærthism of the circulation in pregnancy. The great development of the vascular system of the pelvis, seen in the deep purple colour and the turgid state of the cervix uteri, vagina, and vulva, frequently passes into marked phlebectasis; the varicose condition forming prominent masses in the vagina and vulva, and often being attended by varicosity in the superficial veins of the thighs and legs. This often begins early in pregnancy: an important fact to remember, because it affords strong presumption against the theory that the cause is pressure exerted by the enlarged uterus upon the pelvic veins. Cases have been known of these distended veins bursting and giving vent to fatal hæmorrhage. Mr. Towne of Kingsland told me of a case which occurred under his observation. This phlebectasis usually starts with the first pregnancy, subsides after labour (the veins, however, rarely if ever quite recovering their natural condition), and returns with every succeeding pregnancy. The following cases are ordinary illustrations.

CASE I. *Phlebectasis and Tendency to Exophthalmic Goitre.*—In November 1861, I saw at the London Hospital a woman aged 34, who had had two children. She was then three months pregnant. The veins of both legs became enlarged during the first pregnancy, and again in the second; and there had been some œdema of the legs before the actual pregnancy. In January following, when she was about five months gone, the venectasis was more marked; there was a very large bunch of veins on the inside of the right thigh, very painful and "throbbing". She suffered intense headache. The carotids throbbled visibly. There were increased impulse of the heart, and slight prominence of the thyroid body. She was subject to palpitation, and the face was often injected.

CASE II. *Phlebectasis.*—In February 1862, I saw at the London Hospital a woman aged 28, who had had three children. She was then six months pregnant. She complained of frequent faintings. She had a large coiled mass of varicose veins in the right labium; one vein, of the size of a goose-quill, inside the thigh, communicated with this mass. The right foot swelled; the veins were quite elastic; there were no thrombi in them. She had noticed some varicose swelling with the third pregnancy; this quite disappeared. There was general deep hyperæmia of the vagina, and the superficial veins of both legs were varicose.

CASE III. *Phlebectasis.*—On July 14th, 1873, Mrs. George W. consulted me in her third pregnancy. During her first pregnancy, she began to have dilatation of the veins of the right leg especially, and slightly in the left leg. This subsided after labour. It returned in the second pregnancy, and again subsided after labour. It was now very marked, although she was only about three months gone. The right foot swelled a little at night. The saphena up to the femoral ring was all dilated. There was a large bunch of distended venous plexus at the inner side of the knee. Her general health was good. She had worn an elastic stocking up to the knee.

This is a very common case. The following one is a curious example of the puzzles to which this vascular development may give rise when it is much exaggerated.

CASE IV. *Phlebectasis: remarkable Case, simulating Cancer.*—In February 1863, a woman came under my care at the London Hospital, who had been delivered in 1860, and had since had two abortions. She was seven months pregnant. She "felt something come down" a fortnight ago, which "she believed was the child's arm". There was some flooding at the time. I found a mass of rounded soft botryoidal swellings inside the labia, extending all along the urethra, and filling the vagina. These were varicose veins; in parts, the appearance was like that of small projecting cysts. It suggested, and for a time was mistaken for, malignant disease. She could not sit down. After some weeks, the condition was less prominent. She was delivered without trouble. All varicosity vanished.

The following case is an illustration of the influence of menstruation upon the superficial circulation.

CASE V.—In July 1863, I saw Mrs. G., who had been married three months. Her menstruation had been scanty before marriage; since then, painful and more copious. Between the periods, there was anæmia, and the feet swelled. She had several spots on the legs, which enlarged, reddened, and became confluent, at the menstrual periods.

The following case affords a different illustration of the same thing.

CASE VI. *Nævus increasing under Pregnancy.*—A few days ago, I

* Read before the Metropolitan Counties Branch.

saw at St. George's Hospital a woman aged 44, who had her last child eight years ago. She bears a large naevus on her left cheek. She says it grew bigger every pregnancy, and has ceased growing since she left off having children.

The three following cases are examples of the difficulty under which the heart labours in some cases of pregnancy. In two of them, there was ascertained hypertrophy of the heart.

CASE VII. *Heart-hypertrophy from Pregnancy.*—February 29th, 1863. Mrs. B. had had two children, the last ten months ago, weaned after two months. Menstruation was regular. She was anæmic. She had great palpitation; tumultuous action of the heart; wine set it palpitating. There was hypertrophy of the heart. All her trouble dated from pregnancy.

CASE VIII. *Hypertrophy of Heart and Thyroid Body.*—In November 1861, I saw at the London Hospital a pregnant woman who had had four children and four abortions. At the last pregnancy, two years ago, the placenta "grew to the left side"; puerperal fever followed. She observed enlargement of the thyroid, and suffered from palpitation, soon after the first labour. She was now five months gone. The os uteri was soft and patulous. There was purple congestion of the vagina. She had had two "shows" early in pregnancy. Her feet swelled this pregnancy, as they did in the preceding one. She had a suffocating feel in the throat, with increased impulse of the heart, and a slight blowing sound communicated to the arteries of the neck. The pulse was 100, small. She was relieved by treatment, and was delivered at term.

CASE IX. *Palpitation during Labour.*—In May 1863, I met Mr. Kesteven on the case of a lady in labour, who had had many children. During and soon after her last labour, she was seized with alarming palpitations and syncope. In actual labour, the progress was slow; and, similar impairment of the heart's action being apprehended, Mr. Kesteven sent for me, in case it should be desirable to accelerate labour. But labour was terminated naturally.

The apprehension felt in one of these cases is sometimes realised. Syncope, ending in sudden death, may occur. This, I have little doubt, is the explanation of two cases of sudden death during labour to which I have been summoned; and, if death do not occur by sudden failure of the heart's action, it may ensue from extravasation of blood in the brain. Apoplexy is one of the accidents to which pregnant women are exposed. This is most to be dreaded during the increased tension of the vascular system attending the expulsive act of labour.

CASE X. *Death from Blood-Effusion in Brain.*—In a case observed in the maternity of St. Thomas's Hospital, the woman was in her seventh labour. Convulsion, stertor, and syncope set in before the expulsion of the child. The child was expelled alive. The mother died twenty minutes afterwards. A small clot, quite recent, was found in the left thalamus opticus; and another, of larger size and of a dissecting character, in the left crus cerebri. The abdominal and pectoral organs were healthy.

CASE XI.—On September 28th, 1862, I saw the wife of a medical friend. Her age was 37. She had had ten children, and no abortions. Lately, she had been getting stout, staying much at home. Being about two months pregnant, on September 19th a sudden gush of blood, estimated at a pint and a half, escaped with some pain. In the evening, she suddenly sprang up in bed, and fell back paralysed on the left side. Stertor followed; but there was some return of consciousness next day. Complete coma set in in the afternoon. Dr. Ramsbotham saw her in the morning. He found the ovum not detached. He thought the case hopeless. I saw her at 8 P.M. She was in deep coma with stertor. There was no swelling of the legs. The urine had been suppressed for twenty-four hours; it had not been tested. Thinking it possible that the cerebral symptoms might be connected with albuminuria, I examined the state of the uterus. The cervix admitted the tips of the fingers; the ovum was partly detached. I therefore passed one finger into the uterus, and brought it away. She died the same night.

In the above case, the complication with albuminuria could not be verified; but, in a considerable proportion of the fatal cases of puerperal eclampsia, lesion of the vessels of the brain, and effusions of blood and serum, have been found.

CASE XII. *Effusion into the Pericardium.*—Sometimes effusion of blood takes place into the serous cavities. Thus I remember a singular case of which I saw the necropsy in the service of Dubois, when I was a student in Paris. A young woman in her first pregnancy was expecting her labour. When in the act of straining at stool, she died almost instantly. The pericardium was found full of blood, fluid and coagulated. The aorta had given way through the bursting of a hydatid cyst in its wall. The growth of this cyst had thinned the wall, so that, under the increased tension, a rupture took place.

I have also known blood-effusion into the peritoneum take place in pregnancy, forming retro-uterine hæmatocele. Anyone who has seen the intensely turgid state of the vessels of the Fallopian tubes and broad ligaments during pregnancy, will appreciate the probability of this accident. When effusions take place into the brain, or when the heart fails in its action, death or grave injury is the inevitable result. When effusion takes place into the pericardium, if the quantity of blood be at all considerable, recovery can hardly be expected; but if the peritoneum be the seat of the effusion, the subject may escape after shock and peritonitis. Fortunately, hæmorrhages are more frequent from the mucous membranes; and, therefore, there is provided a natural outlet. Although these mucous hæmorrhages are sometimes so profuse as to induce danger by anæmia, they must in their design and first tendency be regarded as salutary, as instances of a conservative process. It would be easy to adduce examples of hæmorrhage from all the mucous tracts. But I would especially draw attention to some cases of hæmoptysis, or hæmatemesis, of hæmorrhage from the bowel, and from the urinary tract.

Hæmoptysis is of especial interest, because it naturally gives rise to the suspicion of tuberculosis. I have known this error to be committed most frequently in cases of hæmoptysis from disturbance in the menstrual function. But it is very important to remember that bleeding from the lungs may occur as a simple consequence of pregnancy.

The subject of the following case, as well as her family, is well known to me; so that I can affirm, with some confidence, that there is no tubercular element.

CASE XIII. *Hæmoptysis in Pregnancy.*—May 1873. Mrs. J. L. A., a young lady, was seen by me a month before her delivery of a child, now ten months old. She suckled until two months ago; when she left off, because the milk disagreed with the child. She menstruated all through lactation, until four months ago, when she fell pregnant. From that time, she had been liable to cough and morning sickness. On waking at 6 A.M., she felt blood in the mouth; this excited cough; and free hæmoptysis of bright red, in parts frothy, blood mixed with small clots followed; then came vomiting at times to a very distressing degree. She had not lost flesh. The chest was well-developed—*bombé*. There was some degree of harsh respiration in the right chest; the left was quite normal. I prescribed nitric acid, digitalis, oxalate of cerium, and Püllna water. The hæmoptysis ceased in a few weeks. She still vomited at times. She then suffered from palpitation and a disposition to syncope, which she had had to a less degree before pregnancy. The hands and feet swelled. At a later period of pregnancy, she had more œdema, and some albumen appeared in the urine. She was carefully watched, and was delivered of a healthy child at term without further trouble. She nursed the child, and has enjoyed good health, without return of hæmoptysis or cough to the present time. I find a note of an observation made of this lady in 1867, when she was fourteen years old, that there was rather strong respiratory sound in the centre of the right chest. The subsequent appearance of albuminuria is very interesting, as confirming the theory that hæmoptysis was due to increased vascular tension. At this moment she is in good health.

CASE XIV. *Hæmoptysis in Pregnancy.*—October 1874. A medical friend consulting me about his wife, told me that, in the seventh month of pregnancy, she had, every two or three days, severe hæmoptysis. Dr. Peacock, who examined the chest, found no disease.

Dr. Montgomery relates a case in which hæmoptysis recurred in five successive pregnancies; the last one running into hydatidiform degeneration of the placenta.

The two following cases are interesting illustrations of hæmorrhage from the bowel due to pregnancy.

CASE XV. *Hæmorrhage from Bowel during Pregnancy.*—On December 18th, 1872, I saw Mrs. A., with Mr. Lammiman. She was a young woman, five months gone in second pregnancy. During her first pregnancy, for the first time, she had frequent losses of blood by stool. These diminished after labour, but recurred now and then whilst suckling. They had been much more frequent and copious since she had been pregnant again. The blood came sometimes in clots; sometimes fluid and bright. It came after stools, without pain, and daily. She was somewhat anæmic; the pulse had the "hæmorrhagic jerk". She declined examination; but Mr. Lammiman had examined the rectum, and said there were no piles, and no disease as far as he could reach. After her last labour the abdomen remained large. The possibility of there having been some ulceration of the mucous membrane or glands of the colon occurred. But the more probable explanation was hyperæmia of the mucous membrane, or dilatation of the hæmorrhoidal vessels. I advised turpentine enemata, and half-drachm doses of turpentine by the mouth. This treatment was followed for a fortnight; when, being somewhat improved, the patient refused to go on with it. She then took twenty-drop doses of tincture of perchloride of

iron three times a day for about a month, at the end of which time the bleeding had almost ceased. She was delivered on April 7th, 1873. Very little bleeding attended the labour. She continued in good health until January 1875, when she aborted at about three months' gestation. The bleeding from the bowel had occurred very slightly. Possibly (observes Mr. Lammiman) it would have increased had the pregnancy advanced. She bled very moderately during the abortion, and has since (May 13th, 1875) remained in good health.

CASE XVI. Hemorrhages from Bowel and Threatening Mania during Pregnancy.—In May 1872, I saw, with Dr. Williamson of Mildmay Park, a delicate lady who had had seven children in less than seven years. When we met, she was five months gone. From the beginning of pregnancy, she began to have repeated and copious losses of blood by the anus, coming in large clots, and leaving her very blanched and prostrate. Latterly, she becomes almost maniacal and imbecile from the losses. She had also had four hemorrhages from the vagina. She complained of no marked pain in the stomach or intestinal canal. There was no vomiting. As far as could be ascertained, there were no piles or other morbid condition within reach of the finger. The urgent question to determine was whether the pregnancy could be allowed to go on. Looking at her extreme prostration, the likelihood of the losses being repeated, and the danger of her breaking down in body and mind, we decided upon the induction of labour. Dr. Williamson reported to me "that the hemorrhage continued, and that he therefore provoked labour. The hemorrhage ceased immediately after labour; and she made a good recovery. She has since become pregnant, and again the hemorrhages returned. About the third month, she had a mental shock, and aborted. All unfavourable symptoms ceased; and she has been quite well ever since. She has had no maniacal symptoms since. There is no family tendency thereto." Within the last week (May 1875), Dr. Williamson has completed her history to the present time. She has been pregnant a third time, and again the hemorrhages returned. As her strength was giving way, Dr. Williamson induced miscarriage about the third month, and again the hemorrhage ceased immediately. "She has not now been pregnant for a year, and is strong and well. When you saw her, she was anæmic, and very much emaciated; she has now a good colour, and is much stouter; she is much more active, cheerful, and her intellect is clearer and better than it has been for years." The complication with maniacal tendency is extremely interesting. The combined vascular and nervous tension of pregnancy are important factors in the production of insanity.

CASE XVII. Hemorrhage from Bowel after Labour.—Mrs. A. consulted me on April 20th, 1875. She had had five children, the last in October 1874; she did not suckle it. She passed half a pint of blood by bowel after labour.

The following is an example of hæmatemesis. When we reflect upon the extreme pressure thrown upon the stomach by the vomiting of pregnancy, it may seem surprising that hæmatemesis is not more common.

CASE XVIII. Hæmatemesis in Pregnancy.—C., aged 26, had had four children. She menstruated regularly, and during lactation. Her last child was born nine months ago; she had not suckled it. She was now (May 1875) five months pregnant. Since her pregnancy, she had vomited blood two or three times a day. There was no menstrual or leucorrhœal discharge. She was giddy, faint; "her head turned round"; she could not walk; was anæmic. The pulse was very feeble. There was pain in the right hypochondrium. In previous pregnancies, she vomited, but not blood. She took sulphuric and hydrocyanic acids, and got better.

CASE XIX. Eclampsia; Hæmatemesis; Epistaxis; Albuminuria.—In February 1875, I saw, with Dr. Lees of Camberwell, a woman seven months gone in her fifth pregnancy. Her previous labours had been hard, but there had been no convulsion. She was in fair health three weeks ago, when her husband went to sea in very bad weather; she feared he was drowned. Headache, giddiness, and some disturbance of sight came on; and her face was observed to be somewhat puffed. She had not noticed movements of the child for a fortnight. Convulsion broke out on the 23rd and 24th. The ring was a little tightened; there was no other mark of dropsy. Some days before the first fit, she had vomiting of blood. Labour was provoked the same day; some convulsive symptoms appeared. The fœtus was expelled dead; it had been dead sometime. A severe fit attended the extraction of the placenta. She bled at the nose, and considerable uterine hemorrhage took place. After this, there was no return of convulsion. The symptoms were those of anæmia. The urine contained much albumen.

Dr. Lees has kindly continued the history. "A few days after my last report, Mrs. W. was seized with vomiting, which lasted thirty-six hours, followed by dark brown tongue, sleeplessness, and pulse 120,

which, during the following fortnight, fell to 72. Since then, she has become apparently well; has been for a few weeks into Warwickshire. I saw her yesterday; she looks very well; the menses appeared about a week ago, lasting five days. The urine is still albuminous; about one-third as much as when you saw her. She has always had slight hæmoptysis during her pregnancies, never hæmatemesis. She has occasionally troublesome attacks of bladder-irritation." Here, again, we observe concurrence of hæmorrhage from a mucous tract, and albuminuria, illustrating the general increase of vascular tension.

Hæmorrhage from the urinary tract is, in its clinical aspects, the most interesting of the hemorrhages of pregnancy. It is not, however, easy to estimate it at its exact significance. It may be complicated with albuminuria, or it may be simply oozing of blood. Albuminuria may, indeed, be regarded as a form of hæmaturia. The observations of Dr. Mahomed upon this point are of extreme value. I will cite some of his observations. "Previously to the commencement of any kidney-change, or to the appearance of albumen in the urine, the first condition observable is high tension in the arterial system." "If this condition of high tension be sufficiently severe, transudation of the characteristic crystalloids of the blood, notably hæmoglobine, occurs before albumen appears in the urine; and they can be detected in that fluid by the guaiacum test for blood." The transudation of albumen, then, which is so often observed in pregnancy, and which is so often attended by disastrous disease, may be regarded as allied to hæmorrhage. This alliance is further exemplified in the following case.

CASE XX. Pregnancy; Dropsy; Hæmaturia.—I saw in the London Hospital a patient of Dr. Parker, a young woman married about six months. She menstruated one month afterwards; was four to five months pregnant. For some weeks, she had had general dropsy; the labia majora being much distended. There were no nervous symptoms at this time. There were hæmæmia and palpitation. There had been blood in the urine. When this had passed away, some urine which I examined was acid, slightly albuminous. There was no evidence of other disease. The albumen detected here might have been due to a little blood lingering in the urine. There was no opportunity of following up the case.

Here it may be interesting to note the analogy between abortion in uterine gestation, and the cataclysmic hæmorrhage attending rupture of the sac in Fallopian and other forms of ectopic gestation. Rupture of the tubal gestation-sac, which usually occurs about the second or third month, may be regarded as abortion. The conditions are similar. Hæmorrhage, probably under ovarian excitement and increased tension, is an universal phenomenon. Just as uterine hæmorrhages and abortions are especially prone to occur at menstrual epochs, so it is with the hæmorrhages of tubal gestation. Indeed, I have elsewhere shown that uterine hæmorrhage frequently attends the rupture of the sac and the intraperitoneal hæmorrhage.

I have referred to the conservative tendency of some of the hæmorrhages in the preceding cases. In this connection, it is deeply interesting to examine the hæmorrhages which take place from the genital mucous tract. This is obviously the most natural, as it is the most frequent, source of hæmorrhage. Blood escaping by the vagina may be poured out from the body of the uterus, from the cervical canal, from the vaginal portion, and from the vagina. Occurring with more or less marked periodicity, it has been described as menstruation during pregnancy. And provoked, as it undoubtedly often is, by the increased nervous and vascular tension of recurrent ovulation, it may fairly be regarded in this light. During the first two or three months, blood may be discharged from the decidua cavity—that is, from the free surface of the decidua vera and decidua reflexa. But, I believe, a more frequent source is the mucous membrane of the cervical canal; and this is more certainly the case when there is abrasion or loss of epithelium at the os externum. In this latter case, the villi of the mucous membrane, being unprotected, bleed on the slightest touch, and presumably will do so on any increase of vascular congestion or hyperæmia.

All the phenomena we have noted as occurring in pregnancy may be observed under the influence of menstruation, supplying further proofs in addition to the many which physiology supplies of the close affinity between these two conditions.

Mucous hæmorrhages must in many cases be regarded as a means of taking off excess of arterial tension; and thus of averting disastrous hæmorrhages into the brain, or abortion. And in many cases where the hæmorrhage, instead of escaping from the free mucous membrane of the uterus proper and cervical canal, is extravasated into the placental tissue, or into that part of the decidua which is in immediate relation with the ovum, abortion is the almost necessary result. But in many of these cases, too, the same conservative action is manifest, abortion being the means of averting a more serious catastrophe.

To pursue the reflections which the facts and considerations I have so imperfectly stated suggest, into all their bearings and applications, would be a task beyond my present power, and beyond your patience. I must be content with indicating a few general conclusions.

1. There exists in pregnancy a peculiar state of the blood, an increased arterial tension, and a disposition to phlebotectasis, general or affecting particular vascular regions or systems, which may, under certain circumstances, lead to hæmorrhagic effusions.

2. These hæmorrhagic effusions may be salutary or conservative. Hæmorrhages from the mucous membranes, by relieving excess of tension, may avert internal hæmorrhages or abortions, or that oppression of the kidneys which results in albuminuria and eclampsia.

3. Hæmorrhages from the uterus inducing abortion may, in the same way, avert more serious mischief, especially albuminuria and eclampsia.

4. But these hæmorrhages, although we may recognise in them a conservative purpose, easily exceed physiological or useful limits, and may themselves induce danger by anæmia.

5. Hæmorrhages, from whatever part, occurring in women within the period of sexual life, should suggest the probability of pregnancy, or of menstrual disorder.

6. The hæmorrhages described should be taken as indications to reduce vascular tension. This may be done in some cases by bleeding, general or topical; by purgatives; by salines; by abstinence from stimulants; by regulation of diet: by digitalis, hydrocyanic acid, and other means.

7. Bleeding from the arm may avert abortion, not only by reducing arterial tension, but also by a derivative action determining the direction of the blood from the pelvis to the opening in the vein. This derivative action of bleeding was much relied upon in a variety of cases by Lisfranc.

8. In some cases, where the hæmorrhages are frequent and great, and induce serious symptoms, the induction of labour is indicated.

FURTHER OBSERVATIONS ON THE ELECTROLYTIC DISPERSION OF TUMOURS.*

By JULIUS ALTHAUS, M.D., M.R.C.P.Lond.,
Physician to the Hospital for Diseases of the Nervous System.

FINDING that there is still much difference of opinion concerning the therapeutical value of electrolysis as used for the dispersion of tumours, I am led to think that a short summary of my more recent experience on this subject may be welcome to the members of the Association. There are now so many and effective modes of treating the various forms of morbid growths which are met with in practice, that it would hardly be allowable to add another means to those already at the disposal of the surgeon, unless it could be shown that it possessed peculiar advantages of its own over other methods used for the destruction of these growths, or that it was applicable to such forms of tumours as are otherwise unmanageable or rebellious to treatment. This I hope to be able to do for electrolysis in the following communication. It seems to me now pretty well ascertained what this remedy can do and what it cannot do; and I think it unlikely that its limits of usefulness will either be much curtailed or much enlarged by further researches.

It is not my purpose, on the present occasion, to describe the chemical and physiological principles on which the electrolytic treatment is based, as I have done so fully on previous occasions, and more particularly in the last edition of my treatise on *Medical Electricity*. I will, therefore, only say that in electrolysis the constant voltaic current is conveyed to the tumours by means of gold needles, which act either in fixed rows, or singly in any direction that may be required by means of the serres-fines conductor; that either the influence of the negative or of the positive, or of both poles simultaneously, is utilised; and that the effects are not owing to the development of heat, and have consequently nothing to do with the galvanic cautery.

In cases where only the negative pole is used, as, for instance, in bronchocele, the operation is not painful if properly performed; but, where both poles have to be inserted into the tissues, as in nævus, sebaceous tumours, etc., a good deal of pain is generally experienced by the patient, and chloroform or some other anæsthetic may, therefore, be used under such circumstances, if thought advisable.

1. *Nævus*.—One of the commonest tumours met with in practice is nævus of the face or scalp. Although this is not, as a rule, dangerous to life, it is nevertheless desirable to have it removed, as it disfigures the person affected with it. Almost every surgeon has a favourite plan

of treating nævus, with the results of which he is well satisfied; but I doubt whether any other mode of removing some of these unsightly marks is as good as electrolysis, and those who have once used it will probably always use it again. Over excision, it has the advantage of being entirely bloodless; over the injection of perchloride of iron, that it is not dangerous to life; over cauterisation by nitric acid, that it can be better localised, and acts more thoroughly; over the subcutaneous ligature, that, once the operation has been performed, no further suffering is caused to the child, or trouble to the medical attendant; and over the galvanic cautery, that it does not leave a scar. It is rapidly successful in the flat round tumours of the size of a shilling, which are only slightly raised above the skin, but acts less quickly in extensive "port wine marks". Where nævus assumes the form of large fleshy masses or lumps, the treatment is rather tedious, and, unless the patient perseveres, not so satisfactory in its results. An ordinary round flat nævus yields to one electrolytic application, while in extensive "port wine marks" half a dozen or more applications may be required. The current should be directed to the tumour by means of fixed rows of gold needles, connected with both poles of ten to fifteen cells of Becker-Muirhead's battery. As soon as the connection has been made, a destruction of the texture of the nævus is seen to commence, the blood-vessels and the skin withering away rapidly under the eyes of the operator. The destruction is more thorough at the positive than at the negative pole, and the worst parts of the nævus should, therefore, always undergo the influence of the former. As a rule, not a drop of blood is lost during the operation; but if, by sudden movements of the child, one of the needles should come out prematurely and a drop of blood should appear, this can be immediately coagulated, and any hæmorrhage checked, by applying the positive pole to the puncture. The whole mass of the tumour is then gradually brought under the influence of the current, care being taken not to act too long or too energetically upon any one point, as otherwise a scar might be left. When everything morbid appears to have been destroyed, the action is discontinued, and the surface covered with a piece of goldbeater's skin. There is no pain or discomfort after the operation; no dressing is required, for there is no discharge; the scab remains dry, and falls off in ten or fourteen days, leaving a healthy surface which gradually assumes the appearance of the surrounding skin.

2. *Bronchocele*.—Cystic bronchocele yields to a number of operative procedures, such as the seton, injection of iodine, or perchloride of iron, etc. Amongst these means, electrolysis may claim a foremost place from the comparatively painless nature of the proceeding, the absence of risk to life, and the circumstance that there is, as a rule, no open wound or sore produced which requires dressing. The best mode of proceeding is to insert two or three needles singly into the cyst, and connect them by means of the serres-fines conductor with the negative pole of the battery, while the positive electrode connected with a moistened sponge is placed on the skin in the neighbourhood. The consequence of this is, that the liquid in the cyst is decomposed, the chloride of sodium solution being changed into one of caustic soda, whereby the secreting membrane of the cyst is cauterised and prevented from effusing further liquid. From two to six applications appear to be sufficient for a cure.

Solid Bronchocele is much more difficult to deal with, and the ablest surgeons of the present day habitually refuse to interfere in such cases, there being imminent risk to life attached to such operations as were previously practised. These tumours, however, often become dangerous to life by pressure on important neighbouring organs; and electrolysis then steps in as the right thing in the right place. I have of late years combined injections of the tincture or liniment of iodine into the substance of the tumour with the electrolytic applications, as it seemed to me that by such combined treatment time was gained. Iodine, subcutaneously injected, appears to break up the internal structure of the tumour, more especially where this is very old and tough, and aids electrolysis by allowing a freer passage of the current through the mass. In recent tumours, electrolysis alone is sufficient; but most cases which have been under my care have been of many years' standing.

I will now relate the particulars of a case of double solid bronchocele which I have treated in this manner, and which may be considered typical of this class of cases.

CASE.—J. L., aged 37, single, a native of Yorkshire, and engaged in a mercantile firm in the city, came under my care in April 1874. He had for the last ten years been subject to a tumour in front of the left side of the neck, involving the thyroid body, which had very gradually increased until it reached an inconvenient size. The patient had on various occasions consulted the heads of the surgical profession in London, with the view of having it removed. This, however, was

* Read before the Surgical Section at the Annual Meeting of the British Medical Association in Edinburgh, August 1875.

not considered expedient by the eminent men whose opinions the patient had sought, and nothing had been done except painting the skin over the tumour with iodine, which had no beneficial effect. Things had gone on for a considerable time in this manner, when, on April 10th, suddenly a fresh tumour appeared on the right side of the neck, over the collar-bone. This was accompanied by an increase of temperature in the parts, and the swelling showed considerable pulsation. At the same time, alarming symptoms of pressure on the pneumogastric nerve became apparent; viz., loss of voice and of the power of swallowing, a sense of choking in the throat, and severe pain at the back of the head, on the right side. There was regurgitation of liquids through the nose, and the patient had not slept for four days and nights, but was obliged to sit up in bed propped up by pillows, or to lean forward in a chair.

Under these circumstances, he had again consulted Sir William Fergusson, and entreated him to operate. Sir William, however, declined to do so, and the patient was then sent to me by his usual medical attendant, Dr. Black of Islington. I first saw him on April 13th, 1874, and found him in the following state. The pulse was 120; respirations, 36; anxious expression of countenance; eyes staring and protruded; excessive action of the left ventricle. He had not been able to eat or sleep for four days, and could only talk in a whisper. In front of the left side of the neck, there was a tumour of the size of a small orange, which was very hard, and showed no signs of fluctuation. It was limited inferiorly by the thyroid cartilage and the wind-pipe, which were considerably displaced to the right side; exteriorly, by the strongly pulsating carotid artery; superiorly, by the horizontal branch of the lower jaw; and inferiorly, by the apex of the trigonum supraclaviculare. On the right side, there was a small but strongly pulsating tumour occupying the space of the supraclavicular triangle. It was much softer and less prominent than the one on the left side. The circumference of the neck on the most prominent point of the left side was $16\frac{1}{4}$ inches, and on the right side $15\frac{1}{2}$ inches.

The patient was in such a state of prostration, and so racked with pain and distress, that I thought it best to commence the treatment with an external application of the constant current, for the purpose of soothing and strengthening the central nervous system and diminishing the effects of pressure upon the pneumogastric. He recovered his voice almost immediately; had some sleep the night after, and no more regurgitation of liquids. Next morning, the expression was less anxious; the pulse had gone down to 90 beats; respirations, 28; the voice went away and came again from time to time. On April 15th, he reported that he had had four hours' sleep; eating had become easier; he had drunk off a whole tumblerful of beef-tea without trouble, and the voice was stronger. The tumour on the right side was smaller, and its pulsation much diminished. The headache was still intense, and did not seem to be affected by the external application of the current. On April 19th, I introduced a needle connected with the cathode of fifteen cells of Becker-Muirhead's battery into the tumour on the right side, and allowed the current to pass through it for fifteen minutes. On the 21st, the patient reported that he had eaten some fowl and pudding, and that the headache was nearly gone. The old tumour on the left side was now likewise attacked by electrolysis and parenchymatous injections of iodine.

I will not weary your attention by further details about the treatment and progress of this case. Suffice it to say that by the middle of May the tumour on the right side had entirely disappeared, and that the left was then shrinking visibly under the influence of the treatment, which was continued, with some considerable intervals, until the middle of March last. At that time, there was only just a trace left to show that there had been once a tumour; the circumference of the neck was reduced from $16\frac{1}{4}$ inches to $13\frac{3}{8}$ inches. The patient has since resumed his work in the city, and was, when I last saw him (July 1875), in all respects in good health. Sir William Fergusson had an opportunity of examining him again about that time, and expressed to me his gratification at the successful result of my treatment in a case which he had thought beyond surgical interference.

It may be asked whether the result in this case was more owing to electrolysis or to the injections of iodine. Having carefully watched the effects of both, I have come to the conclusion that, of the two agents employed, electrolysis was by far the most effective. Indeed, one of the tumours yielded entirely to this alone in a comparatively short time. The iodine, however, unquestionably aided the action of the voltaic current in the manner described above; and I have since then, in view of this result, treated similar tumours again in a similar manner.

3. *Sebaceous Tumours.*—These occur not unfrequently on the face and scalp, and are excised without difficulty; but, as many patients have a great dread of any cutting operation, however trivial, and as

erysipelas, with fatal results, has been known to supervene upon the removal of sebaceous tumours by the knife, even where the operation was performed in the most skilful manner, it will often be found expedient to resort to electrolysis, which rapidly destroys these tumours without any risk to life, and without leaving a scar. Both poles in the growth act more quickly than the negative pole alone.

CASE.—In June 1874, Dr. Seton of Thurloe Place sent a lady to me who had an atheroma as large as half a chestnut on the scalp. This had become developed, as she thought, in consequence of her having knocked her head against a table about two years ago; and, as it caused disfigurement, she was anxious to have it removed. I electrolysed the tumour on two consecutive days; on the third day, it had almost entirely withered away, and only a small trace of it was left, which was likewise easily removed. The application was unpleasant, but not bad enough for chloroform to be used; and the electricity took away not only the atheroma, but also a headache from which the patient had previously suffered.

4. *Recurrent Fibroid.*—In this form of tumour there is, as its name conveys, great tendency to relapses after excision; and the growth is sometimes so intimately connected with organs important to life, that the ablest surgeons not unfrequently refuse to interfere. Recurrent fibroid is frequently the seat of intense pain; it is very disfiguring when situated about the face and neck; inconvenient, on account of the size to which it may attain in any other portion of the body; and, if allowed to grow, it ultimately exhausts the most buoyant vital powers. As excision fails to cure these tumours, another means of treating them seems, therefore, to be imperatively called for.

My experience with electrolysis in recurrent fibroid is as yet not particularly favourable, probably because the cases which have been under my care were of very long standing, and in them the tumours had attained an enormous size. If the treatment were used immediately upon the first signs of relapse after excision, the result would most likely be better.

CASE.—A gentleman, aged 28, single, who had been a long time in Australia as sheep-farmer, came under my care in December last. He had been living on a very poor diet, eating no vegetables and little else but salt beef for a considerable period. About four or five years ago, he was kicked by a horse on the left cheek, and some months after that a tumour made its appearance, which involved the cheek and left side of the head. This was excised at Sydney three years ago, and a large cicatrix which runs from the ear down to the external angle of the jaw marks now the place where the incision was made. The patient nearly died of hæmorrhage after the operation, but ultimately recovered. It was, however, not very long afterwards that signs of a relapse manifested themselves, and the new growth became at last so large and painful, that he wished to undergo another operation. He, therefore, consulted the heads of the surgical profession in London with this view; but Sir James Paget, Sir William Fergusson, and Mr. Cesar Hawkins pronounced against an operation, and Sir William Fergusson then sent him to me. The patient was of spare habit, and had a feeble pulse. There was an immense tumour occupying part of the left cheek and the left side of the head, displacing the ear upwards and backwards, filling up the stylo-mastoid fossa and reaching a considerable way up to the left parietal bone. He also had large packets of swollen lymphatic glands on the neck, and could wear a collar but with great difficulty. The substance of the tumour was exceedingly hard, more osioid than fibroid, and its surface livid, showing tendency to ulceration. Electrolysis was commenced on December 16th. One of the first results was, that the pain, which had been severe, especially at night, was relieved, the tumour became softer and smaller, and the surface assumed a healthier colour. Sir William Fergusson, who saw the patient again on January 8th, expressed to me his satisfaction at the progress of the case. Unfortunately, the treatment could not be persevered with for a sufficient length of time, as the patient did not live in London, and circumstances rendered it difficult for him to stay. The tumour was still very large when the treatment was discontinued; but, on the whole, the result was so far encouraging as to warrant my recommending an early resort to electrolysis in such cases, more especially where the tumour has not yet attained such an immense size as was the case in the present instance.

5. *Cancer.*—In primary scirrhus, early and complete excision is the best treatment; but, in epithelioma and secondary cancer, electrolysis is often of essential service. We are not able by this means to eradicate the cancerous diathesis, or to prevent the tendency to death; but it is most effectual for the relief of the pain; besides which it promotes sleep and appetite, and appears to soothe and strengthen the system generally. It often renders the last few months of the existence of these wretched sufferers comparatively happy, and smoothes the road to dissolution, which is otherwise for them only too thickly beset with tortures.

CASE.—A housekeeper, aged 38, single, came under my care in November last. Sixteen months ago, she first noticed a swelling in the right breast, which gradually grew larger, and was excised in February 1874. Five weeks later, a fresh tumour had already formed, and was likewise removed by excision. Soon afterwards, numerous cancerous nodules sprang up about the cicatrices in the axillary glands, and also in the left breast; and, as further surgical operations appeared unadvisable, Mr. Irvine sent her to me. When I first saw her, on November 23rd, the cancerous cachexia was strongly marked. There was intense weakness and depression of spirits; the face bore an expression of agony; the complexion was sallow; there was complete loss of appetite, great wasting, restlessness at night, a pulse of 120, and sixty respirations in the minute. Towards evening, well marked febrile movements set in, and there was excruciating pain, more especially in the left shoulder.

Under these circumstances, no treatment could be expected to produce a decided change in the aspect of the case; but, as the patient and her friends were most anxious that something should be done, electrolysis was suggested. On November 30th, I introduced a needle connected with the cathode of Becker-Muirhead's battery into one of the cancerous nodes on the right side of the chest, and placed the anode to the left shoulder. The power of current was gradually raised from ten to thirty-five cells, and it was allowed to circulate for ten minutes. Immediately afterwards, the patient expressed herself as considerably relieved. I saw her again two days later, when she informed me that she had had less pain ever since, had slept better, and felt stronger and more cheerful. On December 14th, the cancerous node which had been electrolysed had disappeared, the tumour in the left breast was smaller, the pain was gone, the pulse had fallen to ninety beats, and the inspirations were only thirty-six in the minute. The patient said that she hardly felt any discomfort at all; looked wonderfully better, and entertained hopes of perfect recovery. During the intense frost which prevailed at that time, she caught a severe cold, which prevented her from coming to see me again, and she died on January 15th, 1875, from congestion of the lungs, but without a return of the pain. I should add that I also prescribed for this patient morphia, chloral, and quinine; but these remedies appeared to do little good, while, immediately after each electrolytic application, a decided change for the better took place.

I have now put before you as concisely as possible what I believe to be the advantages and limits of usefulness of the electrolytic treatment, and trust that you will henceforth use it more extensively in suitable cases than has hitherto been done.

USE OF PERCHLORIDE OF IRON IN POST PARTUM HÆMORRHAGE.

By LOMBE ATTHILL, M.D.,
Master of the Rotunda Lying-in Hospital, Dublin.

THE case recorded by Mr. Boddy, in which death followed almost instantaneously on the injection of a solution of the perchloride of iron, conveys a very important lesson. It is, as far as I am aware, the first recorded case in which there are just grounds for believing that death was due to the use of the styptic; but, even here, the cause of death remains doubtful, there not having been a *post mortem* examination, a matter greatly to be regretted. Mr. Boddy's conclusion that "without doubt death resulted from the action of the solution of iron upon the lining membrane of the uterus" is not, in my opinion, correct. First of all, the uterus has not, immediately after delivery, any "lining membrane" properly so-called; next, Dr. A. H. Ringland has, in several cases of *post partum* hæmorrhage recorded by him, carried the *solid perchloride* into the uterus and applied it direct to the interior of the uterus without producing any injurious results (*vide Proceedings of the Dublin Obstetrical Society*, session 1873-74).

I am not in a position to give an explanation of the cause of death in Mr. Boddy's case; but I believe it proved from Dr. A. H. Ringland's cases, in which he applied the solid perchloride to the inner surface of the uterus, and from my own (*Dublin Medical Journal*, April 1874), in which I injected a small quantity of a strong solution into the uterus, that the application of the styptic to the inner surface of the uterus is not *per se* a dangerous practice.

I would point out that in Mr. Boddy's case an unnecessarily large quantity of the styptic was injected; for, though "the hæmorrhage ceased immediately on the injection of the solution", the process was continued till the patient gave a shriek and died; and to this continuance of the injecting process after the purpose for which it had been employed was attained, the fatal result, in my opinion, is to be attributed,

which probably would not have occurred had but three or four ounces of a strong solution (one part of the strong liquor to two of water) been employed.

I think the profession are under a great obligation to Mr. Boddy for publishing this case.

THE TREATMENT OF SPINA BIFIDA.

By JAMES MORTON, M.D.,
Surgeon to the Royal Infirmary, Glasgow, &c.

PREVIOUSLY to October 1871, it was the habit, with others as well as myself, to regard cases of spina bifida as hopeless, and to discountenance the idea of surgical interference. It was well known that they had been dealt with in a variety of ways, some of these reckless and rash, others more or less prudent, almost all proving in the end unfortunate. It was also known that in some few instances a spontaneous cure had taken place, but these were truly, like angels' visits, few and far between. It was universally admitted that very many died, in truth by far the greater number, the precise numerical proportion being difficult to arrive at; the conviction being general that only a very small percentage lived for any great length of time. As a proof of this, the prognosis usually given was a very hopeless one, and seldom falsified by the result.

So entirely had this view of the malformation taken possession of practitioners, that it was the custom to limit their efforts to what was called the palliative treatment, such as protection, or defence from injury, carried out in various ways, so as to avoid ulceration and bursting of the sac with its fatal ending. Up till the date mentioned, I was a follower of the do-nothing system; but, on October 2nd, 1871, a case was presented in the Glasgow Royal Infirmary, which prompted me to reconsider the question, more especially as the child was otherwise healthy, and I felt a strong desire to give it a chance. On turning my attention to the numerous methods previously employed, too numerous to mention here, it appeared to me that injection was the safest, as that could be effected without permitting the complete escape of the fluid contained in the protrusion. The kind of fluid to be injected next demanded consideration, when it occurred to me that a solution of iodine, less diffusible than either a spirituous or watery solution, would best suit my purpose, as being less likely to permeate the cerebrospinal fluid with rapidity, and, therefore, less likely to cause shock or bring on convulsions. With these views, I caused the following solution to be prepared, which is now known as the iodo-glycerine solution.

R Iodi x gr.; potassii iodidi xxx gr.; glycerinæ j ʒ.
From half a drachm to two drachms of this fluid have been used, according to the size of the spinal protrusion.

Previously to injecting, I considered it prudent to make a tentative puncture, to ascertain whether such interference would be tolerated, and followed this course in the first case and most of the others. To close the openings made both by grooved needle and by trocar, collodion and flexible collodion have both been used, and have served the purpose, so that either may be employed. This mode of treatment was first employed by me in October 1871, and the details of the case are given in the abstract of a clinical lecture which appeared in the number of the BRITISH MEDICAL JOURNAL, dated April 6th, 1872, after having been shown to the members of the Glasgow Medico-Chirurgical Society on February 1st of that year.

The second case was shown to the same Society on May 30th, 1872, and was published in the JOURNAL named on June 15th succeeding.

Dr. J. R. Watt of Ayr successfully followed the same plan in two cases; one of which appeared in the BRITISH MEDICAL JOURNAL of April 26th, 1873, the other in that of January 31st, 1874, with a well executed photograph of the patient after cure.

Another case treated under my own care is published on October 24th, 1874, in the same JOURNAL. More recently a case has been successfully treated by Mr. Angus of Newcastle, which appeared in the JOURNAL for April 17th, 1875; and, in a private note with which he kindly favoured me, he expressed his confidence in the method employed if conducted with due care.

Since the beginning of this month (July 1875), I have treated another case with the like good fortune, and without a disagreeable symptom. The fluid was twice analysed by Professor Ferguson of Glasgow, but gave no indication of the presence of sugar.

During the past winter, a large cervical spina bifida was presented to me, which was several times injected without any appearance of

* Read in the Surgical Section at the Annual Meeting of the British Medical Association in Edinburgh, August 1875.

shock or suffering, but it ultimately succumbed to convulsions caused by the continued escape of the subarachnoid fluid. The domestic circumstances of the mother demanded her presence at home, and unfortunately she was allowed to leave the hospital with her child, and the following night the mischief took place; and, though the flow was stopped, it had already prostrated the child. Every reasonable effort was made to obtain a *post mortem* examination, but without success. I may mention that several analyses of the subarachnoid fluid withdrawn from this child were made, resulting in doubtful indications of the presence of sugar, or of some glucose matter which reduced copper oxide. At present, I have under observation another instance of this defect in the lumbar region; the child is about ten days old, and it has not yet been interfered with.

But the question may be put, How is the cure produced? or, What is the *modus operandi* of this solution when injected? The reply which most readily suggests itself is, that it is analogous to the process occurring in the tunica vaginalis consequent upon the operation for the radical cure of hydrocele.

Though the quantity of albumen in the subarachnoid fluid is small, a coagulum seems to form; adhesive lymph may be produced or deposited, and, at all events, arrest of further collection of fluid results from successful injection. This may be accompanied or followed by closing of the opening or channel of communication between the spinal canal and the protrusion.

The anatomy of this defect at once presents itself as a matter for consideration; and, on this point, I have made some inquiry, and have been rather disappointed to find that anatomists of very prolonged experience had little or nothing to offer me in the way of personal observation of its dissection. Figures of the parts have been given in books, with appropriate descriptions. All authors seem to agree in the local deficiency of the spinal canal, and the protrusion of the covering of the cord, containing a quantity of the spinal fluid, and the cord (or portions of its immediate branches), though it has been affirmed that occasionally the latter is absent. I am not aware upon what evidence this statement rests, and, meantime, prefer to believe in its presence while awaiting further investigation. Such belief may induce caution in treatment, though it need not lead us to doubt the possibility of cure, as a recent writer in the BRITISH MEDICAL JOURNAL seems to do. To assume the absence of the cord, or parts of it, in seven consecutive cases, is so entirely beyond the range of probability as to be altogether inadmissible, while possibly it was present in all. At the same time, I shall feel personally indebted to any one who may procure authentic information on this point, such information as may amount to a demonstration or dissection of parts. I am able to show you here a dorsal case, or rather a preparation of it. The child died, exhausted by the escape of the cerebrospinal fluid; no attempt having been made towards cure. The cord is seen projecting into the tumour, and attached to its walls. I am glad to say that, as yet, I cannot show an injected case, that is, a dissection of a case after successful injection, however much that may be regretted in an anatomical point of view. On this point, authors write very much as follows, which can be seen in Dr. Churchill's work on *Diseases of Children*, and there given on the authority of Dugès. "The condition of the spinal marrow is of considerable interest. Ollivier states that, when the case is not complicated with hydrocephalus, he has generally found the spinal marrow traversing the sac unaltered, except that in some cases it seems lengthened. But, if coexistent with hydrocephalus, or if the canal of the spinal marrow be distended with fluid, the cord may be flattened out, as it were, so as apparently to line the sac. In some few cases," continues Dr. Churchill, "the spinal cord seems to have left the canal, and to be contained within the tumour, forming what some authors have properly called hernia of the spinal marrow. This happens only when the deficiency is at the lower end of the spine."

In a lecture on pathological anatomy published in London this year, Drs. Wilks and Moxon write: "A funnel-like depression or umbilicus in the middle of the tumour, will generally signify the point of insertion of the spinal cord on the walls of the sac." This is worthy of recollection by those about to operate. There is evidently some variety in the position of the cord and the distribution of its branches.

* The statistics of the operation at the present time are the following. This mode of injection has been employed in ten cases. Of these, seven have been successful, and entirely so; the cases being uncomplicated by paralysis or any other deformity, and, so far as known to me, remain well. Of the other three, one has been already referred to as dying from a preventable cause, a well known danger; another occurred in the hands of Dr. Watt, who states that the child was otherwise diseased at the time; and the third is the case published by Mr Burton of Liverpool, manifestly a case in which the spinal protrusion

was but a small part of the whole deformity; though, seeing the child *in extremis*, he considered it his duty to give it even a forlorn chance. We are thus in the position of recording 70 per cent. of cures, and at the worst 30 per cent. of mortality; and, when we revert to the past history of spina bifida, such a result is sufficiently gratifying. I ought to add, however, for the encouragement of others, that all my own lumbar and dorsal cases have proved fortunate hitherto; that they will always do so, I am not sanguine enough to expect, though I can now approach their management with less misgiving. I have been exceedingly pleased to find that this method of treatment has succeeded in the hands of others, and have to thank Dr. Watt and Mr. Angus for the publication of their cases.

In managing a case of spina bifida, the following points are important.

1. The child should be in a thriving condition.
2. Make a tentative puncture with a grooved needle.
3. Draw off not more than half of the fluid contents.
4. Carefully close the puncture by collodion or otherwise, so as to prevent further escape of fluid.
5. When proceeding to inject, use a trocar with cannula of a medium size, not too small, otherwise the glycerine solution will not run readily through the cannula.
6. The parts must be carefully handled and protected by the nurse, and the injection repeated, if required.

R.S.—At the Edinburgh meeting, in August last, Professor Pirrie, of Aberdeen, drew my attention to a wet preparation of a similar case, in which the cord passed through the sac, and was attached to the outer wall of it.

ON THE USE OF NITRIC ACID AS A CAUSTIC IN UTERINE PRACTICE, AND ITS SUPERIORITY AS SUCH TO NITRATE OF SILVER.*

By JAMES BRAITHWAITE, M.D. Lond.,

Co-Editor of *Braithwaite's Retrospect of Medicine*; Assistant-Surgeon to the Leeds Hospital for Women and Children.

I BELIEVE that, in cases in which the use of a caustic is necessary for the cure of ulceration or erosion of the os and cervix uteri, that which is generally, but not invariably, the most suitable for our purpose is nitric acid.

I do not propose to enter upon the disputed question of the pathological importance of these affections, nor upon any other point in their treatment, such as the primary relief of congestion or inflammation. I cannot, however, with Dr. Routh (*Transactions of Obstetrical Society of London*, vol. xi, page 94), look upon the use of caustics as solely for the purpose of relieving congestion by means of the discharge produced, in which case nitric acid would be useless, for it produces no discharge. I find that by curing the ulceration we cure the congestion, generally, but not always, without other treatment.

I think it will be admitted that nitrate of silver is the caustic in most general use, and that it is unnecessary I should take up your time by references to writers on the subject to prove this.

The great fault of nitrate of silver for the purpose in question is the fugitive nature of its action. Its influence seldom extends beyond five or six days, even when rubbed upon and held in contact with the parts. Again, nitrate of silver is more a stimulant than a caustic, causing extreme turgescence of the capillaries immediately below the surface actually influenced. This is evidenced by the frequency of hæmorrhage, often sufficient to obscure the parts before it has been removed from contact with them. The escharotic action of nitrate of silver, such as it is, is too superficial to destroy the diseased surface, and by the production of a slough to stimulate the parts beneath to the healthy activity necessary for its separation. At the second examination, we often find the ulceration or erosion very little, if at all, altered in appearance.

The action of nitrate of silver is thus defective for our purpose—1, in duration; 2, in quality; and 3, in degree; and these faults must be atoned for by its frequent reapplication. This necessitates each time the use of the speculum, distasteful alike to patient and to attendant. I believe in this really lies the source of the opinion held by some eminent men that these diseases require little or no local treatment. Our opinions are often unconsciously influenced by our wishes. Dissatisfaction with nitrate of silver has caused the trial of other applications such as sulphate of zinc points, nitrate of mercury, potassa cum calce,

* Read before the Section of Obstetric Medicine at the Annual Meeting of the British Medical Association in Edinburgh, August 1875.

ignited charcoal-points, and electric heat, all of which either have some disadvantage or are ineffectual. I believe nitric acid to possess these advantages as a caustic in uterine practice. It requires no special preparation, and is always at hand; it cannot affect the system as may a salt of mercury; it does not spread like potassa cum calce, nor is its action so deep; it produces little or no pain, and no hæmorrhage. These advantages are trivial compared with the fact that, when it has once been properly applied, in the majority of cases no further interference is necessary, and thus that opprobrium of our branch of the profession—the frequent use of the speculum—may be done away with. When the second examination is made, it should be after the lapse of a month; and it will then sometimes be found that there is a small spot requiring a fresh application of the acid, but often the sore is seen to be quite healed, or healing satisfactorily. The eschar separates slowly, and the resulting sore has a very strong tendency to heal. The fresh mucous membrane which forms is not cicatricial in appearance, and, when healing is going on satisfactorily, has a sharply defined edge, and, being of a pale rose colour, contrasts strongly with the bright red colour of the sore. The contraction is greater than follows the use of any other caustic; but this is a great advantage, for, on account of the relaxed state of the tissues, it is just what is required to insure the permanence of the cure. The acid is best applied by means of a small and tightly rolled piece of cotton-wool, which is to be placed by means of an ordinary speculum-forceps in contact with successive portions of the surface, until the whole is covered with a white eschar. In a case of chronic endocervicitis, the acid should be applied to the interior of the open cervical canal; and, if it be not open, the case is not one suitable for this treatment. The contraction which accompanies healing is only to a healthy and natural state, provided the caustic has been used with ordinary prudence. I have never seen anything but good follow its use, and the ease with which a chronic case of cervical catarrh with ulceration or erosion may be cured by it is something marvellous. The bulk of my cases have been hospital out-patients, and the comfort the use of nitric acid has been in their treatment is very great, both in certainty of result and in saving of time. Without local treatment, very little can be done for these patients, for hygienic treatment is generally impossible, and medicinal treatment alone is useless. I shall not take up your time by details of cases, although I have copious notes of about forty, as by trial of the remedy you will soon prove your own opinion of its value.

The use of nitric acid as a caustic is so familiar to us all, especially in diseases of the rectum, that I have had some hesitation in bringing the subject before you, and should not have done so, but that I believe it is only used by two or three medical men engaged in the treatment of diseases of women. It is mentioned incidentally at the conclusion of a paper by Dr. Lombe Atthill, upon its application to the interior of the uterine cavity, that he uses it habitually in the diseases in question; and Dr. Roe of Dublin, in an analysis of the cases of uterine disease (*Dublin Journal of Medical Science*, August 1872), relates a case of extensive ulceration in which he employed it. Mr. Robert Ellis has recommended the use of a saturated solution of nitrate of silver in nitric acid; and I believe Dr. Bennet has mentioned its use. But these writers are exceptions to the general rule. It is not mentioned by Tilt in his admirable work on *Uterine Therapeutics*, nor by any other of our standard authors upon diseases of women, all of whom recommend nitrate of silver, or mention its use as the usual practice.

ON A NEW DOUBLE STETHOSCOPE: "THE HEAD-SPRING STETHOSCOPE".

By R. HARVEY HILLIARD, M.D.

THE object of this design is to produce a flexible double stethoscope which is free from the objections that apply to other instruments of this class. The advantages of a double flexible stethoscope are apparent in a moment's consideration. The ease to the auscultator, who may be seated at his patient's bedside, and with comfort to himself and his patient, to apply the instrument to all parts of the body without painful pressure or other inconvenience to the patients on the one hand, or unnecessary straining to himself on the other, is very plain; and if this can be done without loss of conduction of sound, and with an instrument as conveniently carried in the pocket as the ordinary wooden stethoscope, the superiority of the double instrument would be granted by medical practitioners, and eagerly welcomed as a boon long sought for. The objections, however, have been that instruments of this class are too bulky for ordinary practice, and that the acoustic results have been less perfect than the simple wooden stethoscope in almost universal use.

These objections I believe I have overcome by the instrument I now present to the profession.

The "head-spring stethoscope" consists of two simple tubes of finest India-rubber, very smooth, and equal in calibre, from their attachment to the chest-piece (or pieces) to the well adapted "ear-nipples", which are held in the ears by means of a low spring hinged in the middle for greater convenience of carriage in the pocket, which, by its elasticity, retains its position when carried over the head or under the chin. When it is desired to use the instrument as a differential stethoscope (Fig. 1),

the ends of the tubes, which bear suitable mounts, are screwed into separate collectors or cups; but when a binaural stethoscope (Fig. 2), with single chest-piece, is required (which, for most purposes, is the preferable combination), one of the cups alone is used, to which are attached the tubes by means of a branched body-piece which bears corresponding screw-adjustments. These changes can be made at pleasure and almost immediately. Fig. 3 shows one of the tubes fitted with cup and "ear-nipples" for use as a single flexible stethoscope. I have used the instrument for two years with increasing satisfaction; and I believe that experience will prove that I have not overrated its merits.

Messrs. Arnold and Sons of West Smithfield are the manufacturers; and they have bestowed great pains in executing my instructions.

CHRONIC POISONING BY ARSENIC.

By ARTHUR T. HARRY KERR, L.R.C.S.I., Preston.

THE following case of poisoning by arsenic in the manufacture of cotton is, I consider, of importance from a toxicological point.

John L., aged 28, a weaver, commenced to weave, about the end of September last, a green material. About the 25th of October, he first complained of being ill. At the end of October, his symptoms were loss of appetite, nausea, colicky pains, constipation, headache, emaciation, sleeplessness, strangury, inflammation of the conjunctivæ, with intolerance of light. There was no cutaneous eruption, nor local paralysis, which are usually found in chronic poisoning by arsenic. Taking these symptoms into consideration, and the fact that the others employed at the same material were affected similarly, I was led to suspect arsenic as the cause. Accordingly, I obtained some of the green yarn, and made an analysis of it; and I found it to contain a large amount of arsenite of copper (Scheele's green).

This patient was treated by emetics in the first instance; subsequently, by the moist peroxide of iron, albuminous and mucilaginous drinks. The symptoms of poisoning have now disappeared. As he is still weak, he is at present taking tonics.

The habit which weavers have of biting the ends of cotton before knotting has, I have no doubt, been the principal way in which the poison in this case was taken into the system. The absence of skin-eruption and diarrhœa in this case is unusual.

THERAPEUTIC MEMORANDA.

ON INFUSION OF MATICO AS AN INTRAUTERINE INJECTION.

In 1867, I learnt from my friend Dr. Swayne of Clifton the value of infusion of matico as an injection in cases of menorrhagia, and I have repeatedly found it of great service when the flow of blood has not been due to fibroid tumour, polypus, or malignant disease. It is not uncommon to meet with instances of menorrhagia, the cause of which is obscure, but which may be ascribed with some probability to malnutrition of the lining membrane of the uterus, ovarian irritation, or poverty of blood. Local treatment is often as important as the constitutional, and sometimes is the only means at all efficacious. The infusion can be injected with a Higginson's syringe, the nozzle of which need only be introduced into the vagina as far as possible. If the injection be propelled with any fair degree of force, some must enter the uterus; and the immediate benefit which results is a proof that it does so.

There can be no doubt, I think, that alarming and even fatal consequences have happened from the use of perchloride of iron. In the sudden emergency of *post partum* hæmorrhage, I wish to ask whether the infusion of matico has ever been tried. Is it not likely to have a beneficial effect, and probably to be free from the dangers which, under the most careful administration, may follow the injection of the metallic astringent? The point is worth considering, but I can bring no personal experience in discussing it.

I take this opportunity of mentioning that borax is a capital astringent for vaginal leucorrhœa, and may be injected in the proportion of two drachms to an imperial pint of distilled water. It seems to be decidedly superior to the traditional remedies, alum and sulphate of zinc.

JOHN KENT SPENDER, M.D. Lond., Bath.

SURGICAL MEMORANDA.

VERTICAL DISLOCATION OF THE PATELLA.

The enclosed case may, perhaps, be worth admission into the JOURNAL, being, as I think, rather a rare one.

I was sent for yesterday morning (November 1st) to attend a young girl, aged 16. On arriving, I found the patella turned on its long axis to such an extent that the outer edge lay immediately under the skin, whilst the inner edge rested on the femur at a right angle with the shaft of the bone. It appeared that she was in bed with her mistress, who touched her with the heel on the outside of the patella; whereupon she turned sharply over in bed, and suddenly discovered that she was unable to bend the leg. Sudden muscular contraction was probably the cause of the dislocation. I effected reduction without any difficulty, by raising and straightening the leg and manipulating the patella into its place.

CHARLES TERRY, Newport Pagnell.

CLINICAL MEMORANDA.

NOTES ON A CASE OF OPIUM-POISONING: RECOVERY.

I WAS called at 3 o'clock A.M. on October 13th, 1873, to see a gentleman (a druggist), recently married, who to all appearance was suffering from an attack of apoplexy. His wife was awakened by his loud snoring, and, finding him unconscious, she became alarmed and sent for me. The apparent hopelessness of the case induced me to have a consultant, who, having agreed as to symptoms, etc., left to return in a few hours. On making minute inquiry into the history of the case, I learned he had been suffering some months previously from facial neuralgia, and had taken freely of opiates, which, owing to his business, he was supposed to know how to use judiciously. On this night, he took his usual draught about half-past ten o'clock, which subsequently turned out to be pure tincture of opium, the contents of an ounce bottle. He immediately fell into a deep sleep (he usually slept very badly), and gradually passed into a state of coma.

The pulse was slow and full; breathing very laborious and loudly stertorous. The pupils were reduced to a pin's point, and the eyes turned upwards. His teeth were tightly clenched, and there was a cold perspiration all over his body. I immediately administered enema of turpentine, and put flying blisters over the region of the heart and along the spine. Stertor became less marked, and the muscles of the

face were slightly relaxed. I was now able to force down his throat half a drachm of aromated spirit of ammonia in water, and in a few moments his breathing became natural. I now placed him in a sitting posture, and employed assistants to irritate the soles of his feet with feathers. In fifteen minutes, he became slightly conscious, and, after half an hour, he spoke and begged to be allowed to sleep. A drop of croton oil was given with sugar, and hot coffee was administered by consultant, now returned. We agreed to inject one-thirtieth of a grain of atropine under the skin of the forearm. Ten minutes afterwards, the pupils were perceptibly enlarged, and consciousness became more marked. At 7 A.M., I got him to the garden, and kept him walking about between two assistants. At 9 o'clock, the effects of atropine seemed to be passing off. I again injected one-thirtieth of a grain, which restored the pupils to their natural size; but he saw very confusedly. At 10 o'clock, he passed urine, but had no motion. I left for two hours, having given directions that he be kept walking about. On my return at 12 o'clock, the desire to be permitted to sleep continued; but his general condition was much improved. He had some more coffee, a little brandy and water, and some beef-tea. There had been no alvine evacuation. A second enema was administered. He was now (at 2 o'clock) perfectly conscious; but his mind began to wander. He fancied his wife was about to separate from him, and he threatened self-destruction if she persisted in it. At 11 o'clock P.M. on the 14th, the bowels acted slightly. He was suffering much from congestive headache. I gave calomel and a draught of bromide of potassium on the 15th. Hyperæmia of the spinal cord set in, accompanied with much fever. I kept him under medical treatment, with bromide and tincture of belladonna, and had a small blister kept open on the vertex for a week. In the course of a month, he had perfectly recovered, and has never had a return of neuralgia since.

OBSERVATIONS.—In this case, it was too late to think of using the stomach-pump, as all the physiological effects of the drug were exhibited before he was seen, and some time elapsed afterwards before the stomach could be reached. The antagonistic action of the atropine was well marked. Finally, his friends attached no importance to his taking the opium, and consequently there was some difficulty about arriving at the cause.

J. J. MURPHY, L.R.C.P. & S. Edin., Dublin.

RARE CASE OF SPINA BIFIDA.

IN THE BRITISH MEDICAL JOURNAL for October 23rd, I see a case of spina bifida recorded as rare. A case which I met in my practice about two years ago somewhat similar might interest the readers of this JOURNAL.

On December 18th, 1873, I was called to see the child of Mrs. F. It was a male two days old. There was nothing noticed at birth in connection with the labour, which was natural. There was across the loins, about the length of the three last lumbar vertebrae, a bag of loose thick skin about the size of a large orange. There was a hole in the centre of this bag that would admit three fingers. I dressed the hole with a pad of lint well oiled with carbolised oil, 1 part in 30, and then applied a broad roller four or five times round the body. The next day, the hole seemed a good deal contracted. There was a little sanious oozing, yet the tumour never filled with fluid during life. On the fourth day, the child was seized with convulsions. I then omitted the pressure, and gave half-grain doses of bromide of potassium three times a day. The convulsions did not return; but there was loss of both sensory and motor powers, with great wasting of the muscles of both lower extremities, during the last few days. Death occurred on the twelfth day from paralysis. I was unfortunately not allowed a *post mortem* examination.

GEORGE ST. GEORGE, L.K. & Q.C.P.I., Lisburn, Co. Antrim.

OBSTETRIC MEMORANDA.

TREATMENT OF *POST PARTUM* HÆMORRHAGE.

I, and doubtless many readers of the JOURNAL, feel much indebted to Mr. Boddy for the publication in the JOURNAL of October 16th of a case of Injection of Perchloride of Iron in *Post Partum* Hæmorrhage, resulting in Death. Two years since, I had a severe case of flooding after a tedious labour terminated by forceps, in which, had I had the solution of perchloride of iron, I should have felt inclined to use it. While sending for it, I injected water as cold as it could be obtained for about three quarters of an hour. This effectually stopped the hæmorrhage, and the patient made a tedious but perfect recovery.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, NOVEMBER 9TH, 1875.

SIR WILLIAM JENNER, K.C.B., M.D., F.R.S., Vice-President,
in the Chair.

ON DIPHTHERIA AND ITS RELATIONS TO (SO-CALLED) CROUP. BY
R. H. SEMPLE, M.D., F.R.C.P.

THE author began by setting forth the reasons which induced him many years ago to regard as erroneous the doctrines formerly held in Great Britain on what was called "croup", and to propose a new nomenclature for the maladies which that term seemed to include. These reasons were drawn from his study of the French writings on what was called diphtheria, together with his own clinical researches into the pathology of the disease so named by Bretonneau. That physician and other French authors regarded diphtheria when it attacked the trachea as synonymous with membranous croup. When the disease now called diphtheria broke out at Tours, Bretonneau had previously seen only two cases of croup (to use his own language); but, when it showed itself as an epidemic, he studied it carefully in combination with his then pupils Velpeau and Trousseau, and they all found a remarkable uniformity in the symptoms and *post mortem* appearances; and, from the constant presence of the false membrane, Bretonneau applied to the malady the name of *diphthérite*. The physician of Tours, however, not only studied the actual features of the disease as it presented itself to his notice, but he endeavoured moreover to solve the important question whether any such epidemic as he then witnessed had ever presented itself before in the history of the world; and the result of his inquiries was to convince him that his *diphthérite*, although under different names, had existed from all antiquity, and had been described in the earliest medical writings. Dr. Semple, following out Bretonneau's views in this direction, and examining the historical evidence in existence, did not agree with him that diphtheria had been clearly described by the Greek and Roman medical writers; for he (Dr. Semple) had failed to find in the original Greek of Hippocrates or Aretæus, or in the Latin of Celsus, such a distinct description of the false membrane lining the trachea as would constitute such a disease as the *diphthérite* of Bretonneau. But, from researches into the writings of a more recent period, Dr. Semple was convinced that the disease had been accurately described as an epidemic by Spanish, Italian, Sicilian, Swedish, and French physicians. The names of the medical historians and the titles of their works, and references to important passages, were given by Dr. Semple in his paper; the chief authors consulted by him being Herrera, Fontecha, Villa Real, Sgambati, Carnevale, Nola, Ghisi, Cortesius, Wileke, Marteau de Grandvilliers, Bard, Starr, and Francis Home. At the commencement of the present century, owing to the death of a relative of the Empress Josephine from so-called croup, a number of essays on that disease were written by various European physicians; but, after examining them all, Dr. Semple had found that they included under the name of "croup" at least three different diseases. Very soon after the publication of these essays, Bretonneau began his well known researches, in which he confined the term "croup" to those cases in which there was a distinct false membrane in the windpipe; and this view was adopted by his successors of the French school, such as Trousseau, Guersant, Bouchat, Empis, Daviot, Valleix, and Rillicet and Barthez, all of whom adopted Bretonneau's name of diphtheria. Dr. Semple proceeded to adduce cases from his own experience, one of which occurred only a short time before his paper was written, and the preparation from which was shown to the Society. He compared this case with others, also from his own experience, and he showed that they all presented characters exactly similar, both in their symptoms and *post mortem* appearances, to the cases described by Bretonneau. He had also compared his own specimen with others contained in the pathological department of the museum of the College of Surgeons, which were in the catalogue of that museum described as "croup"; and he found that they were exactly identical. He also described the nature of the false membrane, which differed essentially from that which was effused from inflamed serous surfaces, and he showed that the greatest German authorities, like the French, regarded the membrane of croup and tracheal diphtheria as identical. The general conclusions at which Dr. Semple arrived from his own clinical experiences, from the perusal of the literature of the subject, and from his historical researches, were mainly the following. He by no means alleged that croup and diphtheria were synonymous words, but he maintained that the term "croup", as generally employed, comprised at least three very different affections; namely—1. Laryngismus

stridulus; 2. Infantile laryngitis; and 3. Tracheal (or rather laryngo-tracheal) diphtheria. He thought that diphtheria (although under many different names) had probably existed, like other diseases, from all antiquity; and, although its features had not been described with sufficient distinctness by the ancient Greek and Roman medical writers, its epidemics had been clearly indicated by Spanish, Italian, Sicilian, French, German, Swedish, American, and British authors from about the end of the sixteenth century down to the present time. He considered that diphtheria as an epidemic did not visit London until about the year 1858 or 1859; and he regarded as the last European epidemic of diphtheria the visitation of the disease in Florence and the neighbourhood of that city from 1860 to 1870. But, although diphtheria as an epidemic had prevailed only at fitful and irregular intervals in the history of the world, sporadic cases had always existed; the case which accompanied the present paper was of that description, and would probably have been called "croup" by a former generation.

Dr. WEST said that thanks were due to anyone who threw the light of erudition and experience on a subject regarding which there was much room for doubt. But the last word had not been said as to the relations of croup and diphtheria. And, however interesting researches into antiquity might be, he doubted whether they could settle the matter. The old writers, indeed, described accurately what they saw; but they did not give the minute details now regarded as necessary for settling diagnosis. They were like the old anatomists, who described the aorta and vena cava as they saw them accurately enough, but were unacquainted with points known at the present day. In the present day, paralysis was regarded as one of the distinguishing characters of diphtheria; but, in spite of his care in observation, Bretonneau did not seem to have noticed it. Some years ago, at the Children's Infirmary in Lambeth, Dr. West met with cases which must have been diphtheria; but he had no note of subsequent paralysis. Dr. Cheyne, an accurate observer, had described croup, and had employed bleeding successfully in it; and in several cases Dr. West had opened the jugular vein in children with success. These cases, setting in with more or less of catarrhal symptoms, cough, difficult breathing, etc., were distinct from what was called diphtheria, where there was, perhaps, no febrile movement, but extreme depression, and in most cases distress about the larynx. In such cases, bleeding would destroy the patient's life. He asked whether these were one or two diseases—whether it was to be considered that croup and diphtheria were allied to each other, being different manifestations of the same disease, and not more different from each other than the mild and the severe forms of scarlet fever. He had hitherto believed that the two diseases were distinct; that one was a local inflammation, and the other a blood-disease. He still held the same opinion; but his belief was becoming less positive in consequence of the increasing evidence on the other side. The question could scarcely be settled satisfactorily by individual observation; and he would suggest the appointment of a committee of the Society to investigate the subject. The questions to which answers were required were: Do croup and diphtheria prevail epidemically at the same time and in the same locality? Does croup (without albuminuria or paralysis) observe a different rule from diphtheria as to epidemic prevalence? Are cases of the two diseases met with in the same family at the same time? Is the croup of Cheyne accompanied by albuminuria? Are both diseases followed by disorder of the nervous system?—Sir WILLIAM JENNER had till recently held that true membranous croup and diphtheria were distinct diseases, and had strongly expressed the opinion. Larger experience, among the poor as well as among the rich, had made him alter his views; and he now regarded the evidence as all but conclusive on the other side. But still he was not quite sure on the subject. The grounds of his change of opinion were the following. He had seen in cases of croup, albuminuria, which was said to be peculiar to diphtheria. He had also met with a case in which a surgeon had a laryngeal membranous deposit in consequence of the discharge from a diphtheritic patient. Again, he could not allow the idea of a sthenic and an asthenic condition to stand in the way of the identity of the diseases. He thought that Dr. Cheyne had confounded catarrhal laryngitis with croup. In 1817 and 1818, relapsing fever was described by Cheyne and others as typhus; they bled successfully, and the patients recovered, and the conclusion was arrived at that bleeding was the remedy for typhus. He had seen one case of true croup followed by nervous symptoms; and one of apparently true diphtheria coming on after exposure to cold.—Dr. DICKINSON had seen a large number of cases of croup and diphtheria at the Children's Hospital; and he agreed that the last word had not been spoken on the subject. He thought that the view of the identity of the two diseases amounted to nothing less than recognising one cause for all membranous exudations on the larynx. If two causes were acknowledged, one a poison and the other cold, it was easily seen

how one class of cases tended to prostration and the other to the formation of a limited false membrane. He held to the old view, that croup and diphtheria were essentially distinct.—Dr. SEMPLE said that he had spent much time in investigating the subject, and he was pleased to find that authorities of high influence held views similar to his. He had long entertained the opinion that membranous croup and diphtheria were synonymous. Croup was an old Scotch word, merely indicating difficulty of breathing from some cause. No particular significance could be attributed to it. But diphtheria was an entity. Commencing on the fauces and tonsils, it might, and often did, spread into the larynx and trachea; and, when it did so, it was the same disease as that called membranous croup. He had expected more opposition to his views than had been expressed in the discussion. Dr. West, instead of opposing, had confirmed them. He had studied Cheyne's writings, and found that that physician had evidently confounded infantile laryngitis with pseudo-membranous croup. The French writers did exactly the same thing, until Bretonneau clearly distinguished the disease diphtheria. Again, in the early appearance of diphtheria in this country, many disorders were described as diphtheritic which were really not so. In concluding, he said that, while diphtheria was the same thing as so-called membranous croup, it by no means followed that croup always meant the same thing as diphtheria.

Dr. WEST proposed, Dr. DICKINSON seconded, and it was resolved: "That the Council be requested to consider the expediency of appointing a Committee to examine into the relations existing between the diseases commonly known respectively as membranous croup and diphtheria."

Incessant Muscular Movements of Right Arm.—Dr. HUGHLINGS JACKSON showed a man who was affected with constant muscular movements of the right arm. The leg also of the same side was somewhat affected in a similar manner.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, NOVEMBER 2ND, 1875.

G. D. POLLOCK, F.R.C.S., President, in the Chair.

Syphilitic Disease of Viscera in an Infant.—Dr. COUPLAND read the notes of the microscopical examination of the syphilitic patches in the intestines shown by him to the Society on its last meeting. In the heart, round cells were found in numbers betwixt the muscular fibres, especially around and near the blood-vessels, very much as in the case shown by Dr. Burney Yeo last year. In the lung, the gumma consisted of a reticulated network filled with small round cells; the growth was very vascular; at its margins, the alveoli were filled with round cells. The mass in the liver was a typical gumma in the young state ere degeneration or shrivelling had set in; at its edges, atrophied liver-cells were to be seen. In the kidney, there was nothing to be seen by the naked eye to indicate disease; but, when examined microscopically, an infiltration of cells betwixt the tissues was found, as in the heart.

Syphilitic Disease of the Heart.—Mr. PEARCE GOULD showed a syphilitic heart. It came from a man aged 40, who died suddenly when to all appearance he was well. Death was caused by apoplexy of the left lung. The anterior wall of the right ventricle consisted of grey-white material extending into the auricle. It was thought to be cancer by the medical gentleman who made the *post mortem* examination. On microscopical examination, however, it was found to be exactly like Dr. Coupland's case. In the interior of the growth, the normal tissue had disappeared. The left side of the heart was quite healthy. The history threw but little light on the case. The man had for some time complained of pain in the region of the heart, and of dyspnoea.

Syphilitic (?) Lung-Disease.—Dr. GREENFIELD exhibited a case of what he thought might be termed syphilitic pneumonia. The first question that presented itself was this: Was it pneumonia? The next was: Was it syphilis? It occurred in a child twelve months old, who was brought into St. Thomas's Hospital, and died in the out-patient room. There was a doubtful syphilitic history on the mother's side. There was complete consolidation of the right lung, like grey hepatisation, with slight pleurisy. On section, the lung-tissue was smooth, of a grey-white colour, with yellow bands running through it. The neoplasm was most marked around the vessels. There were fibrous septa running through the lung-tissue, with the usual round and spindle-shaped cells. With a high power, the alveolar epithelium could be seen here and there quite normal. In parts, there was the exudation of catarrhal pneumonia engrafted upon the earlier changes. The case seemed one of congenital syphilis of the lung. This change was usually found in the newly born. It was on one side only. Was it merely cirrhosis?

Dr. GODHART had some time ago brought two such cases before the Society. In one case, the mischief seemed set up by an accidental injury. The change occurred in the lower lobe of the lung, where it looked like red hepatisation, only not so solid, but tougher. The disease formed rings round the vessels.—Dr. GREEN felt some doubts as to whether these cases were really syphilitic or not. The changes were identical with those found in chronic pneumonia. Chronic pneumonia was common in syphilitic subjects, especially in infants; but it also occurred in adults. From histological examination, it was hard to say if they were syphilitic. The question must rest upon the collateral evidence. The lung might be affected in its entirety, or in parts only.

Cancer of the Breast in the Male.—Mr. WAGSTAFFE brought forward a case of cancer of both breasts in a male. (The man was shown.) He was first seen by him in 1874, when there was a mass in the left breast as large as a walnut. It was true scirrhus, without ulceration. In the right breast was a small nodule under the nipple. In the left axilla, there were some glands of doubtful hardness. In March, he operated upon him, and removed both breasts. The man did well. In March this year, there were felt some lumps in the left axilla, one very distinctly, as large as a walnut. He removed it in April. The scars were free from any morbid change, and there had been no return. Some indurated glands could be felt in the right axilla. The microscopical examination had been made by Dr. Creighton of St. Thomas's, who found in the nodule of the right breast normal acini of large size, with healthy epithelium. In some, there was germination of the epithelium. The acini were surrounded by connective tissue of several different forms. The fibrous tissue was a perivascular growth. The epithelium of the acini was the starting-point of the disease. It was true scirrhus. In the glands, the epithelium was also affected. In looking up the literature of the subject, Mr. Wagstaffe found that Mr. Milton had recorded forty-two cases, and he had himself discovered nine more, so as to form a total of fifty-one cases of cancer of the male breast. The cases of disease in the right and left breasts were equal; the age of the affected persons extended from 25 to 80; the duration of the disease was from one to eight years. In many, the cancer was evidently constitutional. In one case, after six years, there was no return, the man then dying of apoplexy. In another, eleven years had elapsed without a return of the disease. Infiltration of the neighbouring tissues was common. He could not find any other case where both breasts were affected.

Cancer of the Male Breast.—Mr. CROFT brought forward another case of cancer of the male breast. The specimen, he said, showed badly, and was blanched by keeping. The case occurred in a labourer aged 52, who came to St. Thomas's Hospital in June. He had noticed a lump for three months. It was above the nipple. The man was spare, simple, and not well nourished. The mass measured 4½ in. from above downwards, and 3½ in. from side to side. It appeared as three divisions. The middle third was boss-like, and the skin over it was purple and smooth. The upper third was purple, but not so deep-coloured, and felt elastic, as if containing fluid. The lower third was but slightly raised above the surrounding parts, and there were adhesions betwixt it and the skin. There was no retraction of the nipple; nor was there mischief in the axillary glands. There was a small nodule in the skin. He thought it a case of spindle-celled sarcoma; but afterwards doubted whether it were not scirrhus. On July 14th, he removed it. On section, there was no creaking; the middle lobe was firm, the others juicy. Sections were exhibited, and showed it to be spindle-celled sarcoma. The man lived eight days, and then sank from no definite disease. There was no microscopical examination made of the glands.—Mr. MAUNDER said there was in the London Hospital Museum a specimen of cancer of the male breast removed by himself.—Dr. COUPLAND asked if, in Mr. Wagstaffe's case, Dr. Creighton had found any vacuolation of the cells. The answer was in the negative.—Mr. HOWARD MARSH said there had been a case of cancer of the male breast in St. Bartholomew's Hospital some time ago. It was thought to be scirrhus, but turned out to be really fibrous.—The PRESIDENT said that he had seen three cases of true scirrhus in the male breast. One was the case mentioned by Mr. Wagstaffe, that survived six years, and died of apoplexy. One case, where the cancer was removed in 1869, is still alive; and a third, operated on in 1873, is quite well.

Cystic Oxide Calculi.—Mr. CHRISTOPHER HEATH showed some calculi of cystic oxide. They were really cystine. There were two series of them, in all nineteen, and they were removed by median lithotomy. They came from a man aged 28, who had passed some *per urethram*. There was retention of urine, and, when a catheter was passed, it grated in its passage; so he operated forthwith. In the prostate were found sixteen small stones, and in the bladder three. All showed a greasy section. They were not green, because they had not

been long enough exposed to the air. Cystic oxide calculi became green after time only. All calculi were of renal origin, and why some of these had lodged in the prostate it was not easy to say. In the larger stones in the bladder, the lamination was distinct. The man made a good recovery; there was no cystine in his urine but once, and that was on the third day. This form of calculus was very rare. Sir Henry Thompson had only met with one case. It broke up oddly under the lithotrite.—Mr. HICKS gave an account of the chemical examination of the calculi. They were pure cystine. The method of examination was given. The external layers were concentric. There was no actual nucleus; but, in the larger calculi, large central portions were found. There were two forms of crystals of cystine: 1. Hexagonal prisms; and 2. Four-sided tables.

Epithelioma of Tongue and Jaw.—Mr. HEATH exhibited an epithelioma of the tongue and jaw. It occurred in a man aged 52. The skin was quite healthy. The method of operation by which the mass was removed was described. The tongue was largely healthy. A previous operation had been performed in order to loosen the tongue from the jaw; but it failed to afford relief. The tissues below the tongue were most affected. The pain was felt entirely in the occipital region. A return of the disease was probable; but so far the man was well.

Cancer of the Rectum.—Mr. HEATH showed a case of cancer of the rectum after colotomy. The operation was performed two years and nine months ago, as a mass of cancer protruded at the anus. The case made a good recovery. He removed portions of the epitheliomatous mass from time to time. Then the vagina became involved. She went into the Middlesex Hospital cancer-wards. The anal and vaginal openings formed ultimately one cloacal opening. The bladder was healthy. There was a secondary mass of cancer in the liver.

Carcinoma Lipomatousum.—Dr. HILTON FAGE exhibited a case of carcinoma lipomatousum. It occurred in a woman aged 57, who had no urinary symptoms during life. The left kidney was granular, and weighed four ounces and a half. The other was smooth, with whitish nodules, which were extensions from a mass in the hilus which looked like fat, and grew into the kidney and renal vein. On microscopic examination, it looked like fat-globules in cells, rectangular or of various shapes. When hardened, it was found to be a true carcinoma, but of the very rare form called carcinoma lipomatousum. There was no secondary cancer.

Gangrenous Ovarian Cyst.—Mr. KNOWSLEY THORNTON showed a fresh specimen of an ovarian cyst which had become gangrenous. A week ago, the patient came to the Samaritan Hospital. She was pregnant; the cyst was therefore tapped, and ovariectomy deferred till the pregnancy was over. Pain, however, in the abdomen set in, with collapse. Several doses of opium were given ere relief was obtained. After a consultation, it was determined to remove the cyst. The woman was very ill, and almost dead. She revived during the operation. The cyst was found behind the uterus, with the pedicle twisted. The cyst was black and white mottled. The patient rallied for an hour or two, but sank in the night. The specimen had curiously lost its offensive odour, and the dark parts had become red from the exposure since its removal.

HARVEIAN SOCIETY OF LONDON.

THURSDAY, NOVEMBER 4TH, 1875.

W. H. BROADBENT, M.D., President, in the Chair.

DR. DE G. GRIFFITH exhibited a case of Alveolar Sarcomatous Tumour, and narrated a case of Acute Chorea.

The Diagnosis and Treatment of the Curable Forms of Fibroid Tumours of the Uterus.—Dr. ALFRED MEADOWS read a paper on this subject. These forms of morbid growth being more amenable to successful treatment than was generally supposed, their diagnosis in relation to the uterine walls was of the first importance, and Dr. Meadows relied very confidently on the differential indications of hæmorrhage and pain. Hæmorrhage, according to his experience, pointed to an intrauterine, submucous, and curable form of tumour; whilst pain was usually associated with the subperitoneal or almost incurable class. Coming to more exact means of diagnosis, it was found that cervical displacement arose from a growth in the opposite direction; that a closed os, with small and rigid cervix, were almost fatal signs of incurability; the larger and softer the cervix, the better being the operator's chances; and that, by the use of the sound, very valuable information might also be obtained. As the subperitoneal variety of tumour did not encroach on the cavity of the uterus, there was none of that elongation which was met with in the submucous form in direct proportion to its size; and by working with the sound, in conjunction with the finger

in the vagina, one could tell, by the thickness of tissue intervening between these points, whether the morbid growth occupied the anterior or the posterior uterine wall. As regarded the drug-treatment of these cases, he had only derived real benefit from ergot, which frequently acted well in small soft tumours, by cutting off their supplies of blood, and causing steady compression by contraction of the unstripped muscular fibres in which they were embedded. Operative measures were next discussed; and gastrotomy, which was occasionally performed for removal of subperitoneal growths, was only justifiable if the tumour were fairly out of the pelvis, and the cervix, as well as a good part of the body of the uterus, free from disease. In the submucous varieties, the tumour was reached by dilatation of the os and cervix; and, its investing capsule being broken down, enucleation was done more or less completely with the finger; valuable aid being derived in very large growths from Greenhalgh's olive-shaped cautery, removal being then completed by the expulsive action of the uterus, aided, if necessary, by ergot. As regarded after-treatment, rest was, of course, all-important. Hæmorrhage must be checked by styptic plugging; septicæmia, by antiseptic injections; and inflammation, by opium; it being pointed out that cystitis and cellulitis more frequently followed operations on the anterior than on the posterior uterine wall, in consequence of the larger quantity of cellular tissue which lay between the uterus and bladder, than between that organ and the rectum.—A discussion followed, in which Dr. Wynn Williams, Dr. Bantock, Dr. Gustavus Murray, Dr. Aveling, Mr. John Scott, Dr. De G. Griffith, and Mr. Knowsley Thornton, took part.

GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.

TUESDAY, OCTOBER 12TH, 1875.

W. T. GAIRDNER, M.D., President, in the Chair.

THE PRESIDENT opened the session by a retrospective glance at the kind of work done by the Society since its formation two years ago, and made some suggestions as to keeping the Society strictly to the basis of its constitution as composed of working members.

Cure of Iliac Aneurism.—Dr. WILLIAM MACEWEN showed a patient with multiple aneurism, formerly shown to the Society (*see BRITISH MEDICAL JOURNAL*, May 22nd, 1875). Since then, a successful treatment of the larger aneurism, involving the upper part of the femoral and the lower part of the external iliac artery on the right side, had been carried out. At the meeting of the Society in March, pressure was recommended, and, failing that, galvano-puncture was suggested. The rigid state of the vessels generally seemed to preclude the idea of ligature of the common iliac artery. The patient was treated steadily with large doses of tincture of steel, as a preparative measure. Pressure with Lister's abdominal tourniquet on the common iliac for twenty-four hours having failed to produce more than a mere temporary impression, and other trials of pressure above and below the aneurism for four or five hours each day having likewise failed, another plan was tried on April 13th. The common iliac was compressed till pulsation had completely subsided in the aneurism, and a very fine steel needle was then introduced deeply into the sac, and moved at intervals in various directions during an hour, when it was removed without hæmorrhage; the pressure on the iliac was gradually relaxed, and removed in about fifteen minutes, when the walls of the sac seemed firmer; this was more marked next morning, and on April 18th the tumour was solid and the pulsation had stopped. The patient went to the Highlands in May, and had no accident, with the exception of a small superficial abscess and boil over the tumour. On July 26th, a teaspoonful of pus was evacuated, and a small slough of the cellular tissue came away, and the wound soon healed. As now shown to the Society, he had been free from this pulsating tumour for six months, and he had been regularly at work. Dr. Macewen said he used the needle with the view of trying the effect of a foreign body in producing coagulation; he discussed the question as to whether this part of the treatment had been the cause of the success, or if it were the pressure which had really succeeded; and he raised the question of the success of galvano-puncture depending, in whole or in part, on the presence of the needle in the sac apart from the galvanism.

Patient with Addison's Disease.—Dr. DONALD FRASER showed a typical case in a young man aged 18, employed as a scourer for the last two years. His work consisted in moving bundles of yarn (14 lbs.) backwards and forwards in water; this he managed easily at first; but, about a year ago, he became less able, and of late he had done but little work, although going regularly for eight hours to his business. His father, in whose place the lad worked, thought he was merely lazy, as he did not seem to be in any way ill, and advice was sought on account of an increasing discoloration of the skin, which had been no-

ticed first about eighteen months ago; it began on the lips, and appeared a little later about the navel; the boy used to scrub his skin diligently, thinking it was dirty there. At present, the whole skin is affected; the face, neck, and hands are as dark as those of a Hindoo; at the axilla, the inside of the thighs, the penis and scrotum, and the umbilicus, the tinge is deeper. There are well marked bluish-black stains on the lips, gums, and mucous membrane of the cheeks. There is no affection of the thoracic organs to be made out, although the boy now feels some palpitation on running; there is a nervous *bruit* in the neck; there is no albumen in the urine; the blood seems normal as to white corpuscles; he has not lost much flesh: in 1871, he was 8 st. 4 lb.; in 1874, 7½ st.; and now he is 8 st. There has been no vomiting, and no pains have been felt anywhere. No explanation of the cause of illness can be found; there has been no injury; the family history is good; and the lad used to be strong and active.

Penknife Swallowed and Passed by an Infant.—Dr. HECTOR CAMERON showed a double-bladed penknife, two inches and a half long, which had been swallowed on May 24th by an infant of 8½ months, and passed from the bowels on August 27th. The blades were in great part gone, and the tortoiseshell back of the knife had entirely disappeared. With the exception of dark stools, doubtless due to the steel, nothing unusual was observed in the state of the child from first to last.

Aneurism involving Recurrent Laryngeal Nerve; Unsuccessful Tracheotomy.—Dr. JOSEPH COATS showed a preparation of an aneurism of the aorta. The patient had been admitted to the Western Infirmary with symptoms of acute laryngitis, with profuse expectoration and considerable dyspnoea. There was a history of syphilis. After recovering so far that he could go about the ward and grounds, he began to have recurring attacks of dyspnoea, which were relieved by chloral. A severe attack occurred suddenly one morning, and death seemed imminent, apparently from some obstruction in the larynx. It was noticed at this time (the first occasion on which such a spasm had been observed carefully) that the obstruction seemed to be almost entirely in expiration. As a last chance, tracheotomy was performed, but without advantage, and death occurred in a few hours. A small aneurism was found to arise from the transverse portion of the arch of the aorta, projecting upwards and backwards; it was adherent to the roots of the great vessels by its anterior wall, and to the trachea by a portion of its posterior wall; it bulged into the trachea at its lower extremity, but not sufficiently to cause serious obstruction. The mucous membrane over this swelling was very red, and the redness extended into the finer bronchi, which contained a frothy and bloody mucus. The left recurrent nerve was adherent to, and partly imbedded in, the posterior wall of the aneurism, its fibres being somewhat stretched and expanded.

VERTIGO.—M. Piorry has lately read before the Academy of Medicine at Paris a memoir on vertigo. In his opinion, vertigo, headache, and sea-sickness are merely products of visual disturbances, especially of irisaigia. Therefore, those persons who are subject to it should not look continuously or with much attention at objects which actively stimulate the sight. This advice is especially applicable to those patients who are affected by any degree whatsoever of strabismus. They should remain in the dark, lie down on a bed in a horizontal position, and use all their mental energy to overcome the optical sensation experienced; and call up all the power of their will to drive away any uneasiness they may feel, and to call to mind that the brain has nothing to do with this train of symptoms, which last but a short time, and are scarcely ever followed by accidents or serious lesions of the encephalon. Pressure, frictions of the diseased eye, the application of warm and sometimes cold substances, slight douches, and still more the projection of water on the eyelids, may be of some use. Recourse may be even had to the extract of belladonna, which, being spread on a plaster which is brought into contact with the affected eye, promptly dilates the pupil. It is advisable to make frictions on the diseased side with some opiated liniment containing morphine, etc. A very simple and common treatment, which seems more efficacious because it succeeds very well in preventing headache, consists in provoking the physiological action of the stomach at the outset of the evil by taking a biscuit soaked in a few spoonfuls of good wine—a plan useful in irisaigia, if adopted in the first moment when the irisaigic circle makes its appearance. It is equally important to combat the complications or circumstances which predispose to vertigo: for instance, dyspepsia. Large doses of bicarbonate of soda and bismuth are then given. When the liver is increased in size, extract of berberies or alcoholate of quinine is administered. Plethoric subjects are treated by depletion. For anæmic patients, a treatment consisting of good food, exercise, iron, etc., is indicated.

BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, NOVEMBER 13TH, 1875.

DANCERS' CRAMP.

IN a recent number of the *Wiener Medicinische Wochenschrift*, Dr. B. Schulz describes and comments on a peculiar disorder of which he has seen several cases. He begins by briefly relating a case.

Fraulein Sch., a solo-dancer in the Court Opera in Vienna, complained of suffering very severe pains while dancing. She said that they began in the soles of both feet, and spread, with increasing severity, to the calves of the legs; they at last became so violent, that her feeling of security was lost, the feet seeming as if made of wood. These pains were accompanied with violent palpitation; and, if she continued to dance, she felt faint, and sometimes lost consciousness, the body becoming quite rigid. When the pain and palpitation were less intense, the pain continued after dancing, and ceased very gradually, leaving some tenderness of the soles; and the suffering was reproduced on her again appearing on the scene, to such an extent as to cause her to require assistance. She informed Dr. Schulz that nearly all female solo-dancers were affected in the same way, though not all to the same degree; and that the ballet-master employed the following means of relief when the pain lasted some time. He either tied a handkerchief tightly above the ankle, or had the individual placed on a wooden cylinder, which she rolled backwards and forwards while the whole weight of her body was supported on it. In this way the pain was relieved so that the dancing could be resumed; but its return was not prevented.

The successful treatment of this case by galvanism led Dr. Schulz to be consulted by two other ladies affected in a similar manner, but without syncope. He therefore endeavoured to ascertain the cause and seat of the disorder. He was informed that female solo-dancers alone were affected, not males, nor the male and female members of the *corps de ballet*. The three ladies all told him that during the vacation, when dancing was quite interrupted, not only did the pains never set in, but the tenderness of the feet, which usually continued in the intervals even when they walked, entirely disappeared. He therefore concluded that the cause of the pain lay in the *pas* performed on the points of the feet.

In this step, the dancer places herself on the point of the second phalanx of the great toe, in such a way that she either moves herself forward in musical time in the most different directions on the points of both feet, or, balancing herself on one foot, turns very rapidly on her vertical axis, and from this position attempts by a spring to fall on the same foot or on the point of the other foot, and at the same time to preserve a graceful balance. The centre of gravity of the body passes beyond the extended great toe, and falls only over the little one. To bring this about, the heel being raised, not only must the knee- and ankle-joints be rendered immovable, but the whole foot, and especially the great toe, must be fixed. All the muscles connected with the foot must contract in a co-ordinate manner; and, as this is not provided for by nature, they must be trained to it by innumerable repetitions of most troublesome movements. There is no doubt that the principal share of the work must fall on the muscles which fix the metatarsus and the phalanges of the great toe. Such movements, carried to excess, must

produce mechanical results at variance with the objects of the muscles of the foot.

If a dancer be desired to point her foot while sitting, she extends it in such a way that the dorsum of the foot forms a nearly direct line with the leg; the instep being arched and narrowed, the sole more concave, but less broad; the leg, foot, and great toe seem as if fixed in one piece; the first phalanx of the great toe is a little bent on the head of the metatarsal bone, but rigid; its unguis phalanx only can be moved a little with the hand. The highly developed *abductor hallucis* muscle is readily felt; even in the relaxed condition, it is developed to such an extent as to be indicative of the foot of a solo-dancer.

If the dancer be asked to perform the step with bare feet, she cannot do so; because, as she says, the unguis phalanx requires a certain amount of support. The dancing-shoe is made rather wide; the sole is of soft leather, and shorter than the foot, reaching only as far as the posterior third of the unguis phalanx of the great toe. The upper part, generally of satin, projects forward, and supplies the place of the deficient leather of the sole. This part of the satin is worked with strong silken threads, so that it may not be torn. In the interior of the shoe, over the leather sole, is a layer of thin firmly pressed pasteboard, either extending over the whole breadth of the anterior part, or limited to the length of the great toe. In the former case, it is carried back, gradually narrowed, as far as the heel. The leather sole and its covering are lined with fine kid leather. The heel part of the shoe is quite soft, consisting only of satin; and the shoe is fastened above the ankle by narrow ribbons. Without this preparation, the pointed step is not possible.

Dr. Schulz then describes the effects of electricity on the muscles of the foot. If one pole of an induction-apparatus be applied over the posterior tibial nerve, where it lies superficially at the lower third of the leg, and the other over the flexor longus pollicis pedis, the foot assumes exactly the position of the pointed step, but the unguis phalanx is immovable. The dancer also said, when the experiment was tried on her, that she had the same feeling as when she was bringing her foot in position for the step. Electrification of the posterior tibial nerve alone allows a little movement of the unguis phalanx of the great toe, the rest of the foot being immovable.

Here may be distinctly recognised the action of the long flexor of the great toe, which is capable of fixing the unguis phalanx, with, however, the mechanical assistance of the addition to the sole of the shoe. On the other hand, as the posterior tibial nerve, on entering the calcaneo-astragalar canal, gives off, in its continuation as internal and external plantar nerves, only motor branches to the plantar muscles, and as it is especially those of the latter which are attached to the great toe that are mostly supplied by it, the abductor, adductor, and flexor brevis of the toe may be considered to be those muscles which have to contract most powerfully.

The cause and seat of the disorder being ascertained, it is not difficult to recognise its essential character. The work done by a muscle depends partly on the strength and partly on the amount of contraction; the former being in proportion to the transverse section of the muscle, the latter to its length. Hence, in the above named muscles, in consequence of the increase of their transverse diameter by frequent exercise, the voluntary contraction easily passes into a painful tetanus-like one. The following characters of the malady agree with this explanation.

1. The localisation of the pains, which, on more accurate examination, were found indeed to proceed from the sole of the foot and its inner edge, but were also felt on the dorsum, and spread backwards next along the calf, but at its side. They thus corresponded very closely to the position of the above named muscles; the position of the interossei explained the pain in the soles of the feet.

2. The insecurity of the movements, since, as the dancers expressed it, the feet felt as if "wooden", when they were obliged to continue the dance for some time while suffering severely. It is known that, during pain in the muscles, the ordinary muscular sense is deadened.

3. The result of the remedy employed by the ballet-master for cutting short the pain further indicates a cramped state of the muscles.

In the treatment, before he was accurately acquainted with the details of the malady, Dr. Schulz applied the galvanic current from the cervical vertebrae to the tibial nerve in the popliteal space. The result of this was, that the palpitation and fainting did not return, and the local pain was relieved. He afterwards applied the induction-current in the way mentioned above; and, when the more severe pains had ceased, the disposition to tetanic contraction was treated. A sensation of forced contraction remained, by which, indeed, all female solo-dancers are more or less troubled, but not to such an extent as to diminish their feeling of security in executing the above described steps of the dance.

THE QUARTERLY RETURN OF THE REGISTRAR-GENERAL.

DURING the spring quarter, 1875, the registered number of *persons married* in the United Kingdom was 120,330, and the marriage-rate was 14.7 per 1,000 persons living. In England, the rate was 16.2, and was slightly below the average. The marriage-rate was very high in the June quarter, 1873, and has since declined. The lowest county marriage-rates were 9.1 in Cambridgeshire, 10.1 in Suffolk, and 10.8 in Essex; the highest rates in counties were 19.5 in Lancashire, 20.5 in Northumberland, and 21.6 in Lincolnshire. There was a decline in the number of marriages throughout England generally, except in the North Riding of Yorkshire, and the extra metropolitan portions of Middlesex and Kent; the decline was most remarkable in Westmorland, Cornwall, and Cumberland.

During the quarter that ended on September 30th last, the *births* of 273,499 children were registered in the United Kingdom; the rate being 33.1 per 1,000. In England, the birth-rate for the quarter was 36.0 per 1,000, which was 0.5 above the average rate in the ten preceding corresponding quarters, but was somewhat below the rate in the third quarter of 1874. The slight decline in the birth-rate during the first nine months of this year appears to be partly due to the decrease in the marriage-rate, which commenced in the early part of 1874, and has since prevailed. The birth-rate during the quarter did not exceed 28.4 and 30.2 in the principally agricultural population of the south-western and south-eastern registration divisions, whereas it was equal to 38.7 and 41.6 in the manufacturing and mining population of the north-western and northern divisions. In the eighteen large English towns, the rate was 1.8 above the average in England and Wales; it ranged from 31.5 and 32.3 in Norwich and Nottingham, to 41.6 and 50.0 in Sunderland and Salford respectively. In fifty other large towns, the birth-rate averaged 35.9 per 1,000; and ranged from 24.6 and 25.5 in Cheltenham and Hastings, to 45.5 and 47.1 in Wigan and Gateshead.

During the three months ending September 30th last, 158,811 *deaths* were registered in the United Kingdom, and the death-rate was 19.2. In England and Wales, 121,459 deaths were recorded, equal to an annual rate of 20.1 per 1,000, and 1 per 1,000 below the average rate in the corresponding quarters of the ten preceding years. The rate last quarter was lower than in the same period of any year since 1862, excepting only in 1867 and 1873, when it was 19.9 and 19.5 respectively. The excess of male over female mortality has steadily increased in recent years; and of equal numbers living, the deaths of males last quarter were equal to 114 to each 100 deaths of females. The death-rate in Sussex and the extra-metropolitan portion of Surrey, where the population is principally agricultural, was so low as 14.8 and 14.9 per 1,000; whereas, in Lancashire and in the East Riding of Yorkshire, with a population mainly engaged in mining or manufacture, it was 24.3 and 25.1 respectively. The death-rate amongst the 13,500,000 persons residing in towns, was 22.3 per 1,000; amongst the rural population of 10,000,000 it was 17.2 per 1,000. The urban rate was 1.6 and the rural rate 0.1 below the average of the quarter. Urban rates have undoubtedly in recent years showed a commence-

ment of the results to be expected from the awakening of national interest in sanitary matters. Urban sanitary authorities, with the assistance of their medical officers of health, have in most large towns been for some time earnestly endeavouring to improve the public health, and the death-rate has been reduced. The sanitary welfare of rural districts is for the most part in the keeping of local boards of guardians, who, in a large proportion of cases, have not yet formed a proper estimate of their responsibilities under the Public Health Act of 1872; and, except in certain localities where combined sanitary districts have been formed, the medical officer of health is usually a local practitioner, often without any special qualifications for the appointment, who receives an almost nominal salary. Under these circumstances, it can hardly be a matter for surprise that comparatively little sanitary work has yet been done in rural districts, and that the decline in their death-rate has not kept pace with that of our larger urban population.

In the eighteen largest English towns, including London, with an estimated population of rather more than 6,500,000 persons, the death-rate was 23.8 per 1,000, and exceeded the general urban rate by 1.5. The rates in these eighteen towns ranged from 19.2 and 21.5 in Portsmouth and London to 30.1, 31.3, and 32.4 respectively, in Hull, Leicester, and Salford. In fifty other large towns, having a population of about 2,750,000, the death-rate was equal to 21.4; the lowest rates were 14.8 in Dover, 15.1 in Reading, and 15.2 in Cheltenham. The following were the highest rates: Wigan, 26.3; Northampton, 26.8; Bury, 26.8; Gateshead, 27.3; Stockport, 28.7; Preston, 31.1; and Ashton-under-Lyne, 37.2. The high rates in these last-mentioned towns were almost entirely due to the fatality of the principal zymotic diseases. Their sanitary condition is deplorable.

The 121,459 deaths from all ages, included 37,118 of infants under one year of age, equal to 176 per 1,000 of the births registered. In the agricultural counties of the south-western registration division, infant mortality averaged but 119 per 1,000, and was but 95 in Dorsetshire and 114 in Wiltshire; whereas, in the principally mining population of Durham and Northumberland, it was equal to 222 and 223, in Nottinghamshire to 215, and in the East Riding of Yorkshire to 252 per 1,000; whilst, in the districts of Hull and Driffield, it was so high as 317 and 290 per 1,000 respectively. Excessive rates of infant mortality are almost invariably found in urban populations; but it is also important to bear in mind the wide range in the rate of mortality among infants in different towns. In the eighteen large English towns for which weekly returns are published, infant mortality averaged 222 per 1,000, exceeding by 46 per 1,000 the proportion in the whole of England and Wales, and corresponding with that in the mining county of Durham. In these eighteen towns, however, infant mortality ranged from 149 and 178 in Oldham and Portsmouth, to 277 in Liverpool, 288 in Hull, 300 in Norwich, and 407 in Leicester. The remarkable difference between the rate of 149 in Oldham and 407 in Leicester, appears to afford ground for special inquiry, which could not fail to result in an useful contribution to our at present limited knowledge of the true cause of these wide variations in urban infant death-rates.

The annual rate of mortality among children and adults aged between one and sixty years, was equal to 11.0 per 1,000 living at those ages in the whole of England and Wales; it ranged from 9.7 and 10.3 in Norwich and Portsmouth, to 16.8 and 19.9 in Oldham and Salford. Among persons aged sixty years and upwards, the rate of mortality averaged 5.48; and ranged from 4.51 and 4.63 in Bradford and Bristol, to 7.48 and 101.0 in Newcastle-upon-Tyne and Liverpool. The death-rate among elderly persons in Liverpool still conspicuously reflects the unhealthiness of the town.

The deaths from all causes included 14,006 which were referred to diarrhoea, 4,609 to scarlet fever, 2,883 to whooping-cough, 2,849 to different forms of fever, 1,152 to measles, 628 to diphtheria, and 164 to small-pox; in all, 26,283 deaths, equal to an annual zymotic rate of 4.4 per 1,000, and ranging from 2.2 per 1000 in the south-western agri-

cultural counties, to 5.6 and 5.7 in the principally manufacturing population of the York and north-western divisions. In the eighteen largest towns, the average zymotic rate was 6.5, and ranged from 4.6 and 4.9 in Portsmouth and Oldham, to 11.4 and 12.5 in Salford and Leicester. In the fifty towns ranking next in size, the zymotic rate averaged 5.0 per 1,000; it was but 1.5 in Southampton, 1.8 in Shrewsbury, and 1.9 in Dover, while it ranged upwards to 8.5 in Yarmouth, 9.3 in Northampton, 9.6 in Preston, and 14.1 per 1,000 in Ashton-under-Lyne. In Salford, the zymotic fatality arose from the combined effects of measles, scarlet fever, whooping-cough, and diarrhoea; scarlet fever as well as diarrhoea were exceptionally fatal in Leicester; diarrhoea was the principal cause of the high zymotic rate in Yarmouth, Northampton, and Preston; and in Ashton-under-Lyne, measles and scarlet fever contributed, with diarrhoea, to produce the exceptional annual death-rate of 14.1 per 1,000 from the seven principal zymotic diseases.

The 14,006 deaths from diarrhoea were equal to an annual rate of 2.3 per 1000. In the eighteen largest English towns the death-rate from diarrhoea has steadily decreased of late years, whereas it has increased in fifty other large towns, and increased at a greater rate in the rural portions of England and Wales, which would point to real sanitary progress in the eighteen towns; whilst similar progress has not been shown in the smaller towns and rural districts, where it is much wanted, and where the growing evils of overcrowding, the increasing difficulties of sewage disposal, and continued pollution of streams in many cases used as sources of water-supply, have not even been kept in check. Diarrhoea was very fatal in Birmingham and Leicester.

Next to diarrhoea, scarlet fever was the most fatal epidemic during last summer. The present epidemic commenced in the last quarter of 1873, and increased in intensity throughout 1874. During the first nine months of this year the epidemic has continued to prevail, but as the fatal cases in each quarter have been below those in the corresponding quarter of last year, the climax of the present epidemic probably occurred in the last quarter of 1874. Among the large towns, the disease was more fatal during the last quarter in Bristol, Stockport, Birkenhead, Maidstone, Bradford, and Ashton-under-Lyne. But in many small towns the fatality was more intense, especially in Buckfastleigh, with a population of less than 3,000 persons, where 21 persons (equal to an annual rate of 28 per 1,000) died of the disease. The death-rate from fever, including typhus, enteric, and simple continued fever, has of late years shown a remarkable and steady decline, which was maintained during the quarter now under notice. It was only 0.30 and 0.34 in the mainly agricultural population of the eastern and south-western divisions, whereas it was 0.63 in the manufacturing and mining population of the north-western, York, and northern divisions. In the eighteen large towns, the annual fever-rate last quarter averaged 0.51 per 1,000, and ranged from 0.33 and 0.35 in London and Newcastle-upon-Tyne, to 1.35 in Nottingham and Sheffield. The remarkable decline in the prevalence and fatality of fever in London in recent years affords conclusive evidence of the improving sanitary condition of the metropolis, the result of more complete sanitary organisation, of increased facilities for isolation of fever cases, and of a more liberal devotion of intelligence and money to sanitary purposes. The fever-rate was as high as 1.37 in Carlisle; 1.28 in Dudley; and 1.01 in Ashton-under-Lyne. The deaths from small-pox in England were probably fewer last quarter than at any period since the discovery of the efficacy of vaccination.

The natural increase of population in the United Kingdom produced by the excess of births over deaths during the quarter was 114,688; and in England that increase was 89,322. The emigrants of British origin who sailed from the United Kingdom were 37,560; a less number than in the corresponding period of any year since 1862.

The cold weather, which set in on June 11th, continued throughout July and until August 5th; the mean temperature during this period of fifty-six days showed an average deficiency of 3.1 degrees. On August 6th, warm summer weather set in, and, with few exceptions, prevailed up to the end of the quarter; this period also embraced fifty-six days,

the average excess being 3.2 degrees. The fall of rain during the quarter at Greenwich amounted to 10.3 inches, and exceeded the average by 2.9 inches. The price of meat remained high; but the prices of wheat, potatoes, and coal were lower. The number of outdoor paupers was 30 cent., and of indoor paupers 9 per cent. less than in the corresponding quarter of 1870.

FOOT-AND-MOUTH DISEASE.

WEEK after week, the foot-and-mouth disease is reported from all parts of the country as on the increase. Year after year, the disease is permitted to spread far and wide without any general and systematic effort being made to check it. There exists a well manned veterinary department of the Privy Council; but its action is spoiled by a Permissive Act, which allows local authorities to adopt restrictions, or not, as they please. The result is, that, whilst the stockowners of one district are hampered by regulations, those of neighbouring districts separated by no natural barriers are left free to do as they choose, and disease spreads. Further, it seems to us that the Contagious Diseases (Animals) Act and the Privy Council orders are made subservient to political exigencies, and that they can never be made strong enough to fairly meet the requirements of the country until the public take a greater interest in the matter; until, in fact, popular opinion is so strongly expressed as to warrant Government in acting fully up to the suggestions of their professional advisers.

When the cattle-plague decimated our herds and threatened a meat-famine, public interest was aroused, and active measures were soon successful in stamping out the disease. Cattle-plague was quickly fatal; foot-and-mouth disease is rarely so, and thus the radical measures applied to the one are thought unnecessary for the other. This is true so far as slaughtering is concerned, but absolutely false as to the other essential points of detecting disease and stopping the movements of animals.

It may seem startling to say that foot-and-mouth disease has caused greater loss to the country than cattle-plague; but it is the simple truth. Loss is entailed by a diminished supply of milk, by the depreciation of fat stock, by the abortion of cows in calf, and by many other causes, just as certainly as by death. One of the witnesses before the Select Committee of the House of Commons, in 1873, produced a calculation, showing that, in 1872, the country lost £12,000,000 from foot-and-mouth disease alone. This estimate is applicable only to an exceptional year; but it must be remembered that the disease is always rife, and that it has been so more or less for thirty years.

It is a moderate and safe calculation to say that the contagious diseases of animals cost us over one million a year, and this loss, although first felt by the stockowner, affects the whole community by its action on the price of meat.

The question, then, of the prevention of these diseases, of which foot-and-mouth disease is the most prominent, is one of great interest to the sanitarian and the political economist; but of greater still to the consumer of meat.

Much ignorance prevails concerning the disease. The prescriptions offered almost daily through the press show that an idea is extensively held that the affection is merely one of foot and mouth. It is really a specific eruptive fever, which must run a definite course. The eruptions on the mouth, teats, and feet are simply the local accompaniments, and require palliative treatment. It is quite right to treat the mouth and feet with a view to assisting mastication and locomotion; but it is sheer ignorance to think that any local treatment is capable of "killing" or checking the disease. We offer no treatment. There is not a single modern work on veterinary medicine which does not give thoroughly scientific and reliable information on the subject, and we have no reason to believe that any veterinary practitioner is not quite capable of guiding a herd or flock through the disease, if only his directions be followed.

The treatment of individual cases is, however, a small matter com-

pared with the total extinction of the disease, and this is quite within reach, if only our regulations were framed with judgment and enforced with energy. Foot-and-mouth disease never originates in this country, but is always due to contagion. It was first imported from the Continent, and is now probably occasionally re-introduced by foreign stock. The mere stoppage of foreign importation would, however, never free us from the disease. The movement of diseased home stock is the chief cause of its prevalence, and we look upon Ireland as a great offender in sending a large number of infected animals.

One attack of foot-and-mouth disease gives no immunity to an animal against a second attack; so that, as long as we can send the disease to Ireland and the Irish send it back again, there is no possibility of its dying out. There is no wish to treat Ireland as a foreign country; but it must submit to the same regulations as one of our own counties. So long as it sends us disease, it must be treated as an infected place. The sooner it can show a clean bill of health, the sooner will it find an open market for its produce. It is absurd, from merely sentimental notions, to permit such a natural barrier to the spread of disease as the Channel to be of no effect.

When, during the cattle-plague days, restrictive measures on the movements of animals were in force, foot-and-mouth disease disappeared. Here, then, is a remedy which has been proved effective. Let us again adopt it. Let the cattle-plague regulations (*minus* slaughtering) be applied to foot-and-mouth disease. In a week or two, the necessary movements of cattle and sheep will almost have ceased, purchasers will have obtained their stocks, and stringent regulations will produce the minimum of hardship on individuals. If such a plan be adopted and carried out thoroughly and generally for the space of two months, we have no doubt that the disease will disappear. But what then? Guard against the re-importation of disease, make existing regulations general and compulsory, and we shall remain free.

THE BRUSSELS correspondent of the *Fall Mall Gazette* writes:—A school of medicine for ladies, due to private initiative, will be opened here on the 1st of next month.

DR. CRICHTON BROWNE has issued cards for his annual medical *conversazione* in the hall of the West Riding Asylum, for Friday, Nov. 19th. Dr. Broadbent will deliver an address on the Theory of Construction of the Nervous System.

IN the London School of Medicine for Women there are at present, we hear, upwards of twenty ladies studying. The courses of Anatomy and Practical Anatomy for this (the second) winter session are given by Mr. Reeves and Mr. Mears, of the London Hospital; Medicine, by Dr. T. K. Chambers, Consulting Physician to St. Mary's Hospital, and Mrs. Garrett Anderson, M.D., Physician to the New Hospital for Women; Histology, by Mr. Needham; Physiology, by Mr. Rivington; and Surgery, by Mr. Cowell, Senior Surgeon of the Westminster Hospital.

MISPLACED ENTHUSIASM.

OWING to the many expedients that have been adopted to obtain signatures, the time has passed for numerous signed memorials to carry the weight with them that their bulky appearance or imposing-looking figures would suggest; but, whilst memorials continue to be presented on every conceivable subject, it is as well now and again to draw attention to the manner in which signatures are obtained. Subjects that appeal to the feelings have ready and enthusiastic supporters in ladies, who, guided by impulse rather than by reasoning, are without doubt most useful allies. So, evidently, think the Committee of the Association for the "Promotion of Humane Treatment of Animals", in placing in the hands of young ladies papers for the signatures of their friends. This Committee ought really to be congratulated upon their system of working, if it be carried out so completely in England as we have been informed has recently obtained in Lincolnshire,

where it was suggested that the visitors attracted to the neighbourhood by the festivities incidental to the race-week should be applied to their signatures. How could there be a more perfect way of obtaining opinions on an important scientific question than by sending to young ladies in country houses papers for such a purpose? Happening to see one of these valuable documents, we observed that three-fourths of the names were those of ladies, one of whom, however, wise in her generation, only gave her initials, as she thought that "by so doing her name would carry greater weight". How charming in a ball-room for one of these enthusiastic young ladies to be able to make it a stipulation with her partner that, if she danced with him, he must sign her anti-vivisection paper! It is quite natural that the non-scientific world should feel opposed to vivisection, especially when their minds are stirred up against it by a few well-described revolting stories; but it is really lamentable to think that questions of this vital importance to the human world should be subjected to such treatment.

HOSPITAL SUNDAY IN LIVERPOOL.

THE Hospital Sunday Committee of Liverpool, in making their annual report, regret to be obliged to announce that the collections of 1875 have fallen short of those of 1874 and 1873. The total amount in 1874 was £11,185:8:9; in 1873, £9,821:9:10; and in 1875, £9,716:13:4. This is to be accounted for partly by a depressed state of trade; partly by the fact that Hospital Sunday was wet and stormy; partly also by a belief generally prevalent at the date of the collections that the medical charities would receive a large accession of income from other sources. Fluctuations in the amount of the collections, arising from these and similar causes, are to be looked for from year to year; but the Committee have every reason to believe that the institution of Hospital Sunday retains in an undiminished degree the confidence of their fellow-townsmen.

COWPOX AND FOOT-AND-MOUTH DISEASE.

MR. J. GREENE, of Birmingham, writes to us:

"I notice, in to-day's issue of the BRITISH MEDICAL JOURNAL, that M. Félizet of Elbeuf has inoculated twenty-five beasts with cowpox, and that subsequently these animals had not suffered from foot-and-mouth disease, notwithstanding that it abounded in the neighbourhood. The cowpox to which he refers is probably the 'white pock' of Ceely. During the last few years, I have repeatedly examined herds of cows affected with the 'white pock', and have noticed its apparent protection against foot-and-mouth disease. None of these numerous cows subsequently suffered from this complaint, though it existed severely all round. From recent inquiry, this exemption still continues. The importance of the observations of M. Félizet can scarcely be exaggerated. The subject calls for further experiment and observation, which should be official and on the part of Government. True variolous cowpox is excessively rare at present; but I have had proof that it is not protective against foot-and-mouth disease."

PROGRESSIVE MORPHOLOGY.

THE first part of the new *Journal of Morphology*, issued by Gegenbaur, contains, according to *Nature*, a very notable paper by Dr. Emil Rosenberg, on the Development of the Vertebral Column and of the Os Centrale Carpi of Man. He sets before himself the problem, little touched hitherto, of the discovery of the steps by which man may have developed from the nearest mammalian stock. Taking first the vertebral column, he sets forth the differences existing therein in the various Anthropomorpha, and seeks to reconcile them with that of man. For instance, in two genera, Troglodytes and Hylobates, there are thirteen dorsal vertebrae; while in the Orang and in man there are only twelve. But Dr. Rosenberg has observed in more than one human embryo an actual rib-rudiment on the thirteenth dorsal vertebra; so that the homology of the thirteenth dorsal in man and Troglodytes is established. Another result that Dr. Rosenberg alleges that he has demonstrated from examination of human embryos is, that a process of transformation goes on in the growth of the sacrum, by which vertebrae at the proximal end, with their costal elements, are assumed into the sacrum, while a corresponding number at the distal end undergo reduc-

tion, and are dismissed into the caudal region. And this process, generalised, may be applied to each of the hinder regions of the vertebral columns. Thus, in the history of development, each lumbar vertebra in man is the result of a single transformation from the condition of a dorsal vertebra; each sacral vertebra has previously passed through the lumbar stage; while the caudal vertebrae have been successively dorsal, lumbar, and sacral, before becoming caudal. This is necessarily but a very imperfect sketch of the major subject of this paper, which is of very high interest.

THE CHELSEA GARDENS OF THE APOTHECARIES' COMPANY.

At the last meeting of the Chelsea Guardians, the following motion stood on the paper in the name of Mr. Cox, viz.: "That the necessary steps be taken for applying to Parliament in the next Session for obtaining power to acquire the fee of the gardens belonging to the Apothecaries' Company at Chelsea, and that the solicitor be instructed to give the necessary notices." The subject was referred to the Works and General Purposes Committee.

DIED OF WORRY.

ON Saturday evening, at the Prince Albert, Mape Street, Bethnal Green, Mr. Humphreys inquired into the cause of death of Mr. Thomas Sarvis, aged 53 years, for many years medical officer of health for the parish of Bethnal Green, who fell dead in his surgery, 350, Bethnal Green Road, on the preceding Thursday afternoon. Mr. J. D. M'Donald deposed that he was the deceased's assistant. About five o'clock, witness, who was in an adjoining room, suddenly heard a slight scream, and upon opening the door saw the deceased falling. He never again moved. The deceased had previously told him that he had a sanitary meeting to attend at 6 o'clock, about which he seemed much worried. Mr. Mainwaring said he found death to have been instant from effusion of serum into the ventricles of the brain. The heart weighed 21¼ ounces. There were no traces of poison to be found. Mr. Jacobs, Chairman of the Sanitary Committee, said that the late doctor had neglected to have his report laid before the Board in June last; and, on that very night, there was a notice for him to attend a meeting of that Committee to answer the charge. The jury returned a verdict of "Death from natural causes".

INQUEST OR NO INQUEST.

WE learn from the *Bethnal Green Times* that some discontent has arisen in that district in consequence of an inquest not having been held upon the body of a pauper who died in the workhouse in July last. The circumstances of the case were briefly these. The man, James Harper, left the workhouse on Wednesday morning for an ordinary day's leave. In the afternoon, he was seized with sudden illness. He was faint, and complained much of pain in the chest and right side. His friends gave him brandy, but he was unable to retain it. When somewhat better, he attempted to make his way back to the workhouse. While going, he fell; and was picked up by his daughter, who accompanied him to the workhouse, and told the official that her father was very ill. The porter, however, believing that he was drunk, sent him into the receiving ward, where he was retained the whole night without any medical assistance. The next morning, it was evident that he was ill; and he was removed at once to the Infirmary, where everything was done to relieve him. He died, however, on the following Saturday; and the medical officer gave a certificate to the effect that he died from inflammation of the lungs. His body was given over to his relatives for interment; but the coroner, Mr. Humphreys, gave directions that an inquest should be held. The jury were duly sworn; but, while they were on their way to view the body, they were recalled, and informed by the coroner that, since they had left, he had received a communication from the guardians, through the medical officer, by which it appeared that the inquest was unnecessary. They were, therefore, dismissed. But the matter was not to rest here. A memorial was forwarded to the coroner, requiring him to order a *post mortem* examination, and to hold an inquest as he

originally proposed. To this, Mr. Humphreys consented. But a difficulty arose with regard to a mortuary where the body, if exhumed, could be deposited. Then, at the end of August, it was said that the time had gone past when a *post mortem* examination could be of any value. Thus the inquest was "shunted", but the question is not settled; and we allude to it because it is intimated that it will be brought under the notice of the Home Secretary. The case of James Harper is another example of the dissatisfaction which so often arises from the want of careful discrimination between illness and intoxication; and the main object of the agitation seems to be to secure greater attention to this point at the Bethnal Green Workhouse.

THE CONJOINT SCHEME.

DR. PAGET and Dr. Humphry have been delegated by the University of Cambridge to represent that body on the committee now in course of formation for the furtherance of the conjoint scheme of examination for England and Wales.

MEDICAL MAYORS.

THE list of new provincial mayors contains the names of the following members of the medical profession: Mr. Puddicombe, Dartmouth; Mr. Joseph May, Devonport; Dr. Kelburne King, Hull; Mr. Barrow, Ryde; and Dr. Eyton Jones, Wrexham.

SHIP-SURGEONS.

PUBLIC attention having been recently directed to the fact that passenger-ships frequently sail from the United Kingdom with an unqualified surgeon on board, or with one not registered under the Medical Act, or with no medical officer at all, the Board of Trade issued at the end of last month an official circular to their emigration officers and mercantile marine superintendents explaining the state of the law on the subject, which is discussed in the *Pall Mall Gazette*. The broad interpretation of its provisions appears to be that every foreign-going ship having on board one hundred or more persons, and every ship carrying more than fifty passengers (sailing under the Passenger Acts) shall carry an officer, who shall be a duly qualified and duly registered medical practitioner. But our contemporary points out that the circular affords no practical clue whatever as to how the law is to be put in force. "It gives no power to an officer to summon either master or owner, nor does it even hint that a vessel can be stopped if she sail without an authorised surgeon, although her complement may number several hundred persons. A parliamentary return moved for in June last showed that, during the two previous years, 224 'experienced' surgeons sailed from the United Kingdom whose names did not appear on the *Medical Register*; and that, of this number, fifteen were under twenty-one years of age, and could not have been qualified at all. It does not appear, therefore, that passengers are in a much safer position than they were before as regards medical attendance afloat; and, indeed, it is notorious that several ships have sailed during the last autumn with no surgeon on board, to ports east of the Cape and by the old Cape route, each carrying more than a hundred persons."

THE COST OF HOSPITAL EXTRAS.

AT the last meeting of the Metropolitan Asylums Board, an important report was presented by Mr. Proudfoot on behalf of the Finance Committee, who had been investigating the causes of great differences between the cost of fever-patients at Homerton and Stockwell Asylums. The Committee found that the difference arose from the "medical extras"; these costing, on the average, 6d. a day each patient, and at Stockwell 1½d. Mr. Proudfoot proposed that the report should be sent to the committees of the two asylums. After some discussion, Dr. Curtis suggested an addendum to the motion requesting the committees of the hospitals to give information respecting the death-rate, the average duration of residence in the two hospitals, both of those who recovered and those who died; and the resolution, thus amended, was carried. A wise liberality in the matter of hospital extras is a very desirable element in hospital administration; and, within a certain

range, it is very advisable to allow the utmost latitude to medical officers in "feeding fevers", and in the adoption of costly drugs and costly dietaries for the sick. On the other hand, we have known some very remarkable results to have followed from the analytical investigation of the causes and nature of excess of expenditure under this head; and sometimes the medical officers themselves are not a little surprised at the differences existing between the cost of their patients and those of their colleagues.

STATISTICAL SOCIETY.

THE first ordinary meeting of the present Session will be held on Tuesday, the 16th instant, at the Society's Rooms, Somerset House Terrace (King's College Entrance), Strand, W.C., when the President, James Heywood, Esq., M.A., F.R.S., will deliver his Inaugural Address, and present the Howard Medal to the successful candidate—this being the first award; and Dr. W. A. Guy, F.R.S., will read a paper on John Howard's true place in History, a supplement to his paper entitled John Howard as Statist. The chair will be taken at 7.45 P.M.

BELLIGERENT STUDENTS.

THE new session at Heidelberg was inaugurated by a pitched battle between those members of the University who are natives of Prussia, and those of the other German provinces. The combat assumed such alarming proportions that the whole police of the town had to be called in, and it was only possible to restore order by the arrest and imprisonment of the ringleaders.

HEALTH OF FOREIGN CITIES.

WE learn from official sources, that the population of the twenty-two Indian and foreign cities from which the Registrar-General is favoured with weekly returns, is estimated at about ten millions of persons, and the death-rate therein during the third quarter of this year averaged 28.9 per 1,000, against 23.8 in the eighteen largest English towns. In these foreign cities, the death-rates ranged from 20.9 and 21.4 in Turin and Vienna, to 39.4 in Berlin and 48.6 in Alexandria. Typhoid fever was somewhat prevalent in Paris; both typhus and diphtheria in Berlin; fevers in Rome and Naples; and small-pox and diphtheria in New York. So far as the classification of diseases adopted in the different towns renders a comparison possible, the annual death-rate from diarrhoea last quarter was but 0.18 per 1,000 in Turin, and less than 1 per 1,000 in Amsterdam and Rotterdam; whereas it was 6.0 in Christiania, 6.5 in Munich, and 11.9 in New York. In the eighteen large English towns, the diarrhoeal rate averaged 3.6 per 1,000, and ranged from 1.6 in Bristol to 9.2 in Leicester. Infant mortality, measured by the proportion of deaths under one year to births, which averaged 222 per 1,000 in the large English towns, was equal to 136 in Turin, 238 in Naples, 283 in Rome, 290 in Hamburg, and so high as 508 in Berlin.

DOCTORS AND BONE-SETTERS.

SOME time ago we alluded to the difficulties which have arisen in some of the Welsh quarrymen's medical clubs, in consequence of the predilection of the members for employing bone-setters. The troubles occasioned by this question are not yet settled. A recent correspondent of the *Carnarvon and Denbigh Herald* calls Dr. Roberts of Penygroes to account for allowing his name to be affixed to a set of rules issued by the Nantlle Vale Club, wherein his name stands side by side with a bone-setter; the rule permitting the members to have "the service of a qualified doctor and a bone-setter". We consider that the correspondent is in the right, and that it is much to be regretted that members of our profession should consent to co-operate with bone-setters. It would be much better for them to refuse to have anything to do with clubs that employ unqualified practitioners. Societies for the relief of sickness should be officered by none but fully qualified men. Disastrous results will almost inevitably arise from pursuing any other course; and members of the profession had far better keep entirely aloof from such doubtful arrangements.

PATENT MEDICINES.

THE *Boston Medical and Surgical Journal* reports: "At the meeting of American pharmacologists, Professor Maisch made some very sensible remarks on the disgrace of the great traffic in patent medicines. We are glad to see the matter taken up by this body; for the pharmacologists can do more, we think, to remedy the evil, than the physicians. We must disagree with Professor Maisch, however, when he says that apothecaries can do nothing as long as quack medicines are called for. They always will be in demand till the millennium, but the demand will be lessened if they cannot be procured from respectable druggists. Professor Maisch stated that the question had been agitated as to the best means of informing the public of the dangerous nature of many of these nostrums. Dr. Frederick Hoffman of New York had suggested the publication of a health-almanack similar to those issued by the proprietors of patent medicines, which should contain analyses of such preparations. Circulars had been prepared upon this subject, which Mr. Maisch desired to have distributed to the Association."

SCOTLAND.

AN epidemic of measles and scarlet fever prevails to such an extent in the village of Bunhill, that the School Board, acting on the advice of the medical authority, have resolved to close the public school for a fortnight.

THE general health of Edinburgh is excellent, although there is still a large amount of scarlet fever in the town. The general death-rate for last week was at the low rate of 19 per 1,000. Of the 73 deaths, 23 were due to zymotic diseases, of which 17 are ascribed to scarlet fever.

WATER FOR DUNFERMLINE.

MESSRS. J. and A. Leslie, C.E., Edinburgh, have been recently instructed by the Town Council of Dunfermline to make surveys, with the view of ascertaining the best source of water-supply for the town. They have submitted a report, in which they express a very decided opinion that the only adequate source of supply is in the district of Glendevon. To obtain a supply of one million gallons a day from Glendevon to Craighiscar, they propose to construct a reservoir on Glenquey capable of holding 21,000,000 cubic feet of water, which will be of sufficient capacity to afford liberal compensation, and to supply water for Dunfermline much above its requirements for some years to come. When the consumption of water becomes greater than can be obtained for a reservoir of this size, it can be easily extended. The adoption of iron pipes is recommended. The total cost of the works proposed would not exceed £65,000, of which it will only be necessary at present to expend £42,000. A Bill to further this object is to be brought before Parliament in the ensuing session. The new waterworks at Dundee have cost upwards of £300,000, and a supply of about six million gallons a day is now being received, while the works are constructed to carry eight million gallons. Last week, a testimonial was presented by the inhabitants of Dundee to Bailie Robertson, the chief magistrate, who has been the principal instrument in carrying the undertaking to a satisfactory issue.

THE UNIVERSITY OF EDINBURGH.

In his opening address to the students on the 1st instant, Sir Alexander Grant announced that the subscriptions towards the new University buildings reached nearly £80,000. As showing the urgent necessity for increased accommodation, he quoted from the Report of the Duke of Devonshire's Commission on Scientific Instruction the statement that "the Professor of Pathology has to lecture in a room which is used only one hour before he enters it by the Professor of Moral Philosophy, and one hour after he leaves it by the Professor of Geology". The Report, he said, spoke strongly in favour of a Government grant being given in aid of the extension scheme. He announced, in a later part

of the address, that Professor Huxley would again take the place of Professor Wyville Thomson, and deliver the summer course of Natural History, as the voyage of the *Challenger* is to be prolonged for a few months more than was intended. The total number of students matriculated last academical year was 2,076; being an increase of 146 on the previous year. This increase was made up of 82 in the Faculty of Arts, 60 in the Faculty of Medicine, and 7 in that of Theology. In 1868, there were only 445 medical students; last year, there were 899. Shortly before the close of the address, allusion was made to the recent visit of the Association, and the part which the University played in their reception.

ROYAL MEDICAL SOCIETY OF EDINBURGH.

THE session of the Royal Medical Society of Edinburgh opens on Friday, November 12th, when Mr. Annandale delivers an address. The rooms are on this occasion thrown open to all students of medicine, as has been the case on the opening night for some years past.

THE GLASGOW INFIRMARY AND THE POLICE BOARD.

THE directors of the Glasgow Royal Infirmary and the Police Board have had a conference on the much disputed question of the admission of fever-patients into the infirmary from the suburban burghs, but it did not result in much. The managers of the infirmary denied that they had enabled the authorities of the neighbouring burghs to evade their duties, by admitting their patients. The committee of the Police Board assured the managers of the infirmary that they only desired, for the safety of the citizens, that all cases of epidemic disease should be reported to them. This was ultimately agreed to; but the managers of the infirmary declined to interfere in any way between the Health Committee and the authorities of the neighbouring burghs.

THE PRELIMINARY EXAMINATION IN THE UNIVERSITY OF EDINBURGH.

THE preliminary examination in Arts required by medical students at the Edinburgh University is by no means a mere form. Last month, about 118 or 120 candidates presented themselves at the University, of whom over forty, or more than one-third of the whole, were found wanting, and referred to their school-work. We are glad to find that the examiners are somewhat stringent, as it is very desirable that all members of the profession, and especially those who aspire to the high degree of M.D., should have a thoroughly good preliminary education in general knowledge.

IRELAND.

MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

A QUARTERLY meeting of the Belfast Branch of this excellent Society was held at Belfast on the 3rd instant, under the presidency of Dr. T. H. Purdon. Donations were announced from the chairman, who has, in the aggregate, contributed the handsome sum of £500 guineas to the funds; £100 from Lady Johnson; £150 from Dr. H. M. Johnson; besides a long list of smaller sums. Special allusion was made in the report to the liberal contribution to the funds received from the medical students of Queen's College, Belfast, as showing to the students of other colleges an example worthy of imitation.

THE VICE-PRESIDENCY OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE following have been mentioned as likely to succeed the late Mr. John Hamilton as Vice-President of the Irish College of Surgeons: Mr. Ledwich, Dr. Kidd, Mr. R. McDonnell, Mr. Stapleton, and Mr. Smyly. We understand that the first three are the favourites, and that these gentlemen will arrange among themselves so as to avoid a contest. It would be premature to make any decided announcement as to the matter. It is the custom at the Irish College of Surgeons, that the Fellow chosen as Vice-President should succeed to the Presidency the following year without opposition.

DUBLIN HOSPITAL SUNDAY FUND.

NEXT Sunday, the 14th instant, will be the second Dublin Hospital Sunday. Collections will be made in upwards of 180 churches in Dublin and its vicinity. We regret that the Roman Catholics still abstain from taking any part in the movement. The average collection last year was over £20 per congregation; at the same rate, a sum of close on £4,000 should be obtained this year.

ROTUNDA LYING-IN HOSPITAL: ELECTION OF MASTER.

DR. GEORGE JOHNSON'S term of office having expired, the usual septennial election for master of the Rotunda Hospital was held on the 6th instant, when Dr. Lombe Atthill was chosen master by a large majority over his competitor, Dr. Cronyn. We shall not enter into a comparison between the two candidates, who had both served the office of assistant-master in the Rotunda Hospital, and are both well known obstetricians. We have no doubt Dr. Atthill will fulfil the anticipations of his supporters. Dr. Atthill's work on *Diseases of Women* has already established itself as a text-book, and gained for its author a high reputation as a gynæcologist. The high estimation in which Dr. Atthill is held by Dublin obstetricians is proved by his position as President of the Obstetrical Society. Dr. Atthill's experience as a clinical teacher, gained at the Adelaide Hospital, to which he has been long attached, will prove highly beneficial to the School of Midwifery at the Rotunda Hospital. We cannot wish Dr. Atthill better than that he should prove as successful and popular a "Master of the Rotunda" as his predecessor.

THE SURGEONCY TO THE QUEEN IN IRELAND.

THE office of Surgeon-in-Ordinary to Her Majesty in Ireland, vacant by the death of Mr. John Hamilton, is now the cause of much speculation as to who is to occupy the vacant post. Mr. Edward Hamilton, President of the College of Surgeons; Mr. William Colles, the Regius Professor of Surgery to the University; Mr. Rawdon Macnamara, formerly a President of the College of Surgeons, and now its representative in the General Medical Council; Mr. Philip Smyly, and several others, are mentioned. It is believed that the honour will be conferred upon a political supporter of the powers that be; and, such being the case, it is evident that the chance must rest between the President of the College of Surgeons and Mr. Smyly.

PHARMACEUTICAL SOCIETY.

At a meeting of the Council held last week, it was finally decided by a large majority, that there should be but one qualification for those compounding medicines in Ireland, and that it should be that of pharmaceutical chemistry. An amendment was moved by Dr. R. Macnamara that there should be two classes, viz., pharmaceutical chemists, and chemists and druggists; but the original resolution was carried.

BALLYNAHINCH CHALYBEATE SPA.

DR. HODGES of Belfast, last week, drew the attention of the members of the Chemico-Agricultural Society of Ulster to an analysis he had made of a sample of the above waters, as it was supposed by some, Sir R. Kane among the number, that this spring did not contain any chalybeate properties. During a visit to the Spa this year, he had made an examination of the water, and found it to yield about two grains of oxide of iron per gallon; an imperial gallon on evaporation left 25.2 grains of oxide of a light brown colour, 9.1 grains of which consisted of organic and volatile matters. The mineral and saline matters consisted of peroxide of iron, 1.82 grains; carbonate of lime, 7.70 grains.

PRESENTATION.—Mr. W. J. Fleetwood, who has been connected with the Chester General Infirmary for four years—at first as visiting, and afterwards as house-surgeon—was presented on his resignation, on October 14th, with a handsome case of operating instruments by the visiting-surgeon, matron, dispenser, nurses, and servants of the institution.

THE OPENING OF THE MEDICAL SESSION IN DUBLIN.

DURING the past week, the Dublin hospitals and schools opened their doors for the session 1875-76. The prospects of the session in Dublin seem bright, although the exact number of new entries cannot be ascertained until after the 25th instant, when it is the custom to close the entry-books in Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND: SCHOOL OF SURGERY.—This school was opened by an introductory address by Dr. Little, the professor of medicine; the President of the College occupying the chair. Dr. Little's address consisted chiefly of the usual advice to medical students, given, we are glad to say, in an unusually brilliant and attractive manner. The professor dwelt specially on the importance of hospital attendance and clinical work. Dr. Little criticised ably and soundly the recent changes in the condition of the medical department of the army. Dr. Little concluded as follows. "I would have all of you, both those who are beginning their studies in this school and those who, having passed that stage, are entering on the active duties of life, to remember the responsibility and dignity of the profession in the ranks of which you have enrolled yourselves. Do not listen to those who tell you that professional success is to be obtained by outward display, by an affectation of solemnity or an affectation of benevolence, by servile ways and cunning devices; rest assured that those who do so obtain success pay far more dearly for it than those who gain it by the labour of their hands and the labour of their brains; do you start with the determination that, beneath your professional robe, you will ever wear the invulnerable armour of an honest purpose, and that for victory you will rely on the invincible weapons industry and perseverance; patience and self-denial you may need; but by no other course can you earn a fair fame and secure the richest of all this world's rewards—an approving conscience."

THE UNIVERSITY SCHOOL OF MEDICINE.—This, the largest and most flourishing of the Dublin schools, was opened in its ordinary quiet way, without any display or special address. Each professor said a few words of encouragement to his class, and at once plunged into the active business of the session.

DR. STEEVENS'S HOSPITAL AND MEDICAL SCHOOL.—This, the oldest of the Dublin hospitals, was opened without any ceremony whatever, introductory addresses having for several years been abandoned.

THE LEDWICH SCHOOL OF MEDICINE.—This school was opened by an address by Dr. Ward, who, we regret to state, spoiled an otherwise excellent lecture by references to medical students and their conduct, which have caused no small annoyance among the members of many of the medical classes in Dublin. We refrain from quoting the ill-advised remarks of the lecturer, which we have already heard made use of to increase the false opinions often held with regard to medical students.

THE MEATH HOSPITAL.—The address of Dr. J. W. Moore, the newly appointed physician to this hospital, was of a character far superior to the usual run of inaugural addresses. We regret our space does not permit us to quote more largely from it; but we cannot refrain from quoting his concluding remarks, which were most appropriate. "To be entrusted with the duty of helping to sustain the reputation of this hospital is indeed a high honour; but it brings with it grave responsibilities. My colleagues have each and all recognised this fact, and, without flattery, I may say right well have they so far fulfilled the trust. But for me, if I am spared, my spurs are yet to be won. As far as punctual attendance and diligence in the wards are concerned, I think I may pledge myself, should health permit. But, fellow-students, unless my efforts are seconded by you, they will utterly fail to secure good and lasting results. As you value your success at your final examination, your prosperity in after life, but, above all, your patients' welfare and happiness, be diligent clinical students of disease. Be punctual in your attendance in the wards, lose no opportunity of making yourselves thoroughly and practically acquainted with sickness in its Protean forms; every hour, every moment of your undergraduate life, of your hospital course, is more precious than gold. Above all things, shun, as you would the yawning precipice or the treacherous quagmire, the perilous delusion of merely 'walking' the hospital. Let each one of you become a 'practising pupil' in the fullest sense of the term. In your relations with the sick, make every allowance for their weak and prostrate condition. Act towards them as you would towards the

nearest and dearest of your own loved ones when laid on a bed of sickness. Let no thoughtless levity or want of sympathy on your part repulse the sufferer. Win his confidence by gentleness and loving kindness. 'Be pitiful; be courteous'. And, lastly, let us all remember how great is the privilege of ministering in some degree to the alleviation of the sufferings of our afflicted fellow-creatures: who it was that said, 'I was sick and ye visited me'; the question of surprise, 'Lord, when saw we thee sick and came unto thee?' the glorious answer of the King, 'Inasmuch as ye have done it unto one of the least of these my brethren, ye have done it unto me'. It only remains that, on the part of my colleagues and myself, I should bid those of you who are now about to enter the wards for the first time a hearty welcome. Your fellow-students who are already our friends will likewise greet you, and give you many useful hints. Remember that there is no clashing in the attendance on the medical and surgical *cliniques*, which are held on alternate days. Let us all—teachers and pupils—resolve to be punctual and attentive, and the session which is this day inaugurated will, like many that are past, prove a prosperous, an instructive, and a happy one." The greater portion of the address was devoted to a medical history of the Meath Hospital.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.—The opening address was delivered on Monday last by Mr. Thornby Stotar, one of the surgeons to the Richmond Hospital. Mr. Stotar paid a worthy tribute to the memory of Mr. Adams and Mr. Hamilton, late surgeons to the hospital, who had been removed by death during the past year. The lecturer, having referred to the list of great men who had from time to time advanced the roll of officers of the hospital, concluded with a few words of advice to the students.

THE CATHOLIC UNIVERSITY SCHOOL OF MEDICINE.—The address in this school consisted of an able review of ancient and modern medicine by Dr. Macswiney. The following passage is specially worthy of note:—"The false science I denounce ignores God; but true science, far from taking us away from God, brings us nearer to Him.

'One rule our life was fashioned to fulfil,
That he who tends Truth's shrine, and does the best
Of science with a humble, faithful will,
The God of truth and knowledge serveth best.'

You will find no principles of unbelief amongst the members of the calling you have adopted. The study of medicine has no tendency to create sceptics. This charge has been often preferred against the science of medicine; but the lives of its greatest men triumphantly refute the calumny."

THE MATER MISERICORDIÆ HOSPITAL.—Dr. Hayden delivered an inaugural address. The address consisted chiefly of a review of the relations which the different branches of medical science have to one another. The importance of preventive medicine was specially dwelt upon, and reference made to the recent Public Health legislation for Ireland. Dr. Hayden's address was one of the most suitable to which we have listened, and was free from that glorification of his own institution which, we believe, first brought introductory addresses into disrepute.

IS THE FLESH OF DISEASED CATTLE WHOLESOME?

SOME passages in the Annual Report of the Veterinary Department of the Privy Council Office raise the important question as to whether or not the carcasses of animals slaughtered in consequence of their being affected with pleuropneumonia are fit or unfit for human food? On this question, two departments of the Government are divided in opinion. It appears that the owners of such cattle receive compensation for the loss they have sustained, and that it is a general practice in estimating this loss to consider the flesh as fit for consumption. With reference to this practice, the Local Government Board state that, though not possessed of any conclusive evidence that the flesh of pleuropneumonia animals is hurtful, they are advised by their medical officer that it is unsafe for use as human food. The Lords of the Council, in reply to this opinion, express their regret that the Local Government Board is advised that the flesh of animals which have been the subject of any febrile disease should be considered unsafe for human food, and proceed to point out that, if such an opinion were acted upon, it would entail so large an outlay that they would hesitate to continue their order rendering the slaughter of such cattle compulsory. The importance of the question can hardly be overrated; and though no definite conclusion on the subject has as yet been arrived at, it has been the subject of investigation by some of our most competent physiologists with whom we have been in correspondence. The conclusion at pre-

sent arrived at is, that when the disease is recognised in so early a stage that the animal is killed before general constitutional disorder has been set up, *i. e.*, before the muscular tissue has undergone those changes which, in all febrile diseases, attend the development of the febrile state, it is not unfit for consumption. Consequently, the question whether any given carcass is fit for human food must be judged in each case on its own merits. If, on inspection, the muscular tissue be found to be in a perfectly natural state, and there be evidence to show that reasonable despatch has been used in killing the animal before it has begun to be seriously ill, then it would be unjust for the law to interfere: for, as regards pleuropneumonia, there is not the slightest reason for believing in the existence of any specific contagium in the organism of such a nature as to be itself injurious, irrespectively of the alteration of tissue produced by the morbid process.

In the contrary case, it is undoubtedly highly improper for the meat to be used as food. Hence, we have two practical alternatives: inspection or prohibition. If inspection can be carried out so as to ensure that only such meat as is in a wholesome—that is in a natural—state, is offered for sale, then the use of the flesh of pleuropneumonia animals may be permitted *under this guarantee*. But if such inspection be impossible, the only way is to prohibit the use of diseased meat altogether, for otherwise the public are exposed to the risk of consuming meat unfit for use; not on the ground of any specific infective ingredient it may be supposed to contain, but on the ground of the altered condition of the flesh of animals in advanced febrile disease.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE consideration of the proposition of Mr. Marshall for the establishment of a preliminary examination in anatomy at the end of the first winter session was discussed at a meeting of the Council on the 11th instant. It was resolved that there be a committee appointed to consider the question of an examination in elementary anatomy and other subjects at some period previous to the time of admission to the first examination for the membership and fellowship. At the same meeting of the Council, Mr. John Birkett, one of the vice-presidents of the College, was elected a member of the Dental Board, in the vacancy occasioned by the resignation of Mr. Hancock.

SPECIAL CORRESPONDENCE.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

The Deanship of the Faculty of Medicine.—Clinical Instruction in Paris.—The Chair of Clinical Medicine at the Charité Hospital.—Short-sightedness in France.—The Trepaine Treatment of Diseased Bone.—The Fork-swallower.—Kangaroo-Meat.

THE term of the autumnal holidays having expired, the various political, scientific, and literary bodies have resumed their work, and, as announced in my last, the School of Medicine has reopened its doors for the winter session. The latter institution has been for some time, and is still, in a somewhat anomalous position, owing to its having no dean, as M. Wurtz sent in his resignation some time ago, and, strange to say, the Minister of Public Instruction, in whose hands lies the appointment, cannot find a successor. The appointment has been going a-begging since M. Wurtz gave it up; but none of the other professors seem disposed to accept the offer. The deanship of the Faculty of Medicine of Paris is a very onerous office; and the Minister of Public Instruction is, therefore, devising means to render it more acceptable. One of the projects in contemplation is to appoint two assessors to assist the dean, and thus relieve the latter of a good deal of routine work. A committee has been appointed to investigate the subject, and it is hoped that, under such favourable circumstances, there will be no difficulty in finding a dean.

Many other reforms are in contemplation, and, among others, I may mention that the system of clinical instruction is to be revised, and a committee has been appointed to inquire as to the best means of improving and completing it. Clinical instruction in Paris, although not inferior to that in any other school, is yet very defective, not so much in the character or quality as the difficulty attending its being imparted or received; and this is owing to the system of centralisation rife in France, and which is so ruinous to the country. You are aware that there are only three or four hospitals in Paris (Hôtel Dieu, La Charité, La Pitié, Hôpital des Cliniques) where clinical lectures are officially delivered by professors appointed for the purpose; the consequence is,

the wards of these professors are so overthronged by students, that it is simply impossible to get near the bed of the patients. Many students, however, desirous of becoming thorough practitioners, resort to other wards where they can with ease auscultate, percuss, or examine the patients according to the nature of the case. Any reform, therefore, that may be carried out in this direction would be welcome; and one of the means that suggests itself consists in increasing the number of clinical professorial chairs; even one of medicine and one of surgery to each hospital would be none too many, as, under the present system, there are times when there are as many as a hundred disciples of all ages that may be seen in one ward alone of a clinical professor.

By the retirement of Professor Bouillaud, the Chair of Clinical Medicine at the Charité Hospital has become vacant. In the order of seniority, Professor Hardy, so well known as a "skin-doctor", but who is also professor of medicine at the Faculty, has a right to promotion; but it is anticipated that he would rather forego it than give up his appointment as physician to the St. Louis Hospital, which he has held for the last twenty years, and where he had acquired his reputation for his knowledge of skin-diseases. This, by the way, would be a favourable opportunity for creating a special chair for skin-diseases. Specialties are not officially recognised by the French Faculty of Medicine, and yet there is perhaps no country in the world where a knowledge of special diseases is so thoroughly acquired, owing to the facilities for study, which are liberally offered even to foreigners.

The number of short-sighted persons in France is said to be steadily on the increase; and, as this condition would constitute a serious inconvenience in a military point of view, the authorities have become anxious about the matter, and have requested the Academy of Medicine to investigate the cause, and, if possible, to remedy the evil. The subject has been lately discussed at the Academy, but the conclusions arrived at are not yet known. I should not be at all surprised if the use of spectacles be introduced in the French army. Hitherto only officers have been allowed to wear spectacles; but the privilege will have to be extended to the soldiers in the ranks, if it be desired to muster a strong army, particularly as it has been discovered that, in many cases, myopia is artificially produced, in order to escape the conscription. This is done by reading with strong concave glasses so graduated as to reduce the visual power to the use of the No. 2 or 3 glasses. It is known that the German soldiers who are short-sighted are allowed to wear spectacles, and this does not seem to render them less effective, as was proved in the last war.

Professor Gosselin of the Charité Hospital lately read a very interesting paper at the Academy of Sciences on the use of the trephine as a remedial agent in the treatment of diseased bone. After having referred to the works of David of Rouen, of Sédillot and Sir Benjamin Brodie, M. Gosselin attempted to prove that, in several of the cases in which the trephine was used by the latter surgeon for the opening of abscesses in the substance of bones, there was no discharge of pus or any other fluid indicative of inflammation; but the patients were relieved of the most urgent symptom, pain, and ultimately cured of what was supposed to be abscess of bone. From this circumstance, M. Gosselin concludes that there is such a disease as neuralgic osteitis ("ostéite névralgique"), which up till now has not been recognised in surgical works, and which is perfectly curable by the same method of treatment as in genuine suppurative osteitis; viz., the application of the trephine. But it strikes me that there is some incongruity in the term employed by the worthy professor; for, in pathology, all words ending in "itis" imply the morbid condition known under the name of inflammation. It would, therefore, in my opinion, be more correct perhaps to designate the disease referred to by M. Gosselin osteoneuralgia, or neuralgia of bone, and not neuralgic osteitis, the former of which terms implies absence of inflammation, or of any of its products, in the morbid process under consideration. The object of M. Gosselin's communication, however, is not so much to explain the morbid anatomy of the disease in question as to prove the value of trephining in all cases of diseased bone, whether of an inflammatory or neuralgic character, as in both cases the result is relief of pain, if not cure of the disease; and, as the operation is perfectly safe, he would recommend it to the favourable notice of surgeons for more general adoption.

In a former letter, I related the case of a young man in Paris who, about eighteen months ago, swallowed a fork, and to whom in consequence the appellation of "l'homme à la fourchette" was given. It will be remembered that the case was very properly not interfered with, either medically or surgically; and the daily papers now announce that this young man is not only still alive in his native town, but, notwithstanding the presence of the fork in his stomach, he is as well as if nothing had happened to him. Moreover, being without employment, he has turned his attention to music, and has even recently composed a

polka and a waltz which would reflect credit on a composer of greater pretensions.

The "Jardin d'Acclimatation" in the Bois de Boulogne has just been enriched by the arrival of some hundreds of kangaroos from Australia. Thanks to the efforts of the directors of the garden, this animal may be now considered perfectly acclimatisable in France, and several landed proprietors have introduced them to their grounds, where they are hunted like other game. The flesh is now sold in the markets as an article of food, and is considered a great dainty. Thus we have another viand in the market which is heartily welcomed, as the price of butchers' meat is so high as to be inaccessible to the working classes, who stand most in need of the most substantial food.

BIRMINGHAM.

[FROM OUR OWN CORRESPONDENT.]

Hospital Sunday.—*Medical Institute.*—*Midland Medical Society.*—*Dr. Richardson's Address.*—*Sanitary Improvements.*—*Medical Appointments.*—*Female Medical Education.*

IN the notice of the Hospital Sunday collection, in last week's JOURNAL, there is a printer's error substituting 3 for 5; the total amount now is £5,650, being several hundreds more than in any previous year. As almost all this goes to the Queen's Hospital, and as it has been given at a time when other large subscription lists are open for other public purposes, it is commonly regarded as a substantial vote of confidence in the hospital management and in the recent changes.

The committee of the Midland Medical Institute have arranged with the Council of Queen's College to rent part of their building for library and other purposes. This is considered a very satisfactory arrangement; the rooms and the position are excellent; the local school of medicine is rightly brought into closer connection with the institute; and there is evidence of a burial of the hatchet and smoking of the calumet that is of good omen for future unity.

The library subcommittee have already taken over the periodicals and books of the Midland Medical Society, which has now modified its programme, and has resolved in general meeting: "That it be for the future carried on as a Society for the Promotion of Scientific and Practical Medicine and Surgery by the delivery of addresses, the reading and discussion of papers, and by pathological and other demonstrations." The books belonging to the Society are presented to the Institute, and the subscription fee is lessened.

The Society's Inaugural Meeting, which has become now an annual institution, was held on Wednesday evening, under the presidency of Dr. Johnston, J.P., and was very largely attended. A cordial address of thanks and appreciation was presented to the much esteemed Treasurer Mr. Harmar; and afterwards an able address was delivered by Dr. B. W. Richardson, on the Treatment of the Dying. He observed that Dr. Alison's description of four modes of death required more detail to be useful, and twelve modes might be described as follows:—1. From degeneration of tissue—natural decay; 2. From structural degeneration—as of heart or lung, cancer, etc.; 3. From cold—temperature of 28 deg. Fahr.; 4. From displacement of oxygen of blood or prevention of its combination (this was caused by septinous products; and an experiment showed that vaccine lymph liberated oxygen from peroxide of hydrogen; quinine would, to some extent, prevent this); 5. From loss of blood; 6. From cranial pressure, as in apoplexy (the lecturer had proved direct communication between the cerebral and iliac veins by injecting mercury, and also by lighting at a tube in the cranial substance gas injected into the ascending iliac vein); 7. From uræmia; 8. From shock, arterial spasm, accumulation of motor force (this occurred in narcosis from chloroform and other anæsthetics of the same series—probably from irritant action); 9. From arterio-paresis, as in congestions of the lung or kidney; 10. From muscular spasm, tetanus, colic; 11. From pectous change, as of blood and nerve-tissue—as in croup, pneumonia, rheumatism, and *post partum*; 12. From true asphyxia. Dr. Richardson then proceeded to consider modes of treatment available for some of these—as in 5. transfusion; in 6, 7, 8, and 9. bleeding, which he strongly urged, relating cases; in 10. nitrite of amyl, showing his own plan and Mr. Smith's inhaler; in 11. the administration of liquor ammoniæ to saturation of blood, preserving the horizontal position—he instanced striking cases of recovery after pyæmic symptoms from solution of heart-clot; finally, in 12. artificial respiration after tracheotomy by means of most ingenious bellows, or rather air-cylinders, calculated to remove from, or pump into, the lungs fifteen or thirty cubic inches of air at a time. This, he said, promised to be a most valuable resource, especially in hospital practice; it had not been described before. The

lecturer was listened to with the greatest interest, and received a most hearty vote of thanks.

The early and energetic use which this town proposes to make of the Dwellings' Improvement Act has become well-known throughout the country. We have even seen a French paper containing a fairly accurate account of the scheme, and drawing the attention of its readers to the remarkable fact that it is possible to be a radical and yet an administrator. The original plan, involving an expenditure of one and a quarter millions, was carried by a very large majority of the Town Council, and awaits now a further sanction of the Central Board. The officer of health has now sent in, in due form, a notice that another and neighbouring area is also, to a large extent, "unfit for human habitation". Of the truth of this, there can be no doubt; and the contrasted death-rates of certain streets supplies Dr. Hill with a cogent argument. Whilst the average death-rate of the borough is 26.78, that of some streets named stands respectively at 32, 38, 43, 54, and even 73! After an explanation that this extension of area would not involve more expenditure, but would allow more selection of sites, and that the destruction and reconstruction would be spread over a long time, this addition to the scheme has been carried to-day by the Town Council, with one dissentient only.

At the Children's Hospital, Dr. J. B. Welch has been elected acting physician, and Dr. Warner extra-acting physician. Mr. J. N. Ravenhill has been elected honorary surgeon to the Lying-in Charity. A vacancy for another demonstrator of anatomy at Queen's College will be announced shortly.

The Mayor, as the Chairman of an Association, has written to the Committee of the Queen's Hospital to inquire if women students can be admitted there for clinical instruction in the event of a new medical school being founded for them. The letter has been acknowledged, and its consideration deferred till the next meeting.

ASSOCIATION INTELLIGENCE.

THAMES VALLEY BRANCH.

THE first meeting of the above Branch will take place at the Board Room of the Richmond Infirmary, on Wednesday, November 17th, at four o'clock.

Papers will be read by—

1. Dr. Milner Fothergill: On the use of Digitalis in Aortic Disease.
2. Dr. Donkin: On the Nomenclature of Bright's Disease, clinically considered.
3. Dr. Wiltshire: On the Pathology, Diagnosis, and Treatment of Uterine Polyp.
4. Dr. Fenn: On the Pathology and Treatment of Acute Rheumatism.

There will be a dinner afterwards at the Greyhound Hotel at six o'clock. Charge, 7s. 6d. each, exclusive of wine.

F. P. ATKINSON, M.D., *Hon. Sec.*

Kingston-on-Thames, November 2nd, 1875.

SOUTH EASTERN BRANCH: EAST SUSSEX DISTRICT MEETINGS.

THE next meeting of the members of the above District will be held on Wednesday, November 24th, at 3.30 P.M., at the Royal Pavilion, Brighton; Dr. HENRY MOON in the Chair.

Dinner at Markwell's Royal Hotel at 5.45 P.M. Charge, 5s., exclusive of wine.

The Aquarium, Sussex County Hospital Museum, and the Museum and Picture Gallery of the Town, will be open to members. The first named on presenting their cards.

Sir Cordy Burrows will relate a case of Hip-joint Disease.

Notice of intended communications is requested by the Secretary by Tuesday, the 16th instant.

THOMAS TROLLOPE, M.D. Cantab., *Hon. District Secretary.*

35, Marina, St. Leonards-on-Sea, November 9th, 1875.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.

THE next meeting, to be held in the Music Hall Buildings, Aberdeen, on Saturday, December 4th, at 3 o'clock in the afternoon, will be devoted to a debate on the proper place of Alcohol in Therapeutics. The debate will be opened by Dr. Urquhart, Aberdeen.

J. URQUHART.

November 11th, 1875.

ALEX. OGSTON.

WEST SOMERSET BRANCH.

MEMBERS of this Branch are requested to take notice that Henry Alford, Esq., Taunton, will perform the duties of Honorary Secretary and Treasurer during the temporary absence of Dr. Kelly, who has gone to Mentone for the winter.

GLOUCESTERSHIRE BRANCH.

THE annual meeting of the above Branch will be held on Tuesday, November 16th, at 6.30 P.M., in the Masonic Room at the Bell Hotel, Gloucester.

The supper will be at the Bell Hotel at half-past Eight.

Business of the Meeting.—Election of officers for the ensuing year.

Insular Sclerosis. By Dr. Wilson, Cheltenham.

The attitude of the University and other Examining Boards, and the Medical Profession generally, in relation to the questions connected with the Medical Education of Women. By Dr. Batten, Gloucester.

RAYNER W. BATTEN, M.D., *Honorary Secretary.*

Gloucester, October 8th, 1875.

SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT.

A MEETING was held on October 14th, at the White Hart Hotel, Reigate; J. WALTERS, Esq., M.B., in the Chair. Eleven members were also present; and, as visitors, Sir Thomas Watson, Messrs. Flood, M.B., and Hawken.

Medical Advertising.—Dr. HOLMAN proposed, Mr. E. H. GALTON seconded, and it was carried unanimously:—"That, in the opinion of this meeting, the practice of continuous advertising of medical books in the non-medical public papers is derogatory to the interest and dignity of the profession, and should be abandoned."

Treatment of Colles's Fracture.—Dr. WALTERS read notes on the treatment of Colles's fracture. He advocated the use of a straight wooden splint, padded in the middle, for three or four weeks; then the application of a gutta-percha gauntlet, which keeps at rest the ends of the bone, but allows free movement of the fingers.—Dr. HILL exhibited Gordon's splints for the same injury, and affirmed that, under treatment by them, cases were cured in three weeks, with free rotation of the radius at the end of that time.—Messrs. CHALDECOTT and CHAMPNEYS took part in the discussion.

Specimens.—Dr. WALTERS exhibited the Head and Neck of a Femur removed by himself, also an Uterus and Vagina, with rupture of the latter, which occurred during labour, the patient remaining without untoward symptom for three days.

Acute Dropsy in a Boy.—Dr. CHALDECOTT read a case of acute dropsy, with convulsions, in a boy aged 8. The urine was slightly albuminous and loaded with triple phosphates, contained no casts or blood-cells. The convulsions ceased after the removal of four ounces of blood by bleeding.—Sir THOMAS WATSON and Drs. LANCHESTER and GALTON made remarks on the case.

Specimens.—Mr. CHAMPNEYS exhibited a very small foetus, half an inch in length.—Dr. GALTON exhibited a specimen of salivary calculus from the submaxillary duct.

Femoral Hernia.—Dr. GALTON read notes of two cases of femoral hernia, in one of which erysipelas of the face occurred ten days after the operation, with recovery; in the other, inversion of the patient to an angle of 45 deg. for twelve hours previous to the operation had no good effect.

Fistulous Opening in Neck.—Dr. HOLMAN mentioned a case of fistulous opening at the side of the trachea, which was stated by Sir James Paget to be a still perforate branchial cleft.

Anæsthetics.—A discussion on anæsthetics was introduced by Dr. LANCHESTER, in which opinions were expressed by Drs. Holman and Walters in favour of a mixture of alcohol, one part; chloroform, two parts; and ether, three parts.

Puerperal Fever.—Dr. HOLMAN read notes of four cases of puerperal fever. No. 1, aged 36, nursed a child with scarlet fever at six months' and a half pregnancy. Labour came on three weeks after the child's convalescence. She died on the ninth day. A slight rash appeared just before death. There was no sore-throat. No. 2 recovered. No. 3 had a bad attack, which was conveyed to No. 4. He insisted strongly on the necessity of precaution.—Sir THOMAS WATSON and others made remarks.

Next Meeting.—It was agreed that the next meeting should be held at Croydon on December 9th; Dr. ADAMS in the Chair.

Dinner.—Ten members and two visitors sat down to dinner.

CORRESPONDENCE.

COMPULSORY REGISTRATION OF DENTISTS.

SIR,—Permit me to express my full concurrence in the remarks of both Mr. Napier and Mr. S. Hamilton Cartwright, lately brought forward in your JOURNAL, on the subject of dental reform, and which you so ably criticised a few weeks since in one of your "leaders". Still I cannot but think, putting aside much that was objectionable, that the late meeting at Manchester with regard to the compulsory registration and education of dentists had many good points attached to it as a step in the right direction to bring about (doubtless in a small degree at first) the reform so much needed.

I am, sir, yours faithfully,
HAMILTON CRAIGIE.
13, Portland Place, Cavendish Square, W., Nov. 6th, 1875.

SIR,—Will you kindly allow me a few lines in reply to a letter which appeared under the above heading in last week's JOURNAL?

It might be inferred that Mr. Napier was advocating a new system of practice in deputed to skilled mechanics the purely mechanical part of his work; but it is well known that this is, and has been for years, the general custom among dentists; and that this work is done sometimes in and sometimes out of the house, according to the convenience and extent of practice of the dentist, the advantage of work done in the house being, that it is more directly under the supervision of the dentist at the various stages of its construction.

But surely the place in which the work is done is a matter of very small importance in the discussion. The real question appears to me to be (and this was mooted some time since in the BRITISH MEDICAL JOURNAL) whether the dentist shall give up to the mechanic the entire mechanical branch of the profession, including the adjustment of teeth in the mouth, or not. To this question, the answer must be that he should not; for this requires not only mechanical skill but surgical and anatomical knowledge, as well as æsthetic taste.

I maintain that the dentist who prepares the mouth for artificial teeth, superintends their manufacture, whether in his own house or not, and adjusts them in the mouth, is in exactly the same position as the surgeon who supplies his patients with and adjusts splints and other surgical instruments. I believe that, in this view, I shall have the concurrence of all who are practically acquainted with the subject, and it is to guard against any misconception that might arise from a misunderstanding of Mr. Napier's letter that I trouble you with these remarks.

I am, sir, yours faithfully,
ASILEY GIBBINGS, M.R.C.S., L.D.S.
Nov. 1875.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

A MEETING of ratepayers has been held and a resolution passed, to form a local board in the parish of Sheepshed, Leicestershire.

THE SKIPTON GUARDIANS.

THE proverbial and often false economy of so-called guardians of the poor is exemplified in the recent action of the Skipton Board towards their medical officer, who, after holding his appointment for a year, has applied for an advance of salary, basing his claims thus:—1. The salary has been the same for the past twenty-five or thirty years; 2. An infirmary for contagious and infectious diseases, for the whole union, has been added to the workhouse, without any additional salary; 3. The number of inmates in the workhouse has nearly trebled. To the intelligent minority of the guardians, their medical officer's claim seemed most reasonable; but, on a vote, it was decided to give no advance. The workhouse doctor consequently resigned; and, as his professional brethren in the town are sensible of the justice of his claim, they all refuse to apply for the post. In this dilemma, the guardians are advertising the appointment, and it now remains to be seen whether anyone, or who, will assist the guardians in frustrating the apparently just claims of their medical officer. Considering that there is not a breath of complaint against his professional skill or attention to the sick poor, we hardly think any medical man would be justified in offering himself to fill the vacancy.

EPIDEMIC OF TYPHOID FEVER AT FORT CUMBERLAND, PORTSMOUTH.

THE notice which appeared in the *Times* of Tuesday last respecting an outbreak of typhoid fever amongst the recruits of the Royal Marine Artillery stationed at Fort Cumberland, Portsmouth, is correct in all its details. The origin of the epidemic has been distinctly traced to sewage-pollution. There have been four fatal cases, sixteen pronounced cases, and about forty cases of indisposition arising from the same cause. The whole of the recruits who tenanted the fort have been withdrawn, and sent for the present to Forton, and the cholera-hut at Eastney has been converted into a temporary hospital for the isolation and treatment of the patients, who will be all removed from the hospital in Fort Cumberland. This occurrence should bring about the building of a permanent hospital at Eastney for the use of the sick in the division stationed there, as has, we believe, been frequently recommended by the Director-General of the Medical Department of the Navy.

THE WORKHOUSE AND ITS MEDICAL OFFICER.*

THE general orders of the Poor-law—now Local Government—Board relating to the duties of the medical officer, though defined with much official exactitude, are, on many important matters, perfectly silent, for the reason, as it appears to us, that, in accordance with the traditions of the department, they were originally drafted by some person or persons completely ignorant of matters medical. Dr. A. Sheen, the medical officer of the infirmary and workhouse at Cardiff, having had, during the five years' tenure of his appointment, to educate himself in the duties and obligations of his office, in the *brochure* before us, puts together in easily understood language a ready means whereby the workhouse medical officer, in his noviciate, may without difficulty obtain all the information which will enable him with facility to carry out his varied duties. Considering that such a publication will be of much service to certain of the 665 of our medical brethren who hold these appointments, we will proceed briefly to review his production. It would appear that, when Dr. Sheen was originally appointed, it was obligatory on him, in return for a stipend averaging £104 yearly, to provide all medicines and appliances save cod-liver oil, quinine, iodide of potassium, morphia, and tincture of opium. Since that time, thanks to the continuous agitation of the Poor-law Medical Officers' Association, the salary has been raised to £120 a year, the guardians undertaking to provide all medicines and appliances; not too much, by the by, when it is considered that the workhouse averages 365 inmates, the schools 260 children, and that there is a separate hospital built for 130 beds. Dr. Sheen very properly points out that an establishment of this size should have a resident house-surgeon, and further suggests that the head nurse might be taught to perform all ordinary dispensing. We would, however, much prefer to see introduced into England the plan adopted in similar-sized Irish workhouses; viz., the appointment of a resident apothecary who, by virtue of his professional knowledge, could see every inmate on admission, send for his chief when necessary, and prepare and dispense all medicines. Nevertheless, the idea of instructing the paid nurse of a smaller institution in the knowledge of dispensing is not without value. Dr. Sheen would abolish the system of rating sick poor persons as paupers, and in this we entirely agree. One of the greatest blots of the English method of dealing with pauperism consists in placing those seeking relief in consequence of sickness on the same level as those requiring it through idleness, improvidence, or intemperance. Whilst the latter should be sternly dealt with in workhouses, in our judgment the largest consideration should be shown to those chargeable to the rates through the accident of illness.

Passing to another point—the list of formulæ for workhouse hospital practice—we have much pleasure in commending it to our readers' notice, as it contains many valuable prescriptions that might be beneficially adopted in a more exalted sphere of action. There is, however, one subject to which we desire to draw special attention, and it is that of the dietary table introduced by Dr. Sheen. We write advisedly when we state that there is no more fertile source of contention between the master and the medical officer than the diets ordered by the latter, and everything which tends to harmony between these two officers it is at all times desirable to encourage. We do not find in the list any arrangement whereby the jaded or imperfect appetites of the severely sick can be readily dealt with. In certain workhouses with which we are acquainted, a dietary is specially framed to meet this too frequent class of cases. This consists of either fish, a chop, eggs, beef-

* *The Workhouse and its Medical Officer.* By Alfred Sheen, M.D. Cardiff: Lewis, 1875.

tea, arrowroot, or milk, and is called *ad libitum* diet. The nurse of the ward enters on a card daily the diet which the patient has selected, only one of the six being allowed; at the end of the week, the master or his clerk takes out the total of each diet, which he distributes on his side of the medical relief book among those persons who have been receiving this exceptional diet. This method admits of the fancies of sick people being gratified with a minimum of trouble, and without unnecessary expense.

With this criticism of Dr. Sheen's pamphlet, we commend it very heartily to the attention of all workhouse medical officers.

SIR,—Would it not be far more praiseworthy on the part of such Boards as St. Giles' (the majority of whose members had determined to elect their "chum", regardless of the interests of the parishes and ratepayers of St. George's and St. Giles'), ere the advertisement be issued soliciting candidates for the position of medical officer of health, to first of all record their votes, and subsequently advertise in such a manner as to comply with the Act of Parliament? Such a course would save candidates really qualified to fulfil the duties of medical officer of health the annoyance and, I was going to add, degradation of seeking at the hands of those persons with whom rests such appointments "the favour of a hearing". In the advertisement issued by the clerk of the St. Giles' and St. George's Board, we were told: "Personal canvass of the members of the Board was strictly prohibited"; he might have added, "personal application for the appointment by qualified gentlemen and outsiders will be considered an insult, and treated with the wrathful rigour of constituted authority." Joking apart, can nothing be done to fully expose such jobs? or is the pigmy to usurp the giant's seat for aye? I am, faithfully yours, SPERO MELIORA.

November 8th, 1875.

POOR-LAW MEDICAL APPOINTMENTS.

ARCHER, George, M.R.C.S.Eng., appointed Medical Officer to the Fifth District of the Guiltcross Union, *vice* A. C. Farrington, L.R.C.P.Ed.
 BAILEY, James B., M.D., appointed Medical Officer and Public Vaccinator for No. 6 District of the Bath Union.
 BELLMONT, James T., L.R.C.P.Ed., appointed Medical Officer and Public Vaccinator for the Parish of Dalkeith, *vice* Robert R. Jeffers, M.R.C.S.Eng., deceased.
 BRODIE, Malcolm, L.R.C.P., appointed Medical Officer and Public Vaccinator for No. 2 District of the Bellingham District, Northumberland.
 BROWN, Philip, M.D., appointed Medical Officer to the Winlaton District of the Gateshead Union, *vice* A. Megget, M.D.
 CALDWELL, Samuel, L.K.Q.C.P.I., appointed Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Crossbane Dispensary District of the Baileborough Union, county Cavan, *vice* John Atkin, M.D., resigned.
 CALLAN, Patrick, L.K.Q.C.P., appointed Medical Officer to the Workhouse and Fever Hospital, Ardee Union.
 CLARKE, Thomas, M.D., appointed Assistant Medical Officer to the Workhouse, Brownlow Hill, Liverpool, *vice* A. M. S. Hamilton, M.D., resigned.
 CLARKE, Thomas F., M.D., appointed Medical Officer to the Bradninch District of the Tiverton Union, *vice* S. R. Potter, M.E.
 GRANT, James, L.R.C.P.Ed., appointed Medical Officer and Public Vaccinator for the parishes of Birsay and Harray, Orkney, *vice* G. Garson, L.R.C.S.Ed., resigned, and of Hoy and Gramsay, *vice* C. Macpherson, M.B., resigned.
 GRAY, John R., M.B., appointed Medical Officer for the Knayton District of the Thibst Union, Yorkshire, *vice* J. A. Buchanan, M.D., resigned.
 HEALY, Michael J., L.K.Q.C.P.I., appointed Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Monasterboice Dispensary District of the Drogheda Union, *vice* P. Callan, L.K.Q.C.P.
 IRELAND, Arthur J., M.D., appointed Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Ardahan Dispensary District of the Gort Union, county Galway, *vice* W. J. Nally, L.R.C.S.I., resigned.
 MOORE, John B. G., L.R.C.P., appointed Medical Officer and Public Vaccinator for the No. 1 District of the Ongar Union, Essex, *vice* T. Markby, M.R.C.S.Eng., resigned.
 PATERSON, William, M.D., appointed Medical Officer for the Chorley No. 1 District of the Chorley Union, *vice* George Tobin, M.R.C.S.Eng., resigned.
 NALLY, William J., M.R.C.S.Eng., appointed Medical Officer and Public Vaccinator to the Kinvara Dispensary District of the Gort Union, county Galway.
 POWER, Joseph, L.R.C.P.Ed., appointed Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Borrisoleigh Dispensary District of the Thurles Union, county Tipperary, *vice* J. P. Quinlan, L.R.C.S.I., resigned.
 SANDIFORD, Thomas H., M.D., appointed Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Kilshanny Dispensary District of the Mallow Union, co. Cork.
 SCOTLAND, Thomas, M.B., appointed Medical Officer for the No. 1 District of the Newcastle-on-Tyne Union, *vice* T. C. Nesham, M.D., resigned.
 SOMERVILLE, Thomas A., M.R.C.P.Ed., appointed Medical Officer and Public Vaccinator for the Widmaslow District of the Altrincham Union, Cheshire, *vice* Joshua Bower, M.R.C.S.Eng., deceased.
 SUTCLIFFE, Edward, M.D., appointed Medical Officer to the Peters-Marland District of the Torrington Union, *vice* H. E. Paltinson, M.R.C.S.Eng., resigned.
 SUTHERLAND, William, L.R.C.P.Ed., appointed Medical Officer for No. 6 District of the Bellingham Union, Northumberland.
 TOBIN, George, M.R.C.S.Eng., appointed Medical Officer for the Chorley No. 2 District: and Public Vaccinator for the Chorley and Coppull Districts of the Chorley Union, *vice* J. M. Rigby, L.R.C.P.Lond., resigned.
 TREUTLER, William J., appointed Medical Officer and Public Vaccinator for the Maresfield District of the Uckfield Union.
 WALSH, Samuel, M.B., appointed Medical Officer and Public Vaccinator for the Brewood District of the Penkridge Union, Staffordshire, *vice* Thos. Creao, L.K.Q.C.P.I., deceased.
 WARREN, Alfred, L.R.C.P.Ed., appointed Medical Officer and Public Vaccinator for the No. 8 or Wooburn District of the Wycombe Union, Bucks, *vice* W. H. Hayden, L.R.C.P., resigned.
 WHITE, Richard, M.B., appointed a medical officer for the Carrignavar Dispensary District of the Cork Union.

MILITARY AND NAVAL MEDICAL SERVICES.

FLEET-SURGEON SETON WADE (says the *Army and Navy Gazette*) has been appointed to supersede Fleet-Surgeon James Lilburne at Deptford Dockyard, and this last-named officer has received from the Admiralty a highly complimentary letter, in which their lordships convey to him their approval of the manner in which he had discharged his duties during the three years he had been attached to the yard.

ARMY MEDICAL REFORM.

SIR,—Would you allow me to make one or two observations on a letter which has just appeared in a contemporary? The writer, in his communication, states that the older surgeons have no grievances, that the younger ones are as pleasantly situated, and that it is only his class, who entered under the warrant of 1858, who have any grievance at all. It is such advocates of sectional grievances and reforms who have kept our profession from rising to its proper position in the military service, and whose policy it is to foster such dissensions in order to avoid any reform at all. We can only succeed as a branch of the medical profession by being united on all vital points, no matter how much we may differ as to minor details. Our demand as an united body should be, as it has always been, that, sharing as we do with the combatant officer and the soldier the dangers and vicissitudes of war and tropical service, we should have a corresponding share in the privileges and honours of the army.

To state that in advocating these principles we neglect those committed to our professional care, and are unmindful of the interests of the soldier, is a statement known to be untrue; for, although we are not faultless, we are as humane and kind to the sick as we ever have been as a body of officers. That young men are induced to enter a service under adverse conditions, is no reason why these conditions should not be improved. Such an idea, if acted upon, would preclude all advancement of military science and medical research. To say that the army medical service has produced of late years no great men is probably true, if judged by the green-eyed monster of corps professional jealousy, but it is not true if judged by the current literature of the profession. *Personne n'est prophète dans son pays*. In making demands for an improvement of our position, we are only following the example of the rest of the army, who are constantly obtaining increased and new privileges, while we as a body are as constantly retrograding.

X. Y. Z.

SURGEONCIES IN THE GUARDS.

MUCH surprise has been felt in well-informed circles that, whereas the surgeon-major of the Blues has been forced to retire on reaching the prescribed limit of fifty-five years, the senior medical officer of the Foot Guards is permitted to enjoy the sweets of office, in spite of having considerably overpassed the same period of life. It is well known that Dr. Logie's services were highly appreciated in his regiment, and that he quits active service with regret; and we cannot but feel that he has very good grounds of grievance against the military authorities who have drawn so invidious a distinction in his case.

UNIVERSITY INTELLIGENCE.

UNIVERSITY OF OXFORD.

EXAMINATIONS FOR THE DEGREE OF M.B.—Examinations for the degree of Bachelor of Medicine will be holden in the second and third weeks of December. The second or final examination will commence on the 6th. The first or scientific examination will commence on the 13th. Candidates are requested to forward their names to the Regius Professor of Medicine before November 23rd.

MEDICAL NEWS.

UNIVERSITY OF LONDON.—Second M.B. Examination, 1875. Pass List.

First Division.

Batterbury, George Henry, King's College
 Batterbury, Richard Legg, King's College
 Garlick, George, University College
 Hetley, Henry, Guy's Hospital
 Hobson, Lewis John, University College
 Hullard, Jean Arthur, B.Sc., University College

Jameson, Leander Starr, University College
 May, Bennett, Birmingham General Hospital and Sydenham College
 Rose, William, King's College
 Smith, Herbert Alder, St. Bartholomew's Hospital
 Verco, Joseph Cooke, St. Bartholomew's Hospital
 Voelcker, George Henry, University College

Second Division.

Bogg, Thomas Wemyss, University College
 Buchanan, Arthur, Guy's Hospital
 Crespín, Edgar Reginald Legassick, Guy's Hospital
 Crélin, Eugène, St. Bartholomew's Hospital
 Maclean, Thomas Edwin, University College
 Moore, George Edward, King's College
 Palmer, Frederick John Morton, Guy's Hospital

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their primary examinations in anatomy and physiology at a meeting of the Court of Examiners on the 9th instant; and, when eligible, will be admitted to the pass-examination.

Messrs. J. R. Clark, G. H. Burnham, Colin McLarty, M. D. Stark, and Thomas Millman, student of Toronto; John Christian, W. R. Davies, J. H. March, S. F. Proctor, and E. P. Thurston, B.A. Cantab., of St. Thomas's Hospital; T. H. Lewis, W. A. Dingle, W. F. Mayne, and W. H. T. Winter, of St. Bartholomew's Hospital; Thomas Jones, C. G. W. Lowdell, and J. H. Poland, of Guy's Hospital; C. S. Rundle, C. S. Kilner, and C. A. Walker, of Edinburgh; W. F. Hopwood, and H. A. Layton, of University College; E. C. Beale, B.A. Cantab., and J. C. Saunders, B.A. Cantab., of Cambridge; Charles Knox, of the Liverpool School; A. T. Wilkinson, of the Manchester School; H. B. P. Bnssy, of the London Hospital; W. D. Jefferson, of King's College; and H. W. Thomas, of the Birmingham School.

Twelve candidates out of the forty-one examined, having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their studies for three months.

The following gentlemen have lately been elected Fellows of the College.

Bennett, Joseph Blacker, L.S.A., Cleckheaton, Normanton, diploma of membership bearing date May 18th, 1840.
 Briscoe, John, Oxford, August 15th, 1842.
 Burroughs, John Brames, Clifton, Bristol, January 25th, 1828.
 Flower, Thomas Bruges, Bath, July 9th, 1841.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, November 4th, 1875.

Betty, Samuel George, Park Street, Regent's Park
 Heard, Charles Goodridge, Truro, Cornwall
 Jackson, Edwin, Whalley Range, Manchester
 Kay, Alfred, 311, Commercial Road East
 Knight, John Tomlinson, Sandiacre, Derbyshire
 Marsh, Edwin Addison, 5, Arthur Road, Brixton
 Parkinson, Sidney George, Infirmary, Northampton

MEDICAL VACANCIES.

The following vacancies are announced:—

ARDWICK and ANCOATS DISPENSARY, Manchester—Resident House-Surgeon.
 BURTON-ON-TRENT UNION—Medical Officer. Applications on or before the 15th instant.
 CARMARTHEN UNION—Medical Officer.
 CHARING CROSS HOSPITAL—Assistant-Physician, and Physician or Surgeon. Applications on or before the 25th instant.
 CHORLTON-ON-MEDLOCK, RUSHOLME, and MOSS SIDE DISPENSARY, Manchester—House-Surgeon.
 CRICKHOWELL UNION—Medical Officer and Public Vaccinator. Salary, £35 per annum, exclusive of extra medical fees and vaccination fees. Applications on or before the 13th instant.
 DENBIGHSHIRE INFIRMARY—House-Surgeon. Salary, £85 per annum, with board, washing, and residence.
 DOVER HOSPITAL and DISPENSARY—Resident Medical Officer. Applications on or before the 30th instant.
 EAST SUFFOLK and IPSWICH HOSPITAL—House-Surgeon. Applications on or before December 8th.
 HOSPITAL FOR THE INSANE, Earnwood, near Gloucester—Assistant Medical Officer. Salary, £100 per annum, increasing £10 annually to £120, with board (exclusive of wine), lodging, and washing.
 HUDDERSFIELD INFIRMARY—Physician.
 INFIRMARY FOR CONSUMPTION, Margaret Street, Cavendish Square—Physician in Ordinary. Applications on or before the 18th instant.
 LIVERPOOL INFIRMARY FOR CHILDREN—House-Surgeon.
 LONDON LOCK HOSPITAL—Surgeon and Surgeon to Out patients. Applications on or before the 17th instant.
 METROPOLITAN FREE HOSPITAL—Honorary Assistant-Physician. Applications on or before the 13th instant.
 MIDDLESEX HOSPITAL—Resident Physicians' Assistant. Applications on or before the 13th instant.
 NORTH STAFFORDSHIRE INFIRMARY, Hartshill, Stoke-upon-Trent—House-Physician. Applications on or before the 16th instant.
 PLYMPTON ST. MARY UNION—Medical Officer. Applications on or before the 18th instant.
 RADCLIFFE INFIRMARY, Oxford—House-Physician. Salary, £105 per annum, with board and lodging. Applications on or before the 24th instant.
 ROSS UNION—District Medical Officer and Public Vaccinator. Salary, £100 per annum. Applications on or before the 22nd instant.

TONGUE and FARR, District of, County of Sutherland—Medical Officer. Salary, £150 per annum, and house.
 TRINITY COLLEGE, Dublin—Professor of Botany. Applications on or before January 22nd, 1876.
 WESTMINSTER GENERAL DISPENSARY—Hon. Physician. Applications on or before the 22nd instant.
 WESTMINSTER HOSPITAL—Resident Obstetric Assistant. Applications not later than the 17th instant.
 WEST RIDING PRISON, Wakefield—Resident Surgeon. Salary, £400 per annum, with house, coals, gas, and water. Applications before November 15th.
 WORCESTER GENERAL INFIRMARY—Physician. Applications not later than the 17th instant.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

BRIGGS, H. B., M.R.C.S., appointed Resident Accoucheur to King's College Hospital.
 CROWDACE, James H., L.S.A., appointed Assistant Medical Officer to the East Riding of Yorkshire Lunatic Asylum, Beverley.
 FOOTNES, J. B., M.R.C.S., appointed House-Surgeon to King's College Hospital.
 FOWLER, J. K., M.R.C.S., late House-Surgeon, appointed Assistant House-Physician to King's College Hospital.
 GOULD, A. Pearce, M.B., B.S., appointed Surgical Registrar to University College Hospital, *vice* R. J. Godlee, M.S., resigned.
 GROUND, E., M.R.C.S., appointed Assistant House-Surgeon to King's College Hospital.
 HEBB, R. G., B.A., M.B., appointed House-Physician to King's College Hospital.
 MADDELEY, Edward, M.R.C.S. Eng., appointed House-Surgeon to the Provincial Hospital at Port Elizabeth, Cape of Good Hope.
 WARNER, Francis, M.D., appointed Extra Acting Physician to the Children's Hospital, Birmingham, *vice* John B. Welch, M.B., resigned.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTH.

LINOSAV.—On November 9th, at 21, Grange Loan, Edinburgh, the wife of Robert Lindsay, F.R.C.S.E., Army Medical Department, of a daughter.

MARRIAGE.

LUCE—RYAN.—In Winchester Cathedral, on the 4th November, by the Venerable the Archdeacon of Winchester, assisted by the Rev. Cresswell Strange, M.A., Vicar of Holy Trinity Church, Southampton, James Johnstone Luce, Esq., M.D., Stratford-on-Avon, to Mary, widow of the Rev. John Ryan, Curate of Holy Trinity Church, Southampton, eldest daughter of the late William Barry, Esq., Kilbarry, co. Cork, and grandniece of the late Matthew De Kinzy, Esq., D.L., Clobesmon Hall, co. Wexford, Ireland.

DR. BENJAMIN BARKUS and DR. ROBERT JOSEPH BANNING have qualified as Justices of the Peace for the borough of Gateshead-on-Tyne.

DR. TAYLOR of Paisley, on stepping from a tramway car in Partick, Saturday evening last, was knocked down by a passing lorry, and sustained internal injuries which will confine him to the house for some time.

MR. EDWARD BELLAMY will commence his course of twelve lectures on the Anatomy of the Human Form, at the National Art Training School, South Kensington, on Monday, the 15th instant. Last session, H.R.H. the Princess Louise, Marchioness of Lorne, was a frequent attendant.

MR. CHURCHILL'S WILL.—In the will of the late Mr. John Churchill, the well-known medical publisher, which has just been proved, the following remarkable statement is made in connection with one of the legacies to Professor Wilson, to whom, when he was a pupil, says the testator, "I was introduced by Mr. Liston to direct the drawings for his *Operative Surgery*", requesting him to purchase with the amount of such legacy "some memorial, especially to commemorate his being the father of my series of manuals, a series which added so much to my reputation as a publisher, and produced the substantial reward of a clear profit of *twenty thousand pounds*". Mr. Churchill bequeaths also to his dear friend Dr. Carpenter, F.R.S., with whose literary career both as editor and author I have been so closely connected, the sum of fifty guineas, to purchase some memorial of the unbroken confidence and personal regard that has ever existed between us throughout our intimate association". To each of his three daughters he bequeaths £12,000; and adds, "I have such faith in the integrity and honour of my three sons-in-law, Dr. Clapton, Captain Pepper, and Colonel Robertson, that I have made no settlement of my daughters' legacies, and it gratifies me to give them this proof of my confidence". The following institutions also benefit under the will: the Medical Benevolent College, £500; and the Medical Benevolent Fund, £500. To five religious societies he bequeathed £200 each.

OPERATION DAYS AT THE HOSPITALS.

- MONDAY**Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.
- TUESDAY**Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.
- WEDNESDAY** ..St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.
- THURSDAY** ...St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 3 P.M.
- FRIDAY**Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.
- SATURDAY** ...St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M. and 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

- MONDAY**.—Medical Society of London, 8.30 P.M. The discussion on the Case of Excision of the Astragalus, shown by Mr. Watson on Monday last; Dr. Drysdale, "For and Against Animal Vaccination".
- TUESDAY**.—Pathological Society of London, 8.30 P.M. Dr. Crisp: Fractured Bones of Gorilla—Rickets in Pheasants. Dr. Hilton Fagge: Distended Diverticula of Intestine—Pulmonary Embolism. Dr. Barlow: Tubercle of Pancreas. Mr. Marsh: Tumour of Jaw. Mr. Fairlie Clarke: Tubercular Lupus of Tongue. Mr. Maunder: Fatty Tumour of Male Breast. Dr. Goodhart: Hydatid in Heart. Dr. Dowse: Elijosarcoma of Brain. Mr. Clement Lucas: Larynx after Tracheotomy. Mr. John Morgan: Dilatation of Bile-Ducts. Dr. Frederick Robinson: Aneurism of Aorta. Dr. Habershon: Obliteration of Superior Cava—Ulceration of Duodenum. Mr. Marsh, per Dr. Hlott: Congenital Malformation of Oesophagus. Dr. Dowse: Syphilitic Growth of Cerebral Sinuses. Mr. Alexander Morison: Disease of Pulmonary and Tricuspid Valve. Mr. Thomas Smith: Hæmorrhagic Peritonitis. Dr. Gowers: Elixoma of Brain—Fatty Tumour of Spinal Cord. Dr. Wickham Legg: Congenital Deficiency of Common Bile-Duct.—Statistical Society, 7.45 P.M.
- THURSDAY**.—Harveian Society, 8 P.M. Dr. J. E. Pollock, "On certain varieties of Heart-disease, with reference to Prognosis and Treatment".

NOTICES TO CORRESPONDENTS.

- CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.
- PUBLIC HEALTH DEPARTMENT**.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.
- AUTHORS** desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.
- CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.
- WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**
- COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

EUCALYPTUS.—We do not know. The information could, however, be obtained by writing to Dr. Bond, Medical Officer of Health, Gloucester.

ESERINE DISCS IN TIC.

SIR.—Allow me to explain to Kilogramme that the eserine discs are to be put into the eyes; not to be used internally, as he seems to me to think—I am, yours faithfully.

Cupar Fife, November 8th, 1875.

P.S.—While writing, I may mention that I have lately received from Messrs. Savory and Moore, of New Boud Street, soft gelatine discs, saturated with the extract of Calabar bean (of the kind proposed some years since by Mr. Ernest Hart), for ophthalmic use, which suit very well. One or two as a dose. They may be more easily obtained than the eserine discs.

A DRUGGIST'S OPINION.

AT a recent inquest at Redruth, Mr. S. T. Rowe, druggist, gave the following evidence. He had been giving the deceased medicine for some time. She could not sleep without it; her nerves were out of order; and the object of the medicine he gave was to quiet the nerves, and produce sleep. He had been frequently called to her in the night, when she was in a state of frenzy. The draught which he prepared for her husband on Monday, contained precisely the same quantities of the various ingredients as the draughts usually administered to her. His opinion (without *post mortem* examination) was that death was caused by concussion of the brain. The jury returned a verdict "Died from concussion of the brain, the effects of a fall". Is not such an inquest and such evidence something worse than a farce?

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

PHYSIOLOGIST (Weston-super-Mare).—1. (Elementary) Huxley's *Elementary Physiology*, and Huxley and Martin's *Lessons in Biology*; (advanced) Hermann's *Physiology*, edited by Gamgee. 2. Parkes on *Hygiene*; Hart, Corfield, and Wanklyn's *Manual*. 3. Chambers's *Manual of Diet*, or Dobell's *Handbook of Diet*.

TREATMENT OF INCONTINENCE OF URINE.

SIR.—In reply to the letter of a "Country Practitioner" in your last issue on the above subject, I beg to say that, if the patient have a long prepuce and phimosis, it will be found that "circumcision availeth" something, if not "a new creature". If this condition be not present, the extract of belladonna given internally in doses of one-sixth of a grain, gradually increased till its physiological action is produced, will be found most valuable. Lyiog on the back favours the occurrence of the accident; a cotton reel tied with tape, so as to press on the spine when the patient turns over from his side, will make him "feel his position acutely", and help to prevent him from wetting the bed.—I am, sir, yours obediently,

Long Stratton, November 8th, 1875.

X. Y. Z.

SIR.—In reply to "A Country Practitioner" inquiring what should be done in a case of obstinate enuresis, I would recommend the trial of a seton in the back, over the region of the sacrum, kept open for a few weeks. This succeeded with a patient of mine after trying everything I could think of—my case was older than his patient at the time of using this remedy; and so completely was he relieved, that he afterwards entered the Marine Artillery, where, as far as I know, he still is. The affection was present from childhood; and the young man was so disgusted at his complaint, that he willingly subjected himself to any treatment.

I am, sir, yours truly, F.R.C.S. Eng.

SIR.—I think that if your correspondent, "A Country Practitioner, Dublin", were to give his patient ten grains of hydrate of chloral, with five minims of tincture of belladonna, in an ounce of orange-flower water every night as bedtime, I have no doubt he will find that it will check the incontinence of urine.

I am, faithfully yours, EDWARD IRELAND.

The Limes, Linton, Cambridgeshire, November 7th, 1875.

SIR.—Allow me to inform "A Country Practitioner", through your valuable medium, that I have had several cases similar to the one he mentions, and also one in a young girl, all of which I have cured and prevented the bad habit by means of chloral-hydrate, given every night about seven or eight o'clock, for a few times consecutively, and then gradually less frequently. I would also (as I always do) advise the patient not to be spoken to hastily, or his condition will be aggravated. If a "Country Practitioner" will kindly communicate the result, either publicly or privately, I shall be glad.—I remain, yours very truly,

Maryport, November 6th, 1875. WM. HY. SPURGIN, M.R.C.S. Eng. & Ed.

SIR.—In the JOURNAL of last week, I notice an inquiry concerning the treatment of "enuresis", dated from Dublin, and signed by "A Country Practitioner". I would humbly suggest the trial of the following remedies. 1. Time and patience. 2. Attention to the position in bed; keep the patient from lying on his back. 3. Plenty of outdoor exercise, coupled with good food and the abandonment of too confining an occupation, should such an one come into consideration. 4. Total abstinence from all drugging. 5. Let the patient refrain from taking large quantities of fluid during at least two hours before going to bed. 6. Let him not forget to pass urine immediately before going to bed. It will be well, also, to let the patient know that no effect of weakness can possibly be a disgusting habit, and that it certainly is not a disgraceful one. In conclusion, if the inquirer will but admit time and patience more especially into his medicine chest, he will find more success in the treatment of such cases.—I am, sir, yours truly,

Kirkoswald, November 8th, 1875. MAX R. J. BELVUNDT.

W. T. M. states that the following remedy has acted very satisfactorily, when all others had failed, in stopping the habit. R. Liq. Quorist. strychoia: B.P. ʒss; liq. ferni perchloridi fort. ʒss; aquæ ʒviij. Half an ounce three times a day in water.

A. B. (Wrexham).—1. Tilbury Fox, on *Diseases of the Skin* (Churchill and Sons); 2. Brudenell Carter, on *Diseases of the Eye* (Macmillan), which, we think, perhaps best answer the requirements of our correspondent.

A. B. (Lincoln).—Under the regulations of the University of Cambridge, the examination in State Medicine alone is relied on as a test, and no curriculum is required—a very wholesome precedent, which, we trust, will be followed widely.

MANCHESTER PROVIDENT DISPENSARIES' ASSOCIATION.

SIR.—I am sorry to see, from your remarks in the BRITISH MEDICAL JOURNAL of the 6th instant, that you give such implicit credence to Mr. O'Hanlon's letter on the existing relations between the medical men in Manchester and the Council of the Provident Dispensaries. Mr. O'Hanlon himself proves that the admission of friendly societies into the provident dispensary scheme is a "direct violation of the terms of the original scheme". That scheme was, that no member should be in the receipt of more than an income of 30s. per week; but the Council, finding the admissions were so few on these terms, resolved, contrary to the wishes of the whole of the medical staff, to raise the limit to 35s. Now, in Mr. O'Hanlon's letter to you, he acknowledges that the income of many of the members of friendly societies exceeds that limit; and therefore, apart from a distinct understanding which existed from the first, that friendly societies, as a body, should not be admitted into the provident dispensary, I think you will allow that your correspondent of the 16th October was correct in this part of his statement.

"The very temperate terms" used by Mr. O'Hanlon in his letter to you are not at all in accordance with his conduct to the medical men connected with the provident dispensaries. From the first, if they have dared to differ with the Council (or, in other words, with Mr. O'Hanlon), they have had the threat held out, that if they did not concede to terms, others would be found who would do so. Much to their disgust, and without their sanction, whole districts have been canvassed by house-row, and the canvasser paid a commission on the number of members he obtained, whilst thousands of the enclosed hand-bills and pamphlets have been freely distributed. Under such management, you will readily believe that the provident dispensary charity is more abused than ever any hospital was.—I am, sir, your obedient servant,

JOHN WATSON.

Ardrick Provident Dispensary, Manchester, Nov. 9th, 1875.

STR.—At the entrance of the rules of the above Association stands, bar-like, the following: "The members shall be artisans or others in receipt of weekly wages, whose average family earnings do not exceed thirty-five shillings a week." Of friendly societies, Mr. O'Hanlon admits "that the income of some of their members would, no doubt, exceed the limit fixed by their rules"; and the correctness of that doubt is not doubted by any one. Yet, the extraordinary meeting of the 23rd August noways rescinding or altering the above commanding preamble, that rule of rules, but allowing it to stand untouched, resolved to admit members of friendly societies as such, without any limitation whatever as to income. If this be not *pugnantia secum frontibus adversis componere*, I know not what is. However, Mr. O'Hanlon "fails to see that there has been in this way any violation of the original scheme"; and goes on to say that "a violation can only mean that its rules have not been observed". Thus, speaking of "alterations in the scheme" and "in the rules", he does not see that, whilst they remain unaltered, they have simply been broken. Indeed, he is solicitous only to vindicate the proper observance of the prescribed technicalities. In this, however, he is singularly unlucky. For, first, it does not appear in the rules that it is the business of an extraordinary meeting to "revise the principles upon which the federation is based", that power being vested expressly in the annual general meeting. Again, the notice of the "alteration proposed", if, according to the rules, it ever were forwarded to, appears never to have reached, e.g., the Committee of the Provident Dispensary in Dawson Street, since none of the three medical men attached to it, and of whom I am one, ever heard there anything of such notice. Still further, notice of any proposed "alteration" has to be given in the daily papers one month, not "some weeks", as Mr. O'Hanlon has it, before the date of an extraordinary meeting; yet such notice was not given, as I find, before the 5th August, only eighteen days, that is, prior to the meeting. In that notice, moreover, as you will see in the enclosed copy, the subject of the admission of friendly societies occupies but a secondary position at the tail of the advertisement, whilst assuredly it needed to have had special prominence given to it. The fact that, "at such a meeting, the committee of each medical charity and provident dispensary in the federation are entitled to attend and vote", did and does not now appear to me to imply that all the medical officers are thus entitled; and it was just on that ground that, very reluctantly, I stayed away from the meeting. What "the chief mover of the present opposition to the Association" (?), whoever he may be, may have agreed to at the meeting of his dispensary, is irrelevant. That only three out of the twenty-three medical officers were present at the extraordinary meeting—which was held in the small room where the Council are wont to meet—may have been owing to the neglect of proper notice, asserted above; and, to the ignorance on the part of some as to their right to attend and vote, or to professional engagements. Of the twenty-three medical officers, only one had, so far, been admitted to a seat in the Council; and it so happens that he was one of the three present at the meeting, and that he joined his two colleagues in opposing, though vainly, the infringement of the fundamental rule involved in the admission of members of friendly societies as such.

When, therefore, the great majority of the real workers among the medical officers sent in their protest against the resolution of the meeting, they would have done better, in my opinion, in substantiating their legal and practical objections. However, it was only after the adverse reply of the Council to that protest had been received, that I first heard of the existence of a disagreement. The avowal that the Council for such a reply, on such grounds, had to be indebted to "the recommendation of two of our leading medical men, managers of the two largest hospitals in the city"—whomever that may mean—is, though funny, anything but complimentary to either the counsellors and the counselled. From sincere disapprobation of the course followed by the Council, I did not hesitate to join my name to those of the officers who have sent in a three months' resignation, and, with them, to decline any terms short of the withdrawal of the obnoxious and downright illegal resolution of the 23rd August. Of the pressure and instigation alleged to have been required and exercised, I am totally ignorant. The comparative calculations into which Mr. O'Hanlon enters, I hold, in the present stage, to be beside the question; their accuracy I am as unable as unwilling to impugn. I cannot refrain, however, from inviting your attention to the contradictory terms of the unhappy resolution of the 23rd August, a copy of which I enclose. We find it there resolved: "Firstly, that a branch or lodge shall join collectively, each member attaching himself to the district in which he may reside"; and, "secondly, that the secretary of such branch or lodge shall pay to the treasurer of each dispensary at the rate of twopence halfpenny per quarter for each member who may have joined such dispensary". Here, then, we have compulsion tempered by option; the latter being more explicitly authorised by this further provision, "that the secretary of any branch deciding to associate itself with the provident dispensaries, shall send a list containing the names and full addresses of the members who may have chosen to join, with the names of the doctors chosen by each of them. The requisite number of cards will then be supplied upon payment of twopence each, and the quarterly subscription of twopence halfpenny per member." It is true that I have been informed privately, by a member of the Council, that they really mean compulsion, whatever they may say to the contrary. Old chaos is come again.

Like three others among the gentlemen who have signed the resignation, I had attached my name to the list of medical officers of the association solely from the desire to signalise my thorough appreciation of its aims. Practically, I have no work to do, and absolutely no advantage to gain. A devoted well-wisher from the first, I know that the exertions of the Council, and especially of Mr. O'Hanlon, are worthy of the highest commendation. It is impossible for a citizen of Manchester not to feel proud of the initiative in so thoroughly patriotic and eminently educational a movement. Yet the Council have still up-hill work before them; for not quite twenty out of the hundreds of general practitioners in Manchester and Salford have as yet joined the Association. No "radical alterations" need, however, be made "in the conditions upon which medical men may become connected with it". Let the Association but religiously observe the law of individualising scrutiny that fronts their codex, and there will then be no need to despair of the sustaining power of that other vital principle—viz., that the members shall have their free choice among the affiliated practitioners in their districts.

A very serious defect in the composition of the Council, which should be remedied as speedily as possible, is the all but entire exclusion from it of the medical workers of the dispensaries. Of the twenty-three at present enlisted, there is, as I said before, but one on the Council; whilst the three or four other members of the medical profession belonging to it are, from their position and career, notoriously and, to their credit be it said, avowedly more or less incompetent to fully understand and fairly represent those interests of the bulk of our profession which are involved in the working of provident dispensaries.—I am, sir, etc.,

Manchester, November 8th, 1875.

A. SAMELSON, M.D.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

THE SURGEON-GENERAL OF THE EGYPTIAN ARMY.

The *Boston Medical Journal*, referring to Dr. Edward Warren, of Baltimore, who left his country three years since to serve in the army of the Khedive of Egypt, states that, just as he had reached the highest position in that service, the office of Surgeon-general of the Egyptian army, he was attacked with ophthalmia of a malignant form. After combating it by every possible means in Cairo, he was finally compelled to go to Paris for treatment, after six months of which he is now left with one eye permanently enfeebled, while the oculists declare that if he return to Egypt the right eye will be compromised and lost. He has accordingly obtained an authorisation to practise in France.

CLINICAL LECTURE

ON

VARICELLA-PRURIGO.

By JONATHAN HUTCHINSON, F.R.C.S.,

Senior Surgeon to the London Hospital, and to the Blackfriars Hospital for Skin-Diseases.

GENTLEMEN,—We meet occasionally with an eruption in children, concerning which it might, with some plausibility, be asserted that it is a kind of persistent chicken-pox. When the eruption first shows itself, it either is chicken-pox, or exactly like it. The cases, from the observation of which I make these statements, have seldom been of less than some months' duration, and in nearly all the mother of the patient stated that the doctor who first saw the case said that the rash was chicken-pox. In a few, the original diagnosis had been "modified small-pox"; and in some others it had followed so closely on vaccination that it was attributed to it. In a few others, no medical opinion had ever been obtained, but the mother described the eruption as having come out copiously, and as having consisted of clear watery vesicles. I think, therefore, that I am safe in stating that it is probable that these cases do begin as *boni fide* varicella. Their peculiarity consists in that the eruption, instead of disappearing in a few days, is indefinitely prolonged by the succession of fresh crops, and that the spots ulcerate and scab, sometimes becoming large sores. Great irritation is produced, and the child becomes fretful and thin. The eruption may last for months, and the spots then come to resemble ecthyma on the one hand, or yet more frequently the disease known as "lichen urticatus".

I do not think that after the first stage we ever notice any vesicles so similar to those of varicella as to be likely to be mistaken for them, but throughout its course the disease is attended by the successive formation of fresh vesicles of a certain kind. On parts where the skin is thin, these vesicles are like those of pemphigus on a small scale, become turbid very quickly, and are soon broken by the patient's scratching. On the palms of the hands and soles of the feet, however, it is not uncommon to find perfectly transparent vesicles somewhat deeply placed, which persist for a few days. Wherever on the thinner parts of the skin the miniature bullæ have been broken, red excoriated or scabbed patches result, and on the scalp thick heaped-up scabs like those of porrigo may sometimes be seen. The eruption is attended by intense irritation, and everywhere the child's skin shows the effects of scratching. It is not uncommon for the mother to assert that the child scarcely sleeps at all. Now and then this eruption, as I have said, is attributed to vaccination; but in these cases there is usually the history also of a varicella-like eruption. Some years ago, Dr. Flack of Shoreditch brought me an interesting example of this occurrence. He had himself vaccinated the child, and when the rash not long afterwards came out, he made no question that it was chicken-pox. The rash, however, did not disappear, but persisted for three months, covering the whole surface and wearing the child out by the irritation produced.

I saw this child only once; but, on inquiry some time afterwards, I learnt from Dr. Flack that the eruption had persisted in spite of treatment, and had ended in death. I will read to you Dr. Flack's note, which contains some further particulars of this interesting and important case. It is the only one in which I have ever known death to follow, but in several others the patient has been very ill.

"56, Shoreditch, May 2nd, 1871.

"DEAR SIR,—I find the child you inquire about gradually went from bad to worse, and died in August, 1866, after suffering for nearly five months. Treatment entirely failed. Dr. P. saw the child afterwards, and was of opinion that it was syphilitic, but I could obtain no history to confirm it. I may say that the mother, for eight months of her pregnancy with this child, suffered extremely from pruritus of the vulva, so much so, that fears were entertained of her mind giving way; and this continued within twenty minutes of her confinement. The child was apparently healthy, and very clear in the skin till three months old, and was then vaccinated. The pustules were good and the inflammation not great; but, as the scabs began to form and dry, the eruption appeared with all the symptoms you so well describe. I have thought the sufferings of the mother might have produced such an irritative state of the child's system, that it only wanted an exciting cause to develop it.

"I am, yours truly, JAMES FLACK."

Dr. Flack's suggestion that the child inherited a pruriginous skin is, I think, highly probable. In several other examples of the malady, I have found that there was a history of pruriginous or urticarious complaints in the child's family; possibly it is chiefly in such that vaccination-rashes and varicella become pruriginous and persist. I may add that I had carefully examined this child as to inherited syphilis, and could find no reason to suspect it. An antisyphilitic course which was carried out (not on my recommendation) did no good whatever. This is the only actually fatal case which has come to my knowledge.

It becomes a most interesting question in such cases as this to determine as to what connection the vaccination had with its sequences. It is possible that it has none at all, and that the eruption is a true varicella; for the age at which vaccination is usually performed is the same as that at which varicella is most likely to occur. We must remember, however, that, according to the observations of Mr. Ceely and many others, various forms of exanthem-eruption do occur as the direct results of vaccination, and that a vesicular one is the most common. Indeed, the wonder is not that vaccination should sometimes produce an exanthem, but that it should ever be without one.

A portrait (No. 32*) which has been issued by the New Sydenham Society, illustrates remarkably well the local conditions of the disease under consideration. It was taken from a child, aged three months, in whom the diagnosis of varioloid had in the first instance been given; but as it occurred during the epidemic of small-pox in 1871, it is probable that not a few cases that were really varicella, got the name of the more severe disease. I show you the portrait of the patient referred to, and may remind you that, on a former occasion, you had an opportunity of seeing the child itself. The following are the notes of the case.

George Thornton, aged three months, and at the breast, was admitted on April 21st, 1871, with an eruption which had then lasted for six weeks. It was stated that the rash came out rapidly at first, chiefly on the arms and legs, and that it was said to be small-pox. The patient had never been vaccinated at the time when he was brought to the hospital. No one else in the house had had either small-pox or chicken-pox. The two other children in the house had had no eruption of any kind. The mother described the rash as consisting at first of large clear watery spots. When first seen, the child had a copious eruption of vesicles and pustules on the hands, feet, arms, and legs, and a crop of large porrigo patches on the head. There was no evidence of the existence of itch-mites.

I will now read to you the notes of some other cases of a similar kind. I may here observe that all of these have been sporadic. I have never met with this form of persistent pruriginous varicella, or, more strictly speaking, of persistent vesicular rash following varicella, as an epidemic malady. In a former lecture, however, I quoted a passage from one of Trousseau's lectures, which stated that, during an epidemic of varicella at the Necker Hospital, some cases were protracted for six weeks, and passed into an ulcerating form of eruption, looking like pemphigus. You will find the lecture in the second volume of the New Sydenham Society's *Translation*, and it is well worth reading. Trousseau does not mention prurigo as having been a marked symptom, nor does he say anything about the eruption having occurred on the palms or soles, and he mentions the period of two months as if it had been the extreme limit of duration. Now, in all my cases, the pruriginous element has been a very marked one; the condition of the palms and soles has been a peculiar feature; and the duration of the eruption has been much longer.

CASE I.—Rosina Childs, aged 18 months, was admitted on Feb. 19th, 1869, suffering from a very copious eruption of vesicles or small bullæ on the extremities, trunk, and face. It avoided the flexures, but was very marked on the soles and palms, and this latter feature led to the suspicion that the case might be scabies, but there was no evidence of the presence of the itch-mite. The vesicles when commencing were very firm, and felt quite shotty. The eruption had already lasted four months, and the mother's clear statement was, that it appeared all over the body at once, and that the doctor to whom she took the child considered the disease to be small-pox. She stated that there had been some spots on the head. The rash was attended by great itching. The patient was pale, but seemed in other respects healthy. She remained under treatment for five months without any material permanent improvement. The spots altered somewhat in character; some of the later bullæ were as large as peas, and it was noted after the child had been attending for some months, that many of the spots passed into pustules. As the child was eighteen months old, no doubt she had been vaccinated, but my notes do not mention this point.

CASE II.—Edward Barfoot, aged 16 months, came under my care in

* See my Catalogue of the *Atlas*, p. 107.

May 1869. He was pale, and seemed out of health. He presented a copious eruption of vesicles and papules in various stages, and affecting the face, trunk, and limbs, and, to a slight extent, the scalp. The fresh spots consisted of elevated pointed papules, feeling very firm, and each surmounted by a small vesicle. In the older ones the vesicle had sometimes broken, but in the greater number it had dried up; on the scalp, the spots had sometimes run on to porrigo. There were a few on the palms and soles. The eruption avoided the flexures; was more abundant on the back than on the chest and abdomen. It was evidently excessively pruriginous, and there were numerous scratches. The mother's history was, that the rash had appeared when the child was three months old, and soon after vaccination, and that the medical man in attendance told her that it was "glass-pock". The eruption had varied in intensity at different times, but had never been quite well since its first appearance. He remained under care only two months, and I cannot tell you the final result.

CASE III.—Sarah Richardson, aged 11 months, was brought on June 22nd, 1869, with a papular and vesicular rash on the trunk, limbs, and scalp; it affected the palms and soles. The spots were at first small papules, apparently devoid of fluid; presently these became inflamed and red at the base, while at the top was formed a yellowish point, in the centre of which a little dot was seen; while still later, a considerable red areola was present, and a concave scab was formed on the top of the spots. The mother stated that the eruption had been present for five months, and that it came soon after the child had been vaccinated. When it first came out, she thought it was chicken-pox, on account of the "clear watery heads" which were present at that time. An only sister of the infant was free from any eruption.

CASE IV.—Sarah Ann Tosland, aged 19 months, was admitted on July 13th, 1869. She was suffering from a pruriginous rash on the body and on the backs of the hands and soles of the feet; some of the spots were very like wheals of urticaria. The history given was of a gradual onset of the eruption at the age of five months, the mother thinking that it was like chicken-pox. It was said to have been well in winter. The child was of fair complexion and very stout, and seemed muscular and strong, notwithstanding the constant itching she suffered from the rash. She was the youngest of eight children, and the only one who had suffered from any skin-disease. This case is not very well characterised.

CASE V.—Isabella Brown, aged 12 months, a fair-skinned light-haired child, was brought on account of an eruption in September 1869. The rash was general and pretty thickly distributed; it affected the soles, the face, and the scalp, but not the palms. The flexures were avoided. It was distinctly vesicular, and in parts impetiginous from scratching, but there were no large pustules. It had already lasted seven months, and was said to have come out soon after vaccination. The child was nearly well in six weeks.

CASE VI.—Walter F. Seymour, aged 12 months, in good health, was brought on September 24th, 1869. He had a copious itching eruption of papules and vesicles, with some pustules. The parts affected were the trunk, palms of the hands, dorsal surface of the feet, scalp, and, to a less extent, the face. The bulk of the rash was papular. There were, however, some large irregular vesications, with areolae of congestion, and containing turbid fluid; other spots looked as if they had been about to suppurate, but had dried up before pus was formed in sufficient quantity to break the cuticle; some, especially on the hands and feet, were distinctly vesicular. The rash had been taken in the first instance for chicken-pox. Under treatment, the rash improved for a few weeks, but very soon relapsed and became as bad as ever again.

CASE VII.—Walter Thompson, aged 19 months, admitted on April 2nd, 1869, on account of a very copious pruriginous eruption. He was stout and healthy looking, and was said to have an excellent appetite. He had been nursed till 11 months old. The eruption had appeared for the first time at the age of 15 months, and it came out about three weeks after vaccination; the vaccination spots having done well. His nurse thought it was chicken-pox; but, from her statement, it seemed probable that the spots were not so distinctly vesicular as in that disease. The eruption had steadily become worse until he was brought to the hospital. There was no reason to suspect contagion from scabies or pedicularia as the cause. The eruption consisted, when first seen at the hospital, of very numerous isolated spots, most of them papular and of dusky colour. The early stage, as seen in some recent spots, appeared to consist in the formation of a vesicle on an indurated base; the vesicles were deeply placed, and contained but little fluid, and it seemed that subsequently they either dried up or had their tops removed by scratching. The rash was most abundant on the limbs and face, the forearms and legs being more thickly covered than the arms and thighs; it occurred in tolerable abundance on the palms and soles.

There were no spots on the scalp or forehead, and the eruption specially avoided the parts where the skin was thinnest, the flexures of the joints and the interdigital clefts. Looking at the soles and palms only, we might easily have mistaken the case for scabies; but its symmetry and uniformity, and its avoidance of some parts, such as the bends of joints and the spaces between the fingers, served to distinguish it from that disease. He got quite well in six weeks under arsenical treatment, and remained well for about eight months, when he again (in April 1870) came under care for a dry lichenous rash. This time, however, there were no vesicles, and the palms and soles remained free.

CASE VIII.—Alfred Vernon, aged 2 years, admitted on September 7th, 1869. His mother stated that the eruption, on account of which she brought him to the hospital, began suddenly when he was three months old as an eruption of clear vesicles. She was told that it was chicken-pox. There was no contagion either to herself or the girl who nursed the patient. When first seen, the child presented a copious itching, scratched, papular, and vesicular rash. The vesicles were most conspicuous on the feet. The rash was most abundant on the outer parts of the arms and thighs, on the backs of the forearms and fronts of the legs; it avoided the flexures in a very marked way. The backs of the hands were almost free from spots. He was of fair complexion, and had a thick upper lip and fine downy hair on the general surface of the body; he was much emaciated, probably in part from the incessant irritation. He remained under notice, more or less regularly, for more than a year, and improved very much during the earlier part of his attendance while taking bromide of potassium, cod-liver oil, and quinine, and using an ointment of mercury and lead. The eruption, however, relapsed somewhat towards the end of the time.

CASE IX.—Frederick Manger, aged 1 year and 9 months, was admitted on May 9th, 1871, with a pruriginous eruption of nine months' duration. There were five other children in the house, and none of them had suffered from it. The mother thought it was chicken-pox when it first appeared; but the medical man considered it not to be that disease. The child was not known to have had chicken-pox. The rash had never been well since its first appearance.

CASE X.—Samuel Bristowe, aged 15 months, came on October 12th, 1869, and was under notice, more or less regularly, for about thirteen months. He had a severe papular, vesicular, and pustular eruption, which was worst on the legs; the soles and palms were also severely affected. There were spots on the face. It avoided the flexures. It was then of eight months' duration, and was stated to have come out immediately after vaccination, and to have been considered by the medical man to be chicken-pox. There was great itching, and the child was said to be often awake most of the night. The scratching had produced large porriginous scabs in some parts. The child was somewhat relieved for a time, but the rash relapsed several times. There were three other children in the house, none of whom had had any eruption, excepting one who was subsequently brought to the hospital with eczema-porrigo of the scalp from lice.

CASE XI.—Anne Cridland, aged 3½ years, was brought for an eruption of prurigo urticans in March 1871. It was stated that she had been liable to the rash since an attack of chicken-pox at the age of 2 years.

[To be concluded.]

THE FEVER AT CROYDON; AND INTERMITTENT WATER-SUPPLY AS A CAUSE OF TYPHOID.

By ALFRED CARPENTER, M.D.

THE occurrence of an epidemic of typhoid fever in the district of Croydon, after the cessation of any tendency to that disease for a period of nearly ten years, is worthy of something more than a passing notice, both as to causation and to removal. I propose, therefore, to place the whole of the facts which have come to light with reference to the outbreak before our associates, feeling sure that it contains a lesson worth remembering.

Croydon was visited in October 1865 by an epidemic, which I had good reason to remember. Previously to that date, the ventilation of the sewers in Croydon had been at first suggested to the local authority, and then demanded by those who studied the subject; but for a long time the demand was not acceded to. The facts which presented themselves to the inhabitants at the time of that outbreak were such that the local board, after a long continued struggle against facts, carried out, in 1865, an extensive plan of ventilation by means of shafts connected with the crown of the public sewer, which were placed on the arterial sewers at distances of about a hundred yards from each

other. Energetic means were taken to remove the causes which produced that epidemic, viz., the contamination of the water-supply, and defilement of the upper rooms of the houses of the residents by sewer-gas, which was conveyed by pipes in immediate connection with the sewer, and also by soil-pipes discharging sewer-gases directly into the houses.

On December 6th, 1865, a series of resolutions were accepted by the Local Board, and made to have the effect of bye-laws, by which it was hoped that Croydon would, in the future, be entirely free from typhoid. This was the case, as far as epidemics were concerned, until March last, a period of nearly ten years. The local board of health, impelled at length by a proper sense of responsibility, saw what was wanting, and provided for the want with immediate and excellent effect. Typhoid as an epidemic entirely ceased. Nevertheless, it occasionally happened that a sudden development of slight or more severe illnesses took place in single houses or blocks of houses, in which almost every inmate suffered more or less from sickness, diarrhoea, continued indigestion, or sudden feverish disturbances, which affected most of the inmates in a similar manner in each block.

Having carefully noted the situation of these anomalous attacks, I found that they were generally in the higher parts of the district; that they occurred at rare intervals; that, on three or four occasions since 1865, cases of typhoid fever had occurred in houses in which the sewers were properly ventilated, which had a superior water-supply from the public works, and in which it was supposed that every sanitary requirement had been complied with. After a time, I noted another circumstance, viz., that those cases in which the whole household had suffered from a general cause occurred soon after the district had been placed under an intermittent water-supply, in consequence of the demand for water being greater than the quantity which could be supplied; or because an engine or a boiler required repair; or during a hot season, when the pumping power and the waste together were not equal to the demand made upon the waterworks. Another point was also noted; that, in some cases, the occupants had complained that the water smelt badly, and was not fit to drink, although looking as clear as usual. Occasionally it was discovered to be dull, cloudy, and containing foreign matters. I examined the water obtained from some of these houses; and on several occasions I discovered evidence of sewage-contamination quite sufficient to account for the illness under which the inmates had suffered. The cases which occurred in this way were rare, and in units only compared with the tens which arose before the ventilation of the sewers was provided for. They were, however, sufficiently numerous and sufficiently distinct to make it certain that impure water did find entrance into the service-pipes, which impure water was not supplied by the local authority in an impure state when first sent into the mains. The contamination must have taken place, therefore, at some point between the local board's well and the service-tap in the house. It did not appear that this could be the case on ordinary occasions; for the majority of the mains had a constant pressure from within outwards, often equal to four atmospheres, or 132 feet head of water. But I also observed that, when from any cause, such as from a cessation of pumping at the works, or because the supply was cut off to allow new connections, the water which was drawn from the pipes after such intermission of supply contained a large quantity of fixed air, which escaped as soon as the water was drawn from the tap, the water exhibiting a milky appearance, as if chalk were suspended in it. That it was not chalk was at once manifest; because it cleared immediately, and became as bright as usual. I concluded, therefore, that, when the supply was intermittent, the mains did not continue charged (as in the London district), but that the mains and services emptied themselves; that air did find admission at some points, allowing exit of water at others. This explained the cause of the great waste which occurred in the Croydon water-district—a waste which led to the apparently enormous consumption of fifty-six gallons per head daily.

It is evident that, whilst the pressure was continuous, there could be only leakage outwardly, and no impure water or foul air could find entrance into the fully charged water-pipes; but the moment the pressure was removed, there was no longer pressure from within. If, at that time, the taps on any of the lower parts of the water-district were opened, water might be obtained if there existed any means by which air could be admitted into the services at any portion of the upper parts of the district. Wherever, therefore, there were defects in the services, or faults in the construction of the taps, so that leakage occurred, then, at the moment when the supply which was intended for constant service became intermittent, contamination became possible, and even certain.

The supply-pipes which run from the mains into the houses are often carried through made ground, through a subsoil soaked with old

sewage matters, and abounding with nitrates. The services become rapidly corroded, and a pin-hole pipe results, which lets water out under pressure. When that pressure is removed by a falling water-line on the water-main, there is intermission of supply, nasty water is drawn into the pipe, and is delivered to some one below the point of entrance; or above them if the pressure happen to be restored before the contaminated water is drawn from the pipe. The water which is thus sucked in if the pipe happen to be near to a faulty sewer, may be simply diluted sewage, which even when mixed with a large volume of water is strong enough to do much evil. In Croydon, there was a worse danger even than this from defective services, because much more multiplied. A kind of tap has been allowed to be continued in use among the cottages called a screw-down tap, which is placed on a service-pipe coming direct from the main, and delivering into the pan of the water-closet, by which the pan of the water-closet itself is placed in direct communication with the water-service. If taps of this kind be used without the intervention of a cistern, it necessarily follows that it is only required for the tap to be left partly open to be a channel by which regurgitation becomes certain as soon as the pressure of the head of water is removed, by a cessation of pumping at the engine-house, or by a closure of the valves on the ordinary mains. It is impossible for the majority of persons using these kinds of taps to know whether they are closed or open, if the water-service happen to be intermittent at the time of use. Children especially are unable to close them; and as a consequence, in a great number of instances, they are left open. Thus a direct communication exists between the pan of the water-closet and the interior of the water-main. If a person at this juncture visit a water-closet at a few feet lower level than the first one, water is discharged into the pan of the closet, air rushing in to supply its place from the pan of the first closet, the tap of which has been left open. If, as sometimes happens in poor districts, the water-closet be allowed to choke up, and the pan to become filled with faecal matter, the most dangerous material may actually find its way into the services, and be supplied with water for dietetic purposes to the next house, or, indeed, to any house on that particular main. This event has actually happened. Its possibility places a serious responsibility upon those who, having the good fortune to determine that a constant supply is the right thing, yet allow their arrangements to get into such a condition as compels a return, if only for a short season, to an intermittent one.

For like reasons, when a constant supply is afforded to urinals, or other similar places, it should only be allowed through the intervention of a proper cistern, or with proper stop-valves, which should be imperishable and self-acting; otherwise, when the supply becomes intermittent, there will be a rush of air through the open pipe, carrying with it ammoniacal odours from the urinal, which must necessarily contaminate the water-supply, and may even convey matters which are capable of setting up specific epidemic disease.

I have described the condition of a large part of the old district of Croydon as it now exists, viz., that in which the water-works were first laid down twenty-four years ago. About three thousand screw-down taps exist in association with as many water-closets, which are at this moment violating one of the laws of hygiene, viz., that no water-pipe should be allowed to continue in immediate and direct communication with any part of a sewer-system, and also bringing unnecessary discredit on water-closets. I pointed this condition of things out very forcibly in 1865 to the local authority, but without convincing them of the extreme danger of leaving the closets in the state mentioned. It was considered by many of the members to be a "notion" of mine scarcely worth debating. A resolution was, however, adopted that no new house should be allowed to have any direct communication between the water-pipes and the sewers; and also that all overflow pipes from cisterns, baths, waste water-sinks, or housemaids' closets, should in every case be severed from immediate connection with the sewer. The screw-down taps originally put up were allowed to remain; and although several bye-laws were adopted as to new houses, they were not carried into effect by the then officers of the board, because they were considered to be fads of mine, and altogether unnecessary.

It was only by a steady and persistent following up of individual cases by various persons, and by showing the frequent connection between the want of ventilation in the sewers, or the contamination of the water-supply in a similar manner, that the public were convinced of their connection as causes of disease (and the illness of the Prince of Wales seemed to prove the truth of my deductions).

Another cause of trouble was the persistent refusal of the plumbers to loyally carry out the regulations of the board. Every kind of subterfuge was employed to defeat the object; dummy pipes were put up, so as to apparently comply with the bye-laws. When in real communi-

cation, the ventilators were often twisted and turned about at any and every kind of angle, so as to be perfectly useless for the purposes of ventilation. The sewers, although thoroughly ventilated on the general main, were not as efficiently treated in the house-services and in the branches as they ought to have been.

Nevertheless, from 1865 to this present year, no epidemic of typhoid has ever appeared. Yet I never heard of the possible contingency of intermittent water-supply, without a little terror lest we should have a return of our old enemy; and year after year urged upon the local authority the duty of removing the great blot in our sanitary work, but without great effect. In the year 1870, I prevailed upon the board to have a large number of old iron services taken up and relaid with lead, as more enduring in our subsoil, lead also being unacted on by hard chalk-water, such as ours. This act led to a great diminution of waste, and gave greater power to the local authority to keep up a constant supply, and postponed the evil day.

Still it was, for various reasons, intermittent at times. It was so in the month of January last for a few hours in the *daytime*. It is important to note this; because there does not appear to be the same excessive danger attending an intermittent service in the night-time: the consumption of water after most persons had retired to rest is very small compared with the quantity used in the daytime. Hence it happened that it might be intermittent for several hours in the night without serious evil; for the mains only emptied by slow leakage, and air might be supplied from pure sources; but, when the pressure was removed in the daytime, the whole of the mains would be completely emptied in a single hour. It is always liable to be intermittent in certain districts when extensions or repairs are being made, or in case of fire; and local danger did continually arise.

In February last, three cases of typhoid were known to be in the district. Two of these were imported cases; and I knew of their presence. The water-committee of the local board, at this juncture, proposed an intermittent supply to the water-district for several days, to allow of some repair to some portion of the engine. I most strongly protested against this course in my place at the local board, and wished my protest to be entered on the minutes of the board. The water-committee carried their point against me; and, from March 16th, there was a water-supply provided for six hours a day only. This limited supply was continued for six days; not long afterwards, it was manifest to the medical men that an epidemic of fever was amongst us. By the 30th of April, upwards of four hundred cases were reported as existing in the water-district by Dr. Philpot, the medical officer of health. The subject was at once brought to the notice of the local authority; but the water-committee declined to allow that the water had anything to do with the disease; some members of the board alleging that fever existed elsewhere; that some unknown causes, independent of waterworks, were acting; that it was the heavy rain; that it was atmospheric; that the disease was not propagated by the water. I steadily opposed these notions; but, the water-committee being supported by one portion of the local press, I was assailed in the most virulent manner as a public enemy for the course I took in the matter. My arguments were not listened to; and ultimately I was refused a hearing by the local board; because it was said that my statements tended to bring the town into disrepute, and did harm to its trade and damaged its property. One portion of the local press contained virulent attacks, with not a single line of regret for those who were the victims of the disease. I then published an account of the matter in a comprehensive letter to the *Times*, which brought down upon me the wrath of everyone who had opposed my view, and refused to be parties to the only remedy which could be effectual in preventing a recurrence of the disease. The remedy I had suggested was that the canon law applying to waterworks should be used in its integrity; viz., that, under no pretence whatever, ought a direct channel between the water-services and the sewers to be allowed. To effect this object, all screw-down taps and defective services ought to be removed; and, as a sequence to these repairs, a constant service would be then attainable with the present water-supply. In my communication to the *Times*, I had suggested, as, indeed, I had continually done at the local board meetings, that, if the supply were again made intermittent, a more severe epidemic would immediately follow. For this prediction, I was accused of wishing to bring about a panic, and it was said that there was no foundation for my idea.

The local board determined, however, to meet the case of a constant supply by taking measures for supplementing the present pumping power; digging a new well, and providing a more powerful engine, at an expense of £20,000.

In the meantime, the epidemic of April subsided; typhoid continued to hang about houses with defective and badly ventilated sewers. These were rapidly remedied, when the continued recurrence of cases in houses

satisfied the occupiers that they were in danger. As these were removed, the cases diminished, and the scare was almost forgotten by the general public. At the end of September, however, medical men practising in Croydon were aware that there was a recurrence of a more severe attack of the disease, and that many fatal cases would occur. On comparing notes, it appeared that, whilst the severity of the attack was greater, it did not cover so much ground as on the former occasion, but was in a great measure limited to less than half the water-district; and that that half corresponded with the portion which was commanded by the water-tower, and which constituted what is called the high level. On further inquiry, it also appeared that, on September 16th, the high-level supply had been intermittent in the daytime for five hours and a half; and just as in the former case the height of the epidemic was about five weeks from the time of the intermittent supply, so in this case, at the end of five weeks, it was manifestly and rapidly declining. I believe our energetic and observant medical officer, Dr. Philpot, will eventually have all the facts and all the statistics of this marked outbreak in a form available for publication. In this communication, I only, as chairman of the sanitary committee, wish to point out the principles which have produced the epidemic, and to publish the cause of its appearance in our town. The most marked result after that of the epidemic has been that the local authority has at last determined to follow advice, and to determine that, in the future, the channels by which contamination is possible shall not be allowed to remain; that the water-system shall be put upon the same principles as apply in the London districts; and contamination by regurgitation shall be a thing of the past. This was resolved on, November 2nd; and that which I tried very hard to carry into effect ten years ago, is now accomplished, at the cost of nearly a hundred lives, and very much suffering to many hundred others.

I have been obliged to use the personal pronoun rather more frequently than is pleasant; but as the principle for which I have contended, for the last twelve years, has been mainly promoted by myself in our local board of health—now, however, ably supported by the medical officer of health—it has been almost a matter of necessity for me to write in the singular number.

At the last meeting of the local board, the following recommendation of the sanitary committee was unanimously agreed upon. The epidemic was able to do that which was beyond the power of an individual member; viz., compel the board to obey a canon law of hygiene. The first paragraph of the report contains a law which cannot be disobeyed without mischief resulting sooner or later, viz.:

"The committee are of opinion that it is highly dangerous, and contrary to the first principles of hygiene, to allow the possibility of intercommunication between the contents of sewers and the water-services. That it is very desirable that immediate measures be taken to prevent possible contamination by such channels for the future. The committee recommend that a list of all houses in which screw-down taps are used in the water-closets be at once prepared; and that the water-committee be requested to advise the board as to the most rapid way in which contamination may be prevented in the manner which, at any rate, now appears to be possible. They would also suggest that the services in all these cases be examined, and that inquiry be made as to any possible source of contamination in connection with the water-mains or well.

"The committee again draw the attention of the inhabitants to the fact that, on a request being made to that effect, an immediate examination of drainage arrangements would be made by the board's officers in cases where illness has occurred, or defects suspected.

"The committee directed that a list of urinals which have no back-pressure valves be presented, and also a list of those urinals which have no water laid on."

I have inserted the whole of the recommendations made by the committee. The board also directed the water-committee to give notice to all persons having improper fittings, that such fittings were to be changed, and that it was their intention to institute proceedings against everyone who continued to use defective services after due notice had been given for their alteration.

As regards the fever itself, it is again on the wane; and, if the alterations suggested be carried out in good faith, it is not likely to again arise. It is requisite that the supply shall be continuous in the daytime. It is right to state that Dr. Philpot is also of opinion, in which I certainly concur, that it is not safe even to allow a removal of pressure in the night; but intermittent supply in the small hours of the night has not the serious significance which it has when consumption of water is great, as in the day.

The first epidemic in March and April last was general, and appeared all over the water-district simultaneously; most of the cases which arose from the intermission of the water-supply occurred within

a month of the act. This act of intermission continued in operation for seven days.

The epidemic then subsided; but a large number of sporadic cases occurred in houses in which epidemic cases had been introduced, and in which it was afterwards found that serious defects existed in the house-drains. These defects seemed to expose the inmates to fresh sources of contagion; and others then suffered from the disease who did not in the first instance get a sufficient dose of the typhoid contagia to set up the fever.

The second epidemic, which followed upon the intermission of water-supply on the 16th of September, has not been at present succeeded by these sporadic cases. The larger number of the cases have occurred in the high level district, which includes a large number of the best houses in the neighbourhood, and those which have the best arrangements as to drainage. The first outbreak affected this district equally with the second. The second outbreak mainly affected this district, but including those parts of the low level which are in immediate communication with the high level water-mains. Both epidemics came to a climax five weeks after the act of intermission was committed; but the second has been more simultaneous than the first, because the act was committed for a few hours only, whilst in the first instance it extended over several days. The second, although it occupied a less extended area, has been more general and more severe, which may be easily understood, considering that the foci of contagia were much more numerous on the second occasion than on the first, and the chances of escape from their influence much less.

There are many other points of considerable importance which are worthy of record, and which may form the subject of another notice. One, however, may be mentioned here; namely, that in a certain street the houses are supplied with water from two different sources; those on the right by the Croydon Waterworks, those on the left by the Lambeth Company. The sewer is in the middle of the road, and is common to both. The fever affected only those who were supplied with water from the Croydon waterworks.

OBSTETRICAL STATISTICS.*

By J. G. SWAYNE, M.D.,

Consulting Physician-Accoucheur to the Bristol General Hospital.

THE importance of obstetrical statistics must, at the present time, be obvious to every one who is much engaged in the practice of midwifery. In no department of the healing art is there a greater need just now for clear and definite principles by which we may shape and guide our future practice. Within the memory of most of us, the changes in this department have been so strange and sweeping, that they constitute little less than a revolution. During the last half-century, the practice of medicine and the practice of midwifery seem in this respect to have changed places. The *medicina perturbatrix*, that heroic system of treatment which prevailed in the time of our fathers, is, in these days, superseded by a more careful and expectant plan; whilst, on the contrary, the somewhat timid *laissez faire* policy of waiting upon Nature, and giving her no assistance until she had proved herself incompetent to do her work, has, in the hands of the modern accoucheur, given way to an active anticipation of her wants, and sometimes, I fear, to an officious interference with her operations. To bring these changes to the test of time and experience, which alone can decide upon their respective merits, we require records of cases accumulated by a great number of independent observers during many years of private practice, in addition to the valuable statistics which we already possess from the various lying-in institutions. If every man who is in extensive midwifery practice would keep accurate notes of all his cases, and, on relinquishing the active duties of his profession, would follow the good example set by Dr. Churchill of Dublin, and publish a statistical account of them, what a mass of valuable information we should obtain! The records of lying-in charities are, in their way, most important contributions to obstetrical science, as all must acknowledge who have read, for instance, Dr. Johnston's masterly report of the Rotunda Hospital at Dublin for last year; but they are incomplete in one respect; viz., that they furnish statistics of labour amongst the lowest grade of society only; whereas every one who has been much engaged in private practice knows that the process of parturition is much affected by station and habits of life. It is only, therefore, from careful records of private practice that we can obtain statistical evidence of the manner in which the process is performed in the upper and middle classes of society.

* Read before the Obstetric Medicine Section at the Annual Meeting of the British Medical Association in Edinburgh, August 1875.

Most accoucheurs who have been many years in full practice have had a tolerably wide experience of all classes; for their career usually commences amongst the poor and ends amongst the rich. Hence they are well qualified to make a comparison between the mode in which the process is performed in one class and in the other. And all who are in a position to do this must, I think, be prepared to admit that those who work hard for their daily bread have an advantage in this respect, and that, by a natural rule of compensation, a hard life tends to produce an easy labour. That the function of parturition should be thus affected by habits of life is not so much to be wondered at, when we see how evidently the function of lactation is modified by the same conditions. We all know that, amongst the labouring classes, a woman who cannot nurse her child is a rare exception, whilst amongst the rich and luxurious it is equally uncommon to find a mother who can nurse properly; on the contrary, the milk is deficient either in quality or quantity, and we see the same course of events recurring, and hear the same old story repeated with tiresome reiteration; the mother has nothing, or next to nothing, for the baby, and the child, thus deprived of its natural food, cannot digest the artificial food which is substituted for it, diarrhoea sets in, and the doctor who is called in to prescribe for this state of things is obliged to recommend that the natural deficiencies of the mother should be supplied by a hireling substitute drawn from another grade of society.

In order to institute a fair comparison between the process of parturition amongst the rich and amongst the poor, we require the records of a large number of cases of each sort attended in private practice. By this I mean that, amongst the poor, the patients ought to be attended at their own houses, and not at a lying-in hospital, because there are certain special risks connected with these institutions which would render the comparison an unfair one. It is necessary also that all cases to which the practitioner has been called in in consultation should be carefully distinguished. These conditions being observed, we may class amongst the rich all those who can afford to pay well for the attendance upon them, and amongst the poor all those who are attended gratuitously in connection with some lying-in charity. Most men who have had much experience will have met with a considerable number of cases of each kind, the earliest patients belonging to the poor and the latest to the rich class; and a number of records of this kind will give trustworthy data for making such a comparison as that I have indicated. I have the means of doing so on a small scale from the records of my own practice. During the time I was a student, and during the first years of practice, I attended more than 250 poor patients at their own houses in connection with two lying-in charities. I am, therefore, in a position to compare the first two hundred of these cases with the last two hundred of my patients in private practice, dating back from the end of last June. In both sets of cases, I have excluded those to which I was called in consultation. I have not sufficiently correct notes of the duration of labour in my earliest cases to enable me to compare the first and second stages of labour in each set; my remarks now will be entirely confined to the third stage of labour and its attendant dangers and difficulties. And here I find that, in two particulars, there is a decided advantage in favour of the poorer class.

In the first place, with regard to *post partum* hæmorrhage arising from inertia of the uterus, I find that, in the 200 cases of the poorer class, there were seven cases of *post partum* hæmorrhage, whilst there were as many as twelve, or nearly double, in the 200 of the richer class. Again, none of the seven cases out of the first 200 were very severe, but were readily controlled by such means as cold, pressure, ergot, and the introduction of the hand. On the contrary, some of the twelve cases in the second class were very severe, and two of them required, in addition to the means above mentioned, the injection of perchloride of iron. I should mention that the first 200 cases were attended previously to the year 1846, and the last from February 1872 to July 1875. During the time when I was attending the first set, I was called in to one consultation case which was not severe; whilst I was attending the last 200, I was called in to two cases which were both very severe, one terminating fatally within six hours. These cases are not included in either list. These figures show, then, a percentage of $3\frac{1}{2}$ cases of *post partum* hæmorrhage in the poorer class of patients,* and 6 in the richer class: a fact which confirms the belief which I had previously entertained, that the latter are more prone to *post partum* hæmorrhage than the former. This hæmorrhage arises not so much from a want of contraction in the uterus immediately after delivery, as from a want of persistent contraction during the first hour afterwards. The uterus contracts and again relaxes, so as to allow a considerable accumulation of blood within its cavity.

* Dr. Johnston's report, above alluded to, shows a percentage of little more than 2.

I remember that when, in the early years of practice, I attended chiefly amongst the poor, I was constantly in the habit of leaving the patient in half an hour after the birth of the child, provided there had been no trouble with the placenta, and that the uterine remained well contracted; and I never once had cause to regret having done so. Moreover, I never took any particular trouble about the bandage. Now, however, I never dare to leave a patient within an hour after delivery, even after I have carefully bandaged and left the uterus apparently well contracted. Were I to do so, I should very probably be hastily summoned back to her, and find her at death's door on my arrival.

With respect to adhesion of the placenta, the difference between the two classes is still more striking. I have no single instance of this complication recorded in the first 200 cases, and not fewer than fourteen, or 7 per cent., in the last, besides four consultation cases, which are not reckoned. Dr. Johnston records only two instances in 1,236 in his report of the Rotunda Hospital for 1874. In a paper which I published in the BRITISH MEDICAL JOURNAL for June 19th, 1875, I endeavoured to account for this great disparity by the theory that the deposits of lymph which are always observed upon the placenta in cases of adhesion are due to a depraved condition of the blood, analogous to what is considered to exist in a rheumatic or rather gouty diathesis, and that this condition is caused by high feeding and insufficient exercise. Hence its prevalence in the richer class.

However this may be, my own statistics certainly show that two dangerous complications of labour are much more common amongst the rich than amongst the poor; and I firmly believe that, if we could obtain sufficiently extensive statistics of labours amongst the rich and amongst the poor (not attended in lying-in hospitals), we should find that the puerperal mortality of the former would exceed that of the latter, notwithstanding the want of good nursing and other disadvantageous circumstances accompanying confinements amongst the poor.

It is very difficult to obtain correct information as to the number of puerperal deaths which occur in private practice; but, if it could be procured, such information would be very valuable. There is perhaps no one point connected with midwifery practice about which so many loose statements are made. I have often heard men who have been in extensive practice for many years boast that they have never lost a lying-in patient. As Dr. Matthews Duncan remarked in his Address in Obstetric Medicine last year, "All such beliefs, reports, and statements are mere incumbrances of inquiry, and are to be thrown overboard, if not more ungraciously dealt with". By a careful comparison of the registers of births and deaths in Edinburgh and Glasgow during 1869-70, Dr. Duncan estimates that the mortality of lying-in women is as high as 1 in 120 within the month. And he further remarks that "even now, in 1874, we are only striving to reach a sound conclusion as to this mortality; and, after all our labour, official and private, have no statistics to be relied on for the comparison of the results of successive decades or of longer periods".

In estimating the amount of puerperal mortality in my own practice, I have excluded all cases which I attended as a student, and also all cases to which I was called in consultation by other practitioners. I exclude those which I attended when a student, because such cases were exposed to special risks at that time, when the causes of septicæmia were not so well understood as they are now. At that time, I was a dresser at a large hospital where erysipelas was very prevalent, and I was also much engaged in dissections and *post mortem* examinations. I exclude the consultation cases, because it is obvious that they must be abnormal cases of unusual severity. My whole number of cases is thus reduced to 1,069. In this number, there were five deaths, or one in 213½; viz., one from septicæmia, one from scarlatina, one from ruptured uterus, one from pneumonia (coming on before delivery), and one from convulsions during pregnancy.

This rather low rate of mortality is to be attributed more to my good fortune than to any other cause; for I have never had two consecutive cases of puerperal fever or septicæmia of any kind, nor am I aware of having ever conveyed any infectious disease except scarlatina, which I once communicated to a patient, but she happily recovered. In the death from scarlatina which I recorded, the patient herself caught the disease about a week before her confinement.

The cases which I attended as a student, and which are not included in the foregoing list, presented two deaths; viz., one from septicæmia, and one from phthisis. The list of deaths in cases to which I was called in as consultant is, as might be expected, a rather formidable one, and yet I have omitted in this list a good many deaths from puerperal fever, because my notes of the cases are very incomplete, as I saw many of them some days after labour, and not more than once, twice, or, at most, three times. Out of the consultation cases to which I was called during or just after labour, I have recorded 22 deaths; viz., 7 from septicæmia, 5 from convulsions, 2 from *post partum* hemor-

rhage, 2 from ruptured uterus, 1 from hæmorrhage from placenta prævia, 1 from bronchitis, 1 from metritis, 1 from exhaustion after obstinate vomiting, 1 from jaundice and albuminuria, and 1 from Cesarean section.

The relative frequency of the different cranial presentations has long been a *vexata questio* amongst obstetric authors, and we yet need more extensive statistics to settle the disputed points satisfactorily. Many believe with Baudelocque and the older authorities, that the second position of the head in which the occiput is turned towards the right acetabulum, is next in frequency to the first; whilst others, such as most British accoucheurs, hold Nægele's opinion that the second position is the most rare of all, nearly all the reputed cases of this position being in reality cases of the third position which had been thus converted during the course of the labour. Dr. Leishman, in his work on the *Mechanism of Parturition*, considers that Nægele's views have been too implicitly adopted by British accoucheurs; and the late Dr. Uvedale West, who investigated the subject very carefully, arrived at the same conclusion. I published a paper on this subject in the BRITISH MEDICAL JOURNAL in 1852, and I have just communicated another, based on more extended observations, to the *Obstetrical Journal*. The latter was founded upon statistical observations of 1,000 consecutive cases of vertex-presentation, dating back from the end of last June. My own views as to the relative frequency of the first and second positions are opposed to those of Nægele; and, contrary to the experience of most other accoucheurs, I find that the fourth position is more frequent than the third. The following figures will show the result of my observations.

First position	792
Second "	152
Third "	19
Fourth "	37
					1,000

My own observations also show that it more frequently happens that the third and fourth positions remain unchanged throughout the labour, than that they become converted to the second and first.

The superiority of the practice of midwifery in the present time to that of the past is shown in nothing more signally than in the much greater use which is now made of the forceps in tedious and difficult labour. Up to the year 1844, according to Dr. Churchill's statistics, the forceps was used in British practice only about once in 342 cases. Now, however, as the report of the Rotunda Hospital for last year will show, it may be used as often as once in every nine or ten cases, and with the best effects, provided the operator be skilful and judicious. The above report shows a maternal mortality of about 1 in 27, and an infant mortality of about 1 in 7, which is a considerable improvement upon the mortality after forceps-cases in British practice up to 1844; for the maternal deaths were then as high as 1 in 20½, and the infant deaths as 1 in 4¾. But there is one striking peculiarity in Dr. Johnston's report which would startle many an accoucheur of the past generation who believed and taught that one of the essential conditions for the application of the forceps was, that the os uteri should be fully, or nearly fully, dilated. Out of the 138 forceps operations already mentioned, Dr. Johnston gives the particulars of 42 in which the os was not fully dilated, and in the greater number of these the os was dilated to the size of a crown-piece only. Dr. Johnston has the best of arguments in favour of this practice; viz., its success. The deaths of but two mothers and four children are recorded. In by far the greater number of instances, the operation was resorted to on account of early rupture of the membranes, and escape of liquor amnii before the dilatation of the os, thereby allowing the foetal head to press injuriously on the soft parts of the mother. The os, however, must not be rigid or unyielding. I was called in very lately to two cases of this kind myself, and used the long forceps with the best results, although the os uteri was scarcely three inches in diameter. Beyond this, however, I have very little special experience of my own which will bear upon this question. I had never used the forceps before when the os was so little dilated, although I had many times employed it before the os was fully dilated, especially in those cases where the membranes have ruptured, and where the head, being from some cause arrested at the brim, does not descend upon the os uteri so as to complete the dilatation. I confess, however, that the bare possibility of the forceps coming into general use as a remedy for protracted first stage is enough to make one shudder. What has been said of opium may be well applied to this instrument also—

"Sacra vite anchora circumspicte agentibus,
Cymba Charontis in manu imperiti."

The forceps is a powerful instrument for good or for evil, according to the skill of the operator, and its abuse in unskilful hands may lead to

much worse consequences than are likely to ensue from a protracted first stage: a thing which in itself is very seldom a source of danger. There is too much reason to fear that, by some practitioners who have a large amount of union practice, ergot of rye is sometimes given more with a view to save the attendant's time than to promote the welfare of the patient, and there is no doubt that a similar abuse of the forceps would produce far greater mischief.

With regard, however, to the more frequent use of the forceps in a protracted second stage, my own experience is greatly in its favour. I find that, in my first two hundred cases (after excluding those to which I was called in by others), the forceps was used but twice, and with a favourable result as regards both mother and child; whilst craniotomy was had recourse to three times, the child in one case being previously dead. All the mothers made a good recovery. In my last two hundred cases, the forceps was used seventeen times, with a favourable result to all the mothers and also all the children except one, whilst craniotomy was performed twice, the child in each case being dead before the operation. The result in both cases was favourable to the mothers.

My notes of all the forceps-cases I have had since I commenced practice conclusively prove the safety of the operation. The total number is 138; of these, 54 were patients I was originally engaged to attend, and 84 patients to whom I was called in in consultation. None of the 54 died, and the deaths of but two infants are recorded. Out of the 84 consultation cases, 4 mothers, or 1 in 21, died. Two of these deaths were caused by septicæmia, one from scarlatina, and one from bronchitis. The deaths of 17 infants are recorded. Most of these consultation cases were difficult and dangerous, and, therefore, a maternal mortality of 1 in 21 is not to be considered excessive. On adding the two groups of cases together, the maternal mortality will amount to 4 in 138, or scarcely 3 per cent.

In my own 54 cases, three-fifths of the patients were primiparæ, and the operation was performed on account of delay in the second stage of labour, with scarcely an exception; whilst, in the 84 consultations, the operation was performed in several on account of complications dangerous to both mother and child, such as convulsions, prolapse of the cord, etc., and, therefore, the extra mortality is not to be wondered at, especially if we take into consideration lost time and other unfavourable circumstances. Most of these also were primiparæ. We still require additional statistics to show the relative utility and safety of the long forceps and of version in slight narrowing of the brim of the pelvis. That turning will often succeed in these cases when the forceps will not, is proved by three cases reported in the *Lancet* of March 25th, 1871, by Dr. Phillips of Guy's Hospital. In each of these cases, the long forceps was first tried and failed, and version was then had recourse to with complete success, both as regards the mothers and the children. I myself lately succeeded in delivering two living children by version, in a case in which I induced premature labour at the end of eight months. I had ascertained by measurement that the conjugate diameter of the pelvis was not more than two inches and three-quarters, and in consequence it had been previously deemed necessary to induce labour at seven months on four occasions; but the children were so feeble at this early period, that only one of them had survived. The twins above mentioned are still alive and well.

With respect to the comparative safety of the two operations, I do not think we have yet sufficient data wherewith to form a conclusion, and further statistics are still needed for this purpose.

The rules for the treatment of puerperal convulsions, after having been for a long time extremely definite and settled, have of late years become indefinite and unsettled, chiefly, I think, on account of the altered views which now generally prevail on the subject of bleeding. This, then, is another point which requires to be cleared up by satisfactory statistical information. If there were any disease in which the good effect of bleeding was recognised almost beyond dispute, it was puerperal eclampsia. Now, however, this mode of treatment is very generally discountenanced, for no better reason than that I can find than that in the treatment of all diseases bleeding is gone quite out of fashion. So much is this the case, that it requires some moral courage to recommend bleeding for any complaint whatever; and my esteemed colleague Mr. Michell Clarke, in his recent presidential address to our Bath and Bristol Branch of this Association, regards me as a remarkable phenomenon because I so strongly advocate it in puerperal convulsions. I certainly cannot find any statistical basis for the condemnation of bleeding in this disease. It is true we have of late years acquired two most valuable agents in the treatment of eclampsia, viz., chloroform and chloral; and these have, perhaps, to some extent, caused us to lose sight of the value of bleeding. But yet, it is not the propriety of bleeding only that is now being questioned, but that of another remedy, the efficacy of which has hitherto been universally acknowledged in this country—I mean delivery. For instance, I find in Schroeder's *Manual*

of Midwifery the following remarks respecting the treatment of this disease: "The condition of the woman contraindicates obstetrical manipulations, and every irritation of the uterus, such as introduction of the hand for the purpose of turning, application of the forceps, or even mere friction of the fundus, is apt to cause a fresh attack by reflex action;" but the author adds this qualification: "In the interest of the child, however, active procedure may become necessary."

My own experience of puerperal convulsions being rather large in proportion to my experience of other complications of labour, it may be worth while to examine a little in detail the notes which I have made of these cases. Since beginning practice, I have attended twenty-six cases of puerperal convulsions. With the exception of three, all these were cases to which I was called in by others. Eighteen of the twenty-six cases were primiparæ, or more than two-thirds. This agrees with the experience of most other practitioners. For instance, Drs. Johnston and Sinclair give the particulars of sixty-three cases of puerperal convulsions, out of which forty-nine, or more than three-fourths, were primiparæ.

My own cases of convulsions may be divided into three groups, viz.: 1. Convulsions coming on during pregnancy, before the full term, and accompanied with no symptoms of labour; 2. Convulsions coming on during labour, and in some cases continuing afterwards; 3. Convulsions not commencing until after labour. There are seven cases of the first group; fifteen of the second; and four of the third. Convulsions accompanying labour are, therefore, the most common.

Convulsions of the first kind are, according to my experience, the most formidable and fatal of all. Out of the seven cases, five mothers died and all the infants.

In the second class, or those which accompany labour, there were two maternal deaths in the fifteen cases, and eight deaths out of seventeen children (there being two cases of twins). In the third class of *post partum* convulsions, out of the four cases recorded, no mother and no infant died. Convulsions belonging to this class are, therefore, far less dangerous than the others. It will thus be seen that the total mortality amounted to seven maternal deaths in twenty-six cases, or more than one-fourth; and an infant mortality of fifteen in twenty-eight, or rather more than half. These figures are quite sufficient to show that eclampsia is one of the most dangerous complications of labour.

In the treatment of puerperal convulsions, the three most important remedies are bleeding, anæsthetics, and delivery. The secondary remedies, which were used in nearly all my cases, are purges of calomel and jalap, enemata of turpentine, castor-oil, and assafoetida, cold applications to the head, and counterirritation by blisters, sinapisms, etc. I need not stop to discuss the efficiency of these last, but will merely state briefly my experience of the first three.

Bleeding (the quantity of blood abstracted varying from ten ounces to thirty ounces) was resorted to in twenty out of the twenty-six cases. In fourteen, it was decidedly beneficial, and appeared to be the most efficacious remedy employed. After the bleeding, the fits either ceased or were suspended for a time, or were mitigated both in frequency and in severity. In some few cases, convulsions, which had continued after the use of anæsthetics and delivery, ceased immediately after the abstraction of blood. In case 14 (a case of twins) the fits which continued after delivery and after opiates, at once ceased after bleeding, at the same time the albumen in the urine rapidly disappeared. The relief afforded by bleeding is most marked and striking in convulsions which commence after delivery. In nearly every case in which it was employed, venesection rendered the breathing less stertorous, and the pulse more tranquil and steady. The benefit derived from bleeding arises, I believe, from the diminished stress upon the vessels of the brain, and perhaps of the kidney. At all events, it seems to remove that peculiar condition of the kidney which causes albuminuria.

By anæsthetics, I mean either the inhalation of chloroform or the administration of chloral, either by the mouth or the rectum. These two remedies, which are similar in their action, have now quite superseded opium. They are both very valuable, especially chloral. In four cases, the symptoms were much relieved, or altogether cut short, by chloroform, and in three by chloral. In one case, No. 26, bleeding gave relief for a time, but, the fits returning, the patient was kept under the influence of chloroform for seven hours, and had no more convulsions. In another case, No. 22, chloral in large doses was equally efficacious.

Delivery gave decided relief in seven cases. In five, the forceps was used; and in one, craniotomy; and in one, turning. These two last were desperate cases, but, in all seven, delivery either abolished the convulsions, when other means had failed, or else appeared to complete the cure which had been begun by bleeding and anæsthetics. I cannot, therefore, look upon this remedy as valuable only for the child's sake.

The seven fatal cases of eclampsia, which I have recorded, were thus treated :

1. Date 1854. Convulsions in seventh month. No sign of labour. Bleeding to twenty ounces, six leeches, cold to head, purgatives, sinapisms, etc. Died undelivered.

2. 1863. Convulsions in seventh month. Bleeding to fourteen ounces, purgatives, cold to head, chloroform. Fits ceased, but she died soon after giving birth to a dead child.

3. 1868. Convulsions at commencement of labour. Seven leeches, chloroform, cold to head, purgatives, etc. Delivery terminated speedily after dilatation with Barnes's bags. No more fits; but she died on the third day, from total suppression of urine.

4. 1868. Convulsions at full term. Bleeding to fifteen ounces, purgatives, cold to head, etc. Gave birth naturally to a dead child; no more fits; but she died comatose the following night.

5. 1869. Convulsions in eighth month; no sign of labour. Bleeding to fourteen ounces, purgatives, cold to head and blisters. Twenty-six fits before bleeding, and none after. However, she gradually sank, and died undelivered on the next day.

6. 1872. Convulsions in eighth month; no sign of labour. Bleeding to eighteen ounces, purgatives, cold to head, delivery by turning, chloroform. Fits still continued, abating gradually; she died suddenly at the end of three weeks.

7. 1874. Convulsions in ninth month; no sign of labour. Cold to head, purgatives, chloral in two doses of thirty grains. No fit for an hour after last dose; os too rigid to turn; delivery by craniotomy; convulsions returned two hours afterwards, and she died.

In this last, which was the worst case of all, bleeding was not resorted to, because the pulse was feeble from the commencement. From my own experience, I am inclined to consider bleeding and anæsthesia as the two important remedies, I can scarcely say which is the most important; whilst delivery is very little inferior to them, its inferiority being chiefly due to the circumstance that it is not so universally applicable. I have, on previous occasions, given cases which undoubtedly show that bleeding is very speedily followed by a great diminution in the amount of albumen contained in the urine. To this cause I believe that it owes its great power as a remedy.

The last subject I shall indicate to which statistical investigation may be most advantageously applied, is the etiology of what is commonly called puerperal fever. This is very extensive, and has been so fully discussed lately, that I need not enter upon it at any length. It has been abundantly proved that the same train of symptoms may be produced in a pregnant woman by the absorption of a variety of animal poisons; these symptoms, in general, are rigors on the second or third day after delivery, followed by headache, fever, great rapidity of pulse, and elevation of temperature, suppression of the milk and lochia, and generally local tenderness and pain in the uterine region, spreading over the whole of the abdomen, and accompanied with much tympanic distension. In order to demonstrate what are the peculiar poisons which most frequently give rise to this train of symptoms, so that we may more effectually guard against them, we need a great number of independent observations, especially from men engaged in country practice who are able to isolate their cases. The poison which contaminates the blood of a woman lately delivered may be generated within herself, or, as no doubt more frequently happens, be introduced from without in various ways. Scarletina, as Dr. Braxton Hicks has shown, is the poison which is most frequently introduced from without, and next to this perhaps erysipelas. When scarlatinal poison has been absorbed, I have observed, in several instances, the rash and sore throat characteristic of this disease. But more frequently, I think, these are absent, and only the ordinary symptoms of puerperal fever are recognisable. The same may be said of erysipelas. As an example of the first, I may mention a case which came to my own knowledge lately. A medical man, whose children were ill from scarlatina, was sent for on a Saturday to attend a lady in her confinement. On the Tuesday following, she developed symptoms of puerperal fever, such as I have mentioned above, and on the next Friday the husband, who fetched the medical man, was attacked with scarlet fever in its usual form. Now, there can be no doubt, I think, that though these two diseases were different in symptoms, they were derived from the same source. The poison of erysipelas may thus be modified in a similar manner. My friend Mr. Waugh of Midsomer Norton, Somersetsbire, gave me the particulars of some cases which lately came under his notice, and which I hope he will shortly publish. A midwife, who had been nursing a case of erysipelas, attended a poor woman in her confinement. This woman was attacked with puerperal fever, which ended fatally in a few days. A woman, who had been washing some linen soiled with the discharges of this patient, was attacked with severe phlegmonous erysipelas of the arm and shoulder. Thus it appears that a poison of

a specific kind may give rise, in a woman lately confined, to a peculiar train of symptoms which go by the name of puerperal fever, and yet this woman may communicate the original disease, whether it be erysipelas or scarlatina, to another person. We need a number of very careful observations to show what differences are occasioned in the symptoms produced by scarlatinal poisoning in women who have had scarlatina previously and in those who have not. There is every reason to believe that women who have had scarlatina before, may, if recently confined, be reinfected and have the symptoms of puerperal fever, in the same way that other persons, who have had scarlet fever before, sometimes get a troublesome sore throat, after nursing scarlatina patients. The name puerperal fever is generally applied to several cases; but there is no doubt that when this disease is very prevalent slight cases of septicæmia often occur, just as cases of diarrhœa are frequent when cholera is prevailing; but these are not considered to be cases of puerperal fever. I believe that many cases of puerperal mania are, in reality, the result of blood-poisoning; for I have frequently noticed, before the attack of mania, the occurrence of rigors, some fever, hysterical excitement, sallowness of skin, and especially loss of sleep. Phlegmasia dolens is generally ushered in by symptoms of this kind, and I have often observed them before the outset of mammary inflammation and abscess. I regret very much that, although I have seen at different times a great many cases of puerperal fever, my notes of these cases are so incomplete that I can bring forward no statistics of any value. Nearly all the cases I have seen have been very severe ones, to which I was called in a day or two before the fatal termination; and I have no complete notes of them in the earlier stages. I trust, however, that before long such deficiencies will be supplied by others, who have had opportunities of watching these cases from the commencement, and who have been so unfortunate as to have two or three consecutively. Such information is very difficult to obtain; two or three cases of this kind make such a stir in a quiet country village, and are so injurious to the medical man in attendance on them, that he is glad to have the matter hushed up in every possible way; and to request him to publish the cases is very like asking a witness to criminate himself. All the more honour, then, is due to those practitioners, who for the benefit of medical science and for the public good, nobly come forward, undeterred by any fear of risking their reputation, and publish a candid statement of their experience.

HYDATID DISEASE :

AS ILLUSTRATED BY SPECIMENS CONTAINED IN THE PATHOLOGICAL MUSEUMS OF THE METROPOLIS AND IN OTHERS ELSEWHERE.

By T. SPENCER COBBOLD, M.D., F.R.S., F.L.S.,
Correspondent of the Academy of Sciences of Philadelphia.

III.

QUITE recently, I had an opportunity of inspecting the collection at St. Thomas's Hospital, which I found to be particularly rich in entozoa of various kinds, especially tapeworms and hydatids. I encountered 76 preparations of internal parasites; and, of these, 42 were of the hydatid kind, representing at least 33 different cases. I say "at least", because it is often impossible to decide in instances where no history of the specimens can be obtained. Thus, there are three similar preparations of hydatids passed by the urethra; and, from their appearance, I judge them to have come from one and the same patient; yet there is no statement in the catalogue to that effect.

Of the 33 cases of hydatids represented in the museum, I reckoned 18 as referable to the liver, 2 to the brain, 2 to the bones, 2 to the urinary organs, and 1 to the lung, spleen, uterus, and soft parts of the thigh respectively. There are also 3 that may be classed as peritoneal. There is another choice example in which the disease cannot be referred to any particular organ. I allude to Dr. Peacock's case already published (*Pathological Transactions*, vol. xv), where the lungs, liver, heart, spleen, and some other organs were all occupied by hydatid formations. As an instance of extensive visceral infection by echinococci in the human subject, I believe this case to be unique. The brain-hydatids are particularly fine. In the specimen presented by Mr. Boot of Lincoln, the hydatid, two inches in diameter, is lodged in the anterior horn of the left ventricle. One of the peritoneal cases is remarkable for the amount of forward displacement of the pelvic viscera, caused by four or more hydatids, each of them nearly as large as a cricket-ball. Amongst these abdominal cases, I have also included a recent preparation, to which Mr. Stewart called my attention. The hydatid in question, of the size of a large lemon, existed near the fundus of the

bladder; its walls being one-third of an inch in thickness, and forming an unusually firm tumour. Of all the five specimens of hydatids in the collection, however, none have struck me so much as those affecting the bones. There is a humerus, taken from a man thirty-four years of age, in which the shaft is occupied throughout by small hydatids that have destroyed almost all the cancellous structure; in some places also, the absorption of the cortical layer has gone on to such an extent as to have left little more than the periosteum. Of course, the bone was at last fractured easily. It is a beautiful specimen; and the existence of echinococcus-heads was proved by microscopic evidence. Scarcely less interesting are two preparations illustrative of Mr. Travers' case of a man, thirty-eight years of age, in whom numerous small hydatids occupied both the head of the tibia and the lower end of the femur. Each set of parasites freely communicated with the knee-joint, necessitating amputation of the limb.

The very large museum connected with Guy's Hospital is rich in hydatids. When, some time ago, I spent several days in going over the collection, I examined 76 preparations, representing apparently 70 separate cases of this affection. Amongst the noteworthy specimens, one lung-hydatid was intimately associated with a thoracic aneurism, two others being connected with the pleura; and, of seven abdominal cases, five were connected with the peritoneum, one with the mesocolon, and one with the aorta. This last mentioned instance occurred in a woman of sixty years who, until her death, was treated for dropsy. She complained of incessant pain, which was only relieved when she rested on her hands and knees. Of the three cases affecting the heart, one has been published (Mr. Henderson's), where the patient, a girl of nineteen years, died suddenly whilst in the apparent enjoyment of perfect health. In one of the other two cases (Mr. May's of Tottenham), the left lung was also involved. One case of hydatid disease affecting the spinal column appears to have been originally an ordinary liver case. In Mr. Cock's example of genuine mammary hydatids, the hooklets and echinococcus-heads were detected; but I am not sure that this result of microscopic examination was obtained in the equally interesting example of hydatids of the thyroid gland (also removed by Mr. Cock). There are five bladder-cases, all apparently genuine (of which one has been published); and there are also five other cases referred in the catalogue to the kidneys, of which I regard two as doubtfully parasitic in character. Of three cases of hydatid growths occupying the soft parts of the thigh, two were under Mr. Bryant's care. The museum likewise contains an old preparation of hydatids of the tibia, but its history has been lost. There are also two brain-cases, besides upwards of a score of more or less characteristic and instructive cases of hydatids affecting the liver.

Scattered amongst the museums connected with the larger provincial schools and recognised hospitals, there must be a great many valuable preparations of hydatid disease; at all events, I judge so from the inspection I have incidentally made of a few of the collections.

Of eleven preparations of human hydatids which I observed in the Cambridge Anatomical Museum, apparently representing the same number of cases, seven were connected with the liver and one with the lungs. Those hydatids displayed in the "special series" of entozoa were of uncertain seat. From the recently published and valuable "notes" by Dr. Bradbury, I have no doubt that considerable additions have been made to the Cambridge collection since my last visit.

The museum at Oxford contains some choice specimens of hydatids, but I have only personally inspected a few of them. In the absence of original notes, however, I am indebted to the kindness of Mr. W. Hatchett Jackson for supplying me with several interesting particulars. The anatomical department of the Oxford collection shows from one particular case two hydatids that were found "under the dura mater". In the pathological department, we find one hydatid from the liver of a male subject, and also a preparation showing a number of small hydatids that were "coughed up from the lungs of a female". There are also in this department (Dr. Acland's) two examples of hydatids from the diaphragm, apparently belonging to two separate cases. One is described as a large "hydatid in the diaphragm covered by the pleura"; whilst the other is spoken of as "springing from the diaphragm and projecting into the sac of the pericardium". There is likewise a preparation showing a number of small specimens of hydatids that were passed *per anum* by a female. It is conjectured that they came from the liver.

The small pathological museum attached to the Brighton and Sussex Hospital is particularly rich in hydatids. Amongst others, it contains preparations illustrative of the remarkable case of hydatids in the region of the prostate, communicated by Mr. Lowdell in the *Lancet* in 1846.

The comparatively large museum adjoining the Norfolk and Norwich Hospital displays a choice series of hydatids, chiefly from the collection

of the late Mr. Crosse. That eminent surgeon prepared a special set of specimens to illustrate the process of natural cure by calcareous degeneration; and I may here, perhaps, be pardoned for mentioning that it was the study of these and other entozoa in Mr. Crosse's collection, some thirty or more years ago, that first drew my attention to the phenomena of parasitic life. Illustrations of the helminths in question are still in my possession. In one case (which is instructive as indicating the possibility of death from the simplest form and commonest habitat of an hydatid), a lad, twelve years old, received a slight blow from a playmate. Something gave way, and death speedily followed. It was found by *post mortem* examination that a solitary liver-hydatid, rather larger than a cricket-ball, had been ruptured. Almost unique as the case undoubtedly is, it is nevertheless by no means pleasant to reflect upon the fact that under similar circumstances a friendly "poke in the ribs" might prove fatal to any one of us.

POST PARTUM HÆMORRHAGE TREATED WITH- OUT, AND UTERINE HÆMORRHAGE TREATED WITH, IRON: RESULTS SUCCESSFUL.

By ALEX. MCCOOK WEIR, M.D., L.R.C.S. Edin.,
Assistant Medical Officer, County Asylum, Nottingham.

I AM induced by the invitation of Mr. Boddy to record briefly, and from memory, my experience of uterine hæmorrhage. When assistant to a gentleman in the North of England, about two years ago, I was called to the bedside of a young unmarried woman four miles in the country, and found, on my arrival, the head low in the pelvis, with good pains at regular intervals. It was just midnight, and I anticipated a comparatively short stay, though I always made it a point to remain an hour with a patient after delivery. The pains ceased in their frequency after my arrival, which I attributed to timidity of the patient under her rather trying circumstances; and I was contemplating the use of the long forceps (Barnes's), when a good pain expelled the head; and soon afterwards a plump healthy male child, of more than average size, was born. The placenta was somewhat tedious in coming away, and a little pressure was exercised on the abdomen, and the cord very gently drawn. It soon yielded; and I observed that it was of more than ordinary size, soft and pulpy. I could not now distinguish the uterus from the outside, but conjectured that it had followed the placenta, and was contracted deep in the pelvis, when, to my horror, an instantaneous gush of blood, that inundated the bed and streamed on the floor, took place. The woman turned ghastly pale, closed her eyes, groaned, was pulseless at the wrist, and to all appearances dead. I called for a basin of cold water and a towel, which I instantly saturated and applied over the womb; and forthwith insinuated my left hand (the patient, fortunately, was delivered on her right side) into the vagina, and thence into the uterus. I then found this organ to be as flaccid as an empty bladder, and so extensively dilated on all hands, that my elbow reached the vulva before my fingers impinged on the fundus uteri, and were distinctly traceable through the abdominal parietes by the outside hand. But the cold shocks to the belly, and irritation within, failed to produce contraction; and in a few minutes I withdrew my hand, and was more horrified to see another gush of blood. I instantly reinserted my hand and arm, and there retained them, as a source of irritation and an effectual plug, until the uterus was stimulated to contract by large imbibitions of rum, the only stimulant in the house. As soon as contraction was well begun, I gradually withdrew my left hand, and followed the uterus into the pelvis by the right or abdominal hand, and kept up pressure with the latter for fully two hours. I then applied a thick book, enveloped in flannel, as a pad; and, having bandaged the patient firmly, sustained pressure over the uterine site for nearly two hours longer. In the meantime, the patient, who had had a whole bottle of rum, vomited, opened her eyes, said feebly that she was "better", and gradually assumed a less ghastly colour. I may add that, the moment the first gush of hæmorrhage took place, I pulled away all the pillows, pounded the bedding, and thus left the patient's head considerably lower than her chest. I concluded that the heart, thus relieved, kept up a very feeble action, that fed the brain and sustained weak respiration, though to outward observation she was pulseless, motionless, and dead. I attributed the uterine contraction more to reflex stimulation and sympathy with the stomach on the introduction of the rum, than the improbable effects of absorption; and my hand and arm *in utero* acted as an effectual plug. The patient swallowed the rum automatically. This encounter with death lasted in all about four hours; and, as soon as vomiting ceased, I gave a twenty-five minim dose of tincture of ergot, and left the

patient asleep at 6 A.M. A stupid nurse allowed her to get out of bed, contrary to my positive orders; but I found the mother and child comparatively comfortable at one o'clock next day. She made a rapid recovery, backed, no doubt, by a good constitution; and soon afterwards was married. I do not hesitate to say that, had the perchloride been injected into a womb so unduly dilated, the shock alone must have killed the woman, as it evidently did in Mr. Boddy's case.

The second case was hæmorrhage in a woman aged 50, whose menstruation had degenerated into a "bloody flux", which was slowly undermining her health, and had left her already pale and wan, with anæmic symptoms and inferior appetite. Constitutional remedies altogether failed to arrest the discharge, and Burnes's system was decided upon. Although my principal approved, yet he could not be present; but I nevertheless made a solution of the perchloride (one part in twenty); gave the patient a stiff dose of brandy; and, having filled, pushed the nozzle of a Higginson's syringe well up towards the fundus uteri, and very slowly injected, watching the patient all the time, and pausing to count the pulse occasionally. There was a slight shock (the patient was very nervous) to begin with, and a little pain, which soon passed away. I continued to inject until all traces of blood had disappeared, and left the patient, who was recumbent all the time, pretty comfortable after the operation. The bleeding did not return; but the prolonged anæmia had given rise to such gastric irritability, that the patient persistently refused food, and fell a victim in ten days, as much to her obstinacy as her disease, and certainly not to the operation or its results. I conclude from this case that washing out the uterus with a mild solution of the perchloride in cases of chronic hæmorrhage from a variety of causes cannot possibly do harm, if the operation be judiciously performed; the patient slightly stimulated beforehand, and her attention fixed on the operator all the time, so that the slightest change of countenance may be taken as an index to desist at once.

I may add, for the sake of young practitioners, that it is well to give the placenta good time; and, should a pain not come to expel it in about half an hour after delivery, it is better to insinuate two or three fingers, or even a hand, and grasp the body of the organ, than run the risk of detaching it in part by drawing the cord. This method and gentle manipulation over the abdomen will hardly fail to provoke a pain that will expel the placenta and contract the uterus simultaneously. I suspected partial detachment in my case; but whether it was so in Mr. Boddy's does not appear from his account.

CLINICAL MEMORANDA.

DANCERS' CRAMP.

IN the last number of the BRITISH MEDICAL JOURNAL appears a very interesting leading article, in which some observations on dancers' cramp by Schulz of Vienna are embodied. I have been unable to see the original article by Schulz; but, from the abstract in the BRITISH MEDICAL JOURNAL, the following appear to me to be the main facts. 1. Dancers' cramp occurs in those female dancers who are accustomed to balance themselves on the points of the toes. 2. It does not occur either in male or female dancers who are not called upon to execute this *pas*. Dr. Schulz then states that this pointing of the toe is mainly effected by the abductor, adductor, and flexor nerves of the big toe; and he further informs us that the first of these muscles is very highly developed in the foot of the dancer. The explanation which Dr. Schulz offers of the morbid phenomena is as follows.

"The work done by a muscle depends partly on the strength and partly on the amount of contraction, the former being in proportion to the transverse section of the muscle, the latter to its length. Hence, in the above-named muscles, in consequence of the increase of their transverse diameter by frequent exercise, the voluntary contraction easily passes into a painful tetanus-like one."

Does Dr. Schulz mean to assert that the more highly a muscle is developed, the more liable it becomes to tetanus-like contractions? And, if so, I should like to know whether this is in accordance with the experience of the profession. It certainly is at variance with my own experience, and I have not observed that the muscles of athletes are more liable to cramp than those of other people. On the contrary, it is in the early days of his training that the athlete suffers, and not after his muscles have become developed by exercise. Again, if the mere size of the muscle were the cause of the cramp, surely we ought to find that all dancers are affected alike, since few true saltatory movements can be performed without the aid of the muscles in question, and they are probably very highly developed in dancers of all kinds. We find, however, that the cramp is limited to the executants of a particular *pas*,

and I would venture to offer the following explanation of the phenomenon.

The *pas* in question is not dancing; for dancing consists in regular and rhythmical exercise of the muscles, and the pleasure of dancing is found in the enjoyment of this sense of rhythm, a sense which seems implanted in the whole animal kingdom, and helps probably to secure healthy muscular nutrition by maintaining the balance between contraction and relaxation, in accordance with the rhythmic law of nutrition which has been ably insisted upon by Sir James Paget.

This balancing on the toes is a mere gymnastic feat, and in it the toe and ankle are maintained, often for considerable periods of time, in one position by violent and prolonged muscular exertion. In it the physiological law of healthy muscular nutrition is neglected, the long strong contraction of the muscle is out of all proportion to its period of relaxation, fatigue supervenes, and cramp, one of the symptoms of fatigue, brings the dancer to a standstill.

I have often insisted that the rhythm of the dancer's movements is his safeguard against cramp, and this penalty which the Vienna solo dancers pay for substituting an inelegant *tour de force* for the graceful movements of dancing proper, is an interesting example of a fatigue-disease, brought about, as are other diseases of the same class, by neglecting an important physiological law.

G. V. POORE, M.D., Wimpole Street.

OBSTETRIC MEMORANDA.

A CASE OF UTERINE HÆMORRHAGE SUCCESSFULLY TREATED WITH THE PERCHLORIDE OF IRON.

ON June 29th last, I was sent for to attend, in her third labour, a Mrs. H., residing at Gate Beck, a distance of six miles from my residence. The child, a very large one, had been born about an hour before my arrival. During this period, I was told by the nurse in attendance, flooding to an alarming extent had occurred: a statement fully confirmed by the death-like appearance and pulseless condition of the poor woman, her bed and body-linen being in fact completely saturated with blood. Without a moment's delay or further questioning, I immediately introduced my hand into the uterus (a task easily enough accomplished in its uncontracted and fully dilated state) to bring away the after-birth. Owing to firm adhesions existing throughout its entire extent, the operation was not so easy as I anticipated. The flooding during a portion of this time was most profuse, and I quite thought that, before the operation was completed, my patient would expire. Having removed as much of the placenta as, under existing circumstances, I felt myself justified in doing, and without resorting to other means for arresting hæmorrhage, I at once (feeling the case was one of extreme danger, and a suitable one for a trial of the perchloride of iron) injected, using for the purpose a Higginson's syringe, four ounces of the strong liquor ferri perchloridi of the *British Pharmacopœia* mixed in a proper basin with twelve ounces of water—the proportions, I believe, recommended by Dr. Barnes. The delivery-tube being passed well up into the uterus, so as to touch the fundus before injecting the fluid, each half of it was thrown up gently, and slowly feeble uterine contractions commenced, diminishing greatly the discharge of blood, which, after the withdrawal of the tube, was completely arrested. Feeling her case to be, from previous loss, most critical, I stayed three hours in the house, administering during this period at intervals beef-tea and brandy, and then returned home, leaving strict directions not to move her until I returned. Early on the following morning, I saw her again. The womb had moderately contracted during the night, and there was no further discharge; indeed, she was as well as and even better than I expected to see her. This poor woman has since made a complete recovery, without experiencing the slightest ill-effects of the styptic. I consider this case adds another laurel to the victor's wreath, and as such is worthy a brief notice, feeling sure that (under God) this woman's life is indebted to the perchloride treatment.

OCTAVIAN N. ROYLE, M.D., Milnthorpe.

INJECTION OF PERCHLORIDE OF IRON IN POST PARTUM HÆMORRHAGE.

M., AGED 19, was delivered of her second child. Labour commenced on Thursday, October 20th, and continued until Saturday, the 22nd, 2.30 P.M., when it was decided to perform craniotomy, the forceps having been tried. Temperature, 101.4 deg. The operation was done under chloroform. After the child was removed and the placenta detached, and the patient was just recovering from the effects of the

chloroform, flooding commenced. Large doses of ergot were given; the hand was inserted, and clots were removed. The uterus was grasped from the outside, and cloths dipped in cold water applied suddenly to the abdomen. The hæmorrhage still continuing, and the patient becoming much exhausted, four ounces of liquor ferri perchloridi fortior were fetched from a neighbouring chemist and added to one pint of water, and injected with a small brass enema-syringe. After the whole quantity had been used, the hæmorrhage was stayed, and the patient still lives.

ARTHUR W. KEMPE, Darlington.

THE TREATMENT OF VOMITING OF PREGNANCY.

THE interesting paper in the JOURNAL of November 6th by Dr. Cope-
man, on Obstinate Vomiting connected with Pregnancy, has induced
me to bring into more prominent notice a remedy which, during the
last four years, I have found of great service in relieving, if not in sub-
duing, the ordinary nausea and sickness of early pregnancy. This remedy
is dilute phosphoric acid in doses of from thirty to sixty minims in a wine-
glass of water two, three, or four times a day, as may be required. It is
of special value in cases where the nausea becomes extreme at the sight of
food, as a dose may be easily taken before meals. Amongst all the
remedies for this particular discomfort, I have found none so uniformly
efficacious. It may act by powerfully stimulating the nerves of the
stomach, or as a corrective (if, as is asserted, the vomitings of preg-
nancy are alkaline), or in both ways. It is very pleasant to the taste,
and I have always found that patients who have taken it in one preg-
nancy invariably send for the acid when they find themselves in an in-
teresting condition again.

THOMAS FAIRBANK, M.D. Lond., Windsor.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN.

ST. THOMAS'S HOSPITAL.

CASES UNDER THE CARE OF DR. MURCHISON.

Acute Ascites in a Boy: Rapid Recovery.—An anæmic boy, nine years
old, of somewhat tubercular aspect, was admitted under Dr. Murchi-
son's care on September 5th, with a very considerable amount of
ascites; a few days after admission, his abdomen measured thirty-four
inches in circumference at the level of the umbilicus. His friends
stated that he had enjoyed fair health till July, when he had a sudden
attack of sickness and diarrhœa; the latter continued to trouble him
more or less for several weeks, and, when it abated, his abdomen
began rapidly to enlarge. He had lost his mother from phthisis, and
several of his brothers and sisters had died young. The patient stated
that he had been losing flesh for some time, but no evidence of tubercular
disease could be detected in his lungs. He had neither heart-disease nor
albuminuria. He was ordered a diuretic mixture with iron; and, under
this treatment, the dropsy gradually diminished. His liver was then
found to be somewhat enlarged, and his spleen considerably so, project-
ing quite four inches below the margin of the ribs. The ascites continued
to decrease steadily, and, at the end of six weeks, no fluid could be
detected in the abdomen; the spleen also diminished in size to some
extent, but, at the time of his discharge, it still extended from two to
two and a half inches beyond the ribs. He left the hospital at the
end of October in his usual health. No enlarged glands could be
detected anywhere in the abdomen; but, in the absence of any other
probable cause, Dr. Murchison was inclined to attribute the dropsy to
pressure on the portal vein by some temporarily enlarged lymphatic
glands near the fissure of the liver. The enlargement appeared to
have been consequent on the severe and prolonged attack of gastro-
enteritis from which the boy had suffered in the summer. Acting on
this supposition, the treatment had been chiefly expectant, and the
satisfactory progress of the patient had rendered unnecessary the more
active remedies which would generally be used in such a case.

Right Hemiplegia due to Syphilitic Tumour in the Brain.—This pa-
tient, a publican, aged 28, stated that about January or February,
1874, he began to be troubled with pain in the muscles of his right
arm; this was soon followed by gradual loss of power. Next his right
leg became affected in the same way; his mouth also was drawn to the
left, and his speech became indistinct; but all this time he had no loss
of consciousness or fit of any kind—indeed he had been, and was in

other respects, in good health. On being further questioned, however,
he stated that for two years before the appearance of the paralysis he had
suffered greatly from pains in the head; these were always much worse
at night, and were so severe as to keep him awake. A few weeks
after the symptoms of paralysis appeared, the headache ceased, and
had not since troubled him. Seven years ago, he had a sore on the
penis, which gave him no pain, and discharged but little; it took
about three months to heal. At the time of his admission, the loss of
power in the arm was complete; the leg was less affected. Under a
course of iodide of potassium, the patient decidedly improved, but his
arm was still almost useless, owing to constant trembling and clonic
spasms. Dr. Murchison remarked, that the long continued headache
and the very gradual invasion of the disease pointed to cerebral tumour;
the patient also was young, and he had neither heart nor kidney-dis-
ease. There could be little doubt, also, that the growth was of syphi-
litic origin, although the patient appeared to have remained for five
years free from any manifestation of the disease; the result of the treat-
ment by the iodide confirmed this view. In this case, the primary
facts had been elicited with some difficulty, but it not unfrequently
happened in similar cases that the result of the treatment had to be
relied upon, not only to confirm the diagnosis, but also to supply an
important part of the history.

Large Thoracic Aneurism in a Young Man: History of Syphilis.—
A well-made, muscular young fellow, aged 25, was admitted on Aug.
17th on account of constant pain and throbbing in the chest, and of
great dyspnoea on exertion. On examination, a distinct thrill and
impulse could be felt to the right of the sternum between the second
and third ribs, about two inches to the right of the middle line; there
was also slight pulsation visible in the intercostal space at this point.
In front, there was deficient resonance over the right side of the chest,
amounting to absolute dullness from the apex to the fourth rib. The
breath-sounds, although weaker than on the left side, were not greatly
altered in character. A systolic murmur was audible over the base of
the heart, and also very distinctly to the right of the sternum. The
only remarkable point in the case was the rapid invasion of the symp-
toms. He had been a sailor till a year and a half ago, and had worked
hard as a coppersmith till nine months before admission; the dyspnoea
then came on so rapidly that he thought at first he must have a bad
cold on his chest. He was obliged to give up work, and had since
gradually become worse. At the time of his admission, he was scarcely
able to walk about at all on account of the increased pain caused by
any movement. He had a hard chancre four years ago.

STAMFORD INFIRMARY.

EXTENSIVE SYMMETRICAL NECROSIS OF LOWER THIRD OF EACH
FEMUR: REMOVAL OF SEQUESTRA: RECOVERY.*
(Under the care of WILLIAM NEWMAN, M.D. Lond., F.R.C.S. Eng.,
Surgeon to the Infirmary.)

R. M., AGED 21, was admitted on April 9th, 1872, into the Stamford In-
firmary. Five years ago, he had a severe attack of rheumatic fever (so-
called), and was ill for many weeks. The right thigh first became inflamed
at the lower part, and was much swollen; then matter formed, and was
evacuated by an incision on the inner side of the thigh. Very shortly
afterwards, the left thigh became affected in the same way. From both
thighs, fragments of bone at different times came away, and there was
constant and abundant ill smelling discharge. He had been quite
unable to work since the commencement of his illness, and had often
been confined to bed from pain and weakness. He was very thin,
well-grown, but had the aspect of a man long ill. There were no
chest-symptoms.

At the outer side of the right thigh, about the junction of the lower
and middle thirds, there was a long sinus communicating with dead
bone; and about three inches lower, another similar opening existed
also leading to necrosed bone. In the left thigh, there was a single
opening in the very middle of the popliteal space, and one also on the
inner face of the limb. A probe passed into either opening led
down to dead bone.

April 13th. Chloroform was given. I made free incision on the
outer side of the right limb, from one opening to the other, quite down
to the femur. With difficulty, by the aid of the gouge and bone-
forceps, an opening of sufficient size was made to allow the removal of
several loose large pieces of necrosed bone—one a complete plate from
the posterior intercondylar space of the femur.

May 23rd. There had been no trouble since the operation. There
was now about half an ounce of healthy inodorous pus discharged in
twenty-four hours. He would go home to-day for a month.

* Read before the South Midland Branch of the British Medical Association.

1872. June 21st. He was readmitted for operation on the left thigh.

The two openings noted above still existed. A probe passed from the opening on the inside of the limb could be passed quite across behind the femur, where it glided over the necrosed bone, so that the extremity could be felt through the soft parts on the outer side. The course of action had to be carefully thought over. It was not possible to increase the size of either of the existing openings without danger to important structures: the popliteal artery, if the posterior opening were thought of; the knee-joint, if the internal opening were to be chosen. I determined, therefore, to make a careful attempt to get at the necrosed bone from the outside of the limb, cutting down freely to the outside of the femur, and then making an opening into the popliteal space sufficient for the purpose in question.

June 24th. Chloroform was given. I made an incision fully three inches long on the outer side of the left thigh and in the middle of the lower third of the limb down to the bone; then, partly with the finger-nail and partly with a blunt chisel, I separated the periosteum until I could get my finger well behind the bone and touch the necrosed pieces. The knee was forcibly flexed, so as to relax the hamstring muscles, and then, with cutting bone-forceps, I cut away the thickened outer wall of the femur until I was able to get free access to the loose bone. Many pieces were removed, and a plate also, which was the exact parallel of the one noted as removed from the other limb. I could touch one long sequestrum lying high up in the line of the femur, but this I was unable to remove.

July 16th. The two old openings in the limb had closed. There was free discharge still from the wound of the operation. He went home to-day for a time.

October 18th. He was readmitted.

October 24th. Chloroform was given. I made an incision in the line of the scar of the last operation, taking a cut a little higher up; then I cut away rather more of the outer wall of the femur at the upper part, and could lay hold of the sequestrum, which in June I failed to remove. It was long and large, but at last I succeeded in drawing it down in the line of the femur, until the middle seemed to be opposite to the external wound; then, with a second pair of forceps and a good deal of force, the piece was broken across; and I was able to withdraw first one and then the other half. It was not possible to touch any further piece of dead bone.

November 28th. He was discharged to-day. The wounds still furnished some thin watery discharge from both limbs. He could walk firmly and well.

1873. January 24th. He walked very well. There was still a thin watery discharge from the right leg. The left leg discharged about an ounce of pus in the day; and there was a papilla of granulation at the opening.

June 13th. The local conditions still remained as above. He was in very good health. He had no pain, and could walk three or four miles easily; and had been at work corn-hoeing for the last three weeks.

1874. July 17th. He had been at work for the whole of the past year, and was very well in health. There was still some discharge from the left thigh.

There are one or two points of especial interest about this case to which attention may be directed.

The first is, the accurately symmetrical character of the disease—not only the same destruction of bone-tissue upon each side of the body, but a destruction attacking precisely the same locality. To what condition this should be traced, it was not possible to determine. The family history was imperfectly given, but I could not find any specially faulty point, and nothing could be found to lead to the idea of inherited syphilis.

The next is, the time during which continuous and even profuse suppuration had gone on—for five years, without any evil influence upon the patient's general health other than the indirect result of such an exhausting discharge. There had, too, been, from the poor circumstances of the patient, very little help given to his constitutional power to meet this undue drain on his system.

The operation for removal of the sequestra, simple enough in the right thigh, was far less so on the other side; and the portions of bone removed, and which I now exhibit, will in some degree show this. The principle of cutting through sound parts to reach, for anatomical or other good reasons, the seat of internal disease, is sufficiently recognised; and on this in the free outside incision I was glad to act; possibly, had I made that incision rather more freely and cut away more of the broken outer wall of the femur, I might have at one sitting completed the removal of the dead bone. The difficulty in the breaking through of the long sequestrum was only met by the use of very considerable force, and the expedient employed may be worth recording.

REVIEWS AND NOTICES.

MODERN NAVAL HYGIENE. By Dr. H. DE MERICOURT. Translated from the French by Staff Surgeon JOHN BUCKLEY, R.N. Pp. 69. Griffin and Co.

This is a handy little pocket *vade-mecum*; not containing much beyond the uses of our own navy; but worthy of notice as it supplies the want of such a treatise in our tongue. Ventilation is pointed out to be the one chief desideratum in modern ships of war, which are at times even more crowded than those of the olden time, and to effect this is still the unsolved problem of naval constructors. It is satisfactory to learn that after many ingenious failures, our neighbours are adopting the plan devised by the late Dr. Henry Edmonds, R.N. Steamers have a great advantage over sailing ships, in the necessity for frequent visits to harbours, to fill up the coalbunkers which are the great impediment to ventilation below. In the French expedition to China, in 1859, the mortality was one-third greater in the sailing than in the steam squadron. Monitors and torpedo vessels seem, as yet, to be beyond the range of hygienic ventilation. The heat of the stokeholes and boilers causes a quicker decomposition of the bilge-water; to obviate which great improvements have been made in the timbers and the pumps, and passages have been devised along the keelson lengthways, as well as from side to side, and foul air is sucked from them into the furnaces. As a disinfectant, sulphate of iron is preferred to the chlorides, but charring the timbers is found to be more effectual than any chemicals, and dryness is thought better than any moist preparations whatever. The sick bay is located under the fore-castle, with very great benefit to the sick, which cannot surprise any of our surgeons used to the treatment of tropical diseases on board the old style of brigs and corvettes, in which that was the home of the sick in all weathers. As to dress, there seems but little difference between this and all European navies, excepting the Turkish, which in its own way is well adapted. Among French and English seamen there is too much exposure of the neck and chest, which may account for the prevalence of consumption.

In point of diet, the French sailor may be somewhat better off, in accordance with national taste, than the English. Preserved meats, salt pork, dried vegetables, soft bread, wine, and condiments are issued—the food aliment daily supplied containing approximately in grammes: of nitrogen, 27; of carbon, 309; and of fat, 50; forming a scientifically adjusted scale. Stokers receive an augmentation of wine and farinaceous food while on duty. Drinking water is distilled; and, in order to prevent dry colic and other forms of lead-poisoning, which were very prevalent when pipes of lead were in use, that metal is now prohibited in the condensers, cooking apparatus, and mess utensils; and charcoal filters are used for the drinking water, with the result of putting an end to what was so common as to be classed among the tropical diseases. This has been a triumph of naval hygiene, of which Dr. de Méricourt affords a succinct and instructive history.

In the English navy, lead-poisoning always results from handling lead-paints, and especially in painting in the confined spaces between the inner and outer skins of ironclads, and very rarely indeed from gastric poisoning.

Scurvy is more prevalent in the French navy than in ours, for, strangely enough, the daily issue of lime-juice at sea, which has been the prophylactic with us since 1797, has only recently been so used by them. French surgeons became convinced of its utility in the Russian war, when cruising in combined squadrons with ourselves, who remained free while their crews were suffering from this debilitating disease. It is now used by them. Dr. de Méricourt has assigned too early a date to the supply of it in our navy, and has not stated quite correctly to whom the discovery was due. So early as 1627, Mr. John Woodhall, a barber-surgeon of London, who had made voyages to the East Indies, was engaged to examine the medicine-chests of the surgeons of the fleet destined for Rochelle. He published the first edition of his *Surgeon's Mate*, or guide to the medicine-chest, in which is found, not merely the therapeutical uses of the various drugs contained in the chest, but the modes of resuscitating the apparently drowned, and of embalming the dead. He likewise brought to notice his trephine for the trepan, which is still one of the armamenta of French military surgeons; and he detailed his knowledge from experience of the prophylactic and curative value of the juice of the "lemon family" in scurvy. Notwithstanding this, it was not employed generally, by order, in our navy until 1797, when Sir Gilbert Blane, the first naval physician thus employed, took a seat at the Sick and Hurt Board, at a time when it was no uncommon thing for a fleet to return with from 500 to 1000 men more or less afflicted with scurvy. In fact, it was thus employed only towards the end of a century which comprised

about fifty years of naval wars, that had made England mistress of the ocean by means of crews frightfully cut up by scurvy more than by the guns of the enemy; and this, too, when Captain Cook had obtained from the Royal Society, at the middle of the century, its gold medal for having secured his crews from scurvy in the circumnavigation of the globe. So great was the cost in human life that England paid, for confiding the medical trust of her seamen into the hands of civilians unused to sea life.

With regard to the more laborious duties of ships, Dr. de Méricourt advocates the preparation of all entering the navy by a course of gymnastics, to render them ready and confident in the exercise of their physical powers in emergencies, by which many of the severe accidents seamen are liable to would be avoided; that stokers should always be worked in three, and not in two, watches, alternately, to secure to them proper rest; that natives should be engaged for boat-work and other exposure wherever practicable in hot climates; and that more of the heavy work of ships of war be done by steam machinery in the navy, as is already done in the shipping of the great oceanic companies.

We are happy in the belief that, in regard to several of these desiderata among our neighbours, we appear to be in advance of them; but still more might perhaps be done to complete and perfect these things among ourselves.

We cordially recommend this brief treatise to all naval medical officers; and think that to Mr. Buckley much credit is due for presenting it in an English dress, and in a very portable form, supplying, as it does, at the least temporarily, a notable hiatus in naval medical literature.

REPORT OF THE MEDICAL SUPERINTENDENT OF THE LEPER ASYLUM (OF TRINIDAD) FOR THE YEAR 1874. Legislative Council Paper, June 1st, 1875.

The Leper Asylum at Trinidad is stated by Dr. Gavin Milroy, in his Report on Leprosy and Yaws in the West Indies, to be the best managed of all the West Indian hospitals; and it is satisfactory to find that it yields improving results. Dr. Espinet, the Superintendent, is able to report the mortality as diminished, and probably lower than in any previous year since the hospital was established in 1843, although a larger number of patients have been admitted. He ascribes the lower death-rate to several causes; viz., to the drainage and drying up of adjoining swampy land, the cutting down of surrounding brush-wood, the addition of fresh drains, the regular system of manual labour and exercise introduced on the recommendation of Dr. Gavin Milroy, and improved nursing; together with the exceptionally healthy condition of the island during the year, and the admission of fewer patients *in extremis* to the asylum. Dr. Espinet's observations show that leprosy attacks persons of every race in the island—whites and creoles, as well as blacks; but it is confined principally to the poorer classes, who are under most unfavourable hygienic conditions. Europeans are rarely if ever attacked, however, until after their third year of residence, or about the period of acclimatisation. The disease is most prevalent amongst the Portuguese and Hindoos; but, curiously enough, amongst the latter it is confined almost exclusively to adult males—coolie women and children enjoying a singular immunity. That the greater rarity of female lepers amongst the coolies is out of all proportion to the relative numbers of the sexes, is shown by the statistics of the Immigration Office, and is confirmed by the experience of Dr. Mitchell, the Agent-General of Immigrants, and other medical men in the island. It is, moreover, in accordance with the observations of Dr. Carter in India, who found the proportion of males affected to be 81.4 per cent., as compared with 18.6 per cent. females. This great disproportion does not exist amongst the natives of Trinidad, where the numbers are about 60 and 40 per cent. respectively; and it almost disappears in Norway, where the numbers are 56 per cent. males to 44 per cent. females. The striking difference in the prevalence of leprosy between the two sexes amongst coolies in Trinidad cannot be accounted for by any difference in their surrounding conditions, the occupations and habits and mode of life of men and women appearing to be the same; and Dr. Espinet is unable to find any satisfactory explanation of the disproportion in their relative liability to disease. While the coolie children usually escape, the Portuguese children are especially liable to leprosy; and this is referred to the exceptionally unfavourable hygienic conditions under which the latter are brought up, such as poor diet, want of cleanliness, and the overcrowding of families in small ill-ventilated rooms. Children are more seriously affected than adults; and Dr. Espinet thinks that it may be laid down as a general law, that the earlier the period of life in which leprosy develops itself, the more severe and rapid will be its course; and, *vice versa*, the later the period of life at which it first appears, the less severe and more chronic will be its progress. He has never seen the disease de-

veloped at birth, or at an earlier age than four or five years, even in the children of advanced lepers.

Another point raised in the Report is the question of the influence of hereditary taint, and the limit of the period of incubation. The author expresses his belief that the majority of Indian immigrants in Trinidad who become lepers have the disease by inheritance, and do not contract it after their arrival in the island. Since the disease is endemic in Trinidad, it seems almost impossible to determine, in cases where it appears after a long interval, whether it is inherited or acquired. The fact that the disease in the coolies follows the habit of the disease in India in its preference for the male sex, and not that of Trinidad, where it attacks the natives in nearly equal proportions, is no doubt, in one light, favourable to Dr. Espinet's view. It must be remembered, however, that the comparative exemption of coolie women may be due to some peculiarity in themselves or in the conditions which surround them, and not to any special character of the Indian disease, as compared with that of Trinidad. The probability of the disease being usually inherited is supported by the observations of Professor Boeck of Norway, who examined cases of leprosy amongst Norwegian immigrants in the Western States of America, where the disease is not endemic. In every instance of leprosy developed after arrival in America, the patient proved to be of leprosy family at home; and Dr. Boeck places the limit of the period of incubation at fourteen years. This limit appears to be arbitrarily chosen; and a table appended to the Trinidad Report is given, which shows that, in twenty-two cases, the period of invasion of leprosy after the arrival of Indian immigrants in the island varied from six months to twenty-five years. There is not, however, the same certainty of the disease being inherited or imported in this series of cases as in those of Norwegians in America reported by Dr. Boeck.

Dr. Espinet believes that he can trace a connection between leprosy and phthisis, and with epilepsy and insanity; but the data upon which he rests his conclusions are too vague and imperfect for the speculation to have much value.

The distribution of the disease in the island has not been properly ascertained; but the little that is known militates against the theory of its origin in malaria, since lepers are found to come to the asylum from most parts of the island, and from places the most opposite in topographical character—from dry ground at great altitudes, from low swampy lands, from deep valleys, from high tableland, and from level alluvial plains.

For the prevention of the development of leprosy, the Superintendent suggests that a medical examination of all immigrants should be instituted, and that those found affected with the disease should either be returned to their own country or transferred to the asylum. A more effectual remedy still would, no doubt, be the segregation of the lepers and the separation of the sexes. But a compulsory system of this kind Dr. Espinet deems impracticable; and the voluntary system which he advocates would, it seems to us, necessarily work very partially and ineffectually.

The latter portion of the Report is devoted to the treatment of the disease, and this part is the least satisfactory. In the early stages, careful diet, regular exercise, and tonics, appear to exercise a generally favourable influence; but, although the writer maintains that leprosy, being a general constitutional disease, and not a local affection merely, can only be successfully combated by internal remedies, the best results which he records are those obtained by the external application of cashew-nut oil, after the method of Dr. Beauperthuy. Several cases are given in which decided improvement, and even apparent cure, followed the prolonged use of the oil; but a relapse usually followed in the course of three to six months after the suspension of treatment. In one instance, however, where the disease was of the anæsthetic form, the improvement had continued up to the date of the Report. It is in the early stage of this variety that the treatment proves most beneficial, by its blistering action removing stains, and apparently restoring sensibility by liberating the extreme nervous filaments from the pressure of the albuminoid deposits which surround them. In the tubercular form of leprosy, the tubercles may be entirely removed by cashew-nut oil, and the skin apparently restored to its normal state; but the tubercles return in three or four months after the suspension of treatment, with increased luxuriance. In twenty-two selected cases thus treated by Dr. Brissac in Guadaloupe, an apparent cure followed in five; but it is not stated from which form of the disease the patients suffered, nor whether the cures were permanent.

The Report supplies some useful data and practical suggestions as to the management and control of the disease, scattered among other matter of less value. Its chief defect is the absence of any account of *post mortem* appearances, and of any contribution to the morbid anatomy of this important affection.

BRITISH MEDICAL ASSOCIATION:
SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, NOVEMBER 20TH, 1875.

THE PATHOLOGICAL SOCIETY OF LONDON.

WE have received a good many communications relating to our recent comments on the proceedings of the Pathological Society of London, which seem to have excited considerable interest. Our correspondents are divided in opinion, some agreeing energetically with all that was said by us, and some urging views which are calculated to modify the tenor of our criticisms; but all inviting us to pursue and develop the subject. We would, in the first instance, guard against the supposition that we are insensible in any degree to the great value of this society, or unmindful of its past services. The Pathological Society of London is one of the brightest ornaments of English medical science. It is the home of a kind of research which had long been thought peculiarly ungrateful and unattractive, but which lies at the foundation of medical and surgical progress. It is the nursery of the most distinguished eminence in professional work, and, by its historic labours, it has done more perhaps than any other society to redeem English medicine from the reproach of shallow superficiality which was gathering round it, and from which it is not yet wholly free. Those who founded it did so in the face of sneering discouragement from seniors high in the profession, which, if it were all recalled to mind, would seem now incredible, and of which we have recently been reminded of some singular instances. In its *Transactions*, pathology has, during the last twenty years, been almost rewritten and re-edited; and the meetings of the Society can rarely, we imagine, be attended by the most highly informed person without his gathering solid information, while often he must be both instructed and delighted. Nevertheless, there are, we think, many palpable defects in the nature of the proceedings during the last few years, and they are rather growing than lessening in intensity. This is partly due to the changes wrought by lapse of time and progress of knowledge, partly to a certain negligence which threatens to become stereotyped.

And, first, as to this negligence; it is, we think, a defect both of manner and of matter. The proportion of uninteresting cases brought forward is much greater than it ought to be; and of interesting cases it may frequently be said, that they are not brought forward in a manner which does justice to the specimen and to its reporter, or which is respectful to the Society. To be worthy of the Society, the report presented on any specimen brought under notice ought, we think, to give not only a brief record of the anatomical characters of the specimen, but to point out its place in medical literature and science; and ought to indicate the references to similar specimens on record, and to differentiate it where it shows difference; it ought to indicate the relation of the pathological specimen to the pathological process which it illustrates, and, where possible and desirable, as is most commonly the case, to establish its clinical relations. It may be said that not every specimen would bear such treatment, and that it would make the reports intolerably long and tedious. Such a reply would, however, involve a twofold error. Tediou-ness does not bear a necessary relation to length, but rather to superfluity or dullness of matter or baldness of manner. A very short communication is often dull, and a number of short dull communications are often intolerably tedious. A more pointed statement, satisfying the legitimate requirements of the hearers, would

be far more welcome. But a carefully considered statement is commonly more brief than improvised and hasty talk about a specimen. Experience very soon teaches that it takes time and thought to achieve brevity and condensation, while prolixity is the offspring of carelessness. As a practical illustration of our meaning, we would refer, as an example, drawn from the last meeting, of excellent condensation, and yet of the careful statement of all the points necessary to make a report acceptable and scientifically useful, to the communication of Dr. Gowers. Other examples were not wanting at the same meeting of specimens which have little interest, and which were brought forward without any regard to the elucidation of their scientific, pathological, or clinical relations.

In these respects, we have said that there is a palpable falling off in the preparation of reports by exhibitors generally, with, of course, frequent and sometimes brilliant exceptions. We do not think this by any means irremediable. Looking to the cause of it, we think it may perhaps partly be self-suggested by the difference in wording which we find on comparing the last with earlier lists of rules, for presentation of specimens. The difference may best be observed by comparing Rule 1 as it stands on the cards of 1869-70, and 1870-71. On the card of 1869-70, the first rule runs thus:—"Members intending to exhibit specimens to the Society must, excepting under the circumstances provided for in Rule 3, send the report to the medical secretary at least a week before the meeting at which the specimen is to be shown." In 1870-71, it is altered thus:—"Members intending to show specimens are requested to send notice to the medical secretary, if possible, a week before the meeting, for publication in the journals."

The requirement to furnish a report a week beforehand tended unquestionably to produce the habit of deliberately preparing with due care the statement to be submitted to the Society. Such preparation, at first insisted on was, no doubt, ultimately felt to be irksome, and was gradually relaxed, until at last it was altogether omitted and the rule was annulled. In its fresh modification, the relaxation of the rule led to the reports being prepared just in time to hand in with the preparation. Hence it has led to the frequent omission of any preliminary study of the report to be made, and many exhibitors find it more convenient to submit the specimen, to read a microscopic report on it, and to trust to the inspiration of the moment for any commentary on it, or elucidation of its relations to pathological literature or to medical science. This explains a good deal of what is objectionable and perfunctory in the manner of report. They must be reminded that final success in *impromptu* speaking is only attained, according to the experience of the most able and accomplished persons, by long years of a habit of carefully preparing in writing the matter which is to be orally delivered. The gasping insufficiency of a considerable proportion of the reports at the Pathological Society is the main blot on its proceedings.

We have not much space in which to develop that part of the subject which relates to the change in the method of treatment which is required by the progress achieved with the growing ripeness of the years. Twenty years since, pathological anatomy needed to be reconstructed. Nearly everything which the microscope showed in a morbid growth was more or less of a novelty. Good microscopic preparations and drawings of ordinary morbid specimens needed to be recorded, and even to be multiplied. That necessity does not exist now in the same degree. The histological characters, e.g., of ordinary osteosarcoma, or of medullary cancer and the like, have become matters of elementary knowledge; it is hardly necessary to enter into a minute description in order to identify them. Many preparations are, as it seems to us, now shown at the Pathological Society which would be interesting enough in the lecture-room or laboratory for the instruction of students, but are stale and unprofitable enough for the members of such a society. We should be slow to discourage histological enthusiasm; for the microscope has revealed a new basis of pathology, and it would be presumptuous to think of setting limits to its further achievements. In itself, however, there is nothing much more notable at this date in the histological description of a specimen than in the

description of its naked-eye characters; and a tumour is not suitable for presentation to the Society merely because its exhibitor knows how to make a microscopic preparation and drawing of it, and to describe it in due technical terms. It was so once, but it is so no longer. There must be other claims, and those claims require to be recognised and made good. This is what many exhibitors are apt to forget. We are not anxious to arrest the display of individually interesting specimens; we would rather encourage it; but we are anxious to urge the necessity of defining, developing, and illustrating the points of interest.

There is yet a further step, and one which the Council, we trust, are likely to take without delay. We referred to it on a previous occasion, and since then we believe the idea has ripened towards final decision. There is now much to be gained in attempting to classify the specimens exhibited, and to arrange for the description of series of specimens illustrating particular points of pathology. By fixing beforehand on certain subjects for illustration on particular nights to be set apart at intervals during the session, very instructive and interesting evenings might be spent. We believe that, as a commencement, or by way of trial, early arrangements may probably be made for the exhibition of specimens bearing on certain points in the pathology of syphilis, and that Mr. Jonathan Hutchinson will introduce the subject. Thus a definite and no doubt very attractive and instructive debate may be arranged, and it would be easily possible to multiply similar series.

So much the Council can do; but the multiplication of individual records of separate facts is a function of the Society which must always be kept in view, and to perform this function more effectually than of late is a matter which rests with individual members much more than with the Council.

There are some other points, such as the neglect of chemical pathology and of experimental pathology, to which we hope to be able to afford space for fuller reference. It will remain then also to speak of the substitution of an annual for the biennial term of presidency: a change which we are disposed to urge as likely to be in various ways beneficial; and to combat some prejudices founded, we think, upon misconception, which at present seem to hinder members in exhibiting specimens from dealing adequately with their clinical interest.

THE LOCAL GOVERNMENT BOARD AND COMBINED SANITARY DISTRICTS.

OUR readers are aware that the Local Government Board inserted a clause in the Public Health Act of last session, which was accepted by Parliament, in virtue of which it acquired powers to compulsorily combine the sanitary authorities of any district, with certain specified exceptions, for the purpose of appointing a single medical officer of health, and also to make such regulations in connection with the duties, etc., of such officer as it might think fit. The insertion of this clause was naturally thought by those who have watched the policy of the Board in this matter, to indicate that, after two years of vacillation, it had at last arrived at a definite conviction as to the proper course to pursue in regard to these appointments; and that, after experimenting on the effects of cajoling such sanitary authorities as could be induced to combine to appoint a single medical officer of health, and of tolerating the determination of others to do nothing of the kind, the Board had resolved, on the strength of its experience of the working of these two arrangements respectively, to compel the adoption of the former of the two in all cases except those of towns of a certain degree of importance, in which there might be fairly supposed to be sufficient work to occupy more or less completely the time of a single medical man.

Under these circumstances, those who are interested in the maintenance of combined appointments, and in their being put upon a more satisfactory footing than that on which they at present rest, have been looking forward, since the passing of the Public Health Act last session, in the daily expectation of the issue by the Local Government Board of a memorandum to sanitary authorities and others concerned, explanatory of the course which the Board intends to pursue, and giving

the necessary information as to the conditions upon which combined appointments are to be in future held. Three months have now passed, and still the Government makes no sign. The disappointed expectants who are looking for its fiat can only conclude that, like the Baal of the Elisean period, it is otherwise occupied; that probably it is absorbed in the mind of its own daily routine; or possibly, if it be not heresy to hazard such a surmise, that it is asleep. At any rate, this would appear to have been the view entertained by the gentlemen holding combined appointments under the Public Health Act of 1872, who lately, we are informed, met in London to consider their position and prospects. It will be remembered that these appointments were limited to five years, apparently to give an opportunity of ascertaining how far the experiment would work successfully; and also to allow readjustment of the various districts, in case it should be found desirable to do so. As a matter of fact, the bulk of these appointments were made only for three years; many of them only for two; and some only for one. Of these latter, several have either collapsed altogether, or have undergone such an amount of disintegration, owing to the withdrawal of one or more members of the combination, as to seriously diminish the salary of the medical officer of health. In not one of these cases has the Local Government Board intervened, so far as we are aware, even to the extent of mildly inquiring, after the departmental fashion, on what grounds the seceding authorities had withdrawn from combination. Indeed, in some cases, the incidents which have occurred would seem to indicate that the Board had entirely forgotten the existence of the appointments, and had left both them and their holders to take care of themselves as they best could.

It is, therefore, scarcely surprising that the gentlemen in question, most of whom sacrificed previous connections of a more or less valuable kind, in order to take these appointments, and who did so on the faith that they would not be thrown overboard, unless good reason could be shown for so doing, should have been, as we are informed they were, very unanimous as to the unsatisfactory nature of their position, and as to the desirability of endeavouring to extract something like a declaration of policy from the President of the Local Government Board. In pursuance of this laudable intention, we believe that they waited on Mr. Selater-Booth, and, after stating their case to him with an amount of feeling and force which may be said, judging from the profusion of sympathy which he expressed for them, metaphorically, to have almost brought tears into his eyes (if the quondam Secretary of the Poor-law Board has not altogether abjured the luxury of weeping), must have been considerably surprised, and possibly not a little chagrined, to find that, although the President had plenty of sympathy to offer them, garnished with a few platitudes about the necessity of educating the public, including boards of guardians, to appreciate the importance of sanitary measures, he had not a word to say as to the action which the Board proposed to take in carrying out the powers for enforcing combination, which it had itself obtained. Like the needy knife-grinder of the *Anti-Jacobin*, he might have epitomised his remarks in the sententious formula, "Policy, God bless you, I have none to show, sirs!" We should scarcely have blamed these gentlemen if, in the excitement of their feelings, and ignoring the majesty of the presidential presence, they had forcibly asked Mr. Selater-Booth whether this was the outcome of the vaunted sanitary programme with which the present Government came into office; and whether a minister, whose courage appears to ooze out at his fingers' ends when the time for showing it arrives, is fit to be trusted with the administration of a great department like that of the Public Health. A more pitiable *fiasco* can, in our opinion, scarcely be imagined than for a public department like the Local Government Board, after committing itself to a definite course of action, by the course which it has taken in Parliament, to indicate, as it is doing, that it has no policy of any kind; and that it is quite satisfied, as our Yankee friends say, to let things slide. So long as the Board, or, rather, its subordinate officials, can make sanitary authorities believe that it is very active by writing fussy letters, and meddling, in an irritating way, with matters

of the most trifling importance, in which local authorities might be safely trusted to do as they like, it exhibits an alacrity which it is willing that the public should mistake for effective energy; but when it is called upon to show the courage of its opinions by the exercise of the large legal powers which it has now acquired, it exhibits a lack of intelligent policy and of courage which is gradually making it contemptible, and preparing it for a fate similar to that of its predecessor, the General Board of Health. The public, and especially rural sanitary authorities, are beginning to find out that King Log is not such a terrible personage as they fancied.

If evidence be needed in support of this opinion, and of the utter confusion which reigns at Gwydir House in regard to sanitary administration generally, it may be found in contrasting the results of the interview referred to above, between the medical officers of health to combined districts and the President of the Local Government Board, with the proceedings of one of the inspectors of the Board in North Wales, as reported in the *Liverpool Mercury* of the 12th instant. We are informed that "the proposal to combine all the sanitary authorities in Denbighshire and Flintshire for the appointment of one medical officer of health, at a salary of £800 a year, has met with a very unfavourable reception in the Wrexham Union. Mr. A. Doyle, the Government Inspector, waited on the Town Council on Wednesday; but they decided to wait for an official communication from the Local Government Board before coming to any resolution. Yesterday, Mr. Doyle had an interview with the Wrexham rural sanitary authority; and he intimated, as he had done to the Town Council, that, notwithstanding any adverse motion that might be carried, the Local Government Board would shortly issue a provisional order compelling them to join the combined district. Mr. Baugh, vice-chairman of the board of guardians, condemned the action of the inspector and the Local Government Board; and said that this was in reality a proposal to create patronage for the government. He moved a resolution to the effect that the scheme would be impracticable; that it would be a costly experiment that was neither wise nor beneficial; and that the authority would offer it their determined opposition. Mr. Bradley seconded the motion, which was carried unanimously." What are we to think of all this? Is it merely a case of mere *brutum fulmen*—an inspector brandishing his bottled thunder over the heads of an obstinate Welsh board? or is the Local Government Board really waking up to its responsibilities? Mr. Doyle's efforts in the way of sanitary organisation, however well meant, have not hitherto been very successful; and it remains to be seen whether his threats have more effect than his blandishments. Anyhow, whatever be the issue, it is evident that, if it should turn out that the Local Government Board has at last adopted a policy in this matter, and has resolved vigorously to enforce it, it has only done so at the eleventh hour; but we strongly suspect that it will be found that Mr. Doyle has exceeded his authority in threatening the North Welsh authorities with compulsory combination; and that, when his proceedings come to be reported at head-quarters, he will be greatly snubbed; and the stubborn Welshmen will be allowed to follow their own sweet will, in open rebellion against "all the queen's horses and all the queen's men".

THE Stockport magistrates on Saturday imposed the full penalty of £5 on a woman who had sold some of the clothing of a son who was suffering from small-pox. The result of the defendant's offence was, that several other persons were attacked by the disease.

THE Apothecaries' Company have sent in a claim to the Metropolitan Board of Works for compensation amounting to £14,000, for an alleged depreciation, by the continuation of the embankment, in the value of the land which they hold on trust at Chelsea for the purpose of growing herbs. Eventually, it is stated, this land reverts to Lord Cadogan. The Board have discussed and rejected a proposal to promote an Act for the purchase of the land with the view of extinguishing such claim. The claim, therefore, remains for settlement.

WE regret to hear that scarlatina is prevalent in some parts of the camp at Aldershot.

IN accordance with the text of a resolution passed at the last annual meeting of the British Medical Association, a circular has been this week posted to every member of the Association, "requesting an opinion—yes or no—as to the admission of female practitioners (of medicine) to membership" (of the Association). To the members in the country, 5,220 copies of such circular have been issued, and 1,010 to the members of the Association resident in the metropolitan district; those being the numbers of town and country members actually on the books of the Association, exclusive of members residing in the colonies and abroad.

IN the foregoing list, of course members of the Association only are included. It shows a remarkable numerical strength, and the metropolitan circulation appears to indicate that a majority of the members of the profession in the district are also members of the Association. It may be hoped that what is true of the metropolis and of some other great centres may gradually become equally true of every district in the country. An union so extensive and possessing so many autonomous local centres must always be an organisation productive of the most healthy influences, and capable of exercising great power on behalf of the profession which forms it, and of the great public objects which that profession has at heart.

INCIDENTALLY, we may mention also that the circulation of the BRITISH MEDICAL JOURNAL is maintained at 7,500 copies weekly—a circulation far beyond that which has ever been attained by any medical journal; and that there are continued evidences of the steady growth of these numbers, and the promise of further and considerable early accessions.

AT a quarterly meeting of the Trustees of the Hunterian Collection at the Royal College of Surgeons on Saturday last, the Right Hon. W. E. Gladstone, M.P., was unanimously elected a trustee, in the vacancy occasioned by the decease of Sir Charles Lyell, Bart.

THE *Indian Statesman* of September 24th, of which a copy has been forwarded to us, states that Misses Mitchell, White, and Beale, three young ladies at present studying for the lady-doctor's grade, will enter the Medical College for the ensuing winter sessions, and attend lectures with the other students on all subjects except anatomy and midwifery.

THE choice of a successor to the deanship of the Paris Faculty of Medicine seems to be a matter of some difficulty. The professors met on October 28th to decide whether M. Gavarret or M. Vulpian should be nominated to the Minister of Public Instruction in the place of M. Wurtz. In the meantime, they received a communication from the minister to request that they would appoint still another commission to consider a plan by which the School of Medicine should be governed by a dean and two vice-deans. It is proposed that one of the vice-deans should have the direction of the studies, and the other the general administration of business. M. Vulpian will probably be Dean, with two assessors.

LONDON FEVER HOSPITAL.

WE recently called attention to the accommodation provided in the London Fever Hospital for persons above the pauper class suffering from contagious fever. This institution received during last month sixty-three cases of scarlet fever, and, at the present time, all the private rooms are occupied. A few patients have been admitted into the general wards until private rooms become vacant, and there is no doubt these rooms will be constantly used as soon as their existence is more generally known. It is well to remind medical men of the fact that they need not lose sight of their patients on sending them into the private rooms, but can continue to treat them in consultation with the medical officers of the hospital.

CAPTAIN MONTAGU.

THERE is, we learn, every probability that the injury sustained by Captain Montagu, in whose accident much sympathy is felt, is happily not likely to be followed by loss of vision. Gun-shot wounds of the eye of this kind are commonly very serious; but there has been a combination of fortunate circumstances which promise an unusually favourable result. The shot appears to have passed through the upper eyelid on the outer side, and horizontally through the upper part of the eyeball without traversing the transparent cornea, and behind the iris. There is good reason to believe that it has not lodged in the eyeball. The pupil is regular; the eyesight good—wonderfully preserved, considering the nature of the accident. There is no pain nor sign of inflammation, and repair is going on most satisfactorily.

THE CONJOINT SCHEME.

DR. PHILIPSON and Dr. G. Y. Heath have been appointed by the University of Durham to represent that body at the conference of examining bodies to take again into consideration the formation of a conjoint board of examination for England.

THE SCHOOL BOARD AND INFECTIOUS DISEASE.

THE Leeds School Board now regularly issue a list of children absent from school who are suspected of suffering from disease. The list is very useful to the medical officer of health, to the School Board, and to the town at large; and the medical officer has great faith that, when he gets the necessary machinery at work, he will be able to produce good results by cutting down one fruitful source of scarlatinal epidemics. The same, of course, applies to other children's diseases of a preventable nature.

THE DISPOSAL OF THE DEAD BODIES OF INFANTS AT SOUTHAMPTON.

THE inquiry before the magistrates, after lasting three days, has resulted in the committal for trial of the undertaker Blundell, his wife, and an assistant named Petty, on a charge of larceny. On this part of the case, it would be alike improper to comment and uninteresting to medical readers; but we may note certain parts of the evidence which show a very unsatisfactory state of things in Southampton, and confirm much of what we remarked in the JOURNAL of the 30th ult. It is quite clear that several of these infants were in all probability still-born, while others had lived for periods varying from one day to thirty-one days; and yet it appears that the fee of three shillings for burial was demanded in all cases alike, which is quite contrary to the cemetery regulations. The expense of half-a-crown for a coffin and three shillings for cemetery-fees seems reasonable enough; but even this seems to have been considered a great tax, and one witness asked if it was necessary "to open the ground for a child so young" as thirty-one days. In what other way she proposed that the child should be buried, does not appear. From the medical evidence, it seems clear that some of the infants had been dead a long time, being reduced to mere skeletons; and, in at least one instance, portions of two bodies were found in one coffin; and the description of the cellar under the shop makes it too probable that some of the coffins had been concealed there for a long time. One of the magistrates expressed his astonishment (as he well might) that people could part with the bodies of infants nineteen and thirty-one days old, and never inquire afterwards whether they had been buried or not. One reason, doubtless, was to save the expense of conveyance to the cemetery; and we have already shown how this may be obviated. There appears to be a mortuary at Southampton, whither all these bodies were removed from Blundell's house; and nothing would be easier than to make it a resting-place for infants' bodies till an opportunity was afforded for removing them to the cemetery. Thus a great convenience would be ready to hand, without any sacrifice of decency or prejudice to health. Again, these witnesses all knew perfectly well that there was a pecuniary difference between still-births and children who had lived only one day. They considered it a hardship, and while it exists there will

always be unscrupulous persons ready to assist to remove these objectionable distinctions. We trust that the revelations made in this case will induce the Home Secretary to inquire into the whole subject of infant burial, which, as we have seen, is liable to a special abuse which does not obtain in the case of adults. We observe, from a statement made at the close of the case by the prosecuting solicitor, that "Blundell was liable to be charged with a common-law misdemeanour in having received certain bodies of children who had been baptised for Christian burial, and having undertaken, for a valuable consideration, to cause them to be buried in the ordinary way, and, instead of doing so, kept them concealed in his house, thereby enabling him to misappropriate the burial fees". We were not aware of this, and are glad that it is so.

EDINBURGH UNIVERSITY CLUB.

THE quarterly dinner of this club was held on Wednesday, the 10th instant, at St. James's Hall. Sir William Fergusson, Bart., LL.D., presided, and there was a large attendance of members and guests. Several new members were elected at the Council meeting held previously, and some new names were proposed for membership. The Honorary Treasurer, the Rev. Dr. Cozens Gordon, announced that the affairs of the club continued to be highly prosperous; but it was intimated, notwithstanding, that a considerable number of Edinburgh graduates, both in London and in the home counties, had not yet joined the club, probably from ignorance of its existence and of the advantages to be derived from membership.

THE COMPULSORY VACCINATION ACT.

MR. WILLIAM ABEL RYDER, a grocer in an extensive business at Bicester, was some days ago, at the Bicester Sessions, sentenced to seven days' imprisonment in Oxford Gaol, for refusing to have a child vaccinated, and declining to pay 20s. and 10s. costs. The defendant is known as a public speaker against vaccination. The magistrate sentenced him, instead of issuing a distress warrant for the amount.

THE ROYAL SOCIETY.

A ROYAL Medal has been awarded this year to Mr. William Crookes, F.R.S., for his various chemical and physical researches, more especially for his discovery of thallium, his investigation of its compounds, and determination of its atomic weight, and for his discovery of the repulsion referable to radiation. The other awards are: the Copley Medal to Professor A. W. Hofmann, F.R.S., for his numerous contributions to the science of chemistry, and especially for his researches on the derivatives of ammonia; a Royal Medal to Dr. Thomas Oldham, F.R.S., for his long and important services in the science of geology. It is hoped that Dr. Hofmann may be spared from Berlin for a few days, so as to receive the medal in person. The medals will be presented at the anniversary meeting of the Society on the 30th instant.

POISONING BY PATENT MEDICINES.

THE *Sheffield Daily Telegraph* records and comments intelligently on the most recent of these frequent cases. A child of a person named Scholey being troubled with a bad cough, the father went to one Mrs. Bancroft, who seems to have dealt in drugs, for a remedy. Mrs. Bancroft sold him what was called an "anodyne cordial", made up, it would appear, not by herself, but by some manufacturer of quack medicines. She could neither read nor write, and knew nothing of the composition of the cordial; while neither she nor the person who originally mixed the stuff gave or attached to the bottle any directions as to the quantity to be given. The father, not appreciating the deadly meaning of the word "anodyne", and supposing, it would seem, that he had purchased an ordinary "cordial"—that is, something rather of a stimulant than poisonous nature—gave the child a large dose: two tablespoonfuls. The result was fatal; and, on inquiry, it proved that the anodyne cordial contained a quantity of opium so considerable as to render it dangerous even if given to adults and in

smaller doses. "We cannot see," says the Sheffield paper, "that the father was seriously to blame. There is no reason to think that he had any idea of the peculiar meaning of a word which would convey a warning to educated men, but which the great majority of the lower and lower middle classes would regard as a mere titular prefix to the 'cordial'; nor was the dose, if the child seemed to be suffering much and the medicine was supposed to contain nothing of a poisonous nature, altogether and obviously excessive. But how came a woman like Mrs. Bancroft to be dealing in drugs? Who made up the cordial? If Mrs. Bancroft, why was she not committed for manslaughter? If not she, why was not the person who sold such a drug otherwise than in bottles labelled 'Poison' in red letters, and marked with the quantity to be taken, sought out and brought before the coroner's court? Is it possible to hold that poison may be sold in such fashion, and no one be answerable if death occur? We can hardly think so. At any rate, it is the duty of the Home Office to have the case fully investigated, to ascertain whether the utterly unsatisfactory result of the inquest be due to the perversity of the jury, the carelessness of the coroner, or the defect of the law; and, if the last be not the cause, to bring the vendor or vendors of the drug to justice."

MORTUARIES IN THE METROPOLIS.

THE motion of Dr. Rogers for the appointment of a deputation to wait upon the President of the Local Government Board, regarding the establishment of mortuaries in the metropolis, was carried at the Strand Board of Works on Wednesday last.

ARSENIC IN LADIES' DRESSES.

AT the meeting of the Marylebone Vestry last week, a report was presented from Dr. Whitmore, medical officer of health and analyst to the parish, which stated that he had recently analysed the colouring matter contained in four pieces of tarlatan. Two of the pieces were of a bright green colour, the other two of a pale or apple green. Those of the bright green colour contained arsenic in considerable quantities; one of the pale green colour contained a minute trace of it; but in the other, none could be detected. He had been induced to make these analyses from its having been reported to him that two young ladies had suffered from symptoms of arsenical poisoning in consequence of having worn dresses of this description at an evening party; and he proposed to make further analyses of a similar kind, the results of which he would give from time to time. Dr. Whitmore said that, perhaps, he had gone a little beyond his functions in this matter, but hoped his action would be approved. He had applied what was known as Marsh's test to the pieces of tarlatan; and he thought the result was of sufficient importance to put in the report. The report was approved.

HASTINGS AND ST. LEONARD'S INFIRMARY.

AN important meeting of the governors of this institution was held recently to consider the question whether it was advisable to enlarge the Infirmary upon its present site, or to build a new and larger hospital elsewhere. From the report of the medical officers, it seems evident that more accommodation is needed; and that it would be impossible adequately to provide this by any enlargement of the existing institution, the space at command being very limited. After a good deal of discussion, it was agreed that the proposal to enlarge the present building was unsatisfactory, and must be abandoned. The difficulty that is now felt is to secure an appropriate site. We trust that this difficulty may speedily be overcome. There can be no doubt that, in a flourishing borough such as Hastings and St. Leonard's, which has trebled its population in the last thirty years, the hospital accommodation which was considered necessary in 1840 cannot now be sufficient. There is, therefore, need of an increased number of beds. But besides this, the general arrangements of the present hospital are very deficient; and there is a want of better accommodation in various departments. This reconstruction is demanded, not, as was urged at the meeting, in order to make the Infirmary a place of medical education, which is out of the question in a town of only 32,000 inhabitants, but in order that the

medical officers may be able to carry on their work in a thoroughly scientific manner, and that the nursing of the hospital and its sanitary appliances may be altogether satisfactory.

PROVINCIAL MEDICAL SCHOOLS.

DR. ARTHUR GAMGEE and another correspondent call our attention to a misconception which the return of the Government Inspector of Anatomy, quoted at page 596 of our issue of November 6th, is likely to create as to the actual number of gentlemen pursuing their professional studies at the recognised provincial hospitals. It appears that Dr. J. W. Ogle, inspector of the anatomical schools in connection with those hospitals, receives the names of those students only who are occupied in the study of practical anatomy and dissections during the session to which his return refers, to the exclusion of a considerable number of students who, although not dissecting, are in actual attendance upon lectures and other departments of medical study at those schools; for example, the number of students in actual attendance on lectures at the Liverpool Infirmary during the present session is 105, whereas Dr. Ogle's return gives only 63; and at Manchester, the actual number of students is 152, while, according to Dr. Ogle's return, it is only 119. It is probable that a similar discrepancy would be found between Dr. Ogle's returns and the registers in the six other schools; and therefore this official return, however correct it may be, and no doubt is, so far as the anatomical department is concerned, cannot be accepted as an accurate estimate of the number of gentlemen actually pursuing their professional studies at the eight recognised provincial hospitals. Efforts so great and so highly successful have been made at the Owens College and other provincial schools to provide a highly efficient apparatus of teaching and means of study, that it is particularly satisfactory to learn that their material progress is greater than the official report would lead one to suppose.

ALLEGED EXTRAORDINARY TREATMENT AT KING'S COLLEGE HOSPITAL.

SUNDRY reports of an inquest opened last week by Dr. Hardwicke, and which contained statements reflecting upon the medical authorities of King's College Hospital, having appeared in some of the daily papers, we have been at some pains to collect the following accurate account of the evidence given before Dr. Hardwicke at the adjourned inquest on Wednesday last. A single woman, Mary Jane Bull, aged 31, had been living at Leighton Buzzard, where she had been ailing since April last. Acting on medical advice, she entered King's College Hospital as an in-patient under Sir William Fergusson on October 27th, and was then suffering from incontinence of urine, but had not apparently a serious disease. The patient, according to the mother's statement, complained that she did not once see Sir W. Fergusson, and that the treatment to which she had been subjected was killing her. Sir W. Fergusson did, however, see the patient on the day following admission; and said that he had received a letter from Mr. Wagstaff of Leighton Buzzard, and that the patient was a highly nervous woman. She was sounded for stone in the bladder, but none was discovered. The urine was also drawn off by a catheter, examined, and found not to contain albumen. Her temperature was normal; and she had no physical signs of disease of the heart or lungs. Cold douches once a day were then prescribed for her, and were carried out in the following manner. The patient was seated before the fire in a bath, and water was poured down her back through a colander, to the extent of four small cansful on the first morning, and of two cansful only on subsequent mornings. She was then dried with a warm towel and put to bed, where hot bottles were applied to her feet. The whole process occupied only a minute or two. She only complained once to the house-surgeons (Mr. James K. Fowler and Mr. J. B. Footner) of the treatment; and on November 4th, contrary to the latter gentleman's advice, she was removed to her mother's home near the Regent's Park. She was able to walk out of the hospital at about 5 P.M.; and died eight hours afterwards. It was not known in the hospital that she had

kidney-disease. Mr. Willoughby Davis was called to the patient shortly after her arrival at her mother's, and found her suffering from dyspnoea, and sinking. He discovered no physical sign of disease of the chest during life. She died a few hours afterwards. After death, he found the brain natural, the upper half of the upper lobe of each lung consolidated with tubercular deposit, and congestion of the other parts of the lungs, with old pleuritic adhesions. The heart was thin, otherwise healthy. He had not examined the pulmonary artery for a clot. The stomach was empty. The liver was natural. The kidneys were large and diseased; in the left one was a large abscess; in the right kidney were ten small abscesses, of the size of Spanish nuts. The uterus was in a state of scirrhus. The cause of death, in his opinion, was exhaustion whilst suffering from tubercular disease of the lungs and kidneys. Dr. Davis is further reported in the *Times* to have said that "under proper treatment the deceased might have lived for months. He should say that cold water applied as stated could not be proper treatment, but whether it accelerated death he would not say." The verdict was "that the deceased died from tubercular disease of the lungs and disease of the kidneys, and that the death of the deceased was accelerated by her removal from King's College Hospital by her friends".

PHYSIOLOGICAL DEMONSTRATORSHIP AT UNIVERSITY COLLEGE.

MR. WILLIAM MURRELL has been appointed Demonstrator of Physiology ("Sharpey Physiological Scholar"). The value of the appointment is about £90 a year; and the conditions under which it is held may be of interest to other schools where such appointments are contemplated. There are many, we think, in which they would be useful.

"5. During his tenure of office, the 'Sharpey Physiological Scholar' shall have duties assigned to him in the physiological laboratory of University College. He shall, subject to leave of absence in the vacations to be granted by the Faculty of Medicine, render services in the physiological laboratory, under the guidance and control of the Professor of Practical Physiology; he shall assist during both the winter and the summer sessions in the teaching of the students in the class of Practical Physiology; he shall then, or at other times, if required, aid the Professors of Systematic and Practical Physiology in the conduct of physiological inquiries; and, lastly, he shall be encouraged and have facilities afforded him in carrying on original investigations in anatomy, histology, or physiology, on his own account; but the undertaking of such researches need not form an essential condition of his holding the scholarship.

"6. The usual appointment to the scholarship shall be for three years; but within three months of the termination of a given scholar's tenure of office, the Council, upon a report from the Faculty of Medicine that they have reason to believe that such a course would conduce to the interests of the School, may continue the existing holder of the scholarship in office for a second period, not exceeding three years, instead of proceeding to a new election.

"7. The payments to the Sharpey Scholar shall be half-yearly; and, in the event of a vacancy occurring by resignation, removal, or death, the stipend shall be apportioned up to the date of such vacancy.

"8. The Sharpey Scholar shall be considered a teacher within the meaning of the bye-laws of the College, and may be removed in the manner prescribed by those bye-laws."

MANSLAUGHTER BY NEGLIGENCE.

THE case of the man Downes, a member of the Peculiar People, who was convicted some time ago of manslaughter for not providing medical assistance for his infant child, who died from inflammation of the lungs, but might, it was asserted, have recovered had such assistance been rendered, came on for decision in the Court for the Consideration of Crown Cases Reserved on Saturday, to which it had been remitted by Mr. Justice Blackburn in consequence of a conflict of judicial opinion in similar cases. In the course of the argument on Saturday, it was stated that a recent statute has been passed (31 and 32 Vict., cap. 122, s. 37) by which it is made a punishable offence if any parent shall "wilfully neglect to provide adequate food, clothing, medical aid, or lodging, for his child, being in his custody under the age of fourteen years, whereby the health of such child shall have been, or

shall be likely to be, seriously injured". This statute was passed after the case referred to was tried before Mr. Justice Willes, and appeared not to have been brought to the notice of Baron Pigott or Mr. Justice Blackburn. On the strength of it, the Court now affirmed the conviction. Lord Coleridge, in giving judgment, said it was clear that where the death of a person resulted from another person's neglect or breach of duty, that person was guilty of manslaughter. Here was a duty imposed by Act of Parliament deliberately and intentionally not fulfilled, and the death of another thereby caused. Such a state of facts brought the case within the true definition of manslaughter, and the conviction must be affirmed. Baron Bramwell, Mr. Justice Mellor, Mr. Justice Grove, and Baron Pollock, the other judges, concurred; Baron Bramwell observing that the jury had found that the man thought that to fulfil the duty imposed by statute was wrong. The law, however, did not excuse a man on that account. It was well that this should be known.

UNIVERSAL STANDARD OF MEASUREMENT.

DR. BURNETT writes from Utrecht to the *Philadelphia Reporter*:-

"The scientific world has long felt the need of an universal standard of measurement. In ophthalmology, the employment of the inches of the different countries to designate the focal distance of glasses, and to mark the degree of ametropia, has always been confusing. A number of efforts have been made to adopt the metrical system, and to so number the glasses as to make the series more regular in graduation than the one now in use, but they have all failed until now. At the last congress, it was decided that at this present meeting the matter should be settled; and, after the 12th of September, all measurements are to be taken after the metrical system, and the glasses are to be numbered according to a scale, a copy of which Dr. Snellen kindly gave me. The unit of measurement is the metre, and the glass of one metre focal distance (negative or positive) is to be numbered 1. This corresponds to 37 Paris inches. The lowest number is 0.25, corresponding to 4 metres and 148 Paris inches. The next is 0.5 = 2 metres and 74 Paris inches; then 0.75 = 1.333 metres and 49 Paris inches; then number 1 = 1 metre. The highest number is 20 = 0.050 metres and 11 1/5 Paris inches. These trial-glasses are not yet obtainable, but will be after the meeting of the congress. Dr. Snellen also showed me the proofs of the new edition of his book of test-types, which he is now getting out to correspond to this new standard of measurement. The large test-types known as his, for testing distant vision, he has also modified. The size of some of the numbers, notably the old 100, which has been considerably increased in magnitude, has been changed, and made more gradually diminishing in size from the largest. The largest, formerly called 200, is now numbered 60, and should be seen distinctly, by a normal eye, at 60 metres. The smallest, the old 20, is now numbered 6, and should be clearly distinguished at a distance of 6 metres. The great importance of the adoption of this universal standard of measurement is apparent; and as ophthalmology, I think, is the first branch of science, at least of medical science, to adopt such a standard, it has an additional claim to be considered the most progressive department of medicine."

VENESESECTION AS A HABIT.

AN extraordinary case of habitual venesection is reported by Dr. E. Warren Sawyer in the *Chicago Medical Journal* for September 1875. The subject of the narrative is a retired clergyman, aged 80. His firm step and keen intellect show an unusual degree of preservation for his advanced years. He is a farmer's son; and, during his entire life, has been unusually free from sickness. When seventeen years old, according to the custom of the period, and not for ill-health, he was bled for the first time. This habit of spring bleeding was followed for the next six years. He then became a student; and the change from active farm work to a sedentary life caused a constant feeling of heaviness, to relieve which he resorted oftener to the lancet; and, during the next ten years, he was bled from four to six times a year, always losing from ten to fifteen ounces of blood. The frequency of the venesections increased; and, for the past forty years, the patient has suffered the loss of eight or ten ounces of blood regularly every three weeks. He declares that he is always made better by bleeding; that letting a half-bowl of blood acts as a stimulant, and has never been detrimental to his health. Until he retired from the pulpit, ten yea

ago, he was a hard-working minister, and he is still capable of work. For the past nine months, this man has been under Dr. Sawyer's care, who has every three weeks bled him to the extent of from eight to ten ounces. The demand for blood-letting is shown by a dyspnoea, which obliges the patient to spend the night in his chair, just before his bleeding day. His lips and finger-nails become purple. Bleeding at once relieves the dyspnoea, and the natural colour is restored to the lips and fingers; the man's spirits become lighter, he grows talkative, his voice is no longer husky, and he seems in every respect better. Repeated auscultatory examinations of the heart and lungs have failed to discover any organic disease of the former, and but slight evidence of vesicular dilatation of the latter. The blood-making function of the body has always been active, and there has never been a demand for a peculiar diet; and the frequent and large losses of blood have never seemed to be hurtful or debilitating. The history shows that, for a time, the bleedings were not actually demanded; but for many years past, in the opinion of Dr. Sawyer, it would have been detrimental, and perhaps attended with a fatal result, to attempt a reformation of the habit.

THE WILL AS A THERAPEUTIC MEANS.

M. JOLLY has lately read a paper to the Paris Académie des Sciences, which has attracted a considerable amount of attention in the medical world of Paris. The subject of the paper is, "The Will considered as a Moral Power and a Therapeutic Means". The passages more specially relating to the latter branch of the subject are reproduced below. Speaking of the power of the will in preventing attacks of cough, M. Jolly said: It is possible to struggle more or less successfully against fits of coughing; a fact not only to be noted as a result of the power of the will, but as a remedy which, in many cases, cannot be without importance. Cough may, indeed, be only a vicious habit, without any need of expectoration or specific lesion; becoming of itself and by itself an incessant cause of coughing, to which, for that reason, it is important to put a stop. "Coughing", says Montaigne, "creates coughing; a man who coughs, makes me cough"; and the will alone, and especially the will helped by sensations which distract the attention, or muscular actions capable of diverting it, is the most certain means of curing the cough. It is often seen that, when children suffering from whooping-cough are thoroughly preoccupied with their play, they remain for hours together without feeling the necessity of coughing, whilst they have constant paroxysms when in a state of repose, or are incessantly awakened out of their sleep by the same cause; and M. Jolly states that he has not been surprised to learn that English medical men have been able to cure whooping-cough by distracting the attention, and in some cases by placing the patients near the noise of manufactories. Asthma, properly so called, has likewise undergone the salutary influence of a wisely applied will; whether in surmounting, by forced respiration, the spasm of the bronchial tubes which have become inaccessible to the air, or by diverting by preoccupation, the morbid exercise of the innervation appropriated to their exercise. It is to attain this double end that Laennec recommended certain invalids to read aloud, so as to prolong expiration, and to make inspiration more complete. As a means of distraction, he also recommended the exercise of the senses, even in the course of the night, when the fits seemed, as is frequently observed, to follow the nyctohemeral revolution. On this subject, M. Jolly relates a curious history of a patient who arrested his paroxysms at will by lighting a candle and distracting his mind by inspecting the furniture of his bedroom. It is more difficult to conceive that the will can master attacks of epilepsy; and yet the fact is not unexampled. M. Jolly relates that he saw, in 1827, in the St. Louis Hospital, a man who had suffered for years from this disease, and who could at will throw off his attacks. It was enough for him, to the great astonishment of the pupils who witnessed the fact, to make the muscular apparatus of mastication and deglutition undergo voluntary exercise, by introducing solid food into his mouth as soon as he had a premonition of the return of the paroxysms. A fact well worthy of remark, and of the careful attention of the physician, is that the

will, of which the power is, so to say, incalculable over movements of contraction, remains powerless with regard to movements tending to muscular relaxation. Every one who draws himself up under the dread of pain, remains under the influence of the instinctive power of contraction, notwithstanding the efforts of will which he exercises to overcome it. People inadvertently swallow a fruit-stone, or some smaller or larger body; and yet sometimes the deglutition of a very small dose—nay, of a simple granule of medicine—can scarcely be accomplished by the firmest will; and there is reason to believe that the hydrophobia exhibited by certain nervous women, is frequently occasioned by nothing else than the struggle which goes on between fear and the will to swallow. Other examples show that it is vainly sought to obtain relaxation of the muscles of the abdomen from a patient when it is desired to examine that region; all his efforts of will only increase the contraction he endeavours to master, when the slightest distraction of the will suffices to put a stop to it. The same thing occurs with the patient, when it is desired to reduce a fracture. The more we endeavour to obtain muscular relaxation, the more the state of contraction which forms an obstacle to the reduction of the fracture increases; if then, by any physical or moral cause, any distraction of the will come on, all the muscles become relaxed, and the reduction is performed as though by magic. We also know that sleep, which consists in the relaxation of the muscular powers, must be freed from the influence of the will. If we strive to obtain the boon of sleep, we infallibly drive it away, and voluntarily deliver ourselves up to insomnia.

SCOTLAND.

MR. W. E. FORSTER has been elected Lord Rector of the University of Aberdeen. The votes were:—For Mr. Forster, 378; for Lord Lindsay, 145.

ROYAL MEDICAL SOCIETY OF EDINBURGH.

THE session of the Royal Medical Society of Edinburgh was opened on the 12th ult., when an interesting address was delivered by Mr. Annandale. The subject was reminiscences of the Edinburgh Medical School for the last eighteen years; and the speaker dwelt on the changes that had taken place since he first became a medical student, not only in the methods and extent of medical and surgical teaching, but in the *personnel* of the teachers and professors. He described the appearance and character of some of those who have been lost to us in the interval, and estimated the causes which led to their success. The address was enlivened by many interesting and amusing anecdotes. There was a large attendance of students, and we are glad to learn that more new members were proposed on the first night than has been the case for many years past. The Royal Medical Society is one of the most important auxiliaries to medical study in Edinburgh, and is taken advantage of by all those who wish to make the most of their opportunities as students of this school.

THE EDINBURGH MEDICAL SOCIETIES.

THE Medical Societies of Edinburgh have again begun work. The Medico-Chirurgical met on Wednesday, the 10th ult., at which an able paper on the Natural History and Treatment of Nævus was read by Dr. John Duncan; and two papers, on Jaborandi, and Chloral, its External Uses, by Dr. Craig. The Obstetrical held its first meeting on the 17th, when Dr. Keiller and Professor Simpson read papers; the former, on Congenital Malformation; the latter, on Sarcoma Uteri.

EPIDEMIC ON BOARD THE "MARS".

SOME time ago, two cases of scarlet fever broke out on board the *Mars* training-ship, now in the Tay; and, notwithstanding the precautions taken, the disease spread rapidly among the boys, and, by the 9th current, twenty two boys were ill and two had died. Under these circumstances, the rest of the boys, nearly three hundred in number, were removed, some to the care of their own friends, and others on

board the tender *Lightning*. The committee of the *Mars* applied for the use of the Dundee Fever Hospital, which was then empty, to accommodate one hundred of the boys; and this application the directors at once acceded to. It is suspected that the water used on board the *Mars* was unwholesome, and the subject is undergoing strict investigation. There have been no more cases up to Monday last; that is to say, for nearly a week. One hundred and thirty boys still left on the *Mars*, are quite well; nineteen at the Dundee Infirmary are convalescent.

THE COCA LEAF.

IN an introductory address to the Edinburgh Botanical Society, Sir Robert Christison, its President, related some experiments he had been making with a view to test the "coca leaf", which, he explained, was not to be confounded with the well known cocoa. In Peru, where it grows, coca is reported to have remarkable nourishing properties; and, in order to ascertain the precise nature of these, he chewed the leaf by way of stimulant on the occasion of two ascents of Ben Voirlich. On reaching the top, he felt greatly fatigued, and began to chew his coca; with the result, that he was able to make the descent, not only with firmness but with almost juvenile elasticity. He further stated, that by its use he had found himself able to walk sixteen miles with ease, although when he attempted this feat without such nourishment he felt greatly fatigued.

WATER-SUPPLY OF ELGIN.

AT a special meeting of the Elgin Water Company, held on November 12th, it was agreed that an additional supply of water should be brought into the town, and that the company should be incorporated by Act of Parliament. The Secretary stated, that he had accepted an offer of lease of Foths Wardend and Bardonsburn Wells, Birnie. He also read reports showing the daily supply which each of them would yield, and an analysis by Dr. Macadam of Edinburgh.

IRELAND.

THE first meeting for the present Session of the Medical Society of the College of Physicians was held on the 10th instant, the inaugural address being given by Dr. Gordon, President.

THE first meeting of the Dublin Pathological Society will be held on Saturday, November 27th, when the council and officers for the ensuing year will be elected.

It is now generally understood that Dr. Kidd will be elected to the office of Vice-President of the Irish College of Surgeons, vacant by the death of Mr. John Hamilton. The election will take place on Monday next, the 21st instant.

THE Surgeoncy to St. Patrick's (Swift's) Hospital for the Insane, which is of the nature of a consultant surgeoncy, is sought for by Mr. William Ellis and Mr. Thornley Stoker. Other candidates are in the field. We understand that Mr. Ellis will probably succeed to the office.

THE annual meeting of the Dublin Obstetrical Society will be held this evening (Saturday) at the College of Physicians, at which the officers for the ensuing year will be elected, and the President, Dr. Athill, will deliver the annual address.

DUBLIN HOSPITAL SUNDAY FUND.

THE second annual collection took place last Sunday, and we are afraid that the tempestuous and rainy weather on that day prevented many people from attending any place of worship, so that most probably the sum received from the various congregations will not equal that of last year. The returns from all the churches have not yet been

published, and, therefore, we cannot state at present the general result. In St. Patrick's Cathedral, the sermon was preached by Archdeacon Reichel, who very properly remarked that the whole of Ireland was interested in the maintenance of the Dublin hospitals, which should be regarded as great teaching institutions, where students of medicine, who were afterwards to practise throughout the country, received the education and training necessary for the discharge of their arduous and responsible duties.

THE SURGEON TO THE QUEEN IN IRELAND.

MR. WILLIAM COLLES, Regius Professor of Surgery in the University of Dublin, and Surgeon to Dr. Steevens's Hospital, has been appointed Surgeon in Ordinary to Her Majesty in Ireland. The appointment has caused universal satisfaction in Dublin.

CORK OPHTHALMIC AND AURAL HOSPITAL.

THE report of the institution, read at the late annual meeting, shows that 200 in-patients and 1,740 out-patients have received the benefit of ophthalmic treatment during the past year. Nearly 200 operations have been performed, and 197 cases discharged cured. The economy with which the hospital is conducted is proved by the fact that the total expenditure of the year is set down as £212. The speakers at the meeting awarded a just meed of praise to the medical officers of the hospital, especially to Dr. Macnaughton Jones, for their disinterested efforts in bringing it up to its present state of efficiency and usefulness.

DUTIES OF REGISTRARS.

THE following case, which came before the Court of Exchequer in Dublin, on November 8th, has raised an interesting question with regard to the duties of registrars of births and deaths in Ireland. If the decision be against the defendant, we think many of our brethren who are dispensary medical officers, and therefore registrars, may look out for more dangers in their perilous and unprofitable occupations.

"Byrne v. Halpin.—Mr. John Gibson applied in this case for leave to plead several defences. The plaintiff brings the action against the defendant, who is a registrar of births, deaths, and marriages, to recover damages for alleged libel—namely, for having entered him in the register-book as the putative father of an illegitimate child, and subsequently supplied a certified copy of the entry to a third party. The defendant sought to plead a traverse of the writing and publishing; a traverse of the innuendos; and a plea of no libel. His defence substantially was that, as registrar of births, deaths, and marriages, he was bound by Act of Parliament to make inquiries into the birth of the child in question, and to enter the particulars according to the form of his book, which should contain the name of the father and mother; that he received the particulars from the mother of the girl, who lived in the house with her. As to having supplied the certified copies, he pleaded that under the Act of Parliament he was bound to grant a copy of the entry in the registrar's book on the payment of a fee, and he claimed the matter to be privileged if he believed it true. Baron Dowse said he thought it was a very fair case to raise the point, but he believed they would hear a great deal more about it. Mr. Gibson said, from the fact that the plaint was signed by one of the most eminent counsel at the bar, he believed the learned gentleman must have been inclined to think that a good action would lie. The motion was granted."

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—The second meeting of the session was held at the Royal Kent Dispensary, Greenwich Road, on Friday, November 5th; Dr. J. N. Miller, President, in the chair. Dr. J. Braxton Hicks brought forward some cases illustrating the efficacy of large doses of quinine in some cases of puerperal fever. The next meeting will be held on Friday, December 3rd, at 3 P.M. precisely, when Dr. Tilbury Fox will read a paper.

CIVIC GIFTS TO HOSPITALS.—An annual subscription of £5 5s. has been voted by the Worshipful Company of Clothworkers, two donations of £21 by the Worshipful Company of Fishmongers and the Worshipful Company of Drapers, and a donation of £15 15s. by the Worshipful Company of Girdlers, to the City Orthopaedic Hospital. The Drapers' Company have voted an additional donation of £21, and the Clothworkers' Company an annual subscription of £10 10s., in aid of the Royal National Hospital for Consumption at Ventnor.

CHOLERA IN THE ROUTE OF THE PRINCE OF WALES.

WE have received letters and telegrams of considerable interest from India relative to the medical conduct of the Prince's tour in India, which has been so unfortunately affected by the prevalence of cholera in certain districts which formed part of the contemplated route. It may be well to premise that Dr. Fayer, the medical attendant of the Prince during his tour, stipulated, on accepting that honourable but highly responsible charge, that he was to be left absolutely free as to the ultimate decision of the route which should be adopted. Intimately acquainted with the country and its medical history, he foresaw the probability of what has now occurred.

It will be in the recollection of our readers that it was intended the Prince of Wales should disembark at Bepore for his tour in Southern India. From thence the route was to the base of the Annamally Hills, abounding in large game, and where arrangements were made to give His Royal Highness some days of sport as yet new to him and his party. Leaving the Annamally Hills, the next points were Coonore and Ootacamund, the well known hill sanitaria stations on the Neigherry, or "blue mountain" range, where His Royal Highness would find a climate equal to the best in the south of Europe. Some days were to have been spent there; and thence the royal progress was to Mysore, and to Bangalore, the head-quarter station of the troops of that quasi-independent state, and, as regards climate, the most coveted station in all India. One night by rail would bring His Royal Highness to Madras, whence the tour in Southern India would end. Unfortunately, cholera prevails along the whole line indicated above, some cases having even been reported from Coonoor, probably imported from the plains.

For two years, Southern India had enjoyed an almost complete immunity from the disease, not a case having been brought to the General Hospital at Madras in that time; although in 1818, and on several subsequent epidemics, Coimbatour has been gravely affected by cholera from the end of November to January. For the first time in living memory, cholera has invaded the South of India from Ceylon; its usual course being along the great epidemic highway, from its "endemic area" in lower Bengal—that is, from east to west, and then from north to south, until the extremity of the continent is reached; from thence it has almost invariably invaded Ceylon. On this occasion, the disease appeared in Ceylon, the recrudescence of some former epidemic; and was carried by some coolies to Tutticorin, from whence it has spread all over Southern India, in no place showing itself in anything worthy the name of an epidemic; rather, at the various places named, in the shape of a number of "dropping cases", but quite enough to make it inexpedient to expose the life of the heir apparent to the risk of so dangerous a disease.

Dr. Fayer has had to take into consideration the fact, which a wide Indian experience has shown, that new comers into a locality that has been or is under the influence of the disease, are peculiarly liable to an attack of cholera. Again, wherever the Prince is, there will necessarily be a large camp; and the denser the mass of people collected together, the greater the danger of an outburst of cholera during a period of epidemic predisposition. The Madras Government having been unable to give positive information that the proposed route was free from the disease—but, on the contrary, being compelled to furnish advices of the contrary character—Dr. Fayer's duty has been clear. Much disappointment must be felt by persons expecting to see the Prince, that he do not visit them; but considerations of this kind will, of course, not be allowed to stand in the way of duty, which requires clearly that the Prince should be kept from unnecessary exposure to the influences of this dire disease. There is reason to be thankful that the Prince is in the hands of a physician highly experienced in India and in Indian diseases: a man of calm clear judgment, able to form his own opinion as to the correct course to be followed, and of unalterable firmness in carrying out what he has ascertained to be right and proper.—Our latest written despatches are dated from the *Serapis*, October 30th; and from Aden, October 31st. Writing, first, from the hottest part of the Red Sea, thermometer 80 degs. in the cabins, 120 to 126 degs. in the sun, they report "all well"; they add: "The medical world will be glad to know that His Royal Highness the Prince of Wales is in excellent health; he is thoroughly enjoying the voyage, and is in high spirits. It is certainly rather warm and stuffy, and the air is laden with moisture; but we feel very slight inconvenience from the heat, the ship is so well ventilated, and all means of insuring comfort attended to. It is very satisfactory to know that His Royal Highness has borne the

test of the Red Sea so well. He will have no greater heat to encounter; and there is every reason to hope that he will derive benefit as well as pleasure from the voyage. All the suite and servants are well. It is the same with the officers and crew of the *Serapis*; so that, on the whole, our voyage so far has been most propitious."

COMMUNICABILITY OF FOOT-AND-MOUTH DISEASE TO THE HUMAN SUBJECT.

AN able correspondent in Scotland sends us the following.

During the autumn months, while residing in Morayshire, business and pleasure combined brought me a good deal into contact with the foot-and-mouth disease. The dry statistics hitherto associated in my mind with the disease gradually gave place to a more lively interest as my knowledge of facts increased. The contagion was so subtle that a constant excitement was kept up as to where it would break out next; and, unlike other eruptive fevers, one attack brought no immunity for the future. Hares, rabbits, and all such freeholders of the soil, could deposit the germs of the disease in their midnight depredations; and the wind was supposed to carry it for "two miles".

Each day brought news of fresh outbreaks; until I found my little farm standing alone, like a citadel closely invested by the enemy foot-and-mouth disease. Such being the condition of affairs, I began to remark the prevalence among my neighbours of tied-up heads; and, upon inquiry, was told they were suffering from "an epidemic of festered mouths". Again, in a more distant farm, I found a similar state of things existing simultaneously with the disease among the cattle.

I now began to pursue my investigations in this direction; and found that the country people were so accustomed to the fact that human beings could be more or less affected by the foot-and-mouth disease, that the suggestion never raised a smile. They all seemed to know a laddie or a lassie who had suffered from bringing a cut finger into contact with the sore teats, or with dung; or a bairn who had drunk the milk, and got a festered mouth. Not only had the matter come under their own observation, but they had read in the local papers accounts of people being affected by the disease. I was amused myself one day to read an account of the outbreak of the foot-and-mouth disease among the human animals of an infected farm in England, the writer indignantly refusing to believe that two opinions on the subject could exist.

My next step was to inquire of the leading medical practitioner of the place if he had seen any cases; and, while he expressed much scepticism, he nevertheless admitted that he was then attending a farmer's child whose illness he could account for in no other way. The child, hitherto perfectly healthy, had been drinking the fevered milk; and had also been carried about in the arms of its father, whose attentions were divided between his cattle and his child. The doctor described his patient's mouth as blistered and very sore. A personal friend, whose child, eighteen months old, was chiefly subsisting on a milk-diet, writes to me that the doctor whom she consulted had no hesitation in attributing the cause of her child's illness to the foot-and-mouth disease then prevailing in the farm whence she got the milk. "The toes and fingers were covered with blisters, and also her mouth, which was dreadfully sore. It was most obstinate, and many weeks elapsed before she was cured." Up to that period, the child had been, like my former case, perfectly healthy, and has been so ever since her recovery.

A lady of my acquaintance who suffered, two years ago, from drinking the typhoid milk in the celebrated Marylebone epidemic, gave me an account of a visit she paid lately to the sick bed of a farmer's wife, when she was prevailed upon to drink a tumbler of milk to escape from the more potent and customary beverage of the country. Shortly after this, she began to suffer from a most painful fester in the mouth, between the lower lip and gum, accompanied by a severe spasm, which loosened her teeth by seeming to extract them downwards. On visiting the same farm a fortnight later, she was told that all the cows were suffering from foot-and-mouth disease; but were for the most part recovered, only two being now ill. She asked leave to inspect the mouth of one of those at present suffering; and was not a little astonished to recognise, although in an aggravated degree, an affection of the mouth similar to her own. She added to her statement her private conviction that she alone was capable of interpreting the real sufferings of the animals in that unsuspected spasm. It is natural to suppose that the deleterious effects of the milk would correspond more or less with the intensity of the disease in the cow at the time of fever.

A farmer living near Carron, lost his whole litter of pigs by giving

them the diseased milk to drink. A test of the dangerous periods being over, I am told, is to boil the milk; and, when it no longer curdles, it is considered safe.

A great difficulty with which the farmers have to deal is the rearing of the young calf during the fever of the mother. It is generally removed into safer quarters, and kept alive upon linseed meal and beaten-up eggs; while the cow, like Rachel, is left to weep for her young. The milk does not forsake her, but first assumes a yellowish appearance, then becomes poor and thin as convalescence sets in. If the disease attack the cow at a certain stage of her pregnancy, she either miscarries, or goes on to maturity and brings forth a dead calf. At such seasons, the farmer is in great anxiety for the safety of the animal; and is very thankful when three or four days elapse without the appearance of the fatal "red water", indicating septicaemia. Under these circumstances, recovery is very slow, the emaciation is pitiful, and she does not bear a calf the succeeding year.

Considering the enormous losses that ensue from the orders of the Privy Council to destroy the entire herd of imported cattle if one alone shows symptoms of the disease on landing, and the losses arising within the area of the home farm, it is surprising that more enlightened measures are not adopted for the preservation of life and limiting the spread of infection. Quarantine on the one hand, and the enforcement of sanitary rules on the other, would do much towards attaining both ends. Beyond orders to report the outbreak of the disease, and a few magisterial penalties for various omissions, the farmer is practically left to himself, which is the worst thing, with all his contending interests, to which he could be left. His first instinct is to keep the fact of the outbreak quiet so far as his neighbours are concerned; he allows his diseased animals to graze in their accustomed field, rubbing noses with their friends in the adjoining meadow, and leaving a legacy of infection for the next renters of the park. His clothes become saturated with the slime from the mouths and nostrils of the suffering beasts in his endeavours to press soft food down their throats; and from this fever-lair he will proceed straightway to the neighbouring market, to spread the disease far and wide. A man was pointed out to me as the one virtuous exception to this rule, as he was known always to change his clothes on leaving his farm. I inquired at several farms what was done with the emanations and fevered milk of the infected animals; and found, as a rule, that it was cast into the dung-heaps, to come out as manure the ensuing spring. Another mode of disposal was to throw it into the river passing the door, to be carried to the unconscious animals drinking at the stream lower down. No wonder that repeated outbreaks take place when so many farms create their own vicious circle, and are their own hotbed of disease.

On the other hand, it was interesting to observe that, among the more "advanced" farmers, the disease could be held in check, and sound and unsound animals lodged with impunity within a few yards of each other. Attention to the daily use of disinfectants, ventilation, and cleanliness, is all important, along with a certain amount of discipline among the farm servants. The disease seldom lasts more than three weeks or a month, the season of incubation being from seven to ten days. With proper care, it is not of a fatal character. An innocent idea prevails among the country people that it is a wholesome disease, inasmuch as the beasts are "heart hale a' the time". If they could only swallow the food, they would be all right, and their digestion proved as good as ever. The pigs come in for small commiseration. Being greedy and unable to eat, "they will set up sich a skirling, that naebody on the farm can get a wink o' sleep whaiver". It is not an accepted view that their "skirling" may be due to their sufferings; their greediness and inability are the only things allowed.

Having given my autumnal experiences, I am curious to know if others have made similar observations with regard to the effect of the foot-and-mouth disease upon human beings. The disease is well known in Ceylon among cattle; and whether the two things may be associated or not, a painful mouth-disease is also known to attack Europeans there, for which the only cure is to leave the island.

PROMOTION, ETC., IN THE ARMY MEDICAL DEPARTMENT.—Surgeon-Major J. Leitch, M.D., from half-pay, to be Surgeon-Major, *vice* A. A. Stoney, retired on half-pay.—Surgeon R. C. Lever, M.B., to be Surgeon-Major, *vice* J. P. Loughheed, retired on temporary half-pay, September 16th, 1875.—Surgeon B. J. Jazdowski, M.B., to be Surgeon-Major, *vice* W. A. White, M.D., retired on temporary half-pay, September 16th, 1875.—Surgeon-Major E. Drew retires on temporary half-pay, October 6th, 1875.—Surgeon-Major O. B. Miller retires on temporary half-pay, October 17th, 1875.—Surgeon J. E. Barker, M.B., resigns commission.—Surgeon C. Spurway, on the half-pay list, resigns commission.

ASSOCIATION INTELLIGENCE.

WEST SOMERSET BRANCH.

MEMBERS of this Branch are requested to take notice that Henry Alford, Esq., Taunton, will perform the duties of Honorary Secretary and Treasurer during the temporary absence of Dr. Kelly, who has gone to Mentone for the winter.

SOUTH EASTERN BRANCH: EAST SUSSEX DISTRICT MEETINGS.

THE next meeting of the members of the above District will be held on Wednesday, November 24th, at 3.30 P.M., at the Royal Pavilion, Brighton; Dr. HENRY MOON in the Chair.

Dinner at Markwell's Royal Hotel at 5.45 P.M. Charge, 5s., exclusive of wine.

The Aquarium, Sussex County Hospital Museum, and the Museum and Picture Gallery of the Town, will be open to members. The first named on presenting their cards.

Sir Cordy Burrows will relate a case of Hip-joint Disease.

Notice of intended communications is requested by the Secretary by Tuesday, the 16th instant.

THOMAS TROLLOPE, M.D. Cantab., *Hon. District Secretary*.
35, Marina, St. Leonards-on-Sea, November 9th, 1875.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.

THE next meeting, to be held in the Music Hall Buildings, Aberdeen, on Saturday, December 4th, at 3 o'clock in the afternoon, will be devoted to a debate on the proper place of Alcohol in Therapeutics. The debate will be opened by Dr. Urquhart, Aberdeen.

J. URQUHART.
ALEX. OGSTON.

November 11th, 1875.

SOUTH EASTERN BRANCH: WEST SUSSEX DISTRICT.

THE next meeting will be held at Worthing, on Friday, December 10th; A. H. COLLET, Esq., in the Chair.

Any member desirous of reading a paper, or communicating any case of interest, is requested to give notice to the Honorary Secretary forthwith.

WM. J. HARRIS, *Honorary Secretary*.

13, Marine Parade, Worthing, November 15th, 1875.

SOUTHERN BRANCH: SOUTH-EAST HANTS DISTRICT.

A MEETING of the above District was held at the India Arms, Gosport, on Wednesday, October 13th. Thirty gentlemen were present, and the President (W. H. GARRINGTON, Esq., J.P.) occupied the Chair.

Pyæmia.—Surgeon-General J. MOUAT, V.C., C.B., read a paper on *Pyæmia*. A discussion followed, in which Dr. Manly, Mr. Brook, Dr. Cotton, R.N., Mr. H. Burford Norman, Mr. G. Turner, Inspector-General Smart, Mr. F. Morley, Dr. Nicolson, Dr. L. Owen, and Dr. Ward Cousins, took part.

Cystic Tumour of the Lower Jaw.—Dr. WARD COUSINS exhibited a case of large cystic tumour of the lower jaw, which had been completely cured by sloughing, induced by aspiration.

Dinner.—In the evening, twenty members dined together, under the presidency of Dr. Kealy of Gosport.

SOUTH WALES AND MONMOUTHSHIRE BRANCH: AUTUMNAL MEETING.

THE autumnal ordinary meeting of the South Wales and Monmouthshire Branch was held at the Assembly Rooms, Tenby, on September 30th. In the absence of the President (S. H. STEEL, M.B.), the meeting was presided over by JAMES PROBERT, Esq., of Merthyr Tydfil.

Papers.—Two papers, with illustrative cases, were read by J. H. WATHEN, Esq.: 1. On the use of Ergotine hypodermically as a hæmostatic; 2. On a case of Torticollis treated successfully by *Succus Conii* in doses commencing with two drachms three times daily, increased gradually to ounce doses, with similar frequency. Valerianate of zinc, iron, nux vomica, and faradisation, had been previously unsuccessfully employed.

New Members.—Seven gentlemen were elected by the Branch Council.

cil members of the Association, and eight by the meeting members of the Branch.

Luncheon and Dinner.—Mr. Chater provided most hospitably for the members on their arrival; and, after the meeting, they dined together at the Gate House Hotel.

Remarks.—The meeting was a small but very pleasant one, and it was a matter of general regret that so few availed themselves of the opportunity of a visit under such circumstances to so charming a locality. Some explanation is to be found in the great distance of Tenby from the populous centres of the district comprehended within the limits of the Branch.

SHROPSHIRE ETHICAL BRANCH: ANNUAL MEETING.

THE annual general meeting of the Ethical Branch was held at the Lion Hotel, Shrewsbury, on Wednesday, October 27th, at 1 P.M.; the President, RICHARD WILDING, Esq., of Church Stretton, in the chair.

Notwithstanding the inclemency of the weather and a continuous heavy downpour of rain, the meeting was attended by an unusually large number of country practitioners from distant parts of Shropshire and Montgomeryshire; and, after an animated discussion in reference to the treatment of Dr. Inglis by the Executive Committee of the Worcester Infirmary, the following resolutions were passed unanimously.

¶ *Minutes of General Meeting.*—"That the minutes of the last general meeting be affirmed."

Vote of Thanks.—"That the cordial thanks of the meeting be given to the late President, Vice-Presidents, Council, Honorary Secretary, and Treasurer for their valuable services during the past year."

Election of Officers.—"That John Rider, Esq., be elected President; J. Sides Davies, Esq., and W. Thursfield, M.D., Vice-Presidents; and the following gentlemen Members of the Council, for the ensuing year, in the place of those who retire by rotation or otherwise, in accordance with the 7th General Law of the Branch:—James Bratton, Esq.; Henry Fenton, Esq.; Thomas Groom, Esq.; S. Betton Gwynn, Esq.; and J. R. Humphreys, Esq."

Representatives of Branch in General Council and on Parliamentary Committee.—"That, in accordance with the 8th General Law of the British Medical Association, Richard Wilding, Esq., John Rider, Esq., J. R. Humphreys, Esq., and Dr. Jukes Styrup be the representatives of the Branch in the General Council for the ensuing year; and that the President, Richard Wilding, Esq., be the Branch representative on the Parliamentary Committee."

Medical Advertising.—"That, in the opinion of the meeting, the system of advertising 'medical works' in non-medical papers is highly objectionable, and incompatible with the honour and dignity of the profession; alike reprehensible, also, is the practice of giving written testimony in favour of 'articles of commerce', and tacitly or otherwise sanctioning its publication."

Hospital Charity Abuse and Gratuitous Operations for well-to-do Patients.—"That the members of this Branch, while fully approving the efforts now being made in London to check the gross abuse of 'hospital charity', regret that patients well able to pay a fair surgical fee to their ordinary professional attendants are so often encouraged by hospital surgeons to enter their respective hospitals for gratuitous operation."

Dr. Inglis and the Executive Committee of the Worcester Infirmary.—"That, in the opinion of this meeting, the action of the Executive Committee of the Worcester Infirmary in passing a vote of censure on Dr. Inglis 'for neglect' (so-called) 'of duty by absenting himself from the out-patients of the infirmary, on February 13th, without providing a substitute (other than the House-Surgeon) according to the rules, to the disappointment of two patients in a humble class of life—such absence having been necessitated by a sudden and urgent professional call elsewhere—was harsh and unjust to Dr. Inglis and an insult to the profession, and that such vote ought to be rescinded; meanwhile, the members of the Shropshire Ethical Branch beg to tender to Dr. Inglis their cordial sympathy and support; and further, that the professional loyalty and *esprit de corps* of Dr. Hunt in withdrawing his application for the vacant post of honorary physician, caused by the resignation of Dr. Inglis, is deserving of commendation and public recognition."

Quack Advertisements.—"That the President, Dr. Styrup, and J. R. Humphreys, Esq., be deputed to communicate with the proprietors of county newspapers, and point out to them the immoral tendency of and contaminating effect produced upon the youth and purity of the country by the disgusting 'quack' pamphlets which are advertised and disseminated far and wide through the medium of the press—an effect

which the meeting (representing a large number of medical practitioners in this and the adjoining county of Montgomery, etc.) venture to hope that the local and other papers will, for the future, assist in counteracting by the exclusion of such advertisements from their pages."

Thanks to the President.—"That the cordial thanks of the meeting be given to the President—R. Wilding, Esq.—for the courtesy and ability with which he has conducted the business of the meeting."

Communications, etc.—Edwyn Andrew, M.D., related a Case of Large Abscess treated by the Aspirator and Lister's Plan; and J. G. Wilson, L.R.C.P.Ed., communicated a Case of Poisoning by Hydrate of Chloral treated by Injections of Solution of Strychnine with Brandy and Extract of Meat; also a Case of Tetanus treated by Chloral Hydrate, Bromide of Potassium, and Tincture of Belladonna. The reading of a paper on the Early Detection and Treatment of Stone in the Bladder, by W. F. Teevan, Esq., was unavoidably deferred.

Several new members joined the Branch.

Dinner.—A hearty vote of thanks having been accorded to Dr. Styrup for his valued services to the Branch, the meeting was closed, and an adjournment made to the Ball Room, in which the dinner was served punctually at 3.30 P.M. (for the convenience of the country members, several of whom had to leave by inconveniently early but last trains), under the presidency of R. Wilding, Esq.; the vice-chair being filled by John Rider, Esq., President-elect; and a most sociable evening was spent.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH: ORDINARY MEETING.

THE first ordinary meeting of the session, 1875-76, was held on Oct. 14th, at the Midland Institute, Birmingham; present, Dr. W. F. WADE, President, in the Chair, and fifty-six members and visitors.

New Members.—Mr. H. D. Best (Bilston), Mr. W. Horton (Chase-town), Mr. J. J. Hues (Handsworth), Mr. James May (Nechells), Mr. A. Parkes (West Bromwich Hospital), Mr. Hecket Skipworth (Birmingham), Rev. W. J. J. Welch, M.D. (Stourbridge), and Dr. C. C. Wimberley (Coventry), were elected members of the Branch.

Communications.—The following specimens were presented.

1. *Dilated Stomach.*—Dr. PHILIP BINDLEY showed an enormously dilated stomach, which had been removed from a man, aged 53, a patient of Dr. Foster's, in the General Hospital. On admission, he was greatly emaciated, and complained of epigastric pain and dysphagia. A few days afterwards, the dysphagia having greatly increased, he said he felt "something give way inside him", and immediately experienced much relief, both of the pain and of the difficulty of swallowing, but subsequently they recurred, and were further complicated by repeated profuse hæmorrhages from the bowels. Inquiry into the previous history furnished distinct evidence of chronic gastric ulcer. He gradually sank after having been in hospital about two months. At the *post mortem* examination, the stomach was found to be greatly dilated, and its walls thickened throughout, but especially at the pyloric end. There were numerous firm old adhesions between the pylorus and the neighbouring organs—liver, pancreas, and colon. An examination of the interior of the stomach revealed on its anterior wall, about an inch from the pylorus, a small puckered cicatrix, at the lower border of which was a hole one inch in diameter, with edges partly clean cut, partly ragged. On introducing the finger through this opening, it passed into a cavity about the size of a hen's egg, lying under the pylorus, amongst the organs which had become securely bound together by the adhesions above referred to. It would appear, therefore, that the primary lesion was a chronic gastric ulcer, which caused irritation of the surrounding parts and consequent adhesion. Though the ulcer was partly healed, a solution of continuity probably at some time occurred, through all the coats of the stomach, which permitted some of the contents to escape into the tissues, thus being the cause of increased irritation and further adhesions, and ultimately leading to an abscess which discharged itself into the stomach at the time when the patient said he felt something burst internally. The eroded state of the margin of the opening sufficiently accounted for the hæmorrhage from the bowels, though no ruptured vessel could be demonstrated; but there had been no hæmorrhage for the three weeks preceding death.

2. *Recurrent Tumour of the Eyeball.*—Mr. H. FALES showed a man, aged 49, from whom Mr. J. Vose Solomon had recently removed the whole of the contents of the left orbit, and the greater part of both eyelids, in the treatment of a large recurrent tumour of the left eyeball, which had so involved the surrounding structures, as to nearly fill the orbit and destroy the eyeball (in which till recently the sight had been good). This growth had been removed four times previously, at intervals varying from three to nine months. The patient, who

before the operation was almost in a moribund state, seemed in good health and spirits, and had no enlargement of neighbouring lymphatic glands. The actual cautery was freely applied to the walls of the orbit at the operation, the inner wall being perforated. Subsequent unhealthy looking granulations were treated by the application of chloride of zinc paste. The tumour, which grew from the sclerotic outside, consisted microscopically of large, round, nucleated cells, with some spindle-shaped cells and a scanty stroma.

3. *Exophthalmia*.—Mr. H. EALES also showed a female, aged 41, under the care of Mr. Arthur Bracey, with very marked exophthalmia on both sides, the eyes being protruded beyond the level of the eyebrows. A hard substance could be felt in each orbit to reach forwards to the margin (between it and the globe), and a large semisolid tumour was to be seen on the hard palate. The sight of the left eye, which was most protruded, was very good; but the vision of the right eye was quite gone. This was found on ophthalmoscopic examination to be due to marked atrophy of the optic nerve. There was a clear history of primary syphilis two years ago, with the usual subsequent skin-affection, sore throat, and falling off of the hair, etc.; which was followed by loss of sight in the right eye six months before any exophthalmia appeared, and was no doubt due to syphilitic neuro-retinitis, which ended in atrophy of the nerve. This patient seemed never to have undergone a thorough course of medical treatment. She did not suffer from any enlargement of the thyroid body.

President's Address.—Dr. WADE delivered his Presidential address, which has appeared in the JOURNAL, October 16th.

At the conclusion of the address, Mr. W. C. Garman, Ex-President of the Branch, having taken the Chair, a vote of thanks to Dr. Wade for his excellent address was moved by Dr. BELL FLETCHER and seconded by Dr. HESLOP, and carried by acclamation. Dr. WADE replied, and the meeting separated.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH: PATHOLOGICAL AND CLINICAL SECTION.

A MEETING of this Section was held October 29th, 1875; VINCENT JACKSON, Esq., President, in the Chair. Thirty members were present.

Lupus Vulgaris.—Dr. MACKEY showed three cases of lupus vulgaris, illustrating treatment. 1. A strumous girl, aged 20, had been affected seven years with a tuberculated growth on the nose. It was uncured by excision and by many caustics, and was now removed by zinc nitrate in paste and emplastrum hydrargyri. Reference was made to Professor Corradi's use of metallic zinc after silver nitrate in ulcerations. 2. A strumous girl, aged 12, had been affected seven years with superficial serpiginous ulceration of the face and neck. She was apparently cured after three months' treatment with carbolic acid and emplastrum hydrargyri, but relapsed two months after the omission of treatment. Carbolic acid was found to be very painful, and its action too superficial for permanent good. 3. A strumous boy, aged 12, had been affected since infancy with "impetiginous lupus" of the right cheek. Cure was progressing under silver nitrate and mercurial ointments, with cod-liver oil and tonics.

Lamellar Cataract and Defective Teeth.—Mr. PRIESTLEY SMITH exhibited a boy aged 15, the subject of lamellar cataract in both eyes, associated with imperfections in the teeth. The case was brought forward as an illustration of Mr. Hutchinson's theory concerning this association; namely, that the dental imperfections are due to mercurial treatment during infancy, directed against the convulsions which usually precede the formation of lamellar cataract (BRITISH MEDICAL JOURNAL, March 6th, 1875, p. 307). No history of fits had been obtained in this case; but the patient had had no power in the legs until he was two years old. Grey powders had been taken rather freely during infancy. The impairment of sight was first discovered in the fifth or sixth year. The incisor and canine teeth were eroded and dirty-looking, from loss of enamel on their anterior surfaces. The first molars had no enamel on their opposing surfaces. Iridectomy had been performed downwards and inwards in each eye, with great improvement to vision.

Amputation of the Foot.—Mr. GEORGE EVANS showed a patient whose foot he had removed after Jules Roux's method, and pointed out the advantages of this method over Syme's or Mackenzie's in such cases.

Retro-uterine Hematocoele.—Dr. MALINS showed a specimen of the uterus and appendages from a case of retro-uterine hæmatocoele of large size. The top of the cavity, which contained fully a pint of purulent matter, was arched over by bands of lymph uniting the posterior part of the fundus uteri with the peritoneum behind. This new tissue had

given way, allowing the contained matter to escape into the peritoneal cavity, followed by the death of the patient.—Dr. WADE, after some comments on the case, remarked that he thought that, if the clinical element of the Section were more fully developed, the meeting would become more popular and useful; and he asked Dr. Malins through the Chairman, to give further details of the case.—Dr. Malins complied with the request.

Femoral Aneurism.—Mr. H. L. BROWNE exhibited a specimen of femoral aneurism, and read notes of the case.

BATH AND BRISTOL BRANCH: ORDINARY MEETING.

THE first meeting of the Session was held at the York House, Bath, on Thursday evening, October 28th; W. MICHELL CLARKE, Esq., President, in the Chair. There were also present twenty-eight members and two visitors.

New Members.—Dr. Logan was elected a member of the Association and Branch; and Mr. J. J. Mitchell of Bath, and Dr. Eager of Northwoods, members of the Branch. Several new members were proposed, and will be balloted for at the next meeting.

Discussions at Meetings.—The PRESIDENT reported that the Council of the Branch had decided, "That it would be desirable to try as an experiment this Session, Dr. Brabazon's proposal to set apart two meetings for discussion of some special subject, and that the January meeting at Bath, and the May meeting at Bristol, should be set apart for this purpose. The subject for the January meeting to be settled this evening, and that for the May meeting at the meeting in January." Dr. FALCONER proposed, and Mr. LAWRENCE seconded, and it was carried *non. con.*, "That Dr. Brabazon be requested to be the propounder of the subject of discussion at the January meeting, and that he should select his own subject."

Advertising Medical Books in Public Newspapers.—Dr. FALCONER proposed, Mr. MASON seconded, and it was carried unanimously, "That, in the opinion of this meeting, the practice of advertising medical books in the public newspapers is derogatory to the interests and dignity of the profession, and likely to occasion social inconvenience and annoyance, and should, therefore, be discontinued."

Papers.—1. Mr. F. P. LANSDOWN read a paper on a Fibrocellular Tumour of the Pharynx, which he exhibited.

2. Mr. N. C. DOBSON read a case of Tumour of the Left Palate, successfully removed by Operation, and exhibited it.

3. Mr. CLARKE showed a large Sessile Fibrous Tumour which was expelled from the Uterus.

4. Dr. COLE read a paper on Cerebro-Spinal Meningitis, which excited much interest, and Dr. Brabazon requested Dr. Cole to allow it to be the subject of the special discussion at the January meeting.

SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT MEETING.

A MEETING of this District was held on Wednesday, September 22nd, at 3 P.M., at the Burlington Hotel, Eastbourne; T. F. SANGER, Esq., of Alfriston, in the Chair. Seventeen members were present, and four visitors.

Pathology of Chorea.—Dr. WITHERS MOORE of Brighton read a paper on the Pathology of Chorea. After a brief *résumé* of the literature of chorea, the disease was defined to be a "motor neurosis or derangement of the motor apparatus of a convulsive character, with occasional psychical phenomena". The non-febrile and non-inflammatory character of the disease, its tendency to recovery even in acute and threatening cases, and the absence of any marked and uniform *post mortem* appearances, were duly noticed. The soundness of the view of the embolic origin of the disease, as propounded by the late Dr. Kirkes, and since endorsed by Sir Thomas Watson, Dr. Hughlings Jackson, and other authorities, was questioned, and held not to be sustained by the *post mortem* appearances; especial reference being made to the monograph of Dr. Ogle and to the writings of Drs. Wilks and Moxon, Dr. Peacock, Dr. Murchison, and others, as showing that "the absolute connection between chorea and embolism has not yet been raised to the standard of an acknowledged fact". The frequent co-existence of valvular disease and chorea was fully acknowledged; but it was maintained that rheumatism is a very common disease in childhood, and that the younger the patient the more likely is cardiac mischief to be set up; that rheumatism also depresses the powers of life, and favours much the advent of chlorosis, anæmia, and a state of the circulation below the average in activity and vigour; and that it is exactly under such conditions, according to Dr. Radcliffe, that chorea

usually arises. On the other hand, it was remarked that chorea becomes unfrequent as childhood passes into maturity; and that, although adults may have rheumatic fever and coincident and persistent valvular mischief, chorea is a rare sequel. Dr. Romberg was quoted as saying that "the rheumatic predisposition noticed by English medical men was rarely traceable in the cases which have presented themselves to my notice". Dr. Guy's four cases of chorea with mitral murmur, which disappeared before they left the hospital, were instanced; as also the fact that, out of thirty-six cases treated during last year in St. Bartholomew's Hospital, seven only had heart-disease. Some particulars with respect to the physiology of the brain and spinal cord, which have been ascertained during the last four years, were then briefly narrated, especial allusion being made to the researches of Prochaska and Legallois, as proving not only that the spinal cord, as a whole, is a centre of reflex action quite independent of the brain, but that separate segments may act independently of each other, in confirmation of which Volkmann's investigations as to the rhythmical movements of the anterior and posterior lymphatic hearts in the frog were cited. Further, the existence of separate centres in man was held to be proved by the action of the chorda tympani on the submaxillary gland, through the medium of the submaxillary ganglia, and by the action of the nervi erigentes of the penis. Jaccoud's views on "spinal irradiation" were then detailed; viz., "that the spinal cord has the power of transmitting complex movements which have been previously co-ordinated; the motor cells of the cord are grouped into distinct regions, which are connected with the encephalon by fibres conveying the volitional stimulus, and with the muscles of one group by the motor roots of the nerves; this motor influence is propagated involuntarily to other nervous elements which have not directly received it from the brain, and is effected by the cells of the grey matter of the cord, and the prolongations which connect them with each other and with the motor roots of the spinal nerves". The spinal motor apparatus was taken to be an instrument both of transmission and of co-ordination, and as liable to be brought automatically into action by external bodily or mental stimuli, wholly independent of the will. The parallel between the secondary automatism which man acquires by habit and the original or primary automatism of the lower animals, as worked out by Hartley, was then duly set forth. Returning to the subject of chorea, the author contended that it is a functional disease dependent upon defective nutrition, which may manifest itself, first, in the cerebrum, and be complicated with other symptoms of defective brain-power, such as shortcomings in intellect, memory, speech, etc. The occurrence of the disease from fright, and its occasional cure by a strong mental impression, seem to favour the view of the disease having at times a distinctly cerebral impression as an exciting cause, the remote one being the general state of the system. Secondly, the local derangement may be seated in that part of the cord where muscular co-ordination is brought about; and, lastly, the disease may be eccentric, being due to reflex irritation, such as that of pregnancy, worms, etc., acting on a cord unduly irritable and suffering from the general cachectic condition. Jaccoud defines chorea to be a hyperkinesia of the apparatus of motor transmission and irradiation. This limiting of the disease to the automatic portion of the spinal cord receives some confirmation from Chauveau's statement that, in choreic dogs, he found the abnormal movements continued after the spinal cord had been divided above the atlas, as long as the heart continued to beat, and from the important fact that, in true paralysis, the affected muscles are the seat of movements which, by common consent, are placed in the category of chorea. Although the treatment of chorea was foreign to the scope of Dr. Moore's paper, he referred to it for two reasons: first, to comment on the numerous, and sometimes conflicting, remedies which have, from time to time, been extolled as successful in its cure, and which would seem to indicate its varied origin and the uncertainty as to its true pathology; secondly, to remark that, on looking over the long list of remedies vouched for by undeniable authorities, we cannot but be struck with the coincidence that, with one exception, six or eight weeks are required wherein to bring about a cure—the very time named for the natural duration of the disease. The one exception referred to is the periodical application of intense cold to the spine by means of the ether-spray, as suggested by Dr. Lubelski. This mode of treatment is said to cure in little more than a fortnight, and would seem to confirm the pathological view given in this paper. The mode of application consists in allowing a jet of ether-spray to play over the whole length of the vertebral column for three or five minutes. One sitting a day is sufficient in slight cases; it may be used twice a day in bad cases; and in a few days the cure is complete. It is not unusual to find the first application followed by considerable improvement. Jaccoud says that he has tried the plan four times in choreic children, and has been astonished each time at the rapidity of the cure, the maximum num-

ber of applications being ten. Dr. Moore related two successful cases that occurred in his practice at the Sussex County Hospital, and which were treated simply with the ether-spray. In the first case, that of a child 4½ years of age, the spray had to be intermitted for several days, owing to erythema of the back coming on. This retarded the cure, which, however, was completed on the resumption of the use of the spray every other day, in about a week. Care was taken, in the other case (a married woman), to avoid a similar hitch in the mode of cure. Dr. Moore seemed to be of opinion that the cold acted much as static electricity does when applied in similar cases; viz., by producing a more tonic and vigorous circulation in the cord by contracting the small arterioles which supply that nerve-centre.—A discussion followed, in which Sir Cordy Burrows and others took part.

The Next Meeting will be held in November, at Brighton. Dr. H. Moon will be invited to take the chair.

Medical Advertising.—The following resolution, proposed by Dr. PARSONS of Dover (Branch Secretary), and seconded by Sir J. CORDY BURROWS, was carried unanimously.

"That, in the opinion of this meeting, the practice of advertising medical books in the public papers is derogatory to the interest and dignity of the profession, and likely to occasion social inconvenience and annoyance, and should, therefore, be abandoned."

Dinner was attended by sixteen members and six visitors, Mr. T. F. Sanger presiding.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

FRIDAY, NOVEMBER 12TH, 1875.

GEORGE W. CALLENDER, F.R.C.S., F.R.S., Vice-President,
in the Chair.

Ligature of Femoral Artery with Carbolised Catgut for Popliteal Aneurism.—Mr. HOLMES read notes of the case. The patient was a footman, aged 34, who, three weeks before admission into St. George's Hospital, began to experience pain and stiffness in the left ham, followed, five days before admission, by swelling and œdema of the foot and ankle. There was no history of any distinct strain, and he had always enjoyed good health. Upon his admission into the hospital, there was found to be a swelling, about the size of a walnut, in the left popliteal space, pulsating strongly, and with well marked lateral dilatation. There was neither thrill nor bruit in the tumour, and very slight pressure on the femoral artery caused the pulsation to cease and the swelling to collapse. At first, digital pressure was tried for twenty-two hours. This was attended by a very considerable diminution in the pulsation; the tumour no longer entirely collapsed when the artery was compressed, and the sac appeared to contain a considerable amount of soft coagulium, especially at its outer part. After an interval of twenty-four hours, during which an air-pad was applied to the tumour, digital pressure was resumed and continued for six hours daily for three days. All pressure was then relaxed, and the following morning the pulsation was as distinct as ever. Various forms of instrumental pressure were next tried; namely, by means of a weight in the groin and Carte's tourniquet, and a final effort by digital pressure, which was kept up continuously for thirty-one hours. As, however, all these means failed, ligature of the femoral artery was determined upon. Accordingly, on August 12th, a stout ligature of carbolised catgut was applied to the artery at the apex of Scarpa's triangle. In the course of the operation, a small vein, lying to the inner side of the sheath, was wounded and subsequently secured by a ligature. The wound was dressed according to Lister's antiseptic method, and the limb enveloped in cotton-wool. On the following day, the patient was found to be going on favourably, except that there was a little tenderness along the course of the saphena vein. On the 14th, two days after the operation, no pulsation could be felt in the tumour or the arteries of the limb. The foot was warm, with the exception of the extremity of the great toe, which was cold and of a slightly dusky hue. The dressings were changed; the wound looked healthy; there was no redness nor appearance of suppuration. There were swelling and tenderness along the course of the saphena vein, but no redness. The man went on well until the evening of the 16th, when the house-surgeon was called to him, and found him suffering from undoubted intoxication; he was talking rapidly and incoherently, at intervals shouting out loudly for drink, and endeavouring to strike those who came near him. It appeared that his friends had smuggled in a quantity of gin, which he had drunk. On the following day, he was in a peculiar condition, half-

stupid, with a frightened expression of countenance, answering questions very hurriedly and not to the purpose, and tossing about in bed in a restless manner. He continued much in the same state till the 19th, gradually sinking, with muscular twitching of the limb, incoherence of speech, picking at the bed-clothes, a brown furred tongue, and sordes on the teeth. He died quietly at about 1 P.M. Mr. Holmes stated that he had brought forward this case with a view to comparing the relative advantages of the silk and the catgut ligature for tying the larger arteries in their continuity. His own experience had not been enough to justify him in expressing a dogmatic opinion, as he had only applied the catgut ligature to four of the large arteries in their continuity; viz., to the subclavian and carotid, which were tied simultaneously for thoracic aneurism—in which case the man died eight weeks afterwards from the result of galvano-puncture; thirdly, to the femoral artery, as above narrated; and, fourthly, to the left carotid, in a case upon which he had operated twenty-two days ago. In the first instance, the vessels were found to be closed by a kind of diaphragm of no great extent, and neither of the vessels had been cut through. In the second case, that of the ligature of the femoral, of which the notes had been read *in extenso*, the artery was shown to the members present. The knot of the ligature was visible; but there was nothing to be seen of the rest of the string. The artery was perfectly continuous. In the fourth case, there had been free suppuration from the wound; but now, on the twenty-second day, there was no irritation about it, and no part of the ligature had come away. Such, Mr. Holmes stated, was his experience with the carbolised catgut ligature, and the results, though far from conclusive, were quite consistent with the opinion which he entertained that the antiseptic ligature was a most efficient agent in combating the tendency to secondary hæmorrhage, and that it rendered possible that union by first intention which was John Hunter's object in his first operation on the femoral artery. He further explained that in neither case was Lister's antiseptic treatment entirely adopted.

Mr. CALLENDER thought the Society greatly indebted to Mr. Holmes for his paper, which involved the whole question of the treatment of aneurismal tumours in the extremities. But he thought that surgeons would especially discuss the question of the use of the carbolised catgut ligature for the tying of arteries in their continuity.—Mr. MAUNDER thought the subject most important. He had tied twenty-seven arteries in their continuity at various times, and had applied the antiseptic ligature in nine of those cases, and the carbolised catgut ligature in five of the nine. In two of these cases, the brachial artery was tied for hæmorrhage from the hand. Both cases suppurated. The first patient lay ill for a long time with suppuration; the second died of pyæmia on the tenth day. The inner coats of the artery were then found to have been divided, but the outer coat was not cut through. No trace of the ligature could be detected; there was a clot in the artery on the distal side of the point of operation. In two of the five cases, the femoral artery was ligatured for popliteal aneurism. The first case was that of a spare man, in whom the operation was done at the angle of Scarpa's triangle. The wound healed in forty-eight hours without a trace of secretion appearing. The man went out of hospital, but shortly returned, and died in six months of an aneurism of the aorta. The second patient in whom the femoral artery had been tied was a fat man; carbolised water was liberally poured into the wound, and used upon all the instruments, yet suppuration occurred. That man left the hospital and was now well. Why was there this difference in the two men? The one whose arteries seemed to be almost universally diseased had no suppuration; whilst the other man, with tolerably healthy vessels and with carbolic treatment, had extensive suppuration. The fifth case in which Mr. Maunder had used the catgut ligature, was for axillary aneurism. The carbolic spray was not used during the operation, but Mr. Couper, who had largely employed Lister's plan of treatment at the London Hospital, completed the operation after the tying of the vessel by Mr. Maunder. Carbolic water was most freely poured into all parts of the wound, and the wound was done up in the most approved antiseptic method. Yet suppuration into the chest occurred, of which the patient on the sixth day died. But Mr. Maunder had generally had good success with the carbolic acid treatment, and should continue it. Mr. Holmes's cases, he thought, were unsatisfactory. He (Mr. Maunder) mentioned especially the case of a young man with carotid aneurism whose artery was tied with silk. The wound had done well with the carbolic acid treatment. In answer to Mr. Callender, who inquired if the femoral artery had been examined in the case of the man who died six months after ligature of the vessel, Mr. Maunder replied that it had been inspected, that no ligature was found, and that the vessel was obliterated down to the popliteal space. In reply to Mr. Holmes, Mr. Maunder said that the ligature was found upon the artery in the case of

the patient who died on the sixth day after operation; but was not found on the brachial artery where ten days had elapsed before death occurred. He also observed (replying to Mr. Callender) that in the former case the ligature was not sufficiently softened to allow blood to pass along the artery.—Mr. BARWELL thought nothing had been mentioned by Mr. Maunder derogatory to the catgut ligature. He himself had often used it, and never saw it come away, except on one occasion; it was always absorbed. It was a point of very great value, not to have a foreign body in the wound after an operation; and, as the catgut was absorbed, it could not be considered to be a foreign body. He had tied in this manner the brachial, radial, and both facial arteries (the latter in a case reported in the BRITISH MEDICAL JOURNAL for March 20th, 1875). In this last instance, each artery was tied with two ligatures, and then divided between them, so that there were four ligatures. And yet, in spite of the supervention of erysipelas at the wounds, there was scarcely any suppuration, and no ligature came away. In the case in which the brachial artery was tied, there was slight suppuration, but no ligature came away. The wound produced in tying the radial artery healed by the first intention. If, as he believed, the danger of secondary hæmorrhage and suppuration could be greatly avoided by the carbolised catgut, there was a great advantage in using it. But care must be exercised in having the catgut perfect for use. Assistants and dressers were apt to take it out of the oil, and handle it some time before it was wanted in an operation; it should not be allowed to become dry or hard, but should be used fresh from the bottle.—Mr. MYERS remarked that, whilst Mr. Holmes had mentioned four cases and Mr. Maunder five, he had only used it in one instance, viz., upon the external iliac artery for aneurism, partly of the external iliac, partly of the femoral arteries. Other methods of relief had been first tried, but unsuccessfully; and pressure had pushed the artery almost into the pelvic cavity. Two ligatures were applied to make the operation doubly certain, and the wound was closed. He was not able to show the specimen, for the man was well, and was now doing duty in his regiment. Suppuration had occurred after the operation, but apparently there was no irritation from the ligature. The man had previously had syphilis badly, for which he had been treated in hospital, and was in a cachectic condition. The ligature, although searched for, was not seen to come away.—Mr. GASCOYEN had tied one femoral and one brachial artery, which did well. In another case of ligature of the femoral artery, some inflammation arose, and severe secondary hæmorrhage followed, to which the man succumbed. He had seen and assisted other surgeons in similar operations. He was present at Mr. Myers' case, which was successful; and had assisted Mr. James Lane at the Lock Hospital, when the iliac vessel was tied for sloughing in the groin. That patient died after ten days, the sloughing having continued after the operation; at the inspection, no trace of the ligature was found. In another case of ligature of the carotid, the man did well. In none of the cases was the artery ligatured under the carbolic spray, nor was the antiseptic method of dressing subsequently used. Two cases were peculiar. In one instance, where the femoral artery was ligatured with carbolised catgut for popliteal aneurism, the wound would not close for six weeks; and the man had repeated attacks of inflammation during that time. After the six weeks, something, which was not kept for Mr. Gascoyen's inspection, came away, and then the wound healed. In another case at Hounslow, in which also the femoral artery had been tied, the wound healed by the first intention, with the exception of a small opening, from which, at the end of six weeks, something came away, and then the wound healed. What was that something in each case? If it were not the ligature, perhaps it was the external coat of the artery, which might have been bruised in the operation, and which, after sloughing, came away. Such an explanation had occurred to himself; but he would be pleased to know what light other surgeons could throw on the occurrence.—Mr. BECK remarked that these wounds had healed sooner than if the ordinary treatment had been adopted, and yet all Mr. Lister's precautions had been neglected. Mr. Lister had said that after a few hours all the carbolic acid he might pour into a wound was absorbed; if that were the case, would not all the carbolic acid contained in the catgut ligature be likewise absorbed, and the ligature itself form a foreign body, and in four or five days constitute (in some instances) a ring of putrid material around the artery? Mr. Beck had never seen a catgut ligature come away. Mr. Lister never had the trouble other surgeons had; and, if surgeons proposed to tie according to Mr. Lister's plan, they should carry out that method in all its details.—Dr. MURCHISON remarked that Mr. Holmes's cases were not brought forward as specimens of the antiseptic treatment; and that Mr. Syme had tied the femoral artery twenty-five times without the carbolised catgut and without antiseptics, and that all the cases had recovered.—Mr. PAGE had seen the carbolised catgut applied by a surgeon at the Carlisle Hospital to a femoral artery

at the commencement of Hunter's canal. No attempt had been made to use the antiseptic method; free suppuration ensued, and there was no sign of the ligature coming away. The result was successful. He had used the ligature in many cases of amputation, etc., *i.e.*, to the cut ends of vessels, and had never seen secondary hæmorrhage occur, nor the ligature come away. He thought secondary hæmorrhage, when it did happen, was not due to the nature of the ligature, but to the manner of its tying (as was taught by Professor Humphry at Cambridge). He doubted if a mass of decomposing catgut in a wound was so bad as Mr. Beck had attempted to make out. It was soon absorbed; and was safer than silk, as it did not cause so much damage to the vessel.—Mr. HEATH remarked that one of the causes of the different results was that the vessels were tied by different surgeons. At his first case, he had found it a little difficult to know what degree of strength should be put forth in order to occlude the artery, and yet not hurt unnecessarily the coats of the vessel. His first case was one of tying the subclavian artery for aneurism. The wound was dressed antiseptically; and was found to be healed when, after a week, it was disturbed for the first time. In a second case, the femoral artery was tied in Hunter's canal for secondary hæmorrhage. The wound inflamed, and the patient died seven days afterwards. A clot was found on each side of the ligature. The physical condition of that patient seemed to cause the result. Mr. Heath narrated two other cases; one in which the carotid was tied, and the case of a medical man (who was present and in good health at the meeting), whose femoral artery he had tied for femoral aneurism. In this case, the wound almost healed at the first, with the exception of a small track, from which, on the eighty-second day, something came away; that Mr. Heath thought to be the ligature unabsorbed.—Mr. MAUNDER said that all his nine cases had been done antiseptically, but without the spray. Why, if in 1868 the antiseptic dressing without the spray was sufficient, was it not so in 1875?—Mr. BECK rejoined that Mr. Lister's cases now were much more successful than they were in 1868. At that time, suppuration commonly occurred; now it was often prevented altogether.—Mr. MACNAMARA had tied four arteries with carbolised catgut at Calcutta. The first case was ligature of the brachial artery at the bend of the elbow; there was no suppuration, and the case did quite well. In the second case, the subclavian and carotid arteries were tied for aneurism. The antiseptic method, including the spray, etc., were used, and the patient did well up to the fifteenth day, when sudden hæmorrhage from the carotid ensued, and the patient died. The third case was ligature of the femoral artery for punctured wound of the thigh. The wound there did admirably; in fact, it healed by the first intention. In the fourth case, he had assisted his friend Mr. Cutcliffe in ligaturing the external iliac artery; and the patient made a good recovery. He thought the catgut ligature varied a good deal. If fresh, and not soaked sufficiently long in oil, it was brittle and apt to split. It should be kept in a fish oil; and not soaked too long in the carbolic acid.—Mr. HOLMES had not brought forward his cases with the slightest desire to mention Mr. Lister's treatment in connection therewith; in fact, it was not carried out in any of the cases. Without being an advocate of one method of dressing or of another, he had simply detailed his cases as examples in which the carbolised catgut had been used, and in order to elicit the opinions of other surgeons who might have employed it. The success of a case did not depend upon a little suppuration at the external surface of a wound, but whether the catgut formed an efficient ligature for the artery; whether it compressed the vessel sufficiently long to obliterate its passage before it was itself dissolved. That did not seem to be always the case. He had seen the external iliac tied at Deal for a femoral aneurism. The pulsation returned after the operation, when the surgeon again cut down upon the artery and tied it with a hempen ligature. That patient recovered and returned to his employment. Mr. Holmes thought, that with catgut one could tie the artery effectually without causing subsequent division of the vessel.—Mr. CALLENDER need not say anything respecting the dressing, of which he adopted his own particular method, but he would speak of carbolised catgut applied in the continuity of a vessel. In three instances at St. Bartholomew's Hospital, secondary hæmorrhage had occurred. One of the cases was his own. A young man, docile, had slight atheromatous disease of his arteries; but, with this exception, seemed to be an excellent patient for treatment. His femoral artery was tied in the lower part of Scarpa's triangle. The wound was drained by a piece of carbolised catgut. On the sixth day, at the 130th hour, slight pulsation returned in the aneurism, and in the artery itself below the point of operation. At the 165th hour, the loose piece of carbolised catgut in the wound had melted and divided at its deepest part, and came away in two parts. That is, the catgut round the artery, being subject to tension, divided at the 130th hour; whilst that in the wound, not

submitted to any strain, did not melt and divide until the 165th hour. On the tenth day, secondary hæmorrhage occurred, of which the patient died. At the inspection, the ligature was not to be found; but behind the vessel was a small aperture, the tenth of an inch in diameter, at the point where pressure had been made. The coats of the artery had been injured in the operation and had sloughed.—Mr. HART said there was one point in Mr. Holmes's paper to which he desired to direct attention—*viz.*, as to the various modes of treatment adopted before the operation. Instrumental pressure had been applied. Was it employed whilst the patient was under chloroform or not? Mr. Holmes knew well there were many cases recorded in which pressure under chloroform had cured the aneurism in a few hours; and he believed it never had failed where chloroform had been used. Was the pressure sufficient to arrest completely the pulsation of the aneurism?—Mr. HOLMES stated that the pressure was complete, and was tried for twenty-four and thirty-one hours continuously upon different occasions, but without any effect upon the aneurism. Chloroform was not used, the man being sufficiently tolerant of pressure. Always when the pressure was relaxed the pulsation returned in the aneurism. He thought the aneurism might perhaps be described as a form of aneurismal dilatation.—Mr. HART believed, that without chloroform no pressure was sufficiently complete thoroughly to prevent the passage of blood through an aneurism.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

INFANTILE SUMMER DIARRHŒA.

THE Registrar-General discusses at some length the distribution of infantile diarrhœa in England and Wales. He remarks that beyond an impression that the disease is of excrementitious origin, and the certainty of the powerful influence exercised by high temperature upon its fatality, very little is really known about epidemic diarrhœa. It appears most probable that there was a comparatively small mortality from diarrhœa during the summers of the early part of the present century; but that in recent years the deaths referred to diarrhœa have proportionately showed a marked increase. During the five years, 1838-42, the annual death-rate from diarrhœa averaged 0.22 per 1,000 persons living. In the succeeding decennials, it rose to 0.85 in 1850-9, and to 0.87 in 1860-9. In the year 1860, which was remarkable for its wet cold summer, the rate was only 0.49, whereas it was 0.94 both in 1859 and in 1861. In 1865, the summer was hot, and the diarrhœa rate was 1.13 per 1,000; while in 1868, when the summer was still hotter, it reached 1.39. Since the marked increase in 1865, the death-rate from diarrhœa has not again fallen to the average rates of previous years. The explanation of this increase is not clear. If we accept the excrementitious origin of the disease, how are we to explain the increase of diarrhœa during a period when the filth-nuisances of our town populations had undoubtedly been reduced, and the fatality of typhus and typhoid fevers had unquestionably declined? In seeking for an explanation of this apparent anomaly, the fact that in the past seventy years we have abated the cesspool nuisance at the expense of the purity of our rivers, the source of much of our water-supply, must, of course, be estimated at its proper value. Dr. Buchanan has recently urged upon health-officers the importance of earnest co-operation in the collection of observation and information on this important subject, and the scientific study of such materials as will assist in the formation of accurate conclusions as to the course of this infantile fatality, its varying death results in different towns, and the best means for controlling it.

In England and Wales, 14,006 deaths during the three months ending the 30th of September last were referred to diarrhœa, of which it may be estimated, from the experience of previous years, that 9,224 were of infants under one year of age, 2,948 of children between one and five years, and only 1,834 of persons aged upwards of five years. Fatal diarrhœa is, therefore, essentially an infantile disease. In town populations, the deaths of infants from diarrhœa bear a larger proportion to the total deaths referred to this disease than they do in rural populations. In London, the increase of infant mortality during the past summer quarter was almost entirely the result of diarrhœa. In England and Wales, the proportion of deaths from diarrhœa under one year to the deaths from this disease at all ages has increased steadily in recent years from 44 per cent. in 1847 to 64 per cent. in 1873. It appears that the greater the fatality of epidemic diarrhœa, the larger is the proportion of infants that succumbs to it.

Among those features of the fatality of epidemic diarrhoea which stand most in need of solution, and the solution of which would assist in throwing light upon the true pathology of the disease, one of the most important is the remarkable variation in its fatality in different towns, having similar characteristics as to situation and occupations of their inhabitants. Among the eighteen largest towns, the diarrhoea rate last quarter ranged from 1.6 and 2.5 in Bristol and London, to 7.0 and 9.2 in Birmingham and Leicester; and in other smaller towns the variations in the rate were equally marked. Evidence appears strongly to point to the intimate relation between sanitary condition and the death-rate from diarrhoea, without attempting to decide the true cause of these variations. Such being the case, it rests with the health-officers of the diarrhoea-plagued manufacturing towns to discover the nature of the sanitary shortcomings which lead to this waste of infant life, and the responsibility will then rest with their sanitary authorities to carry out such measures as will secure its decline.

What is the treatment and food of infants in the diarrhoea-stricken towns? Is the fatal disease traceable to any zymotic poison in the dwellings or in the waters? Such are the questions with which the Registrar-General closes his remarks; and we think that medical men might assist materially in their elucidation by the simple plan of always stating on the death-certificate the nature of the food supplied to the child, at any rate, by noticing whether the infant was brought up by hand or suckled.

PUBLIC VERSUS PRIVATE VACCINATION.

SIR,—In the report for 1874 of the medical officer of the Privy Council and Local Government Board, Dr. Seaton, speaking of the imperfect way in which private vaccination is frequently performed, says:—"In certain districts, there are practitioners who bribe, as it were, parents by the offer to vaccinate the children imperfectly, *i.e.*, in one or two places only."

As a public vaccinator, I can affirm that, in a great many instances, parents have remonstrated with me for "making so many places" on the arm, saying that "Dr. A. only does them in one place, and Dr. B. never puts more than two, and sometimes only one". Consequently, when it is known among parents that I never make fewer than three or four good-sized marks, numbers of them prefer to pay a small fee to a private practitioner for imperfect vaccination to having "so many places made for nothing". My brother vaccinators will see another point in this fact: the lessened value of our appointments, and, in the case of those who, complying with the terms of their contract, punctually attend distant vaccination stations, absolute loss of money and time. I am, etc.,
A RECIPIENT OF A VACCINATION GRANT.

November 4th, 1875.

MILITARY AND NAVAL MEDICAL SERVICES.

DEPUTY SURGEON-GENERAL SMALL, who has been for some years at Mauritius, to take charge of a district in Great Britain on promotion.

SURGEON-MAJOR JOHN SMITH CHARTRES, M.D., medical officer of the 43rd Brigade Depot at Chichester, and formerly of the 8th Hussars, died on the 31st ult. at Clifton House, Hampstead, aged forty-seven. Dr. Chartres joined the Army Medical Department as an assistant-surgeon, June 11th, 1852; became surgeon, September 11th, 1860; and surgeon-major, May 9th, 1872; serving as a staff surgeon throughout the Abyssinian campaign, and in medical charge of one of the hospital ships (medal).

In the deep gloom which enshrouds the Army Medical Service, it is gratifying (says the *Broad Arrow*) to note one scintillation of light and hope. We are able to congratulate our army doctors upon the fact that promotion, after fifteen years' service in the rank of surgeon, is, though not accorded by Warrant, a positive reality. The annual promotions of 1st April have at last disposed of those officers whose lengthened detention in the junior rank had become a scandal, and the congestion being thus removed, the period of service prior to promotion is reaching an average of fourteen and a-half years. This is a decided improvement, which we are glad to admit.

THE ASSISTANT PROFESSORS AT NETLEY.

We are informed that the assertion in a military contemporary as to the assistant professorships at Netley being beneficial and lucrative appointments, is made under a misapprehension of facts. The assistants

to the professors have extra work, but have no extra pay, unless they are retained for a longer period than five years; after five years there is a treasury grant of £100 a year. The mistake into which the military journal has fallen is probably due to the fact that, without exception, all combatant officers who are engaged in teaching in military educational establishments, such as Sandhurst, Woolwich, Chatham, etc., do receive extra pay or extra allowances from the first day of their appointment.

HALF-PAY WITHOUT HALF-PAY.

Two or three instances have occurred recently of medical officers finding themselves gazetted to *half-pay without half-pay*. The simple meaning of this announcement appears to be, that the officers concerned are removed from the active to the half-pay list of the department, but that they are not to receive any pay or allowances so long as they remain on the latter of the two lists. This, which is a totally new proceeding on the part of the War Office authorities, is producing profound distrust and alarm among the medical officers of the army. No one knows whose name may next appear in the same category, or what may be the next exercise of authority of an equally startling nature. The names have appeared in the *Gazette* without any explanation of the treatment associated with them. We are assured that in each case there has been no neglect of duty, no offence given, by the individuals concerned. They have been meritorious officers, who have contracted illness while on foreign service, who have been invalided home to England in consequence of this illness, but who, unfortunately for themselves, have not recovered sufficiently speedily in the eyes of the authorities to warrant their retention on the active list. We have no information respecting the length of time these medical officers have been on the sick or convalescent lists, and we can well understand that limits to these periods of absence from duty should be fixed; but what no one seems to be able to understand is the anomalous and contradictory proceeding of placing them on half-pay without half-pay. Where is the rule or regulation on which this mode of dealing with an officer rests? The Warrant regulating the Pay, Promotion, and Retirement of Army Medical Officers provides certain rates of half-pay, according to the length of service, for "every medical officer who is incapacitated by reason of ill-health brought on by the discharge of his duties". Surely, if a medical officer is sent to a climate in which he contracts illness which he would not be likely to contract if he were engaged in his ordinary avocations in the climate of England, such illness is strictly brought on by the discharge of his duties, even though it cannot be directly traced as the result of any particular duty. But, even if the illness be not distinctly traceable to the discharge of duty, the medical officer is still entitled to some consideration in the shape of half-pay. The fourteenth clause of the warrant lays down the rule that, "if a medical officer is placed on half-pay from any other cause than those herein before named, he shall only be allowed a temporary rate of half-pay for such period and at such rate as shall be assigned to him by our Secretary of State for War," etc. It is well known that this clause was introduced to meet cases in which medical officers might be incapacitated by their own misconduct, such as by intemperance. But even in such instances, attended as they would be with disgraceful conduct, some half-pay is to be given, the amount being determined by the War Office authorities, "on a consideration of the length and character of the services previously rendered by the medical officers concerned". *Half-pay without half-pay* is something quite new. It is foolish as a verbal expression; it is an injustice to the medical officers concerned, especially to medical officers who have committed no fault to deserve such treatment; and, from an administrative point of view, it is a blunder which on no account should have ever been perpetrated, considering the exasperating effect it was certain to have on a body of officers who are already in a deplorable state of discontent.

HOSPITAL ARRANGEMENTS AT ALDERSHOT.

In the comments which we felt it our duty to make on the inquest lately held on a lunatic soldier at Aldershot, we re-echoed the surprise expressed by the coroner at the frequent changes in the actual medical supervision of patients in the hospitals at that great military centre. But the explanation is simple enough, when we observe how very short-handed the medical staff there is at the present time, and that whereas, before recent arrangements, fifty-one medical officers were detailed for duty, thirty-six are now held to be sufficient for the entire charge of an equal number of men. It constantly happens that purely military exigencies have to be provided for out of this number; that a battery of artillery must have its surgeon present in the field; that ball-firing has

to be superintended, and a due provision of medical men furnished for those extensive strategical operations for which Aldershot is famous. Considering also that only one surgeon is now allowed per regiment, and that all the varied work connected with its internal economy, in addition to the treatment of its sick, now devolves upon him, we can readily imagine the many circumstances which must often render it necessary for him to depute his purely professional duties to others. Whilst he is toiling after his regiment in the dusty ravines of the Long Valley, his patients fall into the hands of those who have no knowledge of their peculiarities, and who have probably never seen them before; and we have no doubt that the Aldershot case-books could furnish many more instances of that divided responsibility which was so disastrous to poor Orr.

BEARDS IN THE ARMY.

SIR,—Permit me to ask, through the medium of the JOURNAL, whether army medical officers are forbidden by the regulations to wear beards? I believe that combatant officers are compelled to shave their chins; but even this regulation is not strictly enforced, as His Royal Highness the Prince of Wales wears a beard, and he holds a high position in the army as Colonel and Field Marshal.—Your obedient servant,
A MEMBER OF THE ASSOCIATION.

November 4th, 1875.

NAVAL MEDICAL APPOINTMENTS.

DUDLEY, Surgeon John, to the *Foam*.
ISAAC, Surgeon W. D., to the *Seafarer*.
LUCAS, Staff-Surgeon Lemond, to the *Pembroke*.
MACLEAN, Surgeon John C. E., to the *Lynx*.
TERRY, Staff-Surgeon Septimus, to the *Queen*, additional, for temporary service with the *Marines* at *Walmer*.
WHITLEY, Surgeon Alfred W., to the *Fumina*.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners, on November 16th.

Allen, R. G., *Delper*, Derbyshire (Birmingham School)
Angose, W. T., L.S.A., *Hesborough Gardens*, St. Bartholomew's Hospital
Archer, R. K., L.S.A., *Highgate*, Westminster Hospital
Bacon, A. P., L.R.C.P.Ed., *Leeds* (University College)
Bigger, S. F., *Belfast* (Liverpool School)
Bower, E. D., *Leeds* (Leeds School)
Chant, Thomas, L.S.A., *Lowestoft* (London Hospital)
Dennis, Augustine, L.R.C.P.Ed., *Burnham Westgate*, Norfolk (Guy's)
Harvey, T. P., L.R.C.P.Lond. & L.S.A., *Pyrland Road*, W. (London Hosp.)
Hick, Henry, L.R.C.P.Ed., *Wakefield* (Leeds School)
Hutchinson, Joseph, L.R.C.S. Edin., *Luton, Beds* (Manchester School)
Hes, A. R., *Fairford* (St. Thomas's Hospital)
Jacobs, H. R., *Aberdare* (St. Mary's Hospital)
Jenkins, Anselm, L.R.C.P.Ed., *Lauchor*, Glamorganshire (Dublin School)
Kellard, J. T. W. S., L.S.A., *Stoke*, Devonport (Guy's)
Leigh, R. H., L.S.A., *Aberdare*, South Wales (Guy's)
Livy, F. Y., *Bolton*, Lancashire (Manchester School)
Manders, Horace, L.S.A., *Marlborough* (St. Mary's Hospital)
Mason, J. W., M.B. Aberd., *Marston Grantham*, Lincolnshire (Guy's)
Morgan, E. A., L.K.Q.C.P.I., *Liverpool* (Liverpool School)
Phibbs, R. F., L.R.C.S. Ed., *Boundary Road*, N.W. (King's College)
Randle, J. M., L.R.C.P.Ed., *Lizard*, Cornwall (University College)
Simon, K. M., B.A. Cantab., *Nottingham* (Guy's)
Steil, G. R., L.R.C.S. Edin., *Shepherd's Bush* (Liverpool School)
Thain, W. F., *Liverpool* (Liverpool School)
Wilkins, G. H., L.S.A., *Brixton* (St. Thomas's Hospital)
Whitley, E. E., *Birmingham* (Birmingham School)

Admitted members on November 17th.

Amphlett, Edward, M.A. Cantab., *Leamington* (Guy's)
Aplin, Alfred, *Exeter* (University College)
Blake, Henry, L.S.A., *Bedford* (St. George's)
Bowling, C. J. L., *Ramsgate* (St. Bartholomew's)
Brock, C. de L., *Guernsey* (St. Thomas's)
Carrington, R. E., *Brixton* (Guy's)
Edwards, F. S., *St. Peter's Park*, W. (St. Bartholomew's)
Evans, Thomas, L.S.A., *Pwllheli*, North Wales (King's College)
Godfrey, C. W., *Romsey*, (University College)
Harvey, H. F., L.S.A., *Gower Street* (University College)
Heard, C. G., L.S.A., *Tairo* (St. Bartholomew's)
Johnson, W. B., L.S.A., *Vork Road*, S.E. (London)
Kidd, W. A., *Blackheath* (Guy's)
Morshead, E. G. A., *Sidmouth* (University College)
Musgrave, R. E., L.S.A., *Finchley Road* (St. Mary's)
Patmore, T. D., *Hastings* (University College)
Pilkington, Henry, L.K. & Q.C.P.I., *Liverpool* (Liverpool School)
Truman, C. E., *Old Burlington Street* (St. Thomas's)
Woodward, F. E., *Coventry* (St. Bartholomew's)

At these two meetings of the Court, eleven candidates were rejected. Mr. Erichsen, the recently elected member, took his seat on this occasion.

MEDICAL VACANCIES.

The following vacancies are announced:—

ARDWICK and ANCOATS DISPENSARY, Manchester—Resident House-Surgeon.
BIRMINGHAM AND MIDLAND EYE HOSPITAL—Dispenser. Salary, £70 per annum. Applications before the 6th December.
CARMARTHEN UNION—Medical Officer.
CHARING CROSS HOSPITAL—Assistant-Physician, and Physician or Surgeon. Applications on or before the 25th instant.
CHORLTON-ON-MEDLOCK, RUSHOLME, and MOSS SIDE DISPENSARY, Manchester—House-Surgeon.
DENBIGHSHIRE INFIRMARY—House-Surgeon. Salary, £85 per annum, with board, washing, and residence.
DOVER HOSPITAL and DISPENSARY—Resident Medical Officer. Applications on or before the 3rd instant.
EAST SUFFOLK and IPSWICH HOSPITAL—House-Surgeon. Applications on or before December 6th.
GLOUCESTER INFIRMARY—Resident Medical Officer. Salary, £100 per annum, with board, lodging, and washing. Applications on or before the 25th instant.
HOSPITAL FOR THE INSANE, Barnwood, near Gloucester—Assistant Medical Officer. Salary, £100 per annum, increasing £10 annually to £120, with board (exclusive of wine), lodging, and washing.
HUDDERSFIELD INFIRMARY—Physician.
LIVERPOOL INFIRMARY FOR CHILDREN—House-Surgeon.
NORTH WITCHFORD UNION, Cambridgeshire—Medical Officer. Salary, £60 per annum, and extra fees. Applications on or before the 2nd instant.
PARISH OF LISMORE AND APPIN, Lettermore—Medical Officer. Salary, £100 per annum. Applications to the Rev. D. Dewar, Manse, Appin, Argyll.
QUEEN CHARLOTTE'S LYING-IN HOSPITAL, 191, Marylebone Road, W.—Physician to Out-Patients. Attendance at a meeting of the Committee of Management on the 22nd instant, at two o'clock.
QUEEN'S COLLEGE, Birmingham—Demonstrator of Anatomy. Applications on or before the 25th instant—Resident Physician. Salary, £50 per annum, with board, rooms, and washing. Applications on or before the 24th instant.
RADCLIFFE INFIRMARY, Oxford—House-Physician. Salary, £105 per annum, with board and lodging. Applications on or before the 24th instant.
ROSS UNION—District Medical Officer and Public Vaccinator. Salary, £100 per annum. Applications on or before the 22nd instant.
THARSLIS MINES, Province of Huelva, Spain—Medical Practitioner. Salary, £250 per annum. Applications to the Secretary, 136, West George Street, Glasgow.
TONGUE and FARR, District of, County of Sutherland—Medical Officer. Salary, £150 per annum, and house.
TRINITY COLLEGE, Dublin—Professor of Botany. Applications on or before January 22nd, 1876.
WESTMINSTER GENERAL DISPENSARY—Honorary Physician. Applications on or before the 22nd instant.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

BOND, John, L.R.C.P.Ed., appointed Assistant Medical Officer to the Haydock Lodge Lunatic Asylum, Newton-le-Willows.
CROWDANCE, James H., L.S.A., appointed Assistant Medical Officer to the East Riding of Yorkshire Lunatic Asylum, Beverley.
FISHER, Thomas Carson, Esq., appointed House-Surgeon and Apothecary to the Essex and Colchester Hospital, *vice* R. M. Boodle, M.R.C.S. Eng., resigned.
*HAMILL, J. W., M.D., appointed Resident Surgeon to the Working General Dispensary and to the Cottage Hospital, *vice* R. A. Skioener, M.R.C.S. Eng., resigned.
MURRAY, F. R., L.K.Q.C.P.I., appointed House-Surgeon to the Southport Infirmary.
*NETTLESHIP, Edward, F.R.C.S. Eng., appointed Assistant-Surgeon to the Hospital for Diseases of the Skin, Blackfriars, *vice* F. M. Sims, F.R.C.S. Eng., resigned.
RAYENHILL, Thomas Holmes, M.R.C.S. Eng., appointed Honorary Medical Officer to the Birmingham Lying-in Charity, *vice* C. Warden, M.D., resigned.
RIGDEN, Walter, M.R.C.S. Eng., elected Surgeon to the Chelsea, Brompton, and Belgrave Dispensary.
WARDROP, Douglas, M.B., appointed Junior House-Surgeon to the Fiskehead Borough Hospital, *vice* F. R. Murray, L.K.Q.C.P.I.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the communication.

DEATH.

WILSON, George, M.R.C.S. Eng., late a member of the medical staff of the Middlesex County Lunatic Asylum, Hanwell, at 7, Warwick Gardens, Kensington, aged 65, on November 6th.

IN the new Council of the Royal Society, the Medical Sciences are represented by Dr. Hooker, the President, Mr. Huxley, Dr. Gunther, Mr. Wharton Jones, and Dr. Parkes.

It has been decided to erect in Dulwich a trough and drinking-fountain, suitably inscribed, in recognition of the public services of Dr. George Webster, J.P., an old and valued member of this Association.

TESTIMONIAL.—AT a meeting of the Court Duke of Clarence, No. 4, 433, of the Ancient Order of Foresters, Kentish Town, an elaborately carved instand was presented to Dr. R. T. Warn of 37, Ilhigate Road, on behalf of the members, as a token of the high esteem in which he is held, and in appreciation of his services as medical officer of the Court.

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAYGuy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAY..St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAY....St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 3 P.M.

FRIDAY.....Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.

SATURDAY ...St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M. and 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.—Medical Society of London, 8.30 P.M. Dr. De Havilland Hall will exhibit a Pathological Specimen of Tumour of the Liver; Dr. Thorowgood, a Specimen of Cirrhosis of the Liver in a Child, and a New Inhaler and Respirator by Mr. Carrick of Glasgow. Dr. Brunton, "On the Rational Treatment of Tapeworm".

TUESDAY.—Royal Medical and Chirurgical Society, 8.30 P.M. Dr. Pavy will exhibit a specimen of Sugar obtained from healthy Human Urine, and prove its existence by the appropriate tests; Mr. F. H. Welch, "On Aortic Aneurism in the Army, and the conditions associated with it".

WEDNESDAY.—Hunterian Society, 8 P.M. Clinical Evening.

FRIDAY.—Clinical Society of London, 8.30 P.M. Dr. Murchison, "Case of Acute Cancer of the Liver, with Pyæmia, in a man aged 24"; Dr. Murchison, "Two Fatal Cases of Acute Pyelitis and Nephritis, apparently consequent on Gonorrhœa"; Mr. Berkeley Hill, "Case of Amputation at Hip-joint for Fibro-plastic Tumour"; Mr. George Lawson, "Case of Melanotic Tumour of Orbit".—Quekett Microscopical Club, 8 P.M. Mr. T. Charters White, M.R.C.S., "On the Histology of the Hard Dental Tissues".

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with Duplicate Copies.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

THE COMPOUND STETHOSCOPE.

WE have received an interesting communication from Messrs. Ferris and Co. of Bristol, relating to the compound stethoscope made by them from designs by Dr. Spencer of Clifton. It antedates that of Dr. Hilliard, last week described in the JOURNAL, and is an instrument so efficient and noteworthy, that we shall hope next week to be able to devote some space to the description of it, and the discussion of its merits.

ALLOPATHY (Canterbury) must put his question more clearly, and in detail. As he puts it, we do not understand it. The rule that legitimate practitioners do not meet homeopaths in consultation is, we believe, absolute and universal.

QUERIES.

SIR,—Will you kindly inform me—1. Where Dr. Burdon Sanderson's Contribution to the History of Contagion and Morbid Processes of Diphtheria, etc., is to be met with? 2. Where the Registrar-General's Returns may be seen? 3. Whether there is much difference between the actions of the silicated carbon and magnetic carbide filters?

I enclose P.O.O. for medical charities at your discretion. Do not acknowledge by post.—Yours faithfully,

W. L.

* * * 1. In the recent volumes of the *Transactions of the Pathological Society*, and the Medical Officers' Reports to the Privy Council; also in the last volume of the *BRITISH MEDICAL JOURNAL*. 2. The Registrar-General's Reports may be ordered of Hansard, Great Queen Street, W.C., for a very trifling cost. 3. The performances of the two filters are both very good, and are very nearly equal. 4. With our correspondent's permission, we will forward his donation to the Medical Benevolent Fund.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

SPENCER'S COMPOUND STETHOSCOPE.

SIR.—In last week's *BRITISH MEDICAL JOURNAL*, Dr. Hilliard describes a new form of double stethoscope, which has been registered as his invention under the name "head-spring stethoscope". Dr. Hilliard says, with reference to flexible double stethoscopes, "the objections, however, have been, that instruments of this class are too bulky for ordinary practice, and that the acoustic results have been less perfect than the simple wooden stethoscope (*sic*) in almost universal use. These objections, I believe, I have overcome by the instrument I now present to the profession". Dr. Hilliard goes on to describe what we suppose are the means by which he has overcome the acoustic difficulty—viz., by constructing his stethoscope of two simple tubes of finest India-rubber, very smooth and equal in calibre from their attachment to the chest-pieces to the ear-nipples.

Will you kindly allow us to state that the acoustic difficulty had been recognised and overcome by the same means by us prior to Dr. Hilliard's invention? At the meeting of the British Medical Association, held in London in August 1873, we exhibited a new form of flexible double stethoscope, designed by Dr. Spencer of Clifton, and manufactured for him by us. Two essential features in this, our "compound stethoscope", were, "smoothness of interior and uniformity of calibre throughout the tubes". These features expressed principles of construction which, we believe, then for the first time, were asserted and applied as necessary to the production of accurate acoustic results in any tubular stethoscope. The following extract from our prospectus explains our position. "Principles of Construction. 1. It provides accurate acoustic communication between the ears and any area it may be desired to auscultate, so that sounds are conducted without loss of intensity, and without modification of their characters. The acoustic medium is air; it is enclosed in two long tubes, having a smooth interior, and throughout of the same calibre as that of the auditory canals. The interior of the tubes is smooth, in order that reflection may be regular, and transmission of sound rapid and perfect. Uniformity of diameter prevents unpleasant humming from reinforcement of sound by resonance. . . . From the chest-wall to the external opening of the auditory canals, and thence to the tympanic membrane, extends, for each ear, a perfectly conducting column of air of uniform diameter." This was taken from Dr. Spencer's paper, read before the Bath and Bristol Branch of the British Medical Association in November 1873 (of which a first instalment was afterwards published in the *JOURNAL*), in which the acoustic principles were fully discussed. Soon after the introduction of Dr. Spencer's stethoscope, a specimen of Dr. Hilliard's "head-spring stethoscope" came into our hands. This, by a letter from Dr. Hilliard in last week's *Lancet*, would appear to have been "one of my earliest and very imperfect attempts at the production of a binaural stethoscope with head-spring", brought out, he says, about two years ago. In that earlier form there is no trace of the recognition of the principles laid down by Dr. Spencer, which Dr. Hilliard has adopted in his later form recently registered.

Dr. Hilliard may have arrived at the principles of construction of his stethoscope quite independently. We have no wish whatever to insinuate that he has not; but we think it is due to the inventor of the compound stethoscope (who has refrained from protecting his invention by registration or patent) and to ourselves, to point out that the two features of Dr. Hilliard's stethoscope referred to have been anticipated.—We are, your obedient servants,

FERRIS AND CO.

Union Street, Bristol, November 15th, 1875.

MANCHESTER PROVIDENT DISPENSARIES' ASSOCIATION.

SIR.—Mr. O'Hanlon's expected reply to my remarks of October 16th, appears in your issue of November 6th. I hasten with pleasure to place the truth of the whole matter before your readers, especially as your paragraph elsewhere in the same issue gives credit for great frankness and moderation to Mr. O'Hanlon, and throws doubt on the views to which you kindly gave insertion in my first communication.

I may state at the outset that I, and all who joined the Provident Dispensaries' Association, did so with the firm conviction that the principle involved was a good one, and that if it could be worked successfully, should be fairly tried; and our co-operation with the General Council was evidence of desire and willingness to assist in the attempt. As I hope to submit complete details of the working of the scheme on a future occasion, I shall in this letter limit myself, as far as possible, to general statements, and answer Mr. O'Hanlon's assertions *seriatim*.

Mr. O'Hanlon says, "a number of these friendly societies applied for admission" to the Association. Of all the clubs in Manchester, only two of any importance made such an offer; and these had been sounded, and *indirect* pressure brought to bear on them previously. Their desire to join was not entirely spontaneous, nor is there any special wish on the part of Manchester clubs to join in the scheme; they are not less satisfied with their medical attendants here than elsewhere. Many of the practitioners holding clubs in this city can give evidence of having had their societies actively canvassed to join the scheme, by the collectors and other officials employed by the Association. Is this fair to those joining the provident scheme, or to those outside it, when the terms of the Association do not allude to the admission of friendly societies? do not even contain a saving clause by which they might be introduced hereafter? and finally, in the face of a distinct statement made to several practitioners who asked before joining the scheme, whether the Council had any intention of admitting clubs, and received a reply in the negative? Is not this a violation of the spirit of the agreement upon which we were invited to join the Association? Mr. O'Hanlon acknowledges that the wage limit of club-members infringes "the limit fixed by the rules of the scheme" for ordinary members. The Council, therefore, introduce two classes of provident patients in receipt of two distinct wage amounts, practically violating the terms of the original scheme.

Mr. O'Hanlon next describes how a general meeting was summoned to consider this subject. I can assure him that only a portion of the medical staff received any written invitation. Of those invited, four were present. The resolution was passed and published after a single meeting, although medical men present protested strongly against it, and stated their reasons; that it was likely to be injurious to those holding clubs, to those outside more than to those inside the provident scheme; that it was contrary to the original intentions of the Association, and that it forced medical men outside to join the Association unless they wished to lose their clubs *in toto*. This was the only general meeting at which the medical staff had any opportunity of considering so important (to them) a subject; and then they were completely ignored, and hardly listened to, for the simple

reason that the Council had made up its mind to pass the resolution *volens volens*. The medical men expected this treatment from previous experience, and many considered it useless to attend, especially as they had frequently, in private conversation with Mr. O'Hanlon and several members of the Council, strongly expressed their objections to the resolution, and urged its withdrawal, in order that the general scheme might not be jeopardised. This opposition to the resolution was embodied in the form of a protest, drawn up and signed by twenty-one out of twenty-three medical officers, at a public meeting held for the purpose.

After these facts, how can Mr. O'Hanlon say, "The Council would have yielded at once in the present dispute, had there appeared any reasons for supposing that it was acting in opposition to the just interests of the profession"? Mr. O'Hanlon next says, "that the subject was again discussed by the Council, and on the recommendation of two of our leading medical men, managers of the two largest hospitals", it could not be rescinded. None of the medical staff were invited to this meeting; and the two medical men referred to—one the superintendent of the Infirmary, the other senior physician to a Children's Hospital—have no clubs, probably never had any; are not in general practice; know little or nothing of the difficulties and worries of general dispensing practice; and of whose sympathy with the feelings of the profession the less said the better. Would it be believed, from the "moderate" tone of Mr. O'Hanlon's letter, that not a single representative of the class whose interests are seriously affected had been placed on the original Council? Since our resignation, it has been acknowledged that this was a mistake on the Council's part, and *in future* they intend to elect one from each dispensary staff. This is a specimen of the "greatest consideration for the interests of the profession", "the Council's conduct has always been guided by the opinion of its medical men", which Mr. O'Hanlon so courageously announces in his letter. In fact, we are called in to see the body medical, bruised, battered, and butchered, and to sign a death-certificate. After all has been settled, we are asked to express an opinion *pro or con*.

Mr. O'Hanlon is quite at sea when he says "pressure was brought to bear" on the staff by some of its members, and by some club-doctors. Nothing of the kind occurred. The question at issue was the obnoxious resolution, and its consideration was limited to the medical officers of the Association. Mr. O'Hanlon's remark about "trades-unionism" in the movement we can well afford to overlook.

The Council, not satisfied with the overwhelming evidence from their medical staff, that they urgently requested the withdrawal of the ill-advised resolution, again invited them to listen to the Council's foregone determination. Need I say the medical officers declined in a body to assist in such a farce, and informed the Council by letter that they had expressed their objections to the resolution, that their protests were systematically ignored, and that they must adhere to their resignations.

What Mr. O'Hanlon means by his remark, "that it would now be more difficult to carry on the dispensaries, unless radical alterations were made in the conditions on which medical men *may* become connected", etc., I do not know; it looks very like a threat to future freedom of action.

With regard to Mr. O'Hanlon's fiscal view of the admission of clubs, I find that most of the club-doctors here consider 6d. to 8d. out of 3s. per head sufficient to cover the cost of medicines, etc., taking into consideration the small number seriously ill; and that from distance and other causes, many never require the club-doctor. Therefore, 2s. 6d. or 2s. 4d. reach the pockets of the medical man in private practice, under the Provident Association only 2s. 2d., with the additional disadvantage of the club being divided amongst the entire staff; and though portions of several friendly societies be given to the doctor, it is highly improbable that it will pay as well as in private practice, and there it is at a sufficiently low scale already. The Council, however, nullify their own arrangements, by stating in one clause of their terms for admitting clubs, "that an *entire* club must join", and in another, refer to "such members of a club as may *choose* to join".

Mr. O'Hanlon mentions the remuneration made, and to be made, out of the Association. I will give a few examples. One medical man received £4 os. 6d. for three months' work, consisting of a hundred and three home visits and one hour a day at the dispensary, and extra consultations at his house. Another, with two hundred and fourteen families on his list, paid an average of fifteen visits a day, two to three hours' consultation, and for six months received £10. Other examples will be given in a future article. The doctor referred to by Mr. O'Hanlon, as receiving £250, is worried to death with a list of two thousand patients, and can have but little time for private practice, or anything else.

Mr. O'Hanlon concludes his letter with an advertisement for surgeons to fill the places of those who have almost unanimously sacrificed their interests in the general scheme to carry out a movement for the common good. This is at least most undignified, and will not be overlooked by the profession in Manchester, which, he states, is overworked, but certainly not overpaid, as far as it has any connection with the Provident Dispensaries' Association. The number of persons now being admitted, the amount of whose incomes should exclude them from the Association, is rapidly becoming serious to private practitioners, and I am furnished with lists from medical men of cases coming to their knowledge; nor is this to be wondered at, when the collectors are paid by commission on the amounts they collect, and the new members they enrol. It is to their interest to obtain adherents, and they canvass entire streets at a time, urging people to join who are private patients of neighbouring practitioners, and in receipt of large incomes, adding that "they must make up their commission to such and such sums". It is very difficult for the provident medical officers to correct this grievance, as, by remonstrating with the patients, or informing the local committee, they lose their clients altogether.

There are many serious grievances, which I shall leave others to lay before you; but in correcting Mr. O'Hanlon's misleading letter, I have mainly dealt with the cause of dispute, apart from the general principle of provident dispensaries. I trust that the Council will see fit to detach their resolution concerning friendly societies from the body of the scheme, though it is hardly to be expected from a Council a member of which expressed to me his "regret at the spirit of opposition to the profession which it exhibited".—I am, sir, yours, etc.,

CORRESPONDENT.

MEDICAL ETIQUETTE.

MRS. X., of her own accord, requests Dr. A. to visit Dr. B.'s patient. Dr. A. calls on Dr. B., who is from home, and leaves a note, informing him that he has done so, and prescribing a course of treatment. Mrs. X., through the medium of a third party, asks Dr. B. if he has complied with Dr. A.'s suggestions. Give an opinion of Dr. A.'s and Mrs. X.'s conduct, both unknown to Dr. B., and inform Dr. B. how to act towards both.

* * * 1. Dr. A. ought not to have seen Dr. B.'s patient except in consultation with Dr. B. 2. Dr. B. may properly decline to act upon Dr. A.'s advice until after consultation.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, no later than *Thursday*, twelve o'clock.

ROYAL COLLEGE OF SURGEONS.

THE first primary or anatomical and physiological examination for the diploma of membership of the Royal College of Surgeons for the present session was commenced on Saturday last, when forty-one candidates offered themselves, to whom the following questions were submitted:—1. Describe the changes which the blood undergoes in passing through the capillaries of the skin and of the lungs. 2. What is the minute structure of adipose tissue? and what purpose does fat serve in the animal economy? 3. Describe the portions of the bones which form the elbow-joint, and the ligaments which connect them. 4. How would you proceed to display the muscles of the tongue? Give their respective attachments and nervous supply. 5. Describe the structure of the scalp, including its arteries and nerves. 6. In what region is the caecum situated? Describe its connections with the adjoining parts of the alimentary canal, and its structure.—Candidates were required to answer four (including one of the first two) out of the six questions.

MR. WOOD (Shrewsbury).—We agree in considering that the "popular treatise" circulated by "Dr. Eldridge Spratt" is a most unprofessional production; and it is greatly to be regretted that the "Earl of Glasgow" should allow his name to be used in such a connection.

SHROPSHIRE SUPERSTITION.

ONE of the witnesses in a recent disputed will case, who was present at the testator's death, deposed that as the deceased, who was upwards of seventy years of age, was "dying fast uphill", as she termed it, his feet were put into hot water, it being a belief in Shropshire that such an application expedites a dying man's end.

ERRATUM.—In the account of Introductory Addresses at the Dublin Schools (page 623 of last week's JOURNAL), Mr. Thornley Stoker was by accident misprinted Thornby Stotar.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Hastings and St. Leonard's News; The Belfast News-Letter; The Sheffield Daily Telegraph; The Chester Guardian and Record; The Hereford Times; The Bristol Daily Post; The Evening News; The Sheffield Post; The Metropolitan; The Blyth Weekly News; The Edinburgh Daily Review; The Glasgow Herald; The Western Daily Press; The Merthyr Telegraph; The Leighton Buzzard Observer; The Bristol Daily Times and Mirror; The Derby and Chesterfield Reporter; The Lincolnshire Herald; The Sunderland Daily Echo; The Co-operative and Financial Review; The South Wales Daily News; The Macclesfield Courier; The Melbourne Argus; The Southampton Times and Hampshire Express; The Jarrold Express; The Birmingham Daily Post; The League Journal; The Sheffield and Rotherham Independent; The Derbyshire High Peak News; The Liverpool Daily Courier; The National Food and Fuel Reporter; The Worcester Herald; The Norfolk News; The Worcester Chronicle; The North British Daily Mail; The Social Science Review; The Carlisle Express; The Sussex Daily News; The Royal Leamington Spa Courier; The Bethnal Green Times; The South London Press; The Hampshire Advertiser; The Worcestershire Advertiser; The Newcastle Weekly Chronicle; The Worcester Journal; The Hobart Town Mercury; The Weekly Times; The Mid-Weekly Hampshire Independent; The North British Mail; The Western Mail; The Redruth Times; The Indian Statesman; The Birmingham Morning News; The Cork Constitution; The Sunday Times; The Naval and Military Gazette; The Broad Arrow; The Thame Advertiser; etc.

* * * We shall be greatly obliged if correspondents forwarding newspapers will kindly mark the passages to which it is desired to direct attention.

COMMUNICATIONS, LETTERS, etc., have been received from:—

Dr. J. Matthews Duncan, Edinburgh; Mr. Sydney Henson, Manchester; Dr. F. Gordon Brown, London; Dr. F. J. Brown, Rochester; Dr. Stirling, Edinburgh; Mr. George Rigden, London; Mr. F. Lowndes, Liverpool; Dr. David Young, Florence; Dr. Thomas Cole, Bath; Dr. Edis, London; J. H. J.; Mr. Eastes, London; Mr. J. W. Groves, London; Mr. W. Fairlie Clarke, London; Dr. J. CLINICAL LECTURE

ON

VARICELLA-PRURIGO.

By JONATHAN HUTCHINSON, F.R.C.S.,

Senior Surgeon to the London Hospital, and to the Blackfriars Hospital for Skin-Diseases.*

I MUST not weary you by the citation of individual cases; but I have yet one or two others to which I wish to call your attention.

Three children in one family had chicken-pox at Christmas 1869. The two elder were well in a week; but the youngest, then six months old, had his eruption pass into "strophulus pruriginosus". He was brought to me in the following April, still covered with rash. It was of the characteristic form, beginning in some places as papules, and in others as bullæ. Many of the papules still looked like scratched lichen; but, in many, ulcers or excoriations of considerable size had formed. The largest bullæ had, as usual, occurred on the feet and legs; some of the most characteristic on the soles. He had lichen eczema on the face and ears, and porrigo on the occiput. In spite of it all, he had thriven pretty well. His nights had often been much disturbed. He was still at the breast, but was fed also on a variety of food. He had never been vaccinated, having in early life had "much tightness of chest". He had cut six teeth, four before the eruption. He had no kind of eruption before he had the chicken-pox. The vesicles of the latter were very abundant. His mother's expression was, "The chicken-pox never really died away, and every spot festered and went into one of those that he now has". It should be stated that the eruption was specially copious across his loins.

You will observe that the fact as to the eruption having really begun in chicken-pox is very strong in the above case, for three children had it at the same time. It is equally so in the following; the father of the patient being a medical man, and having watched the eruption from the first.

A well known physician, whom I chanced to meet one evening a few weeks ago at a medical assembly, asked me: "Have you ever known chicken-pox last for a year?" "Yes," I replied: "I have just been preparing a lecture on the very subject." "Well," he said, "one of my own children had, a year ago, a most undoubted chicken-pox eruption; and she continues still liable to the appearance of spots." This patient, a girl of about eight, was brought to me a few days afterwards; and I found that she presented a mild example of the disease under consideration. Scattered over the surface were a number of spots which had begun as papules or abortive vesicles, and were now abraded by scratching. They had been very troublesome from itching. The spots were not nearly so numerous as in many other of my cases, but they were quite characteristic.

I might add many more cases to the above list if it seemed advisable; for the eruption is by no means a very rare one. I think, however, I have adduced enough evidence to prove my point, and to illustrate most of the peculiarities of the eruption in question. In order to facilitate the comparison of cases, and to show more clearly what the facts are respecting the age of the patient, the antecedents of the eruption, and its duration, Mr. Nettleship has kindly arranged for me, in tabular form, the cases already given, together with a number of others of which I have the notes. We have compiled two tabular statements; one containing cases in which the original eruption was diagnosed as varicella; and the other, those in which it followed vaccination.

The first list, comprising cases in which the eruption followed varicella, or varioloid, contains sixteen cases, ten of which were in boys, and six in girls. The youngest was six weeks old, and the oldest seven years, at the time of the original attack. In five, the eruption had lasted

for a year or more when the patient first came under observation; and in all it proved very intractable. I can, indeed, only in a minority, assert that anything approaching to a cure was effected. In almost all, however, much benefit resulted; and there appeared reason to think that, in the end, the disease would be conquered. Several of them attended under treatment, however, through many months. In all, the eruption was much alike: a mixed papular and vesicular rash, symmetrically arranged, avoiding the flexures, very pruriginous, and prone to affect the soles and palms. This last point easily distinguishes the eruption from the other forms of prurigo, and also proves that the eruption is not a lichen. Lichen being a chronic inflammation of the hair-follicles and their adjuncts, cannot, of course, occur in parts where no such structures exist.

TABLE I.—Cases of Prurigo following Variella.

Name.	Age at admission.	Duration at admission.	Remarks.
1. Alfred Vernon (Case viii.)	2 years	15 mos.	Began suddenly, and the mother was told it was chicken-pox. Attended 12 months. (In the report of the case given last week the age at which the eruption began is stated to have been 3 months: it should have been 9 months)
2. James Quinlan.....	7 months	5½ mos.	Began as modified small-pox. Under care 8 or 9 months.
3. Anne Cridland..... (Case xi.)	3¼ yrs.	15 mos.	Liable to the eruption since varicella at the age of 2 years.
4. Frederick Manger .. (Case ix.)	1¼ yrs.	9 months	Mother thought it chicken-pox at first, but the doctor said it was not that disease. Attended 4 months.
5. Rosina Childs..... (Case i.)	18 mos.	4 months	Began all over the body at once, and the doctor considered it to be small-pox. Attended 5 months.
6. Sarah Tosland..... (Case iv.)	19 mos.	14 mos.	Began gradually in summer. The mother thought it chicken-pox. Attended 2 months.
7. Walter F. Seymour.. (Case vi.)	12 mos.	No note	Was taken in the first instance for chicken-pox. Attended 2 months.
8. David Forster.....	3 years	2¼ yrs.	The medical attendant called it "glass-pox" when it began at the age of 8 mos. Attended 11 mos.
9. Georgiana Langton..	2¼ years	3 to 4 ms.	Began as large blisters, "like vaccination marks" or "chicken-pox". Attended 1 month.
10. Frederick Tothem ..	3 years	4 months	Some considered it "small-pox", others "chick-n-pox", in the first instance. Attended 2 months.
11. Sidney Lee.....	3 years	3 months	Two doctors said it was a bad case of chicken-pox at first.
12. Charles Bell.....	14 mos.	2 weeks	Began 2 weeks ago as "chicken-pox".
13. Richard Bathurst ..	2 years	6 months	Began like small-pox. Attended 3 months.
14. George Thornton... (Case detailed above)	3 months	6 weeks	Supposed at first to be small-pox, but was probably varicella. Had not been vaccinated.
15. Private Case (M)....	6 months	4 months	Began as undoubted varicella.
16. Dr. G.'s case.....	8 years	1 year	Undoubtedly varicella at first.

It is with very great regret that I bring forward any facts which tend to show that ill consequences do occasionally ensue from vaccination. But in this, as in all other matters, it is far better to know and to make known the real truth. I feel no doubt that varicella does not unfrequently leave a most troublesome prurigo; and I feel equally little that vaccination does, in some of the rare instances in which it is attended by a varicella-like rash, leave a similar ill consequence. The eruption under the two conditions seems to me exactly alike. During the last six months, a number of cases have been sent to me at the Blackfriars Hospital by a committee of philanthropic ladies who are engaged in visiting the poor, with especial reference to the prevention of disease. Having been informed by them that they met with much prejudice to vaccination, and frequent assertions that skin diseases were caused by it, I offered to receive and investigate (and, if possible, cure) all cases of the kind which they would send to me. I was already well aware of the relations existing between vaccination and this form of prurigo; but I quite expected that the majority of the cases I should get would be eczema and porrigo. Such has not been the case, however; and all the cases as yet sent (only, I think, about six or seven) have been examples of the form of prurigo to which this lecture is devoted. Some of them have been very marked cases, and of long persistence.

The following table exhibits the chief facts as to age of patient and duration of eruption in twelve cases which seemed to be more or less closely connected with vaccination. The rash was of the same character as I have described in connection with varicella. It may be

* Concluded from page 632 of last number.

observed that, in several of the cases, the interval alleged to have occurred between the vaccination and the rash was so long as to throw some doubt upon the connection between the two. It is only in those instances in which the rash follows promptly that I would with confidence infer a connection.

TABLE II.—Cases of Prurigo following Vaccination.

Name.	Age at admission.	Duration at admission.	Remarks.
1. Samuel Bristowe... (Case x.)	15 mos.	8 months	Came directly after vaccination; but the medical man said it was chicken-pox. Attended 18 months.
2. Sarah Ellis.....	2 years	18 mos.	Vaccinated at the age of 6 months. Eruption began immediately afterwards. Attended 3½ months.
3. George Humphrey..	14 mos.	11 mos.	Began after vaccination at 3 mos. Attended 3 months.
4. Edward Barfoot... (Case ii.)	16 mos.	13 mos.	Began after vaccination at 3 mos.; was called "glass-pox" by the medical man. Attended 2 months.
5. Sarah Richardson.. (Case iii.)	11 mos.	5 months	Vaccinated at 6 months. Eruption began soon after. Vaccination did not "take". The Mother thought the eruption chicken-pox. Attended 2 weeks.
6. Martin Lewis.....	2½ years	abt. 2 yrs.	Said to have been present since vaccination.
7. Isabella Brown..... (Case v.)	12 mos.	5 months	Came out soon after vaccination. Attended 2 months.
8. Walter Thompson.. (Case vi.)	19 mos.	3 months	Vaccinated at 15 months. Eruption began 3 weeks afterwards.
9. William Welch.....	6 months	2½ mos.	Began 2 weeks after vaccination. Attended 7 weeks.
10. Sydney Woolford..	15 mos.	9 months	Vaccinated at 5 months. Eruption began a month later. Attended 4 months.
11. Caroline Duffell... (Case vii.)	10 mos.	2 months	Vaccinated at 7 months. Eruption began a month later. Attended 3 months.
12. Dr. Flack's patient.. (Detailed above)	Vaccination at 3 months, followed in about 2 weeks by eruption, which Dr. F. considered to be chicken-pox. The child died from the eruption after it had lasted 5 months.

It is difficult to speak with any degree of confidence as to the precise nature of the links which connect this eruption with variella. In attempting to investigate them, I must ask you to remember that variella presents certain curious tendencies which it does not fully share with the other exanthems; chief amongst these we must note that its stages vary in duration very greatly in different cases. Thus, its stage of incubation, which most count as eight or nine days, may, according to Trousseau, extend even to twenty-seven, and is rarely less than fifteen. Its stage of invasion, rarely more than twenty-four hours, may sometimes be three times as long, and its exanthem or eruption stage may, instead of observing the average duration of three or four days, be protracted over ten or twelve. I have myself seen a rash exactly like fading chicken-pox, which was said to have been out a month. The belief that in this instance the rash really was chicken-pox was supported by the fact of its spontaneous disappearance almost immediately afterwards. I have already alluded to Professor Trousseau's mention of the Necker Hospital epidemic, during which some cases were followed by pemphigoid rashes, which lasted a month or six weeks. It becomes a question whether, in these protracted cases, the eruption is throughout the same as at first. In some, as in Trousseau's, it probably differs; but in others, as in my own case of one month's duration, there are no features by which it can be distinguished. Now, if the true variella eruption which has usually a four days' duration, may be protracted to four weeks, there is, perhaps, no definite limit to what is possible as to its stay. These cases may, then, be simply abnormally protracted and extremely pruriginous variella rashes. There is, however, I believe, no reason for believing that such cases continue to be infectious after the first stage. The febrile stage ceases when the pruriginous one begins, and the hypothesis seems more probable that they ought to be regarded as sequelæ of the exanthem, and not as in any strict sense continuations of it. Another hypothesis is that the outbreak of variella in some way so affects the nerve-structures of the skin as to induce a state of pruriginous irritability; to aggravate, indeed, what is often a personal peculiarity, a tendency to itch on the slightest provocation. But the eruption which I have been describing is something more than can be so explained. Its single spots often closely resemble those of variella, and they differ in their vesicular tendencies from those of all other forms of prurigo. I cannot help believing that they result from the same process in the skin-tissues as that which causes the vari-

cella eruption, and that they probably originate in precisely the same parts. Otherwise, it would be most difficult to explain their peculiarities of appearance. We come thus to the question, what are the peculiarities of the variella spot? That they differ much from all other eruptions will be readily admitted, and that their differences are more than merely those of size and shape is rendered certain by the very curious fact that their contents do not contain the germ material from which the disease is reproduced. It is generally believed that you cannot inoculate chicken-pox. In external appearance, a variella vesicle remarkably resembles one of herpes. This similarity has not escaped Trousseau. They are further not unlike herpes in their duration, rapid decline, and mode of healing. Just as in herpes, we occasionally have long protracted pain in the part, so in variella we have occasionally long protracted itching. The parallel fails in this, that we have no such thing as protracted vesicular eruptions in herpes; it is the pain alone which lasts. We know that herpetic eruptions are produced through the agency of sensory nerve-filaments; it is even possible that they may arise over or in nerve-papillæ. It is just possible then, following this line of suggestion, that the variella vesicle originates in irritation of a nerve-papilla. I admit that this is a mere conjecture, but it seems to me not unpalatable, and we need some theory by which to explain our facts.

It is necessary, however, to keep in mind a few other general facts in reference to prurigo, if we would master the whole of the bearings of these curious cases. Even if we grant the suggestion that, as herpes may leave its well known after-pain, so may variella and allied eruptions leave their after-prurigo, we have scarcely explained the whole matter. The next fact which we must acknowledge is, that prurigo, from whatever cause it may have begun, tends to perpetuate or even to aggravate itself. It causes itching, and the itching causes scratching, and the scratching extends the prurigo, and thus the patient goes on from bad to worse. This is true of all forms of prurigo, whether beginning from lice, from fleas, from woollen clothing, half-cured scabies, or from some internal cause. If we could entirely prevent scratching, very few prurigos would assume a severe type. This being so, we can easily explain the alterations which these cases undergo when they persist long. At first, it is probable the rash is really a protracted variella attended with prurigo; its vesicular character proves it to be such; and it may even be the case that the prurigo element is but small. The longer the case persists, however, the less does it preserve the aspect of variella. Vesicles cease to appear, and pruriginous papules take their places; the palms and soles no longer show the eruption, which is almost confined to the parts on which the prurigo of infants (strophulus pruriginosus of authors) is common. It is in these later stages that the diagnosis from strophulus, which was easy at first, becomes difficult, and is, indeed, to be based chiefly on the history of the initial period.

You will notice that these cases all occur at an age at which pruriginous affections are common, and at which restraint as to scratching is almost impossible. They have, indeed, hitherto been counted by dermatologists amongst the considerable group of infantile skin-affections known as lichen infantum, lichen pruriginosus, lichen urticatus, and strophulus pruriginosus. These maladies, or this malady, for they are closely similar diseases, have, as yet, been only named and described; little or nothing has been done as to the suggestion of causes. I am convinced that the facts which I have stated to you to-day give us the clue to the real cause of a large number of them, and I shall not be surprised if, in the future, we are able to extend it to a much larger number than we at present feel justified in allotting to it. The age at which infantile prurigo is met with is the age of children's exanthems; and, although variella appears to stand pre-eminent amongst those which are capable of throwing the skin into a pruriginous condition, it is probably not the only one. I have several times, indeed, known measles assigned as the parent of a long persistent prurigo; and the other exanthemata (perhaps even abortive exanthemata) may sometimes stand in the same relation. It is for the present the general principle only for which I contend; the details of its extent of application we must determine hereafter. That principle is, if you will excuse the repetition, simply this, that *variella, varioloid, the rash which sometimes attends vaccination,* and possibly other exanthems, possess the power in exceptional cases of making the skin irritable, and thus laying the foundation for long continued and most troublesome conditions of prurigo; to which I must add, that this consequence is especially apt to ensue when, as is not infrequent in variella, the eruption is long protracted, and occurs in successive crops.*

* It was to my friend Mr. Ceely of Aylesbury that I was indebted, some years ago, for a knowledge of the fact that an exanthem rash does occasionally show itself after vaccination. I find the fact mentioned both by Ballard and Hebra; and it appears to be well established. It is probably not very common; for I have been assured by experienced vaccinators that they never witnessed it.

ON THE PREVENTION AND MANAGEMENT OF MISCARRIAGES.*

By ARTHUR W. EDIS, M.D.,

Assistant-Obstetric Physician to the Middlesex Hospital; Physician to the British Lying-in Hospital, etc.

IN the following remarks, the term miscarriage is used synonymously with abortion, and is intended to apply to all cases where the ovum is expelled from the uterus before the seventh month; before, in fact, the fœtus has acquired sufficient development to maintain a separate existence.

The subject demands more careful consideration than is usually accorded to it; for miscarriages are far more frequent than is usually supposed. The life of the fœtus is invariably sacrificed, and the mother's life often jeopardised. Even when this latter is not the case, the fecundity of the female is often seriously interfered with; numberless instances of so-called acquired sterility being dependent upon the neglect or carelessness of the patient following a miscarriage.

Apart from this also, much serious discomfort and suffering, through many long years, from uterine disorder, is often entailed from want of a little judicious advice and assistance at the time. Many a valuable life has been sacrificed, and many years of suffering and unhappiness produced, in consequence of making light of a miscarriage, either willfully or ignorantly. A fresh conception is allowed to occur before the process of involution has been completed, abortion following again as a certain consequence, until the severe hæmorrhage, anxiety, and confinement to the house call forth inevitably any latent disposition to tubercle or other hereditary disease; and, whilst sorrowing for the life thus prematurely cut short, or vainly regretting the blighted hopes of a fruitful marriage, the knowledge that this depended merely upon a neglected miscarriage will prove no solace to the friends or comfort to the sufferer.

It has been my lot to observe numberless instances where miscarriage after miscarriage has been allowed to take place without a vaginal examination ever having been resorted to, or any attempt made to ascertain the causal condition of this premature expulsion of the ovum; no instructions having been given to the patient as to what precautions should be taken to avoid similar catastrophes, no injunctions as to resting in the horizontal position, or living *absque marito* until the process of involution has had time to be accomplished; in fact, the whole affair being treated as if it were not worthy of serious consideration by the practitioner, or of any moment to the patient.

Dr. Whitehead estimates that over 37 per cent. of mothers abort or miscarry before they attain the age of 30 years. Dr. Meadows, from a collection of about two thousand cases in hospital practice, found that about one woman in every three and one-fifth aborts.

In a series of nearly 2,000 cases of my own hospital patients at all ages, where the facts had been carefully recorded, there were no fewer than 1,147 miscarriages compared with 4,588 children born at full time—a proportion of exactly one in four. This ratio I find to be as nearly as possible the same among my private patients, the increased development of the nervous system among the upper and middle classes compensating for the diminished risk from the accidents which affect the poorer classes.

In the large majority of cases of miscarriage, they will be found to be due to some deranged state of the mother's health, or to some morbid condition of the uterus or its appendages. There are also many what may be called accidental causes, such as blows, falls, sudden agitations from fright, etc., which disturb the equilibrium of the circulation or strongly affect the nervous system. These are self-evident, and will not be here further referred to, inasmuch as, beyond enjoining avoidance of all unnecessary risks when patients are in the early stage of pregnancy, we can scarcely regard these as preventable causes. I am anxious rather to direct attention to the unnecessary waste of life resulting from the frequent recurrence of miscarriages in the same patient, where there is some deranged condition of the uterus or its appendages: causes that may be termed preventable.

The hope of preventing the recurrence of miscarriage depends upon our tracing out—what in every case exists—the efficient cause of it. It is useless to sit down disarmed and passive under the influence of that ignorant dogma which asserts that women have a habit of abort-

ing; that they are labouring under an abortive diathesis. This is no more than saying that women abort because they abort, which is not very instructive, and leaves us still in ignorance of the cause of this often preventable habit.

Syphilis is so frequent a cause of premature expulsion of the fœtus, that Bunnsted, in his work on *Veneral Diseases*, says:—"Repeated abortions form a valuable element of diagnosis in the investigation of suspected cases of this disease in married life." It is rarely that we have a clear and distinct history of syphilis given; for naturally the husband says nothing about it, even when he suspects anything; and the wife, ignorant of the importance of certain primary symptoms that have been allowed to pass almost unnoticed, lays no stress upon them, and is innocent, indeed, of the very existence of such a disorder. We must, therefore, rely upon the objective symptoms, and not trust alone to the subjective. The intelligent practitioner will generally be able to recognise certain well known symptoms that will afford a clue to the nature of the case, such as pallor of the countenance, languor, precarious appetite, sore-throat, falling out of the hair, more or less emaciation or deterioration of the general health, numerous aches and pains, together with local evidence of constitutional infection in the form of endometritis or granular degeneration of the cervix, together with hypertrophy and induration of this portion of the uterus, evidenced by leucorrhœa, menorrhagia, dysmenorrhœa, and numerous other symptoms. Where, in such a case, we have the history of perfect health and vigour preceding marriage, and there have been repeated miscarriages since, we need have no hesitation in at once placing our patient on a mercurial course. It has sometimes been supposed that the cause of the miscarriage in these cases was not the syphilitic taint, but the mercurial treatment to which the patient may have been subjected. This opinion, however, is erroneous. The careful administration of mercury to a pregnant woman affected with syphilis affords the surest protection to her child; and it is very rare for this mineral to produce abortion, unless given injudiciously and in such a manner as to irritate the stomach or intestines. When both parents are affected with syphilis at the time of conception, and the mother does not receive appropriate treatment in the early months of pregnancy, the fœtus will rarely be carried to the full term of gestation.

In administering mercury to pregnant women, the perchloride is to be preferred. The chief reasons for this selection are the ease with which it can be taken, the almost certainty that it will not produce salivation, and the length of time for which it can be persevered with. Under its influence, the patients regain a state of sound health to which they have long been strangers; they increase considerably in weight, their secretions become perfectly natural, and they eat, sleep, and digest well. Moreover, they lose that fearful mental depression which is a frequent result of the contaminated state of the blood. The dose should vary from one-sixteenth to one-eighth of a grain, given in the form of a pill or in solution with bark.

Metritis, in some form or other, is a very frequent cause of miscarriage as well as consequence. Dr. Bennet, in his valuable treatise on *Inflammation of the Uterus*, says that inflammatory ulceration of the cervix during pregnancy is of frequent occurrence, and is the key-stone to diseases of the pregnant state, and the most general cause of laborious pregnancy, obstinate sickness, miscarriages, and hæmorrhages. Dr. Whitehead also lays much stress on an inflammatory condition of the cervix being a frequent cause of miscarriage. Dr. Tilt, in his *Uterine Therapeutics*, says:—"Inflammation of the womb is frequently produced by abortion or parturition; and I am certainly not overstating the fact in affirming that two-thirds of the serious cases of uterine inflammation can be traced to a bad miscarriage or confinement." The prevention, therefore, of uterine disease in married women is tantamount to the judicious management of pregnancy, abortion, and parturition. Did time permit, I could quote numerous authors in support of this statement; but those who have any knowledge of the subject will, I am sure, deem this unnecessary, and those who have not may accept the statement that inflammatory mischief, whether in the cervix only or in the uterus generally, is not only a frequent concomitant, but also very often the cause of miscarriage.

Aptitude for conception is not at all incompatible with inability on the part of the uterus to undergo the requisite changes that take place during pregnancy. It must not, therefore, be considered that, because a patient becomes pregnant, there can be no serious inflammatory mischief; and, when this fact has not been recognised until pregnancy has actually occurred, there is no reason why treatment should not then be resorted to.

Patients frequently consult us complaining of nausea, constipation, bearing-down, menorrhagia, leucorrhœa, burning pain in the left iliac region, and other well recognised symptoms. On examination, we find the uterus enlarged to the third or fourth month of pregnancy,

* Read before the Section of Obstetric Medicine at the Annual Meeting of the British Medical Association in Edinburgh, August 1875.

with extensive granular degeneration of the cervix. In such a case, unless appropriate treatment be resorted to, miscarriage will almost inevitably occur sooner or later.

And here I would enter a protest against the very prevalent notion that nothing can be done until after delivery. It is a great mistake. We are in a similar position to those who advocate extreme radical views, having emphatically everything to gain and nothing to lose; for, if we shrink from treating the disorder, miscarriage will almost inevitably result; and, even if it should follow the employment of local remedies, it is in spite of, and not in consequence of, our treatment. We are no worse off than before, and have, moreover, the satisfaction of having attempted to prevent the premature expulsion of the fœtus.

Experience corroborates what physiological reasoning suggests; namely, that the cure of a diseased action in the organs of parturition will contribute to the security of pregnancy. The experience of many eminent practitioners, as well as my own, proves conclusively that inflammation and ulceration of the os and cervix uteri, with mucous or purulent leucorrhœa, may coexist with pregnancy, and that they frequently cause abortion; and also proves that they can be treated successfully during gestation, without necessarily disturbing the process. Whenever there are pelvic pain and leucorrhœal discharge in gravid patients who have aborted in previous pregnancies, the condition of the os and cervix uteri should be positively ascertained.

The treatment found most successful in cases of inflammatory excoriation or ulceration of the lower segment of the uterus is sufficiently simple; namely, local abstraction of blood by the application of a few leeches, or scarification, and occasional cauterisation of the diseased sites; every possible care being taken to prevent local and constitutional disturbance following upon treatment. Vaginal injections, whether sedative or astringent, may safely be resorted to, provided due care be taken not to employ too much force. Lotions composed of glycerate of borax, carbonate of soda, acetate of lead, and sulphate of zinc, are generally found most useful. Pessaries composed of oxide of zinc, carbonate of bismuth, tannic acid, and various other agents, are also of much service.

When we consider that, during the early months of utero-gestation, it is the body of the uterus that is chiefly implicated in the lodgment of the ovum—the cervix not being involved till much later—our fears as regards setting up more irritation than we attempt to relieve may be lessened.

Flexions of the uterus are responsible for a very large proportion of the miscarriages which happen; and where we find one miscarriage after another occurring in succession, it may almost be taken for granted that that patient is suffering from flexion, provided that there is not syphilis. Thus, as Dr. Grailly Hewitt asserts, the same circumstances which frequently induce sterility are liable to produce abortion if the patient do become pregnant. Dr. Albert Smith has shown that retroversion, when it does not preclude impregnation, has a great tendency to produce abortion in the early months. The uterus being in an unnatural position with relation to the pelvic organs, and being pressed downwards and backwards by the superincumbent mass of the intestines, the ligaments, instead of holding the uterus suspended firmly and sustaining it with a mobility just sufficient to accommodate it to the unavoidable movements of the body, now relaxed and useless, allow it to be jostled rudely about and irritated by every change in the relation of the surrounding organs. In such a condition of things, the retentive power of the uterus must be greater than it usually is in a primiparous woman to continue its development, resisting the influences which, from the first, operate and set up an irritability in its tissues. The chief symptoms complained of are generally a sense of discomfort and weight in the pelvis, bearing-down pains, dragging in the groins, frequent micturition, occasionally dysuria and straining on defæcation. It is in these cases that we often find a difficulty, in cases where abortion actually occurs, in complete delivery of the ovum.

Careful reposition of the uterus in cases of retroversion and retroflexion is the first thing to be accomplished. This may safely be done by pressing the fundus upwards, guiding it to one or other side of the promontory of the sacrum, and then adjusting a Hodge's pessary to assist in retaining the uterus in its normal position. Lying in the prone position for several hours during the day is generally advisable. Strict attention to the emptying regularly of the bladder and rectum should always be insisted on. The Hodge's pessary should not be removed until after the uterus has risen out of the pelvis—about the fifth month or so—when a vaginal support will no longer be needed.

There are some few points worthy of consideration as regards the reflex phenomena influencing gestation, to which it may be well briefly to refer. Foremost among these is the morning sickness of pregnancy,

which, when exaggerated in degree, often causes much anxiety and suffering, and occasionally induces abortion; though it is astonishing to what an extent—even to such a degree as to cause death—nausea and vomiting may proceed without exciting the uterus to expel its contents. After parturition, the slightest gastric irritation will excite contraction of the uterus; but, during pregnancy, gastric irritation and sickness, even to death, may occur, without disturbing the *fœtus in utero*. In many of these cases, the insertion into the vagina of a morphia and atropine pessary will at once arrest sickness, when all other remedies have been tried.

A vaginal examination should always be resorted to. Many a case of intractable vomiting, where the *Pharmacopœia* has been ransacked in vain, has been found to depend upon a retroflexed condition of the uterus, the vomiting ceasing entirely on replacement of the uterus, and supporting it by means of a Hodge's pessary.

Gestation and lactation ought never to be permitted to go on at the same time in the same individual; and where it is evident that a patient has become pregnant, the child should at once be weaned. Neglect of this precaution has caused many a miscarriage.

Where neuralgia or toothache causes much distress, wakeful nights and restless days, and there seems to be risk of miscarriage, extraction of any diseased tooth should always be effected; chloroform or nitrous oxide being given to lessen any risk from shock.

Obstinate constipation and, in consequence, the too frequent resort to purgative medicine, not infrequently interferes with the development of the pregnant uterus, or produces so much irritation in the pelvic organs as to cause abortion. The employment of the sulphate of magnesia in small doses, or some form of tonic aperient, repeated thrice daily, will obviate this difficulty far better than drastic cathartics.

Where patients have acquired, so to speak, the habit of aborting, we must be careful to eliminate every possible cause; in these cases, continence must be strictly enjoined—the vaginal irritation, together with the ovarian influence, being often sufficient to determine a miscarriage.

In the management of miscarriages when actually threatened, when pain and hæmorrhage are present, our main object must be to conduct the patient safely through the process, provided it cannot be prevented or averted. A vaginal examination should always be made; for, until we know the exact state of the uterus as regards dilatation of the os, protrusion of the ovum, and intensity of the pains, we are not in a position to decide whether there is a reasonable prospect of averting the catastrophe, or whether we ought to facilitate the expulsion of the ovum. In any case, the hæmorrhage must be stopped; and, supposing the ovum is not sufficiently detached or protruding from the os, ergot should at once be given; and here I would call attention to the fact that ergot does not invariably produce expulsion of the ovum, as many imagine. I have repeatedly given it in large doses where miscarriage was imminent, with the effect of restraining the hæmorrhage, the patient going on to her full time, and being safely delivered of a living child. Where the os is not sufficiently patulous to allow the introduction of the finger, the hæmorrhage being severe, the introduction of a sponge-tent into the cervical canal itself will not only arrest the hæmorrhage, but expedite the dilatation and expulsion of the ovum.

The hypodermic injection of morphia is a valuable method for arresting threatened miscarriage; but time would fail me were I to attempt to mention all the various measures that have been resorted to.

When the ovum has been only partially expelled, and the hæmorrhage continues, the injection of the solution of perchloride of iron, as advocated by Dr. Barnes, should not be forgotten; and when, later on, the discharge from the uterus has any tendency to become at all offensive, the intrauterine injection, twice daily, of a solution of carbolic acid will avert any ill effects in the form of septicæmia, and materially assist the removal of any *debris*.

I have no intention of entering more fully into the management of miscarriages, though the subject is one of great importance. My main object in occupying a brief portion of your time to-day was with the hope of directing more careful attention to the consideration of the subject; and if some here object that nothing new has been brought forward, I would crave their indulgence, and beg them to consider that possibly there are others who will not regret having listened to what, after all, may be new to them.

It seems to me that miscarriages are a much neglected study. Case after case rises up before me where lives have been jeopardised and even sacrificed, hopes blighted, homes rendered desolate, and much heart-burning and physical suffering produced, for want of a due consideration of the importance of the subject; and if only the attention of the few be more earnestly directed to the study of miscarriages, my object will have been attained.

ON THE INFLUENCE OF ALTITUDE AND PRESSURE ON THE "VITAL CAPACITY" OF MAN.

By F. CRESSWELL HEWETT, M.R.C.S., late R.N.

THE influence of altitude upon the spirometric measurements of the expired air (vital capacity of Hutchinson) is a subject that has not met with much attention. Rattray, in his researches on climate, published in the *Proceedings of the Royal Society* (1869-72), incidentally mentions that an ascent of 2,000 feet at Ascension lessened the "vital capacity", as judged of by the spirometer, from 266 to 249 and 243 cubic inches. In seeking to verify these results, I determined, as an opportunity offered, to carry out more extended observations upon the subject. Two officers of H.M.S. *Northumberland* (Lieutenants Campbell and Simpson), whose "vital capacity" had previously been frequently noted, volunteered; observations being taken during a period of three days, the altitude of the place of observation, at Madeira, as determined by an aneroid barometer, corrected for temperature, being 2,950 feet, this agreeing with the altitude given by Dr. Hartung in his *Geologische Beschreibung der Inseln Madeira, etc.* The observations commenced on the morning after the arrival of the party at the mountain, being taken twice daily, morning and evening, before breakfast and before dinner, at about 8 A.M. and 6 P.M. respectively. The vital capacity index is taken from the mean of three trials, the height of the barometer and temperature being noted at the same time.

A.—Previous Vital Capacity=325 Cubic inches.			B.—Previous Vital Capacity=270 Cubic inches.		
First Day.			First Day.

2. 312			2. 262		
3. 310			3. 262.5		
1. 314	}	313.8	1. 254	}	263.5 27.61 52
2. 317.5			2. 268		
3. 320			3. 268		

The previous vital capacity was determined by a series of trials similar to the above; the barometer fluctuating between 30.31 and 30.01 inches; the thermometer between 62 and 69 degrees Fahr.; the maximum variations in the vital capacity being 15 and 19 cubic inches respectively.

If we look at the vital-capacity index under the heading of "trials", we find that there is both in the case of A. and B. a considerable variation in the number of cubic inches registered in each separate series. In the case of A., we find a difference of nine cubic inches between the maximum and minimum indications on the morning of the second day; whilst, in the case of B., there is a difference of six cubic inches. Although, of course, the highest indication registered the true vital capacity, the examination of the whole series of trials leads us to the conclusion that these differences are due to the incomplete filling or emptying of the lungs; and that in a series as the present, where the same cause of error is always acting, for purposes of comparison, the mean of the three trials will be the safest index for our purpose.

Taking, then, the means of the several trials as a fair expression of the vital capacity, we find, in comparing the means, that there is a gradual increase from the morning of the first day to the afternoon of the third. In the case of A., there is a progressive increase from a vital capacity of 290.5 cubic inches to 313.8, or an increase of 23.3 cubic inches; and so, also, in the case of B. (the progression being interrupted on the second day), there is an increase from 241.3 cubic inches to 263.5 cubic inches, or a total increase of 22.2 cubic inches; the amount of increase being strikingly similar in both cases.

Looking now at the thermometric and barometric records, we find that 9 deg. Fahr. and .17 inch embraced the whole of the fluctua-

tions of temperature and pressure, the former ranging between 61 deg. Fahr. and 52 deg. Fahr., the latter between 27.78 inches and 27.6 inches. These changes, being so minute, cannot come to our aid as explanatory of the progressive increase of the vital capacity in both cases, the only explanations remaining being either (1) increased proficiency in the art of "blowing"; or (2) an accommodation of the lungs to the decreased pressure, whatever cause that first occasioned a diminution in the vital capacity being removed or neutralised. The first cannot be explanatory; for, at the sea-level, the vital capacity is almost constant in both cases during a similar series of observations; and, moreover, the steady increase above noted could not be explained by increased proficiency in "blowing", as both had been accustomed to "blow", and had evidently reached their maximum capacity, as evinced by the uniformity of the vital-capacity index during the series of trials at the sea-level.

There only remains the second hypothesis to consider—viz., the gradual removal or neutralisation of some impeding cause to the introduction of air to the lungs. Firstly, are we to consider that the diminution of vital capacity is due to decreased pressure upon the pulmonary tissue, causing the presence of an increased amount of blood in the lungs, and that the diminution of the vital capacity was due to the increased space taken up by the blood, and was an index of the superfluity? and that we are to account for the re-established "vital capacity" by the subsidence of the pulmonary hyperæmia; or, this subsisting, is there compensatory dilatation of the pulmonary air-cells? This latter is most possibly the explanation for the diminished pressure on the lungs still existing; there would be still cause for the hyperæmia, and, therefore, without dilatation of the pulmonary air-cells, still cause for a diminished vital capacity.

Comparing the previous vital capacity with the results of the experiment, we find that, in the case of A. with a previous vital capacity of 325 cubic inches, there was at first a diminution to 290 cubic inches, or a total decrease of 35 cubic inches; which deficit, on the afternoon of the third day, was reduced to only 5 cubic inches. In the case of B., with a previous vital capacity of 270 cubic inches, this was reduced to 241 cubic inches, or a deficit of 29 cubic inches, which deficit was lessened on the third day to 6.5 cubic inches.

From these observations, we may deduce the following conclusions.

1. The vital capacity of man is at first reduced by a diminution of pressure.
2. After a few days, the average capacity is re-established.

ON CEREBRO-SPINAL MENINGITIS.*

By THOMAS COLE, M.D. Lond.,
Physician to the Royal United Hospital, Bath.

IN the present paper, I propose to sketch briefly, and make a few remarks upon, eight cases which were probably examples of the above-mentioned disease. They were all hospital patients. I am indebted to Dr. Coates for the use of notes of three of them (Cases II, VII, and VIII).

CASE I.—George R., aged 12, a schoolboy, became an in-patient on January 25th, 1875. He cut his finger with a hatchet a month previously. His illness began, two weeks before, with headache, loss of appetite, and vomiting. He got out of bed several times without knowing what he was doing. On admission, he complained of pain in the occiput and left side. He could open and shut the mouth well. The head was thrown back; the muscles of the neck were rather firm; the knees were contracted; the flexor muscles somewhat stiff. During his illness, the tongue was fairly clean, and his appetite good. The bowels for a considerable time were obstinately confined; afterwards the motions were passed involuntarily. Once there was slight difficulty in swallowing. The urine was normal, but often passed in bed. Several times, there was much sweating. The nights were sometimes good, sometimes bad—from pain; at others quiet, but sleepless. There was much retraction of the neck, and great pain on trying to bend the head forward. Opisthotonos existed for many days, with occasional spasm of the legs. Once it was difficult to make him open the mouth. The tongue was always well protruded. At one time, there was blowing with the mouth, also temporary drawing down of its left angle, and, at the same time, right internal strabismus. Twitching of the mouth, and slobbering out of its right corner, also occurred. The pupils were always normal, once rather large. The legs became flaccid, and the arms and hands seemed to lose all power, and eventually the right

* Abstract of paper read before the Bath and Bristol Branch.

arm was quite paralysed. One day, the breathing was occasionally stertorous. He was rather stupid now and then, and once lay half-insensible on his back. There was considerable pain in the back of the neck, especially on movement, also varying pains in the left side, trochanters, and knees. Asthenia and wasting were marked. The morning temperature varied between 97.4 deg. Fahr. and 103.4 deg. Fahr., averaging about 99 deg. Fahr. The evening temperature varied between 99 deg. Fahr. and 103.2 deg. Fahr., averaging over 100 deg. Fahr. The pulse varied between 54 and 108; usually it was but little accelerated, and once only a little uncertain in rhythm. Respiration, as a rule, was slightly hurried. The treatment consisted of nourishing diet, chloral to relieve pain, and extract of physostigma. The latter was given in one-eighth of a grain doses every six hours on January 22nd; on the 23rd, every five; on the 25th, every four; on the 31st, every three hours; on February 8th, every six hours. On February 22nd, it was omitted.

CASE II.—Catherine II., aged 2, living at Weston, was taken ill on April 24th, 1875, with sickness, headache, and retraction of the neck. She fell into a well fourteen days before, but suffered no visible injury. She kept crying, and, when touched, was very hyperæsthetic all over. She was arched up like a bow. The motions and urine were passed in bed. She was very feverish, and much wasted. There were no bed-sores. A few days before death, the child lay in a half-conscious state, and died quietly on May 22nd, 1875, the symptoms having continued unrelieved. No *post mortem* examination was permitted. The treatment was at first liquor ammoniæ acetatis, and afterwards the liquor hydrargyri perchloridi.

CASE III.—Henry T., aged 13½, a butcher's boy, living at Lambert's Buildings, was admitted on April 5th, 1875. He was taken ill on March 29th with frontal headache, followed the next day by pain down the whole back and vomiting. The head had been retracted and turned to the right side since the second day. The illness began without appreciable cause. He lay in bed crying, from pain from the occiput to the sacrum, extending over the whole dorsal surface. There was much tenderness when he was touched. There was also pain half-way down the back of the right thigh and over the surface of the abdomen, which was also tender. The tongue was dry in the centre; the edges were whitely furred. Bowels confined. Temperature, 103.4 deg. Fahr.; respirations, 30; pulse, 108. During the illness, the appetite was usually fair; the tongue was more or less coated, and often very dry; thirst prevailed; sickness was very common; and the bowels were nearly always, sometimes obstinately, confined. There were great emaciation and weakness. The urine was normal until April 21st, when it was albuminous. On the 22nd, it was acid, smoky, and the specific gravity 1020. It became more and more bloody till the 27th, on which day it was clear. It was again albuminous on the 30th; on May 1st, bloody; on May 3rd, there was no albumen; from the 4th to the 9th, it was albuminous; on the 10th, it was bloody again; on the 13th, clear but albuminous; on the 20th, alkaline from amorphous phosphates; no albumen, but some hyaline granular and epithelial casts; on the 24th, it was normal. Some nights were very bad; but hypodermic injection of morphia generally ensured a good one. There was occasional sweating. The right ear became dusky inflamed from pressure, and two large bedsores formed over the trochanters. They perfectly healed. Great retraction of the neck and opisthotonos existed nearly all the illness through, gradually relaxing towards the end. Once he could not clench the right fist well, nor extend the fingers. The pupils were often unequal, the right being usually larger than the left; occasionally they were dilated. He was very deaf. There was occasional nocturnal delirium. The day the urine became albuminous, he seemed quite unconscious and very much changed; but the day after he was quite rational. Very severe pain was suffered all the time. It affected the forehead, back of the neck, shoulders, right arm, gluteal regions, and legs; and there was much hyperæsthesia. The respirations varied from normal to 44 per minute. As a rule, they were rather accelerated. Coarse râles were discovered on the day the albumen appeared. The pulse was not quite regular then. It varied between the normal and 144, being usually over 90. The temperature varied in the mornings between 97.8 deg. Fahr. and 104 deg. Fahr.; the evening temperature between 98 deg. Fahr. and 104.4 deg. Fahr., generally over 100 deg. Fahr. He left the hospital well on June 14th. The treatment consisted of generous diet and wine. Bromide of potassium and chloral were at first added, with hypodermic injections of morphia sometimes combined with atropia. The latter were of immense benefit in relieving the pain. The extract of Calabar bean was ordered two days after admission, in one-eighth of a grain doses every four hours; next day, every two hours; next, one-sixth of a grain every hour; next, a quarter of a grain every hour; three days afterwards, a quarter of a grain every half-hour; next day, half a grain every half-hour. This last dose was

continued for twenty-four hours, and then the drug was abandoned. He subsequently took iodide of potassium, ergot, perchloride of mercury, bark, and phosphorised cod-liver oil, with aperients.

CASE IV.—Clara S., aged 3½, was admitted on April 1st, 1875. She was taken ill fourteen days before with frontal headache and vomiting. Three days afterwards, the head became retracted. On admission, the muscles of the back of the neck were in a state of spasm, and the child complained of much pain in the head, crying out in her sleep, "Oh dear, my head!" Temperature, 101 deg. Fahr.; respirations, 24; pulse, 115. During the attacks, the nights were fair. The appetite was pretty good; but there was a great deal of vomiting, with furred and dry tongue. The bowels were at first regular, afterwards more confined, and the breath offensive. There were much emaciation and debility. The urine was normal. The pupils were once dilated. There was much retraction of the neck, and warping towards the right side. She had considerable pain in the head, chiefly the forehead and back of the neck. Once she was drowsy. The hair fell off very much. The pulse was generally over 130. The respirations were a little hurried. The morning temperature varied between 97 deg. Fahr. and 101.4 deg. Fahr.; generally under 100 deg. Fahr.; the evening temperature between 99 deg. Fahr. and 102.6 deg. Fahr.; generally over 100 deg. Fahr. Generous diet was given. Bromide and iodide of potassium were first tried; then juice of conium and calomel were added. Quinine followed, and afterwards bichloride of mercury and bark.

CASE V.—Henry II., aged 2½ years, was admitted on March 15th, 1875. The mother stated that she had lost one child from convulsions; another died a fortnight previously from a similar complaint to that from which this child was suffering. He was taken ill a month ago with sickness, thrice in one day, and diarrhœa. He had been quite healthy up to that time. The sickness did not recur; but he rapidly lost flesh, and presented symptoms like those now present. He had bed-sores; lay with his eyes half-open; the pupils widely dilated on moving. He kept rolling the eyes about. The head was tonically retracted. There was no actual paralysis. He kept moving his limbs about, drawing the legs up, and opening and shutting the mouth. The *tâche cérébrale* was not marked. He screamed, ground his teeth, and coughed. Temperature, 100.1 deg. Fahr.; respirations, 20; pulse, 104. He had fair nights all through, and did not appear to suffer very much pain. He was sick very often, and had no appetite for some time. The bowels sometimes were very loose, at others very confined. Once there was a smart attack of diarrhœa. As he was getting better, the abdomen became tumid, the veins full, and the liver somewhat enlarged. This may have been due to the quantity of food he took during convalescence. The pupils were always very widely dilated, and vision was, no doubt, at times very imperfect. The head was retracted, and the legs were drawn up. He occasionally ground the teeth. If lifted up, he would fall backwards immediately, as if he had no power over his body and limbs. The temperature was once over 100 deg. Fahr., but soon became normal. The pulse was very rapid at first. He was emaciated and weak a long time, and could not walk alone. On June 3rd, he left quite well. He took iodide of potassium and bark; afterwards syrup of the iodide of iron and phosphorised cod-liver oil.

CASE VI.—Alice C., aged 3 months, became an out-patient on May 3rd, 1875. Ten days previously, on taking her from the cradle, her mother found the head drawn back and the legs drawn up. The child cried much, and once or twice was sick. She still suckled, but was much wasted. She cried loudly when the head was moved forwards. She was ordered a grain of hydrargyrum cum cretâ three times a day.—May 13th. The neck was just as retracted. She cried very much; she had very bad nights. The powder was repeated twice daily, with five grains of bromide of potassium every night.—May 17th. She had no appetite. The neck was the same. She evidently suffered much pain. She cried incessantly.—May 24th. The head was not quite so retracted. She was ordered a grain of iodide of potassium, four grains of bromide of potassium, and two grains of ammonio-citrate of iron, three times a day.—May 27th. She was greatly emaciated. Cod-liver oil and steel wine were ordered. The child became gradually worse, and died a few days afterwards.

CASE VII.—Arthur N., aged 12, living at Limpley Stoke, a quarry-boy, was admitted on April 24th, 1875. On coming home on March 13th, having been quite well, he complained of pain at the back of his head, and the neck soon became retracted. There was no sickness. He had been delirious on and off, and, on several occasions since, had vomited round worms, the last four days ago. Three weeks ago, he became hemiplegic on the left side. The bowels were at first confined, but were now regular. When admitted, he lay in bed with the head turned to the left side, and complained of great pain in the back of the neck when it was moved. There was left hemiplegia, the tongue was

protruded to the left, and the mouth drawn to the right side. He could not tightly close the left eye. The left half of the tongue was more flabby than the right. The left arm and leg were wasted, and the thigh and leg were hyperæsthetic. There was a slight tendency to œdema of the left foot. There were a few yellow opaque sudamina over the abdomen and chest. He complained only of pain in the thigh and in the back of the neck when not touched. Tongue clean. The pupils were equal and normal. He passed urine in bed. The nights were bad at first; were relieved by morphia, and soon were good without it. The appetite remained fair. The motions were usually passed involuntarily. No worms were evacuated after santonin and jalap. There was constant incontinence of urine. It was normal. The pupils were equal and normal. When he left the hospital on August 26th, the paralytic symptoms were but little relieved. All through, he had much pain in the neck, left leg, and arm. This gradually abated. The pulse was usually quick, but became normal before he left. The temperature never exceeded 100.2 deg. Fahr., and soon subsided. Treatment consisted in the administration of iodide and bromide of potassium, the hypodermic injection of morphia, then the hypophosphite of soda, and subsequently the syrup of the iodide of iron, cod-liver oil, and strychnia.

CASE VIII.—John G., aged 14, stable-boy, was admitted on October 15th, 1875. He was taken ill five days before with pain in the head and legs, and sickness. He had slept badly, with talkative delirium. The bowels were open several times a day. On admission, the head was retracted; there was pain all over it and in the thighs. The tongue was a good deal furred, and moist. His appetite was better than at first. The bowels were regular. He was slightly deaf. The first two nights were bad, with much talking and shouting; hypodermic injections of morphia gave him a succession of good ones. The sixth of a grain had to be used. This lost its effect after a short time, and the nights were restless. The dose was augmented with success, and the morphia was left off on October 30th. The tongue was furred and foul at first, then became dry, and there was much thirst. The bowels were more or less confined unless medicine was given. The pupils were normal. The neck was much retracted, so that he could not lie on the back; it was gradually relaxing. There had been a great deal of pain in the head, back of the neck, and right thigh; it was much abated on November 2nd. He had been very deaf. Herpes came on the upper lip. At the beginning, the urine was loaded with urates, very acid, with a specific gravity of 1023. It gradually cleared, and became neutral. On October 23rd, albumen appeared; it was absent the next day. The urine was alkaline. On the 30th, he was very apathetic; on the 26th, respiration had been slightly hurried. The pulse had never exceeded 108; one day, it was a little intermittent. The morning temperature varied between 100 deg. Fahr. and 103.8 deg. Fahr.; the evening temperature between 103.4 deg. Fahr. and 105.6 deg. Fahr. On October 31st, it sank in the morning to 98.6 deg. Fahr.; in the evening to 99 deg. Fahr. On November 1st, it was 98.6 deg. Fahr. The case is not yet complete; but there is every prospect of speedy recovery. Treatment has consisted in the administration of the bromide of potassium all through, with hypodermic injections of morphia. The iodide of potassium was given at first, and a blister applied to the nape of the neck. November 22nd. He is quite well.

REMARKS.—At the outset, the question naturally arises, Were these cases examples of cerebro-spinal meningitis? If they were not, what disease did they represent? Were they tubercular meningitis? If so, the results of that malady were never so favourable in eight consecutive cases. For six out of eight to recover is an event unknown in the practice of any single person, or even in the collective experience of the whole profession. The numerous cases that have come under my care have always terminated fatally. Nor do I remember to have seen one in which persistent retraction of the head occurred. Case VI perhaps approximates rather closely to this disease; and, taking into consideration the tender age of the child (although epidemic meningitis attacks infants), and the absence of *post mortem* evidence, I am rather doubtful as to the diagnosis in this instance. The peculiarities of the pulse so common in tubercular meningitis were absent in all those under consideration, with trifling and temporary exceptions. And it is rare to get so many successive cases of such long duration. In all except one, there was a total absence of convulsions. Many other points of contrast could be noticed, did time permit. Were they simple cerebral meningitis? This complaint is generally ushered in by violent convulsions, with intense fever, headache, and rapid breathing; and runs a hurried course, very seldom lasting longer than six days, and often terminating in two. Were they tetanus? The first case had a history of cut finger, which was somewhat calculated to mislead. There was no previous injury in all the rest; so that, if they were tetanus, they must have been idiopathic in their origin. There were no exacerbations of

the painful spasms, as in lock-jaw; no trismus; no marked difficulty of swallowing; and fever and more or less head-symptoms were present. But, granting they were cases of cerebro-spinal meningitis, did they come under the sporadic or the epidemic variety? This point is of great interest and importance. Sporadic cerebro-spinal meningitis, in which the membranes of the base and ventricles of the brain, with the sub-arachnoid space of the spinal cord, are especially inflamed, is, according to Dr. Gee, comparatively common in London. The symptoms are similar to those of the epidemic form of the disease, so far as the meningeal condition is concerned. Herein lies the chief difficulty. It is well known that there are three distinct varieties of the malady:—Firstly, the simple form, in which there is a predominance of the nervous phenomena; secondly, the fulminant, in which there is terrible blood-change, evidenced by hæmorrhages into the skin, and accompanied by marked depression of the vital powers; thirdly, the purpuric form, in which the former two exist in varying proportions together. In each epidemic, cases are observed which link together all three forms of the disease; and even the symptoms of them all may be grouped together in one individual. Our cases were clearly of the simple kind, although it is interesting to note the renal hæmorrhage which occurred in No. 3 Case. It is certainly worthy of notice that all of them occurred between January 7th and April 24th, 1875, except the last. During that period, I saw one or two others of a suspicious character, but have purposely excluded them from present consideration. Since I have been in practice, I have seen no cases at all resembling them. There can be no doubt that they did not represent an epidemic constitution of any severity. This is proved by the comparative mildness of the cases themselves, their chronic course, and the limited nature of the outbreak. The patients lived in various quarters of the city; one at Limpley Stoke, and another at Weston. Still, it is somewhat remarkable that so many exactly similar cases should have been under treatment at the same time.* Perhaps some of my brethren here can offer, from their experience at that period, some evidence towards the solution of this difficulty. I cannot but think myself that there must have been an epidemic origin to account for the coexistence of such a number of cases. The ages of the patients furnish another point of interest. They varied from three months to fourteen years. It is stated that in some epidemics children mostly suffer. This would coincide with what took place on this occasion. Many points of resemblance may be noticed between the symptoms in the several cases presented. Thus, in the initial stage, six out of the eight had intense headache, mostly frontal; the other two being too young to express themselves on this point. It is, however, a significant fact that they screamed and cried a good deal. Six had vomiting; all had retraction of the neck; in two, it was also drawn to one side. Pain down the spine and general hyperæsthesia were also prominent symptoms. With regard to temperature, I felt at the time that the thermometer would have registered much higher had the cases been more recent when they came under observation. Case VIII corroborates this impression. The temperature was sometimes considerably lower in the evening than in the morning. The pulse ran high in some of them—up to 150 or 180; the younger the child the higher the pulse. There seemed to be some relation, although not a very strict one, between the temperature and pulse. Yet sometimes it was surprisingly slow, being in the first case as low as 66 per minute. The rapidity of respiration seemed in all to depend upon the febrile movement. The asthenia, rapid wasting, and tendency to bedsores, were remarkable. Vomiting, obstinate constipation, or involuntary action of the bowels, occurred in nearly all. The condition of the urine in Case III was remarkable. I attribute this to the elimination of some morbid material, and it seems to me to link the case with the purpuric variety of the disease. It is strange that temporary albuminuria occurred also in Case VIII. The frontal and occipital headache, pains in the neck, back, legs, sides, abdomen, and arms, the general hyperæsthesia, retraction of the neck and opisthotonos, and spasms of the legs, occurred too frequently to be accidental symptoms. Delirium and fleeting unconsciousness happened three or four times; but there was general torpor in them all. The condition of the pupils and eyes, and the various degrees of paralysis, demanded attention. I cannot divine the etiology of these cases. Supposing them to be examples of cerebro-spinal meningitis, its causation is wrapped in obscurity. It seems to prevail especially in cold seasons of the year. High and low latitudes, healthy and unhealthy places, well drained and badly drained, suffer alike. Some believe it to originate in an analogous manner to the zymotic class, others do not recognise any resemblance. Diseased grain has been blamed as the cause. Although there is evidence to the contrary, the Massachusetts Medical

* The mother of one of the children stated that she had lost a child fourteen days before from the same sort of illness.

Society agreed in its non-infectious nature. It attacks more children under 14 years of age than adults. With regard to treatment, a variety of remedies was employed. The bromide of potassium, chloral, and henbane were useful in relieving pain; but the hypodermic morphia carried off the pain, and I believe Case III would have succumbed without it. It would require much more experience to state positively the value of the other drugs employed. I am inclined to believe the disease is very little influenced by drugs. The cod-liver oil, especially phosphorised, was of undoubted service during convalescence. I can also recommend the ice-bag to the spine. The Calabar bean seemed to produce no physiological effect. It was obtained from three different sources, and I believe was well prepared. Yet one patient took it in fair doses for a month, and another in very large doses. Twenty-four grains in twenty-four hours is a considerable quantity for a boy only 13½ years old. But there was no more loss of motor or reflex activity of the cord nor diminution of pain; no more enfeebling nor slowing of the heart's action, nor interference with respiration, than during the time the patients were not taking the medicine. Nor did it produce any giddiness, torpor, excessive secretion of tears and saliva, vomiting or purging, muscular twitching, or the least contraction of the pupils. It would seem that the bean cannot be so poisonous as it has been stated to be. I think much of the success of these cases is due to the *vis medicatrix nature*, a power which has a far higher place in the cure of disease than we often suspect or allow. I should be much disposed, were any new cases to come under my care, to push belladonna, with purgatives and other eliminants. Such an occurrence may at any moment enhance the interest and importance attaching to this group of maladies. The few drops of silently falling rain to which we pay but little heed may usher in a terrific storm, pregnant with destruction, desolation, and death.

P.S.—I should be grateful if any members who may have seen similar cases would kindly communicate them to me, as the matter will be more fully discussed at a subsequent meeting of the Branch.

THE PRESENT EPIDEMIC OF SCARLET FEVER IN BRISTOL.

By DAVID DAVIES, M.R.C.S.Eng.,
Medical Officer of Health for the City.

I.

THE *bête noire* of health officers is here in force; and has, after a struggle of seven months, set our regulations at defiance, and re-asserted its usual fatal character. I will give an account of my knowledge of it in the form of short propositions.

History of the present Epidemic.—A few cases, isolated and at different points, appeared in the autumn of 1874. These were, so far as I know, successfully stamped out by isolation and disinfection. Cases kept dropping in at intervals during the winter of 1874 and 1875. By redoubled energy, we succeeded in keeping the disease within narrow limits, and at isolated points. All infected houses and clothing were disinfected. Drains in localities wherein the disease prevailed were kept saturated with disinfectants, viz., sulphate of iron and carbolic acid. Handbills containing instructions and cautions for the prevention of its spread were freely circulated.

With the approach of spring, the cases multiplied; in the summer, still more so; until, last week, we had 28 deaths from it in a population of 196,000. Judging by the history of former epidemics, I do not think we have yet reached the highest point, which, in the epidemic of 1870, was 35 deaths in one week. We still disinfect and do our utmost to prevent its spread; but I acknowledge most freely (as with regard to this disease I always have) that we have utterly failed to produce much effect on it, except to postpone it in an epidemic form for four or five months. During the quarter ending September 30th, we lost 161. In Bristol, the disease, as an epidemic, has very regularly observed a cycle of about four years; of the cause to which this is due, I can form no opinion.

Type of the Epidemic.—A small proportion of the cases have been of a most malignant character, the poison destroying life in eighteen or twenty-four hours by acting on the blood, and through the blood as a depressant on the nervous system. Death in these cases has taken place before there has been time for the development of the rash on the skin. A considerable number of the cases have been of the middle type, usually called "scarlatina anginosa". Many of these have died from excess of zymosis and throat-affection; but, judging by the returns of mortality and the frequent entry of "scarlatina", "dropsy", or "nephritis" in the returns, I believe that more than one-third of the

fatal cases were originally light, and became fatal through an affection of the kidneys, produced by exposing the skin to cold during the convalescent stage. Having formed this opinion, I had a handbill of cautions on this head circulated extensively among the poor. I believe it has done some good. This form of death is more frequent among the poorer class than among the rich.

In connection with this subject, I append a letter which I have received from my friend Dr. Gray, the experienced medical officer of the Children's Hospital. As the letter is, in my opinion, a very original communication and a most important one, I give it in full, hoping that Dr. Gray will publish a more extensive account of his experience in a separate paper.

"Bristol Hospital for Sick Children, Royal Fort,
St. Michael's Hill, November 20th, 1875.

"My dear Sir,—May I draw your attention to what I believe to be a sufficiently marked feature of the present scarlet fever epidemic to deserve special recognition, viz., the occurrence of a number, probably no small proportion, of cases of the latent form of the disease? I would include not only those where dropsy has followed an attack of the fever so slight as to have escaped notice, but also those in which the renal complication was primary; for it seems to me certain that here and there cases have occurred, without rash and without sore-throat, in which at the very outset the whole force of the poison has fallen upon internal organs—cases for which the term "scarlet fever" is literally a misnomer, and which can only be regarded as such from the fact of their occurring during an epidemic of that fever, and also because they seem to be quite as capable of communicating the poison as those in which it develops itself in the usual way. It is solely on account of the importance of this latter point that I have ventured to trouble you on the subject, because I think you will agree with me, that such cases are very likely to be a means of propagating the disease in an insidious and dangerous manner that is easily overlooked. I suppose I must have observed nearly a dozen of them, the last having presented itself only on Thursday; and I have thought that perhaps the occurrence of this latent form has not happened to come under your notice, as no reference has been made to it in your reports. You will know best whether there is any use in cautioning the public to beware of it. Probably you would think it futile to bid them beware of an invisible enemy! The only effective precaution that I can see lies in their being very suspicious just now of every attack of illness in their children, until its non-identity with scarlet fever becomes quite manifest.

"I imagine that isolated cases of this obscure kind do occur in most epidemics, but they must surely have been unusually numerous during this one.

"If I can furnish you with any further particulars that would be of any interest to you, I shall be happy to do so.—Believe me, my dear sir, yours sincerely,
"JOHN H. GRAY."

"David Davies, Esq., Medical Officer of Health."

As my paper is given in the capacity of a public officer, I offer no views on the medical treatment of the disease.

LIGATURE OF THE EXTERNAL ILIAC ARTERY WITH CARBOLISED CATGUT, FOR ANEURISM IN A SYPHILITIC SUBJECT.

By A. B. R. MYERS, M.R.C.S.Eng., Surgeon, Coldstream Guards.

PRIVATE A., Coldstream Guards, aged 33, service fifteen years, was admitted into hospital October 4th, 1874, for a large pulsating aneurismal sac implicating the right external iliac and femoral artery. Three weeks before admission, the patient strained himself in running, and soon afterwards observed this swelling, but he failed to report himself sick until compelled to do so by pain. In 1863, he was in hospital for the first time, and only for twelve days, for primary syphilis. The following year he was under treatment twice for a most severe secondary pustular eruption, which was treated with mercurial fumigation; and since then he has been in hospital eight times with specific ulcers of the leg, which, as a rule, readily healed under an iodide of potassium treatment, leaving, however, very brown stained cicatrices.

On admission, the sac, circular in shape, had a diameter of three inches, and pulsed very strongly; and, owing to the patient's great muscular development, much force was required to compress the external iliac sufficiently to even partially arrest the circulation.

It is needless here to record the treatment day by day of this case; suffice it to say that to November 20th mechanical and digital compression with and without the administration of large doses of chloralhydrate were tried, with great perseverance and to the utmost endurance

of the patient, and also flexion of the thigh on the abdomen, but with no benefit, excepting, no doubt, in developing to some extent the collateral circulation, and thus assisting much in the future treatment. On November 24th, the aneurism measured four and a half inches longitudinally, and four and a quarter inches transversely, the increase having taken place chiefly on its proximal side; and I then performed the following operation, assisted kindly by Mr. Gascoven of St. Mary's Hospital, as well as by my colleague Surgeon-Major Trotter. Having made the usual external incision, commencing about an inch above, and to the inner side of the median line of Poupart's ligament, the oblique and transversalis muscles were, owing to their great thickness, very freely divided. No notice was taken of the transversalis fascia. The peritoneum, with abdominal contents, was thus easily detached and drawn inwards; but the artery was with difficulty reached, as it seemed to have been considerably pushed inwards by the long course of mechanical pressure, but, pulled outwards slightly with a forceps, the ligature needle was readily passed round it without any attempt being previously made to open the thin sheath which surrounds the vessels there. Perfectly fresh carbolised catgut was used; and, owing to the fear that the first ligature might not have been well applied, and having a great belief in its non-irritating properties, I put another round of the same material, and in juxtaposition. The wound was then sewn up, and the whole limb, having been well enveloped in cotton-wool, was raised, and a hot bottle applied to the foot.

On examining the foot a few hours afterwards, it was warm, and the patient was quite comfortable. Again I will omit the course of the case, beyond stating that a great portion of the wound towards each end healed by first intention, and that this process was partially retarded by his having a troublesome cough, which strained the abdominal parietes; and for a time there was a rather free discharge, due to the man's state of health, and not apparently set up by the ligatures, which were never observed to come away in it.

On January 6th, he was allowed to get up; and on February 8th, he rejoined his battalion, when his general health was good, and hardly any traces of the aneurism were left; and, I may add, the man has continued quite well to the present time.

This case is published by permission of Surgeon-Major Cay.

SPONTANEOUS CURE OF AN OVARIAN CYST.*

By W. JACKSON CUMMINS, M.D.,

Physician to the Cork South Infirmary and County Hospital.

THE patient, a married lady, aged over 40, with no children, had for some years been off and on under my care for a muco-sanguineous discharge from the bowels. In December, 1873, she received a fall from her horse, and a few days afterwards called on me, as she complained of being slightly hurt in the abdomen. On examination, there was no trace of injury to be seen, but the hypogastric region was found occupied by a tumour tending rather to the left side, and looking like a pregnant uterus. The lady was entirely unaware of its presence, and stated that she menstruated regularly, and had no signs or symptoms of pregnancy. After repeated and careful examination, the diagnosis of ovarian cyst was made, and, in order to confirm this, she was advised to consult Dr. Kidd in Dublin, which she did, and who, in consultation with Mr. Hamilton, reported on the case as follows. "On introducing the uterine sound it was found to pass two inches and no further. The tumour is without doubt 'ovarian', nearly unilocular, and tolerably free from adhesions. No operation should be attempted at present, as it has not interfered with the patient's general health, and no certainty exists as to its rate of growth." She was ordered iodide of potassium ointment and Blanchard's pills, and advised to return home and await the progress of the case. The following are the measurements of the tumour then taken, in inches.

	1874.	Jan.	21st.	29th.
Circumference of abdomen at ninth rib	-	-	-	27½
" one inch above umbilicus	-	-	30¼	30½
" at crest of ilium	-	-	33¾	35
Distance from end of sternum to umbilicus	-	-	5¾	6
" " umbilicus to pubes	-	-	7½	7¾
" " umbilicus to right anterior superior spine of ilium	-	-	7	7½
Distance from umbilicus to left anterior superior spine of ilium	-	-	7	7½

There was slight crepitus to the right of the umbilicus on full inspiration.

* Read before the South of Ireland Branch.

On her return I saw, but did not examine her, and some time afterwards she began, with my permission, to drink broom-tea. Previously to this time, she suffered severely from cramps in the stomach, and one night was awakened with a kind of violent wrench in the part, which occurred twice in a few seconds. This was followed by a gradual cessation of the cramps, but there was no diminution in the size of the tumour, but rather the contrary. Shortly afterwards, she was seized with a severe bilious attack, and took a dose of castor-oil, which was followed by purging and vomiting. As the menstrual period came round, the left leg from thigh to toe became stiff and swollen, with inability to put it to the ground. It was at this time (March 1874) that she commenced to take the broom-tea, and ceased the use of the pills and ointment; the tumour being in precisely the same condition. From this time, however, it gradually diminished in size, and, in seven weeks, had entirely disappeared. She had taken during that period a wineglassful of the broom-tea twice daily. I had no opportunity of examining the lady after her reported cure; but, as she was to pass through London on her way to the Continent, I wrote to Mr. Spencer Wells, stating the nature of the case, and Dr. Kidd's opinion, and asking him to examine her, which he did, and replied as follows. "Mrs. M.'s case is probably one of rupture of an ovarian cyst into the peritoneal cavity, with absorption of the fluid. Its occurrence during the use of broom-tea can hardly be more than a coincidence. The base of the cyst can now be felt about as large as an orange to the left and in front of a rather large uterus."

Dr. Kidd, to whom I communicated the result, seemed to agree with Mr. Wells's view of the case, as I also do myself, though the very gradual diminution of the tumour testified to, both by the patient herself and her husband, a clergyman of high intelligence and judgment, would seem unfavourable to this explanation of the cure. This case agrees to a great extent with the views expressed by the most celebrated ovariologists of the day, who, when speaking of the utter inutility of drugs in such cases, mention the fact that spontaneous cures have taken and will take place during the use of some inert *placebo*.

Whether the cure here took place by rupture into the peritoneal cavity, and consequent absorption of the fluid; or, whether it was the result of direct absorption without rupture of the cyst-wall, is a question on which I shall be glad to hear the opinion of the members, though it may not necessarily arise in connection with the interesting case I have detailed.

THERAPEUTIC MEMORANDA.

NITRIC ACID AS AN UTERINE CAUSTIC.

I HAVE read with much interest an article from Dr. Braithwaite, in the BRITISH MEDICAL JOURNAL for November 13, on nitric acid as a caustic in uterine practice, and I can fully confirm all he says as to its superiority to other caustics. I believe that I have tried them all; but, after using the nitric acid for at least twenty-five years, I have no doubt of its superiority. It does just what is wanted and no more, rarely gives any pain, and leaves no ill-effects. If Dr. Braithwaite will turn to pp. 245, 285, etc., of Churchill's *Diseases of Women*, he will find additional testimony to that which he has quoted; and I may add that it is used and held in high esteem by all the Dublin obstetricians.

F. CHURCHILL, M.D., Fellow and ex-President of the King and Queen's College of Physicians, Ireland.

TREATMENT OF CANCER BY CITRIC ACID.

S. C., AGED 69, mother of seven children, had always had very good health. About two years and a half ago, she first found difficulty, with occasional pain, in swallowing, followed by regurgitation of food after a variable interval. Twelve months ago, she applied for treatment. There was then no marked cachexia; no emaciation; very little pain. She had regurgitation of food after every meal, and in the interval constant regurgitation of viscid fluid, clear and colourless; never any blood, etc. By the aid of œsophageal auscultation, an obstruction could be easily made out to be at the cardiac orifice of the stomach. She was then treated in a London hospital, and returned apparently dying; anæmic, cachectic in a marked degree, and unable to swallow anything, everything going down a certain distance and then being vomited. At her urgent request to give her something to "cut the phlegm", I gave her large doses of citric acid, combining with it minim-doses of ipecacuanha wine, on Dr. Ringer's plan, the good effect being very marked; the vomiting was almost stopped, and, from being unable to swallow anything, she could eat and enjoy bread and cheese and beer; she gained flesh and strength, and even did her own washing. After a few

months, the urgent symptoms returned, and she now complained of obstruction higher up. On trying to feed her with the stomach-pump, a stricture could be felt a few inches below the fauces, which could be passed, and another impassable one lower down. Nutritive enemata slightly relieved; but she gradually sank and died on December 4th, 1874. Thinking that perhaps the relief in swallowing was due to ulceration through the stricture, I several times stopped the citric acid, and once or twice substituted tartaric acid, but always with the result of bringing back the difficulty. The citric acid, as she said, "always cut the way for the food". A necropsy was made thirty-six hours after death. The abdominal parietes were loaded to the thickness of one inch with very yellow fat. The heart and lungs were healthy. Four inches from the fauces, the œsophagus was reduced to the size of a No. 11 catheter by a ring of hard cancerous matter about an inch and a quarter in depth. The cardiac orifice of the stomach was surrounded and almost occluded by a mass two inches and a half by three inches in diameter, hard and nodulated on the outside, but pulpy and disorganised where the œsophagus passed through. On section, it had a firm white fibrous stroma, and presented all the naked eye characters of scirrhus. The œsophagus was largely dilated. The stomach and bowels were not much reduced in size.

JOHN H. WOOD, M.B., Great Bradfield.

CLINICAL MEMORANDA.

IMPROVED METHOD OF PERFORMING SYME'S AMPUTATION.

DURING my absence on the Continent last month, a short paper appeared in the JOURNAL by Dr. Joseph Bell of Edinburgh, describing a "modified and improved" method of performing Syme's amputation "by saving the periosteum of the os calcis"; and, in the subsequent number but one, Dr. Aitken of Carlisle was so kind as to bear evidence that he had seen me do this fourteen times successfully between 1869 and 1873.

I do not at present wish to enter into any statement of the merits or advantages of this departure from the usual plan, nor the further "modification" of rarely sawing off any portion of the leg-bones, except the malleoli, which I also employ, but will content myself by saying that for ten years I have occasionally, and for eight years almost invariably, followed the plan described by Dr. Bell in every case in which it could be put into practice, and that the success has been almost unbroken. I have referred to it in frequent clinical reports, and a short mention of it is made in a paper of mine giving the results of fifty amputations at the ankle, in the BRITISH MEDICAL JOURNAL for August 28th, 1869. I hope before long to lay a second series of cases before the profession, in which this practice will be explained.

GEORGE H. B. MACLEOD,

Regius Professor of Surgery, University of Glasgow.

TINEA CIRCINATA OCCURRING IN VERY NUMEROUS PATCHES, AND WITH UNUSUAL RAPIDITY.

ALFRED and EDITH G., aged 9 and 4½ respectively, were brought to me at the Hospital for Diseases of the Skin on November 11th. Edith, the younger, presented a large number of circular patches of ringworm on her face, neck, and extremities. Alfred also had numerous patches on his face and neck. The girl who acted as their nurse also had several patches; and I was told that an elder sister was beginning to suffer in the same manner.

One point of interest in the case lay in the superficial resemblance between the ringworm and an early or slight condition of psoriasis in the child Edith. The eruption consisted of very numerous patches and rings, none larger than a halfpenny, and many no larger than three-penny pieces, situated on the face, neck, backs of forearms, and fronts of knees; a few were scattered on other parts of the limbs; there were, at least, forty patches in all. The symmetry of the eruption was very marked. Although the typical psoriasis regions were affected, there were, however, no patches exactly on the tips of the elbows, nor precisely on the centre of the fronts of the knees, while the amount of epidermic scale, though somewhat deceptive on the smallest spots, was nowhere large in quantity nor silvery as in psoriasis.

The child's grandmother said that the eruption had begun only a fortnight before, and she pointed out the largest ring, one on the face, as having been the first spot to appear. Thus the rapidity with which numerous successive transplantations of the fungus took place was another unusual feature in the case. The same peculiarity was ob-

served in the boy; his first patch appeared some days later than the girl's; at his first visit, the patches were already numerous, though much less so than in his sister; a week later, notwithstanding the use of remedies in the interval, he had a number of small fresh patches. In the nursemaid also, several patches appeared in a very few days. There were no patches on the head in any of the cases. The mycelium, which was very plentiful both in the smallest and in the largest patches, was, on the average, larger than in some other specimens with which I have carefully compared it; and the spores, found abundantly in some of the fine hairs, were somewhat smaller than usual. This apparently slight departure from the ordinary type of the ringworm fungus may be noted, without assuming that the peculiarity has any necessary bearing on the rapid spread of the disease in these cases. It would be interesting to inquire whether atmospheric conditions, such as prolonged and excessive damp, favour the growth of the skin-fungi, as is the case with many other fungi; and whether any special prevalence of rapidly spreading ringworm has been noticed during the late excessively wet autumn.

EDWARD NETTLESHIP, F.R.C.S.Eng.

A CASE OF OPIUM-POISONING.

ON October 25th, at 6.30 P.M., a child, aged twenty-one months, was brought to my surgery, having had administered to it, in mistake, a teaspoonful of laudanum. The mother, who gave the dose, asserted that the spoon was full, and I have myself ascertained that its contents would be, at least, eighty minims. Twenty minutes must have elapsed from the administration of the drug to my seeing the child. It was then quite wakeful, and the pupils natural; but in about ten minutes the latter began to contract, the eyelids to close, and the head to droop. I gave strong emetics of sulphate of zinc and mustard, with only partial success, as the contents of the stomach were not ejected for fully an hour afterwards. Knowing that keeping the child awake was its only chance of life, I ordered it home, and followed immediately myself. I then had recourse to cold water, galvanism, ammonia, strong coffee, etc.; and, on my departure, left instructions with the parents to keep it awake, if possible, till 4 A.M. With constant perseverance, they succeeded in doing so, and at the hour named the drug had apparently exhausted itself, as the child began to cry and sit up voluntarily. Soon afterwards, it was put to bed, and, I am happy to say, is now quite recovered.

I should mention that I had been giving the child medicinal doses of opium three times a day during a fortnight previous to this occurrence, which would fortunately have a tendency to render it less susceptible to the action of the poison.

I consider this case interesting in a medico-legal point of view, inasmuch as it shows the interval from the administration to the poisonous symptoms setting in; the time necessary for the action of the drug on the system to be expended; and also the recovery of so young a subject from so large a dose of a drug known to be peculiarly active in the case of children.

J. McFADDEK, Batley.

LARGE DILATATION OF CARDIAC EXTREMITY OF STOMACH.

IN 1858 and 1859, I attended a lady, 39 years of age, for abdominal enlargement and faulty digestion. She was the mother of one child, whom she had suckled partially, and who was then about seven years old. No second pregnancy. Her catamenial visitations had been regular but scanty. There was no uterine disease. Her chief trouble was inappetence and rejection by eructation—not by vomiting—of all or the greater part of everything she took as food or beverage. The ejected material was usually a thin mucous fluid, often without taste, or tasting sometimes of the liquid food she had swallowed. Solid food in any form could not be taken. She had no desire for food or drink, but requested only to be left quiescent. The urging to take ingesta was done simply to maintain vitality; but she would have preferred to starve. The bowels were very inactive, and every form of aperient returned by eructation. The abdomen, which had a girth of about forty inches at the umbilicus, gave no sign of solid formation in any part, but was clearly fluctuant all over, with a thin wave on percussion, and not painful. I proposed to remove the fluid by tapping, believing the case to be one of ascites; but the operation was not allowed, and she gradually sank from anorexic starvation. On opening the abdomen after death, no effusion was found in the peritoneal cavity. The abdominal space was found to be occupied by an enormous cyst, which contained from twenty-four to twenty-six pints of a hazy mucous fluid, largely albuminous. The cyst consisted of a dilated state of the cardiac end of the stomach, at which point it had a diameter of three or four inches, but expanded largely over the sigmoid region,

across the hypogastrium, upwards in front of the ascending colon, and across under the liver and in front of the stomach as far as the splenic region. The organs of the chest and head were quite healthy.

JAMES WHITEHEAD, M.D., Manchester.

DISINFECTANTS.

THE question of the value of different substances as disinfectants is so important in the practical treatment of many medical and surgical cases, that it appears remarkable that at present we are unable to estimate the potency of some of those most commonly in use. It must have occurred to some who were present at the discussion which took place at the Clinical Society on the treatment of surgical wounds and injuries with salicylic acid, that there might possibly be some difference between the acid when dissolved in water combined and uncombined with phosphate of soda. The solution employed by Mr. Callender was, we may presume, a combination of one part of salicylic acid, three of phosphate of soda, and fifty of water. The extent to which salicylic acid alone is soluble in water is about 1 in 300; it is not correct to reason of the effects of solutions of such different composition as are referred to as though they were the same. This instance of our liability to disregard apparently unimportant details should lead us to examine results of experiments with various disinfectants with some care; for it is important that such practical tests as those employed by Mr. Callender should be attended with such definite results as the time and labour bestowed upon them deserve.

It might, for example, be suggested that the local inflammatory condition which followed the use of salicylic acid, when combined by means of phosphate of soda with only fifty parts of water, was not an improbable result of such a combination. It is also quite a fair question to put to anyone who advocates some particular substance in some particular form or degree of dilution, what reasons he may have for the assertion he makes. There are many who imagine that it makes very little difference whether we use Condy's fluid, permanganate of potash, carbolic acid, or any other disinfectant. It is a pity they should remain under this delusion, which is kept up by the theoretical views entertained of the *modus operandi* of disinfectants. A most able and scientific chemical friend of mine was quite certain that "disinfection" was only another name for "deoxidation", and most implicitly believed that the permanganate of potash was the best material for disinfection; at least he held that belief till a short time since, when, by some persuasion, he was induced to look at a slide under the microscope on which he saw some of those mysterious and active agents of disease (which Professor Lister has no insufficient reasons for regarding with some respect) gyrating in the interior of a blood-corpuscle apparently as freely as we move about an ordinary room. It would be a breach of confidence to repeat the expressions of surprise my friend uttered. It was sufficient that he renounced all chemical notions of disinfection, and rather experienced the absolute impossibility of dealing with living organisms of such extraordinary activity, yet of such minuteness.

Still we can deal with them with very good results; and many of those who speak of Professor Lister's method afe, I am certain, unacquainted with the very basis of his practice, which, it was satisfactory to hear, was approved of by Mr. Smith and Mr. Heath, who stated that they had taken the trouble to judge of it for themselves. Now, by an example, I may illustrate the kind of research which must be carried out before the method adopted by Mr. Callender of testing the practical value of such a disinfectant as salicylic acid can be fairly employed.

If we take a solution of the acid of strength 1 in 300, and introduce into it some fresh organic matter, a piece of animal tissue not decomposing, we shall find that, at the end of three or four weeks, and probably longer, there is no disagreeable odour given off by it, and that by microscopic examination we can detect very few, if any, traces of decomposition. I say very few, if any, because temperature has some effect. If, on the other hand, we introduce some decomposing substance into a similar solution, the arrest of decomposition is not effected. The living organisms continue to live and move. Again, on treating a solution of carbolic acid of 1 in 50 in the same way, we find that decomposition is at once arrested. But it would be unfair to compare a solution of 1 in 50 of carbolic acid with 1 in 300 of salicylic acid. Thus we see that, to obtain any satisfactory results in respect of any particular substance, we must make a separate series of experiments. We might find perhaps that, in the case of a recent wound, a solution of salicylic acid of 1 in 300 would answer every purpose, and prevent decomposition; but, in a chronic case, where the odour of the discharge would lead to the conclusion that decomposition of fluids and tissues was actively going on, we might obtain better results from the use of a solution such as carbolic acid of 1 in 50.

Many facts such as these must be generally known before we can expect unanimity amongst practical physicians and surgeons on the important question of antiseptic treatment. It is on such facts that Professor Lister has advanced to his present position; and his success in practical results is the best proof of the accuracy of his scientific observations.

ROBERT J. LEE.

OBSTETRIC MEMORANDA.

POST PARTUM HÆMORRHAGE: SEVEN CASES: RECOVERY.

IN three hundred cases of labour attended by me, and of which I have notes, *post partum* hæmorrhage occurred seven times. All the women recovered. In four cases, the bleeding was severe. In six cases, it was checked by placing the patient on her back, introducing the hand into the uterine cavity, injecting cold water, and tight bandaging. In one case, perchloride of iron was used. When I first saw this case, the os uteri admitted the tip of one finger. The cervix was remarkably thick, and this, together with a smart bleeding which had occurred an hour previously, led me to think that the case might be one of placenta prævia. This, however, it was not. The head presented. The hæmorrhage recurring and no good progress being made, I ruptured the membranes and gave ergot, with little or no effect. I then dilated the os uteri with Barnes's dilators, and delivered with long forceps. The placenta came away speedily, and was followed by sharp hæmorrhage. This was readily checked by injecting a solution of perchloride of iron. The patient made a good recovery. My experience leads me to believe, with Dr. Weir, "that it is well to give the placenta good time"; and I think that many cases of flooding are induced by hurry and rough handling in its removal.

JOHN CRAIGIE, M.B., Lyme Regis.

ON INJECTION OF PERCHLORIDE OF IRON IN POST PARTUM HÆMORRHAGE.

THE case of death recently recorded in the JOURNAL by Mr. Boddy, which resulted from the injection of perchloride of iron into the uterus, induces me to forward notes of a case I attended on the 25th of September, 1874, and the recovery of which I entirely attribute to the speedy injection of the above solution. Mrs. H., aged 40, a multipara, had been extremely anxious for some time about the result of her pregnancy, in consequence of having met with a fall when in her sixth month, and also of having subsequently experienced pain and uneasiness over the right inferior abdominal region. On the date named, I was summoned in the forenoon to attend a primipara, and had just finished adjusting the binder after the removal of the placenta, when a messenger arrived informing me that Mrs. H. was in labour, and urgently wished my early attendance. I was in time to witness the birth of the child, and the almost simultaneous expulsion of the placenta from the uterus; but in a few seconds there followed a most alarming gush of blood, which continued at short intervals. After having manipulated the uncontracted uterus externally, removing clots and applying cold to the genitals without avail, I injected five ounces of solution of perchloride of iron (*viz.*, one part of the strong pharmacopœial solution mixed with four parts of water). This had the immediate effect of arresting the hæmorrhage, and also of causing the uterus to contract: for several hours afterwards, the patient had all the symptoms of threatened fatal syncope; in fact, I never saw a case so near approaching a fatal termination. After having been fed carefully for some hours with wine, brandy, chicken-broth, etc., given in spoonfuls every few minutes, she progressed in strength, and ultimately made a good recovery. As I was single-handed at the time, and situated at a distance of seven miles from the nearest practitioner, the case made a strong impression upon me, and so fully demonstrated to my mind the value of the perchloride injection that I now never attend a case of confinement without first providing myself with an injecting apparatus and solution ready for use.

It may also be interesting to mention that, in April last, I was in attendance upon a case of placenta prævia, where palliative treatment had failed, and where delivery of the child at seven months was necessary. In this case, there was a tendency to hæmorrhage; I, therefore, took the precaution, before passing my hand up to remove clots, membranes, etc., to dip it in a solution of the perchloride, and also afterwards injected an ounce of the fluid. This case terminated favourably to the mother.

REPORTS AND ANALYSES

AND

DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

LEITER'S HYPODERMIC SYRINGE.

PERHAPS no pain-annulling remedy at the present day is more frequently employed than morphia injected by the hypodermic syringe; and nothing except a few slight drawbacks, which have hitherto seemed to be inseparable from the use of the instrument, has prevented its almost universal employment. All improvements rendering it more nearly perfect are, therefore, likely to be highly acceptable to medical

men and their patients. An apparatus invented and manufactured by Mr. J. Leiter, of Vienna, appears to possess in many respects considerable advantages over other syringes. Its most distinctive feature is the rapidity with which the needle is inserted (by means of a spring) beneath the skin; and it was anticipated by the inventor that by this device the operation might be deprived of pain. As is well known, a severe injury, if suddenly inflicted, even with a blunt instrument, is, in many instances, scarcely felt at the time. With a full appreciation of the importance of this fact, Mr. Leiter has constructed this syringe, which consists of three metal tubes (*a*, *b*, and *c*, fig. 1), a vulcanite injection-syringe (*d*, fig. 2), two needles, a bottle for the solution (*a*, fig. 2), and a very compact vulcanite case (fig. 6), fitted for the enclosure of these several parts.

The following are the directions for use. 1. In order to charge the syringe, it is plugged upon the small mount of the bottle containing the solution, the syringe being at first uppermost. Next, the position of the united syringe and bottle is reversed (as in fig. 2), and the top (*b*) of the bottle is slightly unscrewed, so as to allow air to pass in and out above the solution, when the piston of the syringe is drawn down. The piston should be worked in and out once or twice that all air may be forced out of the syringe, which may be assumed to be the case when no more bubbles can be made to rise up through the liquid in the bottle. The syringe having now been charged with the quantity of solution which is to be injected, the top (*b*) is again firmly screwed on, the bottle and syringe are separated, the cap being replaced on the mount of the bottle, and the needle screwed into the syringe. The syringe, apparently, holds a cubic centimetre of liquid, a trifle less than twenty English minims; and the rod is marked in tenths, so that each mark corresponds to two minims. This point must be carefully im-

he might re-mark the piston-rod. 2. The bottle having been replaced in the case, and the needle screwed into the syringe, any air in the needle should be expelled by pressing the piston slightly upwards, until the injected fluid becomes visible at the outlet on the point of the needle. 3. The charged syringe is next to be placed in tube *b* (Fig. 1), the needle projecting from its conical end; and the tube *c*, sliding over the tube *b*, and regulating the depth to which the needle shall penetrate the skin, is to be placed at the position intended for the ensuing operation. 4. The spiral spring in the long tube *a* (Fig. 1) is next pressed together by the trigger (*f*), and locked in the slot *g* (Fig. 1); the tube *b*, inside which is the charged syringe, is screwed into *a* (as shown in Fig. 3), and the instrument is ready for use. The point of the apparatus being placed and held in position, the needle is forced beneath the patient's skin by the release of the trigger of the spring, whilst the continued pressure of the spring at once forces down the piston and discharges the fluid into the subcutaneous tissues. In Fig. 4, the appli-

cation of the needle by a second person is shown, the skin being pinched and raised between the finger and thumb. Figure 5 is supposed to represent the mode of application by the patient himself when he has not a hand free for pinching and raising the skin. The needle then enters the limb in a slanting direction. But we doubt if even with this instrument any patient can be trusted to inject himself, as it would be so very easy for him, whilst suffering from severe pain, to insert a poisonous quantity of the strong solution of morphia, when using this or any of the ordinary hypodermic syringes. The only safe instrument by which a patient might perhaps be permitted to inject himself is one containing no more than the quantity prescribed for him; but even then, as the liking for the soothing effect of the morphia increased, the times of its application would be liable to become too frequent. In Fig. 6, the various parts of the apparatus as fitted in the case are ex-

hibited. The syringe lies in the tube with the conical end. The sliding-tube, by which the depth to be reached by the needle is regulated, is pushed home upon the tube it encloses, otherwise it is too long for the case. The needles are made of steel, with a coating of platinum inside, and are nickel-plated on the exterior, to prevent rust. A bundle

of the usual fine wire is also found in the case, with which to remove any obstruction in the needles. To fill the bottle *a* (Fig. 2) with the solution, the top, *b*, is unscrewed. The syringe can of course be used simply as any other ordinary injection syringe. Messrs. Krohne and Sesemann are the appointed agents in London for its supply, and the low price (eighteen shillings) at which it is sold is not the least of its recommendations. If manufactured in England, its cost would probably be double the present price. As regards the nature of the operation, we cannot quite endorse the sanguine description of the inventor, who calls his instrument an *apparatus for painless subcutaneous injection*; but we have always found the patient upon whom this and the ordinary syringes have been used give the decided preference to Leiter's, on account of the quickness with which the operation is effected, and the comparative absence of suffering with which it is accompanied. One man suffering with ulcer of the stomach, associated with very severe pain and much vomiting, so that he could retain scarcely any medicine (not even opium) administered by the mouth, was always relieved by morphia, hypodermically injected; but the ordinary syringe frequently caused him to weep from the pain it produced, whereas on the forty or fifty occasions when Leiter's syringe was used, he gave but little heed to the trifling smarting which it caused.

The piston-rod should be occasionally looked to, washed, and freshly greased, that it may accurately fit the interior of the syringe, which must also be air-tight in all directions except at the point of the needle, because upon the release of the trigger the solution is forced to escape wherever the smallest passage exists. We do not know how the vulcanite syringe will be found to stand continued usage. It seems to be made with thin walls; if thicker, it might perhaps be less liable to crack or become warped. But, under all the circumstances of the case, vulcanite seems to be the best material of which it could be formed.

The metal tubes should be kept bright and clean, and always rubbed with a dry cloth directly after use, and a small wire placed in the needle before that it is replaced in the case. With these precautions, it would seem that Leiter's instrument cannot easily get out of order. It is certainly an ingenious, valuable, and low-priced addition to the armamentum of the physician and surgeon.

DOUBLY DISTILLED WHISKY.

EXCEPT in the private cellars of persons who make sure of having their spirits, particularly whisky, of full mature age, by laying it down like port wine, there is scarcely the possibility of procuring Scotch whisky of sufficient age to assure the elimination of amylic alcohol (fousel oil). The process of ageing usually adopted has less to do with any certain lapse of time than with a system of continuous blending or mixture. Whisky almost direct from the still is vatted with other previous mixtures from time to time, extending back perhaps ever since the commencement of the distillery. How much of the old whisky really remains, would require a calculation almost equal to that of the differential calculus. Whatever advantage of flavour is derived by these means, we may be certain that the fousel oil of the newer distillate cannot in any way be removed thereby. It is therefore gratifying to find that, casting prejudice aside, a most successful attempt has been made to get rid of the fousel oil during a process of reduplicate distillation. The Scotch whisky produced by Messrs. Bernard and Co.'s new double distillation process has been examined by Drs. Stevenson Macadam, Paul, and H. C. Bartlett, who certify that the removal of the fousel oil has been most complete and efficacious; and although the fousel oil has been so perfectly removed, the more delicate ethers which constitute the true flavour of whisky are as pronounced and agreeable in this whisky as in any malt whisky, not peat reek, after years of laying down.

GARD'S PATENT MEAT-ESSENCE EXTRACTOR.

WE have received a drawing and account of a machine made by a Mr. Gard of Colchester for making extract of beef in a steam-jacketed saucepan of easy use and portable size. It is alleged—and with justice, we think—that such an apparatus for making beef-tea gives an extract far superior to what is obtained by the usual methods. The price of the machine is eight shillings. It is recommended to our notice by Dr. Bree of Colchester.

QUINETUM.

A PREPARATION of the whole alkaloids separated from East India red bark has been used for some time in the Indian hospitals, as well as in private practice, with great success. The concurrent testimony of

medical men in our Indian possessions is to the effect that quinine is not so greatly superior to the whole alkaloids as to make it worth while to separate the sulphate in its pure state. Mr. Thomas Whiffen of the Quinine Works, Battersea, now offers to the profession a similar preparation, which he calls quinetum. It is in the form of a fine granular non-adherent powder of a pale buff colour. The proportions of the various alkaloids present will of necessity vary with the sample of bark used; but, we think, not so much as to be of moment therapeutically. Sulphate of quinetum is a white crystalline body with a faint pink tinge, greatly resembling sulphate of quinine; and we are informed that the preparation can be supplied to the profession at about one-half of the cost of quinine.

SELECTIONS FROM JOURNALS.

SURGERY.

FALSE ABSCESSSES OF THE BONES AND NEURALGIC OSTEITIS.—At the meeting of the Paris Academy of Medicine on October 5th, M. Gosselin remarked that, in 1836 and 1846, Brodie published nine cases which drew attention to that form of osteitis in which, after the disease had lasted for a long time and without necrosis as a necessary accompaniment, the inflammation terminated by supuration and the formation of an interstitial abscess more or less deeply hidden in the thickness of the bone, and without communication with the exterior. Since that time, other cases had been published by several authors, amongst others by M. Edouard Cruveilhier (Thesis 1865), by M. Broca, etc. M. Gosselin had been led to consider that the symptoms attributed by the authors to this affection, and especially the obstinate and acute pain which is said always to accompany them, are not characteristic. From the details of six cases he had himself seen, and from the critical analysis of those which other writers had recorded, he thought himself warranted in deducing the following conclusions. 1. In the long bones condensed by an old osteitis, cavities may exist which are not abscesses, and there may be neuralgic pains which have no reference to the presence of these cavities. 2. Neuralgic osteitis may exist even without any symptom, but always in a bone hypertrophied by long-standing osteitis. Trephining may be useful, and is not dangerous in these cases of hyperostosis with osteo-neuralgia.

AMPUTATION BY A COMBINATION OF THE CUTANEOUS AND MUSCULO-CUTANEOUS PLANS.—Dr. D. Hayes Agnew (*Philadelphia Medical Times*, August 7th, 1875) recommends the following method of amputating, as obviating the objections to the ordinary methods. He makes two oval cuts through the skin down to the deep fascia, on opposite sides of the limb, raising the integument only a short distance, say three quarters of an inch; and then applying the knife at the junction of the skin flap and the deep fascia, cuts the muscles obliquely back to the bone or bones, as the case may be; or, if transfixation be preferred, thrusts the knife through at the angles of the tegumentary wound, and cuts from within out. He finds, however, the former the more convenient plan. The adjustment between the divided surfaces will be complete. This method is adapted to any part of the forearm, arm, or thigh, and even to the leg.

THERAPEUTICS.

SUBCUTANEOUS INJECTIONS OF WATER.—Dr. Lélut, in a communication to *L'Union Médicale* of October 5th, states that, during the last three months, he has employed subcutaneous injections of water only for the relief of pain, with the most successful results. He relates how he was induced to adopt this method of treatment by pure accident. He had left a bottle containing a solution of morphia on his desk. His servant upset the bottle, and filled it with water to conceal her carelessness. The next day, Dr. Lélut, having occasion to repeat a hypodermic injection in the case of a patient suffering from sciatica, used the liquid from the usual bottle. When he saw his patient the next day, he found him in a most lively frame of mind, and was thanked by him in the following terms. "Oh! doctor, how grateful I am to you. You relieved all my pain without making me feel sick." He was astonished at this result in a patient who had suffered from nausea and vomiting after each injection. He naturally proceeded to examine the solution used, and was astonished to find only pure water in the bottle. He repeated the experiment during the ensuing days on several patients, and invariably found that he gave them relief and avoided nausea and vomiting; he has consequently, as above stated, continued to employ the same plan from June last up to the present time, with, as a rule, satisfactory results.

BRITISH MEDICAL ASSOCIATION:
SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, NOVEMBER 27TH, 1875.

RAILWAY PATHOLOGY.

THE case of Harris v. the Midland Railway Company, tried before Baron Pollock recently, is of interest from several points of view. In the first place, we are glad to find that at least one learned judge correctly appreciates the ambiguity of some medical cases. He is willing to admit that we may entertain opposite views without being either dishonest or ignorant. After hearing the evidence of the plaintiff's witnesses, counsel announced that they had agreed to a settlement. Baron Pollock thereupon said "he had come to the conclusion that this was one of those cases in which the learned counsel on both sides would have to leave to the jury a question of the highest physiological and scientific refinement, on which the most eminent men in the medical profession were not agreed"; and that, therefore, he approved of a settlement having been arrived at, saving both sides the additional cost of a more prolonged trial.

Turning now to another aspect of the case, we find in it some points of great scientific interest. The history of the man we have gathered from the *Times* report, which, though, as usual, excellent in its way, is of course not detailed. We should very much like to see the *verbatim* report of a dozen or two railway cases in print. The consideration of such a volume would do a great deal to promote the formation of sounder, because less exclusive and dogmatic, opinions on many points; but we fear no one will be public-spirited enough to incur the cost of so unremunerative an undertaking.

The accident occurred on December 10th, 1874. The present symptoms are paralysis of sensation and voluntary and reflex motion of the foot, leg, and lower half of the thigh on each side, with absence of wasting and presence of faradaic muscular excitability. The man also suffers much pain in the head, back, and sides. From these facts, his medical witnesses, Dr. Ramskill and Mr. Erichsen, properly—indeed, necessarily—inferred that the paralysis was of a functional (outside courts of law called hysterical) nature. Mr. Erichsen seems further to have stated that "the whole of the plaintiff's symptoms might fairly be referable to concussion of the spine". We are fain to confess that the true pathology of hysterical paralysis is unknown to us. Brodie's notion, still held by many, that it is a paralysis of the will, is to our minds quite inconsistent with the usually attendant anaesthesia and analgesia. We can conceive a patient not having the will to move his legs, but we cannot conceive his being able to avoid the perception of pain by being unwilling to perceive it. We think that it would be better for writers on the subject of railway cases to employ Dr. Abercrombie's more exact term, "concussion of the cord", when they are speaking of that disorder, rather than the very inexact one commonly used, of "concussion of the spine". Surgeons always say concussion of the brain, not concussion of the skull.

To return to Harris. Whilst we are willing to admit that some of the local manifestations of hysteria may depend upon disorder of the cord, we cannot admit that at present the evidence or the arguments justify us in considering this as proved. In the recent edition of his work on *Concussion of the Spine*, Mr. Erichsen admits that the general hysterical condition which not unfrequently follows railway accidents is referable rather to mental shock—that is, fright—than to any mecha-

nical one. He also assumes, on the authority of Hammond, that hysteria depends upon anaemia of the cord. That even spinal irritation has this origin we cannot admit to be an indisputable theory. But, even if it were beyond question, there are undoubtedly other hysterical phenomena which cannot be so accounted for. The emotional centres are certainly not in common parlance to be styled parts of the spinal cord, and yet their disturbance is one of the leading features of hysteria. But, if we cannot accept Mr. Erichsen's arguments, neither can we submit to his authority on the subject of hysteria. His views are both vague and inaccurate. For example, he says, speaking of the "more intense cases" of anaemia of the cord, "the legs and feet are cold; there is no reflex sensibility or movement in them; they are not susceptible to the electric stimulus, either as regards muscular irritability or cutaneous sensibility". Now, it is a received dogma that, as Meyer puts it, "except in cases in which the hysterical is united with peripheral paralysis, the electro-muscular contractility of the muscles, whose motions are not under the command of the will, is perfectly preserved, although their sensibility is lessened or entirely gone". If the paralysis be produced by concussion of the cord, it is not peripheral, and therefore the muscles ought to be electrically excitable, as they are in Harris's case; but, as Mr. Erichsen says in his book, they are not in cases of hysteria or spinal anaemia. Again, speaking of hysteria generally, he says it is a "word which serves as a cloak to ignorance, and which merely means a group of symptoms *all subjective*". Now, without insisting that cutaneous insensibility or indifference to most powerful batteries is scarcely to be put aside as a subjective symptom, we must remind Mr. Erichsen that the symptom which is most nearly universal in hysterical cases is the discharge of a large quantity of limpid watery urine. This is not merely not a subjective symptom, but one which it is ordinarily impossible for any one to produce directly at will. With regard to the anæmic cord, he seems to throw doubt upon his own views by suggesting that the so-called condition may arise from "concussion or vibratory jar, in consequence of which its molecular condition is disturbed". If this be so, why assume a further condition of anaemia or anything else? Again, he suggests that the anaemia of the cord may be due to a primary concussion of the sympathetic system, constricting the spinal vessels. It appears to us, in the first place, that there is no organ in the body less liable to be concussed than the sympathetic system, as distinguished from the cord. In the next place, disordered blood-supply, if it exist, is much more likely to arise from concussion of the vaso-motor centre or centres of the cerebro-spinal system, from which, and not from the sympathetic, the vaso-motor nerves are, according to Schiff, exclusively derived. It is true that this view would justify Mr. Erichsen in attributing the phenomena to which we have been referring to concussion of the cord. To this we have no objection: our object being, not to start theories of our own, but to inculcate the necessity of moderation in dogmatizing upon very intricate and obscure lesions. Some cases which have come under our notice at an early date after injury would seem to show that the brunt of a concussion may fall elsewhere than on the spinal cord. In two instances, the chief symptoms have been slow pulse, slight icterus, and concentrated scanty urine. A very similar collocation of symptoms presented itself to us in the person of a lady who had been greatly shocked by hearing that her daughter had the small-pox. Cases of sullen jaundice from fright are well known, and sudden loss of appetite from the same cause still more common. In these cases, it is likely that there has been commotion either of the nucleus of the pneumogastric in the floor of the fourth ventricle, or of some portion of the vaso-motor centre. This is a branch of railway pathology worthy of more attention than it has yet received. We are encouraged to point out such deficiencies as these by the fact that, since we in a similar manner called attention to the importance of oxaluria with excess of urea as a sequela of railway accidents, Mr. Erichsen has referred to it, although inadequately, in his last edition. Probably, with more time for investigating its relation to these cases, his next edition will enter more fully into the subject; and in the meantime we

draw his attention to the fact that, in speaking of oxaluria, he does not distinguish the simple form from that much more important one which is associated with excess of urea in the urine.

We may take this opportunity of raising another question of very wide bearing. Given a case of concussion of the spinal cord, is the result a reduction in the emission of nerve-force from the concussed grey matter of the cord, or an increase of it? Probably most persons would say the former; but it is, on the contrary, probable that, at all events, in many cases—for example, in the two above mentioned—if not in all, the effect of such a commotion is to facilitate the escape of the nerve-force.

The questions we have raised have an interest beyond the necessities of the trial or scientific curiosity. They cannot fail to influence the treatment of these persons, which is at present, as far as drugs go, eminently fruitless and unsatisfactory. Above all, we commend to all concerned in this investigation the sage dictum of Baron Pollock, that we have here to do with questions “of the highest physiological and scientific refinement”.

TYPHOID FEVER AT CROYDON.

A DEPUTATION of gentlemen living at Croydon, Selhurst, and South Norwood, waited upon Mr. Sclater-Booth at the Local Government Board on Nov. 18th, with reference to the recent outbreak of typhoid fever in those districts. Mr. Grantham, M.P., introduced the deputation, and, in the course of his remarks, said that the fever had brought desolation into many homes in Croydon; he said that the public had been rather startled, especially as no steps were being taken to ascertain the cause of the outbreak. Mr. Grantham also stated, that “the matter had been warmly debated at board meetings, but nothing practical was done”; he stated, also, that some members of the Board of Health were in favour of an investigation, while others were not; and the public had consequently lost confidence in the capacity of their local representatives to deal with the evil. A long memorial was then read by Dr. Chambers, urging upon the Local Government Board the duty of instituting an investigation into all the causes which gave rise to the outbreak. The memorial branched off into a number of possible and impossible causes, the information regarding which was mainly obtained from unofficial sources, and suggestive merely; whilst, if the reports which are now before us of the proceedings of the local board itself are correct, some of the statements are scarcely borne out by the facts, especially that which makes out that the fever was not mainly confined to the district supplied by the Croydon waterworks.

Mr. Sclater-Booth, in reply, said he could not at all be surprised that a second outbreak of the serious character described should have aroused their attention and that of the public at Croydon, and that they had taken such steps as they had upon the subject. When he was made last familiar with the matter, it seemed to him that there was very little doubt, if any, as to the cause of the outbreak, which then seemed to be confined exclusively to districts supplied by the Croydon waterworks. That, however, he understood, was not now the case. He regretted being unable to give a direct answer off hand to what had been urged, but had the deputation been fixed for a later period of the year, he would have been prepared with a distinct reply. But it was only that morning that he had received from the Local Board of Health of Croydon an official and authoritative answer to inquiries made by his office. Their report was an elaborate one, and contained a document which appeared to be an expression of perfect confidence on the part of several gentlemen residing in the neighbourhood in their medical officer. Those papers must be carefully read over before he would be in a position to give a positive answer to their question. Steps should be at once taken to accomplish this, and a reply would be furnished without delay. The deputation thanked Mr. Sclater-Booth for his courtesy, and retired.

We are not surprised that the residents have waited upon the President of the Local Government Board; but they went too late. If

wiser counsels had existed among them, they would have taken care that their interests were confided to the care of better hands.

Whilst we sympathise with them most sincerely in the affliction which has fallen upon them, we cannot give that sympathy unreservedly. The election of the members of the local board is in the hands of the ratepayers. They have chosen certain men to legislate for them; and, now that the fruits of that legislation are visible, they, like the frogs in the fable, call out; but it is too late as regards the past. We have the reports of the Croydon local board before us. We find in those reports that their colleague Dr. Carpenter warned the members (the elected of Croydon and Norwood) of the danger they were certain to incur, if they continued in the course of wasted water and intermittent supply. They gave no heed to his warning. Their representatives gave no attention to his warning, and the memorialists allowed his opposition to be unsupported by any outside help. Even when the fever did come, every obstacle was put in the way of the sanitarians upon the board; by some of the memorialists themselves, every kind of wild suggestion was made but the right one; and now that Dr. Carpenter's opinions are shown by a tremendous weight of evidence to be right, and the board have yielded to that evidence, deciding to do everything which has been pressed upon them by our Associate, and which it appears that Dr. Carpenter has urged on them for the past ten years, the ratepayers rush to the Local Government Board for help, instead of taking measures to help themselves.

We thought Englishmen were self-dependent and did not want extraneous help. We think now, that the way in which the Croydon memorialists ought to act is to elect men to govern them who are competent to do it, and not to have upon their board individuals who are unable to see anything which is beyond the value of a bit of paving or a load of bricks. It is to the material of the board that the ratepayers must turn their attention, and not to the Local Government Board. They will have an opportunity of making a sweeping change next March, and if the memorialists wish to save themselves from future visitations, they will take care that a better class of men represent them in the future.

The medical officer of health, Dr. Philpot, has presented to the Local Government Board a very full report upon the matter, which will be worthy of perusal, as it bears out in all the principal features the points which have been urged upon the attention of the local board of health of Croydon by their colleague for many years past.

If anything would do local self-government a serious harm, it is the action now taken by those who have memorialised the Local Government Board, and who appear to be scarcely aware of the position in which they place the whole question.

THE UNIFICATION SYSTEM ON ITS TRIAL.

IT is, no doubt, satisfactory to those who have at any time considered themselves imbued with the spirit of prophecy when their predictions become accomplished facts; and we must plead guilty to some measure of this human weakness, on learning the turn which army medical matters have recently taken at Aldershot. We need scarcely remind our readers that, on the appearance of the now famous warrant of March 1873, we took the earliest opportunity of pointing out some fatal defects in its construction, and more especially drew attention to the injustice of the subsequent circular, which made medical officers in charge of hospitals directly responsible for stores. Public opinion shared our apprehensions, and a strong protest against this and other clauses was transmitted to the Secretary of State for War by the entire medical staff at Malta, and a copy of this temperate and well reasoned document is now before us as we write. Although it might reasonably have been expected that serious annoyance and discomfort must arise from interrupting medical men in their purely professional career, and inflicting extra duties upon them for which they have had no special training, and for which not one farthing of special remuneration has been allowed, we did not anticipate so speedy a confirmation of our

views. But the fact is, that so many and serious have been the appeals made against charges for articles of hospital equipment at Aldershot, that it has been found necessary to assemble a board of military and medical officers, who will thoroughly investigate the entire question. We understand, for example, that the surgeon in charge of the first station hospital is held responsible for £85; that between £30 and £40 are written to the debtor side of the medical officer until recently responsible for the second establishment at Aldershot; and that one of our military colleagues in the Bermudas has a similar heavy debt hanging over his head. Although the court of inquiry will probably have concluded its labours before we go to press, we shall not at present do more than place these facts before our readers, in the full conviction that Major-General Primrose and his colleagues will acquit themselves of their difficult task with skill, fairness, and discretion.

THE Grocers' Company have made a grant of £50 to the North-Eastern Hospital for Children, Hackney Road.

DR. JOHN CHARLES BUCKNILL, Chancery Visitor of Lunatics, has resigned that office, owing, we regret to learn, to failure of health. The post, which is of the value of £1500 a year with travelling allowances, is in the gift of the Lord Chancellor.

WE would call the attention of our readers to the meeting of the medical profession which is to be held on Tuesday next, at the Medical Society's rooms, to consider the advisability of endorsing and supporting the British Medical Defence Association.

MR. W. A. RYDER, a merchant at Bicester, has been presented with a piece of plate by a number of anti-vaccinators at Banbury, in recognition of his having gone to prison for seven days rather than vaccinate his child.

PROFESSOR LEOPOLD DITTEL of Vienna lately received on his name-day, from a patient of his, Baron Sina, a valuable present in the form of an elegant casket containing twelve notes of 1,000 *gulden* each (in all about £1,250).

A STATUE of Dr. Schuh, formerly professor of surgery in the University of Vienna, who died about ten years ago, was publicly unveiled in the General Hospital of that city on November 9th. The principal address was delivered by Dr. Salzer, *primarius* of the hospital.

WE are happy to be able to state, after careful inquiry, and on the authority of Mr. A. Southey, medical officer of health, who has investigated the matter personally, that the report as to typhoid fever having made its appearance in Eton College is entirely without foundation.

A NEW society for the "Protection of Vivisectionable Animals", is announced, of which Miss Cobbe and Dr. Hoggan are the secretaries. The prospectus is brief, but it announces comically that the programme "will be pursued with as much moderation as is compatible with its objects".

DR. HEBRA, the distinguished professor of dermatology in the University of Vienna, has been suffering from an attack of pleuro-pneumonia. He has so far recovered as to be able to leave his bed; but the commencement of his course of lectures is deferred until Dec. 13th, and in the meantime he has two months' leave of absence to complete his convalescence.

ACCORDING to the *Journal Officiel*, there is so considerable an accession to the ranks of the medical students at the University of Vienna, that the lecture-theatres are too small to accommodate them. The same state of things has occurred in the Faculty of Medicine, where, for some of the courses of lectures, double the number of students that can be received have put down their names.

ON All Saints' Day, there was not a single body waiting for *post mortem* examination in the mortuary in Vienna. For more than ten years not a day had passed in which the mortuary did not contain bodies from the General Hospital (with 3,000 or 4,000 patients), or from elsewhere. A white flag was hoisted on the building to give public notice of the rare event.

THE commissioners appointed last session to inquire into the practice of experiments on animals will meet on December 11th to receive final evidence; after which, they will proceed to consider their report. A circular has been issued by the Commission to several public institutions in which physiology is taught, asking for information as to the number of animals, including frogs, which are annually made use of for experimental purposes.

IN conformity with orders issued by the Government of India, a subordinate medical establishment has been organised to accompany the staff during the tour of His Royal Highness the Prince of Wales to the various parts of India. The European apothecary and the native doctor, who served the Duke of Edinburgh under the orders of Dr. Fayer during his late visit to India, and who are now employed in the Lahore circle, have been appointed to the medical establishment.

SCARLET FEVER AT ALDERSHOT.

SCARLET fever is happily not making much progress at Aldershot. Ten or eleven children are under treatment in the contagious ward adjacent to the female hospital, and one nurse has caught the infection; but it is satisfactory to note that no case had broken out a few days ago among the men, although several had been under observation. Sore-throat, as often happens during the threatening of such an epidemic, is, however, very prevalent in the camp.

THE ABOLITION OF SMALL-POX.

It is, remarks the Registrar-General, worthy of note that no death has been referred to small-pox during the past four months in London, which has an estimated population of 3,445,166, although the corrected average number of fatal cases of this disease in the corresponding period of the last ten years is 337. This complete immunity from fatal small-pox in London for so long a period is without parallel since civil registration was established; and may be safely assumed to be entirely unprecedented. We note that one death was last week classed to small-pox, but that it was a fatal case of chicken-pox; and that, during the last eighteen weeks, 16 deaths in London have resulted from that disease. (*Brit med. Journal*)

THE MANCHESTER PROVIDENT SCHEME.

WE have lately published a correspondence upon this subject. At the commencement, we took occasion to say how important, in our opinion, was the experiment which is now being tried at Manchester; and how sincerely we wished it success, both in the interests of the profession and of the public. We regard it as a fortunate circumstance that the movement is supported by influential laymen, who have no personal or pecuniary interest in the matter, and who are solely actuated by philanthropic motives. In some respects, their independent position is, no doubt, an advantage, by enabling them to judge impartially on many questions which must arise in the management of a comprehensive scheme. But, on the other hand, the fact that they are laymen may, perhaps, prevent them from entering into the feelings of the profession. We have always maintained that, if provident institutions are to be permanently successful, they must be so constituted as to be acceptable to the medical men who serve them; and to ensure this, it is necessary that the medical officers should have a fair share in their management. This argument is all the stronger in proportion as the dispensaries become self-supporting. As the number of benefited members increases, it is essential that the medical men should have the power of checking the admission of unsuitable applicants. The difficulty which has formed the subject of the recent correspondence in our

columns seems to have arisen from a neglect of this precaution. There is no greater danger to the very existence of a provident dispensary than the admission of persons of a higher social grade than that for which it is intended. Medical men must, in self defence, protest against such a step. The proposal to admit friendly societies naturally suggested danger on this score. But if greater care had been taken to ascertain the individual opinions of the medical officers, we believe that the present difficulty might have been avoided, and a scheme agreed upon which would have been acceptable to all. We hope that even now it is not too late to reconsider the question; and that such modifications will be introduced into the rules as will not only restore confidence, but ensure in the future an even greater amount of success than that which has been already achieved.

MEDICAL ADVICE IN NEWSPAPERS.

AN inquest was held last Saturday on the body of a young man, Edward Saunders. It appeared by the evidence that he had been for a long time very reserved and strange in his manner, and that he suddenly disappeared in October last. His body was found floating in the Thames last week, and in his pocketbook was found a note, apparently from the editor of the *Family Herald*. This note was to the effect that deceased would have an answer to his communication on a future occasion, and in the meantime recommended him to consult a medical man. The following entry in the pocketbook was in the handwriting of deceased.

"Should my body be found, which I devoutly hope it may not, I think it as well to give some explanation of what will be called a rash act. Having written to the editor of the *Family Herald*, and received such an answer as to lead me to suppose myself mad, I have made up my mind to kill myself. I might, for aught I know, go raving at any moment, and do some one else a mischief. The only thing that has hitherto restrained me from suicide has been the fear of causing sorrow to my parents, but that may be soon got over; whereas, if I were to live a lunatic, they would be always in trouble about me, and by doing this—i.e., killing myself—I end their trouble and my own. I have not written this with the hope of getting my body buried in consecrated ground, that being an affair of little moment to me, but simply in order that the cause of my death should be known."

A verdict of suicide while of unsound mind was returned.

RECENT URBAN MORTALITY.

DURING last week, 5,557 births and 3,696 deaths were registered in London and twenty other large towns of the United Kingdom. The mortality was at the average rate of 25 deaths annually in every 1,000 persons living; and the death-rates in the various towns were as follows. Sunderland, 16; Wolverhampton, 17; Norwich, 18; Portsmouth, 19; Hull, 20; Liverpool, 21; Sheffield, 23; Birmingham and London, 24; Leeds, 25; Manchester, 26; Glasgow, Nottingham, and Bristol, 27; Edinburgh and Leicester, 28; Newcastle-upon-Tyne and Bradford, 29; Dublin, 31; and Oldham and Salford, 35. The zymotic death-rate was 8.1 and 9.1 in Salford and Nottingham respectively. The 529 deaths from the seven principal zymotic diseases in the eighteen large English towns, included 185 from scarlet fever, against 226, 231, and 260 in the three preceding weeks. The annual death-rate from scarlet-fever last week was equal to 1.5 in London, 2.8 in Bradford, 3.5 in Salford, 4.3 in Bristol, and 4.5 in Nottingham. The fatality of scarlet-fever showed a general decline, whereas that of measles had increased. In London, 2,462 births, and 1,603 deaths, were registered. The births were 116 above, whereas the deaths were 71 below, the average of the week. The annual death-rate was equal to 24.3 per 1,000, and was 22 per 1,000 in the west, 22 in the north, 28 in the central, 24 in the east, and 26 in the south groups of districts. The 1,603 deaths included one from small-pox, 51 from measles, 96 from scarlet fever, 14 from diphtheria, 63 from whooping-cough, 27 from different forms of fever, and 30 from diarrhoea, or 282 deaths in all, and 9 above the average of the week. The fatal cases of small-pox and fever were considerably below the average, whereas those of each of the five other zymotic diseases showed a marked excess. Scarlet fever

was especially fatal in Mile End Old Town, and in Gray's Inn Lane, St. James', Bermondsey, and Somers Town registration sub-districts. The death classed to small-pox was a fatal case of chicken-pox. The deaths referred to diseases of the respiratory organs, which in the five previous weeks had steadily increased from 194 to 349, further rose last week to 371, but were 38 below the average of the week; 213 resulted from bronchitis, and 113 from pneumonia. The Asylum District Fever and Small-pox Hospitals at Homerton and Stockwell contained 352 patients on Saturday last, of which 66 were under treatment for fever, 270 for scarlet fever, and not one for small-pox. The London Fever Hospital contained, also, 101 patients, including 12 cases of enteric fever, and 82 of scarlet fever. In outer London, the general and zymotic death-rates were 19.2 and 3.1 per 1,000 respectively, against 24.3 and 4.3 in inner London. Eight more fatal cases of fever were registered in Croydon. Of 10 deaths in Wimbledon during the past two weeks, 9 have been referred to measles. At Greenwich, the mean reading of the barometer during the week was 29.73 inches; the mean temperature of the air was 45.8 deg., or 3.8 deg. above the average. The general direction of the wind was S.W., and the horizontal movement of the air averaged 19.6 miles per hour. Rain fell to the amount of .32 of an inch.

SHILLING DISPENSARIES.

WE frequently receive handbills or advertisements purporting to set forth the advantages of some new "provident" dispensary; but, on examination, we find that they have nothing "provident" about them, and that the name is only adopted at the present time as one likely to meet with public favour. Sometimes the name is varied, and they are styled "independent", or "self-supporting" dispensaries. But, in all of those to which we allude, the system is the same. Persons are attracted by the offer of cheap or gratuitous advice, while the "manager" or "principal" of the so-called provident institution maintains himself in fact by the sale of drugs. We do not complain of this mode of earning a livelihood. It is but a modified form of "counter-practice", and such practitioners are almost a necessity. Last week, the advertisement of such a "provident, self-supporting medical dispensary", appeared in a Hull newspaper. In it advice is offered "to the labouring and poor classes by a physician of twenty-five years' experience in general practice. Medicines charged for—adults one shilling, children sixpence, to be paid for at the time". The "principal" is himself a member of the Independent Order of Good Templars, and the institution is said to be "conducted on temperance principles". Query, does this mean that no alcoholic tinctures are prescribed? The principle of ready-money payment is undoubtedly good for the poor, and saves them from the burden of debt. But it is scarcely honest to call such institutions "provident", for the essence of providence is to *provide for the future*; and that which makes it possible for high-class men to accept provident dispensary appointments is, that the continuous subscriptions in health form a remuneration in some degree adequate to the attendance during sickness.

THE PLYMOUTH PUBLIC DISPENSARY.

A MOVEMENT has been set on foot with the view of converting the public dispensary at Plymouth into a provident institution. For the last seven years, there has been a provident dispensary in the town, but the gratuitous relief which could be easily obtained at the public dispensary has been a great obstacle to its progress. Now, however, the governors of the public dispensary seem inclined to reconsider the basis upon which their institution stands, and we trust they will give the provident system a careful consideration. Mr. W. H. Algar has addressed a letter to the governors in which he points out the special advantages of provident dispensaries, and, in order to show that they are united to the wants of a large section of the working classes, he says:

"It may be asked, What class of persons avails itself of the provident dispensary in this town? To this it may be replied, that about

85 per cent. receive wages of less than 21s. per week, and an examination of the list of members will show that 'labourers, artisans, and the wives of artisans (who are already members of sick clubs), servants, dressmakers, tailoresses, porters, fishermen, sailors, soldiers, and policemen's wives, laundresses, and people of this sort, are those who avail themselves of this institution. There is scarcely one per cent. whose average earnings would amount to 30s. per week, but there are many whose weekly wages are as low as 14s., 13s., and 12s. The rate of wage of the servant and dress-making class would certainly be even less than this. The under secretary informs me, that it is a constant remark of the members, that they 'much prefer paying a penny a week than to go about begging for a paper'; and they greatly appreciate the privilege of selecting their own doctor. If 836 persons of this humble class (representing 1,141 possible patients) voluntarily join a provident dispensary, in spite of the attraction of gratuitous medical relief freely offered close by, are we not bound to look well into the matter and see if the time has arrived when the public dispensary should be altered in its character?'

These figures prove that the provident dispensaries are found to be a boon even by persons earning very small wages. In a town like Plymouth, there must surely be room for more than one such institution; and when the wants of this class are fully met, there can be but a very trifling number of cases besides those whose care properly fall to the Poor-law medical officers.

THE WEST RIDING ASYLUM.

THE annual *conversazione* at the West Riding Asylum, Wakefield, which has now been held by the Director, Dr. Crichton Browne, for the last few years, came off last week with great success. The chair was occupied by Mr. Spencer Stanhope, M.P., Chairman of the Visiting Committee of Magistrates; and Dr. W. H. Broadbent, of St. Mary's Hospital, London, delivered an address on the Theory of Construction of the Nervous System. The address embodied the leading points in the papers in which Dr. Broadbent has of late years forcibly enunciated some extremely interesting views as to the construction and functions of the nervous centres, and still further developed their applications to the study of disease. The lecture was full of matter of great interest and value, and we shall have the opportunity of shortly publishing it for the information of our readers. There were present at the meeting between three and four hundred medical men of the locality, including Drs. Heaton, Clifford Allbutt, and Eddison, Messrs. Wheelhouse, Teale, and Jessop, of Leeds; Dr. Rabagliati, of Bradford; Mr. Dyson Wood and Mr. Fowler, of Wakefield; Dr. Harrington Tuke, of London; etc. At the conclusion of the address, Mr. Ernest Hart moved a vote of thanks to the orator, observing that English medical science boasted in the last generation a Bell and a Marshall Hall, who laid the foundations of progress in the anatomy and physiology of the nervous system, and the treatment of diseases of the mind and nervous system. We might add now to the list Lockhart Clarke, Ferrier, Hughlings Jackson, and Broadbent, as no unworthy followers in the footsteps of those benefactors of mankind. The West Riding Asylum, under the initiative of its present most able director, was affording facilities for the furtherance of the studies of these men, and for the application of their work to the treatment of mental disease; and in doing so, with the hearty concurrence of the visiting magistrates, Dr. Browne was setting a high example, which could not but be fruitful in great results, and might well be widely imitated. Dr. Heaton seconded the vote, which was passed by acclamation. Dr. Tuke proposed, and Dr. Orange of Broadmoor seconded, a vote of thanks to the chairman. The meeting then proceeded to examine a series of tables which were provided with objects of professional interest in the body of the hall; and, after doing honour to the liberal refreshment provided by Dr. Browne for his guests, dispersed well pleased with an evening of rare professional interest. Among the objects displayed from the West Riding Asylum were many pathological specimens of value shown at a table presided over by Dr. Robert Lawson, one of the medical officers of the asylum. They included a very instructive preparation of the brain of a chimpanzee, and a comparative series of brains, most useful for the study of function. Four

brains, showing localisation of adhesions in general paralysis, were prepared by a new method (steeping in a nitric acid solution). This method is obviously very superior to the ordinary modes of removing the membranes, and promises to yield useful results. The table presided over by Dr. Herbert Major and Dr. Bevan Lewis was crowded with a quite unique collection of microscopic preparations from the collection belonging to the asylum, illustrating the histological condition of the convolutions of the human brain in the healthy adult, in the fetus, and in various forms of insanity; and similar series of the medulla oblongata, spinal cord, sciatic nerve, and sympathetic ganglia. Among these preparations were the series illustrating Dr. Major's thesis for the M.D. degree at Edinburgh, which received the gold medal, and his own and Dr. Lewis's papers in the West Riding Reports. At another table, presided over by Dr. J. Arbuckle and Mr. Bracey, were a series of drugs and medicinal preparations. Among those "in use at the West Riding Asylum", we noticed picrotoxine, conia, hyeseyamine, solamine, etc., which have been made the subject of an important investigation, which will be found in the forthcoming annual volume of the West Riding Asylum Reports. Altogether, the tables presented the reflection of an intellectual activity and clinical zeal which are only too rare in asylums, and which are also observable not only in the valuable annual volume of Reports which this asylum now produces, but in the resulting order, cheerfulness, and alert vigilance of the whole administration. It is satisfactory to note that the administrative results are admirable, both as to cures and to expenditure. The good results of the infusion of the spirit of scientific research into a great curative establishment are nowhere more apparent than at the West Riding Asylum, which, under the singularly able direction of Dr. Crichton Browne, is in every respect a credit to the county and an honour to this country.

TYPHOID FEVER AT UPPINGHAM.

APROPOS of some observations in our recent report, Mr. Bell writes to us: "I deny the right of the sanitary authority to censure a medical practitioner entirely unconnected with them. I deny the power of the medical officer of health to summon me to a meeting, which he did verbally, through the inspector of nuisances. I distinctly deny that I withheld information; as, previously to the meeting, I had two or three conversations with Mr. Haviland, and answered all his questions, and had daily been called upon by the inspector of nuisances, to whom I had given all information in my power."

THE WORCESTER INFIRMARY.

AT the monthly meeting of the Executive Committee on Monday, the appointment of Dr. James Wilson as physician to the infirmary was moved by the Right Hon. Earl Beauchamp and unanimously agreed to. This was the only application for the office, which was rendered vacant by the resignation of Dr. Inglis. Dr. Wilson holds several degrees, and has seen a great deal of service, having served with distinction in the late American war as surgeon to the forces, and subsequently held an appointment as surgeon in the British navy, which he has just resigned after eight years' service. He has also held office on board the Duke of Edinburgh's ship.

MR. RADCLIFFE'S ADDRESS.

OWING to some curious chapter of accidents, we have not received, nor have we seen in any other medical paper, any report or notice such as is usually forwarded of the President's address at the Epidemiological Society. A rather full report of a portion of it appeared in the *Times*, loaded with adulation of Sir William Jenner, whose genius and industry, it seems, have solved the riddle of continued fevers, and brought us, with the help of Mr. Simon and his staff, to our present vantage-ground. We are loth to criticise reports in daily papers of medical addresses; but there is something in the prominence which has been given to this address, and the circumstances which surround it, which have called for remark. We have often insisted on the value of Sir William Jenner's admirable work, and cannot be supposed

to be less impressed with its value than others. Nevertheless, we regret to find in this report that Stewart's skilful investigations and Murchison's splendid labours are ignored, and their names not so much as mentioned. Mr. Radcliffe must know well how vastly these labours and those of Budd have contributed to the acquisition of the knowledge upon which Dr. Farr and Mr. Simon and his staff have based their investigations and reports; and, if the fault of omission were with the *Times'* report, we should have been glad to see Mr. Radcliffe correct it in the columns in which the report appeared.

THE EARL OF DENBIGH ON HOMŒOPATHY.

SPEAKING at Birmingham a few days ago, at a luncheon in connection with the opening of a homœopathic hospital, erected at a cost of £17,000, the Earl of Denbigh said he had been a homœopathist forty years, having begun to practise the system when at Eton. The foundation of a "homœopathic hospital" could hardly have been more appropriately inaugurated than by such a speech. Homœopathy, as such, can hardly be said to exist, although a scientific juggle which takes the name of that ancient delusion still persists. It is, however, exceedingly interesting to know that this intelligent nobleman's convictions were acquired when a schoolboy at Eton, and that "he began to practise the system there."

DR. INGLIS.

A MASSIVE silver salver and a purse of gold have, we are pleased to see, been presented to Dr. Inglis of Worcester, on his leaving that town for Cheltenham, after resigning office as a physician to the infirmary, under circumstances highly honourable to himself, and to which we have several times referred. The salver, which is inscribed with suitable expressions of esteem from his numerous friends, was presented in the Worcestershire Medical Society's rooms, by Mr. G. W. Hastings, in the presence of a number of influential residents.

SCOTLAND.

IT has been arranged that Lord Derby, the Lord Rector of Edinburgh University, shall deliver his address to the students on the 17th of next month. He is to be presented with the freedom of the city on the 18th.

THE late Mrs. Marshall of Glasgow has bequeathed the sum of £1,000 to the Glasgow University for the foundation of two bursaries; one in divinity, the other in medicine. She has also left upwards of £800 to the local charities.

IN January last, Mr. Isaac Jolly bequeathed the residue of his estate, valued at £2,500, in equal parts to the Royal Infirmary and Incurable Hospital, Aberdeen. The first instalment of £500 each, free of legacy duty, has just been paid. No conditions were attached to the bequests.

A SCHEME is on foot for introducing a new supply of water into Burntisland; and estimates have been given in, according to which 350,000 gallons of water *per diem* will be supplied, the cost of the works being estimated at £16,000. A *plebiscite* among the ratepayers is to be taken on the subject.

NEW SMALL-POX HOSPITAL IN GLASGOW.

FOR some time past, the ratepayers in the neighbourhood of the old small-pox hospital have been very pressing in their claims for its removal to some part of the town less densely inhabited. It was consequently determined by the authorities to build a new small-pox hospital in the neighbourhood of Belvidere, near the fever infirmary. This building is now approaching completion. It consists of five pavilions running north and south, each pavilion being divided into four wards, two in the centre for cases in an acute stage, and one at each end for convalescents; the two centre wards have no communication with one another, except from the outside. Each of them will

accommodate 11 persons, and each of the convalescent wards 7; giving a total accommodation of 110 beds for acute, and 50 for convalescent cases. There is a nurses' room attached to each pavilion, and all the internal details and arrangements are carried out upon the most approved principles. The hospital is in an excellent situation, away from the noise and smoke of the city, and close to the banks of the Clyde. At present, there are no cases of small-pox known to exist in the city, nor has one been reported for the past two months.

THE VACCINATION ACT.

AT the Edinburgh Sheriff Court last week, Andrew Howieson was charged with having contravened the eighteenth section of the Vaccination (Scotland) Act by refusing to allow the operation of vaccination to be performed on his child, aged twelve months. He pleaded guilty; and was sentenced to pay a fine of five shillings and expenses, or, in default, to suffer ten days' imprisonment. This is the second offence under this Act committed by Howieson.

ADULTERATED TOBACCO.

IN consequence of complaints having been made to the Inland Revenue Office regarding the sale of adulterated tobacco in Edinburgh and Leith, an inquiry was instituted during the past summer, which ended in the prosecution of a number of tobaccoists in the police courts last week. The tobacco was in all the cases found to contain sugar and liquorice, the full penalty for such act of adulteration being £200. A modified penalty of £50 was imposed in a number of cases.

DISEASE IN GREENOCK.

THE burgh medical officer of Greenock, Dr. Wallace, in a recent report to the police committee, has stated that typhus fever has appeared in a severe form in some districts of the town; and has enjoined on the authorities the necessity of providing additional hospital accommodation as well as a convalescent home. The report also pointed out the considerable destitution at present existing in the town, owing to slackness of trade; and suggested that help should be given to the sufferers. At a meeting of the Town Council, on the day the report was sent in, it was agreed to expend £200 in purchasing clothes, blankets, etc., for the poor; and arrangements were set on foot for opening the Craigie Knowes Hospital.

THE PROPOSED HOSPITAL AT CRIEFF.

THE local authority, acting in concert with the parochial board, have met to consider the question of hospital accommodation. Lady Willoughby, whose handsome offer towards a building and endowment was announced some time since, had suggested that the house be erected for surgical operations only, and not for infectious diseases; but the meeting considered that, in a place like Crieff, that would be impracticable. It was agreed to communicate with Lady Willoughby, and point out the urgent necessity for an hospital for infectious diseases in preference to any other.

ELECTION OF LUNACY BOARDS.

AT a meeting of the Edinburgh County Commissioners, a letter was read from the county of Argyle regarding the mode of election of lunacy boards. At present, these boards are elected by the prison boards, but should be elected by the commissioners of supply, and made financially responsible to them. The committee of the county of Argyle had, last session, had an interview with the Lord Advocate on the subject; but his lordship could not promise any action then. The Edinburgh county board agreed with the views expressed in the letter; and decided to communicate with the Lord Advocate, with a view to see whether a Bill on the subject could be introduced next session.

FREEDOM OF TEACHING.

WE observe that Mr. John Chiene, in his introductory address to the students of the extramural school in Edinburgh, makes reference to the initiation of what may or may not be a similar kind of school in

Glasgow. We would commend to the notice of the directors of the Royal Infirmary the following paragraph.

"This essential feature of our method—to allow each to choose his place on our teaching staff—directly encourages the individuality of the taught. Individuality means freedom. You are free to choose your teacher, and in most branches you have an abundant choice. You choose your teacher on account of his individual worth. He may have certain peculiarities; it is desirous he should ventilate them. He may believe in his methods of conveying instruction; he can put them to a practical test; and, if he be a true prophet, his labours will be followed by well-merited success. Glasgow, I am glad to see, is beginning the good fight. All success to those gentlemen who have obtained permission to lecture in the Royal Infirmary of that city. The results to themselves will be self-improvement. The result to their University will, I feel sure, be an increase in its efficiency."

It is this freedom of teaching which we have repeatedly contended for in these columns; and we are sure that, if the directors of the Infirmary take the experience gained in the extramural school in Edinburgh as their guides, the result will be an immense stimulus to medical teaching in Glasgow; whereas, if they simply set up a second "institution" with a full staff of professors, it will be a struggle for existence between it and the Andersonian. Such a struggle would hardly subserve the interests of medical teaching in Glasgow, and would postpone indefinitely that competition with the University which is much to be desired.

THE TREATMENT OF FEVER AND SMALL-POX IN PAISLEY.

THE neighbouring town of Greenock has provided itself with a hospital to meet any possible epidemic of small-pox; but we regret to observe that the authorities in Paisley seem to have no intention of stirring in this matter. During a recent epidemic, no fewer than eighteen cases of small-pox occurred in the infirmary among patients admitted for other diseases; and of these, five died. The small-pox temporary hospital was in connection with the infirmary, and there was no doubt as to the source of infection. Startled by this epidemic, ground was acquired for a small-pox hospital; but, now that the immediate danger has passed away, there seems no intention of proceeding with its erection. We suspect that the authorities are much more anxious to improve the appearance and respectability of the town than to promote comprehensive measures for its sanitary improvement. It is well known that Paisley has next to no drainage, and yet there is the greatest disposition to give this subject, as well as that of a small-pox hospital, the go-by. We trust that the inhabitants will succeed in persuading their rulers that it is not safe to trifle with the lives of the community.

IRELAND.

THE President of the Surgical Society of Ireland has issued cards of invitation for the opening meeting on the 26th instant.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE College held a meeting on Saturday to elect a Vice-President in room of the late John Hamilton, Esq., and a member of Council in room of Dr. George H. Kidd, who resigned his seat on the Council. Dr. George H. Kidd was unanimously elected Vice-President, and Dr. John Cronyn was elected a member of Council in the room of Dr. Kidd. Dr. Cronyn was opposed by Dr. Darby of Bray, who stood second on the list. The other candidates either did not appear or were in a small minority.

DUBLIN HOSPITAL SUNDAY FUND.

THE returns received up the present show the amount of the collections to be over £3,000. Returns from nineteen churches have not yet been received. These are estimated to be equivalent to about

£200, which, together with additional and special subscriptions, are expected to raise the fund to about the same as last year. About fifty churches have co-operated this year which had not collections last year. The number of collections was about one hundred and ninety. It would thus seem that there has been a falling off. This, however, is not really the case; for Messrs. Moody and Sankey had a collection, which amounted to the large sum of £270. No similar sum was expected this year; and the new churches joining have for the most part been small, and situated in remote parts of the country. We are glad to state that there has been an increase in the amount collected in the majority of the churches which co-operated last year. In spite of all difficulties and opposition, Hospital Sunday may now be considered an established institution in Dublin.

THE DUBLIN BARRACKS.

WE regret to learn that the prevalent rumours of death sickness among the officers and men quartered in Dublin are well founded. There can be no doubt that zymotic disease has prevailed to an unusual extent in the Dublin barracks, and that for over a year enteric fever has been almost constantly present in one or more of the barracks. There are situated in Dublin the following barracks. 1. Royal (cavalry and infantry); 2. Linnen Hall (infantry); 3. Aldborough (infantry); 4. Richmond (infantry); 5. Island Bridge (cavalry); 6. Beggar's Bush (infantry); 7. Portobello (artillery); 8. Pigeon House (a fort in the sea at mouth of river, miscellaneous staff and engineers); 9. Ship Street (infantry). Enteric fever has prevailed in Nos. 1, 4, 5, 6, and 7; in all cases, officers have been attacked and deaths have occurred. Enteric fever at present prevails in No. 1. Dublin is badly drained, there is no system of main drainage, and the authorities are fighting about the matter with the citizens. Dublin is a filthy and unhealthy city, with a death-rate of over 30 per 1,000 within the city, and 27 in the district, a great portion of which is almost rural. In Beggar's Bush, the unhealthiness was traced to bad drainage, which has been remedied. In Richmond, the drainage is, we believe, into a cesspool. Linnen Hall is not much used, and is unfit for use as a barrack. Aldborough is said to be healthy. Richmond has been unhealthy, but is said to be improved by better drainage and water-supply. Island Bridge is in a very low district, and cannot be properly drained until a main drainage system is established for the city. Beggar's Bush seems now to be in fair condition. Portobello has generally been healthy, is well situated on high and open ground. Pigeon House may be said to have no drainage, it is practically in the sea; it is, however, usually healthy, and the enteric fever seemed to be contracted outside in a filthy Dublin suburb called Ringsend, which is near the fort. Ship Street is badly situated, and surrounded on two sides by old and unhealthy houses. The other sides are bounded by the castle grounds; in fact, the barracks and castle are connected with one another. The castle itself is not healthy, and enteric fever has from time to time prevailed even among members of the Lord Lieutenant's household. The Dublin physician who sends us the above details, adds, "I have had myself to treat patients from Island Bridge, Richmond, and Royal barracks, all suffering from enteric fever".

DUBLIN OBSTETRICAL SOCIETY.

THE first meeting of the thirty-eighth session took place on Saturday evening, at the College of Physicians, Kildare Street; Dr. Lombe Athill, President of the Society and Vice-President of the College of Physicians, occupied the chair. There was a large attendance of members and visitors. The Honorary Secretary (Dr. J. R. Kirkpatrick) read the report of the Council, which alluded to the business of the Society during the past session. Reference was also made to the retirement of Dr. Churchill in terms of the deepest regret; and his reply to the address presented to him by the Society prior to his departure from Dublin was also read. The report also showed that at the present time there were 11 honorary and 148 ordinary members, and 13 associates on the roll of the Society.—Dr. M'Swinye moved

the adoption of the report; and, in the course of his remarks, congratulated the Society on its continued prosperity. He referred with pleasure to the graceful allusion in the report to that distinguished ornament to the science, Dr. Churchill.—Dr. Cranny seconded the motion, which was agreed to.—The President then delivered the inaugural address. He thanked the members for the honour they had done him in placing him in the chair—an honour enhanced by the fact that it had been filled by men so distinguished as his immediate predecessors. Since the last meeting, Dr. Evory Kennedy and Dr. Churchill had withdrawn from practice. To them a few words of homage were justly due. The former, were it only on the grounds that he founded the Society, should be held in grateful remembrance. But he had besides other substantial claims on regard. Placed forty-two years ago at the head of the Rotunda Lying-in Hospital, he speedily recognised the field which lay before him in the investigation of the then unknown affections which are peculiar to women; and if, to those who profited by the labours and experience of Bennet, Simpson, Marion Sims, and a host of other writers and thinkers, Kennedy's observations, published more than thirty years ago, seemed imperfect, it must be remembered that he was a pioneer and an original observer. Dr. Athill believed that, as he was founder of this Society, so he was the first Irish practitioner who directed special attention to that important branch of our profession now embraced by the term gynæcology. Of Dr. Fleetwood Churchill he felt it difficult to speak. Kind and frank by nature, rendered doubly so by the unostentatious yet fervent piety which pervaded his every action, he was a kind and sincere friend, ever ready to impart to others that information which his great experience and untiring industry had enabled him to acquire. In his early career, he had much to contend against; and, when success had crowned his exertions, it seemed to be his greatest pleasure to encourage those who were, while struggling, down-hearted and desponding. Dr. Athill said he should remember with gratitude the words of encouragement afforded by Dr. Churchill to him in bygone years, when, weighed down by care and disappointment, he almost despaired of success. Dr. Churchill retired with the sincere and deserved regret of all, and the equally well deserved respect of every member of this Society. There were few of the members who had not from time to time availed themselves of his professional skill in trying and difficult cases; while his reputation as an author was probably greater than that of any other Irish practitioner. The President then proceeded to review the transactions of the Society during the past session, which, he considered, compared favourably with those of other societies, to which he also referred in terms of commendation. The President was warmly applauded at the close of his address.—On the motion of Dr. Denham, seconded by Dr. Kidd, it was decided to print and publish the President's address in the *Proceedings* of the Society.—The result of the balloting for the officers of the Society for the ensuing session was then declared as follows:—*President*: Dr. Lombe Athill. *Vice-Presidents*: Dr. Cronyn and Dr. More Madden. *Treasurer*: Dr. Roe. *Secretary*: Dr. J. R. Kirkpatrick. *Committee*: Dr. Denham, Dr. Johnston, Dr. Kidd, Dr. McClintock, and Dr. Ringland.—Dr. McClintock moved a vote of thanks to the distinguished visitors who had on that occasion honoured the Society by their presence.—Dr. Byrne seconded the resolution, which was cordially adopted.—The President of the College of Physicians (Dr. Gordon) and Dr. Kidd (Vice-President of the College of Surgeons) responded.—The Lord Mayor-elect (Dr. Owens) also returned thanks, and defended the general conduct of the much-abused corporation; and said that, if people knew the time its members devoted to the business of the municipality, the body would not be maligned to the extent it was.—The Deputy-Governor of the Apothecaries' Hall having also returned thanks for the compliment that had been paid the visitors, the proceedings were brought to a close.

NAVAL MEDICAL SERVICE.—An examination of surgeons in the Royal Navy who are eligible, and who may be desirous of qualifying for the rank of staff-surgeon, will be held at the Royal Naval Hospitals at Haslar and Plymouth, on Tuesday, January 18th, 1876.

ASSOCIATION INTELLIGENCE.

WITH a view to giving increase of prominence to the scientific proceedings of Branches, and to the improved classification of matter, we propose henceforth to report only the official and administrative business of Branches under the head of Association Intelligence, and to transfer their medical and scientific reports to the columns in which are recorded the proceedings of Societies generally. We shall be much obliged if the Honorary Secretaries will kindly arrange their MSS. accordingly.

WEST SOMERSET BRANCH.

MEMBERS of this Branch are requested to take notice that Henry Alford, Esq., Taunton, will perform the duties of Honorary Secretary and Treasurer during the temporary absence of Dr. Kelly, who has gone to Mentone for the winter.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.

THE next meeting, to be held in the Music Hall Buildings, Aberdeen, on Saturday, December 4th, at 3 o'clock in the afternoon, will be devoted to a debate on the proper place of Alcohol in Therapeutics. The debate will be opened by Dr. Urquhart, Aberdeen.

J. URQUHART.
ALEX. OGSTON.

November 11th, 1875.

SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT.

A MEETING of the above Branch will be held at the Greyhound Hotel, Croydon, on Thursday, December 9th, at 4 P.M.; Dr. ADAMS in the Chair.

The following papers are promised.

1. Dr. Wiltshire: Two Cases of Puerperal Hyperpyrexia treated by Cold.
2. Dr. Tilbury Fox: Remarks on Lichen Rubra.
3. Mr. Christopher Heath: A Case.
4. Dr. Duncan: Prognosis in various forms of Apoplexy.
5. Dr. Lanchester: Case of Tamariind-stone in the Trachea, fatal in Four Months.

Dinner will take place at the Greyhound Hotel, at 6 P.M. Price 6s. a head, exclusive of wine.

JOHN H. GALTON, M.D., *Honorary Secretary*.

Woodside, Anerley Road, S.E., November 22nd, 1875.

BATH AND BRISTOL BRANCH.

THE second ordinary meeting of the above Branch will be held at the Royal Hotel, College Green, Bristol, on Thursday evening, December 9th, at 7.30 P.M.: W. M. CLARKE, Esq., President.

EDMUND C. BOARD, *Honorary Secretary*.

Clifton, November 24th, 1875.

SOUTH EASTERN BRANCH: WEST SUSSEX DISTRICT.

THE next meeting will be held at Worthing, on Friday, December 10th; A. H. COLLET, Esq., in the Chair.

Any member desirous of reading a paper, or communicating any case of interest, is requested to give notice to the Honorary Secretary forthwith.

WM. J. HARRIS, *Honorary Secretary*.

13, Marine Parade, Worthing, November 15th, 1875.

SOUTH-EASTERN BRANCH: WEST KENT DISTRICT MEETING.

THE first meeting of the nineteenth session (1875-76) was held at Rochester on November 10th; ROBERT ROSS BROWN, Esq., in the Chair.

Next Meeting.—It was decided to hold the next meeting at Gravesend in March 1876; Dr. Gramshaw to be Chairman.

Papers were read by Mr. A. W. Nankivell, Mr. R. Cobb, Mr. R. R. Brown, and Dr. J. V. Bell.

Dinner.—The members and visitors, to the number of thirteen, dined at the Bull Hotel.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, NOVEMBER 23RD, 1875.

SIR JAMES PAGET, BART., D.C.L., LL.D., F.R.S., President,
in the Chair.

Sugar in Healthy Urine.—Dr. PAVY made a brief communication on the presence of sugar in healthy urine, which he stated to occur more frequently as a transitory condition than was generally supposed. He demonstrated and explained the tests which he used; viz., 1. boiling with liquor potassæ; 2. boiling with bismuth, potash having been added; 3. boiling with sulphate of copper, tartrate of potash and potash having been added to the urine; 4. fermentation.

ON AORTIC ANEURISM IN THE ARMY, AND THE CONDITIONS ASSOCIATED WITH IT. BY FRANCIS H. WELCH, F.R.C.S., NETLEY.

THE object of this paper was to endeavour, by deductions made from a series of *post mortem* examinations conducted at the Royal Victoria Hospital, Netley, to place certain features of causation and pathology of aortic aneurism upon a basis of stability. The average death-age was 32 years; average period of service performed by the soldier, 12 years; average duration of the lesion, 1½ years. In five instances, the dilatation was multiple, the largest number of aneurisms in any one case being four; and, in two instances, an innominate aneurism was superadded to the aortic sac. The lesions (otherwise than the sac itself) observable in the bodies were arranged under two heads; (a) those mechanically produced by the aneurism; and (b) those indicative of a diathesis or general internal agency, generally syphilitic. The author stated that statistics of aortic aneurism in the army showed that the disease was not peculiar to climate, station, or occupation, nor connected with age or any condition of system brought about by length of service; and upon this negative basis was superadded the positive basis furnished by the morbid anatomy and life-history of the cases comprised in the paper. The deductions arrived at were placed in the form of two propositions, the first of which referred to the condition of the vessel, and was as follows. "The aneurismal tumours are associated with, and preceded by, a diseased condition of the contiguous layers of the internal and middle coats of the vessel: a tissue-growth, terminating in degeneration, which, by impairing the elasticity and contractility of the walls, allows their expansion and dilatation under the tension of normal arterial blood-pressure, or this abnormally increased by any cause." The term "atheroma" was regarded as unsatisfactory, as it expressed one possible phase only—that of degeneration; and allowed the accumulation, under the same nomenclature, of structural changes, divergent in origin and progress. Two forms of deterioration were embraced by it; one a distinct tissue-growth—an endarteritis, an active lesion—having, as one of its sequelæ, the aneurismal sac; the other, a mere opacity or occasional fatty degeneration of the inner surface of the vessel—a passive phase—followed, apparently, by no very deleterious results between eighteen and forty years of age, the period of the soldier's service. The pathological chain of continuity between the aortic disease characterised by a tissue-growth, and the aneurismal sac, was complete; and hence the important problem in etiology was to elucidate the exciting agencies in the development of the endarteritis of the internal and middle coat; and these were given in the second proposition as follows. "These two forms of textural derangement of the aorta" (the two spoken of as included under "atheroma") "are dissimilar in origin and causation. The limited passive opacity is connected with long-standing diseases of various kinds, inducing a diminished vitality of the system at large; the structural growth is, in the major number of instances, associated with syphilis, and, in a minor degree, with rheumatism and alcoholism as causation. Hence it follows that, as the latter phase is the commencement of that pathological sequence of events under one aspect, terminating as aneurism, the means for the prevention of the aneurismal tumour must be essentially directed towards the elimination of these special exciting agencies." The 34 cases of aneurism analysed stood as follows. In 50 per cent., the subjects were saturated with the syphilitic virus, and had no other diseased conditions of importance: in 14 per cent., syphilis was probably present, but not beyond doubt; in 5.8 per cent., there was acute rheumatic diathesis; in 5.8 per cent., excessive intemperance; in 2.9 per cent., syphilis, rheumatism, and alcoholism combined; in 17.64 per cent., there was absence of information as to any known conditions; and in 2.9 per cent., no associated condition could be elucidated. A table was also given to show the associated systemic conditions of the aortic lesion, as exemplified in 117

cases as follows: 46.1 per cent. in undoubtedly syphilitic subjects; 6.8 per cent. probably syphilitic, but not beyond doubt; 21.3 per cent. in phthisical subjects; 14.2 with no records for determination; 5.9 with heart-disease; 5.7 with various other diseases individually small. The table included both forms of the aortic disease: the active growth as well as the passive degeneration; but showed a great preponderance with syphilis. The lesions were separated as follows. In 56 cases of syphilis terminating fatally through special lesions, 60.7 per cent. illustrated aortic nodulation, the major part of a severe type; and in about one-third of these (*i.e.*, 15 out of 56), the vessel-disease had led to dilatation, more or less pronounced: that is to say, were in the infantile stage of aneurism. Adding these infantile aneurisms, and including one infantile aneurism subsequently mentioned as due to the acute rheumatic diathesis, to the 34 of this paper, the total was 53; and of these, 66 per cent. occurred in subjects infected with syphilis, but with no other diseased conditions to neutralise the deductions. Again, in 106 *post mortem* examinations, the non-existence of syphilis was fairly deducible, and the following results were obtained. Five cases of aneurism were present, which were included in the table under acute rheumatism, intemperance, and no known cause. The aortic disease in one instance was severe, and had led to dilatation, in an acute rheumatic diathesis with great intemperance; in five, the inner wall of the vessel was corrugated, but not dilated; three were phthisical; one had alcoholism; one had aortic valve-disease; in 29, the lesion had the form of atheroma, or mere opacity; and of these, 15 were associated with phthisis, and the remainder with renal affections, dysentery, diabetes, scrofula, lupus, and cancer, in nearly equal proportions. The author inferred that the syphilitic virus must be regarded as a very potent cause of the arterial lesion, and its sequel, aneurism; but not as the only one, for the acute rheumatic poison and alcohol must be regarded as minor agencies. The chest-constrictions to which the soldier was liable from accoutrements, pack, &c., acted as fostering influences to the diseased conditions engendered by syphilis, rheumatism, and alcoholism, probably inducing dilatation in the deteriorated vessel, though no such result might ensue under ordinary circumstances, and under such amounts of physical exertion as pertained to the civil portion of the community. With regard to the adoption of preventive measures against aneurism, the author remarked that attention must be primarily directed to the suppression of the causes of the aortic disease, notably syphilis; and, secondarily, against the conditions of dress, &c., which assisted in its development.

THE PRESIDENT said that the point in the paper demanding special attention was the relation between syphilis and aneurism of the aorta. He thought that the idea was becoming prevalent among surgeons that there was a connection between syphilis and aneurisms in other parts—such as popliteal aneurism, &c.—especially in younger subjects.—Dr. DOUGLAS POWELL thought that the description of the pathological conditions was accurate and minute, and was an addition to our knowledge. But it was a question whether the lesions could be regarded as special to syphilis. He had met with only one case of arterial lesion which could be traced to syphilis; and here the depressions were present not only in the aorta, but also in the pulmonary artery. He thought that army-surgeons had been led to exaggerate the relations between syphilis and disease of the aorta. An opinion could not be arrived at as to the underlying cause of aortic aneurism, without considering the causes of disease of the heart and of the whole circulatory system in soldiers. And certainly syphilis was a very rare cause of disease of the heart in adults. He thought that Mr. Welch had been somewhat biased by the life-history of the patients. In the army, the fact that a soldier had syphilitic disease, in however slight a form, was noted; but what would be here considered an intemperate use of liquors was not, unless the men were actually drunk. He had been struck by the great proportion of cases of constitutional syphilis in the army returns; being as many as all other diseases of the genito-urinary organs taken together. The heart was not stated to be syphilitically affected in Mr. Welch's cases.—Mr. BRIDNELL CARTER asked for a more precise definition of the term syphilis; whether the term included mild as well as severe cases. He had met with a case of aortic aneurism occurring twenty years after a slight attack of syphilis.—Mr. MYERS differed from Mr. Welch as to the cause of aortic aneurism in soldiers. Dr. Maclean of Netley had published statistics which indicated that syphilis was not a special cause of aneurism; and was it to be supposed that medical men in London, where syphilis was very prevalent, would have failed to observe the connection between it and aneurism if it existed? It was known that syphilis produced degeneration, and so might give rise to disease of the aorta. Netley was not a favourable place for investigating the relations of syphilis to aneurism; for soldiers were brought thither from all parts of the world, suffering from an accumulation of diseases. The production of aortic aneurism was

favoured, in great measure, by constriction from without. It was well known that aneurism was liable to be developed at points subjected to strain.—Dr. DRYSDALE said that it would have been better if there had been a more detailed description of the cases described as syphilitic. He thought that the slightness of an attack of syphilis did not negative the idea that an aneurism occurring after many years might be connected with it.—Sir WILLIAM GULL objected to the use of the word nodes in speaking of deposits in arteries. These deposits occurred in all forms of arteritis. The author of the paper admitted syphilis to be a cause in common with other conditions; but as he (Sir W. Gull) understood syphilis, it had special characters common to nothing else. Referring to the cases of aortic aneurism said to have been cured by iodide of potassium, he thought that there had been errors in diagnosis. He believed that syphilis was a cause of aneurism, but only indirectly.—Mr. WELCH said that the life-histories were taken from the medical history sheets. These, as well as the records of the *post mortem* examinations, were drawn up by different surgeons; and there could be no doubt that the cases recorded as syphilitic were such; there being distinct records of such symptoms as sores, skin-eruptions, sore-throat, nodes on the tibia and cranium, diseased tonsils, cirrhosis of the testicle, etc. No doubt other causes than syphilis would produce aortic aneurism, just as nodes on the leg might have a non-syphilitic origin.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, NOVEMBER 16TH, 1875.

G. D. POLLOCK, F.R.C.S., President, in the Chair.

Cancer of the Male Breast.—Mr. MAUNDER exhibited a cancerous breast, removed fourteen months ago, and the man from whom it was taken. The man was forty-four years of age. For two years, his left nipple was cracked, and a sanious fluid exuded. The cancer grew to the size of a Tangerine orange; it was removed. The man did well, and there was no return of the disease in the scar or in the seat of injury.—The PRESIDENT requested that an opportunity should be afforded for an examination of the histological characters of this tumour by the Morbid Growths Committee; and this request was acceded to.

Sclerosis of Brain and Spinal Cord.—Dr. GOODHART showed a specimen taken from a married woman, aged 38, who had had several children, and was free from syphilis. Two and a half years ago, she first felt her legs becoming stiff, especially on wiping her shoes. Then came on spasms, both clonic and tonic, with jerking of the head and nystagmus. There was no impairment of sensibility; and the electro-motor sensibility was unaffected. Ultimately, the soft palate became paralysed, pneumonia set in, and the woman died. There was found grey induration in patches. The cord was most affected, and the white matter of the brain. Under the microscope, the usual characters of sclerosis were found.

Ulcerative Endocarditis.—Dr. COUPLAND brought forward a case of ulcerative endocarditis. The man had suffered from dyspnoea, with valvular lesion, producing a murmur; and died of dyspnoea. He was a man in good health, except rheumatic pains in his limbs at times. He was ill one month; and the most prominent symptom was pain in the præcordium. There was hypertrophy and dilatation, most marked on the left side. In the left ventricle was found a pouch of the mitral valve—an aneurism of it, in fact. There was extensive disease of the aortic valves. The mitral valve was diseased on its ventricular surface.—Dr. HILTON FAGGE asked if the vegetations from the aortic valves touched the mitral valves. Friction and the contact of such vegetations often set up secondary disease in the parts touched by them.—Dr. COUPLAND replied that the same view had suggested itself to him in other cases as well as this one. In this case, there were no vegetations long enough to have so acted; at least, none now left.

Fracture in a Gorilla.—Dr. CRISP showed a well united fracture in a long bone of a gorilla. He said that, in the lower animals, fractures often united very neatly; and such was the case in this instance.

Rickets in the Pheasant.—Dr. CRISP exhibited specimens of rickets in the pheasant. The tibiae were bent at right angles. The bones were cartilaginous, and little ossific matter was present. These pheasants were reared under hens, and lived in a confined space. The skull was fairly ossified, and the spinal column was also good. The lower limbs were the most affected. Many of the birds quite recovered, and had since been shot.

Embolism of the Pulmonary Artery.—Dr. HILTON FAGGE brought forward a case which occurred in a medical man who had been suffering from enteric fever with a high temperature. He improved much, when he was again taken ill with much dyspnoea, and died. The intestinal ulcers were healthy, and the lungs were free from disease. The heart was flabby, and there were clots in the right heart. The first part

of the pulmonary artery was free from clot; but, at its division, a clot was found consisting of four cords, of the size of a lead-pencil, twisted together. On examination, it was found to consist of one single long clot folded on itself. The vena cava and its branches were normal. It could not have been formed *in situ*, and must have come from a long and large vein, possibly the femoral.—Dr. CRISP thought this view ought to be received with caution.

Diverticulum of the Intestine.—Dr. HILTON FAGGE showed an instance of distended diverticulum of the intestine. It occurred in a female who had acute strangulation of her intestines. An exploratory examination was made, and a knuckle of intestine was found in the right femoral ring. The patient died shortly afterwards. A pouch of mucous membrane was found forced through the serous layer, in two places, both in the jejunum. There was some atrophy of the heart, and the intestines were matted together, with little tendency to replace themselves.

Tubercle of the Pancreas.—Dr. BARLOW exhibited a case of tubercle of the pancreas, the existence of which was denied by English pathologists. It occurred in a girl aged two years. There was a strong consumptive family history on both sides. She herself had had health following an attack of measles. On *post mortem* examination, miliary tubercle was found throughout the lungs. There were tubercular granulations in the kidneys, and nodules on the peritoneum. There were some diseased glands near the pancreas, which was all right apparently. When the pancreas was cut into, the disease was at once evident. Under the microscope, there were seen cell-growths betwixt the lobules and around the vessels. The gland-elements were granular.

Osteo-sarcoma of the Jaw.—Mr. HOWARD MARSH brought forward a tumour of the jaw from a boy aged 14. It existed six months. There was no pain. The growth was entirely on the anterior aspect. It was punctured, and thought to be sarcomatous. The whole bone was removed, and the case did well. On microscopic examination, it was found to be osteo-sarcoma.

Tubercular Lupus of the Tongue.—Mr. FAIRLIE CLARKE exhibited a case of tubercular lupus of the tongue, which had shown itself in a patient of Mr. Teevan's at the West London Hospital. The patient was a bricklayer, aged 18. The family history was good; there was no cancer, no phthisis, and no syphilis. The adjoining mucous membrane was thick and velvety. The soft palate was gone. The case was seen by Sir James Paget, who confirmed the diagnosis. On examination by the microscope, the interstices of all the affected tissues were found to be filled with small round cells. Tubercular lupus of the tongue was very rare. Such a case had never been brought before the Society hitherto; there were a few notices among continental writers.—The PRESIDENT asked if the soft palate had healed at all; if there were any cicatrix.—Dr. HILTON FAGGE had seen a similar ulcer some time ago, with these tubercular ulcerations elsewhere. On microscopic examination, it was found not to be truly tuberculous. He had once seen a laryngeal ulcer spread into the soft palate.—Mr. HOWARD MARSH said Sir James Paget had described tubercular ulceration of the tongue some time ago.—Dr. GREENFIELD said several cases had recently been described in a Parisian journal.—Dr. GOODHART asked if the man died of phthisis.—Mr. SPENCER WATSON agreed with Mr. Clarke, that primary lupus in an ulcerative form was extremely rare on mucous surfaces. He instanced, however, a case of isolated, if not primary, lupus of the conjunctiva of the eye as having been associated in one individual, with lupus of the nose. At the same time, he thought that the erythematous form of lupus was not so very uncommonly met with in the mucous membrane of the nose, and that many cases of *ozæna* were due to that disease within the nostrils.—Mr. F. CLARKE replied that there was attempt at healing in the soft palate. The man died of the disease, and not of phthisis.

Fatty Tumour of the Male Breast.—Mr. MAUNDER brought forward a case of fatty tumour of the male breast. It was merely a lump of fat, which, however, gave to the man's breast the appearance of a woman's breast when in full lactation.

Hydatids in the Heart.—Dr. GOODHART showed hydatids in the heart from a man aged 20, who had no symptoms, and was actively at work when he died. He had been on the treadmill some time before, and occasionally fell, but was thought to be malingering. On *post mortem* examination, the pericardium was found adherent, and pus escaped from a cavity in the septum ventriculorum in tearing off the pericardium. The remains of a hydatid were found, with hooklets attached.

Syphilitic Growth in the Cerebral Sinuses.—Dr. DOWSE brought forward a case of syphilitic growth of the cerebral sinuses from a man aged 39, who was healthy, but had had syphilis. He had had pain in his skull, but no fits. His sight had failed, and his smell was impaired. His motor power was affected. The bowels were constipated. Over the

brow, a cicatrix was found. There was neuro-retinitis. The gait was unsteady, but there was no paresis. Sensation was good. His head felt heavy. The intellect was little affected. On *post mortem* examination, the cranium was found thick. The inner surface was normal. Near the torcular Herophili was a mass which had invaded the tentorium cerebelli. There were adhesions to various parts. The mass was yellow and firm. On microscopic examination, it was found to consist of wavy tissue and round cells.

Gliosarcoma of the Brain.—Dr. DOWSE showed a gliosarcoma of the brain. It was found in a man aged 48, who belonged to an excitable family. He had fits when young. His gait was peculiar, and his memory was impaired. There was pain in the head. The man was not able to stand or to balance himself; but he could run without falling. There was evidently no sclerosis. He had epileptic fits. There was no special change before death. On *post mortem* examination, there was no atheroma. The growth itself was of cone-like form, not unlike the choroid plexus, and was found in the anterior portion of the corpus callosum. Both hemispheres were invaded. Under the microscope, the mass was found to be highly vascular, and to contain round, oval, and spindle-shaped cells.—Dr. GOWERS asked if both sides were affected.—Dr. DOWSE said they were; the right side most.

Glioma of the Brain.—Dr. GOWERS showed a good specimen of glioma of the brain. On section, it was found degenerated in its centre. It was translucent and greyish. On microscopic examination, it was found to consist of minute fusiform cells, with prolongations. It was in the left cerebral hemisphere; the paralysis was complete. When the patient first came to the hospital, there was loss of consciousness, and convulsive seizures; the paralysed side was rigid. The movements were chiefly on the sound side. The left side ultimately became paralysed. The tumour was situated where the fibres radiate out from the corpus callosum to the hemispheres. There was no other lesion.

Congenital Malformation of the Œsophagus.—Mr. HOWARD MARSH showed, for Dr. HOTT, two cases of congenital malformation of the œsophagus. The blind extremity terminated at the cricoid cartilage in each case. The lower end terminated at the division of the bronchi. All causes of this malformation were alike; the lower end joined the trachea. They were cases of arrested development. No operation could be of any service. In answer to a question from Mr. Thomas Smith, Dr. HOTT said they were not the children of the same mother. In one of the cases, the arteries were abnormal. Food found its way from above into both bronchi.—The PRESIDENT said there was a specimen in St. George's Hospital from an old gentleman whose food regurgitated, where there was a pouch at the upper part of the œsophagus, very like those shown.—A MEMBER said a similar œsophageal pouch was in the Hunterian Museum.—Mr. WAGSTAFFE said a similar pouch had come under his notice.—Dr. HOTT said the deformity was congenital. The pharynx ended in a pouch. A probe passed from the lower end into the trachea.

Tracheotomy.—Mr. CLEMENT LUCAS showed parts after tracheotomy. The interest lay chiefly in the operation, which was performed by a single thrust of the knife.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, NOVEMBER 3RD, 1875.

WILLIAM OVEREND PRIESTLEY, M.D., F.R.C.P., President, in the Chair.

THE PRESIDENT announced that Dr. Farre had accepted the Honorary Presidency of the Society.

Hydrocephalic Head impeding Delivery.—Dr. EDIS exhibited an infant, which presented by the breech. Traction upon the trunk failing to accomplish delivery of the head, Dr. Edis was sent for. Examination of the abdomen showed that no second child was present, so that the question of twins with locked heads was negatived. The patient was a pluripara, and vaginal examination failed to detect any deformity of the pelvis. The child being dead and the head evidently much enlarged, perforation behind the right ear was effected; a gush of clear fluid confirming the supposition that had been made, that the case was one of hydrocephalus. Delivery was then readily accomplished. The head, when distended with fluid, measured seventeen inches in circumference. The patient convalesced normally. The placenta had been examined microscopically by Dr. Coupland, who failed to detect any change in its structure throwing light upon the case.

General Anasarca in a Fœtus.—Dr. PROTHEROE SMITH exhibited a fœtus of six months and a half, the subject of general dropsy. The mother, aged 35, had previously had three living children born, three miscarriages, and three premature labours at the twenty-sixth week following each other. The last fœtus was now shown. In the last two

pregnancies, she had suffered from albuminuria and liver derangement. Before the eighth labour, the patient was kept lying up and well fed; before the last, she got about, and was thin. On both occasions, there was incompressibility of the pulse and flushing of the face; and the labour was attended by considerable hemorrhage both before and after. The body of the fœtus was anasarcaous; there was a large quantity of clear brownish yellow fluid in the peritoneal cavity, and also some fluid in the pericardium and pleural sacs. The kidneys were healthy. The placenta was large, and consisted of only the fœtal portion.—The PRESIDENT inquired whether there was any trace of syphilis in the mother, and whether the œdema existed during the life of the fœtus, or was only a *post mortem* appearance, the result of decomposition.—Dr. SMITH replied that the fœtal heart had been heard the day before birth.—Dr. BRAXTON HICKS inquired whether there was any symptom of obstruction to the funis, to which Dr. Smith replied in the negative.—Dr. SNOW BECK stated that the fœtus when born was in such a fresh healthy condition, as to preclude all idea of decomposition.

Case of General Dropsy in a Fœtus.—Mr. LAWSON TAIT related the particulars of a case, where the skin was so tense that it was not possible to bend the limbs without risk of bursting the skin. The scalp was so distended that the bones could nowhere be felt; and, in fact, the head had been mistaken for the breech during labour. The abdomen was enormously distended by highly albuminous fluid, as also the pleura and pericardium. The placenta was large and very œdematous. The cause of the general dropsy seemed to be the premature closure of the channel between the auricles, there being no direct opening between the auricles through the foramen ovale.—Dr. PROTHEROE SMITH considered this to be evidently a disease primarily and altogether of the ovum; whereas, in his own case, the disease had originated from the disordered health of the mother. He would like to know whether any of the Fellows had met with similar instances—hyperæmia, with liver-derangement. There was in his own case great peculiarity of the pulse, which was extremely incompressible; the mother's lips were of a crimson tint; and she had had several abortions. One woman, who had aborted seven times, he had bled once, and she went to full time. In his case, he had tried abundance of fruit and wine in one pregnancy, and exactly the reverse in the latter; the result being the same in both. He had witnessed in a few cases frequent consecutive abortions at about the fifth and sixth month arrested by venesection, and followed in succeeding pregnancies by living children.—Dr. MADGE could hardly accept Dr. Smith's explanation as to the cause of the death of the fœtus. He had given considerable attention to the subject, but he had never understood that a common disease or derangement of the liver in the mother could affect the child *in utero* in a somewhat similar way. It was well known that the mother may be morbidly affected in many ways, even with albuminuria resulting in convulsions, and still give birth to a perfectly healthy child; a syphilitic history, if such existed, might afford an explanation: the foetal liver receiving the tainted blood direct from the mother became affected with syphilitic inflammation and deposit, leading to obstruction of the portal system and ascites.—Dr. ROUTE inquired if there had been any specific examination of the foramen ovale of the first child.—Dr. HEYWOOD SMITH replied that the heart on examination was found to be perfectly normal. The last three times, pregnancy had ceased at the twenty-sixth week, showing that there was some disease of the ovum. The liver was also disordered in former confinements. He would be glad if any Fellow of the Society could throw any light upon the intermittence of the albuminuria during pregnancy.—Dr. SNOW BECK remarked that he had the opportunity of examining both Dr. Smith's cases, and had also seen two other very similar specimens. The clinical histories of both had been very much alike: healthy living children at first; then, premature expulsion of dead fetuses about the sixth month, presenting evident signs of previous and serious disease. Effusion of fluid into the peritoneal cavity existed in all, far too large in quantity to be the result of *post mortem* change. The organs, excepting the liver, were healthy; this was paler than normal, soft, readily torn with the finger; the liver-cells being much broken down. The parents were singularly free from even the suspicion of a syphilitic taint. The effused fluid was too large and too generally diffused to be caused by any mechanical disturbance of the circulation. The only probable explanation of this condition of the fœtus appeared to be from some deficient or altered state of the nutrition: whether foetal or maternal, it appeared impossible to determine from the facts at present known.—The PRESIDENT said that, in considering the pathology of these cases, it was well to bear in mind that the subcutaneous cellular tissue in children after birth was prone to become œdematous from the infiltration of serum in certain depressed conditions of health. It was no uncommon occurrence in hospitals to find children who had been ill fed and exposed to adverse influences the subjects of a general œdema, which might

proceed to an extreme degree, without such malformation or disease as to account for it. The villi of the placenta in Dr. P. Smith's case had the appearance of being atrophied, and he might suggest that possibly the redema in the child was due to its imperfect nutrition *in utero*, and to the passive congestion thus induced.

On a New Form of Blunt Hook and Sling for assisting Delivery in Cases of Breech-Presentation.—Dr. J. G. SWAYNE (Bristol) brought forward a communication on this subject. The instrument consisted of an ordinary blunt hook, with the end curved back upon itself, so that a loop could be hitched upon it. When the hook was withdrawn, after being passed over the groin, the sling, consisting of a piece of strong silk cord with a loop at each end, was left *in situ*. Traction was then made in the usual way; and, as the sling was padded, there was less risk of injuring the soft parts of the child than when the ordinary blunt hook was employed.—Dr. BRAXTON HICKS thought that in the use of the blunt hook sufficient attention had not been given to the assistance afforded by external pressure applied to the fundus uteri in breech cases, and the delivery of the aftercoming head through the brim. He thought half the strain was taken off the thigh, and that without undue crushing of the uterine wall by the hand pressure. Text-books generally omitted to notice the great help given; and, although he had no doubt some practitioners employed extreme pressure, yet very frequently it was never thought of, but all the force was put upon the hook.—Dr. MADGE had had reason to be dissatisfied with the blunt hook. He was afraid that in any case when much force was required some injury must be inflicted, whatever the plan adopted. He had suggested covering the hook with India-rubber, compressed sponge, or wash leather. If this could be properly carried out, it would probably be a safer instrument than Dr. Swayne's, and could be much more quickly and easily applied.—Dr. AVELING remarked that the duration of India-rubber was only about three years; it then became brittle; and, if put aside, would then be found useless. He feared, therefore, that the suggestion, though ingenious, was not very practical.—Dr. C. GODSON agreed that, whenever a foot could be brought down, in impacted breech, it was the best plan to adopt; but where this was impossible, the hook must be employed. He had recently tried that known as Lazarewitch's, but found that the bulb at the extremity of the hook was the point which received the force applied, and pressed severely upon the tissues. He regarded it as a dangerous instrument. In one instance, the skin had been cut through, and much bruising of the surrounding soft tissues produced by its employment.—Dr. LAWRENCE had seen a case where the saphena vein had evidently been lacerated from the use of a blunt hook. The sling was far less likely to cause injury.

Prolapse of the Funis during Labour.—Dr. GEORGE ROPER read a paper, tending to show that this accident was rarely primary, but mostly the result of some other abnormality. After alluding to the various conditions predisposing to this complication of labour, and mentioning the different methods of accomplishing reposition, he stated that the real difficulty consisted in keeping the cord within the uterus after it had been returned. The best means of doing this seemed to be in securing the firm adaptation of the presenting part to the os uteri. The question of turning in place of forceps was then considered; the author preferring the latter method, considering that there was no shock to the mother. Reports of six cases were given. The author concluded by stating that prolapse of the cord was, for the most part, associated with some other complication of labour; and that it behoved us to make observations as to what that complication might be, as the management of the cord would, in a great measure, depend upon the nature of the complication; in some cases, the funis could be saved from pressure; in others, not.—Dr. BRAXTON HICKS had employed cephalic version in transverse presentations with prolapse of the cord, using one hand externally to press down the presenting part into the os uteri, the funis being pushed up simultaneously by the internal hand.—The PRESIDENT asked if Dr. Hicks combined the postural method with reposition of the cord.—Dr. HICKS replied that he had not found it necessary. He had experienced no difficulty in pressing up the head and carrying the cord up by the same hand as quickly as possible, and then the outside hand pressed the head into the os. In prolapse with head-presentation, pressing the breech to the fundus was not needed as in transverse presentations.—Dr. J. BRUNTON thought Dr. Roper had not given sufficient prominence to the postural method. He (Dr. Brunton) had found it the most satisfactory of all methods of treatment of prolapse of the cord, and considered it applicable in all cases. He questioned whether Dr. Hicks would be able with his middle finger to reduce a long loop of cord protruding from the vagina; by the postural method this could be done.—Dr. EDIS called attention to the correct postural position being the genu-pectoral or knee-shoulder, not knee-elbow position, as had been spoken of by many.—The PRESIDENT referred to a paper read by Dr. Thomas of New York eighteen years

ago.—Dr. ROPER asked what was the rationale of the postural position. Gravitation would not account for it. (*British Medical Journal*)

Note on a Diseased Placenta.—Mr. LAWSON TAIT narrated briefly the outlines of a case. The patient, aged 29, miscarried three months after marriage. She bore a child at full term next, which died of convulsions three days after. She next miscarried between the sixth and seventh month; and again about the seven and half month, the child being alive. When six months advanced with her next, Mr. Tait put her upon chlorate of potass and perchloride of mercury, and she went her full time, and was delivered of a healthy living child. The chief point of interest was in the appearance of the placenta. It was disproportionately small to the size of the child; and fully two-thirds of its surface had undergone a peculiar change. This the author had examined most minutely, and described most thoroughly; the communication being one of much scientific interest.

CORRESPONDENCE.

NIGHT MEDICAL SERVICE.

SIR,—I was surprised to see in the JOURNAL for November 6th that the Parisian authorities had only lately determined to begin a night medical service for urgent cases in that city, as we have had such a service in Rome for nearly two years, and Paris is generally thought to be ahead of the Italian capital in most sanitary matters. Here the charge of the public health is undertaken by a special sanitary branch of the municipality.

When the night service was established, a pharmacy was selected in each of the five Rioni—the old Regiones—into which the city is divided for municipal purposes. These five pharmacies remain open all night, and are marked by a gas-lamp of peculiar form, coloured red, and distinctly inscribed "Servizio Sanitorio notturno". To each of these are attached a certain number of physicians and surgeons—the distinction between those two branches of the profession being carefully maintained throughout Italy—who attend in rotation, receiving for each night of such attendance (from 10 P.M. to 6 A.M.) the sum of seven francs, and any fees they may recover if called to patients who can afford to pay. I do not know what sum the chemists receive. I may add that there are city guards attached to each pharmacy.

The system works well, and the municipality publishes a monthly account of the number of persons attended to during the night by the medical men in the five districts. The cases are numerous enough to make me certain that the Prefect of the Seine has greatly underrated the sum he will require, in the event of the pauper patients in Paris bearing a like proportion to population that they do here.

I am, sir, yours truly,
LAUCHLAN AITKEN, M.D.
52, Via Frattina, Rome, November 12th, 1875.

MEDICAL EDUCATION.

SIR,—In the report of the meeting of the Council of the Royal College of Surgeons, I observed a suggestion by Mr. Marshall of a compulsory examination at the end of the student's first winter session, or immediately after the commencement of the succeeding summer session.

I trust that the expression of an adverse opinion will not be considered by the Council an act of presumption on my part, but I cannot think that the multiplication of examinations can prove beneficial. What with frequent *viva voce*, and occasional written class examinations, prize examinations, and at some schools even *test* examinations, it would appear that our students are already over examined. It is true that the examination proposed would be more authoritative, but we are not told what would be the result in the case of those who failed to pass it, or how long in such an instance the primary examination proper would be postponed.

The blot in our present system, now that so much is required of our students, seems to be that men are allowed and even required to attend hospital practice and lectures on the practical subjects, while they are working in the dissecting-room and physiological laboratory. Students who seek the degrees of the University of London, or who intend to remain at a medical school four years, are careful to avoid this overlapping of subjects, but still they are obliged to put in an appearance in the wards to comply with the College requirements. On the other hand, the majority of students adopt the plan of crushing through all their hospital practice and lectures in two years and a half, or at most in three years, and present themselves badly prepared for all their examinations. See what this means in one of these student's second winter

session. If he be industrious, he endeavours to attend lectures on anatomy and physiology, to work in the dissecting-room and in the physiological laboratory, to read up for his primary examination, and, perhaps, for a prize or two in his own school. One would think that this was sufficient for an ordinary brain to inwardly digest; but no, he is not content, he further vainly tries to profit by attending lectures on medicine and surgery, and by an *assiduous* attendance in the medical and surgical wards, on clinical lectures, and at *post mortem* examinations and demonstrations: and I have even heard of a man taking a dressership. Can it be wondered at, that a student should be somewhat bewildered on presenting himself for the primary examination?

In my humble opinion, and I have already given expression to it, the remedy is, to separate entirely the curriculum for the primary examination from that for the pass examination, the latter to be commenced after the primary examination has been passed. I am aware that reasons are given for maintaining the present system, but I am quite sure that the objections to it far outweigh these reasons. The knowledge of anatomy and physiology can be kept alive by testing it in its practical bearing upon medicine and surgery at the pass examination, and the result would be more satisfactory than at present if an uninterrupted study of those subjects had been previously secured. I believe that, if our examining bodies enforced such a change as I have suggested, the "number of rejections" would rapidly diminish, and that "many would be diverted from" what is now too often "an idle and profitless course of study".—I am, sir, your obedient servant,

GEORGE COWELL.

George Street, Hanover Square, November 13th, 1875.

CATGUT LIGATURES.

STR.—With reference to your report of the account which I gave at the last meeting of the Clinical Society of a case which had been under my care in St. Bartholomew's Hospital, will you allow me to state that the opening in the femoral artery, from which bleeding took place, was in the front wall of the vessel, and immediately beneath the knot of the ligature? The assumption is, that the coats of the vessel, bruised at this point by the ligature, ultimately sloughed and separated by ulceration. The coats of the artery had not been injured in the operation, except through this action of the ligature-knot. The wound healed by the first intention, but reopened to a slight extent at the part opposite to the sloughing process in the vessel. After recurrence of the bleeding (despite the treatment employed for its control), it was thought right to amputate the limb, and the patient died the day following. I am, yours faithfully,

GEORGE W. CALLENDER.

November 24th, 1875.

HOSPITAL OUT-PATIENT REFORM.

STR.—I shall feel much obliged if you will permit me to draw the attention of members of Branches of the Association throughout the country, and particularly of the secretaries of those Branches, to the important service which they can render to the cause of hospital reform by passing resolutions similar to that which appears in to-day's JOURNAL as having been passed unanimously at the annual meeting of the Shropshire Ethical Branch. "fully approving the efforts now being made in London to check the gross abuse of hospital charity".

From communications which have reached me from time to time, I have reason to believe that, in many provincial cities and towns, the abuses complained of, though not reaching such enormous proportions as in London, are still much felt, and an expression of opinion similar to that quoted above would greatly strengthen the hands of those in the metropolis who have now for some years been struggling against difficulties in the way of reform, which at a distance can perhaps hardly be fully appreciated.

I desire also, with your permission, to direct the attention of your readers to an able article bearing on this subject in the current number of *Fraser's Magazine*, in which, writing on the subject of the ventilation of hospitals, "S.E." quotes from Mr. Erichsen's *Hospitalism, and the Causes of Death after Operations*, four principal causes of mortality, among which we find the following as No. 2:—"The out-patient department being under the general roof of the hospital, this not merely demoralises the public, occasions less and injustice to the medical practitioner, wastes and embarrasses the funds of the hospital, and carries disease all over the building, but, being generally near the entrance, obstructs the passage ways and exposes all who come in and go out to dirt and disease." Commenting upon this particular cause of mortality, "S. E." observes that "the question of out-patients has been entrusted to special committees, who will, doubtless, arrive at some means of settling it: but we are inclined to think that the whole business should be handed over to dispensaries, supported either by private

subscriptions, by parish funds, or by a co-operative system of the poor of each parish, by which a small weekly or monthly contribution would entitle the payer to medical attendance when ill, and the physicians would be paid something for their services. At any rate, hospitals should not be burdened with this dangerous, expensive, and thankless work."

These sentiments so fully express what has been for some time the growing conviction of my own mind, that I rejoice to see them urged in such a forcible manner as can hardly fail to attract the attention of the profession and the public. I am, of course, quite aware that many of the former will consider the change proposed as of too radical a nature: and, indeed, I feel convinced that it is to the timidity or hostility of many of our profession who are connected with hospitals that so little has yet been accomplished in the way of reform of so-called medical charity in London. In writing this, I do not for a moment forget the valuable services rendered to the cause by Dr. Meadows, the late Dr. Anstie, Mr. Fairlie Clarke, Mr. Wordsworth, and others connected with the metropolitan hospitals; but these form, as I think, bright exceptions to the general rule. The question, however, really concerns the rank and file of the profession quite as much as those who are its leaders, and it is for the former, if the latter will not do so, to consider the subject fully in all its bearings. I would, therefore, suggest that this subject of out-patient reform should be brought before as many branches of the Association as possible for discussion, and that, when it has been well debated by them, a representative meeting should be held under the auspices of the Metropolitan Counties Branch, at which delegates from other Branches might be invited to attend.

I am, etc.,

H. NELSON HARDY.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

BARNHILL POORHOUSE, BARONY, GLASGOW, AND ITS
MEDICAL OFFICER.*

WE have before us a pamphlet of forty-six pages, being the report of Dr. Srethel Wright, Physician to Barnhill Poorhouse and Hospital, to the House Committee, as to the hospital arrangements existing in this, the largest parish workhouse in Scotland. It is in many respects a most remarkable document, whether regard be had to the courage implied in laying before the parochial authorities the structural and sanitary defects of the building, or to the proof it exhibits of unusual professional ability and research on the part of the author, an ability not always seen in persons content with a workhouse sphere of action. We, therefore, propose to lay before our readers a brief epitome of its contents, referring those who are interested in such matters to the pamphlet itself.

It would appear that Barnhill poorhouse during the last ten years has had an average population of 1,000 inmates; and here let us remark that, from Dr. Wright's figures we learn, that in this workhouse there has been the same steady growth of the sick and infirm element that is noticeable in all our urban establishments. Thus, in 1864, of a total population of 1,202, 299 were sick or infirm; in 1874, the number of inmates had fallen to 878, while the number of sick and infirm had increased to 536, of which amount 213 were actually sick. During the year 1874, 1,930 persons were treated in hospital, of which number, 723 were discharged cured, 413 discharged relieved, 184 died in hospital, 85 in the infirm wards, and 6 in the ordinary wards, total 275; leaving 511 under treatment.

Dr. Wright, in a series of carefully compiled tables, gives a complete analysis of the cases he has treated. Our space will only permit us to quote the summary, and from this we learn that, of constitutional diseases there were, 341; disorders of the thoracic organs, 599; disorders of the abdominal organs, 155; disorders of the brain and nervous system, 95; where more than one organ was affected, 7; other diseases, 27; fevers, 96; surgical affections of the thorax, 5; of the abdomen, 29; of the head and neck, 35; other injuries, 229; disorders of the genito-urinary organs, 35; skin-diseases, 200; diseases of the eye, 2; pregnancy and parturition, 74.

It will be seen from these statistics, that the Barnhill poorhouse is nought else than a huge infirmary. Let us note what are the arrangements which have been made by the parochial authorities to deal with this mass of diseased humanity.

The poorhouse is built on the summit of a rising ground, but many

* Report by Medical Officer of Poorhouses to House Committee as to Hospital Arrangements. George Watson, Printer, 53 and 64, Ingram Street, Glasgow.

of the wards and passages are on different ground levels; and, as the subsoil is a tenacious clay, and the drainage imperfect, many of the apartments used for the sick and infirm are necessarily damp—the day nursery for children particularly so. The female hospital wards, ten in number, have an average cubic space of 531 feet; while in the eight wards on the male side, the cubic space averages 596 feet—in one ward sinking so low as 353 feet.

The female infirm wards, like the sick, being day and night wards, average 535 feet, and the male infirm wards 647 feet. The atmosphere of these wards, which must be always more or less impure from overcrowding, is frequently farther deteriorated by the proximity of the St. Rollox chemical works; and when the wind blows from the south-west, the pungent taste and odour therefrom are readily recognisable. Four wards are specially to be noted: ward 65, containing nine beds, the cubic space per bed being only 487 feet, has been selected for female phthisical patients, because it can be ventilated without draught; while 519 feet only are allowable on the opposite side for males. In the children's sick ward, only 497 feet are allowed; the hygienic condition of this ward, as well as of the lying-in ward with only 502 feet, can be readily imagined. The male and female skin-disease wards have respectively 353 and 358 cubic feet.

Again, it would appear that the wards are so crowded that not unfrequently sick children have to sleep two in a bed: that no separate accommodation exists for the treatment of cases of venereal disease, of which there are a considerable number, these being mixed up with other patients; and it not unfrequently happens that persons admitted with one form of skin-disease contract another, the want of space constantly cramping the classification of patients, they having to be placed wherever room can be found for them. The supply of baths and hot water is very defective. There are only eight baths altogether, and of these two are out of order; and, from the bad supply of hot water, it not unfrequently happens that when baths have been ordered they have not been given. The supply of drinking water is faulty, the taps being placed in the water-closets. It appears, moreover, on the male side, each water-closet serves for $23\frac{3}{4}$ patients, and on the female for $29\frac{1}{2}$. Can it then be a matter of surprise that they constantly emit a foul smell, or that there should have been 28 cases of erysipelas and 96 of fever, in all 124, or $6\frac{1}{2}$ per cent. of the cases treated? The only wonder to our mind is, that the inmates have not been decimated thereby, for it is well known that these two diseases are, in most instances, distinctly traceable to sewer-gases. *When will the so-called guardians of the poor discover that three-fourths of all our pauperism is traceable to sickness, and that it is the falsest of all economies to stint the means and appliances for the prevention and cure of disease?*

The nursing staff consists of two paid nurses, of whom one was, previously to her appointment, an ordinary inmate without any prior education; and yet these two women have to superintend the nursing of from 260 to 330 persons.

Having given a description of the house and the diseases he has had to treat, Dr. Wright proceeds to suggest what should be done to mitigate or abolish the evils he complains of. He advises: (1) That a separate workhouse hospital should be built, and that it should be placed under the sole control of the medical officer; (2) That paid nurses in the proportion of one to every 23 or 28 patients in hospital wards, and one to every 36 or 40 patients in the infirm wards, should be appointed; (3) That the opportunities afforded by the treatment of this great and varied aggregation of diseases should be utilised for educational purposes by the admission of students for clinical instruction. A similar suggestion was made at the time when the Metropolitan Poor Act was introduced, but it was stifled—so at least has been alleged—by some hospital physicians who managed to get the ear of Mr. Gathorne Hardy.

There are many other points relating to dietaries, the classification of disease, etc., to which we would gladly refer; but our space is exhausted, and we must conclude by expressing the hope that Dr. Wright may not have to suffer for having so completely exposed the sanitary and other defects of Barnhill Poorhouse Hospital; a fate which has befallen other workhouse surgeons who have dared to become Poor-law medical reformers. But this has been in England; in Scotland we look for better things.

MEDICAL OFFICERS WITHOUT VITAL STATISTICS.

THE late Dr. Sarvis, the Medical Officer of Health for Bethnal Green, issued, just prior to his death, which took place suddenly in his surgery on the 4th instant, his nineteenth annual report of the vital statistics and sanitary proceedings of that parish for the last twelve months. In opening the same, he remarks at considerable length on the following subject. He says:

"I am sorry that it should devolve upon me, at the outset of my

task, to have to state that the compilation of this report has been effected under difficulties such as have not been encountered in former years, in consequence of not receiving returns which were previously furnished weekly to the medical officers of health of the various parishes and districts within the metropolitan area. The documents in question contained information of a nature which rendered it highly desirable that they should be supplied with promptitude and regularity to all medical officers of health appointed under the Metropolitan Local Management Act, as they set forth the number of children born in each place, and showed the relative proportions of the sexes in these additions to the population. They also afforded particulars of every death occurring within the limits to which they severally related, specifying in each case the sex and age of the deceased person, the address where the event took place, and the cause from which it resulted."

Dr. Sarvis then proceeds to describe the mode in which the registrars of the four subdistricts of the parish submit their reports, which, he says, are forwarded weekly to the Registrar-General at Somerset House. There they are copied into books kept for the purpose, and thus is formed the basis of the weekly returns which appear in the daily newspapers. Until the passing of the last Act, it had been the practice of the Registrar-General, after copying the reports of the sub-district registrars, to enclose them, together with a copy of the printed return issued weekly by himself, to the medical officer of health for the parish or district to which they are respectively related. By this means, attention was at once drawn to any outbreak of zymotic disease, and the medical officers were thus enabled to inspect the houses, and take the necessary measures to prevent the spread of the epidemic. He need hardly remark upon the disastrous results that might possibly follow from the abrupt termination of such an arrangement; but he thought it a matter for congratulation that, so far, no evil consequences have been experienced. It was necessary, in order to fully appreciate the value of the information conveyed in the returns alluded to, to bear in mind that, although the books of the medical officers in the service of the guardians were always open to inspection, yet there were large numbers of cases of zymotic disease that were attended by private practitioners, and that these were not brought under the notice of the sanitary authority until the death of the patient took place and was registered. He was quite at a loss to conceive why an Act of Parliament was passed to discontinue the supply of these returns, which, after they were copied, could be of no value to the Registrar-General; and, considering that the plan of distributing them to the persons whom they concerned in the manner herein described had been in operation for eighteen years, it was difficult to understand why such an alteration in the law should have been made.

Dr. Sarvis winds up by stating that the law provides that the vestries should pay the local registrars for what information is required at the rate of twopence an entry; and some parishes have adopted that course. Had this been done in Bethnal Green during the past twelve months, the outlay incurred would have been £26 3s. 8d., which would have been divided amongst the four district registrars. This was not a large sum to expend in a matter where life was concerned; but he earnestly hoped that the old course would again be adopted.

The number of persons who succumbed to zymotic disease during the past twelve months in the parish of Bethnal Green was 573, being a decrease of 64 on the number occurring the preceding year. The deaths during the year numbered 3,142; and the annual rate of mortality was 24.7 per 1,000, 1 death in 5.6 being attributable to zymotic disease. The births during the year were 5,152.

DUTIES OF REGISTRARS.

SIR,—I think the practice of English registrars not to record the name of the putative father of an illegitimate child is legal, prudent, and just. The legal father of a child is the husband of the mother; if she have no husband, the child has no legal father; it is illegitimate. It is most just to omit the name of the putative father, because it has not been legally proved, and may be unknown to the informant, as it was in the case reported at page 651, where the informant was not the mother, but the grandmother of the child. That this omission is most prudent is shown by that case, which, however decided, must cause the registrar cost, trouble, and anxiety.

The seventh section of the English Registration Act of 1874 expressly directs that the registrar shall not register the name of any person as the father of an illegitimate child, unless at the joint request of the mother and of the person acknowledging himself to be the father, both of whom shall sign the register.

I am, etc.,

P. H. HOLLAND.

London, November 22nd, 1875.

POOR-LAW MEDICAL APPOINTMENTS.

BROWN, Joseph L'Oste, L.R.C.P., appointed Medical Officer for the Sheriffhales District of the Shifnal Union, Salop, *vice* J. E. Mayer, M.D., resigned.

COLLIER, Richard M., L.R.C.P., appointed Medical Officer to the Gloucester Union Workhouse, *vice* A. D. Cookson, M.R.C.S. Eng., resigned.

CROSSLE, Francis C., M.D., appointed Medical Officer, Public Vaccinator, and Registrar of Births and Deaths for the Newry No. 2 Dispensary District; also, Sanitary Medical Officer for the same district.

DEANS, John, M.R.C.S. Eng., reappointed Medical Officer for the Coldridge District of the Crediton Union.

DEVANY, Patrick C., L.R.C.P. Ed., appointed Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the No. 2 Division of the Sligo Dispensary District, *vice* James Tucker, M.D., deceased.

HARRISON, Thomas W., L.R.C.P. Ed., appointed Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Doneraile Dispensary District of the Mallow Union, county Cork, *vice* R. Reardon, M.D., resigned.

HILL, Philip Edward, M.R.C.S. Eng., appointed Medical Officer and Public Vaccinator for the Crickhowell District of the Crickhowell Union, *vice* Evan Parry, M.R.C.S. Eng., resigned.

NORTH, John Cunningham, M.B., appointed Medical Officer *pro tem.* to the Brecknock Union Workhouse.

TURNOUR, Henry Edward, M.D., appointed Medical Officer and Public Vaccinator for the Tealby District of the Caistor Union, *vice* R. Read, M.D., resigned.

VALENTINE, Edmund W., M.R.C.S. Eng., appointed Medical Officer for the Second Division of the Shepton Mallet Union.

WALKER, Thomas O., M.R.C.S. Eng., appointed Medical Officer and Public Vaccinator for the Crick District of the Ruaby Union.

YOUNG, Christopher, M.D., appointed Medical Officer and Public Vaccinator for the Yarm District of the Stokesley Union, Yorkshire.

MILITARY AND NAVAL MEDICAL SERVICES.

LOSSES OF STORES AT ALDERSHOT.

We understand that a court of inquiry is now sitting at Aldershot to investigate important points connected with certain recent losses of stores. It will be within the recollection of our readers that a circular issued shortly after the famous warrant of March 1873 placed the responsibility for hospital stores and equipment directly on the senior medical officer in charge, and that we took occasion to protest against an arrangement which could not fail to cause much unpopularity and annoyance. Although the plan has worked with much friction, things have only come to a crisis some little time ago, when very heavy claims were made against the surgeons in charge of the first and second station hospitals, on account of their responsibility in these matters. Considering that in one case the amount of damages exceeded £80, we cannot feel surprised that the victim did not hasten to satisfy the official demands, and that the matter was referred for the decision of his superiors. This course of action has resulted in the appointment of a mixed board, in whose composition the medical department has every confidence, and whose verdict will be awaited with the intense anxiety which only those can feel whose future prospects may be most seriously affected by their judicial summing up. In the meantime, however, we can hardly be accused of contempt of court if we point out in a few words the folly and injustice of taking a medical man from his own proper professional duties, and making him a mere storekeeper, with a financial liability which only those properly trained for that kind of work should hold.

The senior surgeon in charge of a station military hospital is now entirely removed from all care of the sick; instead of being a consultant on whose opinion and advice his junior brethren may rely in case of need, he is nothing more than a head clerk busily occupied in stock-taking and the superintendence of official returns. At a place like Aldershot, with its scattered huts and deficient storage, his anxieties must be very great, and the discomfort of his position correspondingly irksome. Principal medical officers are apt to perpetuate this vicious system by devoting their inspection to matters of petty detail rather than to professional matters, and, instead of being a centre of scientific progress, his office is too often devoted to nothing higher than red tape and routine. We cannot conceive anything better calculated to crush out all professional zeal and interest than those dry and unprofitable duties from which the Right Honourable Sidney Herbert emancipated the department many years ago. In the memorable words of the report which the committee on the Purveying Department sent in to that most able Secretary at War:—"In doing this, we have liberated medical officers from numerous matters of detail formerly within their province, although quite alien to their professional duties." We shall conclude these few remarks, hoping that we may be able to congratulate our army brethren ere long on some definite termination to their present anxieties.

ARMY MEDICAL APPOINTMENTS.

BOILEAU, Staff-Surgeon John Peter, B.A., appointed Medical Officer 29th Regiment, *vice* Surgeon-Major Meade, posted to and Brigade Dépôt, Carlisle.

NAVAL MEDICAL APPOINTMENTS.

ADAMS, Fleet-Surgeon John S. Y., to the *Hercules*, to be appointed to the *Pallas*, when recommissioned.

MCADAM, Surgeon John A., to the *Hercules*, to be appointed to the *Pallas*, when recommissioned.

MESSER, Fleet-Surgeon John C., M.D., to the *Undaunted*, for the *London*.

OBITUARY.

WILLIAM CROSS, F.R.C.S.E.

The death of Mr. Cross, which took place early in the morning of October 26th, is greatly lamented at Clifton, where he had spent his whole life of sixty-five years, and had been in active and extensive practice for half of that time. William Cross was apprenticed to his relative Mr. Charles Smerdon, that fine specimen of the old English surgeon-apothecary, who, having attained an almost patriarchal age, died at Clifton but a few years ago; and, after spending some time at St. Bartholomew's (where he made many lasting friendships), and obtaining his diploma at the College and Hall, he returned to Clifton, where he subsequently became a partner of the firm of Smerdon, Burroughs and Cross. Ultimately, after Mr. Smerdon's retirement, Mr. Cross carried on practice alone with great credit and success. In 1852, he was honoured with the fellowship of the College of Surgeons. For many years, he enjoyed the friendship and confidence of the late Dr. Symonds, who was then the leading physician in the West of England. His kindly and benevolent nature, his genial temper and hearty manner, his industry, which made him a student and a reader as well as a practical worker to the very end of his life; his manual dexterity and familiarity with all the details of practice—made him a general favourite, and were rewarded with many sincere friendships, and an unusually extensive clientry among the upper classes of Clifton. He died suddenly, after having made, as it appeared, considerable progress towards recovery from an illness of several weeks' duration, which had begun with thrombosis of the veins of the lower extremity. Two sons and two daughters survive him.

EDWARD SCOTT JONES, L.R.C.P. ED.

THIS young and promising member of our profession has died at the early age of thirty-one, from an attack of typhoid fever, contracted in the discharge of his duties, on Wednesday, November 17th. Mr. Jones was the son of Mr. William Jones, surgeon, of Weston-super-Mare. After receiving his education at Crewkerne, he entered as a student at the Bristol School of Medicine; and, in 1861, became M.R.C.S. Eng. and L.R.C.P. Ed. Shortly afterwards, he was appointed as the first house-surgeon to the Weston-super-Mare Hospital, which office he filled for five years with universal satisfaction to all. At the termination of his office, he began practice in Weston on his own account; and obtained the greatest esteem, love, and regard for his fellow-town-men, and from all with whom he was associated, either in his professional pursuits or in the everyday duties of life. At his funeral, the inhabitants closed their shops and attended in a large body at the cemetery. Mr. Jones had been married but little more than a year, and leaves a young widow and twin daughters.

MEDICAL NEWS.

UNIVERSITY OF LONDON.—Second M.B. Examination, 1875. Examination for Honours.—Medicine.

First Class.

Batterbury, George Henry (Scholarship and Gold Medal), King's College
Verco, Joseph Cooke (Gold Medal), St. Bartholomew's Hospital
Crétin, Eugène, St. Bartholomew's Hospital

Second Class.

Hetley, Henry, Guy's Hospital
Garlick, George, University College
Moore, George Edward, King's College

Third Class.

Hobson, Lewis John, University College
Voelcker, George Henry, University College

Obstetric Medicine.

First Class.

Smith Herbert Alder (Scholarship and Gold Medal), St. Bartholomew's Hospital
Batterbury, George Henry (Gold Medal), King's College
Verco, Joseph Cooke, St. Bartholomew's Hospital

Second Class.

Garlick George, University College
Buchanan, Arthur, Guy's Hospital
Hobson, Lewis John, University College
Hullard, Jean Arthur, B.Sc., University College

Third Class.

Hetley, Henry, Guy's Hospital
Jameson, Leander Starr, University College
Voelcker, George Henry, University College

Forensic Medicine.

First Class.

Verco, Joseph Cooke (Scholarship and Gold Medal), St. Bartholomew's Hospital
Jameson, Leander Starr (Gold Medal), University College
Hullard, Jean Arthur, B.Sc., University College
Voelcker, George Henry, University College
Crélin, Eugène, St. Bartholomew's Hospital
Hetley, Henry, Guy's Hospital

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners, on November 18th.

Blakiston, A. A., L.S.A., Wallington, Surrey (University College)
Carcenac, Edward, Mauritius (St. Bartholomew's)
Cary, Adrian, Guernsey (Guy's)
Cooper, H. D., L.S.A., Bengal (University College)
Parker, F. W., Peckham (St. Thomas's)
Dobbie, R. J. A., L.S.A., Buileigh Salterton, Devon (London)
Don, A. G., Hammer-nith (University College)
Gairdner, John, Maidenhead (University College)
Goofrey, B. G., Clapham (University College)
Harmar, J. R., L.S.A., Birmingham (Birmingham School)
Hopgood, W. C., L.R.C.P.Ed. & L.S.A., Chipping Norton (University Coll.)
Jackson, P. J., L.S.A., Merton, Surrey (Guy's)
Knight, J. T., L.S.A., Sandiære, Derbyshire (Guy's)
Lewis, J. I., L.S.A., Milborne Port, Somerset (Guy's)
Lloyd, J. H., Milner Street, S.W. (St. George's)
Mathias, James, L.S.A., Cardigan (St. Bartholomew's)
Price, H. E., Stamford Hill (London)
Shann, Frederick, E.A.Cantab., Brompton (St. George's)
Sherwin, F. M., Garsford Street, Camden Road (University College)
Sleddall, T. W., Pontypridd (Liverpool School)
Smith, S. M., Surbiton, Surrey (St. Bartholomew's)
Tredinnick, Ernest, Canborne, Cornwall (St. Thomas's)
Twining, F. T., B.A. & M.B.Cantab., Southport, Lancashire (St. Thomas's)
Ward, Charles, Greenstreet, Kent (London)

Thirteen candidates out of the eighty examined having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their professional studies for six months.

The oral part of the first examination for the Fellowship was commenced on Saturday last, when the following gentlemen passed; and, when eligible, will be admitted to the final examination.

Messrs. Edward Barton Gardner, L.S.A., diploma of membership dated November 12th, 1861, of St. Thomas's Hospital. William Lewington Barker, L.R.C.P.Lond., November 17th, 1863, of St. George's Hospital; James William Smith, L.R.C.P.Lond., November 15th, 1864, of Guy's Hospital; George Jackson, L.R.C.P.Lond. and L.S.A., November 15th, 1864, of University College; Frank Fuller, M.D., January 28th, 1870, of the Toronto and St. Thomas's Hospitals; Arthur William Prichard, L.S.A., July 21st, 1874, of the Bristol School; Thomas Frederick Chavasse, passed primary membership April 8th, 1873, of the Edinburgh and Birmingham Schools; and John Lewis Jaquet, primary membership April 15th, 1873, of the Westminster Hospital.

Of eighty candidates for the diploma of membership of the College, thirteen were rejected; four were approved in medicine, but referred in surgery; three were referred in medicine, but approved in surgery; six, who only went in for surgery, were approved, and, when qualified in medicine, will be admitted members of the College, as were fifteen gentlemen who had passed in surgery at previous meetings of the Court of Examiners; and one candidate, examined under the old regulations, was referred to a written examination. The following is an analysis of the medical qualifications possessed by the candidates. There were fourteen who held the L.S.A.; two, M.B.Edin.; two, L.K.Q.C.P.I.; one, L.R.C.P.Edin. and L.S.A.Lond.; one, L.R.C.P.Lond.; one, M.B.Cantab.; and one, M.B.Aberd. Forty-seven candidates were examined in medicine.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, November 18th, 1875.

Blakiston, Arthur Alexander, Wallington, Surrey
Harmar, James Raffles, N-whall Street, Birmingham
Gathergood, Benjamin William, Terrington St. John's, King's Lynn
Mapes, Reginald, Spalding, Lincolnshire
Pulkiton, Henry, Liverpool
Williamson, George Edward, North Shields

The following gentlemen also on the same day passed their primary professional examination.

Chadwick, John, Manchester Infirmary

Macintire, John Henry Lee, Middlesex Hospital
Roberts, Gordon Money, Guy's Hospital
Sidebotham, George William, Manchester Hospital

MEDICAL VACANCIES.

THE following vacancies are announced:—

- AMERSHAM UNION—Medical Officer. Salary, £70 per annum, and extra fees. Applications on or before December 6th.
ARDWICK AND ANCOATS DISPENSARY, Manchester—Resident House-Surgeon.
BERKS COUNTY ASYLUM, Moulsoford—Assistant Medical Officer. Salary, £80 per annum, with board, lodging, and washing.
BIRMINGHAM AND MIDLAND EYE HOSPITAL—Dispenser. Salary, £70 per annum. Applications before the 6th December.
BOOTLE BOROUGH HOSPITAL—House-Surgeon. Salary, £80 per annum, with board, furnished apartments, and washing. Applications to the Honorary Secretary.
CARMARTHEN UNION—Medical Officer.
CHIPPENHAM UNION—District Medical Officer, Public Vaccinator, and Medical Officer of Health. Salary, £18:3:4 per annum as Medical Officer, and £17:0:10 as Medical Officer of Health, in addition to extra fees. Applications on or before December 10th.
CHORLTON-ON-MEDLOCK, RUSHOLME, and MOSS SIDE DISPENSARY, Manchester—House-Surgeon.
DENBIGHSHIRE INFIRMARY—House-Surgeon. Salary, £85 per annum, with board, washing, and residence.
DOVER HOSPITAL and DISPENSARY—Resident Medical Officer. Applications on or before the 30th instant.
DUMFRIES and GALLOWAY ROYAL INFIRMARY—Assistant House-Surgeon. Board and washing. No salary. Applications to the Treasurer.
EAST SUFFOLK and IPSWICH HOSPITAL—House-Surgeon. Applications on or before December 8th.
GREAT NORTHERN HOSPITAL, Caledonian Road—Surgeon. Applications on or before December 9th.
HAMBLEDON UNION, Surrey—Medical Officer. Salary, £53 per annum, with extra fees. Applications on or before December 15th.
HOSPITAL FOR THE INSANE, Barwood, near Gloucester—Assistant Medical Officer. Salary, £100 per annum, increasing £10 annually to £120, with board (exclusive of wine), lodging, and washing.
HUDDERSFIELD INFIRMARY—Physician.
LIVERPOOL INFIRMARY FOR CHILDREN—House-Surgeon.
MOFFAT HYDROPATHIC ESTABLISHMENT—Medical Man to take charge. Applications to Messrs. Bruce and Kerr, W.S., Edinburgh.
PARISH OF LISMORE AND APPIN, Lettermore—Medical Officer. Salary, £100 per annum. Applications to the Rev. D. Dewar, Manse, Appin, Argyll.
REDDITCH and DISTRICT MEDICAL AID ASSOCIATION—Medical Officer. Salary, £200 per annum, extra fees, and unfurnished house. Drugs, cab hire, etc., found. Applications on or before December 9th.
ROTHERHAM HOSPITAL—Resident House-Surgeon. Salary, £120 per annum, with board and furnished apartments. Applications on or before December 23rd.
ROYAL LONDON OPHTHALMIC HOSPITAL, Moorfields, E.C.—House-Surgeon. Salary, £50 per annum, with board and residence. Applications on or before December 6th.
TIARSI'S MINES, Province of Huelva, Spain—Medical Practitioner. Salary, £250 per annum. Applications to the Secretary, 136, West George Street, Glasgow.
TONGUE and FARR, District of, County of Sutherland—Medical Officer. Salary, £150 per annum, and house.
TRINITY COLLEGE, Dublin—Professor of Botany. Applications on or before January 22nd, 1876.
WELLS UNION—Medical Officer. Salary, £80 per annum, and extra fees. Applications on or before December 7th.
WESTMINSTER HOSPITAL—Resident Obstetric Assistant. Applications by December 1st.
WORKSOP UNION—Medical Officer and Public Vaccinator. Applications on or before December 7th.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

- BEATTY, Joseph, F.R.C.S.I., appointed Surgeon to the Rathdown Hospital and Dispensary, Monkstown, co. Dublin, *vice* William Plant, M.D., J.P., deceased.
*BUCHANAN, Walter, M.R.C.S.Eng., appointed Surgeon to the Chatham Division of the Kent County Constabulary.
DUDLEY, William L., M.D., appointed Physician to the City Dispensary, *vice* J. Middleton, M.R.C.P.Ed., resigned.
HAMILL, J. W., M.D., appointed Resident Medical Officer to the Worksop General Dispensary.
*SHEWEN, Alfred, M.D., appointed Assistant Physician to the Metropolitan Free Hospital.
*THOMSON, W. A., L.K.Q.C.P., appointed Second Assistant Medical Officer to the Brookwood Asylum.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTH.

- BOGGS.—On the 21st instant, at Paris, the wife of Alex. Boggs, M.D., late of H.M.'s Indian Army, of a son.

MARRIAGES.

- FREW—McLELLAN.—At Galston, Ayrshire, on the 16th instant, by the Rev. Thos. Mathewson, assisted by the Rev. R. Hislop, Kilmarnock, William Frew, M.B., C.M., Newmilns, to Sarah, second daughter of J. McLellan, Esq.
McKANE—WATFORD.—At Byers' Green Parsh Church, on the 9th instant, by license, by the Rev. Dr. Hoopell, rector of the parish, Dr. G. O. McKane, to Catherine, youngest daughter of Mr. Watford, Byers' Green.

OPERATION DAYS AT THE HOSPITALS.

MONDAY	Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.
TUESDAY	Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.
WEDNESDAY	St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.
THURSDAY	St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 3 P.M.
FRIDAY	Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.
SATURDAY	St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M. and 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

WEDNESDAY	Royal Microscopical Society, 8 P.M. Professor Rupert Jones, "Remarks on the Foraminifera, with special reference to their variability of Form: illustrated by the Crustellarians"—Obstetrical Society of London, 8 P.M. Dr. Heywood Smith, "Notes of a Case of Ruptured Vagina during Labour: with Recovery"; Dr. Wiltshire, "Spontaneous Rupture of the Vagina; Recovery"; Dr. Routh, "Case of Extra-uterine Fibroid successfully treated by Gastrotomy"; Dr. John Williams, "On the Mechanical Action of Pessaries"; Dr. Oswald, "On Casarean Section", and other communications.
THURSDAY	Harveian Society of London, 8 P.M. Dr. Sibson, F.R.S., Harveian Lectures "On Bright's Disease and its Treatment, considered mainly in relation with Arterial Tension from Blood Contamination".

NOTICES TO CORRESPONDENTS.

- CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.
- PUBLIC HEALTH DEPARTMENT.**—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.
- AUTHORS** desiring reprints of their articles published in the *JOURNAL*, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.
- CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.
- WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**
- COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the *JOURNAL*, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

UPPINGHAM SCHOOL.

We are requested by Mr. Haviland, who is investigating the recent outbreak of enteric fever at the Uppingham School, to say that he will be much assisted in his inquiries if the medical attendants upon boys who have fallen ill after leaving that school, will kindly favour him with notes of the facts of illness, and particularly of the dates of the commencement of illness. Letters should be addressed to him at Northampton.

A DUBLIN CORRESPONDENT.—We cannot but regard the frequent outbreaks of irritable dis-satisfaction of our contemporary as the highest compliment which can be paid to the value of this part of the *JOURNAL*, and to the ability of our correspondents. The number of our subscribers in Ireland is steadily increasing.

BRANCH ORGANISATION.

T. C. (Aberdeen).—The Branches have each an annual president and a "bureau" of annual officers. The method of organisation of district Branches is a matter for the consideration of each branch. The presidents of each district meeting may be elected annually, or at each meeting, or just as is thought best. Both practices, we believe, exist. In some Branches and districts a set subject for discussion is arranged, and speakers send in their names beforehand. It generally provides a good debate.

The printed paper which Dr. Birkbeck Nevins forwards, "On the Latest Government Statement as to the Influence of the Contagious Diseases Acts", shall have our early attention.

IGNORANT MIDWIVES.

T. W. (South Shields) in a letter (of which it is probably not intended that we should publish the text) mentions two cases in his practice, in one of which an ignorant midwife had excised the womb, and showed it to him on a plate, with the observation that "she had had a good deal of trouble to get it away"; in the other, the womb was "completely turned inside out". We hope there was an inquest in the first case. Such cases plead very strongly for the better education and regulation of midwives.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the *BRITISH MEDICAL JOURNAL*, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, no later than *Thursday*, twelve o'clock.

THE COMPOUND STETHOSCOPE.

SIR,—In the *BRITISH MEDICAL JOURNAL* of this date appears a letter from Messrs. Ferris and Co. of Bristol, relative to a stethoscope invented by Dr. Spencer of that town, and made by them, which is called the "compound" stethoscope. They seem to have discovered some similarity between my double stethoscope (a description of which you kindly permitted to appear in the *JOURNAL* of the previous week) and theirs, and take a great deal of trouble to explain that their instrument preceded mine. Which was invented anterior to the other is a matter of considerable doubt, but must be of very little importance, as the two instruments are unquestionably entirely dissimilar, except in such points as are most common to all hiilar or differential stethoscopes.

I have within the last few weeks seen Dr. Spencer's "compound" stethoscope for the first time, and am at a loss to imagine how any one could see a resemblance between it and my invention. The tubes in my instrument are, as I describe them, plain and equal in calibre from beginning to end; those of the other are each in three portions, of which one is metal, and two of rubber tubing of different thicknesses. It must be granted that, with such variety of tubing, an equality of calibre is difficult, if not impossible, to secure, while in other respects the instrument is, in my opinion, too complex to admit of its being manufactured with uniform and lasting efficiency.

The simplicity which characterises my "head-spring stethoscope", while insuring greater efficiency, permits its being produced at much less cost; and the head-spring and arrangement of the different parts are points of originality beyond dispute. The only true estimate of the respective merits of these double stethoscopes will be elicited after they have stood the test of time and experience.—Yours truly,

R. HARVEY HILLIARD, M.D.

5, Belgrave Terrace, Upper Holloway, N., Nov. 20th, 1875.

A STUDENT is referred to our advertisement columns.

THE WILL AS A THERAPEUTIC MEANS.

SIR,—In your abstract of M. Jolly's paper on the above, in the *JOURNAL* of November 20th, there is a passage, which, as implying the great rarity of the case referred to, I may be allowed to quote in full. "M. Jolly relates that he saw, in 1827, in the St. Louis Hospital, a man who had suffered for years from this disease (epilepsy), and who could, at will, throw off his attacks. It was enough for him, to the great astonishment of the pupils who witnessed the fact, to make the muscular apparatus of mastication and deglutition undergo voluntary exercise, by introducing solid food into his mouth as soon as he had a premonition of the return of the paroxysms." At the Royal Infirmary Dispensary in Glasgow, a somewhat similar case came under my notice; and, as I made a hurried note of it at the time, I shall simply give you this as it stands.

February 5th, 1875. P. L., aged 47.—If the patient want food for more than two hours, he is seized with a fit, which, from the description of a friend who is with him, may be considered epileptic. He is certainly insensible during the fit, for he has frequently injured himself. Both patient and friend distinctly state that an attack can always be prevented by taking food; and if some tea be poured down his throat, even when in the fit, he almost immediately recovers. I should add to this, that I remember that the friend referred to was a most intelligent man—being, in fact, the manager of the work in which the patient was employed; and, as he had frequently seen the patient in the attacks, his account of the case can be depended on. There is this, however, to be noted further: Dr. Scott Orr informs me that the patient was admitted to one of his wards shortly afterwards, and in a day or two became insane, and had to be removed.—Yours very truly,

Glasgow, November 22nd, 1875. W. ANDERSON.

ALPHA.—1. No. 2. Yes. 3. Yes.

ROYAL COLLEGE OF SURGEONS.

The following were the questions submitted to the candidates at the written examination for the diploma of membership of the Royal College of Surgeons on Friday and Saturday last. *Surgery.*—Candidates were required to answer at least four (including one of the first two) out of the six questions. 1. Describe the dissection required to expose the right common carotid artery. On what part would you place a ligature? 2. Mention the structures divided in a circular amputation through the middle of the arm. 3. Describe the symptoms and treatment of delirium tremens following injuries. 4. What are the microscopic appearances presented by articular cartilage when undergoing the changes described as "absorption"? 5. Give the pathology, diagnosis, and treatment of psosa abscess. 6. What are the symptoms of a complete transverse laceration of the urethra in the perineum? How would you treat the injury? and what would be the most probable results? *Medicine.*—1. Describe a typical case of typhoid fever, with its treatment. For what other diseases might typhoid fever be mistaken? and how would you distinguish between them? 2. Mention the chief morbid changes to which the valves of the heart are liable. State the effects produced on the walls and cavities of the heart by these affections; and give the leading signs by which they may be recognised during life. 3. Indicate the medicinal qualities of the following preparations, and the class of cases in which they are used, together with the doses: ext. ergotæ liquidum; tr. digitalis; elaterium; zinci sulphas; acidum gallicum; extractum belladonnæ; plumbi acetas; hydrargyri perchloridum; liquor arsenicalis.

At the half-yearly examination of candidates for the Fellowship on November 19th, the following questions were put to candidates for the primary or anatomical and physiological examination, all of which were required to be answered. 1. Describe the influence which the function of respiration, including the respiratory movements, has upon the circulation of the blood. 2. State the evidence in support of the current views concerning the functions of the fifth cranial nerve. 3. Describe the course and relations of the arteries which enter the cranial cavity anterior to a transverse line drawn in front of the foramen magnum, limiting the description to the interior of the skull. 4. In a transverse section of the neck through the fourth cervical vertebra, name the parts seen in their order from before backwards.

QUESTIONS FOR THE ARMY MEDICAL DEPARTMENT.

T. H. J.—The examination questions for the Army India Service and Navy are the same, and will be found printed every year in the Appendix of the Statistical and Sanitary Report, presented every year by the Director-General to Parliament, which is often called the Departmental Blue-book. It may be procured at Haslewood's, Great Queen Street, W.C.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

APPRENTICESHIP.

SIR,—Allow a young medical student to make a few remarks about medical apprenticeships. I fully agree with your correspondent "S. T.," as I think two years in a medical establishment of some sort will give a student such a practical knowledge of some parts of his profession, that he will find in after life that he is the gainer by that knowledge. I think the majority of medical students of the present day go in for a mere superficial knowledge of materia medica and pharmacy—as much as will pull them through their examinations; but, when they are qualified, they find their mistake; when, perhaps, they are not able to write a proper prescription, and, when ordering a tonic mixture for a patient, they give tinctura cinchonæ composita with ferri perchloridum, or some other equally unpractical combination. I think the medical men thirty or forty years ago were by far better masters of their profession than our newly fledged two years' making doctors of the present day.—I am, yours,

ONE WHO HAS SERVED HIS TIME TO AN APOTHECARY.

AN EX-PROFESSOR.—Prior to 1800, it was customary to give the College medal to each professor on the conclusion of his course of lectures. Originally, the medal was of silver, but no record can be found of the change to the more precious metal. The last to receive it as such was Professor James Wilson, as appears from the following record. "Court of Assistants, July 3rd, 1800.—Resolved, that the usual gold medal be presented to Mr. James Wilson, the late professor of anatomy, for his services during the past year." They are now rewarded with special honorariums.

MORTUARIES IN THE METROPOLIS.

SIR,—As I am desirous of making out a complete case for legislative action on the question of the establishment of mortuaries in the metropolis, at the forthcoming deputation of the Strand Board of Works to the President of the Local Government Board, will you permit me to request the medical officers of health, Poor-law medical officers, and others, to forward me any information they possess as to the evils that arise from the want of such accommodation?—I am, your obedient servant.

JOSSEPH ROGERS.

33, Dean Street, Soho, November 22nd, 1875.

IDYLLIC MEDICINE.—A number of curious analogies, illustrating the parallelism of pathological phenomena with metrical (harmonic) laws, have, it seems, been collected by Dr. Samuel W. Francis, in a late essay, entitled "Scanning in Therapeutics, or the Metrical Treatment of Disease." He notes the similarity of pulse-tracings to metrical marks; and believes that not only may diseases be classified by the rules of prosody, but that remedies may be administered by the same system. He inquires: "If there are such affections as choriambic convulsions, dactylic spasms, or anapestic fevers, should there not be iambic doses and trochaic remedies?"—*Curious Facts in Man and Nature*, p. 12.

DR. BODDY'S CASE OF DEATH AFTER INTRAUTERINE INJECTION OF PERCHLORIDE OF IRON.

SIR,—The case of death after injection of a solution of perchloride of iron into the uterus to restrain *post partum* hæmorrhage, recently published by Mr. H. W. Boddy, has given rise to several comments on the subject; but, so far as I can see, to no satisfactory explanation of the cause of death. It is seldom that a so-called remedial agent proves so directly more deadly than the disease or danger it was intended to alleviate or control as in this instance. It is, therefore, a subject which ought, if possible, to be satisfactorily accounted for at the earliest opportunity; and it is much to be regretted that no *post mortem* examination of the body was in this case obtained. In the absence of such an examination, we are compelled to form our opinions from the condition of the uterus previous to the injection, its condition and the general symptoms afterwards, and the known action of the agent used; and upon these data, I venture to think that the death in this case was due to embolism of the pulmonary artery from coagulation of the blood, caused by the admission of the injected fluid into the general circulation through the uterine veins. In the first place, the condition of the uterus previous to the injection was one of flaccidity; the mouths of the uterine veins were, therefore, patulous; the solution was doubtless sent up with some force, perhaps exactly into the surface upon which these venous mouths opened, possibly injected into them. Whether this was the case or not, or firm contraction of the uterus, which took place quickly, a portion of the injected solution would very probably be forced along the veins, the natural outlet, the "os uteri" being occupied by the injection-tube, around which, we are told, it was firmly contracted. If this be allowed, then the result, death from "sudden asphyxia" is easily accounted for, from the well known coagulative action of perchloride of iron upon blood, causing embolism of the pulmonary artery.—I am, etc.,

J. HIGHAM HILL, F.R.C.S.,
Medical Officer St. Paucras Workhouse.

MR. F. LE TALL (Woodhouse).—The fee for attendance before a magistrate to give evidence in cases of misdemeanour does not exceed half a guinea; unless the witness resides two miles beyond the city, borough, or parish, in which the examination is held, when a sum not exceeding one guinea is allowed. Mileage is paid at a rate not exceeding threepence per mile.

SHAM DEGREES AND DIPLOMAS.

GENERAL SCHENCK, the American Minister, calls the attention of the public to a systematic fraud, the perpetrators of which should, if possible, be punished. Ascertaining that persons have been engaged in this country in selling degrees or diplomas purporting to be conferred by certain American colleges and universities, General Schenck has made the imposture a subject of correspondence with the United States Government. Inquiry has been especially made in relation to the "Philadelphia University of Medicine and Surgery," and the "Livingstone University of America," of which there are professed agencies in London and elsewhere. There are no such institutions known in the States of Pennsylvania or New Jersey, nor are their Acts of Incorporation in existence. The charter of an institution by the corporate name of the "Philadelphia University, or American College of Medicine," was revoked in 1872, for the issue and sale of diplomas to persons not qualified to receive the same.

F.R.C.S. EXAM. (St. Thomas's Hospital).—Dr. Charles Edward Saunders, of Lower Seymour Street, Portman Square, is not, as stated in the *Medical Directory*, a "F.R.C.S. Eng., 1874"; neither is Dr. Alexander Marsden of Lincoln's Inn Fields, who made a similar return a year or two ago, entitled to the distinction. On these matters you should address yourself to the secretary of the College of Surgeons.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

THE TWO SYSTEMS OF EDUCATION.

SIR,—It is now more than a year ago since I read in the JOURNAL, published on July 25th, 1874, of a discussion taking place in the General Medical Council with reference to class examinations, compulsory attendance at lectures, the advisability of extending the tutorial system, etc.; and I certainly did not think that the evils of the present state of things were laid bare as they should be. The fact that a large number of students have a tutor, entirely unconnected with the hospital and college at which they are supposed to be imbibing knowledge derived from lectures, shows that, as a rule, students do not place reliance on lectures, but trust much more to tutors and to private study for their theoretical knowledge. Many of them, I am persuaded, regard the money spent for the so-called privilege of attendance on lectures, as simply the fee for the signature of their cards, and in every other light as so much waste of cash. Attendance is the irksome condition necessary to procure the said signature, and is the bane and obstacle to thorough self-application to study for any period during the day beyond an hour or two, and is the provoking incentive to sleep and drowsiness, in stead of mental activity, at night. For myself, I chanced to be entered at a London College, where attendance at lectures was compulsory, in order to obtain the professors' signatures to my cards. I attended nearly the total number of the lectures of those professors, from whose teaching I derived profit; but regarded the compulsory attendance at the discourses of those from whom I learnt nothing with the utmost abhorrence. I wish now I had only thought once or twice of demanding the return of the sum paid for a course of worthless lectures. I might have expended it much more profitably elsewhere; but it is experience which teaches these things. *Appropos* of the entrance of students at the medical schools, I would strongly advise that no student should pay a large sum down on entrance for the purpose of admitting him to a set course of lectures for three or four years at any one school in particular; but rather let him pay for one course of lectures in the subjects he has first to study; and let him do this if possible, at a school where attendance is not compulsory, and where he is not required to pay in advance. The withholding of the signature of the lecturer to the card of attendance would be sufficient guarantee for the payment; and then, if the lecturers instruct him, let him take out such courses afterwards as may be necessary. By adopting this plan, he will be able, if he find he does not learn at one school, to go to another. What is the present system of teaching pursued at most of the medical schools in England? 1. We have a number of lecturers undertaking to deliver a certain number of lectures on definite subjects, at certain times of the year, for a fixed stipend; the amount of the stipend given to each lecturer being constant, and irrespective of the number of students attending his class, and also irrespective of the success of the students whom he is supposed to instruct. 2. The present system requires, for the most part, that a student, on entering his name at a medical school, shall pay in advance a considerable sum of money, as an equivalent for instruction, which it is stipulated will be imparted to him in the shape of lectures. He thus makes a bargain in the dark; and the medical schools, by requiring payment in advance for the lectures he is to receive, prevent his taking advantage of the time when he discovers that he has paid a great deal for nothing.

The system of giving a regular and fixed stipend to each lecturer is, I would respectfully maintain, anything but calculated to stimulate them to teach well, and is very likely to foster carelessness. On the other hand, it helps to deter the student from obtaining redress against bad teaching; for he knows that, if he stay away from the lectures, he will in no degree damage the lecturer; but, on the contrary, if compulsory attendance be the order of the day, he will make his own part of the bargain much the worse, for he will lose the signature to his cards.

Compulsory attendance, then, when enforced under every condition, is bad; and I think it is so, also, under any circumstances. Now, suppose that a lecturer is conscientious, and that he is an admirable teacher; but that he has a number of lazy or indolent students in his class. Why should these men be made to attend under the supposition that they can be made to learn, if they have determined not to do so. Are they not old enough, as a rule, to know their own interests? At any rate, they do not merit the treatment of boys. Why should a lecturer "saddle" himself with the responsibility, which I would humbly maintain belongs to the student himself, and to the examiners at any board before which he may present himself for examination for a degree, diploma, or license—viz., the responsibility of coming out into the world as a man thoroughly competent to practise, if not adorn, his profession? A man's knowledge should not be judged of by the number of courses or sessions of lectures he has attended; but by the results of his study, irrespective of the manner in which his knowledge may have been acquired.

Class-examinations at the schools seem to be attended with good; but the subjects of examination should be appointed at such sufficient time previously as shall allow thorough preparation in them; and men should be allowed to prepare as they will. Attendance upon a certain number of class-examinations held in this manner might be made compulsory, in order to obtain a certificate of fitness (from a lecturer in the particular subject) for presentation for examination at either of the qualifying colleges; but I think that the thraldom of the student should not extend further. Certificates of this sort might take the place of those very questionable cards of attendance. It is certainly to the student's interest to work; and if he have not the sense to see that it is so, why use compulsion? Never-dowells and drones are not wanted in our profession; we have already enough and to spare; and, moreover, medicine would reap dignity and advantage from their exclusion.

A system of class-examinations, thorough and searching, written and *visà voce*, on one day in each week or fortnightly, together with the institution of a good staff of tutors, chosen for their ability and on account of the success of their pupils, would, I believe, lead to admirable results. Each student should be at liberty to choose and change his tutor as often as he may think fit; and the tutors' fees should not be too exorbitant. The wandering about of men from class to class might be obviated by the tutor allowing each pupil a certain number of lectures free, to enable him to judge of their suitability to his wants; and, on the expiration of that probation time, requiring the payment of his fee. By these means, a student would learn self-government, his own personal responsibility, his own capabilities. He would gain confidence in himself, would find out his failings, and those worth instructing would learn to delight in the acquisition of knowledge. A teacher should instruct and ask questions of his pupils, in order to test the results

of his instruction. A student should learn, and, if necessary, ask questions of his teacher, in order to clear his views on any matter about which he may feel uncertain. These conditions seem much more likely to be fulfilled by the system just now advocated than by any other. As to the correction of incorrigible idlers, tutors should have the option of removing or refusing pupils; and as most tutors, for their own credit, would refuse a known mental lout or an idler, they would have in their hands a considerable weapon of chastisement.

One more word as to the class-examinations. If, a few days after each examination had taken place, a list were made of the names of those who had attended it, and they were arranged in order of merit according to the number of marks each had gained, healthy emulation might form a useful adjunct to the system of teaching, particularly if it were known that the tutor would withhold a certificate of fitness from all who did not attain a certain number of marks. For motion, I know from experience, is at public schools a considerable inducement to work.

Having derived great benefit from having a tutor when I was studying in London, I commend these lengthened and, I am afraid, rather rambling remarks to all whom they may concern; and have the honour to be, sir, your obedient servant,

A GRADUATE IN MEDICINE.

DR. MALCOLM.—The skin of the cow from which the first vaccine matter was taken by Jenner was presented to St. George's Hospital in 1851, by Colonel Jenner, where, we believe, it may be seen in the museum. The discoverer of vaccination prized it highly, and was always pleased in showing it to his friends and visitors.

POISONING BY CARBOLIC ACID.

SIR,—The case of accidental poisoning by carbolic acid related in the last number of the JOURNAL, leads me to speak of a similar one which lately came under my observation, and in which a life was lost simply through the want of a distinctive poison-bottle containing the liquid. The carbolic acid, in this instance, was obtained, for disinfecting purposes, in a soda-water bottle, to which was attached a poison label, coloured red. In the house was another bottle of the same sort, containing soda-water (or soda-water and brandy), and labelled accordingly, with a red label also. The latter was for the use of a patient suffering from diarrhoea (and also from mental excitement); and the mistake which he made, of taking a draught from the disinfectant bottle, is not at all surprising considering the resemblance both of bottles and labels. Death occurred within half an hour. I do not see that any fault can be found with the vendor of the acid; but the occurrence is a very practical illustration of the necessity of manufacturers issuing such articles for retail trade only in easily distinguishable bottles.

It is not my intention to discuss the general question whether or not it should be compulsory to use a poison-bottle for all poisons, solid and liquid—laudanum, oxalic acid, etc.; but I may mention a case in which such a precaution would have been the means of saving a life. A woman obtained from a druggist a quantity of muriate of morphia for her own use, and, at the same time, a seidlitz-powder for a child. She told a neighbour to give the powder to the child; but the neighbour, not knowing anything about the appearance of seidlitz-powders, gave the morphia in-tead; and the result was the death of the child. Both articles were properly labelled; but had the morphia been put up in a bottle of peculiar shape and colour, the distinction would have been so obvious as hardly to admit of the error which occurred.—I am, sir, yours truly,

JOHN C. M'VALE, M.D.

Kilmarooock, November 9th, 1875.

CAESAREAN SECTION.

THE *Pall Mall Gazette* has the following, which seems to require further explanation.—An extraordinary piece of conduct on the part of a priest was disclosed at a coroner's inquest held at Manchester. A young woman named Conelly, the wife of a labourer, who had been ill, but it was thought not seriously, died suddenly while her husband was at work. Mr. Brendon, a Roman Catholic priest, having heard that the woman was near her confinement, induced Mr. Frank Holmes, a surgeon, to perform the Caesarean operation, in order that the child might, if alive, be baptised. According to the evidence, of another surgeon, who made an examination of the body at the request of the coroner, the operation had been unskillfully performed. The coroner said that the Rev. Mr. Brendon had no authority to order the surgical examination of the deceased, that power being vested only in her friends, the coroner, or the Home Secretary. The jury returned a verdict of "Sudden death from natural causes", and unanimously expressed their disapprobation of the conduct of Mr. Holmes and of the Rev. Mr. Brendon, who had authorised the operation to be performed without the consent of the woman's husband.

MEDICAL PRACTICE IN AMERICA.

SIR,—In your issue of October 9th, "An M.D. of the New York College of Physicians and Surgeons" undertakes to correct my former statement as to the status of medical practitioners in America. What sort of regularity this gentleman imputes to "a regular graduate from some regular school of medicine, no matter whether allopathic or otherwise", I fail to comprehend; but I can vouch for the fact that very many practitioners whose position is unquestioned by law are decidedly "otherwise". Not only are homoeopathic and "eclectic" colleges chartered to confer the degree of M.D., but the same power is exercised in New York by "a hygeo-therapeutic college", which abjures therapeutics *in toto*, save as regards hydropathy and vegetarianism. The New York Board of Health has ineffectually tried to break up the business of sundry advertising abortionists and baby-farmers; but in the absence of any definition of what constitutes "regular" practice, no further prosecution is possible, and scores of irregular practitioners (without even an "otherwise" qualification) openly ply their charlatany un molested.

A considerably longer professional experience in New York than that of your correspondent may entitle me to speak quite as positively as he on a matter which is notorious, and of which the evidence should have been familiar to him as a sanitary inspector (he forgets the title of his own official position). An act of state legislature was passed in New York in 1873, decreeing that every medical practitioner must have either a diploma from some chartered school, or a license from the censors of a medical society; but, in the first place, there were no means of ascertaining the genuineness of diplomas purporting to have been granted in other states or in foreign countries; in the second place, diplomas from irregular schools had to be recognised; and, in the third place, irregular "medical societies" acted under the letter of the law in granting licenses to all comers; so that the enactment in question had the practical result of legalising an immense amount of ignorant quackery. Beyond the multitude thus practising under theegis of irregular diplomas or still more irregular "licenses", there are scores of self-dubbed "Professors", "Drs.", and "M.D.s" plundering the public without stint; several of them having set up obtrusive establishments under high-sounding titles—e.g., the "New York Medical University", in flattering allusion to my Alma

Mater the University of the City of New York. Numerous similar instances ought to be within the ken of your correspondent; and a glance at the advertising columns of the *New York Herald* will show him how successful have been the prosecutions by the Board of Health in suppressing even the criminal abortionists.

I am, etc., AN AMERICAN M.D.

GALVANISM IN POST PARTUM HÆMORRHAGE.

SIR,—In answer to A Busy Practitioner's request in the JOURNAL of October 30th, I beg to say that I think very highly of electricity as a remedy for post partum hæmorrhage. I either place the positive pole of an electro-magnetic battery at the nape of the neck or the lumbar spine; or, I think, the best place, in the anterior-inferior triangle of the neck, above the clavicle, and the negative pole (sponge-conductor) over the uterine region; and invariably, in my hands, satisfactory uterine contraction follows; first ascertaining that the uterus is clear of clots, etc., is advisable. I have used voltaic electricity also with success, but I prefer the induced current. My last case was very satisfactory. I delivered with the forceps in the evening; next morning I was sent for, as the woman had smart hæmorrhage. I cleared the uterus, and applied a faradaic current. Contraction of the uterus instantly followed, and the woman said, "Oh, sir, I feel tightening and bracing up finely"; and I felt the uterus in a firm contracted state. She recovered.—Yours, etc., W. H. SANDHAM.

REMARKS

ON

ONE OF THE CAUSES OF DEATH DURING THE
EXTRACTION OF TEETH UNDER
CHLOROFORM.

By T. LAUDER BRUNTON, M.D., F.R.S.,

Assistant-Physician and Lecturer on Materia Medica and Therapeutics at
St. Bartholomew's Hospital.

In a clinical lecture delivered by the late Professor Syme, several years ago, he made the somewhat remarkable statement that, notwithstanding his constant use of chloroform for many years, he had never had a death from it occur in his practice. The reasons he gave for this success were two. "First," said he, "we always use good chloroform; and, second, we always give plenty of it." Now, others besides Professor Syme have used good chloroform—have used, indeed, chloroform by the same makers, and altogether undistinguishable from that employed by him; and yet they have had to deplore the occurrence of deaths during its administration. This fact of itself is sufficient to show that the second reason given by Professor Syme for his success is of great importance; and that, in administering chloroform, it is just as necessary to give plenty of it as to use only the best quality. It is, indeed, very extraordinary to see how timidity in the use of chloroform seems to be associated with a more than ordinary fatality; and how the careless—one would say almost reckless—employment of it is frequently unattended with any inconvenience. In Snow's work on *Chloroform*, p. 151, the following passage occurs. "In Guy's Hospital and St. Thomas's, the medical officers had a strong objection to narcotism by inhalation for the first two or three years after the practice was introduced, and chloroform was used much less generally in these institutions than in any other of the hospitals of London; yet it was precisely in these two hospitals that two deaths from chloroform occurred before any such accident had happened in any other hospital in this metropolis." Dr. Snow seems inclined to attribute both of these deaths to the administration of chloroform; but a careful consideration of them may lead us to another conclusion. Before attempting to analyse these cases, however, I wish to recall to the memory of some here an anecdote regarding the introduction of chloroform into the Edinburgh Infirmary, which Mr. Syme was accustomed to relate in his clinical course. One of the surgeons of the Infirmary, I believe the late Professor Miller, had agreed to Sir James Simpson's request to perform, for the first time, an operation under chloroform. Everything had been prepared, and the tray containing the instruments and bottle of chloroform was being conveyed into the operating theatre, when the bearer stumbled and fell, and the whole contents of the bottle were irretrievably lost. There was no time to get more chloroform, and the operation was performed without it. The patient died on the table. Had chloroform been administered, the death would have been put down to the anæsthetic, and not to the operation; and, in all probability, not another drop would ever have been used.

This case shows us—and it is only one of many—that deaths used to occur from shock during operations before the introduction of chloroform, but they were then put down to their true cause; whereas, since its introduction, one hears little or nothing of death from shock, and much of death from chloroform. Another circumstance which is well worthy of notice, and which ought to be borne in mind, is the frequency with which the remark occurs in the descriptions of these so-called deaths from chloroform, that a fatal result was all the more extraordinary and unexpected because the quantity of chloroform administered had been exceedingly small. Mr. Syme would have said that, instead of being extraordinary, it was the very thing to expect; and if, like him, the operators had given plenty of chloroform, their patients would not have died.

And now let us look at the first two cases of death under chloroform—I will not say from chloroform—in these two London hospitals, where such a dislike to the anæsthetic was felt.

John Shorter, aged 48, a porter, known to Mr. Solly for some time as a very active messenger, of intemperate habits, but apparently in perfect health, was admitted into George's Ward, under Mr. Solly, on the 9th October, 1849, suffering from onychia of the left great toe, which had existed some time. It was determined to remove the nail, the man having decided, before entering the hospital, on taking chloroform.

On Wednesday, October 10th, at a quarter before 2 P.M., he began to inhale the chloroform, with one drachm in the inhaler. It had no visible effect for about two minutes; it then excited him, and the instrument was removed from the mouth, and about ten drops more were added; he then almost immediately became insensible; the chloroform was taken away, and the nail removed. He continued insensible; and, his face becoming dark, the pulse small, quick, but regular, respiration laborious, his neckerchief was removed, and the chest exposed to fresh air from a window near to the bed; cold water was dashed in his face, the chest rubbed, and ammonia applied to his nose. After struggling for about a minute, he became still, the skin cold, pulse scarcely perceptible, and soon ceased to be felt at the wrist; respiration became slow at intervals, but continued a few seconds after the cessation of the pulse.

The subject of the second case was Alexander Scott, aged 34, a police constable, who died in Guy's Hospital in June 1850, whilst undergoing an operation for the removal of a portion of the right hand. Mr. Cock, the operator, said that he was certain there was no disease about the patient. He described the accident as follows. The ordinary machine was used; and, as it had not the effect, witness directed that a napkin should be folded into the shape of a cone, which was applied with chloroform. The removal of a portion of the bone occupied one minute and a half; but, before it was completed, the blood, which was gushing out, suddenly stopped, when witness directed Mr. Lacy to feel the pulse of the deceased, and they found that the deceased had expired.

The sudden stoppage of the hæmorrhage shows that, in this case, as in others, the action of the heart was suddenly arrested. The first attempt to cause insensibility failed in this as in some other cases.

Let us take yet another case, the second one ever recorded of death under chloroform. The patient, a healthy woman, thirty-five years of age, was taking chloroform in order to have several teeth extracted. The following account of what occurred was given by two female friends of hers who were present at the operation. "The respiratory movements appeared to be free; chest heaving. Whilst inhaling, the face became pale. At the expiration of about one minute, the instruments were applied, and four roots of teeth were extracted. The patient groaned, and manifested what they regarded as evidences of pain, while the teeth were being extracted, although she did not speak, or exhibit any other sign of consciousness. As the last root came out, which was about two minutes from the beginning of the inhalation, the patient's head turned to one side, the arms became slightly rigid, and the body drawn somewhat backwards, with a tendency to slide out of the operating chair. At this instant, Mrs. Pearson states, she placed her finger upon the patient's pulse, observed it was feeble, and immediately ceased to beat. The face, which was previously pale, now became livid, as did also the finger-nails; and the lower jaw dropped, and the tongue projected a little at one corner of the mouth, and the arms were perfectly relaxed. The females regarded her as being then quite dead."

In two of these cases, death occurred after the inhalation of chloroform had been discontinued; and in the third, the chloroform seemed to have no bad effects until the operation was begun. In all of them, the death followed the operation, and must, I think, be attributed to the shock caused by it. But what is shock? and is there more than one kind of it? for the symptoms were not the same in all these cases. In two of them, the heart seemed to stop suddenly; while, in the third, it failed gradually, although it ceased before the movements of breathing; and the death must therefore be attributed rather to arrest of the circulation than of the respiration. The circulation is kept up in the body by the heart constantly pumping the blood out of the veins into the arteries. Whenever the heart stops pumping, or whenever it gets no blood to pump, the circulation will stop. It does not matter how much blood is in the vena cava or right auricle waiting to be sent into the arteries, if the heart be not beating; nor is the case a whit better when a wound in the jugular has drained away all the blood, so that no efforts of the heart, however numerous and however vigorous, can send a drop of blood into the aorta.

It must be recollected that blood is only useful to the tissues when it is in the arteries, just as water is only available for household purposes while it is in the cistern or supply-pipes. Once the water gets into the sewer, it is of no more use, unless it can be filtered and again pumped back into the cistern; and once the blood has got into the veins, it is no more use unless it can be purified by the lungs and pumped back into the aorta, from which it may once again pass to nourish the tissues. The only difference between blood still in the veins and blood which has run out of them into a basin, is that, when in the basin, it cannot get to the heart, and be pumped by it into the arteries; while, so long as it is in the veins, it generally reaches the heart readily. But

although it generally does reach the heart easily, it does not always do so. Sometimes it accumulates in the veins of the abdomen, and never reaches the auricle; so that it might just as well be in a basin for any use it is to the heart or body. This was shown by Professor Goltz of Strasburg by a remarkable experiment. After exposing the heart of a frog, he noticed that it beat regularly, and at each beat sent a quantity of blood into the aorta, again becoming full of blood in the interval between the pulsations. The frog's heart is partially transparent; so that it is easy to see by its colour when it is empty and when it contains blood. He now struck the frog's intestines pretty hard, and found that the heart stopped. The irritation produced by the blow had been conducted up to the medulla oblongata; and, being reflected down the vagus nerves to the heart, had stopped it. After a little while, the heart seemed to recover, and began to pulsate again. But there was a very remarkable difference between its appearance now and its appearance before the blow had been given. Instead of becoming filled with blood during each diastole, and assuming a deep red colour in consequence, it remained quite pale and empty; and, although it contracted vigorously, the circulation stopped, for the heart had no blood to propel. On looking at the vena cava, Goltz found the cause of this phenomenon. The frog was hanging with its legs downwards, and the vena cava was not full up to the level of the heart. Usually the vena cava and veins of the intestines are kept in a state of semicontraction or tone by the vaso-motor nerves, but now they had become completely relaxed; so that the blood which usually would have filled them completely up to the heart was not sufficient, and so they were only about half full. On laying the frog in a horizontal position, the blood ran towards the heart. It was thus evident that the blow on the intestines had done something more than stop the heart. It had also stopped the usual action of the vaso-motor centre; so that the veins, instead of remaining in a state of tonic contraction, became widely dilated. And, he it noticed, this dilatation of the veins in Goltz's experiments was more permanent than the stoppage of the heart, and continued after the cardiac pulsations had recommenced. But all frogs are not alike; for sometimes a blow on the intestines will stop the heart without having much effect on the veins; and sometimes it will cause the veins to dilate, and will not stop the heart, although very often, as I have already said, it will do both. The same effects seem to follow blows on the abdomen in man and in the frog, but with this difference: in the frog, the heart may stop for some time, and again go on without much injury to the animal; in man, the stoppage of the heart produces death in not many seconds. A good example of this is to be found in Sir Astley Cooper's *Lectures on Surgery*: where he relates that a healthy labourer belonging to the India House was attempting to lift a heavy weight, when another labourer came up and said, "Stand on one side; let an abler man try". At the same time, he gave the former a slight blow on the region of the stomach, when the poor fellow immediately dropped down and expired. On examination of his body, there was not any mark of violence discovered. Here, no doubt, the blow in the abdomen stopped the man's heart, just as it does in the frog; and death occurred before the organ had time to recover from the shock. In another case, described by Professor Fischer, a young man was struck in the abdomen by a carriage-pole; and, after the accident, lay pale and motionless, with a feeble pulse, empty arteries, deep sighing respirations, and a livid tinge on his hands and lips. In this instance, the heart had either not been stopped at all, or had speedily recovered itself; but the abdominal veins had been so dilated that all the blood in the body could hardly fill them sufficiently to leave a dribble over for the general circulation, although a little still did trickle into the heart so long as the patient remained in the recumbent posture.

We have, then, two forms of shock, according as the injury produces its effect chiefly in the heart or chiefly in the vessels. But it is not merely blows on the abdomen which have the power of producing shock; irritation of other parts can do so likewise; and this seems to be peculiarly the case with regard to bones. Thus Pirogoff records two cases in which death occurred during operations before the introduction of chloroform. In both, the pain and loss of blood during the operation was only a little greater than usual; yet in both, *immediately after* the bone had been sawn through, the face became pale, the eyes staring, the pupils dilated, a peculiar rigidity of the body occurred, and death immediately took place.

The symptoms in these cases of Pirogoff's are almost exactly the same as those of Mr. Cock's case I have already described; but Pirogoff's deaths were put down to the operation, because no chloroform had been given; while the death in Cock's case was ascribed to the anæsthetic, because some chloroform had been administered; although, on account of the operator's unwillingness to give it at all, the quantity was probably very small.

In all three, it is evident that the heart stopped suddenly; and this in itself was sufficient to cause death, though it is highly probable that dilatation of the abdominal vessels also occurred.

In Mr. Solly's case, the dilatation of the abdominal vessels seems to have been the chief cause of death; for the pulse became gradually, though rapidly, weaker and weaker, and then stopped altogether, just as we would expect it to do if the heart suddenly ceased to be supplied with blood.

In the third case I have described, probably the heart was chiefly affected; for, just as the fourth stump of a tooth was removed, the pulse was felt to be exceedingly weak, and almost immediately afterwards became imperceptible.

Stoppage of the heart's action, then, being of such importance as a cause of death, we must now inquire how it is produced. The heart is kept pulsating rhythmically by the motor ganglia which it contains within itself, and will continue to pulsate for some time after its complete removal from the body. But though it thus shows its power to contract independently of the central nervous system, it is, nevertheless, influenced to a great extent by the nerve-centres within the cranium. It would never do to have the heart acting without reference to the wants of the system, and pumping blood vigorously into the arteries when the pressure within them was already too great, or acting slowly and feebly when the limbs were engaged in severe work, and wanted an abundant supply of blood to enable them to perform it. There are, therefore, nerves, some accelerating and others retarding the heart, which pass to it from the medulla oblongata, and, acting as the spur and reins of a rider do upon his horse, regulate its beats in accordance with the wants of the system. The retarding fibres are contained in the vagus nerve; and, when this nerve is irritated strongly, the heart will either stop immediately in diastole, or will beat very slowly and more feebly. Nor is it only by direct irritation of the vagus that this result can be attained. Just as irritation of a sensory nerve sets motor nerves in action, and produces various muscular movements by reflex action through the spinal cord, so may irritation of a sensory nerve set the vagus in action and produce stoppage of the heart, by acting reflexly through the medulla oblongata. A good many sensory nerves can do this; but there is one which possesses the power in an especial degree. The roots of the fifth nerve are anatomically closely connected with those of the vagus; reflex stoppage of the heart is produced more readily by irritation of the fifth than of any other nerve. In many rabbits, the heart can be instantaneously stopped by irritating the nasal branches of this nerve by a pungent vapour, such as ammonia, held before the nose. In every rabbit, or almost every rabbit, indeed, we can stop the heart by a pungent vapour applied to the nose; but we do not always do it in the reflex manner I have just described. The animal always closes its nostrils to prevent the entrance of the vapour, and keeps them closed so long, that the carbonic acid accumulating in the blood begins to act on the vagus and stop the heart. But this only occurs after the vapour has been held before the nose for some time; while the reflex stoppage which I have just mentioned takes place at once, almost simultaneously with the closure of the nostrils. This reflex stoppage has been shown by Hering and Kratschmer to be due to the irritation being conveyed along the nasal branches of the fifth nerve to the medulla, whence it is reflected along the vagus to the heart, and stops it.

Yet, notwithstanding the stoppage of the heart, the rabbit does not die; nor is it, indeed, any the worse. Why is this? Usually, when the heart is stopped, as, for example, when a ligature is put round the aorta, the blood all runs out of the arteries into the veins; and then, as I have said, it is useless for nutrition. But there is a nervous arrangement which prevents this when the heart stops, in consequence of an irritation applied to the fifth nerve. This nerve not only contains branches which are connected with the vagus and stop the heart or retard it; but it also has branches which go to the cerebral hemispheres, and there excite an action which passes down the vaso-motor nerves, causing the auricles to contract, and preventing the blood from running out of the arteries into the veins, except very slowly indeed; so that, as soon as the irritation stops, the circulation is ready to go on normally. But it is only when the cerebral hemispheres are in good working order that this occurs. When they are removed, or when their function is destroyed by chloroform, morphia, or chloral, irritation of a sensory nerve, such as the fifth, no longer has the same effect; and it then always, according to Cyon, lessens the pressure of blood in the arteries. As it is, the pressure of blood within the arteries which keeps up the flow within them, just as it is the pressure of water within the pipes supplying a town which keeps up the supply to the houses, we can readily see that the diminished pressure which occurs on the irritation of a sensory nerve after the cerebral hemispheres have been rendered useless by a small quantity of chloroform is a most serious

thing for the animal. But here it is a little chloroform which is a dangerous thing; and a full dose prevents any risk from this reflex stoppage of the heart. For the small dose acts on the cerebral hemispheres first, and destroys the reflex action, which contracts the vessels, while it leaves the ganglia at the base of the brain and the medulla unaffected, and thus allows the reflex stoppage of the heart to go on as usual. A full dose, on the other hand, affects not only the cerebral hemispheres, but the ganglia and medulla, and prevents any reflex action whatever on the heart. I have found that, when a full dose of chloroform has been given to a rabbit, one may hold either strong ammonia or glacial acetic acid before the nose, and not the slightest slowness in the beats of the heart can be observed. Sometimes, indeed, it has seemed to beat rather more quickly than before.

Now let us try to apply these observations on the lower animals; and, by them, try to explain the action of chloroform on man, and the danger of employing it in the extraction of teeth, as well as in other slight but painful operations. For it is precisely in these slight but painful operations—extraction of teeth and evulsion of nails—that death most frequently occurs; and it is just in them that little chloroform is given, because the administrator thinks: "Oh, the operation won't last above a few seconds; and it is no use giving the patient enough to keep him or her snoring for half an hour." We know perfectly well that many and many an one has teeth drawn under chloroform without any bad result; and we have already seen that every rabbit has not the same liability to reflex stoppage of the heart from irritation of its fifth nerve; but every now and then we meet with a peculiarly sensitive animal, and every now and again we meet with a case of death from the extraction of a tooth under chloroform.

If the nervous system in man be at all like that of the rabbit, the violent irritation of the fifth nerve caused by the extraction of a tooth will tend to stop the heart. But it will also cause contraction of the blood-vessels; and thus extraction of a tooth in the waking state is rarely attended with any serious consequences. But if the reflex action on the blood-vessels, which usually occurs in the cerebral hemispheres, be prevented by a small dose of chloroform, just enough, as in the case I have related, to abolish consciousness without preventing reflex action in the ganglia at the base of the brain, and if the heart of the individual be at the same time peculiarly sensitive to the impression made on the fifth nerve, it may be stopped, and the pressure of blood in the arteries may sink so low that it never rises again. But if, on the other hand, chloroform be given, as Professor Syme recommended, with a free hand, so as to produce total abolition of reflex action, no irritation of the fifth nerve by the extraction of any number of teeth will have any effect; the heart will pulsate as usual; and no danger is to be apprehended from this cause.

I do not at all mean to say that the administration of concentrated chloroform-vapour is free from danger—far from it; but the limits of my paper will not allow me to enter into this subject. All I can attempt to do is to direct attention to the observation of Professor Syme, whose acuteness and accuracy few will question; and to try to impress it, by showing the probable physiological reason why one ought always to induce perfect anaesthesia before beginning any operation under chloroform. At the same time, I would observe that, just as the circulation, which had ceased in the frog in Goltz's experiment so long as it hung vertically, went on again when the animal was laid in a horizontal position so that the blood found its way to the heart, so it may go on in man; and, therefore, the safest position for operations is the recumbent one.

The two rules, then, for preventing death during the extraction of teeth under chloroform are: put the patient thoroughly over, and lay him in a horizontal position.

CONGENITAL DISLOCATION OF THE KNEE-JOINT.—Drs. Porter and Richardson report (*Boston Medical and Surgical Journal*, September 16th) two cases in which the knee-joint was dislocated at birth, the displacement having occurred *in utero*, as was evident from the furrows above and below the joint, and the deposition of vernix caseosa in the angle of flexion. In one case, the leg was in a vertical position, the inner malleolus facing towards the umbilicus, and the foot strongly rotated outwards. In the other, the leg was in such an extreme state of tension as to amount to reversed flexion, being turned upward and forward on the thigh, so that the anterior surfaces of the leg and thigh touched each other, the sole of the foot looking directly towards the face of the child, the toes pointing backward, the heel forward. By gentle firm traction, the dislocation was in each case reduced; and the use of a splint in the more severe instance, and of a simple bandage in the other, sufficed to keep the bones *in situ*, and resulted in perfect cures.

ABSTRACT OF CLINICAL LECTURE ON PUNCTURE OF THE BLADDER *PER RECTUM*.

Delivered at the Westminster Hospital.

By RICHARD DAVY, F.R.C.S.,
Surgeon and Lecturer on Anatomy at the Hospital.

GENTLEMEN,—This operation is a most valuable one for cases of retention of urine, where any physical obstruction prevents the introduction of a catheter into the bladder, after fair trial on the part of a competent surgeon. It was originally introduced into practice by Mr. Cock, consulting surgeon to Guy's Hospital; and his wide experience coincides with my own comparatively limited observation, that there is scarcely any surgical operation so devoid of danger as puncture *per rectum*. The necessary detail of the old operation is now demonstrated to you on this dead body; and the instruments are the same as generally used; viz., a solid trocar and cylindrical cannula, the latter being retained in the bladder by tapes.

In 1870, being impressed with the disadvantages of retaining for any length of time an unyielding tube *per rectum et vesicam*, I introduced the instrument (Fig. 1), in which the steel slotted cylinder is outside,

Fig. 1.

and acts as a perforator, carrying the elastic catheter as an inside passenger. Fig. 2 shows the catheter withdrawn, also the reduplication of the tip of the catheter, by means of which it is retained in the bladder. The patient is placed after the operation on a mattress having a circular hole corresponding to the buttocks; the end of the catheter falls through this hole, and conducts the urine into a receiving vessel on the floor below. Faces also are thus passed without moving the patient.

Fig. 2.

I have yet further applied this principle of giving the urethra rest to those cases of obstinate perineal fistulae that are *not dependent* upon an obstructed urethra for their persistence. I am of opinion that a simple operation like puncture *per rectum* is more effectual and easy than periodic introductions of a catheter; the object being in both cases to avert the irritating urine from the damaged urethra and fistulae, especially so because in some cases men have not the power of retaining their urine; and it is impossible by the most skillful catheterisation to avoid some disturbance to the urethra, and some extravasation of urine over the exposed surface of it and the fistulae.

I have been in the habit of comparing the *rationale* of puncture *per rectum* in fistulous cases to the method pursued by workmen when repairing the damaged banks of a running stream. Their first object is to completely divert the stream from the seat of their repairs, so that one day's wash shall not outweigh one day's work; and this argument applies with double pathological force to the irritating urine as compared with the pure water. But a moment's reflection makes a surgeon see how inapplicable Cock's method would be for opening an empty bladder; and, at the risk of the charge of superfluity, I venture to bring you acquainted with a new instrument, and a new method of operating on this much operated on human perineum. The instrument consists of a staff, on which slides a silver cylinder, and a remov-

able handle. (Fig. 3.) The silver tube runs from the bulge at the right end of the staff to the commencement of the curve on the left. The thin stem underneath the handle is for the attachment of a retentive catheter.

Fig. 3.

New Method of Operating.—First introduce the staff into the bladder; turn the tip of the staff towards the base of the bladder and rectum; feel for the point with the finger in the rectum, and carefully cut the recto-vesical tissues until you can pass the staff out at the anus. Next unscrew the handle and affix the stem of one of Napier's retentive catheters to the thin end of the staff; soap well the India-rubber; then, holding the silver tube firmly in one hand, draw the catheter (excepting its bell-shaped end) completely into the silver tube by withdrawing the staff at the anus. Lastly, draw back the silver tube and catheter through the urethra into the bladder; push in the catheter, and free the silver tube by also withdrawing it through the rectum out at the anus. The campanulate end of the catheter unfolds itself in the bladder, and its stem loosely hangs at the anus.

I will now briefly narrate two cases of perineal fistulae that have been operated on by this method in the Westminster Hospital.

CASE I.—W. H., 35, M., slater, in 1859, fell on his perinæum across a door. Extravasation of urine resulted, and he was treated in the Yarmouth Hospital by free incisions. On leaving, the urine passed through a fistulous opening *in perinæo*.

In 1862, a surgeon, while attempting to pass an instrument, pushed the catheter into his rectum; after that, the patient thought operative procedures had better be discontinued.

In 1869, on rearing a heavy ladder, extravasation of urine recurred, and Mr. Teevan admitted him into the West London Hospital. Mr. Teevan on three occasions divided his stricture without any guide, and lastly, on account of the cartilaginous state of the parts, opened the urethra from the stricture to the bladder; No. 12 was tied in, and in five weeks he left.

In 1871, Mr. Barnard Holt split him, because two catheters had been broken and many bent in his urethra by surgeons.

On March 18th, 1873, he was admitted into Luke Ward. The perinæum was a mass of cicatrices and puckerings. There were five fistulae, one cartilaginous, at the central point of the perinæum. He had complete incontinence of urine. At the point where the penis joins the scrotum was an urethral dilatation holding three and a half drachms of urine, not albuminous. No. 10 sound readily entered the bladder. The man's general condition was good, and his spirits plucky.

On March 25th, 1873, I performed the operation of opening his bladder by the new method. A retentive catheter, as shown in Fig. 2, was inserted, and kept in for six weeks. He most faithfully lay on his back on a circular air-cushion, urine and feces passing through the circular hole in the cushion. After six weeks of this endurance, four of the five fistulae were firmly healed; the grand central perineal fistula was not. An urinal was easily adapted to this single outlet, and he left the hospital on June 6th, 1873, well satisfied with the result. The recto-vesical opening was completely closed.

CASE II.—E. P., 24, S., porter, was admitted into Luke Ward on July 24th, 1874. Five months previously, he had gonorrhœa; a month subsequently, a lump formed in the perinæum, and an urinary fistula resulted. The man was of strumous aspect. The urine was not albuminous. A No. 10 sound could be passed.—July 26th. I injected the fistulous course with compound tincture of iodine, but with no result.—August 21st, 1874. The same operation was performed, and the same treatment pursued as in Case I, until September 15th, 1874. The house-surgeon injected the fistulous track with tincture of iodine, which set up urinary infiltration, and the retentive catheter was withdrawn.

My colleague Mr. James Keene (who had charge of my beds during the autumn vacation) repunctured his bladder *per rectum*, and watched the case with much anxiety; but the extravasation continued. On my return, October 5th, the patient's condition was critical, the inflammatory process extending up the abdominal wall to the umbilicus. As the urine freely came through a sloughy hole in his perinæum, I at once withdrew the catheter from his bladder. He was well supported with nutritious food, stimulants, and opium. On October 14th, his perinæum being very sloughy, I laid the parts freely open; he lost much blood during the operation, and died collapsed the same evening.

POST MORTEM EXAMINATION.—The friends only gave permission for the bladder to be examined. The perineal structures were a confused mass of sloughy shreds; there was recent lymph thrown out over the vesical peritonæum. The interior of the bladder was apparently healthy; the first puncture had completely healed; the second admitted but a small pin; the sloughy mass extended along the scrotum upwards over the whole of the abdominal wall below the umbilicus.

The conclusions arrived at from these two cases are the following.—Case I. Puncture *per rectum* is insufficient *per se* to cause the obliteration of an intractable cartilaginous fistula, but affords the means of occluding lesser and more recent fistulae *in perinæo*. A retentive soft catheter may be retained in the bladder for six weeks, and the wound made in the recto-vesical tissues will subsequently heal. Case II. The injection of iodine through a fistulous track in the perinæum of a strumous patient is a dangerous practice; but the injury inflicted on the recto-vesical floor admits of complete repair after a retentive catheter has been twice maintained in the bladder of the same patient for three weeks.

From a careful consideration of both cases, I conclude that there is no evidence militating against a repetition of this operation as a *dernier ressort* in these miserable afflictions, and that it is our duty to lay such experimental facts before the surgical branch of our profession.

ON THE VALUE OF NITRIC ACID IN THE TREATMENT OF DISEASES OF THE NECK OF THE WOMB.

By EDWARD JOHN TILT, M.D.

DR. BRAITHWAITE'S high estimation of nitric acid as a caustic for diseases of the cervix will have due weight with me when I prepare another edition of my *Handbook*; but he will find it already stated there, "that the acid nitrate of mercury and the acid nitrate of silver owe their causticity to their free nitric acid, while the metals may give these preparations alterative properties that their free nitric acid does not possess". Récamier first used the acid nitrate of mercury. It was the principal caustic used by Lisfranc; and, in the beginning of his professional career, Dr. H. Bennet tried to ascertain its effects, as compared to nitric acid, in a certain number of similar cases, and he convinced himself that the acid nitrate of mercury was the better of the two. Dr. Braithwaite's fear of mercurialising the patient need not count for much; for, although I thought right to warn against this possibility, it has never occurred in my practice.

I quite understand the excellent results that Dr. Braithwaite has obtained from the use of nitric acid in a certain set of cases; but I think he is far too general in its recommendation, and that he undervalues nitrate of silver because it is so often used where it can do little or no good. Every practitioner has witnessed the good effects of this agent in morbid conditions of the fauces; and when the mucous membrane lining the cervix is alone inflamed, and *recently* so, there is no better remedy than the liquid or the solid nitrate of silver, and the patient should be cured in from three to six weeks. Occasionally, nitrate of silver causes slight bleeding of an uterine sore; but, judging from my practice, Dr. Braithwaite has exaggerated this occurrence; and then it is easy to have recourse to carbolic acid, or to tincture of iodine. Knowing that such cases can soon be cured by nitrate of silver—an agent which is easily applied, gives less pain than nitric acid, and can scarcely do harm—I still recommend its use to those who have little experience of uterine surgery; for, until they have acquired the habit of using nitric acid, they will find that it has an ugly tendency to run, and so increase the size of the sore to which it was applied, supposing they examine a week or ten days after its application.

In a second set of cases, it will generally appear from their history, that endocervicitis set in after a miscarriage or a confinement, and that it has already lasted several years; without, however, causing any marked damage to the substance of the cervix. Dr. Braithwaite's advice applies admirably to these cases; for their treatment by nitrate of silver is distressingly long, whereas it is singularly curtailed by one or two thorough applications of a strong acid.

I demur, however, to Dr. Braithwaite's recommendation to leave the patient without examination for a month, unless the os uteri be patulous, and the calibre of the cervical canal such as to render its contraction rather an advantage than otherwise. It often happens,

however, particularly in the unmarried, that the cervix will just allow the uterine sound to pass through a mucous membrane so diseased as not to be willing to get well unless it be touched with a strong acid. After applying the acid nitrate of mercury or nitric acid to the cervical canal in such cases, the practitioner had better examine the patient every week, and pass into the cervical canal a pencil laden with a solution of nitrate of silver, or, at the end of two or three months, he would have the annoyance to find that his treatment has induced cervical stricture.

A third and less numerous class of patients comprise women in whom long continued chronic cervicitis is accompanied by considerable hard hypertrophy of the cervix, inflammation of the mucous membrane having caused its surrounding tissues to become hypertrophied. Sometimes the enlargement of both the body and the neck of the womb appears to have begun in defective uterine involution. At all events, when I am consulted on such cases, they have lasted seven or eight years, or longer, to the misery of the patient, to the calamity of the family, and to the opprobrium of the profession, for such cases go the round of all those who are accepted as authorities for diseases of women. The patients do not get cured, because consulting men have no faith in the only way of curing such cases—the application of potassa fusa cum calce, or some equally strong caustic, to the cervical canal. Dr. H. Bennet put this forcibly before the profession twenty years ago. He made converts of Sir James Simpson and of many eminent practitioners in this and in other countries; and I discussed, in the best way I could, this mode of treatment, in all its bearings, in thirty pages of my *Handbook*. The treatment is solidly based on the recognised utility of caustics in a host of surgical complaints, and it has been well established by the Lyons school of medicine; but when such patients come and tell me what they have had done to them by men in authority, I never learn that a strong caustic has ever been applied. I hear of long ineffectual treatment with nitrate of silver, of an acid having been used, of a pessary to support the womb, of uterine dilatation, of division of the cervix, or of the leaving in the womb of one of those thirty intra-uterine pessaries which were handed round on a tray, one night when I had the honour of presiding over the Obstetrical Society of London. I even have heard that there are practitioners who believe that they can benefit their patients by introducing the index into the vagina, to attempt to rectify a moderate amount of uterine displacement, three times a week, for two or three months; but I never hear that trial has been made of the only mode of treatment likely to effect a radical cure of these cases.

To resume the preceding remarks: instead of advising nitric acid in all cases of cervical disease requiring a caustic, as Dr. Braithwaite seems to do, I now hold—1. That, in comparatively recent cases of endocervicitis, nitrate of silver, tincture of iodine, or carbolic acid, suffices; 2. That chronic cases of endocervicitis had best be treated by acid nitrate of mercury or nitric acid; 3. That hyperchronic endocervicitis with considerable cervical hypertrophy requires potassa fusa cum calce, or some strong acid.

Since these remarks were penned, Dr. F. Churchill of Dublin has endorsed Dr. Braithwaite's views respecting the all-sufficiency of nitric acid in all cases of chronic cervical inflammation, and I am sorry to differ from so eminent a pathologist.

THE PRESENT EPIDEMIC OF SCARLET FEVER IN BRISTOL.

By DAVID DAVIES, M.R.C.S. Eng.,
Medical Officer of Health for the City.

II.

Sceptical Misgivings regarding our Present Hygienic Views and Practice with regard to Scarlet Fever.—One failure starts a doubt in a believer's mind; a second confirms it; a series of failures makes one look out for a better creed. Are we doing any good with our present preventive means? If they could be universally enforced, as they have been in isolated families with disciplined minds, I grant they would succeed; but when this is attempted with large thickly packed communities, can they be, or have they ever been, successfully enforced? By the imperfect execution of them through the length and breadth of the land, do we increase or lessen the mortality from disease? I feel certain that we increase the anxiety of the domestic and social troubles of the public by our preventive measures; and I feel doubtful of the answer to the former question. Take, for example, an imaginary but typical case in private practice.

There is a family named X., in easy circumstances. They have five

children—three boys and two girls. There is an epidemic, of a very mild type, of scarlet fever in the locality. Hundreds have had the disease; but there has been no death. The season is July; the weather rainy, the atmosphere moist. The youngest boy, aged 4, contracts the disease in the prevalent mild type. The other four children, by the advice of their medical attendant, are sent to a distance, and escape the infection. The sick child recovers. Two years elapse. The eldest son goes to Eton, Rugby, Marlborough, or some other public school. An epidemic of a severe type has just broken out where he is; he contracts the disease. The parents are telegraphed for to see their son, supposed to be dying. They travel to and fro three hundred miles. The patient ultimately recovers, and escapes only by the skin of his teeth. The school is temporarily broken up. The convalescent is sent to a fashionable watering place before he is properly disinfected, and there he spreads the disease. The second son has escaped, through being kept at a distance from his brother. He has, in the course of time, taken his degree at college; has been admitted as a barrister; has, after a long struggle, made his position; has been married. He passes through Paris on his honeymoon. The weather is cold, the wind easterly. In Paris, an epidemic of scarlet fever prevails. He contracts the disease, and dies in a strange land; and leaves his young bride a widow among strangers. In time, the eldest girl is married to a rich man. She is in due time confined of her first-born. The bells are ringing, and all goes on merrily as a "marriage bell". A fortnight afterwards, that house is desolate. In that house are now only a bereaved husband and a motherless infant; the subtle seeds of this mysterious disease have been inadvertently introduced to the puerperal patient in the nurse's shawl, or on the sleeve of the doctor's coat. I will not follow this case further; but ask, in all seriousness, would not life and suffering have been saved if all this family had been allowed to pass through the disease when it first appeared among them in a mild type, when they were all children? I wish it to be thoroughly understood that, as a health-officer, I have never had the moral courage to discard my former profession of faith, and to undertake the responsibility of giving practical effect to my doubts. I have never used disinfectants so extensively as during the present epidemic, and yet our failure is complete.

The doubts I have expressed do not in any way extend to typhus and enteric fevers, small-pox, and Asiatic cholera.

It is a fact beyond contradiction that occasionally this tiger of pathology seems to stalk abroad, having left both claws and teeth at home. Could we not play with him *then*? Inoculation from mild cases of variola previous to the discovery of vaccination proved of immense benefit. We cannot inoculate scarlet fever, but it can be imported. We can choose our type and season of the year. I lay these thoughts before the profession most humbly, "seeking for more light" under a failure in the midst of a great epidemic. I have never practised the suggestions, either in public or private, except in my own family, and with my own children, and these, thank God, with the best result.

Is there a milder exanthem of an allied species that can prevent or modify this disease?—Rötheln is nearly allied; is very infectious, but harmless. Does it modify scarlet fever, or is it modified by it? I have for some time looked upon it with affection, but am afraid to theorise on the subject. Can anyone throw light on this unexplored field? Observation convinces me that there is some unknown condition which gives immunity to some persons from scarlet fever: what is this condition? An analogous condition was known in the Vale of Berkeley regarding small-pox before the days of Jenner, and might have remained unknown to the outer world had not that great man unearthed it.

Who will be the Jenner of scarlet fever?

This pest, which broke out in Italy about the middle of the seventeenth century, is now two hundred years old. It has surely committed havoc enough among our race. In the kind provision of nature, there must be an antidote somewhere. Who will discover it?

A Delusion concerning Bristol.—It appears in some of the daily metropolitan papers that there is an impression abroad that my good and talented friend Dr. William Budd succeeded in preventing epidemics of scarlet fever; and that he was in some way or another connected with our sanitary arrangements. Both these views are erroneous. Scarlet fever was never more prevalent and more fatal in Bristol than when Dr. Budd was at the zenith of his well-deserved fame. No family suffered more severely than his own. He lost his eldest son from the disease—a blow from which, I believe, he never fully recovered. He could never mention his loss to me without tears. In individual and isolated families, his instructions have succeeded, but not on a large scale. My good, kind, and most talented friend Dr. Budd had never any connection with the sanitary arrangements of Bristol, either as director or as administrator.

NOTES OF AN UNUSUAL CASE OF EPILEPSY.*

By P. MAURY DEAS, M.B.Lond.,

Medical Superintendent of the Cheshire County Asylum, Macclesfield.

I AM induced to lay before the Section some notes of this case, now under my care, both because it presents, so far as my experience goes, some singular and anomalous features, and also in the hope that the experience of other members may be able to throw some light upon it, or to cite similar cases. Epilepsy and the affections allied to it have been so long and so carefully studied, that it is with great diffidence I venture to bring forward a case as presenting unusual or novel symptoms; but there is a combination of symptoms in the case which I have not myself met with before, and have not found recorded.

I am sorry to say that I have failed, as yet, to trace out the earlier history of the case as carefully as is desirable, the patient having come from a distance, and having been under my care only about six weeks.

E. W., female, aged 22, was admitted into the asylum on June 14th of this year, under an order of transfer from the General Lunatic Asylum at Northampton, where she had been under treatment for nearly four months. The certificate on which she was received into the Northampton Asylum stated that she had had "maniacal paroxysms succeeding epileptic fits, talking violently, throwing herself out of bed, threatening to destroy herself as well as others; that she had been subject to epilepsy for six years, that she was incoherent in language, that she tried to strangle herself and to jump out of the window; sometimes talking and hallooing all the night." It seems that she had been in the Wellingborough Workhouse Infirmary for some months prior to this; and I obtained the following information from the medical officer, Dr. W. Clarke. "Before she was sent to this Workhouse Infirmary, she was subject to fits and aggravated hysteria while at service. She became worse, difficult to manage, and, at times, violent; and was sent to the Union Infirmary, where she became periodically noisy, violent, and dangerous. I considered that she might have disease of the brain; and, as she became dangerous to herself and others, and there being no accommodation for such patients here, I was obliged to send her to the Northampton Asylum. She has been frequently as you describe."

From Mr. Bayley, Superintendent of the Northampton Asylum, I ascertained that E. W. "was subject, while there, to violent attacks of epileptic mania. She had a contracted foot when she was admitted, and was never able to walk without help. She got much stronger and better during the time she was with us."

The following was her state upon admission. She was little, stout; of fresh healthy colour, and apparently in good health. Height, 5 ft. 3 inches; weight, 10 stones. Her tongue was large, and rather white; the bowels were inclined to be constipated. The left foot was contracted and distorted exactly like a bad case of talipes varus; she walked with difficulty, and on the outside of the foot. There was, also, a certain amount of contraction at the knee-joint, with some wasting of the muscles of the calf. Two fingers of the left hand were stiff and useless. The circulatory system was normal; pulse regular, about 80. The respiratory system was normal. She was very quiet, spoke readily and rationally, and presented little evidence of mental weakness.

She was reported by the nurses who brought her to have many and severe fits; and to be at times violent, excited, and destructive, requiring to be placed in the padded room; also to have shown suicidal tendencies. Her history, as given by herself, was as follows; and I believe it may, to a great extent, be relied upon. When well, she conversed very readily; her memory seems pretty good, and she writes sensible, coherent letters.

She stated that, as a child, till she was about eight years old, she was subject to St. Vitus's dance, which was worst down the left side. This left her, and she subsequently began to take fits, but not to any extent till she was grown up; and even then she was once for twelve months without any. She had been in service at different times, and was so shortly before last Christmas; then the fits came on badly, and she went to an aunt. Then she had a very bad attack; and, when she came to herself, she was in the union, and she found that her left foot was twisted as it was on her admission; it had never been straight since. It was very painful to walk upon it; and she would give anything, or suffer anything, if it could only be straightened again. Before this, her foot was quite right. She thought herself that a bone was out, and that she had got it hurt in some way while she was ill. Eighteen months ago, she said, her left hand swelled and gathered. She was in

hospital with it for some time. It was twice cut, and then a splint was put on for a time. The hand had not been strong since; she had not much use in two fingers. Before that, there was nothing the matter with her hand. She said that she suffered much from her head; she often had a full feeling in it; so bad, at times, that she would like to have it cut open. This was before she had fits. Just before a fit came on, she felt as if there were something which boiled up towards her head; then it boiled over, and she remembered nothing more.

On the day of her admission, E. W. had several fits, which were reported as being "odd sort of fits". The following day, she was very well during the day; but, about 7 P.M., she began to have fits, and continued to have them, one after the other, in rapid succession. About 9 o'clock, I was sent for to see her. I found her lying on a mattress on the floor, with two nurses beside her, to prevent her from hurting herself from the violence of the fits. She was lying quiet, almost completely unconscious; her hands up at her head, pulse small and quick, skin cool and dry. In a little while, she gave a groan or two, and moved about restlessly; the nurses said, "She is going off again", and immediately seized her arms. I asked why they did it; they said, if they did not hold her arms, her hands would be bitten severely. In a few seconds, strong tonic spasms began in the limbs, the arms being strongly flexed. At the same time, a peculiar rhythmical lateral movement of the head began, becoming rapidly more violent, so that the head was thrown violently from side to side. The head described a complete semicircle or more each time; and the movements were of the most regular character, the oscillations being at the rate of about a hundred a minute. So powerful was the muscular action, that, applying all my strength with both hands, I could not hold the head. The face was much flushed, the eyes partially open, and the eyeballs turned forcibly upwards and inwards. The movements of the head were accompanied by a short rapid expiration, producing a peculiar barking cry; each double oscillation being synchronous with one of these. The convulsive movements of the head and the rigid spasms of the limbs continued increasing for about three minutes, when the lateral movement of the head ceased, the latter becoming fixed and thrown back; and the tetanic spasms became more general and severe, accompanied by several prolonged respiratory efforts. The face became congested and livid; the spasms increased in intensity; closure of the glottis took place, the face and neck becoming turgid and swollen; the whole body became rigid, and was arched in a state of complete opisthotonos; respiration was arrested, and suffocation seemed imminent, when, with a final effort, as it were, relaxation suddenly took place, the whole body became helpless and quiescent, the respiration blowing and stertorous, with frothing at the mouth; and, in fact, the typical appearances were presented of the final stage of an epileptic fit. In a short time, the stertor diminished, and a condition of semiconsciousness ensued; the hands went up to the head again, and, with a groan, were pressed against it. In the course of a few minutes, the premonitory signs of another attack showed themselves. I motioned to the nurses not to hold the arms. In a few seconds, the fit began; and, in an instant, both arms were violently flexed, the hands thrown towards the face, and the fingers of the right hand seized between the teeth, and severely bitten. It was with some difficulty they were released, and the arm brought down. Precisely the same succession of phenomena now ensued as before, and ended in the same way. I remained and watched several attacks throughout; but there was no material variation in the symptoms. A noticeable point was that, even at the height of the convulsions, the skin remained cool and dry. Consciousness during, and for some minutes after, each fit was completely suspended, the pupils being insensible to light. At no period, even of the intervals, could she be roused, or got to swallow anything. She was ordered a stimulating injection, containing castor-oil and turpentine.

On visiting her again about twelve o'clock, I found that she was still having the fits; but the intervals were longer, and there was more consciousness during them. She was able to swallow a little milk; and once or twice said, "Oh, my head", as she put her hand to it. I noticed now that the right foot was becoming inverted similar to the left; and, in the next paroxysm, could watch it being forcibly contracted under the influence of the spasms. The injection had acted freely, and brought away a considerable quantity of feces. The fits continued till 4 A.M., but diminishing in number and severity. They then ceased, and the patient fell into a heavy sleep, having had at least forty fits during the night.

Next day, she was better, but weak, and her mind was confused; she had several fits during the day. She passed next night pretty well, without fits. Next day, she was up, and much better, though weak. She was quiet and sensible, and very much distressed about her feet. She was now quite helpless, the right foot being distorted nearly as much as the left, and resisting any ordinary effort to straighten it, the

* Read before the Section of Psychology at the Annual Meeting of the British Medical Association in Edinburgh, August 1875.

attempt causing, also, intense pain. The following night she had no fits, but complained much of pain in her legs and feet, which prevented her from sleeping. Next day, June 18th, she was worse, and had nine fits. The tendency to bite the fingers was very marked, so much so that leather gloves were put on to prevent injury from this cause. During the following night, she had a succession of fits, lasting till 5 A.M., when she became a little better; but during the succeeding forty-eight hours she was more or less constantly having fits. Maniacal symptoms now began to show themselves; she became restless, noisy, and excited. On the 28th, the following note was made.

"All last week, she was in a maniacal state, but did not have many fits till two nights ago, when she had a series till 11 o'clock, and the same last night. They are generally worse at night. Several nights last week, she was very noisy, singing, shouting, etc., and, at times, destructive. Two doses of chloral were necessary more than once before she got any sleep. During these last two nights, the left hand has become inverted and distorted in a similar manner to the feet. To have a blister on nape of neck 4 × 4 in.; and bromide of potassium, one drachm, three times a day. In the intervals of a series of fits, she always puts her hands to her head; and, when sensible at all, says, 'Oh, my head'; and at times asks to be killed."

The storm of fits seemed now to have exhausted itself for this time; and, in the course of another week, the maniacal symptoms had also gradually subsided, and she was again mentally in the state noted on admission. The distortion of the hand passed off spontaneously in a few days, but that of the foot remaining persistent; and, the crippled condition of the poor girl being very pitiable, the question presented itself to me if an effort could not be made to overcome it. Accordingly, I determined, though with no very sanguine expectations, to try the effects of chloroform. On July 9th, therefore, Dr. Lyle administered it, while I took charge of the foot. It was with some difficulty that she was brought fully under its influence; but, when this was at last effected, I was gratified to find that, by the use of very gentle force, the contracted state of the foot was overcome, and it was easily restored to its normal position. An ordinary straight splint was then applied on the outside of the leg and foot. No bad effect followed, except that the following night she complained of a good deal of pain. In a week, the splint was removed, and the foot found to be quite straight. Although the ankle was swollen and stiff for some days, she was soon able to walk upon it, and to get about as she did before.

On the 17th, I find the following note.

"She has a heavy, dull expression to-day. She complains of her head. She says she has a full feeling in it; would like it cut open. The forehead is hot, and face flushed. A few minutes afterwards, she had a fit; she fell off her chair like a log, without any cry. The fit had the same characters as noted before, only not so violent, and it was over in two or three minutes. There were the same violent and rhythmical movement of the head, the same 'barking' respiration, and the same tonic spasms of arms and legs, ending with general ones of the body, and opisthotonos; then blowing respiration, frothing at the mouth, and relaxation."

On the 21st, it was determined to make an effort to overcome the deformity of the left foot; though it was felt that, owing to the length of time that had elapsed, and her having walked so much on it, the result was very doubtful. Greater difficulty than before was experienced in producing the full effects of the chloroform; and, after succeeding in effecting a partial straightening of the foot, a splint was applied, and further efforts desisted from for the time. I may mention that, shortly after the inhalation began, a fit came on; but it appeared to be, to a great extent, aborted by the chloroform; the characteristic phenomena were greatly modified, and the fit cut short. Five days afterwards, a second and more successful attempt was made. The foot was got, without using undue force, into an almost perfectly straight position, and was kept so by means of a pad and a Dupuytren's splint on the outside. The final result as to this leg cannot yet be given, although it must, in any case, be much more doubtful than the other one; but there can be little doubt that, had the same means been employed equally early, the result would have been equally satisfactory, and a most distressing deformity averted.

The patient, during this month, has had no further bad attack, the fits having only been slight and occasional. It is, of course, very doubtful how long this remission will continue. She has continued the bromide, and careful attention is paid to the state of her bowels. I may say here that she has menstruated twice since her admission.

One or two questions now present themselves as to the precise nature of this case. In the first place, am I right in calling it one of epilepsy? Although the symptoms are, in many respects, peculiar and anomalous, I think it has so many of the features generally allowed as distinctive

of an epileptic seizure, that it must be placed in the same category. These points are:

1. The undoubted evidence there was in the whole seizure of a "nervous discharge".
2. The existence of a premonitory sensation or "aura".
3. Complete unconsciousness during the fits.
4. The fits occurring, at times, in a rapidly following series, inducing a comatose or semi-comatose state.
5. The closure of the glottis, with venous congestion, frothing at the mouth, and stertorous breathing.
6. A series of fits being followed by the characteristic transient epileptic mania.

The peculiarities in the seizures, as compared with an ordinary epileptic one, I have sufficiently indicated in the account of the case, and I will only here summarise them as follows:

1. The rhythmical oscillations of the head.
2. The predominance of tonic spasm.
3. The permanent deformities remaining after the convulsions have passed off.

Another question, however, suggests itself, which is: How far an element of hysteria may enter into the case, or have modified the symptoms. There can be little doubt that this girl was constitutionally predisposed to neuroses of a convulsive nature; and that, as she approached maturity, she suffered from "aggravated hysteria". It is hardly necessary, I think, to argue seriously the point that hysteria, even in its most Protean forms, could never account for the series of phenomena described.

The symptoms which I have indicated as pointing strongly to epilepsy are alone sufficient to negative the idea of the convulsions being hysterical; but, further, there was an absence of all the more usual phenomena of hysteria; such as globus, alternations of laughter and tears, rapid sobbing, respiration, etc. But I think, nevertheless, that it is quite possible that the strong hysterical temperament may have had some effect in modifying and moulding, as it were, the particular form which the epileptic seizures should take, and may serve to account for some of their peculiarities. It is, perhaps, even a question whether, under certain circumstances, hysteria might not develop into true epilepsy, by the constant repetition of impressions on nervous centres predisposed to irritability and instability, in a way somewhat analogous to the development of a predominant idea into an actual insane delusion. To make my meaning more clear, we know that the essence of hysteria lies in the will ceasing to control phenomena which it itself originated; and it is only a step further for these or similar phenomena to arise automatically without the intervention of the will at all—the nervous centre involved having acquired, through habit, the requisite irritability.

I will only notice one more question which arises; and that is: how far some of the symptoms point to the existence of anything like serious organic mischief, such as a tumour. It will be recollected that the patient complains much of pain in her head at times, especially in the intervals of a series of fits; presses her hands on it; cries out, "Oh, my head"; and even asks wildly to have it cut open, or to be killed. Then the marked predominance of tonic spasm and the prolonged contraction of groups of muscles, as well as the forcible turning up of the eyes, rather point to some organic source of irritation in the brain or its membranes. On the other hand, there is no symptom of paralysis, and there is no progressive or steady aggravation of the symptoms going on.

The case is incomplete at present; and it may be expected that, in its further development, some light will be thrown on points which are now doubtful. In the meantime, I present it as it is, as a case of some interest, of which some of the features admit of discussion, and are open to different interpretations.

Since writing the above, I have ascertained some additional particulars as to the patient's history through Dr. Clarke. It appears that she suffered from convulsions during infancy, but seemed quite to recover; and there was no paralysis. When grown up, she became subject to hysteria and slight fits, which prevented her from continuing in service. About two years ago, it seems that the catamenia ceased for a time. Her statement as to the cause of the contraction and stiffness in the left hand is confirmed, and, generally, the account she gave of herself. The important fact is added, that there was no contraction or deformity formerly.

A very important item in the history is that, about eighteen months ago, she had a severe fall upon the back of her head; and her sister says she has been worse since; and it seems that she had no bad fits till after this.

Dr. Clarke adds that he "considered it a very unusual and peculiar case, and thought there might be a tumour or some mischief going on in the membranes".

THERAPEUTIC MEMORANDA.

THE SUBCUTANEOUS INJECTION OF WATER.

MENTION is made in the JOURNAL for November 27th, of the subcutaneous injection of water as a successful expedient for relieving pain. I wish to say that Dr. Léclut was not the first to inject this simple agent subcutaneously for the relief of pain; nor was its use in the instance to which I refer in any way accidental. The experiment was made by Dr. G. W. Moore, at that time an excellent house-physician in King's College Hospital, on a patient of my own, who was suffering from thoracic aneurism, and who could not sleep on account of the troublesome neuralgic pains with which it was accompanied. He had been injected several times with a combination of morphia and atropine, when it occurred to Dr. Moore to try the effect of the hypodermic injection of pure water. The experiment was entirely successful. We did not, however, think of claiming for our expedient any other virtue than that of making a mental impression on our patient's nervous system; a means, probably, of relieving many troublesome symptoms which we do not sufficiently estimate; or which we are prone to confound with "doing nothing", which is a wholly different thing.

I. BURNEY YEO, M.D. Senior Assistant-Physician in King's College Hospital.

SUBCUTANEOUS INJECTIONS OF WATER.

IN the BRITISH MEDICAL JOURNAL of November 27th, 1875, there is an allusion to Dr. Léclut's communication to *L'Union Médicale* on the subcutaneous injection of water only, for the relief of pain.

To the advantages of this method in a number of instances, I can bear corroborative evidence, having now for many years adopted it. In 1868, a lady, newly arrived from America, called on me and told me she was in the habit of having morphia injected three times daily; that she could not get any sleep without it; and that, in fact, she lived on it. I first injected half a grain; in a few hours, she came back, saying that it was of no use whatever. I then injected a grain. After the lapse of some hours, she returned and craved for more, telling me she had been in the habit of having three grains at a time. Reluctant to give her any more, I resorted to the artifice of drawing some hot water into the syringe and injecting it. After this, sleep was induced. On subsequent occasions, I injected a small dose of morphia once a day, following up such administration of the sedative by the hot water hypodermic injection, until I reduced the quantity of the drug used to a very minute dose.

Since then, I have attended many patients who had been in the habit of taking morphia, and have treated them with the hot water plan, to the great improvement of their health, and the weaning them of the baneful poison. Even in cases of delirium tremens which had been accustomed to the injections, and in the fury of delirium persisted in calling out for them, I have employed the hot water and so lulled them to rest. But here I would pause to admit that sometimes this plan would fail me, and then I would fall back upon the injecting a small dose of morphia first, following it up with the use of the hot water in two, three, or four hours.

But it is in the cure of sciatica and deep-seated pain, as well as in brow-ague and similar distress, that I have found the hot water injections most beneficial; indeed, I cannot recall an instance of failure. For the purpose of carrying out this method of cure, I had, in 1868, a hypodermic syringe made after my own plan. The needle is some inches in length; the cylinder is silver (I had broken many glass-tubes or cylinders when drawing in the hot water), and contains a drachm and a half of fluid, if such an amount should be required to be thrown in. The piston has not a screw action, but runs up and down like an ordinary syringe, in order that the water may be expelled with the amount of force the operator may think best. In some instances, burying the needle up to the very end, I force in the hot water amongst the muscles, and then withdraw the instrument immediately afterwards, placing the tip of my finger on the perforation point, and, by a rolling movement, dispersing the fluid in its bed. The long nozzle of the syringe acts as an acupuncture-needle; the fluid as an additional counterirritant; the patient complains of a smarting, burning sensation, soon followed by relief from the pain; and, if the operation be done in the patient's own home, and while he is in bed, sleep will often supervene. In this manner, I have frequently stopped sciatica, the agony of acute lumbago, or that resulting from a sudden strain or fall, besides other minor pains.

G. DE GORRQUER GRIFFITH,
Senior Physician to the Hospital for Women and Children.

CLINICAL MEMORANDA.

VARICELLA-PRURIGO.

IN conjunction, doubtless, with many others, I feel much indebted to Mr. Hutchinson for his able exposition of what seems to have been hitherto an undescribed affection. I have met with several cases identical in all essential points with those described by Mr. Hutchinson, which at first puzzled me not a little. In one case, a boy aged 7 years, the rash came on suddenly, and presented all the appearances of ordinary varicella, for which it was at first mistaken; but, as it continued for several weeks, and the irritation produced by it was most distressing, scabies was diagnosed, and at this period I was requested to see him. The boy seemed well nourished, and there was nothing particular in the general state of his health to throw any light upon the nature of the disease. There were four other children occupying the same nursery, none of whom were similarly affected. On examination, the trunk and extremities were found to be studded over with small vesicles; some clear, more pustular, and some broken and inflamed, evidently from having been scratched. There were several deep-seated transparent vesicles on each hand, and some also on the sole of the left foot. The irritation produced was such as to interfere materially with sleep, and the mother was ashamed to let the child come down into the drawing-room for fear it should be suspected that the boy was suffering from itch; but careful examination failed to detect any of the well known characteristics of scabies, and the scattered appearance of the rash was also opposed to this view. Bark and nitric acid, restricted diet, more especially as regards animal food, and a mild aperient on alternate mornings, succeeded, in the course of a few weeks, in relieving this condition; but it was not until at least two months had elapsed that the vesicles ceased to make their appearance.

Another case was that of a very active, intelligent little girl, aged 8, who was brought to me in May last at the Middlesex Hospital by one of our midwives. Several diagnosed the case as varicella, but were rather nonplused when told that the rash had already been out over seven weeks; others expressed their opinion that it was scabies. The irritation produced was very great, and in some places the skin was very much inflamed from the scratching that had been resorted to. The itching was described as always worse at night. Warm baths, attention to diet, diminution of the amount of animal food, gentle aperients, and an acid tonic succeeded in alleviating the condition, but only after treatment had been persevered in for some weeks. The child ultimately recovered perfectly, and has had no relapse. I inclined to the belief that the irritation arose from injudicious and excessive feeding.

Other cases have occurred in my practice; but I cannot lay my hands on the notes at the present moment.

ARTHUR W. EDIS, M.D.,

Assistant-Obstetric Physician, Middlesex Hospital, etc.

DIPHThERIA AND CROUP.

WHILE reading the report of the paper on Diphtheria and its relation to (so-called) croup, read before the Royal Medical and Chirurgical Society by Dr. Semple, I called to mind three cases I saw in Birmingham a few years ago. In the same house and on the same night, three persons—a father and two children—died; the children of scarlatina, and the man of diphtheria. The house was situate on the bank of a stream which passes through the town before reaching the neighbourhood, and at that time (I do not know if it be so now) the water was dark, muddy, and offensive, and had the appearance of having received a great deal of sewage matter in its course. I have no doubt whatever of the nature of the diseases; moreover, I had the advantage of consultation with Dr. James Russell. The children had a remarkably fine scarlatina rash, but died apparently from congestion of the brain and lungs, from the great amount of blood-poisoning they had received. The man had no rash; but the whole mouth, tongue, and fauces were absolutely covered with diphtherial deposit. I had so many times seen diphtheria at the same time that scarlatina also prevailed, that at that time I felt sure some intimate relation existed between them, and these cases tended strongly to confirm that opinion. The man may, however, have got his contagion from a different source than that from which the children received theirs. I have hitherto believed that croup and diphtheria were separate and distinct diseases, and shall look with great interest for the result of the investigation of the committee recommended to be appointed to consider the subject.

SAMUEL LLOYD, M.R.C.S. and L.S.A.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN
THE HOSPITALS AND ASYLUMS
OF GREAT BRITAIN.

LONDON HOSPITAL.

STRUMOUS DISEASE OF KNEE-JOINT; FIBROUS ANKYLOSIS; SUB-
CUTANEOUS OPERATION.

(Under the care of Mr. MAUNDER.)

In a recent number of the JOURNAL (November 6th), we published the account of a new operation by Mr. Maunder for the relief of fibrous ankylosis of the knee-joint, the result of injury. We now record a case in which the same operation was employed to remedy ankylosis following disease of the knee-joint. For the report of it we are indebted to Mr. John Job, house-surgeon.

Charlotte B., aged 6½, was admitted into hospital on September 28th, 1875. The patient's mother said that her little child struck the knee two or three years ago. It then became swollen and painful, and remained so for a long time. She had a doctor for it, who called the disease "white swelling". The child was fairly nourished, but rather anæmic; she had dark hair and eyes; was very intelligent. On examination, the left thigh and leg were found to be a good deal wasted. The leg, when fully extended, formed an angle of 115 deg. with the thigh. The patella was absolutely immovable, and fixed to the outer condyle of the femur; the leg was somewhat rotated outwards and slightly displaced backwards.

Mr. Maunder said that he had no doubt that the medical man who first saw the case had formed a correct diagnosis. The case had been originally one of gelatinous disease of the synovial membrane, which had run its course and left the limb thus maimed. The question was, how to straighten it, and to approximate its pristine usefulness. Mr. Maunder pointed out that the first obstacle to extension of the leg was the adherent patella; possibly next in order, the biceps muscle; and, lastly, the fibrous tissues at the back of the joint. He proposed to attack these in turn.

Operation, October 6th. The patient being under ether, Mr. Maunder passed a tenotome into the knee, entering it towards the outer and upper boundary of the joint, and carried it directly downwards behind the middle of the patella, when it was made to divide the adhesions in all directions. This done, and the patella being now movable every way, the knife was withdrawn, and the wound closed with a compress and strapping, as after the common operation of tenotomy. The limb was placed on a McIntyre splint, and ice-bags were to be employed for forty-eight hours. Mr. Maunder explained that the object of his operation was twofold: first, to dislodge the patella, in order that the leg might be passively extended on the femur; secondly, and most important, that, the patella being again liberated, the quadriceps extensor femoris might now be able to resume its original function of actively extending the leg upon the thigh. Dr. Thorowgood and Mr. Curling chanced to be present in the theatre, and the latter expressed himself as "quite satisfied with the immediate result of the operation which Mr. Maunder had in view when undertaking it" (setting free the knee-cap).

October 7th. She slept fairly well; there was no pain nor discomfort in the joint. Temperature, 98.2 deg.

October 9th. The splint was removed, and a weight of 5 lbs. attached to the foot by way of extension.

October 10th. The child was perfectly well. The patella was freely movable without pain. Two pounds were added to the weight.

October 15th. The weight was increased to 10 lbs.

October 20th. Mr. Maunder divided the biceps tendon, and placed the limb on a McIntyre splint.

October 23rd. The splint was removed; the weight was reapplied.

October 25th. The leg was already much straighter. The patella was movable without pain. There was no sign whatever of irritation about the knee-joint.

November 7th. The leg still continued to get more and more in the axis of the thigh, the angle at the knee being about 160 deg. (already a gain of half a right angle). There was not the slightest evidence of inflammation about the joint, the child suffering it to be pressed and moved without complaint. The patella was freely movable. The 10 lbs. weight was constantly employed, and counterextension was obtained by a perineal band adjusted to the groin of the opposite side.

The parents this afternoon expressed themselves as being much surprised and pleased to see the great improvement in the condition of the limb, and would be satisfied with it even in its present state.

The adult above alluded to was exhibited. He could both flex and extend the leg, and walked with a scarcely perceptible halt. Mr. Maunder was of opinion that this operation offered a ready and safe means of relief from apparently permanent and distressing deformity, many of which deformities could only otherwise be remedied by excision or amputation.

BIRMINGHAM GENERAL HOSPITAL.

CHOREIC MOVEMENTS IN AN OLD CASE OF HEMIPLEGIA.

(Under the care of Dr. RUSSELL.)

As much interest attaches to the "choreic" movements sometimes observed in the paralysed limbs of a hemiplegic patient, a description of these movements exhibited in the following case will not be without interest. They occurred in a young man, aged about 25, who had been partially paralysed in his right side from his second year of age. He ascribed the paralysis to a fright, but could give no further particulars respecting it. The movements in question affected those muscles of the right side which are the seat of the paralysis in hemiplegia. They consisted of rapid energetic clonic contraction of all the muscles more or less simultaneously.

On some occasions, with considerable muscular action, the movements of the affected limb were of the most limited description; the antagonist muscles all contracting at once counteracted the effect produced by one another. Dr. Russell placed his hand on the limb, and felt all its muscles in active intermitted contraction, the contraction travelling down the limb from the shoulder, and yet the position of the scapula was little affected; the arm remained by the side, only the shoulder being slightly rotated inwards or outwards, in consequence of slight overaction of one or other of the scapular muscles. The fingers were more active, being chiefly extended and spread out, the former posture resulting from the flexors of the fingers losing their purchase, owing to the permanently bent position of the wrist. Of course, a marked exception was presented by the mouth, which was under no opposing influence from the opposite muscles; the muscles acting upon the right angle of the lips drew the angle forcibly outwards, and these muscles were aided by the violent action of the platysma on the same side, so that great distortion of the lower part of the face was the consequence. But at other times, especially when the movements were most violent, the exact opposition of antagonists was not maintained, and considerable movement resulted, though apparently wanting much of the complexity and range observed in chorea.

These movements differed from those of chorea in another and more characteristic particular: though the patient could not restrain the muscular action which has been described, he yet retained the power of employing the various groups of muscles in any manner he pleased. He could walk well, without deviating from a direct course, though occasionally, if he had a violent "snatch", he ran against persons in the street; he could grasp my hand or any other object without any trouble; but, owing to the permanent predominance of the flexors, he was quite unable to release his hold until aided artificially; yet the fingers simply closed on the object, and manifested none of the fidgetiness and intermitting grasp characteristic of chorea. Of course, he was quite incapable of performing the more delicate movements of the hand. The muscles affected were notably those of the right angle of the mouth; the right platysma, to a remarkable degree; the scapular muscles and those operating upon the shoulder; and the muscles of the upper and lower extremities. The muscles of the upper suffered much more than those of the lower extremity. The bilaterally acting muscles were spared almost, if not completely. Those of the upper part of the face entirely; and also the muscles of the tongue. The chin could be raised during a violent paroxysm, and the sternomastoids were quiet. The abdominal and lumbar muscles sometimes were slightly in action; but it seemed rather for the purpose of steadying the body. The wrist and the knee were maintained permanently in a semiflexed position, owing to the predominating action of the flexor muscles; but they could be extended artificially with facility. The movements occurred in paroxysms; but one often saw the patient almost still. They were quiet during sleep, but were remarkably under the influence of excitement. A dream would bring them on, and rouse the patient from sleep, or any mental excitement by day. During the day, he was quiet whilst he was reading, or whilst his mind was fully engaged; but sometimes a paroxysm of movement would last all the day.

The limbs were of the same length with those of the opposite side.

The girth of the right wrist equalled that of the left; but the girth around the heads of the metacarpal bones on the right was half an inch below that on the left side. The fingers were rather slender. The muscles of the right arm were smaller than those of the left, occasioning a lessened girth of one inch in the upper arm and of half an inch in the forearm. Sensation was normal. The fundus oculi was healthy, excepting for a posterior staphyloma. The sounds of the heart were natural.

The man was well developed, fully intelligent, and had good health. The movements, it should be added, had been present so long as he could remember, but not with so much severity as for the last few years.

REVIEWS AND NOTICES.

DISEASES OF THE HEART.*

FOR a number of years, there was a complete pause in the issue of works on diseases of the heart. The observations of Laennec, Bouillaud, and of Hope as to the indications of murmurs, the causes of the sounds of the heart, and the diagnosis of the different forms of disease of this organ, had become crystallised in the well known works of Walshe and Fuller, and were absorbed in the grander work of Stokes. Having learned to recognise the different diseases of the heart, and formed some vague ideas as to their progress and prognosis, the profession calmly folded their hands and went to sleep over the matter, paying but little heed to what physiology was finding to say on the subject. Nothing could remove the inflammatory products from a distorted valve, nor stay the progress or reverse the career of fatty degeneration; so what was there to be done but to build up careful diagnosis and shrewd prognosis? No work could give the diagnosis more distinctly or more accurately than Walshe's had done; Fuller's book was fairly good all round; and heart-diseases were left to wait their time, while the interest in them centered itself round the diverse views of the action of digitalis, involving as it did the value of palpitation in diagnosis, and the place of hypertrophy in pathology.

But, under all this indifference, good substantial work was being done, which was to explain how diseases of the heart were brought about, and, with that, how a great many of them were to be avoided. The investigation into the action of drugs upon the circulation found many and able labourers, until our views have of late undergone some profound modifications. The observations of Lauder Brunton, that there was a rise in blood-pressure during an attack of angina pectoris, revolutionised our views as to that puzzling malady, and showed that angina is not a nervous malady always, nor is it a primary failure of the heart; it is a failure of the heart, in the face of a high blood-pressure. This observation pointed at once to those means of relief which physiological research into the action of remedies had indicated; and dilatation of the peripheral vessels by the nitrite of amyl was the result, giving relief to the patient. The sphygmograph had taught us much about blood-pressure, its variations and their causes, and explained the causal relationship betwixt renal disease and consecutive affections of the heart. In addition to this, German workers had tracked out the different consequences of arrest of the circulation, and, with this, the importance of treating the heart-lesion so far as was possible; and workers at home, notably Clifford Allbutt, had pointed out how disease of the aortic valves was related to certain forms of labour. In fact, the time would appear to have arrived when a treatise on the diseases of the circulation was feasible, which not only should give the diagnosis clearly, but which would describe the oncome and progress of heart-disease, and, still further, would give definitive indications for the choice of remedial agents, and explain their *modus operandi*; so as to remove heart-diseases from the list of ailments merely diagnostically interesting, and refer them, to a large extent at least, to the class of maladies which could be treated with benefit, both as regards prevention and relief, aye, even cure or repair.

Such a work was attempted in the treatise by Dr. Milner Fothergill; but the book has never become a popular one. We pointed out a number of objections to it at the time when it was issued; and, if these objections be removed in a future edition, the work may become one in common use. It indicated an advance in a right direction, if the execution had only been more careful.

In the two works now before us, there is no such advance, but a dis-

* *Diseases of the Heart.* By R. Hunter Semple, M.D., Physician to the Bloorbury Dispensary. Pp. 296. London: J. and A. Churchill. 1875.

Diseases of the Heart and the Aorta. By Thomas Hayden, Professor of Anatomy and Physiology to the Catholic University, Dublin; Physician to the Mater Misericordie Hospital. Illustrated. Pp. 1232. Dublin: Fannin and Co. 1875.

ting return to the works of an earlier date. In this these works agree, and the diagnostic divisions are in every way superior to the sections on treatment. But there is a wide difference in merit between the two works.

Dr. SEMPLE'S book is much the smaller one, and is a handy book in size. It contains some shrewd suggestions as to estimating the gravity of each case of chronic heart-disease, taking their origin apparently in the writer's experience as physician to an insurance company. But the work generally is not on a level with the knowledge of the present day. The views of the early writers, especially of the French school, are given at great length; though, no doubt, of much value at the time, and of interest as matters of history now, they are now somewhat out of date as regards practice. The old views about the causes of the sounds, the fanciful varieties of murmurs made by Laennec, and the lengthy discussions on the treatment of the acute inflammations of the serous coverings of the heart by mercury, are antiquated and belong to the past. But more recent information does not seem to have come within the sphere of the writer's cognisance, or, in the instances where it has been recognised, it is but imperfectly understood. Dr. Semple's mind seems to be still associating with the shades of the leaders of the French school, and not to have ranged itself alongside modern thought.

Dr. HAYDEN'S book is a work of a much more ambitious character, and is written by a physician of extensive experience, whose contributions to cardiac literature entitle him to be heard at length. It must be admitted that he has used this last privilege somewhat mercilessly; and a monograph of over 1,200 pages is a serious matter for any reader. It is unfortunate that the work, when found to have grown to its present dimensions, was not divided, so as to form two handy volumes. It is evidently Dr. Hayden's aim to make a complete and elaborate treatise. His work is indeed painstaking, laborious, and erudite; his material is good and ample, and his numerous cases are well chosen and illustrative. The work furnishes abundant evidence of opportunities of which the writer has availed himself; it demonstrates his familiarity with the subject-matter in hand, and is a warranty of his extensive experience. And yet, after all, it is not the book on heart-disease for which we are on the outlook.

The anatomy and physiology of the heart are given at length with care and accuracy in the commencing chapter, and this chapter is a good one. "Milk-spots" are described as the result of long-continued friction in persons engaged in active labours: doubtless a correct view. They are of no moment. The account of the innervation of the heart is good. Several pages are devoted to the cardiac cycle of Lancisi, which may be interesting to many readers.

The second chapter, on the phenomena of the heart's action in relation to its modification by disease, is long and carefully done. The reduplication of the first sound, of the second, and the accentuation of the second sound, are discussed fully; and diastole is discussed at some length.

In the third chapter, the physical signs of disease are reviewed: palpitation, irregularity, and intermittency are appraised, while murmurs are described at much length. The notice of presystolic murmur is very complete, and contains all we know about it. The remarks on hæmic murmurs are very good, and worthy of careful perusal. Dynamic or non-organic murmurs at the auriculo-ventricular orifices are well described.

The fourth chapter, on the causes of diseases of the heart, is very poor. It is chiefly taken up with rheumatism, though Bright's disease, dress, and occupation are included. But the relations of Bright's disease to heart-disease are stated very imperfectly; and the causal relationship of endocarditis to exanthematous fevers little better; while the description of the effects of deformity of the chest upon the heart is not what might have been expected from a pathologist of Dr. Hayden's standing and erudition.

The fifth chapter is taken up with pericarditis, and is a long one. Dr. Hayden does not agree with some other writers as to pericardial effusion, following pericarditis, taking place in the first instance at the base of the heart and around the roots of the great vessels. His views of the treatment of acute pericarditis are still more widely different from what is usually held. Bleeding by lancet-punctures or leech-bites is the first matter. "Immediately blood in sufficient quantity has been abstracted by a first leeching, my invariable practice in acute cases is to administer mercury in small and frequently repeated doses. . . . Administered in this manner, I push the use of mercury to slight salivation, and am satisfied when the imprint of the teeth, with white and elevated lines of union, appears upon the inner surface of the cheeks; when the gums present a swollen, soft, and spongy appearance, and when coppery taste is experienced, and a slight drivelling of saliva at the angles of the mouth takes place." Alcohol may after this be ad-

ministered, and an opiate is often useful. Warm poultices are only referred to to encourage bleeding from leech-bites, or to accelerate the action of a blister. "In the treatment of liquid collections in the pericardium", he writes, "I have no faith in blisters, and rely mainly upon diuretics and hydragogue purgatives". Paracentesis pericardii is discussed at full length. In the treatment of myocarditis and endocarditis (acute), the same reliance on "moderate local depletion, followed by mild but rapid mercurial action", is exhibited.

Diseases of the substance of the heart are considered in Chapter vi, and the view taken of hypertrophy is in accordance with the most recent investigations. The view of Dr. G. Johnson as to thickening of the muscular walls of the arterioles, followed by hypertrophy of the left ventricle, is espoused. As to its progress, Dr. Hayden says:—"Action and reaction, with alternate increase of muscularity of the ventricle and of the minute arteries, might thus go on indefinitely, were it not for failure of nutrition and consequent tissue-deterioration in both. In the ventricle, this assumes the character of fatty degeneration of the muscular fibre, and induces debility and dilatation; whilst in the arteries it consists in a similar change of the contractile fibre-cells and atheroma of the middle coat, with consequent liability to aneurismal dilatation and rupture." The diagnosis is all through the book carefully done, except the part relating to enlargement of the two sides of the heart; and the diagnosis betwixt right and left side enlargement (alluded to at page 571) is not given distinctly; at least we have been unable to find it, the index affording no clue or aid.

In the seventh chapter, endocarditis and disease of the valves are discussed. In speaking of the diagnosis of acute endocarditis, Dr. Hayden writes:—"The associations of a systolic apex-murmur in acute endocarditis are of great importance in regard to differential diagnosis and the prospects of the patient. A murmur accompanied by a first sound and a regular though quick and weak pulse indicates simple endocarditis; but replacing the first sound, and especially if attended with a failing and irregular pulse, such a murmur should be regarded as diagnostic of endomyocarditis. The weakness of the left ventricle, consequent upon inflammation of its muscular wall, serves to explain both the irregularity of the pulse and the suppression of the first sound; the valve-element of this sound being abolished by the inflammatory thickening and softening of the mitral curtains, and the impulse-element by the debility of the ventricle consequent upon similar changes in the myocardium." The diagnosis of the different valvular lesions is well done. In speaking of hæmoptysis in mitral stenosis, Dr. Hayden says:—"Hæmoptysis, in moderate quantity, need not cause alarm. The condition which it indicates, namely, congestion of the lungs and engorgement of the right side of the heart, is best treated by active purgation, dry cupping of the chest, and, if the discharge be copious or persistent, by the use of ergot or ergotine." In dropsy, the use of purgation is advocated. That "the treatment of mitral inadequacy should be directed mainly to the consecutive changes of dilatation of the left ventricle and debility of its parietes" will be a new view to many who hold that failure of the right side is the thing especially to be feared. It is not a mistake of "left" for "right", but is deliberate.

Chapter VIII is taken up with the formation and migration of blood-clots, and is a very good chapter, well and skilfully written.

The neuroses of the heart form the subject-matter of Chapter IX. Cardiac asthma finds its place here, as does a well told case of gouty palpitation; also angina pectoris; they should surely be somewhere else. Dr. Hayden's book is remarkable for the erudition displayed, and the views of Edward Jenner as to the pathology of angina pectoris, and its associations with gout, given by Parry in 1799, and here quoted, are in singular accord with what we are but now learning. Exophthalmic goitre is well handled.

The concluding chapter is devoted to the consideration of aneurism and other diseases of the aorta. It is a thoroughly good chapter, and done in a masterly style. If all the work had been as excellent as this section, it would have called for unqualified praise. The different forms of aneurism, the diagnosis and the treatment are all fully considered; and a long and valuable list of cases of thoracic aneurism is given. Abdominal aneurism is also well handled.

Taken as a whole, Dr. Hayden's book is one which will be very acceptable to many men, and is especially good in the literature of the past, though not so rich even here as to more recent works, especially German. Its deficiencies are chiefly in the direction of treatment, and a philosophical consideration of the progress and indications for treatment of chronic heart-disease is wanting. The opinion about digitalis is wavering, as if old views could not be laid aside; while the employment of mercury, as given in several places, is in distinct contradiction to modern views. The use of opium in advanced heart-disease, and of chloral-hydrate in angina pectoris, though usually held unsafe, is

advocated here; and no reference is made to the eloquent sentences of the late Hyde Salter as to the use of soporifics in advanced disease of the organs of the circulation. The cases related are very numerous, but, though good, are not so arranged as to point out principles distinctly. The illustrations are too often poor, and are not well selected. It is the largest work we possess on diseases of the heart, and is probably the last of the present race of these works. Heart-diseases must be described for the future in short clear chapters, and the pruning-knife must be used energetically to lop off or circumscribe the views of the past. The relations of causation to the management of these affections must be vividly appreciated, and diseases of the heart must be less regarded as diagnostic puzzles than they have been. The satisfactory work on diseases of the heart has yet to be written. When it is written, the writer will find much in Dr. Hayden's work which will be very useful to him.

DISEASES OF THE KIDNEY AND URINARY DERANGEMENTS. By W. HOWSHIP DICKINSON, M.D. Cantab., F.R.C.P., Physician to and Lecturer on Pathology at St. George's Hospital; Physician to the Hospital for Sick Children, etc. In three parts. PART I.—DIABETES. Pp. 236. London: Longmans, Green and Co. 1875.

DR. DICKINSON'S work *On Albuminuria*, published seven years since, has been favourably received by the professional public, and is shortly to be republished with additions, as the second of a series of three, of which Part I is now before us. The author, in his introduction, expressly asserts that "diabetes is a disease of the nervous system characterised by the secretion of saccharine urine", and, therefore, although this subject is placed first, it clearly comes under the second head of "urinary derangements"; a term, by the way, which is by no means nice-sounding or unequivocal in meaning. This is, however, a minor matter, and provided the medical public gets a good book at a moderate rate, it cares little for the title, and still less for the nosological arrangement. We can very safely anticipate its verdict in regard to the work before us. It is a good book, especially in its clinical portions. At the same time, in common perhaps with most monographs, it is not equally good all through. What we may call the historical portion, in other words, the chapters on the physiology and pathology of diabetes mellitus, are not of equal value with the purely clinical parts. No doubt Dr. Dickinson may plead that he has selected some of the best, most certain, and most fruitful of the experimental researches in the production of glycosuria. But the addition of a very few pages, and the condensation of others, would have given space for other experiments, and for a wider view of the subject. We cannot find (as might reasonably be expected) any notice of the discrepancy between Brücke and Seegen as to the occurrence of sugar in normal urine, nor any description of the tests to be employed for the detection of sugar, although the various methods are by no means of equal value, or equally easy to use. Here our fault-finding, as far as regards the author's part, must cease; our only other ground of complaint is in the illustrations. Looking at the price of the work, which is only ten shillings and sixpence, it may be said to be profusely illustrated; but there is a diagrammatic harshness about the figures which is far more German than English, whilst Plates I and II, which are taken from the *Medico-Chirurgical Transactions*, are far too faint and "washed-out" looking to be at all pleasant. On the other hand, the type is clear and readable, with marginal notes, a luxury which is supplemented with a really good index. Dr. Dickinson's original researches on the morbid changes in the nervous centres, found after death in cases of diabetes, including the microscopic appearances, are reproduced in this volume and very freely illustrated. There are numerous tables of the comparative frequency of diabetes at various ages and in different countries. The general arrangement of the work is exceedingly clear, methodical, and logical. The section relating to the other constituents of urine containing sugar, seems particularly deserving of note, as containing much original matter. In the parts relating to other organs besides the nervous centres, e.g., lungs, kidneys, liver, etc., there is also much original work. We feel confident that this volume will not only sustain but greatly increase the author's reputation as an excellent clinical observer, and as a scientific as well as practical physician.

The cases from his own note-books (whether in hospital or in private practice they are clearly detailed) have evidently been studied in all their bearings, and show, as regards treatment, a full knowledge of all the remedial measures which have justified a trial in this serious and too often intractable complaint. The principal conclusions arrived at by the author are as follows.

1. Diabetes (mellitus) is a disease of the nervous system. (P. 1.)
2. "Both forms of diabetes—the slight or early kinds in which

sugar is only transmitted, ceasing from the urine when sugar and starch are withdrawn from the food; and the more severe kind in which the sugar discharged is made in the body out of albumen and the like—may equally be described as failure of the liver to make glycogen, or the due proportion of glycogen, out of what should form it. In the first instance, the liver loses its hold only of some of the superabounding glycogenic material of sugar and starch, but can deal normally with the smaller proportions presented in nitrogenous food. In the second case, the glycogenic elements from both sources elude transformation. The two kinds would thus appear to be merely different degrees of imperfection in hepatic glycogenesis; and that they are closely allied, is evident from the manner in which they pass into each other. The imperfect (or in the other view the excessive) formation of glycogen has its immediate cause in an unnatural excitement of the circulation within the liver, which may be due to direct irritation of the organ, to mechanical expedients which increase the quantity of blood sent to it, and apparently to conditions like respiratory embarrassment which prevent the free discharge of blood from it. But of all the causes which, presumably acting through the blood-vessels, excite the gland to the action necessary to diabetes, nervous disturbance is the chief. This in its nature appears to be irritation rather than interruption, analogous to that which causes tetanus; the incidence of irritation in the one case being upon the cord, in the other upon the liver. In position, the nervous irritation of glycosuria has a wide range. It may arise in many parts of the sympathetic; in the cervical region of the cord; or anywhere in that great cerebral tract which lies between the cord and the crura cerebri. The medulla oblongata contains the structures, the irritation of which causes the exaggeration of function with the greatest facility and profusion. Impressions pass thence to the liver, first through the cord, afterwards by a route which has been sufficiently defined. [A diagram of this route is given at p. 15.] This chain of communication represents the cerebro-spinal, or excitor nerve of the gland. Every gland, as Bernard first showed with regard to the salivary, has nerves of two kinds, which are derived from different sources, and have antagonistic functions, one stimulating, the other repressing, secretion. The vaso-motor nerves which belong to the sympathetic contract arteries, lessen blood-supply, and diminish secretion. The cerebro-spinal nerves accelerate circulation, dilate ducts, and excite to secretion and function. The cerebro-spinal nerve of the liver has its origin at the fourth ventricle. Irritation at or directed upon this spot, or striking the nervous chain between it and the liver, causes, if transient, temporary glycosuria; if permanent, diabetes." [Pp. 27-29.] This long extract will give a fair idea of the general style of the work.

3. The chief *post mortem* changes are—1. In the nervous system, increased vascularity in some cases, wasting, softening, minute excavations and erosions, extravasations (hence hæmatin, etc.), degenerations, sometimes miliary sclerosis, with vitrefaction and corpora amyacea; 2. In the liver, increased size, increased vascularity, and overgrowth of fibrous elements (*hypertrophic cirrhosis* of Trousseau), and of epithelium; 3. In the lungs, not true tubercle usually, but a variety of pneumonia—chronic, circumscribed, and caseating—which rapidly leads to the formation of cavities; 4. In the kidneys, a preponderance of congestive and subinflammatory changes; 5. In other organs a general wasting prevails, notably in the heart; 6. In the blood, besides sugar, there is increased fat, more water, less corpuscles.

4. Males are most prone to diabetes.

5. It is very rare in infants, rare in children, and most common in middle life. The article by Dr. Hirschsprung of Copenhagen on Diabetes in Children, of which there is an abstract in the *London Medical Record* for February 18th and 25th, 1874, does not appear to have attracted Dr. Dickinson's attention.

6. It is often hereditary. Of this, the author gives some striking instances, and his position is greatly strengthened by the observations of Dr. Schmitz of Neuenahr. (See *London Medical Record*, January 13th, 1875.)

7. Diabetes is often traumatic. [P. 81.]

8. Mental emotions, particularly grief and anxiety, are the most frequent causes. [P. 75.]

9. There are two great clinical types, one the severe form of the text-books, often acute and rapid; the other milder, intermittent, and often harmless. [P. 97, etc.]

10. Diabetes rarely kills under six months; more often between six months and four years; occasionally it is very chronic. [P. 107.]

11. Urea appears to be always increased. [Pp. 116-120.] Chlorides are generally increased also, and so are the earths and alkaline salts in many cases.

12. Dietetic treatment is most important and most successful. A very useful diet table is given at page 131.

13. The saccharine treatment, that by "skimmed milk", and that by "ozonic ether", are all condemned; the first unsparingly. Chloral hydrate and bromide of potassium proved useless; so did belladonna, Indian hemp, and Calabar bean.

14. Strychnia is of all medicines the most constantly useful. Iron is the one remedy for diabetic œdema. Other tonics, iodide of potassium, and opium, are sometimes of great service. Though the latter sometimes cures, it more often kills. [P. 138.]

The author appears to us to rather underestimate the remedial effects of quinine, and the curative ones, if continental observers are to be believed, of alkaline waters, such as those of Vichy and Carlsbad; although the *genius loci* has doubtless much to do with their reputed cures, still some credit must be given to the waters. No mention at all is made of carboic acid, which appears to have done good service in a certain class of cases in the hands of Ebstein and Müller.

Dr. Dickinson concludes this part with a brief, but excellent, account of the kindred disease known as diabetes insipidus or polyuria. In taking our leave of his volume, we may say, "although we have found a few faults, we have found more beauties", and are sure that both we and our readers will heartily welcome the parts which are promised to complete the work, as well as any future publications by the same author.

DISEASES OF THE HIP, KNEE, AND ANKLE-JOINTS, AND THEIR TREATMENT BY A NEW AND EFFICIENT METHOD. By HUGH OWEN THOMAS. Pp. 101. Liverpool: T. Dobb and Co. 1875.

MR. THOMAS begins by informing his readers that he will introduce them to an "efficient method of treating diseases of the hip, knee, and ankle-joints", which is a vast improvement on all the modes of treatment hitherto practised in this department of surgery; that he will explain to them "surgical appliances and details, etc., which involve radical changes of treatment, and are now for the first time made known to the medical profession".

We have looked in vain through the one hundred and one pages of the volume for a method of treating joint-diseases hitherto unknown to surgeons. We find very complete immobilisation of joints—in other words, perfect rest—insisted on; but this method of treatment cannot be looked upon as new to either surgeons or physicians. The author, however, introduces us to new surgical appliances, to which we will presently direct attention.

The preface also states "that the means usually employed by surgeons in treating diseases of those joints have rarely been followed by resolution"; and that "it is no exaggeration to assert that a majority of those cases that are benefited are but defectively cured". It appears to us that Mr. Thomas would find great difficulty in substantiating the first part of that statement, and the second part will not bear discussion.

Before describing the new machine for use in the treatment of hip-joint disease, he mentions and condemns the instruments of the following surgeons and authors: Bonnet's "grand appareil", and Charrière's modification of it; Dr. H. G. Davis's, Dr. L. Sayre's, Taylor's, Washburn's, and Dr. J. C. Hutchinson's; Dr. Andrews' and Dr. Baner's; Barwell's and Professor Hamilton's; the weight and pulley apparatus, and the long outside splint. In Mr. Thomas's estimation, those instruments are not efficient in fixing the joint. He admits that the long outside splint possesses merits beyond any others; yet he says "it has its faults, as, being applied laterally, it can only partially control the joint-movements, and the nursing of the patient is not without pain".

He alleges that his treatment "is free from the defects of all previous appliances; is cheap, and within the reach of the poorest"; "is light, and enables the attendant to nurse the patient without pain".

The apparatus, which is well adapted to its purpose, consists of a long iron splint for application behind the hip-joint, to extend "from the lower angle of the shoulder-blade" to "the extremity of the calf of the leg". To the upper end of this, a cross piece is attached to embrace the chest below the axilla; another cross piece is fixed a little "below the fold of the buttock", to half-encircle the thigh; and a third lower down, to half encircle the leg below the knee. The upright and cross pieces are severally to be carefully moulded to the limb, that excoriations, inversion and eversion, or movements, may be prevented. The upright is to be made of malleable iron, "one inch by a quarter for an adult, and three-quarters of an inch by a quarter for children". The cross pieces are to be made of hoop iron. The aid of the blacksmith is required for riveting the cross pieces, and the instrument is to be covered with basil leather by the saddler; but the moulding is to be accomplished by the surgeon, with the assistance of wrenches delineated on Plate S.

The patient is secured in this machine by a strap and buckle at the

upper cross piece, and by bandages round the limb; but there is not any special arrangement for making extension, as in the machine for the knees. Until night-pains have ceased, the patient is to be confined to bed; but when this stage has been passed, an addition is to be made to the machine, to enable the patient to go about with the assistance of crutches. This addition consists of an iron patten to be placed under the shoe of the sound limb. We are to infer the object of this, as in Taylor's apparatus, to raise the diseased limb out of reach of the floor. Braces are, at the same time, added to the upper cross piece, to keep the machine in its place; and a bandage is passed round the pelvis, to keep the upright close to the body.

In the after-treatment, first the framework is to be left off at night, then the patient is to go about with patten and crutch only. These are to be set aside only when the surgeon is well satisfied of the permanence of the cure.

To illustrate the efficiency of this method, Mr. Thomas records ten cases of hip-disease, but does not give any statistical account of the one thousand cases of joint-disease of which he says he has had experience.

After case No. 1, the author makes a statement at variance, we believe, with surgical experience generally. "Stiff joints are *not* the result of too long confinement in an immovable position, but, rather, are caused by permitting movement too soon; that is, before all inflammation has subsided." That stiff joints are the result of too long immobilisation, is too often true.

Mr. Thomas states that he has used this machine to correct contractions and deformities, strongly advocates it in preference to division of tendons and forcible extension, and gives cases in illustration. The body and limbs unfold by mere position.

The last case, No. 10, is that of a lad aged 18, who was suffering from suppuration in the left hip-joint. He was fixed in the apparatus, the abscess was laid open; and, later, the head of the femur was excised, but with no permanent benefit, for the lad died twenty days after operation.

Mr. Thomas seems to ignore any classification of diseases of joints, and does not touch upon their pathology; but he dwells at some length upon a method of discovering and measuring disease of the hip-joint, upon which he has great reliance. He makes manifest the degree of flexion at the hip by means of test movements, based on the well known fact that the lumbar spines and the popliteal spaces in the healthy should be able to touch (or all but do so) the surface of a level table when the person is lying flatly on it. He estimates the duration of the disease by the amount of the flexion.

The appliance for the knee-joint consists of two parallel rods, one for the inner side and the other for the outer side of the limb; the inner should extend from the perineum to three inches beyond the sole of the foot, the outer from a little below the crest of the ilium to the same level. The upper ends are connected by a complete ovoid ring of iron, of the same thickness as the bars, viz., three-eighths of an inch. The lower ends are connected by a cross bar, in which is a temporary staple for retention purposes. For the support of the limb, especially of the knee, a sheet of basil leather is stretched from bar to bar. The ring round the top of the thigh is to be well padded, and secured in its place by a shoulder-strap. A bandage is to be used to confine the limb in the apparatus. A patten is worn on the sound side. When the patient may bear weight on the diseased limb, a patten is substituted for the staple on the machine. This instrument Mr. Thomas has used for overcoming contractions successfully. Eleven illustrative cases are inserted. Writing of case No. 5, he says: "This patient was placed in the appliance when partially ankylosed, and retained in it for three years continuously; yet was found, at the expiration of that period, with the movements of the knee restored." Case No. 8 is even more marvellous. The same appliance is used by Mr. Thomas in treating diseases of the ankle and tarsal joints.

Under the head of ankylosis and its causes, some observations occur on the value of rest in the treatment of joint-diseases, but they do not embrace anything new. Of atrophy in these diseases, he writes that he believes (contrary to the usual teaching) "the more the muscular tissue becomes atrophied, the less will there be of spasm and consequent irritation of the joint"; for this and more trivial reasons, he deems muscular atrophy to be an advantage.

The book has been evidently written in haste. Nevertheless, it should be read by all practical surgeons.

NOTES ON BOOKS.

We do not remember that Dr. BATHURST WOODMAN'S *Address at the Opening of the London Hospital College* on October 1st, 1875 (now

reprinted by Wertheimer, London), was published *in extenso* at the time of its delivery. It is, however, a particularly interesting and pleasing composition, and on the whole, we think, the best of the addresses of the year.

WE are glad to welcome Dr. PAVY'S *Treatise on Food* (Churchill) in a second edition. We took occasion to review this book on its appearance at length; and are gratified to find that the favourable opinion which we expressed of its scientific merits has been endorsed by its popularity.

DR. CAMPBELL BLACK'S treatise on the *Functional Diseases of the Urinary and Reproductive Organs* (Churchill) appears, also, in a second edition. We cannot, however, express a favourable opinion of it. It is diffuse and overwritten; and, in our opinion, does not add to useful medical knowledge.

MR. HEATHER BIGG'S title to his new venture, *The Gentle Treatment of Spinal Curvature* (Churchill), is open to obvious objection; and he has shown so much good taste and good sense in his former books, that we are surprised that this should have occurred. "The gentle treatment" appears to be eclectic; on p. 43, it is explained as "stimulus to muscular action by the adoption of some adventitious force which shall be an aid to, but *not a substitute for*, natural action". This is accomplished, it is explained on page 54, "by the adoption of an appliance which, while so spring-like in construction as to admit of the wearer bending the body freely or performing any amount of muscular movement, yet, at the same time, acts like the erector muscles of the back themselves, and, what is of the utmost importance, causes the hips to be tilted backwards, so as to restore gradually the normal angle of 140 deg." This appliance appears to have been improved in accordance with suggestions by Sir James Paget.

MR. H. K. LEWIS, London, publishes a third edition in a more portable form of the very useful *Syllabus of Materia Medica* by Dr. Harvey and Dr. Davidson of Aberdeen. This selection of the more important articles and preparations gives in a very compact form a classified view of the chief articles of the *Pharmacopœia* in such a way as to indicate their properties, relative value, and doses. The present edition has also an index for practitioners.

WE note at once as a valuable addition to medical literature long desired, the issue of the first volume of the eighth edition of *Quain's Anatomy* (Longmans, London), edited by Sharpey, Allen Thomson, and Schäfer. The first volume of Quain's classic work is admirably edited and rewritten, so as to bring it up to the level of the latest knowledge, and it will quickly resume its place in the very foremost rank of anatomical text-books.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

RICHARDSON'S PHOSPHORISED COD-LIVER OIL EMULSION, AND COD-LIVER OIL EMULSION WITH QUININE.

THESE preparations of cod-liver oil are likely to prove very useful, as they are so carefully prepared that many invalids who are unable to take cod-liver oil in its usual form will find less difficulty in assimilating it in the shape in which it is offered by Messrs. Richardson of Leicester. The same recommendation would apply with equal force in the case of children for whom cod-liver oil is prescribed. The combination of quinine and phosphorus with the oil will help to enlarge the field of its usefulness in practice.

MAGNESIYLNE, OR MAGNESIUM CITRATE.

MESSRS. KINMOND AND CO., of Kenilworth Street, Leamington, have forwarded to us a new preparation of magnesium citrate, to which they have given the compound title of magnesiylne. This preparation is said by the makers to contain 60 per cent. of citrate of magnesia. It effervesces freely in water, is agreeable to take, and is the nearest approximation yet manufactured to a true granular effervescent citrate of magnesia. It is also very portable; and will, therefore, we doubt not, be found useful by medical men who find it necessary to prescribe magnesia in the course of their practice.

BRITISH MEDICAL ASSOCIATION:
SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, DECEMBER 4TH, 1875.

THE PATHOLOGICAL SOCIETY OF LONDON.

II.

IN returning to the subject of the present management of the Pathological Society of London, we have the satisfaction of knowing that the force of our recent comments is generally acknowledged, and is fully felt by many of the most prominent members and the best friends of the Society. We have laid stress upon the desirability of more careful preparation of the notes read, the preparation of abstracts in advance; of a classification of specimens so as to allow a broader method of treatment; of an attempt to give point to the statement of the points of interest in the specimens by reference to former records and to the existing views of British and foreign pathologists; of a recognition of the fact that the mere cataloguing of the histological characters of known forms of disease is no longer the function of a pathological society, although an useful exercise of the amphitheatre and the laboratory. We shall not at present further develop these views; but we desire to add a few words as to the error of supposing that clinical details have not a special interest in a pathological society. The fact is, that at present this is precisely one of the most interesting aspects of pathology; mere deadhouse pathology is for the present partly worked out. We desire to see at the Pathological Society specimens illustrative not merely of altered structure or of heterologous formation, but of the relations which such pathological conditions have to disordered function and to morbid processes. To illustrate this proposition by present examples, we should be glad to see encouragement given for the exhibition at the Pathological Society of the preparations which Sir William Gull and Dr. Sutton have for some time been collecting of "arterio-fibrosis", and a careful discussion of their characters, and of the relation of these changes to symptoms during life or to the march of disease. We should like to see there submitted to discussion the preparations by which Dr. Braidwood and Mr. Vacher have been guided in their research on the life-history of contagium, of which we are about to publish shortly the first report to the Scientific Grants Committee of the British Medical Association. We should desire to see brought there Dr. Creighton's specimens of cancer, and Dr. Klein's preparations of diseased intestine in typhoid fever. It must be obvious to all thinking persons, that the work by which pathologists can at present most aid the progress of medical science is the investigation of pathological processes, rather than the mere inspection of ultimate pathological results. No one in this country seems to have more clearly perceived this than the Medical Officer of the Privy Council; and, if we were asked to say where the most remarkable pathological investigations and altogether the best pathological work are being done, we should say outside the Pathological Society, under the auspices of Mr. Simon and Dr. Sanderson. During Mr. Simon's presidency, the Pathological Society shared for a time markedly in the movement of scientific pathological research. The great subject of the inoculability of tubercle was brought forward under his auspices; and it produced a debate, and led to a series of researches by himself, Sanderson, Wilson Fox, Andrew Clark, and others, which reflected permanent credit on English pathology, and added some valuable contributions to our knowledge of a subject of the first importance. It is to work done

under the same impulse that we owe in a great measure the valuable contributions by Dr. Sanderson to the Society's *Transactions* on some Infective Forms of Inflammation. But how strange it is that the Society at large shows little enthusiasm or interest in the cultivation of this most fruitful department of pathological work, and that it takes so rarely the initiative in bringing forward the verifactory pieces on which the greatest modern investigations are founded. With what extreme interest would the profession follow a demonstration from specimens by Professor Lister of his recent work on the relations of parasitic growth to morbid change in the fluids. Is it possible that it is thought that the last word has been said on the subject of the inoculability of tubercle, to which we have just referred? If so, a reference to recent continental work will show how unfounded is such a supposition. Who has seen the results of Dr. Creighton, Dr. Klein, or Dr. Braidwood, except the favoured few? It may be said that the Society would welcome them, if spontaneously presented. But it is precisely the duty of the President, Council, and officers of the Society to direct the labours of the Society, to invite communications which place the members in sympathy with the pathological movement of the day, and to make the transactions of the Society a true reflex of its activity.

It is curious to note how greatly one of the most important departments of pathological research is neglected there. How little do we hear of the pathology of the fluids; of chemical pathology, or pathological chemistry, as it is sometimes called. Is there such a department of pathological work, and has it any value for medical science? So far as the transactions of the Pathological Society would indicate, it might hardly be supposed to exist; or, if it exist, it can only be supposed to be of infinitesimal importance. If we hear of such fluids as the blood, the bile, or the intestinal secretions, it is only in relation to what the microscope reveals, and that is not always very instructive. This subject was raised in the Council a couple of years since, we believe, by Mr. Gay. The services of an eminent medical chemist were proffered, but rejected, and a Committee, we believe, was appointed. Where is that Committee now? What has been referred to it? How far has it stimulated or aided the researches of the Society or its members? We believe that one report was made, and that it was found that such researches involved a certain expenditure, which promised, if repeated, to be more than the Society could conveniently afford.

It is, of course, not likely that the Pathological Society of London would ever be stopped in any such matter by a want of funds. But, if any such consideration should intervene, we may be permitted to say that any research recommended by the Council to the Scientific Grants Committee of the British Medical Association could not fail to meet with a ready response. This by the way; for, irrespectively of such a question, the Pathological Society will always rise to the capacity of fulfilling any mission which it conceives itself called upon to undertake. We commend, then, to the governing members of the Society the advisability of surveying their position and that of the Society from a high stand-point. It is desirable that they should cast off the skin of routine which gradually grows up and thickens and hardens around the limbs of every official organisation, and put forth fresh efforts to make their proceedings something more than a transcript of the *post mortem* records of metropolitan hospitals. The young members, who are, we rejoice to see, flocking in every year from among the flower of the rising men at the hospitals, seeing what is expected of them, will quickly prove equal to their task, and will move out of the old lines in which they have so long been treading in solemn and funereal procession.

We are not seeking to discourage the record of rare or interesting anatomical morbid specimens, but to point out that this is not the sole or chief means of usefulness, or the one function of the modern pathologist; it is only the easiest.

To impress such a movement on the Pathological Society demands some freshness of thought, some vigour of action, and a lively sympathy and full acquaintance with the scientific movement of the day, not only in London itself, but in the provinces and throughout Europe. The chief responsibility rests with the president and secre-

taries, and collaterally with the Council. It has always been an excellent feature in the selection of officers of the Pathological Society that seniority has not been too strictly regarded. A certain proportion of very young members has always been added to the Council. To some extent, claims of early services have, however, limited the selection of presidents; and the adoption of a strict rule of a biennial tenure of office, and of the alternation of a medical with a surgical president, has tended still further to narrow the choice of a president, and to make this office one of routine duty. There have been too many examples of presidents of the Pathological Society whose pathology has long ago run to seed and flowered into large and active practice, which has estranged them from the cultivation of the science of which the president of such a working society should be an accomplished adept, rich in a perfect knowledge of all its most recent acquisitions, and in the ready perception of its present needs. Too many examples occur to the memory of the timid senior, too cautious to criticise, and too candid to discuss what he feels he hardly understands, since it is all "new since his day", and of the audacious senior, to whom everything presents itself as having been done in a rougher and a more satisfactory way a quarter of a century ago. There is no reason why the President of the Pathological Society should not be selected solely for his high present position as a pathologist, and his authority in that department of science, irrespectively of his vogue as a practitioner, or of his eminence in other departments of the medical hierarchy. We speak now prospectively, and, we think, of more than one man who ought, in the interests of the Pathological Society and of pathological science, to be president long before it is likely to "come to his turn" under prevailing collateral rules of precedence. Nor can we see why the election should not with advantage be annual, subject to the right and custom of re-election for one, two, or three years, if the president prove pre-eminently useful to the Society, just as is the rule at the College of Physicians. There may be advantages at such a society as the Royal Medical and Chirurgical in adopting some tolerably definite rules of succession, although there the effect of the system in vogue threatens to reach the *reductio ad absurdum*; but we can see excellent reasons why no rule should be adopted at the Pathological Society, except that of electing the most eminent and highly qualified president, who is willing to serve the Society zealously, and keeping him there until another highly qualified president is willing to serve. Mr. Pollock, in his opening address, expressed to the Society his opinion that a biennial term of presidency might not, in his opinion, be the most desirable arrangement. He has served his year of office with great credit, and he has, it is understood, placed himself in the hands of the Council unreservedly as to the next year. If he be re-elected, he will unquestionably do his duty well, with the amenity and kindness of character which distinguish him, and with the knowledge which is due to a long apprenticeship to pathological work in the deadhouse and museum of St. George's; but we think it better that henceforth high accomplishment in pathological research should be the main qualification for the office of President of this Society. Our remarks have, of course, no personal application of a kind which could be held to reflect upon the present president. They have a much wider and more general scope, and we desire them to be considered as an abstract argument on a subject of great importance to the progress of medical science.

THE ARMY MEDICAL DEPARTMENT.

THE dissatisfaction with the manner in which the medical duties at Aldershot and other large military stations are conducted continues unabated. The medical officers complain that they are overworked, that they are subjected to endless harassing changes of occupation, and that the patients in the station hospitals suffer from want of that thorough acquaintance with their diseases and systematic treatment, which can only be obtained when they remain throughout their illness under the observation and care of one and the same surgeon. That confusion must be created, and that mistakes must occur, in the

diagnosis and treatment of diseases under the present arrangements seem, indeed, to be inevitable. The station hospitals are called general hospitals, but the patients in them are grouped according to the regiments to which they belong. The regimental groups of patients are attended by the medical officers attached to the regiments from which they come. The medical officers attached to regiments are not unfrequently detached to undertake other duties, when fresh medical officers are sent to the regiments in their stead. Hence, as a necessary consequence, the patients who are grouped regimentally in the station hospitals, find, with each change of surgeon attached to their respective regiments, a change of hospital attendant in their own cases. All the benefits of a general hospital system which might be afforded if the surgeons were stationary, if they formed part of the staff of the station hospital, are thus destroyed; while the surgeons attached to the regiments, who have plenty of other duties to occupy their time, are unnecessarily worried by calls to the station hospitals, and feel that they have thrust upon them responsibilities which they are aware they are unable adequately to fulfil. It is not merely the discontent among the medical officers, however, that is to be deplored; the greatest mischief of this jumble of systems is the injury that is done by it to the public service. The sick soldiers cannot but suffer from it. If this mongrel system of hospital administration be the offspring of an endeavour to satisfy both those who advocate the general plan, and those who desire a restitution of the regimental plan, of military medical arrangements, it has certainly failed signally in its object. It has satisfied neither party and has irritated both. All the army medical officers appear to agree in thinking that either of the two systems pure and simple—either the regimental or the general hospital system—would be better than the present plan, which is neither one nor the other. All agree in saying that the sooner its existence terminates the better it will be for themselves and the service at large.

Although the manner in which the medical officers of the army are required to discharge their professional duties constitutes a prominent complaint among them, it is by no means the only one. The hope deferred of the new warrant, which was promised long ago, causes a feeling of more than disappointment—a feeling of deep distrust. This want of confidence in the promises of those who are placed in the highest positions of authority, and even in the terms of the published documents which emanate from them, is a state of things most deeply to be regretted. It keeps those concerned in a state of restless uncertainty, and prevents them from giving their thoughts and attention to their ordinary duties with that earnestness which alone can ensure a right and satisfactory performance of them. These sentiments of distrust are widespread; they have existed ever since the Royal Warrant of 1859 was first tampered with, and they have grown as fresh warrants, and circulars, and memoranda have appeared, each as a general rule over-riding or explaining away some of the provisions embodied in one or other of its predecessors. On the question being put to the Minister for War as to the position of surgeons attached to regiments, the reply assured the House that they were regimental officers as much as any other officers in the regiments with which they were put to do duty; yet, in practice, they find themselves regarded in them as aliens, and they find applied to them by the War Office in matters of leave on private affairs, on account of sickness, rules and restrictions which make them feel but too sensibly how little there is in common between them and their combatant brethren. The latest blow is the novel expedient of half-pay without half-pay to which we recently called attention, and of which we publish to-day further particulars. The sources of distrust and discontent among the army medical officers to which we have just alluded have formed subjects of frequent remark and remonstrance in our own pages and in those of some of our cotemporaries, both medical and military; they have been specially brought to notice by deputations from the British Medical Association; and, doubtless, they have been fully and often represented by the successive chiefs of the army medical department, whose administration of the affairs of the important

branch of the army which they have been selected to direct must be greatly hampered by the disturbed state of the officers serving under them. If we now again advert to this topic, it is because we have the strongest conviction that such a state of things cannot continue without producing more serious mischief than is apparent on the surface; that it must tend to degrade the professional character and reputation of the army surgeons, and, with diminished prestige, to lessen their usefulness in the sphere of action in which they have been placed. The position of a military surgeon ought to be one of the most honourable in the profession of surgery; it ought to be one heartily desired and keenly competed for by the best among the juniors who are about to make their start in life. In what estimation it is really held the numbers on the examination lists sufficiently show. For the sake of the army, we trust that those in power will not be much longer before they wake to the necessity of placing the medical department in a less unenviable position than it holds at present in the eyes of its own officers and in those of the outside public.

PROFESSOR MARSHALL, F.R.S., commenced his course of lectures on Anatomy at the Royal Academy, Burlington House, on Monday last, before a large and distinguished audience.

WE are requested to state that the date of Dr. Sibson's second Harveian Lecture has been unavoidably altered to Thursday, December 9th. The first lecture will take place, as announced, on December 2nd.

THE *Fabellon Medico* of November 21st quotes from *La Correspondencia* the statement that a young man from Alcozer, twenty-six years of age, and 2.80 metres (9 feet 2¼ inches) in height, named Augustin Luengo Capilla, has been presented to his Majesty the King of Spain.

THE late Professor Jüngken, of the University of Berlin, has bequeathed his collection of instruments to the Augusta Hospital of that city. A letter of thanks has been addressed to his widow by the Empress Augusta.

A SERIES of lectures on Unhealthy Trades will be delivered before the Society of Arts by Dr. B. W. Richardson, who has been appointed by the Council of the Society to make special inquiry into the subject. These lectures will be delivered on Friday evenings, commencing on December 3rd.

A LARGE ship, says the *Pall Mall Gazette*, arrived in the Victoria Docks on Saturday with six or seven cases of scurvy on board; and an official inspection was immediately ordered by the Marine Department of the Board of Trade. This is the eighth arrival with cases of this disease during the past three months.

HERR JOSEPH TÜRK, court-jeweller in Vienna, who died on June 20th, has, in memory of his brother the late Professor Ludwig Türk, bequeathed the residue of his estate (after legacies to his sister and others) to found a stipend or bursary in the University of Vienna for students of medicine, without distinction of religious creed. It is expected that the stipend will be a valuable one.

MR. STEPHEN ALFORD has issued a brief popular statement on the subject of Drink-Craving and the necessity for repressive legislation, which will, we hope, assist to form public opinion in favour of such legislation. The subject will, we hope, be vigorously prosecuted by the Committee of the British Medical Association formed at Edinburgh, and by the Branches which have shown an interest in it.

FOR the appointment of Chancery Visitor in Lunacy, rendered vacant by the resignation of Dr. Bucknill, there are already several candidates in the field, amongst whom are mentioned Dr. Crichton Browne of the West Riding Asylum, Wakefield, Dr. Orange of Broadmoor, Dr. Sherlock of Worcester County Asylum, Dr. Sheppard of Colney Hatch Asylum, and Dr. Sibbald, Deputy Commissioner of Lunacy in Scotland.

H.R.H. THE PRINCE OF WALES.

OUR special correspondent with the party of H.R.H. the Prince of Wales, writes to us under date November 8th, from H.M.S. *Scaphis*:—"We are at Bombay all safe and well. We have had a very fine passage from Aden; cool north-east breeze and ports open all the way. The thermometer fell to 79-80 degs. when we left the gulf of Aden, and it has risen again since we get near Bombay. The heat has been so tempered by the breeze that we have not been incommoded. H.R.H. the Prince of Wales is in excellent health, and so is every member of the suite and the servants. On the whole, so far, our voyage has been most propitious. The Prince bears the heat remarkably well, and it is no exaggeration to say that he is as strong as, if not stronger than, any of his suite. We land this afternoon, and no doubt we shall feel it rather hot; but every care will be taken to avoid overfatigue or exertion, and there is reason to hope that no inconvenience will result. I am sure every one will be glad to know that His Royal Highness is so well."

THE DEATH OF MRS. CHILDERS.

A VERY few words seem necessary *à propos* of the painful calamity of the sudden death of Mrs. Childers, from the inhalation of chloroform self-administered. They are the more necessary, that two deaths, equally sudden and sad, were recorded last week from the use of chloral—solidified chloroform—self-prescribed by its victims. Medical science, in bringing these divine narcotics to the relief of human suffering, has conferred a boon, which, inestimable as it must be considered, is liable to great abuse. It should never be forgotten that of the three most potent anaesthetics now known, ether, nitrous oxide, and chloroform, the last is by far the most dangerous. It gives death suddenly, mysteriously, and often when least expected on *à priori* grounds. The medical practitioner who administers chloroform, either by inhalation or in the solid form as chloral, incurs a great responsibility, of which he is conscious and of which he is able to measure the extent; the unskilled person who indulges in these narcotics for the relief of pain, or as a nervous sedative, on his own responsibility, takes an unmeasurable risk, of which the fatal consequences are but too often shown publicly by sudden death; while the more subtle mischiefs which they produce, though less liable to occasion startling public catastrophes, are not the less widely observed by medical practitioners. The unauthorised use by unskilled persons of dangerous anaesthetics is a practice fraught with the utmost peril.

CAPTAIN MONTAGU.

WE are pleased to learn that Captain Montagu is progressing most satisfactorily. The wound in the eyelid is healed; the pupil is small, and active under the influence of light; there has never been a trace of inflammation in the eyeball; and Mr. Critchett sees no cause to fear that the shot may be still in the eye. All the evidence points to the conclusion that it is not there. There is considerable impairment of vision, probably due to the extravasation of blood into the vitreous chamber, which, it is hoped, may be gradually and completely absorbed.

THE WAINWRIGHT CASE.

THE protracted nature of the proceedings at the Central Criminal Court in the trial of the Wainwrights for the murder of Harriet Louisa Lane, renders it impossible for us to give in this week's impression a scientific review of this remarkable case. In the mutilation of the body, it resembles the case of the woman Brown, for the murder of whom a man named Greenacre was tried and convicted in 1837. On this occasion, the body of the murdered woman was cut into three portions—the head was found at Paddington, the trunk in the east of London, and the limbs, six weeks afterwards, in the district of Camberwell. The identity of the body was clearly made out in spite of this attempt to defeat justice. In the Wainwright case, the evidence shows that an attempt had been made to dispose of the body by burying it under the floor of a room, a quantity of chloride of lime being thrown over it

and freely mixed with the earth of the grave. This was the mode in which the Mannings, husband and wife, disposed of the body of a man named O'Connor, of whose murder they were convicted at the Central Criminal Court in 1849. These criminals used oil of vitriol and unslaked lime in burying the body, with a view of causing rapid decomposition. According to the evidence given in the Wainwright case, a large quantity of chloride of lime was used for the purpose, as it is suggested, of destroying the smell likely to arise from the putrefying remains, and concealing the crime. The attempt thus made to conceal an atrocious act of murder has signally failed. Assuming the correctness of the general and circumstantial evidence laid before the Court during the last week, this crime has been accompanied by circumstances which only find a parallel in the former proceedings of the thugs in India, so well described by Captain Meadows Taylor. The unsuspecting victim, while feeding with the assassins one on each side of him, was within a short distance of the grave in which his body was to be laid. The digging of the grave went on while he was engaged in friendly converse with his hospitable murderers! According to the evidence adduced for the prosecution in the case of the Wainwrights, the grave had been deliberately prepared for the victim, and the chloride of lime had been already purchased as an aid to concealment. The medical evidence presents a number of important features which are likely to render this a leading case in medical jurisprudence. We reserve our comments on this evidence until next week.

MADemoiselle DÉJAZET.

OUR Paris correspondent wrote, under date Paris, November 28th, 1875:—"You will be sorry to learn that Mademoiselle Déjazet, the celebrated *artiste* and *comédienne*, is lying dangerously ill from an attack of pleurisy. She has been already twice tapped, and her medical attendant had entertained great hopes of her recovery, but she has just had an attack of inflammation of the throat, which is looked upon as a serious complication, as she is unable to swallow any food or medicine. Mademoiselle Déjazet is about seventy-five years of age, and it is said that, feeling her end is drawing nigh, she has asked to receive the last rites of her church, observing at the same time, although she has not lived altogether as a Christian, she would not like to die as a heathen!" The death of Mademoiselle Déjazet was announced on Thursday.

MEDICAL MISSION IN EAST AFRICA.

EARLY in July last, a dispensary was opened at Mombasa, on the east coast of Africa, under the superintendence of Mr. E. W. Forster, M.R.C.S., an agent of the Church Missionary Society. Up to the end of September, the number of persons who attended it was 563, and the medical officers had been called upon to treat others at their own homes. This dispensary supplies a great want, for the natives are quite ignorant of scientific medicine and surgery. The *m'ganga*, or medicine men, of the Swahili tribe, form a secret society, using certain empirical methods of practice, but relying chiefly in serious cases upon their charms and incantations. Some of their methods are reasonable enough, though carried out in a rude fashion. Thus, they employ the actual cautery in chest-complaints and in articular rheumatism. The mode in which they apply it is with the broad head of a large nail, the number of the applications varying with the intensity of the pain. It is no uncommon thing to see the chest spotted with twenty or thirty hard fibrous scars, the result of this treatment. Wood-ashes are given in heartburn and acidity. Ginger is ordered to be chewed for flatulence; and sulphur, mixed either with water or with sensem oil, is applied externally in skin-diseases. Bluestone is applied to ulcers. Bleeding is practised by free cutaneous incisions, and sometimes cupping is employed by applying a horn over the incisions, the air being exhausted by the operator's mouth. This remedy is used for headaches and for ophthalmia, in which latter case the operation is performed on the temples. Warm baths are prescribed during convalescence from fever. The Swahili appears to be unacquainted with purgative medicines, and the use of emetics. In fractures of the long

bones, they apply a rude form of splint; but, as the patients are very restless, they often remove it at the end of a fortnight, and the result is seen in distorted limbs. The attendance at the dispensary during the first three months of its existence shows that its value is appreciated. Mombasa is near Frere Town, the settlement which is now being formed for the reception of rescued slaves, and as a means of aiding in the suppression of the East African slave trade. The importance of a medical establishment in such a locality is obvious; and it seems probable that, at no distant date, the requirements of the settlement will lead to the formation of a central dispensary at Frere Town, of which the Mombasa dispensary will be a branch.

THE BLANE MEDALS.

ON the recommendation of the Presidents of the Royal Colleges of Physicians and Surgeons, London—viz., Sir George Burrows, Bart., and Sir James Paget, Bart.—and of the Director-General of the Medical Department of the Royal Navy, Sir Alexander Armstrong, the undermentioned medical officers of the Royal Navy have been awarded the Sir Gilbert Blane Gold Medals; viz., Fleet-Surgeon Timotheus James Haran, L.R.C.S. Ireland, 1849, of H.M.S. *Glasgow*, 1874; and Staff-Surgeon Richard Eustace, M.R.C.S. Eng., 1853, of H.M.S. *Himalaya*, 1873.

THE FREE MEDICAL SCHOLARS OF EPSOM.

A SOMEWHAT novel, and among medical men, as far as we know, an unprecedented mission, has been carried out by the acting treasurer of the fund now being raised to establish free scholarships at Epsom College. Dr. Carr has paid a visit to Liverpool and Manchester, bringing before his medical brethren and the public the claims of these scholarships. From several sources, we learn that he has been well and successfully received, the fund largely benefiting thereby. Still further contributions are required; and we shall be glad if this appeal of ours induce any who have not yet responded to do so, in order that the required amount of £7,000 may be completed. Already, nearly £5,000 has been funded in the names of three trustees; consequently, little more than £2,000 is required. The late Sir James Clark, who contributed liberally to the fund, suggested that every member of the profession should give £1 1s.

THE NEW EXAMINING BOARD AT THE LONDON COLLEGE OF SURGEONS.

IN reply to the official notices which have appeared from the Council of the Royal College of Surgeons of England, inviting its Fellows to become candidates for the membership of the Board of Examiners in Anatomy and Physiology, the following gentlemen have responded to the call. The authorities will have no difficulty in selecting from the long list the required number. Taking them in alphabetical order, they are: Mr. James E. Adams, Assistant-Surgeon and Demonstrator of Anatomy at the London Hospital, Fellow of 1869; Mr. W. Marrant Baker, Assistant-Surgeon and Lecturer on Physiology at St. Bartholomew's Hospital, Fellow of 1864; Mr. Thomas H. Bartleet, Surgeon to the General Hospital, and Professor of Physiology in Queen's College, Birmingham, Fellow of 1871; Mr. Richard Barwell, Surgeon and late Lecturer on Descriptive and Surgical Anatomy at the Charing Cross Hospital, Fellow of 1853; Mr. Edward Bellamy, Assistant-Surgeon and Lecturer on Anatomy at the Charing Cross Hospital, Fellow of 1870; Mr. J. N. C. Davies-Colley, Assistant-Surgeon and Lecturer on Anatomy at Guy's Hospital, Fellow of 1870; Mr. Arthur E. Durham, Surgeon and Lecturer on Surgery at Guy's Hospital, Fellow of 1860; Mr. George G. Gascoyen, Assistant-Surgeon and Lecturer on Surgery at St. Mary's Hospital, Fellow of 1858; Mr. Christopher Heath, Surgeon and Holme Professor of Clinical Surgery at University College Hospital, Fellow of 1860; Mr. H. G. Howse, Assistant-Surgeon and Lecturer on Anatomy at Guy's Hospital, Fellow of 1868; Mr. John Langton, Assistant-Surgeon and Lecturer on Anatomy at St. Bartholomew's Hospital, Fellow of 1865; Mr. Benjamin T. Lowne, Lecturer on Physiology at the

Middlesex Hospital, Fellow of 1873; Mr. Jeremiah McCarthy, Assistant-Surgeon and Lecturer on Physiology at the London Hospital, Fellow of 1873; Mr. Francis Mason, Assistant-Surgeon and Lecturer on Anatomy at St. Thomas's Hospital, Fellow of 1862; Mr. Henry Morris, Assistant-Surgeon and Lecturer on Anatomy, Middlesex Hospital, Fellow of 1873; Mr. Arthur T. Norton, Assistant-Surgeon and Lecturer on Anatomy, St. Mary's Hospital, Fellow of 1867; Mr. Thomas W. Nunn, Surgeon, and formerly Lecturer on Practical Anatomy, Middlesex Hospital, Fellow of 1857; Mr. Urban Pritchard, Lecturer on Physiology at King's College, Fellow of 1872; Mr. Walter Rivington, Surgeon and Lecturer on Anatomy at the London Hospital, Fellow of 1863; Mr. W. W. Wagstaffe, Assistant-Surgeon and Lecturer on Anatomy, St. Thomas's Hospital, Fellow of 1868; and Mr. John Wood, F.R.S., Surgeon to King's College Hospital, and Professor of Surgery in King's College, Fellow of 1854. It will be seen that Birmingham is the only provincial town sending a candidate, and that neither of the following metropolitan hospitals have sent one, viz., St. George's and the Westminster; whereas Guy's, the London, and Middlesex Hospitals send three each; St. Bartholomew's, St. Thomas's, St. Mary's, King's College, and the Charing Cross, send two each; and University College one candidate. At present, the following are the representatives of metropolitan hospitals on the Court of Examiners; viz., Mr. J. Birkett, the Chairman, and Mr. J. C. Forster, of Guy's; Messrs. L. Holden and W. S. Savory, F.R.S., of St. Bartholomew's; Messrs. John Marshall, F.R.S., and J. E. Erichsen, of University College; Mr. F. Le G. Clark, F.R.S., of St. Thomas's; Mr. T. B. Curling, F.R.S., of the London; Mr. H. Spencer Smith, of St. Mary's; and Mr. Timothy Holmes, of St. George's. The election is looked forward to with much interest; and at the last moment, we understand, it will be competent to nominate other candidates for election in addition to those now published.

COMMON SENSE ON CONTAGION.

MRS. FRANCES HOGGAN, M.D., appears to have told some home truths to the lady agitators for free trade in contagious diseases at the recent Annual Meeting of their Central Executive Committee, which took them by surprise, and were very far from welcome. Speaking of the arguments which they used, "showing that they were determined to have no legislation on this question, but to leave the plague to carry unchecked its own punishment upon guilty and innocent alike", she described them as "appalling". Speaking of "moral and religious grounds" on which they oppose these Acts, she described them as "untenable"; and added, on the subject of "injustice to women": "While the inequality in the application of these Acts is to be condemned, we must not forget that there is such a difference in circumstances as to make any equality in the form of the application of these Acts to both sexes alike almost impossible." As a physician, she was "forced to look upon syphilis as a contagious disease to which all the plans for stamping out all other contagious diseases ought to be rigorously applied". Finally, on the subject of examinations by the speculum, she said:

"I believe that, if care were taken in the choice of the medical inspectors, and that if evidence of an unquestionable kind were required as to the fact of prostitution in the women, those latter ought not to be regarded as aggrieved persons. The womanly sensibilities of prostitutes are blunted; and it is an indubitable fact that women of the class referred to have already lost that delicacy of feeling which it is customary to speak of as being violated by the examination to which they are forced by law to submit themselves. The examination is not designed to be an outrage, but is the natural and ordinary method of ascertaining the presence of disease and applying the remedies prescribed for its cure. Respectable women, who innocently become infected with these diseases, are obliged to put themselves voluntarily under the same treatment. It is agreed that the compulsion exerted is here the grievance; but it seems to be forgotten that the women in question are exercising a lucrative trade, which to respectable women is repulsive beyond the power of words to express, but which, in the majority of cases, is not repulsive to themselves. In as far as it is a trade which may spread disease, these carriers of disease naturally fall

within the jurisdiction of good government; just as people carrying on offensive trades, such as chemical works, are likewise placed under control, and they have, therefore, no claim to escape control of a reasonable nature, and to injure with impunity the health of the community."

Mrs. Hoggan's objection to the Acts is that they are incomplete and incompetent for the purpose to which they are applied. Her view is that, if Government is to help us at all effectually in this matter, it must be by making the communication of venereal disease knowingly to any human being a crime against the person. In that view, we entirely concur; it would be a further progress in the direction of stamping out the contagious diseases, which these Acts are intended to restrict. Until such further legislation is agreed upon, however, we shall be sorry to see the Contagious Diseases Acts abolished. Mrs. Hoggan's very sensible speech appears to have been particularly unpalatable to her hearers. If they were at all accessible to reason, however, they might learn a most useful lesson from it; and might so modify their programme as to leave a hope that they might one day achieve some good in place of the harm that they are now doing, and the still greater harm which they are trying to do.

THE EVELINA HOSPITAL FOR SICK CHILDREN.

A CORRESPONDENT writes to us:—Every one who is interested in children's hospital management should visit the Evelina Hospital in the Southwark Bridge Road. Visitors will find much to praise and admire, and little to criticise. Good and economical management, perfect order and comfort, complete sanitary arrangements, all combine to make this hospital worthy of special notice. At the Evelina, the serious errors which many children's hospital managers have committed have been avoided. For instance, at some hospitals, the children's wards are more like drawing-rooms than sick-rooms, and the convalescent playroom is furnished with a luxury more suitable to a royal nursery than to one for the sick children of the poor. We have seen patients decked out in the cast-off clothes of the young nobility, and made to feel, by the luxurious treatment they received at the children's hospital, that it is better to be sick and at ease in a hospital, than healthy and wretched at home. All these abuses have been avoided at the Evelina; and we could wish that they were everywhere abolished from children's hospitals, and that all these institutions would adopt in their place the simple homely comforts of the cottage. The eye of a visitor who is at all familiar with the scene usually presented by the ward of a children's hospital is at once struck with the simplicity, neatness, and comfort of all the arrangements at the Evelina. The bright happy faces of the children tell their own tale; and we are not surprised to hear that this hospital is so popular amongst the poor, that the urgent and numerous applications for admission render it necessary that forty extra beds should be opened. To meet this increased expense, the Committee require £1,500; and we commend this useful work to the warm sympathy and support of all who are able to give, in the hope that they will place, at any rate, a portion of their Christmas offerings at the disposal of the Committee of this useful hospital.

A DEARTH OF SUBJECTS.

WE never remember any season in which the complaints were so numerous of the great dearth of subjects for dissection in the anatomical rooms of the metropolitan hospitals. The state of things which a "St. Thomas's Student" describes as prevailing there, exists, we believe, throughout the metropolis. There is not, we hear, one school which has yet received more than half enough subjects to set the students at work; and those which have a fair stock of material for half the men wanting to dissect, owe most of their subjects to the provision by which the managers have injected antiseptically bodies during the autumn. We call the attention of the Inspector of Anatomy to this subject; as the grumbles against his assumed neglect of the interests of the schools in not looking up the unclaimed bodies in hospitals and workhouses are loud and general. We have no doubt that Mr. Charles Hawkins has a good explanation of the scarcity; but a little activity in following up his subordinates, and in seeing that all the unclaimed bodies

are really forthcoming, would be very acceptable. A few bodies for each of the schools would be more acceptable than any other response to the grumble. Anatomical studies are sadly interfered with, and are very backward this year, in consequence of the dearth of subjects.

ANTI-VACCINATORS.

At a meeting of the Keighley Board of Guardians, held this week, Mr. Crabtree, one of the anti-vaccinating majority, proposed a resolution in respect to the writ of mandamus issued against the guardians by the Court of Queen's Bench, declaring that the time had arrived when no further resistance to the writ of mandamus should be made by the board, but that they accept the decision of the Court of Queen's Bench, and carry out the compulsory clauses of the Act. The motion was carried; the Chairman and three anti-vaccinating members only voting against it. Mr. Crabtree then also proposed that the vaccination officers of the union be instructed to produce their books at the next meeting, with a list of vaccination defaulters, with a view of carrying out the compulsory clauses of the Act. This motion was seconded and carried; the Chairman and two others only voting against it.

RECENT DEATH-RATES FROM PULMONARY DISEASES.

DURING the week ending November 6th, the temperature of the air second week of November it was 43.0 degs., or 0.6 deg. below the average; in the third week 45.8 degs., or 3.8 degs. above the average; at Greenwich it was 48.2 degs., or 1.4 degs. below the average; whilst last week it was 36.0 degs., or 5.7 degs. below the average. In the first of the above weeks, the deaths in London from diseases of the respiratory organs were 322; in the second week they were 349; in the third week 371, or 38 below the corrected average of the week; and last week they were 374, and 73 below the average. Of these 374 deaths, 218 resulted from bronchitis, and 108 from pneumonia, differing but slightly from the numbers returned in the previous week. So far, therefore, the table in the returns which is mainly influenced by cold weather, exhibits a satisfactory condition; but it must be remembered that the temperature of the early part of November was above the average, and the effects of the recent cold are not yet apparent in the death returns. It is to be feared that the severe frost of the last few days will no longer permit the deaths from the above-mentioned class of diseases to remain below the average.

UNUSUAL AMENITIES.

AN unfortunate collision on the Great Western Railway has not only resulted in the death of a guard, but has led to a curious and most unusual medical episode. The accident happened at 8.30 P.M., and the poor guard was not released from his shattered van for twenty minutes. Dr. Maclean of Swindon happened to be a passenger by the train, and saw the man as soon as he was extricated from the *débris*. He then conveyed him to the station, and thence to the Angel Hotel at Chippenham, where he stayed with him till after one o'clock in the morning. Dr. Maclean stated at the inquest that death was caused by exhaustion and shock. Mr. Briscoe of Chippenham gave similar evidence. What follows is taken *verbatim* from the report of the proceedings in *Keen's Bath Journal*.

"Dr. Jay and Mr. Stiles, who were on the jury, thought that Mr. Harrage, who, with Mr. Spencer, also attended the deceased, ought to be called, as there was a rumour in the town that a difference of opinion arose between the medical men as to the advisability of amputation. The coroner and jury dissented from this opinion."

Both the medical witnesses above mentioned were rigidly questioned by Dr. Jay, who had armed himself with several books respecting medical practice. Dr. Jay appeared to think that the leg of deceased ought to have been taken off at Chippenham Station, instead of his being "removed in an omnibus to the Angel Hotel. In support of this view, extracts were read from medical authorities, and a lengthy examination, in the face of the impatience of the coroner and jury, was gone into with respect to the nature, position, and action, in case of fracture, of certain arteries and veins; in fact, the discussion would have been

highly edifying for a class of medical students. Medical men, like lawyers and clergymen, are exempt from serving on juries, and, therefore, the voluntary presence of two or three on one lasting all day speaks well for the health of Chippenham. Dr. Jay endeavoured to show that the injuries to the calf of the leg (a compound comminuted fracture) were such that, in spite of the pad which Dr. Maclean had placed over the wound, and the bandages he had applied to stop the hæmorrhage, there might have been internal bleeding to such an extent as to induce greater weakness than was incidental to the accident. In reply to these inquiries, Dr. Maclean pungently replied that he had "passed his examination once", and stoutly maintained that no bleeding of consequence occurred after his bandages had been applied. He added that, as the case had been given into his charge, he would never have given his consent to the use of the knife, as, from the feeble state of the pulse and the general state of collapse exhibited by the injured man, he should have looked upon amputation as nothing short of manslaughter. He admitted that deceased was sensible, and up to the time he left him; but maintained that, apart from the injuries he had sustained, his age (63) would have been greatly against the success of an amputation. In questioning Mr. Briscoe, Dr. Jay directed his examination principally towards ascertaining the effect of the use of the tourniquet, and appeared to imply that the instrument could not check the flow of blood from all the arteries, especially as the bone was badly splintered, and the arteries ran closely adjacent to the bone. To this Mr. Briscoe replied that the best evidence of the effectiveness of the tourniquet to prevent the hæmorrhage in this instance was that no blood flowed. Had it done so, he should have been aware, as there was an open wound. He added that the four medical men (and he warmly acknowledged the skill of Dr. Maclean, and his courtesy, and also that of Messrs. Harrage and Spencer) were unanimous in their opinion that the amputation would hasten the danger to life, as the pulse was so low." The man died the day after the accident. Unless the *Bath Journal* has misstated or garbled the facts in a way not customary in the press of this country, they would seem to admit of little explanation, and to require but little comment. The supreme law of public safety does sometimes require us to prove the malaproxia of one of our fellows. It may even, in rare cases, demand that one of us should draw attention to such malaproxia. Neither position is one which would be sought by any man of proper feeling towards his brother practitioner, or who was really jealous of the honour of our honourable profession. What, then, can we think of the conduct of Dr. Jay, the ringleader in this attack, or of Mr. Stiles, his abettor? They found themselves on the coroner's jury. We do not know the custom of the Chippenham coroner, or of his summoning officer, but we can only say that in other places it is not usual to find two surgeons figuring in such a capacity. Being there, what did they? Intimated that the amount of collapse was not so great as to render amputation an impropriety. Probably they are the only two surgeons in England who would not admit that this is a question to be decided only by those who see the patient. They further insinuated that the measures adopted to prevent loss of blood were inefficacious; to which the answer on oath was, that they did, as a matter of fact, stop the bleeding. Lastly, they suggested that there was a difference of opinion as to the propriety of amputation. This, again, was on oath point blank denied; and any questions on this point should have been asked first, if at all, and no further criticism suggested by the medical jurors when it appeared that the four surgeons who saw the patient agreed in the propriety of non-interference—an opinion which the speedy death of the patient amply justified. We are thankful to say that such an exhibition as that of these two surgeons is as rare, and we trust that it may be long before we have to report its fellow.

THE INOCULABILITY OF TUBERCULOSIS.

THE adversaries of the doctrine of the inoculation of tuberculosis increase and multiply. At the recent Medical International Congress at Brussels, Professor Crocq strongly attacked several points in M. Ville-

min's doctrine, and, at the meeting of the Academy of Medicine on November 16th, Dr. Metzger continued the onslaught. Some months since, M. Metzger read a memoir before the Academy, in which he set forth the result of his first experiments on the non-inoculability of tubercle. The second memoir, to which we now refer, is the affirmative and extended complement of the first. Dr. Metzger has chiefly devoted his memoir to the demonstration of these two points. 1. The inoculation of tuberculous matter produces a change which differs entirely from tubercle. 2. The inoculated animals which withstand these changes, and which are allowed to live for six months after, do not at the end of that time show any local or general lesion. Dr. Metzger bases his demonstrations on one hundred and thirty experiments performed on rabbits. A committee of seven members of the Academy has been appointed to examine and report on M. Metzger's memoirs, and to decide the important question of the inoculability and specificity of tuberculosis.

INTERMITTENT WATER-SERVICE IN NEW SOUTH WALES.

A DOCUMENT has recently been ordered to be printed by the New South Wales Legislative Assembly relating to the unsatisfactory nature of some portions of the Sydney water-supply; and it is satisfactory to note that the experience as to the danger of intermittent water-services which has been so dearly bought in this country, and yet so little taken advantage of, is being made use of by our colonial brethren. Professor Liversidge, to whom the subject was referred, found that various samples of water taken at different points in the city were "most grossly contaminated with fecal matter"; and he stated that this form of pollution was due to the high-pressure service, associated as it was with the practice of nightly allowing a reservoir to run empty, by which process the intermittent system of supply was ensured. Pollution of water arising from this circumstance is the more insidious, because, as Professor Liversidge remarks, it may only occur at a few scattered points along the mains; and, in some cases where a sample drawn for chemical examination is at one time found to be wholesome, it is quite possible that another sample drawn from the same spot a few minutes later might exhibit signs of serious contamination. Further investigation is promised as to the exact manner in which the alteration in the quality of the water takes place during its passage through the mains; and in the meantime Professor Liversidge, referring to the experience gained in this country, both during the late epidemic at Lewes and also at Hull, lays it down as indispensable conditions that the water-supply must be constant, and that the water-closets must on no account be allowed to be connected with the water-mains without the intervention of cisterns. We trust that before this the recommendations made have been complied with, and that Sydney is no longer liable to suffer from this serious, though easily remediable, source of danger.

HEREDITY IN TWINS.

AT the meeting of the Anthropological Institute on November 9th, Mr. Francis Galton read a paper on this subject, of which the following is an abstract. He said that, on comparing the number of twins found among the uncles and aunts of twins with those found in similar classes of society generally, it appears that twin-bearing is hereditary, in so far that there is in excess per cent. of three individuals of twin birth in the former group. It further appears, that the male and female lines contribute the twin-bearing tendency in identical proportions. The families are very large in which twins are born; even those of their parents average nearly seven persons, but the twins themselves appear neither to marry so frequently nor to be so prolific as other persons. However, the common belief that both twins are in no case fertile is quite untrue. Starting with the generally admitted view that the body consists of a multitude of organic units, each of which is to a certain degree independent of the rest, and with certain postulates which that view implicitly recognises, there exists, according to Mr. Galton, a firm basis on which to establish a theory of heredity. By these and their necessary consequences, the object of double parentage, and

therefore of sex, was first explained by the likeness and dissimilarities observed between brothers and sisters, and the still more remarkable similarities and contrasts between twins of the same sex, were then accounted for. It was argued that the germs which were selected for development into the bodily structure had very small influence in an hereditary point of view, but it was those germs that were never developed but remained latent, that were the real origin of the sexual element; by this hypothesis the almost complete non-transmission of acquired modification was explained; also the occasional fact that strongly marked characteristics in the parents were sometimes barely transmissible; and, again, that of certain diseases skipping alternate generations. It was further supposed, in the successive segregations and segmentations of the earliest germinal matter, that the divisions were never precise, and therefore that alien germs were ultimately included in each structure; thus latent germs of all kinds became distributed over all parts of the body. This accounted for much that Mr. Darwin's theory of Pangenesis overaccounted for, and was free from objections raised against the latter. The assumed evidence that structural changes under modified conditions of life reacted on the sexual elements was then discussed, and it was pointed out that much that had the appearance of heredity was not so in fact, but was due to changes of the sexual elements collaterally with the structural ones. A modification of Pangenesis was adopted, as a subsidiary part of the main theory, to account for the occasional and limited transmission of acquired modification. The precise character of the relationship that connects the offspring with the parents was then defined.

SCOTLAND.

WE understand that, after examination, the Sibbald Medical Scholarship at the University of Edinburgh has been awarded to Mr. Charles Begg.

THE Edinburgh water-supply has again risen to the average quantity, there having been a rise during the past fortnight in all the reservoirs. The delivery has been accordingly increased, and is now at the rate of 26.53 gallons per head daily to a population of 275,700.

AT the last meeting of the Royal Medical Society of Edinburgh, the following gentlemen were elected annual Presidents; Dr. A. Turnbull, Dr. T. Ronaldson, Dr. A. Coldstream, and Dr. T. Wilson.

EDINBURGH OBSTETRICAL SOCIETY.

AT a meeting of the Edinburgh Obstetrical Society held on Wednesday, November 24th, the following gentlemen were elected office-bearers for the next two years. *President*: Professor A. R. Simpson. *Vice-Presidents*: Dr. James Young, Dr. Alexander Milne. *Treasurer*: Dr. William Craig. *Secretaries*: Dr. Charles E. Underhill, Dr. James Carmichael. *Members of Council*: The Office-Bearers, Dr. Angus Macdonald, Dr. Robert Bruce, Dr. John Burn. *Librarian*: Mr. J. Jamieson.

MALIGNANT PUSTULE.

A CASE of malignant pustule is reported as having occurred in Galashiels, and as being under treatment at the poorhouse. The patient is a girl fourteen years of age, and was in the service of a cowfeeder in the town, whose cattle had been affected with foot-and-mouth disease. It is conjectured, though not affirmed, that the disease was contracted from the affected cows.

BURNTISLAND WATER-SUPPLY.

THE result of the *plébiscite* taken at Burntisland as to whether the Town Council shall proceed with the Dour water scheme was declared last week, when the eyes were found in a majority of eighteen only. The Council resolved to ask the Board of Supervision whether they were justified in proceeding with the scheme on so narrow a majority,

and to be guided by their advice. On Saturday last, an answer was received from the Board of Supervision, advising the Local Authority to proceed without delay with the steps necessary for introducing a supply of water in terms of the report of their engineer. The letter continues, "It is the statutory duty of the Local Authority to provide a sufficient supply of wholesome water for the use of the inhabitants, and no vote of the ratepayers, or of any section of them, can absolve the Local Authority from the obligation thereby imposed upon them to execute the Act". The Local Authority of Aberdeen have written to the Burntisland Town Council, requesting a conference as to their participating in the proposed supply.

SURGEONSHIP OF THE EDINBURGH COUNTY PRISON.

THE appointment of Surgeon to the Edinburgh County Prison has become vacant by the resignation of Dr. James Simson, who has held the office for forty years. There are a number of candidates in the field. The emolument connected with the appointment is £200 a year.

THE WATER QUESTION AT DUNFERMLINE.

AT a special meeting of the Dunfermline Town Council, it was unanimously resolved to approve of the action of the waterworks committee in taking the necessary preliminary steps they have already done towards procuring an Act of Parliament during the ensuing session for obtaining an additional supply of water to the town from the district of Glenderson; and, secondly, to instruct the committee to take such further measures as they may deem necessary to obtain an Act in accordance with the plan of the engineers.

EXPENSES UNDER THE FOOD AND DRUGS ACT IN GLASGOW.

DAVID FERGUSON, milkseller, Glasgow, appeared before the Sheriff on November 24th, charged, under the Sale of Food and Drugs Act, 1875, with having sold either adulterated milk, or milk from which the cream had been removed. The summons concluded for a substantial penalty with expenses, but his Lordship said he suspected that the prosecutor, who was in the present instance Inspector of Nuisances, could not claim expenses. When a summons was raised under an Act of Parliament, it had to be considered along with the Summary Procedure Act, the 64th section of which provided that costs should not be awarded either for or against the prosecutor. The charge was found proved, and the Sheriff imposed a penalty of £2, with the alternative of twenty days' imprisonment.

GLASGOW WESTERN INFIRMARY.

THE first annual meeting of this hospital was held on November 25th; and, on the whole, the report was favourable. It was intimated that the ordinary income was £1,399 less than the expenditure; but this had been more than met by a special effort, by which £3,736 was collected. It should also be remembered that the hospital was opened very suddenly a year ago, and the expenditure began without a penny having been collected to meet it. There is no doubt that in future sufficient funds will be forthcoming. The number of patients treated in the wards during the year is 1,400; and, as the accommodation has this month been increased to over two hundred beds, this number will probably be considerably exceeded next year.

FEVER AND MILK.

WE are glad to see that the suggestions of the Police Board of Glasgow as to precautions against the spread of fever by milk have been approved of by the Board of Supervision. They have issued a circular recommending all local authorities in whose district there may be dairies or dairy farms, the produce of which is either sold directly on the spot or distributed through retailers of milk or otherwise, to observe the following rules and precautions. 1. All such dairies and farms, together with their steadings and other surrounding circumstances, should be carefully inspected from time to time with reference to their water-supply and their general sanitary arrangements, such as the arrangements

as to washing-houses and disposal of excrement, and the position of midden-steads. 2. The local authority should also cause inquiries to be made from time to time as to the existence of contagious or infectious disease at such dairies and farms; and, whenever such disease is found to exist at any of them, they should immediately (1) take such steps as their medical officer may advise, with a view to prevent the dissemination of the disease; and (2) give notice of the facts to any other local authority within whose district milk from the infected premises may be distributed or sold. These, together with additional precautions for the safe storage of milk in town premises, and for its distribution in sealed cans, have now been successfully enforced for some time on a large scale in London.

REGISTRAR-GENERAL'S QUARTERLY RETURN FOR SCOTLAND.

THE quarterly return by the Registrar-General of Scotland has been issued, and from it we gather the following particulars. The birth-rate was rather less than the average, reaching only 3.415 per cent., the average being 3.450. The deaths during the quarter, ending September 30th last, were in the annual proportion of 207 to every 10,000 living at the middle of the year, the average death-rate of the third quarter being 198.8. Thus the mortality of Scotland during the quarter has been unusually heavy, though less than in the corresponding months of 1874. The deaths were distributed in proportions varying from 235 in the principal towns to 138 in the insular-rural group. For every 10,000 persons in Greenock, which heads the list, there were 324 deaths, and in Aberdeen only 173. As usual, September was the most healthy month of the quarter in the eight principal towns; but the month of August was rather exceptional, as it slightly exceeded that of July. It is satisfactory to notice that the number of deaths in each month was considerably less than in 1874, without taking into account the increase of population in the meantime. The zymotic disease most rife was scarlatina, which in the eight large towns caused nearly 360 deaths in the quarter. Diarrhoea, however, was credited with upwards of 500: 126 in July, 253 in August, and 201 in September. Enteric fever has been far more frequent and fatal than typhus.

IRELAND.

IT is reported that Dr. John McDonnell, the medical commissioner of the Local Government Board of Ireland, will resign during the present month. The candidates for the office are Dr. Burke, medical superintendent at the General Registry Office; Dr. Croker King, one of the Local Government Board inspectors, Dr. Grimshaw, and Mr. Macnamara.

ZYMOTIC diseases in Dublin last week caused forty-eight deaths; an unusually high mortality. To measles, ten of these were ascribed; this disease caused in the preceding week twelve deaths, the highest number of deaths for many months from this disorder.

ROYAL COLLEGE OF SURGEONS.

DR. McDONNELL is a candidate for the vice-presidency of this College at the next election in June, and it is most probable that he will be successful, even though other candidates for the honour present themselves. No other name, however, has up to the present been put before the electors.

DUBLIN MAIN DRAINAGE SCHEME.

THIS gigantic system of intercepting sewerage, which was estimated by its promoters to cost £500,000, has, we are informed, died a natural death. This result has arisen owing to proceedings taken by some ratepayers in the Vice-Chancellor's Court, who obtained an order prohibiting any further proceedings, which injunction will prevent the Main Drainage Amendment Bill from being proceeded with in the next session of Parliament. A member of the Corporation this

week stated that the expenses connected with the scheme had already cost no less than £22,000: a proof of the jobbing that was going on, and which explains the reluctance of various members of the Corporation to relinquish their pet scheme.

PATHOLOGICAL SOCIETY OF DUBLIN.

ON Saturday the 27th ult., the following were elected as office-bearers for the ensuing year—*President*: Henry Kennedy. *Vice-Presidents*: Sir Dominic Corrigan, John Denham, Samuel Gordon, George H. Porter, William Moore, Edward Hamilton. *Secretary and Treasurer*: Edward Bennett. *Honorary Secretary*: William Stokes. *Secretary for Foreign Correspondence*: Robert D. Lyons. *Council*: John T. Banks, Anthony H. Corley, A. W. Foot, Thomas Hayden, George H. Kidd, James Little, Thomas Little, Alfred H. McClintock, Robert McDonnell, Benjamin McDowel, A. M. Purser, William Stokes. The subject chosen for this year's essay, the prize for which is a gold medal, is "On Bursitis, and its Pathology".

SURGICAL SOCIETY OF IRELAND.

THE first meeting of the present session was held on November 26th, the inaugural address being delivered by Dr. Edward Hamilton, President of the Royal College of Surgeons, in the course of which, having referred to the late Mr. John Hamilton, he briefly reviewed the business done in the preceding session, and concluded an interesting discourse by alluding at considerable length to Professor Tyndall's late address before the British Association at Belfast last year.

NEW BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

WE have the pleasure of announcing that, at a meeting held in Glasgow on November 30th, it was resolved to form a Branch of the Association, to be called the West of Scotland Branch of the British Medical Association. An influential committee was appointed to put the Branch into shape.

RUMSEY TESTIMONIAL FUND.

THOSE desirous of subscribing to this fund are requested to do so at once, as the list will be closed before Christmas.

Subscriptions may be forwarded to Dr. Buchanan, New Government Offices, Whitehall; to the Honorary Secretary; or to Messrs. Roberts, Lubbock and Co., Bankers.

Cheques should be made payable to the Rumsey Testimonial Fund or bearer, and crossed "Roberts, Lubbock and Co."

Post Office Orders should be drawn on the Curzon Street Post Office, and forwarded to the Honorary Secretary.

W. H. CORFIELD, Hon. Sec., 10, Bolton Row, Mayfair, W.

SPECIAL CORRESPONDENCE.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

Death of M. Giraldès.

I REGRET to have to announce the death of M. Giraldès, which took place suddenly on Friday, the 26th instant. It was only last Tuesday—that is, two days before the melancholy event—that M. Giraldès' voice was for the last time heard in public. He had just entered the field of discussion that had been going on at the Academy of Medicine respecting the mechanism of myopia, and, strange to say, his adversary on that occasion, M. Jules Guérin, was the very man who was delegated by the Academy to represent it at his funeral. M. Giraldès was a great *savant*, and member of several learned societies. He was an *Agrégé* of the Faculty of Medicine of Paris, and was well known in connection with the Children's Hospital, in which institution he had been for many years surgeon, and which he had to quit about two years ago, in obedience to the regulations in vogue in France, which require hospital physicians and surgeons to retire at the ages of 64 and 65 respectively.

ASSOCIATION INTELLIGENCE.

WITH a view to giving increase of prominence to the scientific proceedings of Branches, and to the improved classification of matter, we propose henceforth to report only the official and administrative business of Branches under the head of Association Intelligence, and to transfer their medical and scientific reports to the columns in which are recorded the proceedings of Societies generally. We shall be much obliged if the Honorary Secretaries will kindly arrange their MSS. accordingly.

WEST SOMERSET BRANCH.

MEMBERS of this Branch are requested to take notice that Henry Alford, Esq., Taunton, will perform the duties of Honorary Secretary and Treasurer during the temporary absence of Dr. Kelly, who has gone to Mentone for the winter.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.

THE next meeting, to be held in the Music Hall Buildings, Aberdeen, on Saturday, December 4th, at 3 o'clock in the afternoon, will be devoted to a debate on the proper place of Alcohol in Therapeutics. The debate will be opened by Dr. Urquhart, Aberdeen.

November 11th, 1875.

J. URQUHART.
ALEX. OGSTON.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

THE next meeting of the session will be held in the Council Room of the Midland Institute on Thursday, December 9th, 1875. The Chair will be taken by the President at 3 o'clock P.M. precisely.

The following papers are promised.

1. Mr. J. F. West: Excision of the Ankle.
2. Mr. Hugh R. Kerr: Death under Chloroform.

Members are invited to exhibit Pathological Specimens at the commencement of the meeting.

BALTHAZAR FOSTER, M.D. } *Honorary Secretaries.*
JAMES SAWYER, M.D. }

Birmingham, December 1875.

SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT.

A MEETING of the above Branch will be held at the Greyhound Hotel, Croydon, on Thursday, December 9th, at 4 P.M.; Dr. ADAMS in the Chair.

The following papers are promised.

1. Dr. Wiltshire: Two Cases of Puerperal Hyperpyrexia treated by Cold.
2. Dr. Tilbury Fox: Remarks on Lichen Planus vel Ruber.
3. Mr. Christopher Heath: A Case.
4. Dr. Duncan: Prognosis in various forms of Apoplexy.
5. Dr. Lanchester: Case of Tamarind-stone in the Trachea, fatal in Four Months.

Dinner will take place at the Greyhound Hotel, at 6 P.M. Price 6s. a head, exclusive of wine.

JOHN H. GALTON, M.D., *Honorary Secretary.*

Woodside, Anerley Road, S.E., November 22nd, 1875.

SOUTH EASTERN BRANCH: WEST SUSSEX DISTRICT.

THE next meeting of the above District will be held at "Skindle's" Marine Hotel, Worthing, on Friday, December 10th, at 3 P.M.; A. H. COLLET, Esq., in the Chair.

The dinner will be served at 5.30 P.M. Charge, 6s., exclusive of wine. Mr. Collet will be happy to see any member to luncheon at 1, Montague Place, from 1.30 P.M. to 2.30 P.M.

The following communications are promised.

1. Case of Opium Poisoning. By H. Collet, Esq.
2. On a Spontaneous Cure of an Ovarian Cyst after Four Tappings. By Dr. A. Hall.
3. Cases in Aural Surgery. By G. F. Hodgson, Esq.
4. Case of Retention of Urine. By W. J. Harris, Esq.

W. M. J. HARRIS, *Honorary Secretary.*

13, Marine Parade, Worthing, November 27th, 1875.

BATH AND BRISTOL BRANCH.

THE second ordinary meeting of the above Branch will be held at the Royal Hotel, College Green, Bristol, on Thursday evening, December 9th, at 7.30 P.M.: W. M. CLARKE, Esq., President.

EDMUND C. BOARD, *Honorary Secretary.*

Clifton, November 24th, 1875.

SOUTH OF IRELAND BRANCH: ANNUAL MEETING.

THE first annual general meeting was held on November 9th, at the Royal Cork Institution; Dr. GREGG, President, in the Chair.

New Members.—Dr. Redmond of Cappoquin, Dr. White of Carrignavar, and Dr. Kelly of the 23rd Royal Fusiliers, were admitted members of the Association.

President's Address.—The President, in the course of a brief address, referred to the extent, importance, and objects of the British Medical Association. He said: In the working of its branches and their scientific meetings, the grants now given by its Council for promoting scientific experiments in medicine, the contributions to its JOURNAL, the original essays and experiments at its annual gatherings, the means it affords of bringing medical men from different parts of the kingdom together for purposes of scientific discussion, the British Medical Association is, without doubt, one of the foremost agents at present existing for the advancement of our profession and the furtherance of its great object—the cure of disease. As a Branch of this Association, we have, in common with its other members, the same object. This is the end of our first year's labours. Every beginning is weak, but already, in this short space of time, we have done some good practical work. Those who attended our meetings, held fortnightly during last session, do not require to be told of the highly useful and interesting matter which was brought before the notice of the members, or the information which was elicited by the discussions on the various papers which were read. I can safely say that I never enjoyed any meetings for the discussion of medical topics with the same degree of pleasure as I did those over which I was privileged to preside during the past winter. I hope that those to be held in the ensuing one will be replete with information as those that are past; and if they are, I think we may be all perfectly satisfied. This is, as you are aware, the first Branch of the British Medical Association in Ireland, and already we number fifty members; we have every hope that before long the number will be doubled. I trust that all connected with this Branch will throw their energies into it, and work it, so as to make it alike useful to the profession, and a credit to the South of Ireland. They can best do this by attending the regular or ordinary meetings of the Branch and contributing papers, narrating the history of important cases, sending pathological specimens, assisting in microscopical investigations, enlisting the sympathy and co-operation of members of the profession outside, and in enlarging the ranks of the Association by the enrolment of new members. At present, our object is mainly scientific; we do not interest ourselves in purely ethical or medico-legal matters. At the same time, there are subjects which are intimately connected with the welfare of the profession, and which, from time to time, may be brought before the notice of the Branch by the desire of the General Council of the Association; if so, these will, I feel sure, receive that attention at your hands which their importance may demand. I congratulate you on your entrance into a second year of active duty. I congratulate the promoters of this movement and the founders of this Branch on its well-merited success; and in doing this, I desire to make special allusion to our honorary secretary, Dr. Jones, to whose active and continuous exertions the formation and success of this Branch is mainly due. I congratulate the profession in the South of Ireland on the formation in its midst of so valuable and useful an Association.

Report of Council.—Dr. MACNAUGHTON JONES, Secretary, read the report of the Council, from which it appeared that the subscriptions which had been forwarded to the treasurer met all the expenses connected with the formation of the society and its working during the past year. Fortnightly meetings were held during the session, which extended from October to April, and those meetings were devoted to the discussion of scientific subjects, and were attended by the students of the Queen's College. The Council suggested that any ethical subjects should be only discussed at a general meeting of the Branch convened for that object, and that the secretary on the requisition of three members might summon a meeting of the Council, with whom would rest the power, if they thought proper, of summoning the Branch. They also considered that steps should be taken to enlarge the Branch, and that members should be requested to exert themselves in that direction. The honorary secretary resigned his office.

Officers and Council.—The following were elected. *President:* W. J. Cummins, M.D., Cork. *President-Elect:* H. Macnaughton Jones, M.D., Cork. *Vice-Presidents:* J. G. Curtis, L.R.C.P.Ed., Cork; D. B. O'Flynn, M.D., Glanmire. *Council:* P. Berry, Esq., Mallow; Dr. Cagney, Cork; Dr. D. Cremen, Cork; Dr. P. J. Cremen, Charleville; W. J. Cronin, Esq., Queenstown; Dr. Eames, Cork; Dr. Golding, Cork; Dr. Gregg, Cork; Dr. Hobart, Cork; Dr. MacDonagh, Killarney; Dr. Macgill, Cork; Dr. O'Reilly, Lismore; Dr. Ronayne, Youghal; Dr. Scott, Queenstown; Dr. Smyth, Cork. *Honorary Secretary:* [Ringrose Atkins, M.D. *Treasurer:* A. O'Connor, M.D.

Meetings of the Branch.—It was agreed that at least six monthly meetings should be held, on Saturdays; the Council to have power to summon others if necessary, notice of the meeting to be given three days beforehand.

Votes of Thanks.—Dr. CUMMINS having taken the second chair, Dr. CURTIS said he did not think they should separate without giving their unanimous approval to the way in which their worthy ex-President, Dr. Gregg, had carried them through the last session, and for the dignified manner in which he had presided that day.

Dr. O'CONNOR had great pleasure in seconding the vote of thanks.

The motion passed amidst applause, and Dr. GREGG returned thanks.

Dr. CREMEN proposed a vote of thanks to Dr. Macnaughton Jones for the manner in which he had discharged the duties of honorary secretary. His attention to the working of the Branch, and the interest he took in its establishment, justified them in paying him this compliment. Were it not for his exertions, it would be many years before the members of the profession could have the advantage that they had now.

Dr. O'FLYNN seconded the vote of thanks.

Dr. JONES, in acknowledging it, repeated that if there was an idea in the mind of any member of the profession in the south of Ireland that there was anything exclusive in the formation of this Branch he was deceiving himself, because it was founded in the most open manner. There was nothing in connection with its formation that could enable any one possibly to say that it prevented him from becoming a member. He was sure the society would be of great advantage to the profession in the south of Ireland.

The proceedings then terminated.

Dinner.—Several members dined together at the Victoria Hotel in the evening.

BORDER COUNTIES BRANCH: AUTUMNAL MEETING.

THE autumnal meeting of the Border Counties Branch was held at the County Hotel, Carlisle, on Friday, October 29th, 1875. In the absence of the President, Dr. L'ANSON of Whitehaven took the Chair. At a subsequent stage of the proceedings, Dr. L'Anson vacated it in favour of Dr. Taylor of Penrith. Fifteen other gentlemen were present.

Papers were read by Dr. Campbell, Dr. Crerar, Dr. Brown, Dr. Barnes (Carlisle), Dr. Murchison (Dumfries); and cases were exhibited by Dr. Maclaren and Dr. Elliot.

Dinner.—The members and their friends afterwards dined together, Dr. Taylor being in the Chair, and Dr. Barnes in the Vice-chair.

GLOUCESTERSHIRE BRANCH: ANNUAL MEETING.

THE annual meeting was held at the Bell Hotel, Gloucester, in the evening of Tuesday, November 16th; W. H. PAINE, M.D., of Stroud, the President, in the Chair.

President for 1876.—Thomas Wright, M.D., of Cheltenham, was elected President for the year 1876.

Insular Sclerosis.—After the transaction of the ordinary business, Dr. WILSON of Cheltenham read a paper on a case of insular sclerosis now under his observation and care in the Cheltenham Hospital.

Medical Education of Women.—The SECRETARY brought forward the subject of which he had previously given notice; viz., "The attitude of the University and other Examining Boards, and the medical profession generally, in relation to the questions connected with the medical education of women". A very full discussion of the subject followed, in which nearly all the members present took part; and the following resolution was proposed and carried *nem. con.*: "That this meeting believes that the exclusion of women from the medical examinations to be wrong in principle and vexatious and useless in practice, and would, therefore, urge on the various examining bodies the importance of making every examination perfectly open."

Disease of the Fauces and Larynx.—Dr. BOND of Gloucester called the attention of the members to the large number of cases of disease of fauces and larynx and trachea which had occurred during the last few months, being anxious to ascertain if there was any relationship, and, if so, what was its nature, between such diseases and the foot-and-mouth disease in cattle. The discussion on this question was adjourned until the next meeting in February, in order to give an opportunity for careful observation.

Supper.—The members afterwards supped together at the Bell Hotel.

STAFFORDSHIRE BRANCH: ANNUAL MEETING.

THE second annual meeting of the Branch was held on Thursday, October 28th, at the London and North-Western Railway Hotel, Stafford: present, R. GARNER, Esq., President, and thirty members. The President introduced his successor, Dr. HENRY DAY of Stafford, who then took the Chair.

Vote of Thanks.—Dr. TOTHERICK proposed, "That the best thanks of this meeting be given to the retiring President for his services during the past year." This was seconded by Mr. F. WESTON, and carried unanimously. Mr. GARNER acknowledged the compliment.

New Members.—The following gentlemen, being members of the Association, were elected members of the Branch: Mr. J. J. Bunch, Wolverhampton; Mr. A. Averill, Longton.

President's Address.—The President delivered an elaborate address upon the study of medicine.

Mr. FOLKER proposed, "That a cordial vote of thanks should be given to Dr. Day for his valuable, learned, and thoughtful address." Mr. ORTON seconded the motion, and it was carried with acclamation.

Report of Council.—Mr. VINCENT JACKSON read the annual report, which was as follows. "The Council of the Staffordshire Branch have much pleasure in presenting the first annual report; and, in doing so, they take the opportunity of recording as well as of reminding the members, that the nucleus of the Branch was the North Staffordshire Medical Society, a Society which had for a quarter of a century acted as a scientific centre, as well as a bond of friendly union to the medical profession resident throughout the populous district of North Staffordshire. The work of this Society had been of so utilitarian a character that it was considered, and your Council think wisely considered, that a strong effort should be made to extend the area of its work; and as Staffordshire contains at least seventy towns in which there are resident medical men, the plan which appeared the most likely to be successful was to amalgamate the Society with the British Medical Association; and this line of action was determined upon at a meeting of its members at Stoke-upon-Trent, on Thursday, April 9th, 1874. At a subsequent meeting of Staffordshire medical men held at Stafford, April 30th, 1874, the following resolution was approved and confirmed. 'That a branch of the British Medical Association be now formed, under the title of the Staffordshire Branch of the British Medical Association.' Your Council consider that time has demonstrated that the formation of this Branch has supplied a long felt want—viz., the means of medical union and association; for, owing to the annual and ordinary meetings being held in succession in the towns of Stoke, Stafford, and Wolverhampton, all parts of the county are brought under its influence, by the convenience of each district being studied; and thus it is to be hoped that a long future of scientific usefulness and friendly intercourse is in store for the members of the Staffordshire Branch, which, although the most recently formed, yet is by no means the least in numerical strength of the Branches of that great medical society, the greatest in the world, the British Medical Association. Your Council take this, their earliest opportunity, of acknowledging, as well as of reciprocating, the congratulations and good wishes which have been accorded to them by neighbouring Branches. Your Council feel assured that the kindly feeling which prompted these expressions of hearty goodwill emanated from an impulse as ingenious as it was fraternal. The number of members at the present time is eighty, and your Council trusts in time to be able to report the enrolment of every Staffordshire medical man as a member; and, for this end, it asks for the friendly co-operation and the efforts of all who are interested in the numerical progress and growth of the British Medical Association. During the session 1874-75, three ordinary meetings have been held; the attendance of members at each has been large. [A list of the papers, etc., was here read.] Your Council finds, from an examination of the Treasurer's account, that the receipts for the year have been £5:5:0, the disbursements £14:18:6, leaving a balance due to the Treasurer of £9:13:6. It is hoped that this balance, which was incurred by paying for the necessary expenses when the Branch was

formed, will be paid from a fund which is at the disposal of the Treasurer of the North Staffordshire Medical Society."

Place of holding next Annual Meeting.—Dr. J. H. TYLECOTE proposed, "That the next annual meeting be held at Wolverhampton." This was seconded by Mr. CLENDINEN, and unanimously passed.

Proposed Alteration of Rule.—Dr. MILLINGTON proposed, and Mr. CLENDINEN seconded, "That the annual meeting of the Branch shall be held in July, instead of, as in accordance with rule 5, October." After a long discussion, the motion was withdrawn.

Votes of Thanks were passed to the Treasurer and Honorary Secretaries.

Election of Officers for 1875-76.—The following gentlemen were elected. *President-elect:* W. Millington, M.D. *Vice-Presidents:* J. Weaver, M.D.; R. Garner, Esq. *Honorary Secretaries:* Vincent Jackson, Esq.; Ralph Goodall, Esq. *Treasurer:* E. F. Weston, Esq. *Council:* W. E. Clendinnen, Esq., Stafford; C. H. Crawford, M.D., Stafford; E. Fernie, M.D., Stone; W. H. Folker, Esq., Hanley; S. P. Gosling, Esq., Biddulph; A. J. Harrison, Esq., Walsall; C. A. Newnham, Esq., Wolverhampton; C. Orton, Esq., Newcastle; J. J. Ritchie, Esq., Leek; J. V. Totherick, M.D., Wolverhampton; J. H. Tylecote, M.D., Sandon; J. K. Wynne, Esq., Eccleshall. *Representatives in the Council of the Association:* J. T. Arlidge, M.D.; H. Day, M.D.; W. H. Folker, Esq.; J. Y. Totherick, M.D.

Dinner.—The members and their friends dined together. The President was supported by the Mayor (Alderman Shallcross) and the Rev. W. P. Vincent. R. Garner, Esq., occupied the vice-chair.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

FRIDAY, NOVEMBER 26TH, 1875.

SIR WILLIAM JENNER, Bart., M.D., D.C.L., F.R.S., President, in the Chair.

Two Fatal Cases of Acute Pyelitis and Nephritis, apparently consequent on Gonorrhœa.—Dr. MURCHISON read notes of these cases. In consequence of both patients having been admitted into hospital in an unconscious state, no history was obtained of either till after death, and the real nature of the cases was only revealed by *post mortem* examination; hence no observations were made as to the temperature and the character of the urine; still the *post mortem* appearances left little doubt as to the exact state in each case.

Stephen H., aged 28, a grocer's assistant, was admitted into the London Fever Hospital on June 4th, 1865, in a state of profound coma, with low muttering delirium and dry brown tongue. Three hours after admission, he died, having had several attacks of general convulsions. After death, it was ascertained that he had been suffering from gonorrhœa for some time, and that the cerebral symptoms had come on suddenly, only thirty hours before admission. After death, the entire length of the urinary passage, from the anterior end of the urethra to the pelves of the kidneys, was found to be in a state of intense inflammation; the mucous membrane being brightly injected, and the surface bathed with pus. Both ureters were full of thick yellow pus. Both kidneys were in the first stage of acute nephritis, and their pelves were full of pus. The lungs were much congested in their dependent parts, and in the lower lobes were a few small patches of incipient lobular pneumonia.

Maria D., aged 25, a lady's maid, was admitted into the London Fever Hospital. She was unconscious, but constantly moaning. Her countenance was dusky; her breathing laboured. The pupils were equal, but there was slight internal strabismus of both eyes. No note was made of the pulse or temperature, but there were signs of hypostatic congestion of the lungs. She gradually became comatose; and, after two convulsive fits, died on the second day after admission. After death, it was ascertained that the symptoms had come on suddenly on the day before admission.—At the *post mortem* examination, the membranes and substance of the brain were found to be intensely hyperæmic; but there was no exudation of lymph, and no sign of tubercle either within the cranium or in the lungs. The lungs were congested in their dependent parts, but in other respects were healthy. Both kidneys were in the early stage of acute nephritis: large, smooth, and almost black from intense congestion. The ureters and the pelves of the kidneys were full of thick yellow pus. The bladder also contained pus; and the lining membrane of the vagina, urethra, bladder, ureters, and pelves of the kidneys, was intensely red.

Dr. GREENHOW said that he was reminded of a somewhat similar

case, which he saw when he was a student at Edinburgh. He was present at the *post mortem* examination of a man, who had died in a state of coma, lasting thirty-six hours. He was supposed to have been poisoned, but he was the subject of gonorrhœa, for which he had been taking copaiva, and using injections. Sir W. Newbiggin at the time attributed the symptoms to "cerebral metastasis" from gonorrhœa checked by treatment.—Sir WILLIAM JENNER asked if it were quite certain that the female patient had gonorrhœa.—Dr. MURCHISON replied that there was no history to be obtained on this point; but the *post mortem* appearances were similar to those in the male patient. In answer to Mr. Berkeley Hill, he also stated that the duration of the gonorrhœa in the male patient was not defined; it had existed for some time. He further stated, in reply to a question put by Sir W. Jenner, that the man had been under treatment for the gonorrhœa, and he could not say that he had taken cantharides. Opposed to the view of the inflammation of the kidneys being primary, was the fact of the distension of the passages with pus, the ureters appearing as thick cords. Chelius had mentioned that gonorrhœal inflammation occasionally extended to the kidneys; and the occurrence could not be so very exceptional, since two cases occurred within six months of one another at one London hospital.—The PRESIDENT remarked that inflammation spread usually upwards to the secreting organs, as from the bladder to the kidneys, and not in the contrary direction.

Acute Cancer of the Liver, with Pyrexia.—Dr. MURCHISON read notes of this case, which occurred in a man, aged 24. James C., a carpenter, was admitted into St. Thomas's Hospital on November 6th, 1872, with the history of a strain six months previously, which caused swelling and pain in the left testicle. About six months before admission, he began to complain of pain in the right side, and to lose flesh. There was no hereditary history of cancer. When admitted, he was emaciated, and there was a hectic flush on his face. He suffered much from pain on the right side of the abdomen, and from dyspnoea. The temperature was 101.3 deg. Fahr. On the right side of the abdomen was a visible bulging, continuous apparently with the liver; its lower margin extending almost to the brim of the pelvis. The surface of the swelling was firm, smooth, and moderately tender. The skin and conjunctivæ were jaundiced; there were no ascites nor enlargement of the abdominal veins. The tongue was moist, slightly furred; there was no appetite; much thirst; no vomiting; the bowels were open, but not loose; bile was passed in the stools; and the urine had a specific gravity of 1018, and contained copious lithates, some bile-pigment, and a trace of albumen. He lay on his right side. The respirations were 32, thoracic; he had some cough, but no expectoration; sibilant râles were audible over both lungs, chiefly on the right side; and the breath-sounds were feeble, and there was slight impairment of resonance on percussion. Pulse, 120. The heart-sounds were normal. The left testicle was twice the size of the right, hard, but not tender. He lived ten days after his admission, during which time he had rigors, constant vomiting of green bilious matter, and an uniformly high temperature; on two occasions, the thermometer registering 103 deg. Fahr. The liver continued to increase in size; he became delirious, rapidly weaker, and died on November 16th.—*Post Mortem Examination.* The liver was much enlarged, and measured before removal twelve inches and a half vertically. Its entire substance was studded with large masses of cancerous deposit. There was a mass of similarly affected glands found in the neighbourhood of the left kidney, and extending along the vessels to the left testicle, which also contained a vascular tumour of the size of a cherry. Dr. Murchison remarked that little was known as to the range of temperature in cancer, but that he believed that, in this disease, unless there were some inflammatory complication, the bodily temperature was at or about the normal standard. But the case quoted proved that this rule was not absolute. In this case, moreover, the age of the patient was opposed to cancer of the liver, while not only the pyrexia, but the rigors, the previous injury and enlargement of the testicle, the rapid course, and the delirium, all favoured the diagnosis of pyæmic inflammation in preference to that of cancer of the liver.

In reply to the President, Dr. MURCHISON stated that, as regarded the condition of the hepatic tissue between the cancerous nodules, there was a good deal of injection in such situations; but nothing like opacity, or infiltration, or exudation, into the liver-substance, which was examined microscopically. There was nothing like pyæmic infiltration, or any sign of recent peritonitis around the liver. In reply to Dr. Southey, Dr. Murchison remarked that the structure of the growth in the testicle was just like the growths in the liver. The testicle had not grown much; but a secondary chain of enlarged glands ran from the testicle up by the side of the spine, towards the liver.—Dr. MOXON asked whether the condition of the veins of the liver was noted. About three years ago, he had published in the *Lancet* notes of a somewhat

similar case. It was that of a gentleman, aged 26, at Highgate, whom he had seen in conjunction with Dr. Lucey; he had symptoms resembling those of suppuration in the liver, and often had a temperature of 102.5 deg., accompanied by rigors, night-sweats, and pronounced symptoms of hectic. After death, nothing but cancer was discovered. The growth was curious. It had grown into the branches of the portal vein in the liver, which were stuffed with it "like a sausage". In places, portions of the liver-tissue were pale and sunken. The case was an instance of excessively severe and sudden cancerous changes, with symptoms of pyrexia, because the growth was so sudden. He would say that, just as oxygen usually fed combustion, yet one might produce a fire with chlorine, so inflammation usually produced pyrexia, but cancer might also cause it.—Dr. MURCHISON remarked that, in his case, cancer was certainly not present in the larger veins; but that, as regarded the smaller ones, he could not speak so positively.—Dr. SOUTHEY had seen, in a case a fortnight before, the same appearances as had been described by Dr. Moxon. In the portal vein were growths attached, and lying in the vein. The pyrexia observed in Dr. Murchison's case, he (Dr. Southey) thought, was not very uncommon in quickly growing cancer. With all such growths in all parts of the body, temperature was high. In abscess of the liver, there was elevation of temperature.—Dr. MURCHISON asked if ascites was present in the cases of Dr. Moxon and Dr. Southey. There had been none in his own case. He thought that cancer running a quick course might, perhaps, give an elevated temperature; but that, in a critical case of diagnosis, the fact of elevation of temperature would rather be against cancer.—The PRESIDENT mentioned the case of a boy who had a lump in his abdomen, of which Mr. Cæsar Hawkins thought very seriously. Another eminent surgeon thought lightly of it; but the boy died in a fortnight. The cancer was largely disseminated; the diaphragm was invaded, and the internal wall infiltrated, and yet the temperature was not much elevated—was certainly never 102 deg.—Dr. MOXON had always regarded his case as a notable exception to the fact that, with obstruction of the portal vein, one necessarily had ascites. Dr. Moxon had also showed, at the Pathological Society, a specimen in which the coronary sinus was closed, and yet there was no hydropericardium; and another specimen in which the veins of the brain were closed, and yet no water on the brain was found. In cases of cancer of the uterus, the pelvic veins were frequently quite closed, without there being œdema of the feet. Therefore he thought there were certain conditions in which a vein might be closed without the existence of œdema behind it.—Mr. CARTER remarked that Mr. Hutchinson had brought forward a case at that Society in which the ophthalmic vein was quite closed by a cranial aneurism, and yet there was no œdema of the optic disc.—In reply to Mr. Callender, Dr. MOXON stated that not all the coronary sinus, but only a part about an inch from the auricle was blocked in the case he had mentioned. The other veins of the wall of the heart had probably enlarged, and carried on the circulation.—The PRESIDENT thought that, where the passage of blood was impeded, and the blood dammed back, it must get out somewhere. Probably other veins enlarged.—Dr. MOXON thought that, in the case of cancer in the portal vein, there might have been enough connection between the parietal veins of the abdomen and the venules of the portal system to carry on the circulation.—Dr. COUPLAND stated that Mr. Hulke had, for a long time, taken the temperatures of his cancerous patients in the Middlesex Hospital; and that he found the temperature was almost always normal or sub-normal, scarcely ever above normal.

Skin-Grafting upon a Stump after Amputation.—Mr. BERKELEY HILL exhibited a female, twenty-nine years old, from whom he had amputated the left thigh at the hip on August 12th, 1874, to remove a very large rapidly growing tumour of round-celled sarcoma. The new growth completely imbedded the femoral artery, so that the anterior flap was dissected from it; and, thus deprived of its nutrient vessels, it sloughed as high as two inches above Poupart's ligament. The after-healing occupied several months, during which time more than one hundred skin-grafts were transplanted. The strain on the healing surface, caused by the weight of the buttock, was at length effectually supported by a frame bearing round the pelvis, which thrust forwards the buttock by a spring and pad. This was worn till cicatrization was complete. The patient was exhibited, fifteen months after the operation, in excellent health; no recurrence of the sarcoma being apparent in the lumbar glands or liver; and the scar was small, soft, and supple, and easily movable over the pubes and iliac spines, the islands of skin-grafting being very distinct. The acetabulum, dry and free from scabs, was filled up to a cavity about as large as half a walnut-shell.

Mr. CALLENDER remarked that, with the abdominal tourniquet, transfixing and making an anterior flap had fallen into disuse. A flap of skin was now made, and the limb was cut through transversely, so

as to prevent the splitting of the artery during the cutting of the vessel ; and vessels were to be preserved for the nutrition of the anterior flap. As regarded the skin-grafting, the grafts were so numerous that they would probably represent several square inches of skin. Why were so many necessary?—Mr. HILL stated that the operation was performed in this particular way, because the growth enveloped the femoral artery, so that the flap was skin-flap only. The division had to be done high up, in order to remove the tumour entirely, and Mr. Hill supposed that the vessels which supplied the flap might have been divided. The grafts were over one hundred. They were put on at different times, but probably many of them died ; but, as the skin was supple, he thought the majority must have lived. The cicatrix did not resemble fibroid tissue, it was so very supple.

Tumours of the Orbit.—Mr. GEORGE LAWSON exhibited two patients, from each of whom he had removed a tumour of the orbit. The cases were essentially different ; but each presented points of great clinical interest. The first case was that of an elderly woman, who was admitted into the Middlesex Hospital with a large melanotic tumour, involving the eye, and filling up the whole orbit. This growth Mr. Lawson removed, and then applied the chloride of zinc paste, and in such a manner that he succeeded in saving the upper eyelid. One of the great disadvantages, he remarked, of the use of the chloride of zinc in such cases had been that, owing to the running of the paste into the cellular tissue of the eyelids, both lids had been destroyed by it. The plan which he now adopted, when practicable, was the following. After the eye and tumour had been excised, pressure was made in the orbit until all bleeding had ceased. The mouth of the conjunctival bag, from which the globe had been enucleated, was then held open with two pairs of forceps, whilst the chloride of zinc paste spread on small strips of lint was plastered round the sides of the orbit. A small piece of cotton-wool was next introduced to keep the strips of lint *in situ*, and the mouth of the conjunctival bag was closed over the whole by a single continued suture. A layer of lint was then placed over the conjunctiva, and upon this the lids were closed and kept in position with a compress of lint and a roller. The patient progressed well, and had suffered no pain, and had no recurrence of the disease since she left the hospital on May 25th. In the second patient, Mr. Lawson removed a tumour from within the orbit without inflicting any injury on the eye. The growth occupied the floor of the orbit, and seemed to spring from the periosteum far back in the orbit. It was about the size of half a walnut, much flattened where it was pressed between the eye and the orbit, but rounded at its free external border. The specimen was examined by Dr. Coupland of the Middlesex Hospital, who pronounced it to be a lymphoma.

Dr. MURCHISON related the case of a man, from whose orbit a spindle-celled sarcoma involving the eyeball had been removed by Mr. Hulke. The growth returned nine years subsequently in the liver, and gave rise to symptoms closely resembling those of hydatid, but which were proved not to be so by puncture. He died ; and his liver was then found to be studded with spindle-celled sarcoma.—Mr. CARTER mentioned a case in which, four years before, a spindle-celled sarcoma had been removed by himself, and had not yet returned. It had simply left an ugly appearance of the orbit ; and he had thought whether he should fill up the gap by transplantation of skin. Mr. Lawson's case reminded him of yet another. A young man came to St. George's Hospital with the orbit filled with a large growth, and with the eyelids and eyelashes much hypertrophied. The growth had come in his infancy, and had grown rapidly until he was four years of age. It had then grown simply with his growth. Mr. Carter had removed it by a large incision ; and the tumour was found to be a degenerated naevus. The eye then went back, and the deformity was much relieved. The eyeball of that side was larger than its fellow ; and the corresponding palpebral fissure was also large. Mr. Carter united its two sides for about half an inch at the outer canthus, and the man's appearance was much improved. After a time, the growth was found to be increasing, when Mr. Carter again opened the orbit, and took away the growth which was returning. Erysipelas and suppuration followed ; and it was to be hoped the latter process had destroyed all the naevoid tissue in the orbit.—Mr. LAWSON considered that the cases fitted for treatment by the chloride of zinc paste, as he had described, were only those in which there was a piece of conjunctiva of which to form a bag in which the paste could be sewn up.

New Method of Performing Iridectomy for the Improvement of Sight. Mr. B. CARTER exhibited a patient who had been greatly benefited by the performance of this operation (a description of which was given in the BRITISH MEDICAL JOURNAL for October 16th, 1875, page 509), and in whose eye the effects of the operation were very visible.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.

WEDNESDAY, NOVEMBER 3RD, 1875.

II. JACKSON, M.D., President, in the Chair.

On the Spontaneous Origin of Typhoid Fever. By DYCE BROWN, M.D.—Dr. Brown, in this paper, began by stating that, while the profession generally were agreed as to there being a connection between drains, sewer-gas, and typhoid fever, there was great difference of opinion as to the part played by the gas in the production of the fever : some considering that the fever might originate from exposure to sewer-gas alone, and others that this was but the nidus, and required for the production of the fever a special poison. On the one hand, cases are recorded where the fever had occurred without any previous cases having been known in the district, but where the sanitation was defective ; on the other, cases of excessively bad sanitation were given where no typhoid fever had followed. Both parties agreed that the most powerful cause of the spread of typhoid was the presence of previous cases in the locality ; but the one denied that typhoid ever occurred without a specific cause, while the other asserted that observed facts could only be accounted for by allowing the occasional spontaneous occurrence of the disease. The author reviewed several recorded cases quoted by different authorities on the non-spontaneous side where "dormancy" was stated to have existed for weeks or even for years, and considered that, in those cases where no case had been known in large districts for more than six or seven years, the more reasonable view was to regard the origin spontaneous rather than to assume the existence of dormancy for such a length of time. Dr. Brown then proceeded to give the history of two cases occurring in his own practice, which he considered valuable as a contribution to the question. They were mysterious, if typhoid could not originate spontaneously, but easily accounted for on the supposition that that disease might originate without specific poison. On March 5th of the present year, Mr. G. was seen in Jute Street, Aberdeen, and, in the beginning of the second week, the diagnosis of typhoid was confirmed by observing the rose-spots. Four days after his attack, Mrs. —, who lived in the back room of the same house, and on the same floor, was taken ill also of the same disease. The former was a very severe, the latter a mild case ; but both recovered. These two cases were in a new house on virgin soil, and there had not been any other cases heard of in the neighbourhood for a considerable time. The drinking water was supplied by the town, and taken from the Dee, twenty-two miles from Aberdeen. The drainage was bad, as, from some cause or other, the owner of the house had neglected to connect any pipes with the street sewer, and there was no water-closet or other convenience ; all the sewage from the house being led into a hole in the garden at the back, which was above the level of the floor, and on a level with the back windows. The smell from this hole had been for some time most offensive, especially when the wind was in the direction of the house.—Dr. ANGUS FRASER could not consider Dr. Brown as having any ground to regard the two cases reported as examples of non-spontaneous origin of typhoid. He thought the conclusions arrived at not justified by the facts, as the man and woman might have got the disease when absent from their houses, by drinking water, or in other ways (typhoid being in the town at the time). As to the two cases happening about the same time in the same house, that was but a coincidence.—Dr. F. OGSTON objected that the lower animals, as dogs, might have carried the infection, and were supposed to be subject to similar diseases. Besides this, though the cases were said to have occurred in virgin soil, yet it was well known that new ground was often old rubbish. Perhaps also the pit was, as was not unfrequently the case in half-finished streets, more or less public.—Dr. A. OGSTON thought that typhoid occupied a peculiar position in regard to the opinions entertained of its origin by the profession. No one doubted that English cholera was spontaneous, neither did anyone believe small-pox to be spontaneous ; but most medical men had seen cases of typhoid which had, for the time at least, given rise to a doubt as to whether, in some cases, there might not be a spontaneous origin of this disease. He had just heard of a case in a country district near Aberdeen which had staggered one of the greatest of our non-spontaneous authorities ; still the amount of the typhoid-poison required for the spread of the disease was so minute, that there had were no doubt many cases which at first sight might appear to be spontaneous, but on more particular examination might turn out not to be so.—Dr. BLACKIE SMITH wished to know, from Dr. Brown, where the milk used by the affected persons was got, as he had had a case in a milkman's family, near the Small-pox Hospital, not far from Jute Street, about the middle of February last.—Dr. CROMBIE thought that, as typhoid attacks depended partly on the condition of the patient's system, the long dormancy in some of the recorded cases might easily be accounted for.—Dr. STEPHENSON related a case in consultation practice which was supposed to be spon-

taneous, but was discovered on more careful investigation to be caused by typhoid poison being imported in the milk supplied. A relative of the milkman had come from Glasgow to the village where the case occurred to recruit after an attack of typhoid, but still having the bowels affected, and was the cause not only of the case mentioned, but of several more in the village, beginning with the milkman's own family.—Dr. COWAN (H.M.S. *Clyde*) supported the spontaneous origin, and mentioned a case which seemed unaccountable on any other supposition.—Dr. JACKSON was of opinion that he had seen cases in which the origin of typhoid fever was spontaneous.—Dr. DYCE BROWN replied, and said he had not attempted to dogmatise. The question must be decided by evidence, and the two cases he had brought forward appeared to him to contribute to the solution of the question. He would not detain the meeting longer, but conclude with the remark that one positive was equal to many negatives, and that, if he had proved his cases to be spontaneous, it was unimportant.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

THE Gloucester guardians have voted Mr. Ambrose D. Cookson a superannuation allowance of £53:6:8 *per annum*, being two-thirds of his salary, on resigning as Medical Officer to the Union Workhouse.

THE SKIPTON GUARDIANS.

AT their meeting last Saturday, only one candidate offered himself for election as medical officer to the Skipton Workhouse and Infirmary at the salary of £35, which had been refused by the late medical officer; and this candidate was elected subject to the approval of the Local Government Board. We cannot but think that it would be wise that that approval should be withheld, as this gentleman only possesses one legal qualification (there are three or four doubly qualified practitioners in the town willing to take the post at a fair salary), and as also we are informed that his brother practitioners refuse, under the circumstances, to meet this gentleman; so that he might be unable to comply with No. 200 of the Consolidated Orders as to naming a substitute in case of sickness or absence.

APPOINTMENTS OF MEDICAL OFFICERS OF HEALTH.

BOOTH, Lionel, M.D., appointed Medical Officer of Health for the Accrington Urban Sanitary District, *vice* G. M. Gillespie, M.D., deceased.
 BLYTHMAN, Clement S., M.B., appointed Medical Officer of Health for the Swinton Urban Sanitary District.
 *HALL, Cornelius S., M.R.C.S., appointed Medical Officer of Health for the Rural Sanitary District of Carlisle.
 LOVETT, Samuel R., L.R.C.P.E.D., appointed Medical Officer of Health for the St. Giles and St. George District, *vice* George Ross, M.D., deceased.
 PERKS, Charles, L.R.C.P., appointed Medical Officer of Health for the Burton-on-Trent Urban Sanitary District, *vice* P. Blicher, L.R.C.P., resigned.
 REDWOOD, Thomas Hall, M.D., reappointed Medical Officer of Health of the East Molesey Urban Sanitary District.
 WILLIAMS, William F., M.R.C.S. Eng., reappointed Medical Officer of Health for the Bedwelly Rural Sanitary District.
 YELD, Henry John, M.D., reappointed Medical Officer of Health for the Sunderland Port Sanitary District.

MILITARY AND NAVAL MEDICAL SERVICES.

THE CASE OF SURGEON SPURWAY,

LATE SURGEON OF THE ARMY MEDICAL DEPARTMENT.

WE have received copies of a correspondence between Surgeon Spurway, who was recently placed on *half-pay without half-pay*, and the authorities of the Army Medical Department at Whitehall Yard, with a request to publish it for general information. We are unable to publish this correspondence, which extends to a considerable length; but, as the case of Mr. Spurway, who has now resigned his appointment in the Army Medical Service, has attracted a great deal of attention, not only among the medical but also among the combatant ranks of the army, we think it may be useful to furnish a short digest of it.

Mr. Spurway premises that he is a sufferer from "migraine", and that his disease was so aggravated by the climate of India, that, when ordered to return thither, he sought an exchange, but that this was not permitted. On August 12th, a curt unsympathising official letter was sent to Mr. Spurway, written in the name of the Director-General, to inform him that, as he had received "the six months' sick leave to which medical officers are limited", and as his "disability was not

contracted in and by the service", the authorities have decided that he "shall be placed upon the half-pay list, but without half-pay", for six months from the previous June 23rd, after which time he is to be re-examined by a medical board. The following day (the 13th), Mr. Spurway writes a short but indignant letter at the injustice done to him, and places his resignation as surgeon in Her Majesty's service at the Director-General's disposal. Twelve days afterwards, a letter is sent to Mr. Spurway, returning his letter of the 13th, expressing surprise at the intemperance of its language, and requesting him, if he adhere to his intention of resigning, to "respectfully renew his application". Mr. Spurway replies on the following day that his letter was simply the expression of the indignation he felt at the gross hardship and injustice with which he had been treated "after ten years' good service". He reminds the Director-General that "half-pay without half-pay to one who is without friends and without private income implies simply starvation in a case like his for six months"; that such injustice is not to be met with in any other branch of the service; and he contrasts his treatment with that of some medical officers who have been put on half-pay on account of being addicted to intoxication. He, therefore, renews his application to resign his commission. No reply appears to be sent to this letter until two months afterwards. On October 22nd, the Director-General himself writes to Surgeon Spurway, and informs him that his case "has been under the consideration of the authorities"; that no modification of existing rules can be made in his behalf; and that his resignation of his commission will, therefore, be submitted to Her Majesty. He points out that "the course of placing him on half-pay without half-pay was adopted as a necessity rendered absolute by the precise language of the regulations, which only justifies the issue of half-pay for disabilities contracted in and by the service"; and that the treatment extended to cases of misconduct is governed by a portion of the Warrant of March 1873, viz., par. 31, clause 22, under which he could not be brought. To this letter, Mr. Spurway sends a lengthened reply, pointing out how much his disease had been aggravated by foreign service, though not contracted in and by the service, again contrasting the treatment dealt out to him with that to others, and referring especially to a case—one which was not long since before the public—in which a medical officer of intemperate habits was tried for the murder of a brother officer, but who was yet put on half-pay (it was said in some journals permanent half-pay), on account of past service. Mr. Spurway adds that he has submitted his case to old commanding officers, and "they one and all say I have been treated shamefully". So ends the correspondence. We may add that the fact of Surgeon Spurway being gazetted out of the Army Medical Department was noted in a recent number of the JOURNAL.

We confess we have perused the correspondence, of which the foregoing is a digest, with much surprise. How the "authorities", whoever they may be, can so add to the fuel of discontent, which is surely burning strongly enough in the Army Medical Department already, by such a line of conduct as is exhibited in this instance, we are at a complete loss to understand. But, however impolitic such a treatment of an army medical officer who has done good service for ten years may be, is it justified by the language of the Warrant quoted in the correspondence? We believe not. In the Royal Warrant of March 1873 (Article 28), a scale of half-pay is laid down for medical officers who are "placed on half-pay by reduction of establishment", or "in consequence of wounds or ill-health caused in and by the discharge of his duties". The correspondence shows that it was decided that Mr. Spurway could not be placed on half-pay under this latter head, although, according to his own statement, his disease, severe periodical headache, was increased by service "in one of the worst stations in Lower Bengal, where repeated attacks of fever enervated me so that my constitutional ailment became intensely aggravated". The next article refers to half-pay on retirement after twenty years' service, and Article 30 on retirement after twenty-five years' service. But the following article of the Warrant (Article 31) lays down the rule that "a medical officer placed on half-pay from any other cause than the foregoing shall be allowed only a temporary rate of half pay, not exceeding the rates specified in Article 28, for such period and at such rate as our Secretary of State for War shall decide with reference to the services rendered to the public by such officer".

There is no allusion in the Warrant anywhere to the absurd contradiction of half-pay without half-pay. Clearly, then, it appears to us that Mr. Spurway was entitled by Article 31 to a temporary rate of half-pay, and by the same article the Secretary of State for War should have decided what the rate should be according to his ten years' previous service. The Director-General himself states, in his letter to Mr. Spurway, that he was not placed on half-pay without half-pay "as any slight upon his previous service"; and, in one of his letters, Mr. Spurway challenges the authorities to contradict the fact that he

had always conducted himself as a gentleman, and performed his duties with credit. This is not denied, and we cannot, therefore, but come to the conclusion, on the evidence of the correspondence before us, that a medical officer who has served his country honourably for ten years, and who has been unfortunate enough to have undergone deterioration of health in an unhealthy climate like that of Bengal, has been placed on half-pay without half-pay in direct opposition to the terms of the Royal Warrant of March 1873, and has, in short, in the end been needlessly lost to the public service. It is evident that the case of Mr. Spurway is not likely to stop where it now stands. Its effect has already been very hurtful; it has greatly shaken the confidence of officers not only in the Army Medical Department, but in other branches of the army; and, in the interests of the public as well as of the army, something must be done to rectify the error which has been committed.

OBITUARY.

GEORGE WEBSTER, M.D., F.R.G.S., DULWICH.

THE numerous members of our Association who have known and esteemed Dr. George Webster of Dulwich, will regret to learn that, having on the previous day appeared to be in excellent health, he was found on the morning of November 13th to be senseless from an attack of apoplexy, of which he died on the 19th, at the age of 78.

Dr. Webster, who was a native of Forfarshire, became a licentiate of the Royal College of Surgeons of Edinburgh in 1815; and obtained the degree of M.D. at Aberdeen in 1829. His original intention of entering the army was abandoned in consequence of the peace of 1815, and he at once settled in Dulwich, where he remained to the end of his life—a period of sixty years. Here, after a partnership with the late Mr. Hall, he carried on a general practice with much success, enjoying the confidence and esteem of his *clients*. He did not confine himself to his professional duties, but took an active interest in the schools and other public matters connected with his place of residence. In the profession, he has long been known for the energy which he for many years displayed in regard to medical reform. It was through his influence that, about thirty years ago, a combination of medical practitioners was formed under the name of the "British Medical Association", of which he was the first (and, we believe, the only) President. This Association, which had but a short existence, was altogether distinct from the present British Medical Association, at that time known as "Provincial".

In our Association, both as Provincial and as British, Dr. Webster was held in high esteem. He was one of the founders of the Metropolitan Counties Branch, and was its fourth President. He was on many occasions returned by the Branch as a member of the General Council of the Association; and, at the time when, before the passing of the Medical Act of 1858, medical reform was a topic of frequent discussion in the Association, he was one of the members of the Special Committee on the subject.

For some years, Dr. Webster had retired from the active duties of his profession; and had undertaken the duties of a magistrate of the county of Surrey.

Among his numerous acquaintances in the profession, Dr. Webster's genial manners and integrity of character gained him a high degree of respect and esteem; and he will be long remembered as an energetic promoter of the interests of his profession, and of every good cause that came within his reach.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, November 25th, 1875.

Fonmartin, Henry de, Lying-in Hospital, York Road
Mahoney, Laurence Francis, Amhurst Road, Dalston
Roberts, Gordon Money, 87, Finchley Road
Stephens, Meredith Lloyd, Belper, Derbyshire

The following gentlemen also on the same day passed their primary professional examination.

Buckell, Ernest H., University College Hospital
Co'quhoun, Daniel, Charing Cross Hospital
Greenwood, Arthur, Charing Cross Hospital
Hyne, Frederick Alexander, Guy's Hospital
Roche, Eugenius A., St. Mary's Hospital

MEDICAL VACANCIES.

THE following vacancies are announced:—
ADDENBROOKE'S HOSPITAL, Cambridge.—Dispenser. Salary, £60 per annum. Applications on before December 15th.

AMERSHAM UNION.—Medical Officer. Salary, £70 per annum, and extra fees. Applications on or before December 6th.
ARDWICK AND ANCOATS DISPENSARY, Manchester.—Resident House-Surgeon.
BERKS COUNTY ASYLUM, Moulsoford.—Assistant Medical Officer. Salary, £80 per annum, with board, lodging, and washing.
BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Dispenser. Salary, £70 per annum. Applications before the 6th December.
BOOTLE BOROUGH HOSPITAL.—House-Surgeon. Salary, £80 per annum, with board, furnished apartments, and washing. Applications to the Honorary Secretary.
CARMARTHEN UNION.—Medical Officer.
CHIPPENHAM UNION.—District Medical Officer, Public Vaccinator, and Medical Officer of Health. Salary, £18:3:4 per annum as Medical Officer, and £17:0:10 as Medical Officer of Health, in addition to extra fees. Applications on or before December 10th.
CHORLTON-ON-MEDLOCK, RUSHOLME, and MOSS SIDE DISPENSARY, Manchester.—House-Surgeon.
DENBIGHSHIRE INFIRMARY.—House-Surgeon. Salary, £85 per annum, with board, washing, and residence.
DUMFRIES and GALLOWAY ROYAL INFIRMARY.—Assistant House-Surgeon. Board and washing. No salary. Applications to the Treasurer.
EAST SUFFOLK and IPSWICH HOSPITAL.—House-Surgeon. Applications on or before December 8th.
GENERAL HOSPITAL and DISPENSARY FOR SICK CHILDREN, Pendlebury, near Manchester.—Superintendent. Salary, £100 per annum, with everything found.
GLOUCESTER INFIRMARY.—Surgeon and Assistant-Surgeon. Applications before January 27th, 1876.
GREAT NORTHERN HOSPITAL, Caledonian Road.—Surgeon. Applications on or before December 9th.
HAMBLEDON UNION, Surrey.—Medical Officer. Salary, £53 per annum, with extra fees. Applications on or before December 15th.
HOSPITAL FOR THE INSANE, Barnwood, near Gloucester.—Assistant Medical Officer. Salary, £100 per annum, increasing £10 annually to £120, with board (exclusive of wine), lodging, and washing.
Huddersfield Infirmary.—Physician.
INFIRMARY FOR CONSUMPTION, Margaret Street, Cavendish Square.—Visiting Physician. Applications on or before December 16th.
LIVERPOOL INFIRMARY FOR CHILDREN.—House-Surgeon.
MOFFAT HYDROPATHIC ESTABLISHMENT.—Medical Man to take charge. Applications to Messrs. Bruce and Kerr, W.S., Edinburgh.
PARISH OF LISMORE AND APPIN, Lettermore.—Medical Officer. Salary, £100 per annum. Applications to the Rev. D. Dewar, Manse, Appin, Argyll.
REDDITCH and DISTRICT MEDICAL AID ASSOCIATION.—Medical Officer. Salary, £200 per annum, extra fees, and unfurnished house. Drugs, cab hire, etc., found. Applications on or before December 9th.
ROTHERHAM HOSPITAL.—Resident House-Surgeon. Salary, £120 per annum, with board and furnished apartments. Applications on or before December 23rd.
ROYAL LONDON OPHTHALMIC HOSPITAL, Moorfields, E.C.—House-Surgeon. Salary, £50 per annum, with board and residence. Applications on or before December 6th.
ST. PANCRAS and NORTHERN DISPENSARY.—Resident Medical Officer. Salary, £100 per annum, with residence, and £20 for servant's wages.
SALOP INFIRMARY, Shrewsbury.—Dispenser. Salary, £70 per annum. Applications on or before the 11th instant.
SHEFFIELD GENERAL INFIRMARY.—Physician. Applications on or before January 5th, 1876.
STROUD GENERAL HOSPITAL.—House-Surgeon. Salary, £60 per annum, with board, furnished rooms, attendance, and washing.
THARSIJ MINES, Province of Huelva, Spain.—Medical Practitioner. Salary, £250 per annum. Applications to the Secretary, 136, West George Street, Glasgow.
TONGUE and FARR, District of, County of Sutherland.—Medical Officer. Salary, £150 per annum, and house.
TRINITY COLLEGE, Dublin.—Professor of Botany. Applications on or before January 22nd, 1876.
WELLS UNION.—Medical Officer. Salary, £80 per annum, and extra fees. Applications on or before December 7th.
WORKSOP UNION.—Medical Officer and Public Vaccinator. Applications on or before December 7th.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTH.

DOBSON.—On November 17th, at 11, Lansdown Place, Clifton, the wife of *Nelson C. Dobson, F.R.C.S., of a son.

MARRIAGES.

BREBNER-SIMPSON.—At Christ Church, Georgetown, Demerara, on October 25th, 1875, by the Rev. J. Elliott Fox, M.A., the Incumbent, assisted by the Rev. Thomas Farrar, Rector of St. Paul's (cousin of the bride), William Brebner, M.B., C.M., M.G.C.U.E., Surgeon H.M.P.S., to Ellice Innis, eldest and only surviving daughter of James B. Simpson, S.C.P. (No cards).
CAMPBELL-MACDONALD.—At Edinburgh, on November 25th, by the Rev. C. G. Hutchins, M.A., Rector of Duoton, Bucks, Edward E. Campbell, M.B., C.M., to Johanna Catherine Macleod, youngest daughter of the late Alexander Macdonald, Esq., Tormore, Isle of Skye.

DEATHS.

BUCHANAN, Thomas Cox, F.R.C.S.E., for many years one of the Surgeons of the County Infirmary, Gloucester, at 11, Spa Walk, Gloucester, aged 71, on November 24th.
CHAPMAN, Henry Thomas, F.R.C.S.E., formerly of 27, Lower Seymour Street, Putman Square, London, at 2, Segrave Villas, the Park, Cheltenham, aged 60, on November 19th.

OPERATION DAYS AT THE HOSPITALS.

MONDAY	Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.
TUESDAY	Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.
WEDNESDAY	..	St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.
THURSDAY	St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 3 P.M.
FRIDAY	Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.
SATURDAY	...	St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M. and 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.	—	Medical Society of London, 8.30 P.M. Mr. Maunders (living specimen), "The Arm seven years after Excision of the Elbow-joint"; Mr. Alfred Freer (of Stourbridge), "Case of Impaction, with <i>post mortem</i> Results four years and a half afterwards"; Dr. Robert Lee, "Different Forms of Pessaries".
TUESDAY.	—	Pathological Society of London, 8.30 P.M. Mr. Hutchinson: Molluscum Contagiosum. Mr. John H. Morgan: Dilatation of Bile-Ducts. Dr. Fred. Robinson: Aneurism of Aorta. Dr. Habershon: Obliteration of Superior Cava. Dr. Habershon: Ulceration of Duodenum extending into Vena Portæ. Mr. A. Morison: Disease of Pulmonary and Tricuspid Valves. Mr. Thos. Smith: Hæmorrhagic Peritonitis. Dr. Gowers: Fatty Tumour of Cord. Dr. Wickham Legg: Congenital Deficiency of Common Bile-Duct and consequent Cirrhosis. Mr. Nunn: Injury to Radius. Mr. Nunn: Deformity from Rheumatic Gout. Mr. T. D. Griffiths: Cirrhosis of Liver in Child. Mr. Godlee: Recurrent Epithelioma in Chest and Toe after successful Excision of Tongue. Dr. Greenfield: Cancer of Heart and Supra-renal Capsules. Dr. Greenfield: Cancer of both Breasts and Ovary. Mr. Walsham: Tumour of Clavicle. Dr. Fred. Taylor: Aneurism of Aorta opening into Stomach. Mr. Alban Doran: Arrest of Development of both Forcarns. Mr. Spencer Watson: Report of Sequel of Dr. Walker's Case of Recurrent Sarcoma of Leg. Dr. Goodhart: Embolic Infarction in Heart Muscle.
WEDNESDAY.	—	Hunterian Society, 8 P.M. Council Meeting at 7.30 P.M.; General Meeting at 8 P.M., when Mr. Herbert Tibbits will read a paper on Electro-Therapeutics, and illustrate it by Instruments.—Epidemiological Society, 8 P.M. "On the Recent Cholera Epidemic in Syria", by John Wortabet, M.D., Physician to St. John's Hospital, Beyrout.
THURSDAY.	—	Harveian Society of London, 8 P.M. Dr. Sibson, F.R.S., Second Harveian Lecture "On Bright's Disease and its Treatment, considered mainly in relation with Arterial Tension from Blood Contamination". [Date altered from December 16th.]
FRIDAY.	—	Clinical Society of London, 8.30 P.M. Dr. Donkin, "Case of Diabetes treated with Skimmed Milk"; Mr. Haward, "Case of Lymphadenoma"; Dr. T. S. Dowse, "Case of Thrombosis of Cavernous Sinus: Sudden Loss of Vision: Hæmorrhage into Anterior Lobe"; Mr. Vealing, "Case of Congenital Tumour".

NOTICES TO CORRESPONDENTS.

- CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.
- PUBLIC HEALTH DEPARTMENT.**—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.
- AUTHORS** desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.
- CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.
- WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**
- COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

GARO'S PATENT MEAT ESSENCE EXTRACTOR.

SIR,—Please correct error in last JOURNAL. Gard and Co. live at Dunstable. The machine was the invention of a Colchester man.—Yours, etc., C. R. BREE. Colchester, November 29th, 1875.

L. M. (Tiverton).—An examination for the "L.M." of the College of Surgeons will take place about the 8th of the present month. Write to the secretary.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

WHARFEDALE CONVALESCENT HOME.

The Committee of Management of this institution has issued cards to the members of the medical profession, announcing that the Home will be opened for the reception of convalescents during the whole winter months, and that the arrangements for heating and ventilation are of such a nature as to insure the most perfect warmth and comfort to the inmates. This determination has been arrived at through the strong wish of the founder, Mr. Charles Semon, to extend to middle and working-class convalescents, and also to those amongst the working-class, who, from depressing mental and bodily causes, require change of air and scene during the winter months, the same benefits as those which can be obtained by their richer brethren at the Ilkley Wells House and other kindred establishments throughout the county. The Committee announce that the charge per week will be the same during the winter as the summer—namely, *ros. 6d.*

We doubt not that the Committee, in this making known to the medical men this decision of Mr. Semon's, is taking the best and most judicious method of reaching the very class which he intended to benefit. The Home itself is situated in one of the most picturesque, bracing, and splendidly watered localities in Yorkshire.

The *jeu d'esprit* which Æsculapius Quindune forwards us, "On a New Longitudinal, Versatile, Flexible, Clinical Stethoscope", is amusing, but too long and laboured for insertion.

SCARCITY OF SUBJECTS.

SIR,—I hope it will not be considered presumption on my part to venture to direct the attention of the medical profession to the present extraordinary scarcity of subjects for dissection in most of the London schools of medicine, and to inquire, through your valuable JOURNAL, the reason of it. At the present time, when the anatomical examinations are notably becoming more searching and severe, it seems doubly unfortunate that those who are studying for them should be deprived of the means of attaining a thoroughly practical knowledge of anatomy, which is universally admitted to be the only true foundation of success in the practice of medicine and surgery. In my own school (St. Thomas's), at which there have been seventy-four entries this October, and, I believe, over sixty last year, making over a hundred and thirty men, who ought to be spending a great portion of their time either in attending demonstrations or dissecting for themselves, we have had only eleven subjects, and I am assured there is no chance of obtaining more till after Christmas. Other schools are, I believe, worse off; so altogether the chances are, that the percentage of "plucked" men at the forthcoming examinations will be larger than usual.

Apologising for trespassing so much on your valuable space, I am, sir, your obedient servant,

Albert Embankment, S.E., December 1st, 1875.

A SECOND YEAR'S MAN.

DR. RINGROSE ATKINS' (Cork) letter shall be attended to.

SNAPPING A TESTIMONIAL.

SIR,—Is there any remedy against the introduction of my name into a touting advertisement, to which I am neither directly nor indirectly a party? This morning, a paper was put into my hand lauding a certain liqueur. Among the medical testimonials I find a note to the following effect:

"Dear Sir,—My friend Dr. —, physician to —, was here yesterday, and tasted and approved your liqueur. I enclose a cheque for two cases.—I am, dear sir, your truly, G. T. D."

I have a faint recollection of once receiving a present of the said liqueur, but I should have absolutely refused it had I known the penalty I should have to pay in seeing my name thus paraded.—I am, dear Mr. Editor, yours faithfully,

November 30th, 1875.

THE ABOVE DOCTOR.

* * * The question is a legal one. There can be no doubt that a grave breach of confidence is involved, and we do not think any respectable tradesman would continue to use a "testimonial" so obtained. In the first instance, therefore, the tradesman himself should be communicated with: in the event of persistence, a solicitor might suggest some means of relief.

We shall be happy to receive clinical memorandum of the case which Mr. Johnston Macfie mentions.

GALVANISM IN POST PARTUM HÆMORRHAGE.

SIR,—In answer to "A Busy Practitioner", I beg to reply: Hæmorrhage is arrested *post partum* when ergot or brandy is given, or cold or pressure applied only by contraction of the uterus. Iron, being an irritant, causes contraction; it is questionable, even if it have the property of acting as a direct styptic, if this is to be desired, the probable danger being greater than the benefit gained. Any uterine irritation will probably cause contraction; the hand introduced does so; the introduction of the blade of a forceps is often followed by an unusually severe pain; galvanism or electro-magnetism may in like manner sometimes be beneficial in *post partum* hæmorrhage.

Sir James V. Simpson records (*Obstetric Works*, by Priestly and Storer, pp. 375-393) the result of galvanism in eight cases; in one case, the pains were more frequent in recurrence but shorter in duration during the application of galvanism; in five, the employment of galvanism did not increase the average frequency or duration of the pains; in one, the pains ceased whilst galvanism was applied, and returned on its removal; in another, pains not only ceased during the application of galvanism, but did not return for twenty-four hours after the current was withdrawn; so that, generally speaking, galvanism is not only unreliable as a promoter of uterine contraction, but is a direct antagonist rather.

Fraserburgh, N.B.

A. D. L. NAPIER, M.B., C.M.

Mr. J. B. BRIERLEY (Manchester).—We should have been happy to publish Mr. Brierley's letter, but for its great length and the mass of correspondence which we received on the subject. We are compelled to make a selection in such cases.

J. W., M.D.—Mr. Joseph Swan died at Filey, Yorkshire, October 4th, 1874, aged 83, where he was buried on the 8th. The preparations are in the museum of the College of Surgeons.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

CÆSAREAN SECTION.

THE following is Mr. Holmes' explanation of the circumstances referred to in a paragraph which we recently quoted from the *Pall Mall Gazette* under this head, and which, we observed, seemed to require explanation.

"I was called in as I passed to see a woman just dead. I made no inquiries, but ordered them to give information to the police. Shortly afterwards I was met by the clerical gentleman named in your report, who stated that the woman was at her full time, and that there was evidence that the child was alive. He begged of me to go at once and take away the child by 'Cæsarean section'. Never doubting the gentleman's having the consent of the family (which is one of the three authorities named as requisite), as she was one of his church, and as an operation of that description (if the child be living and can be saved) must be performed at once, I had no hesitation in acceding to his request. Not having my instrument-case, with an ordinary bleeding lancet I opened the body, and, on finding there was not any appearance of the existence of a full-grown child, my examination went no further. It was quite evident that the symptoms of advanced pregnancy were owing to distension from dropsy. I did not make any *post mortem* examination in the full professional meaning of the term, so that the remark referring thereto as 'unskillfully performed' does not apply, my sole operation being that simply narrated above, and very likely not presenting a fair specimen of surgical skill from the nature of the instrument. If the police did ask me to give a certificate, how could I do so? not having seen the case alive, nor made a *post mortem* examination after death to find the cause. I of course declined to give an opinion verbally for the same reasons. And, further, I may state that if the authorities require professional men's time and opinion, they cannot reasonably expect to have them without remuneration, which is implied in cases where they are invited to give evidence without being subpoenaed. It appears to me that there would have been much greater cause for speaking of 'a grave scandal to society' if no effort had been made to save a living child. Such separation of child from its mother, under the circumstances which I assumed existed, is not uncommon, and would assuredly be made by any surgeon."

Dr. R. Brebner (Openshaw) adds: "At the inquest held at Gorton on Saturday, November 6th, I understand that I am reported to have said that the operation was 'unskillfully performed' by Mr. Holmes. I now write to say that that statement was not made by me, as a reference to my attested evidence in the hands of the coroner will verify."

"* * We are bound to say that Mr. Holmes does not appear to have acted with due caution in omitting to ascertain on what authority he was asked to perform this operation."

ADMISSION OF LADIES TO THE BRITISH MEDICAL ASSOCIATION.

SIR,—I think there is something very abrupt—"stand-and-deliver-like"—in the tone of the "resolution", which I have received from the General Secretary to-day and have answered, calling for the opinion of members of the British Medical Association "as to the admission of female practitioners to the membership". To do this in this curt fashion precludes the expression of the reasons—some good, some bad, no doubt—that may have influenced members in determining their votes, and so precludes the possibility which should be kept open for us in the future, of modifying our opinions with the advance of thought, and the interchange and conflict of all the reasoning that the subject may draw forth, which is as yet all too unthought over by most of us to insure a sound final judgment on it. Further, I think that the time is not yet ripe in very many relations for the innovation and liberality of action which may, and perhaps will, be admissible and proper fifty years hence, so that we should not commit ourselves now, without exhibiting our reasons, to any judgment which, fifty years hence, our reasons not being recorded, may be reversed to our discredit. I speak here only of that discredit which a more advanced age of our own profession may cast on our judgment. Yet it is but fair also to consider what imputations of jealousy, unreasonableness, prejudice, etc., may be thrown at us by the outside world now, if we do not produce reason for our judgment, which will without doubt be freely criticised, and to weigh the importance, whatever it may be, of any adverse stricture or imputation.

I have answered "No" to the question propounded in the resolution, and these are the grounds for my doing so. 1. The British Medical Association is not only a very distinguished medium and arena for the display of advancing science, but it is also a body professing, and acquiring still more largely, a great measure of public influence beyond the limit of its own members—an influence which has weight, and will yet have more, with many governing local bodies in their charge of the public good, and even with the supreme governing powers of the country. This influence, which we ought by all means to promote, I think the admission of female practitioners to membership, whatever may be their excellence or their attainments in the study of medical science, will derogate from and harm. When the experiment has been found to succeed elsewhere, of admitting women to a place in deliberative or legislative associations or assemblies, it will then be proper, perhaps, for the British Medical Association to follow the example; but I do not think that it is for the British Medical Association to be among the foremost to hazard such an experiment. Can one not also, with but small exercise of the imagination, present to one's mind the sarcasm which, from an opposing party, would meet the opinions or pleading on any public question of an epicene British Medical Association? 2. However admirable female practitioners, and however great blessings they may be in the circumstances for which they are specially adapted, I think their excellence and the blessedness of their calling are such as to be only especially excellent and blessed in the private exercise of their gifts. It is true that a female practitioner may, as well as any male practitioner, have something of experience or teaching to impart to the advantage of the science of the profession; and it may be, also, that the difference of physiological constitution in herself may, indirectly at any rate, be a source of special excellence in such experience or teaching. But in all such cases it is open for the female practitioner to communicate by writing, and receive the commendation or thanks of the profession for the experience or teaching she may have to impart, without necessarily personally assuming a place in public. 3. When it can be shown that the British Medical Association, as a public body, is likely to be benefited or raised to higher influence by the public appearance or action of women among its members, or that it is due to women, either socially or morally, to admit them to a public standing with men, it will be time enough then to introduce them to the membership.

I have written at greater length than I anticipated doing, and an apology is

due to you for thus venturing to tax your attention so long, perhaps uselessly; and yet I seem to have written with such shortness as almost to be gruffness. If I have indicated what I intended to say, however, it is enough—I am, dear sir, yours obediently,

R. LINDSAY, F.R.C.S.E.

21, Grange Loan, Edinburgh, November 19th, 1875.

G. H. D. (Chorlton) is referred to the note on "Sham Degrees and Diplomas" in the Notices to Correspondents of November 27th. Holders of the sham degrees of the "American University of Philadelphia" are liable to prosecution for pretending to practise medicine as though legally qualified; and if our correspondent will put himself in communication with the Secretary of the British Medical Defence Association (George Brown, Esq., 12, Colebrook Row, Islington), he will probably obtain assistance and advice in the pursuit of his objects.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Hastings and St. Leonard's News; The Belfast News-Letter; The Sheffield Daily Telegraph; The Chester Guardian and Record; The Hereford Times; The Bristol Daily Post; The Statesman; The Birmingham Morning News; The Cork Constitution; The Newcastle Weekly Chronicle; The Worcester Journal; The Hobart Town Mercury; The Weekly Times; The Mid-Weekly Hampshire Independent; The Lincolnshire Herald; The Sunderland Daily Echo; The Co-operative and Financial Review; The South Wales Daily News; The Macclesfield Courier; The Glasgow Herald; etc.

* * We shall be greatly obliged if correspondents forwarding newspapers will kindly mark the passages to which it is desired to direct attention.

CLINICAL LECTURE ON CASES OF INJURY TO THE HEAD.

Delivered in University College Hospital.

BY CHRISTOPHER HEATH, F.R.C.S.,
Holme Professor of Clinical Surgery.

GENTLEMEN,—During the past month, there have been three cases of head-injury in my wards, which you have had the opportunity of watching to their terminations. Two of these patients made good recoveries, but the third died; and the *post mortem* examination yielded the specimen of fractured base of the skull now before you. The first case was that of a cabman, who was in the first bed on the right hand in No. 1 Ward at the beginning of the session, having been admitted on September 23rd, under the following circumstances. The night before, his cab, a four-wheeler, was accidentally upset, and he was thrown off the box, being stunned for the moment, but quickly recovering himself, with a recollection of having fallen on his right side. He was able to assist in righting his vehicle, which he then took home; and, about midnight, he applied here for the treatment of his bruised ribs. At that time, the house-surgeon found nothing wrong with his head, and therefore dismissed him; but, when he appeared next day among the casualties, Mr. Collins noticed some recent ecchymosis beneath the conjunctiva of the eyeball, which had not been there before, and therefore, very properly, at once admitted him. When I saw him the following day, the man complained of headache, and his pulse intermitted, but the ecchymosis had not increased; and, after a few days' quiet in bed, the headache passed off, the blood began to be absorbed, and he was discharged on October 6th.

Now, here was a case which presented few symptoms, but one of them of possibly grave import—I mean the subconjunctival ecchymosis. The ordinary ecchymosis of the orbit from a blow—the familiar “black eye”—consists principally of blood effused beneath the skin, which may possibly extend to the palpebral conjunctiva, and even beneath the conjunctiva of the eyeball, though this last is rare. But, then, there is a distinct local injury, and the hæmorrhage occurs immediately after its infliction. In this case, on the contrary, the hæmorrhage did not appear for at least two hours after the fall (probably later still); and there was no bruising of the neighbouring parts. Hæmorrhage of this kind occurring beneath the ocular conjunctiva must always be viewed with anxiety; for it may depend upon some fracture of the orbit, or of the anterior fossa of the base of the skull, the blood finding its way forward along the sheath of the optic nerve. With no further development of symptoms to guide us, we may hope that the patient had no serious injury, and that the hæmorrhage arose from some capillary rupture of no consequence; but the second case I have to bring before you shows how cautious one must be in drawing conclusions in cases of head-injury.

The second patient was also a cabman, and was in No. 1 Ward. He, also, was thrown off his cab, breaking his collar-bone; and was admitted on September 16th, with bleeding from the left ear. Now, bleeding from the ear may or may not be a serious symptom, according to the amount of it. A blow on the ear may cause slight hæmorrhage by lacerating the lining membrane, or rupturing the membrana tympani; but when blood flows continuously from the ear, as in this patient, for twelve hours, the case is obviously a grave one. Where did the blood come from? Not from one of the large sinuses of the skull; because, if one of these were torn, the hæmorrhage would almost necessarily be fatal, as I have seen in a case of bad fracture; but from the small vessels which supply the temporal bone and the organ of hearing, and are derived partly from the internal, and partly from the external, carotid. No plugging could be of any avail to arrest such bleeding; and the treatment consisted simply in keeping the patient quiet, with a bladder of ice to his head. The hæmorrhage ceased, as I have said, at the end of twelve hours, and was not followed by the flow of any other fluid from the ear; but the patient remained deaf on that side. Feeling pretty certain that the temporal bone had been injured, we left the patient quiet, and on low diet; and, at the end of seven days, the diagnosis was continued in the following way. In the evening, the man complained of difficulty in closing his eye;

and, the next morning, the facial paralysis on the affected side was fully developed. I frequently called your attention to his condition when going round; and I hope you all studied his case, for facial palsy is easily misunderstood. You will remember that the left side of the face had a peculiar lifeless appearance, while the right side was slightly drawn. He was unable to close his eye, to whistle, or to blow out his cheeks, owing to the portio dura of the seventh pair, the motor nerve of the facial muscles, being paralysed. Clearly this paralysis was due to injury to the nerve itself, and not to any cerebral lesion; for we know that, in facial paralysis accompanying an ordinary paralytic stroke, and dependent upon brain-disease, the fibres supplying the orbicularis palpebrarum usually escape.

What, then, is the explanation of this occurrence? It is that, at the time of the accident, the temporal bone was fractured, or, at least, fissured, in such a way as to permit the flow of blood into the tympanum, from which it flowed through the ruptured membrana tympani. The fracture was not sufficiently severe to give exit to any cerebro-spinal fluid, or to lead to inflammation of the meninges of the brain; but it undoubtedly passed close to one, or probably both, branches of the seventh pair. When, at the end of seven days, the lymph poured out for the repair of the bone began to be organised, it caused temporary pressure upon the nerves, giving rise to the facial paralysis and part, probably, of the deafness; but, after a few days more, either some absorption took place, or the nerve became accustomed to the pressure, as nerves undoubtedly do; and the patient gradually recovered entire use of his facial muscles, though he still remains somewhat deaf. He was discharged on October 20th, and has been here occasionally since to have his clavicle seen to.

The third and fatal case was that of a boy, aged 10, who was admitted on October 28th, having shortly before fallen to the ground head foremost from a furniture truck on which he was playing. On admission at 8 P.M., the patient was pale and slightly collapsed; pulse 72, small and soft; respirations 20, regular; pupils dilated, equal, reacting readily to light. He answered questions when spoken to, and said he was deaf, which he had not been before. A slight bruise was felt two inches above the left eyebrow. He had been, and was, vomiting. He was left in the casualty-room for half an hour; and, at the end of that time, blood-stained serous fluid was noticed trickling from the left ear. He vomited again, and then this fluid was shot out from the ear in considerable quantity. He was at once admitted to Ward 5; and it was then noted that the tongue was protruded straight, that there was slight drooping of the left upper eyelid and left angle of the mouth, and that there were slight twitchings of the left arm and all the right side. By 3 A.M., an ounce of the clear fluid flowing from the ear was collected. This gave the reaction for sugar, with Fehling's solution, very distinctly, a red precipitate being thrown to the bottom of the test-tube, which you all had the opportunity of seeing. The fluid was alkaline in reaction, and showed a trace of albumen.

When I made my visit on the following day, you will remember that we found the boy lying in a quiet drowsy state, exceedingly deaf with both ears, but quite conscious when we succeeded in rousing him. The pupils were equal, and of natural size, acting slowly under the stimulus of light. The tongue was clean and moist, and was put out straight. There was no evidence of paralysis, and no twitching at this time. The pulse was small and rather hard—75 per minute. The boy was unable to pass his urine, and it was drawn off with a catheter. The bruise on the forehead was distinctly visible, but no line of fracture could be detected. The clear fluid continued to flow from the left ear in considerable quantity.

Now, there could be no doubt in one's mind that this boy had sustained a most severe and probably fatal injury; since the symptoms I have detailed, and particularly the last, pointed unequivocally to fracture of the base of the skull, involving the left temporal bone. But there was more than this. The patient, who had heard perfectly well before, was now stone deaf; and, although no fluid poured from the right ear, yet this fact pointed to injury of that side, probably from extension of the line of fracture across the middle line of the skull. Under these circumstances, there was very little prospect of the patient's survival, the great risk being the occurrence of meningitis and suppuration within the cranium. With the object of combining this, I ordered one grain of calomel every four hours, and had the boy's head shaved and kept cool. You will find a divergence of opinion among surgeons as to the propriety of administering calomel in these cases of head-injury; but I have seen so many of them die without calomel, whilst I have seen three or four undoubted cases of fracture of the base recover under its administration, that I should not feel justified in omitting it; and I am glad to have such an eminent authority as Mr. Jonathan Hutchinson on my side. To do any good, however

the calomel must be pushed so as to affect the system rapidly; and I would remind you that, in young children, the best evidence we have of the constitutional effect of mercury is the passing of green motions resembling chopped spinach.

The patient was very restless during the following night; and the next day (30th) he was quite conscious, but perfectly deaf. The fluid still flowed from the ear. An ice-bag was kept to the head, and the calomel continued. At midnight, the boy was noticed to be little less conscious than before. At 3 A.M., the house-surgeon found him partially comatose; he gave a short sharp cry, and appeared to be in pain. At this time, the pupils were normal, and there was no squinting. At 10 A.M., the temperature was 100.2 deg., and pulse 132. He continued in much the same state till 3.15 P.M., when he suddenly became very livid, the respirations fell to four per minute, and he rapidly died.

At the *post mortem* examination, twenty-four hours after death, on the calvaria being exposed, you will remember that I called attention to there being no fissure or fracture opposite the bruise on the forehead, nor in any other part of the vault; and I shall have to refer to this point again. There was considerable congestion of the membranes of the brain, which was a little opaque. There was some recent lymph in the cavity of the arachnoid, especially on the left side and within the circle of Willis. On the brain being removed, the dura mater over the temporal bones was seen to be uninjured; but a clot of blood lay beneath the dura mater and the bone on the left side, and a smaller quantity in the same situation on the right. On stripping up the dura mater, we found a crack in the left temporal bone running from the upper border of the squamous portion, along the anterior surface of the petrous bone, as far as the foramen lacerum medium. Another small fissure extended from the jugular foramen of the left side to the petrosal sinus, lying a little external to the auditory meatus, and not joining the other. On the right side, there was a fissure at right angles to the axis of the petrous portion, passing from the jugular foramen through the internal auditory meatus. The membrana tympani was ruptured on the left, but entire on the right side. On the under surface of the brain were two spots of ecchymosis on the right side, corresponding to the position of the fissure. There was fluid in both lateral ventricles, but not in large quantity; otherwise the brain was healthy.

The *post mortem* examination thus confirmed the diagnosis made during life. The patient had a fracture of the base of the skull, involving both temporal bones, and hence the deafness; and he died of incipient meningitis, with effusion into the ventricles. This effusion was not sufficient to distend the ventricles; but, no doubt, occurred suddenly, and was sufficient to destroy life by pressing upon the great ganglia in the floor of the ventricle.

And now let me say a few words on the causation and pathology of this serious accident—a fracture of the base of the skull. The boy fell from no great height, but he fell on his head, and his head came into contact with the pavement. Now, according to the old and now exploded pathological doctrine, this would have been a good example of "fracture by *contre-coup*"; for one side of the skull was struck, and that opposite to it was broken; but we know now that fracture by *contre-coup* does not really exist, and that any fracture found must be the result of force applied to the bone more directly. When this boy fell, the weight of his trunk gave him the momentum which brought him violently to the ground; and when his skull was suddenly "brought up" against the paving stones, the whole of the impetus which his body had acquired came suddenly upon the base of the skull. No doubt he struck the left brow against the stones; and it was this that determined the direction of the fracture, which is in the line of force transmitted from the condyles (upon which the vertical column would impinge) towards the frontal bone; and had he fallen more directly upon the top of his head, the force would have been transmitted upwards from the condyles; and then the fracture would probably have been in the posterior, instead of in the middle fossa of the base of the skull. I must tell you that this view is not maintained by all surgeons; and notably Mr. Prescott Hewett, in his valuable article on Injuries of the Head, expresses the opinion that the fracture starts from the point of impact, and spreads to the base of the skull. In this case, however, I was most careful to examine the vault of the skull for any fissure, and none was discovered, the fracture through the squamous portion of the temporal bone being completely covered in by the temporal muscle and fascia, and there being no evidence of a blow at this point. Mr. Hewett quotes some experiments of Dr. Aran in support of his view; and in so far that "the part of the vault which first struck the ground gave, as it were, the key to the fracture which would take place at the base", I agree with him, but simply because the direction of the line-force transmitted from below is no doubt thus determined.

Then with regard to the flow of fluid from the ear: this was not

noticed at first; but, half an hour after the accident, it was seen by Mr. Collyns, the house-surgeon, and at once decided the question of the admission of the patient. Fortunately, every child that falls on its head and is stunned for a time, does not break the base of its skull; but you must be careful not to give too confident an opinion as to the nature of the case directly after the accident, lest a symptom of such great gravity should develop a little later. And yet, let me say, although we all nowadays lay so much stress upon this flow of fluid from the ear, it is remarkable that the older surgeons, who must have seen it often enough, appear to have attached no importance to it. It is less than forty years since the symptom was recognised as denoting fracture of the base, although one or two cases of its occurrence had been put on record at a much earlier date. And even when it was recognised, surgeons were not agreed as to the source of the fluid. Now, there is but one fluid which is clear and alkaline, and contains a trace of albumen and some sugar; and this is the cerebro-spinal or sub-arachnoid fluid. You will remember that, on one occasion, when the patient vomited, the fluid is reported to have shot out of the ear—*i.e.*, that when, by the effort of vomiting, the brain became more congested, the fluid was driven out of the cavity of the skull; and Mr. Hilton narrates an experiment he made on a case of fracture of the base to prove the same fact, in which he temporarily produced congestion of the brain by closing the patient's nose and mouth, with the result of causing this fluid to shoot out. All authorities are, I think, agreed as to the nature of the fluid; but it is a little difficult to explain its escape. As Mr. Hewett tersely puts it, "the escape of the cerebro-spinal fluid implies a fracture cutting across the meatus internus, and communicating with the tympanum, a laceration of the tubular sheath of the cerebral membranes surrounding the seventh pair of nerves within this meatus, and a laceration of the membrana tympani". Now, on the left side, we had a rupture of the membrana tympani, and a fracture involving the meatus internus and tympanum. I could not demonstrate to you that the tubular sheath of the seventh pair was ruptured; but we may conclude that this was the case; and there could be no doubt about the escape of the cerebro-spinal fluid. On the right side, there was no fracture into the meatus internus, but no rupture of the membrana tympani, and, therefore, no flow of fluid from the ear. There was a fracture into the tympanum; and this had, no doubt, broken the connection of ossicula across that cavity, and hence the deafness. It would have been interesting to have ascertained, had the gravity of the case been less, so as to justify the inquiry, whether the child could have appreciated the note of a tuning-fork or the sound of a watch applied to the bones of the head, since this would have shown that the auditory nerves themselves remained uninjured. His best chance of life, however, consisted in maintaining perfect quietude, and I did not like to have him disturbed.

CLINICAL LECTURE

ON THE ADVANTAGES OF ETHER OVER CHLOROFORM.

BY JAMES SAWYER, M.D. Lond., M.R.C.P.,
Physician to the Queen's and Children's Hospitals, Birmingham.

GENTLEMEN,—I purpose to offer you a brief comparison of the relative values of chloroform and ether as anæsthetics. It has very frequently been my duty during the last ten years, in hospital and in private practice, to induce anæsthesia for the performance of surgical operations. Until a year ago, I invariably used chloroform; during the last twelve months, I have always employed ether. I shall offer for your consideration some reasons why ether should be preferred to chloroform—reasons which have induced me to rely upon ether as the better anæsthetic.

Surgical anæsthesia was unknown in modern times until thirty-one years ago. I say in modern times, because there is good reason for believing that some means by which the painless performance of operations could be ensured were known to practitioners of the art of surgery long before the present century. In Middleton's comedy, *Women beware Women*, printed in 1657, the following passage occurs.

"I'll imitate the pities of old surgeons
To this lost limb; who, ere they shew their art,
Cast one asleep, then cut the diseased part."

On December 11th, 1844, nitrous oxide gas was successfully used as an anæsthetic by Mr. H. Wells, of Hartford, Connecticut. (Townsend's *Manual of Dates*.) From this time, the use of anæsthetics has rapidly spread in surgery. Anæsthesia has become a want of the age; the

public demand it at our hands; and with us rests the grave responsibility of determining how it can be supplied most safely. Nitrous oxide soon fell into disuse. On September 13th, 1846, in Boston, United States, a man named Frost had a tooth extracted painlessly while he was under the influence of ether, given by a dentist named Morton. (*Chloroform, its Action and Administration*, by A. E. Sansom, M.D., 1867.) This was the real commencement of modern surgical anaesthesia. The news of the discovery of the means of rendering the performance of operations painless soon reached England, and ether was at once largely employed by Mr. Liston, Mr. Fergusson, and other surgeons. In March 1847, Flourens laid before the Academy of Sciences of Paris some observations of the anaesthetic powers of chloroform upon animals. (Sansom, *op. cit.*) On November 4th, 1847, the late Professor Simpson of Edinburgh, who for some time, in the hope of finding a better agent for producing insensibility to pain than ether, had been experimenting with various substances, first tried the effects of the inhalation of chloroform upon some medical friends in his own house, and he saw at once that he had found a prompt and pleasant anaesthetic. Six days afterwards, Dr. Simpson brought the subject before the Medico-Chirurgical Society of Edinburgh. Chloroform was at once accepted by the profession; it soon displaced ether, at least among the British; and it has since held amongst us, until a few years ago, an undisputed priority over ether and other anaesthetic agents. I think I may safely say that chloroform was almost the only anaesthetic used in operations in these islands eight or ten years ago. Since that time, however, various new substances have been employed in place of it. About five years ago, an ether-revival began, and it has gradually grown, until ether-inhalation now seems likely to supersede all other means for the production of insensibility during painful surgical procedures.

A medical practitioner never assumes a greater or more direct responsibility than when he undertakes to induce general surgical anaesthesia. Insensibility to the knife is not allied to sleep; it is more nearly akin to death. In sleep, a very feeble stimulus—a noise, a touch—is often enough to rouse the perceptive faculties into vigilance. But in perfect surgical anaesthesia the perception of painful impressions, even the most painful, is annulled; the will is extinguished; the intelligence is suspended; nothing remains of life but the organic functions; the nervous centres are paralysed down to the parts which preside over the performance of respiration and circulation. Life hangs in a trembling balance. No hands can be too skilled to hold the scales. Perhaps unskillfulness has killed some of those who have died under anaesthetics.

We must answer two questions before we give up chloroform for ether. Can we produce as perfect anaesthesia by means of ether as by chloroform? Is ether safer than chloroform? I believe both these questions may be confidently answered in the affirmative.

No one who has given ether a fair trial, even in one case, can doubt or disparage the perfectness of ethereal anaesthesia. I have employed ether very frequently in private and in hospital practice. I have given it for the severest and for the most protracted operations: for ligation of the common carotid artery, ovariectomy, amputation at the hip-joint; and, in eye-surgery, for squint and for enucleation of the globe; for excision of the breast, the gouging out of diseased bone, the removal of piles, etc.

But is ether safer than chloroform? This is the most important question. No complete anaesthetic is perfectly safe. We cannot fairly attribute all deaths which have occurred during artificial anaesthesia to the anaesthetic agent in employment at the moment. I wish to make the fullest allowance for all deaths from other causes. I will remind you that the first patient to whom Dr. Simpson intended to give chloroform was a boy who was about to undergo lithotomy. When all was ready, the boy unexpectedly died. No chloroform had been given. Had a few whiffs been taken, death might have been attributed to the anaesthetic. A surgeon, about to perform lithotomy, marked out a line on the patient's skin with his finger, and the man fell dead. Other similar instances might be quoted. But I have seen a hale and hearty labourer, free alike from all emotional excitement and organic disease, laid with a crushed foot upon the operating-table; chloroform was given; and before the operation was commenced, without any previous embarrassment of the respiration, the man suddenly died: died because the heart was stopped by chloroform. Of this event I was only a spectator. I believe the man died because the chloroform was given without due dilution with air. In its depressing action upon the heart lies the greatest danger from chloroform. Any one who has given chloroform largely, and with attention to the evidences of its action, knows that it usually diminishes the force of the pulse. In a few cases, however, in which the pulse is small and weak before the operation from emotional disturbance, the beats become fuller and

stronger as insensibility is coming on and the circulation is liberated from emotional control; but, as a general rule, the inhalation of chloroform weakens the pulse. It is often necessary to suspend the administration because the pulse has become feeble and flickering, without the occurrence of any signs of respiratory difficulty. Here, in the fewest words, is a typical case of a cardiac death from chloroform. "A young lad named G. J. Weston, aged 14, died at the Royal Free Hospital whilst under the influence of chloroform. Mr. F. J. Gant, surgeon, said that, when the deceased was admitted, it was thought that the hip had been dislocated. When he examined the lad, it gave him great pain. He ordered the house surgeon to administer chloroform. The chloroform was administered for about two minutes, during which time about sixty drops were inhaled. The deceased seemed to be half-sensible; and, on looking round, they saw the lad fainting and in a dangerous state. Silvester's respiratory method and galvanism were applied, but without effect, for the lad died at once. A *post mortem* examination was made. All the organs were sound. The cause of death was syncope from the effects of chloroform." (BRITISH MEDICAL JOURNAL, December 19th, 1874.) I have selected this case, because it is a typical example of death from sudden stoppage of the heart's action during the administration of chloroform. No one can maintain that degeneration of the heart's walls existed in this young lad. Chloroform, however, like ether, can kill, and has killed, by interfering with the regularity of the respiration, and finally stopping it before the cessation of the cardiac contractions. Death is more avoidable when impending in this manner. The suspension of the inhalation of the anaesthetic, the free admission of fresh air to the lungs, and the performance, if necessary, of artificial respiration, will generally save the patient when dangerous symptoms of respiratory embarrassment show themselves while the heart continues to beat. But we are powerless, or nearly so, when the heart fails first. There is no room to dispute the fact that, in those recorded cases of death from chloroform in which the signs of danger have been sufficiently noted, indications of cardiac failure have greatly prevailed over those of respiratory difficulty. Taking one hundred and nine fatal cases, in nearly all of which the mode of death was assigned, and which were embodied in the Report of the Chloroform Committee of the Royal Medical and Chirurgical Society, we find a decided preponderance of cardiac over respiratory deaths. Here is the table, as given in Dr. Sansom's excellent book on chloroform.

Syncope	56
Syncope during stage of excitement	6
Died suddenly	6
Died in a fit	10
Pulse and respiration ceased together	9
Failure of respiration (pulse not noted)	6
Failure of respiration (pulse remaining)	2
Not stated	14

109

Dr. Snow, to whom we are indebted for much valuable information concerning chloroform, made a series of experiments and observations with the view of determining the manner in which death occurs in the human subject from chloroform. He arrived at the following conclusions. "Chloroform-vapour, if it be inhaled in large proportion with atmospheric air, destroys life by paralyzing the heart. In smaller proportions, but long continued, it produces death apparently by the brain, and by interfering with the respiratory function. In such cases, the heart is found to beat after respiration has ceased. Chloroform-vapour, if it be blown upon the heart, paralyzes it immediately." (Quoted in Dr. Farrer's *Abridgment of Dr. Pereira's Materia Medica*, 1865.)

It is not fair to make a comparison of the absolute number of deaths from chloroform and from ether respectively. As yet, in this country, chloroform has been given infinitely more frequently than ether. Only the ignorant deny that ether-administration has ever been fatal. Trousseau collected details of nineteen deaths from ether. But chloroform has had hundreds of victims. Writing more than ten years ago, Dr. Sansom puts the number of deaths attributable to chloroform at "nearly 300". Perhaps the number may have now reached 500. I know that many deaths from anaesthetics have never been recorded.

Just as the great danger of chloroform lies in its power as a cardiac depressant, so does the relative safety of ether consist in its action as a cardiac stimulant. No one can give ether without being struck by its favourable influence over the circulation. In most of the cases in my experience, I have found the pulse improve in force and volume during ether-inhalation. Mr. Clover, who gave chloroform for many years, and than whom we have no more careful or more experienced administrator of anaesthetics, concerning the comparative safety of ether

and chloroform, writes: "Ether is undoubtedly safer; that is to say, life is not so quickly destroyed by it." ("Remarks on the Production of Sleep during Surgical Operations." By J. T. Clover, F.R.C.S. BRITISH MEDICAL JOURNAL, February 14th, 1874.) In Dr. Neligan's well known work on *Medicines*, edited by Mr. Macnamara, I find it stated that "the great recommendations (of ether) are the complete state of anaesthesia it produces, and the safety attending its employment—a safety so remarkable that its exclusive use has become a law in the Massachusetts Hospital".

But we may ask some further questions before we decide to give up chloroform for ether. Are the more remote ill-effects arising from ether-inhalation greater than those which spring from the use of chloroform? So far as I have seen, vomiting, the chief troublesome after-effect of anaesthetics, is met with as often after one agent as after the other. Speaking of the remoter consequences of breathing ether, Mr. Clover says: "Sickness is about as frequent as after a moderate use of chloroform." Dr. Neligan mentioned, as one of the disadvantages of ether, "the subsequent persistent taste and odour of ether experienced even for days by those to whom it had been administered". There is, perhaps, a little truth in this; but, with the liberal admission of fresh air, the taste and smell of ether, which are not unpleasant to most people, soon pass away. It has been said that bronchitis may arise as a consequence of ether-inhalation. I have never met with such a result, nor with anything approaching to it. The condition which has probably been mistaken for bronchitis is one which I have observed, and one to which Mr. Clover has drawn attention in the following words. "The flow of saliva is considerable; and the larger air-tubes are often obstructed by fluid, which makes a loud moist rhonchus; but it does not appear to be of much consequence, as it passes off afterwards." Patients who have taken ether usually complain of nothing more than a slight feeling as of recovery from drunkenness. Are there any other inconveniences attending the administration of ether as compared with that of chloroform? It takes a very few minutes longer, as a rule, to produce anaesthesia with ether than with chloroform. But I have induced perfect surgical anaesthesia with ether, so as to permit the painless performance of the operation for squint, in three minutes. Ether is not quite so pleasant to breathe as chloroform, and it is more apt to cause a feeling of suffocation during the first few inhalations. But no inconveniences of such a trivial and temporary kind as those I have mentioned—inconveniences involving time, or taste, or trouble—ought to deter us from using the safest anaesthetic we possess. If our patients were able to decide the question, safety would be the paramount consideration with them.

I have generally found it best to give a little chloroform at first. One drachm is usually sufficient. I give a drachm as a dose, poured upon a thickly folded towel, held about two inches from the patient's mouth. After this quantity of chloroform has been inhaled, ether can be borne, in most cases, without giving rise to any choking. There is rarely more effect from this quantity of chloroform than a little mental obscurity. I then give the ether, in doses of an ounce at a time, poured upon a sponge, fixed at the top of a cap-shaped inhaler, made from an ordinary bedroom towel. The inhaler I use has been devised and described by my friend Mr. Lloyd Owen. It must be applied closely around the nose and mouth; I like it to be large enough to include the nose and the chin. But little air must be admitted. The dose of ether must be renewed about every two minutes, removing the inhaler completely from the face, and allowing one or two inspirations of air, until anaesthesia be induced. When the insensibility is perfect, it may be maintained by giving smaller doses of the ether, half an ounce, at less frequent intervals. We can only judge whether to stop or continue the administration by the condition of the patient. We must give enough ether to produce anaesthesia, and we must continue to give it so as to maintain anaesthesia, so long as the operation may last. But it must never be forgotten that even ether is not absolutely safe when given to full anaesthesia. The administrator must never cease to watch the patient closely, observing, with undistracted attention, the breathing, the pulse, and the colour of the face; he must have nothing whatever to do with the operation or the operator, not even to look at it or him; he must be wholly occupied with his own most important and responsible work. Whether chloroform or ether be given, it must be given with carefulness, but yet with confidence; "we must get rid of fear, we cannot act at all till then"; we must avoid alike timidity and temerity.

And now, gentlemen, I have done. I have been obliged, from a regard to time, to leave unsaid much that I should like to have said concerning anaesthetics, concerning more especially the relative values of the various methods of administration. I have been obliged to omit all mention of many little practical details which I have acquired in a somewhat lengthened experience of the employment of chloroform

and ether. But I have striven to confine myself to the question before me, and to discuss it fairly, which is the better anaesthetic, ether or chloroform? I have endeavoured to justify my conclusion that ether must have the preference. I hope I shall not be misunderstood when I say that, on giving up chloroform, I had to overcome that kind of prejudice which springs from habit. We ought to have no prejudices in such matters as those before us; we can none of us advance in scientific or in any other kind of truth until we can more or less completely get rid of prejudice. Its "rotten pales" should never confine us. But I was insensibly and not unnaturally biassed towards chloroform, because I had given it largely for several years, because I had given it safely more than a thousand times. But I have had a growing sense of the danger of chloroform; and the results of my reading and of my experience, and my sense of duty towards those who have been placed in my hands, have led me to give up its use for that of ether.

RAILWAY PATHOLOGY:

CASE OF HARRIS *versus* THE MIDLAND RAILWAY COMPANY.

By JOHN CHARLES HALL, M.D.,

Senior Physician to the Sheffield Public Hospital; Lecturer on Medicine at the Sheffield Medical School; Physician to the Midland Railway Company; etc.

IN a leading article, the BRITISH MEDICAL JOURNAL of November 27th directs attention to the case of Harris *v.* the Midland Railway Company, recently tried at Westminster Hall before Baron Pollock and a special jury; the case being one in which the plaintiff claimed compensation for personal injuries said to have been sustained on the defendants' line, through the negligence of their servants. As the consulting physician to a large portion of the line over which the trains of this company run, as it was in my district that the accident happened, as I saw Harris the day after the accident, and as, owing to the case being settled out of court, the defendants are as yet medically unheard, I venture to supply some pathological particulars which cannot fail to be of interest to our profession.

It is said in the article referred to, "We should very much like to see a *verbatim* report of a dozen or two of railway cases in print". I have already supplied a good many to the JOURNAL,* and promise ere long to send more. In this case, the medical men called in by Mr. Harris were Dr. Sterling, Mr. Maunder, Mr. Erichsen, Dr. Hardwicke, Dr. Ramskill; by the Midland Company, Mr. Saville, Mr. Skelding, Mr. Gay, Mr. Jonathan Hutchinson, Dr. Keadcliffe, Dr. J. C. Hall. It must be remembered that part of the attendance was at The Holmes, near Rotherham; part in London. Hence the number of medical men engaged.

We may have had to deal with what my lord was pleased to term "questions of the highest physiological and scientific refinement, concerning which there might be difference of opinion amongst the most distinguished members of the profession"—questions which I deeply regret an opportunity was not afforded of discussing before Baron Pollock and the jury; but, in a *l.s.d.* point of view, it doubtless saved the Midland Company money to get rid of the enormous costs of another day's trial, as the very able counsel and solicitors of the company, on the suggestion of the judge, at once perceived. No one denied for a moment that the man was entitled to some compensation; the points in dispute being the nature, amount, permanence or otherwise, of the injuries alleged to have been sustained; and was there, or was there not, great exaggeration? I think all the medical men engaged were of opinion that the man would recover. In how short a time—the case settled, the trial over, the verdict of the jury given, and the damages paid—was a question about which there would have been, no doubt, a difference of opinion. For my own part, I thought, and, for the sake of Mr. Harris, most sincerely hoped, he would very soon be restored to his usual health. The evidence of his own witness, Dr. Ramskill, as reported in the *Times*, is well worthy perusal.

The accident happened near The Holmes Station, on the night of Thursday, December 10th, 1874. (This date will be found of importance in considering the length of time the patient's symptoms lasted.) Plaintiff was in a third-class carriage; he had come that day all the way from Exeter, a distance of about two hundred and seventy-five miles. The weather was very cold, and there was a deep snow on the ground. I may say that, at the time of the accident, the train was "pulling up"; and, so far as my experience goes—and few men living have seen more of these cases than myself—in estimating the probable severity or otherwise of the injuries sustained, it is most important to

* Now published separately, "Medical Evidence in Railway Accidents".

ascertain the speed at which the train was moving at the time of the accident, the nature and weight of the opposing obstacle, and whether it was fixed or moving. These are all questions affecting the probable severity or otherwise of the injuries sustained; for, like any other kind of accidents, those occurring on railways may be serious or the reverse. The presence or absence of cuts, bruises, or fractures, will also assist us materially in estimating the force of the collision.

I may remark, with regard to this accident, that, in addition to Harris, I saw, in consultation with different surgeons, many of them living long distances from Sheffield, thirty-nine other cases, which I attended in consultation until they had all recovered. Every case was *settled by the Company, through its authorities, without trial, save that of Harris.* Of course, I never attempt to settle any case, that being no part of my duty. Had I gone into the witness-box, I should have proved that all the cases in this accident had recovered; that they were comparatively slight. They were all third-class passengers. The most severe cases were, a publican who had a slight fracture of one rib, and a lady who miscarried. She had previously done so, and possibly this accounts for it. So far as I know—and in this opinion I am confirmed by the late Dr. J. Ogden Fletcher, of the Manchester, Sheffield, and Lincolnshire Railway Company—this is not a very frequent result of collisions on railways.

At the time of the accident, neither his own surgeon, Dr. Hardwicke, Mr. Saville, nor myself, regarded this case as a serious one. It is only right to say that Dr. Hardwicke subsequently, at the trial, modified this opinion; but then my old friend had been up to London; had seen, and had conferences with, some of the most distinguished consulting surgeons of the age; and possibly this may have been only another instance, in which we northern lights have paled before metropolitan luminaries.

At the trial, the plaintiff, who was carried into the court on a couch, swore he could not move his legs, walk, or stand. (During the first part of the examination, the right leg, like the left, had been straight. As the examination continued, it was drawn up, and described a half-circle. To this I drew the attention of the junior counsel, Mr. Gould; Mr. Waddy, Q.C., being at the moment out of court.) He knew nothing of what took place at the time of the accident. For some days afterwards, his mind was a blank. He said "he did not pass water for several days after the accident". Dr. Hardwicke said at the trial that this statement "excited his suspicions". He was at times sensible; at others, not so. What does intermittent sensibility mean? He said: "I recollected nothing of the accident until the Sunday morning." (The accident was on a Thursday night.) "I then found myself in a strange room. I saw my mother; felt pain in my feet and shoulders." The memory of Mr. Harris in the witness-box as to the accident appeared to be gone; not so as to his earnings and calling at Exeter. He did not remember that he had a conversation with the station-master at The Holmes, as to the cause of the accident, the night it occurred; nor his conversation, as sworn to by Dr. Hardwicke, with Mr. Saville and himself, when they gave him, as he sat by the fire, brandy and water; nor the visit of Dr. Hall the following morning, when he came to consult with Mr. Saville. No person from The Holmes Inn was called to say what was his condition during the time he resided there. All the witnesses were members of his own family, save the Jewish rabbi resident in Sheffield.

Extract from my Note-book, made at the time.—The Holmes accident, December 10th, 1874. The Rev. Mr. Harris, seen at The Holmes Inn, Rotherham, December 11th, 1874. I first saw Mr. Harris, aged 22, December 11th, 1874, the day after the accident, in consultation with Mr. Saville. I found him in bed. He appeared feeble, very badly nourished, pale, and looked more like a man suffering from long exposure to cold and want of food than anything I could discover. He was nervous, and, I thought, hysterical. He said "he had travelled all the way from Exeter the day before, and had been in the railway collision at The Holmes last night". He was perfectly clear and collected, and answered every question I put to him at once. He had a very slight abrasion over the eyebrow, and one on the toe, so slight as not even to require a bit of plaster. He said "he had pain in the head". He did not complain of any pain in the back or spine; nor did pressure produce any. He said he was unconscious, he thought, when the collision took place, for a short time. When he came round, he felt sick, but did not vomit. He could turn over in bed, and had perfect power over his arms and legs. The pupils contracted freely on the light of a candle being brought before them. Examined with the ophthalmoscope, both eyes were found natural. The urine was passed freely, as was the case during the whole of my visits in consultation with Mr. Saville, occupying a period of eighteen days. I saw it at each visit. The respirations were natural; pulse 74; temperature 98.5 deg. There was the most perfect command over the

sphincters. The whole of my attendance—I may say from the time of the accident to the day of the trial—whenever I saw him, this was so. There was never a complaint made to me of dribbling of urine—or suppression of urine—or retention of urine. In truth, when I saw him after the accident, there was no single symptom indicative of injury to the *brain or chord.* He walked, on leaving The Holmes—so he stated at the trial—from the hotel at The Holmes to a cab, leaning on the arm of a friend, and came on by railway to London. In London, he was seen in January, 1875, by Mr. J. Skelding of Euston Square, on behalf of the company. I have Mr. Skelding's report before me, who says: "He made the remarkable statement, that he did not pass water for several days after the accident—that is, four days—from Thursday to Sunday." Here I can only repeat that the memory of Mr. Harris failed him. Mr. Saville saw the copious pale-coloured urine which he passed daily. I saw it at each of my visits so long as he remained at The Holmes. There never was the slightest distension of the bladder, nor one symptom leading me to suspect suppression of urine; and I think that, after a failure to secrete, or, if secreted, to pass urine for so long a period, the symptoms would have been marked indeed. I carefully examined the abdomen at each visit, and especially so for this reason, Mr. Harris feared he had been ruptured by the accident. My frequent and careful examinations convinced him such was not the case.

I did not see Mr. Harris again until June 12th, 1875; Mr. Maunder, Mr. Erichsen, Mr. Jonathan Hutchinson, Mr. Skelding, Mr. Gay, myself, and others, being present. Mr. Hutchinson, at my request, attended for the Midland Railway Company. Compared with his appearance when I saw him at the Holmes, Mr. Harris was much improved. There was no expression of pain or distress in his countenance, nor was there a trace upon it indicative of pain or serious disease. His pulse was 98; his breathing natural; temperature 98.2 deg. His tongue was moist and fairly clean. His pupils were natural, and acted well; said he "could see and read well", but was "soon tired". There was nothing in his muscular system to call for remark. A slim-made man naturally, his thighs and calves were as large as could be expected, taken in proportion to the rest of his development. There was no difference in the size of his calves (carefully measured); nor could any difference of temperature be detected on the one side or the other. He could move the upper part of the body well. Asked by Mr. Hutchinson to grasp his hand, he did so very feebly; but, on Mr. Hutchinson assisting him to raise himself, he was seen to grasp his hand and pull with force. He sat on the couch with much apparent difficulty. When the support was taken away, he fell back helplessly. Afterwards he sat on the edge of the couch without any material support.

He did not raise his lower limbs at first; then he raised his knees, but never lifted his heels. When they were lifted, he complained of pain in the ankles, knees, and hips, but when it was tried to bend these joints, there was considerable resistance. It appeared to me during this examination, that the muscular resistance was much greater at one time than another. He was next tested as to the loss of sensation in the two limbs. He asserted that he could not feel even when the soles of his feet were tickled. Mr. Hutchinson then took hold of the hairs on the front of his legs, and, by them, he lifted the skin. Harris said, "I cannot feel in the least; I cannot tell my leg is touched". This, if so, looked to me like an almost perfect loss of sensation, and yet he again and again detected at once a light touch from the blunt end of a gold pencilcase, which I handed to Mr. Hutchinson.

Asked as to the pain in his back, he pointed to the middle of the lumbar region. At this part, he flinched on a touch light as a feather. But the same touch caused flinching over the crest of the ilium, or over any of the bones of the spine; or, in fact, over any part of the back.

He said he only passed his urine once in twenty-four hours, and that he did not pass much at a time. He stated to Mr. Hutchinson, that "he was unconscious for several days after the accident, and that when he came to himself he was in bed at an inn". It is matter of great professional interest to inquire how far it is consistent—although doubtless there may be exceptions to every rule—with the experience of physicians and surgeons, that inability to move the lower limbs for months, can exist with muscles seen to be in a perfectly healthy condition. He stated, June 1875, that he could not move his limbs, and yet, he could exert the muscles with no little power to resist the bending of the limbs. Sensation was said to be lost. Is such a state of things consistent with the amount of muscular resistance and power undoubtedly retained? This is a case of such importance in every way, that I should be glad indeed if my remarks may induce my friend Mr. Jonathan Hutchinson to publish in this JOURNAL his opinions of the many interesting phenomena we discussed as to this patient again and again.

The next time I visited Mr. Harris was a day or two before the trial. I saw him at the residence of a friend of his in Whitechapel, November 8th, 1875. Mr. Erichsen, Dr. Sterling, and Mr. Maunder, met Dr. Radcliffe, Mr. Skelding, Mr. Jonathan Hutchinson, myself, and others at the house. The plaintiff said, "I am better in health, but not so well in the use of my legs and feeling". He appeared to me looking better than when I saw him in June. The bladder was distended, and I suggested to Mr. Erichsen that a catheter should be sent for. This was placed on the table. He said, "I will try". He was placed upon the edge of the couch. He passed a large quantity of pale-coloured urine freely, and with force. He said he had no sensation down to a certain part of each thigh, which was marked by him with a pen and ink. The battery brought by Dr. Radcliffe having been broken in removing it from his carriage to the house, we agreed to meet again in consultation the next day.

November 9th. Mr. Erichsen was not present with us to-day, but Dr. Ramskill attended on the part of Mr. Harris for the first time. The power of motion and sensation was tested by Dr. Radcliffe; the continuous and induced current (Faradic) being employed. The test fully proved that the muscles had not lost the power of moving, nor had he lost sensation, whatever amount of spinal anemia may or may not have been present. The battery applied, the feet, which had been everted, were drawn together, and the heels raised from the couch; the current removed, one would naturally have supposed, with such an asserted loss of muscular power, that the feet would again have fallen outward. They did not do so. The experiment repeated, a sharp cry indicative of pain proved the existence of sensation—I ought to say, the current applied was very weak. May we take it for granted that the excitation of contractions, when the induced magneto-electric current (Faradic) is passed through healthy muscle, as was the case here, proves that at any rate, to some degree, it was susceptible to the electric current, and possessed electro-muscular contractility, or irritability; and that the cry of pain indicated electro-muscular sensibility?

There are many other points in this case that it is to be regretted for the present, from want of time, I must pass over. But to me, in any man it does appear in the highest possible degree unaccountable, that with an alleged paralytic condition of the lower extremities, there should continue to be enjoyed perfect control over the bladder and rectum. The absence of all objective symptoms in all such cases is matter for the most grave and serious consideration before forming an opinion. When, therefore, I am called to see a patient who has been in a collision on a railway, and who is seeking compensation, who has remained in bed for months apparently without the power of turning over or moving his lower limbs, in which it is stated he has lost sensation, who has a healthy aspect, no difference of temperature between the parts said to be paralysed and the rest of the body, perfect command over the rectum and bladder, pulse natural, temperature normal, no bed-sores, no marked lesion of nutrition, no flattening of the nates, no wasting of the calves of the legs; I venture to say, and that, too, without wishing in any way to dogmatise, that there is the total absence of those objective symptoms which we expect to find, and do find, in injuries to the spine of a severe nature, in patients who have not recovered months after accidents of this nature.

Let us hope, however, that the railway spine, if not already so, will soon become a thing of the past, and that the views I expressed in this JOURNAL so long ago as in the year 1867, will be now generally held to be correct by the profession, confirmed as I am again by Mr. Erichsen, in his work *On Concussion of the Spine and Nervous Shock*.

MR. ERICHSEN, 1875.

"Injuries to the spine and spinal chord occur not infrequently in the ordinary accidents of civil life. If, in these lectures, I speak more frequently of the injuries of the spine arising from this" (railway collisions) "than from any other class of accidents, it is not because I wish to make a distinction of injuries of the spine according to their causes, and still less to establish anything like a speciality of railway surgery" (p. 2). Again, he says, "I do not consider that these injuries stand in a different category from accidents occurring from other causes in civil life" (p. 5). He speaks of "railway injuries as peculiar, not different."

DR. J. C. HALL, 1867.

"The railway spine, as it is termed, I confidently submit, has no right to the peculiar place assigned to it. An injury to the spine, whether occasioned by a collision on a railway, or by a fall from a scaffold, can only be dangerous in proportion to the extent in which, at the time of the accident, or subsequently, the spinal chord or its membranes are affected."

It is quite impossible for a moment to associate the case of Mr. Harris with one of permanent injury to the brain or chord. At the time of the accident, there was no evidence of concussion, and, to use a homely proverb, at the worst, he was far more frightened than hurt. At the most, his could be, this November, but a case of hysterical paralysis, the traces of which must rapidly pass away. I find, after many railway accidents—which hardly deserve the name—patients give themselves up to despair, they lie in bed or on the sofa, take no exercise, and voluntarily resign themselves to an emotional condition, painful alike to themselves and to their friends.

Speaking of those who suffer from hysterical manifestations after comparatively slight injuries, in his recent very able work, to which attention is directed in the article in the JOURNAL, Mr. Erichsen writes, p. 203, "My experience of these cases leads me to consider the prognosis as much more favourable than might have been anticipated; or, than I was at one time disposed to consider it".

That they recover—rapidly recover—is certain; but, without a wish in any way to insinuate deception or feigning on the part of any who have been in a railway collision, every-day experience goes to prove that in such cases—and I have such a one under my care now—there is no modification of symptoms, no entire restoration to health and peace of mind, until the trial is over, and all the bitter fears and miseries of impending litigation have passed away. So far as I know, railway companies are ever ready to deal with all who may have suffered, fairly and most liberally. How much, then, of pain, sorrow, and anxiety would be saved, if the claimants would at once grasp the friendly hand held out to them, instead of enduring for months the anguish inseparable from the anticipation of the day on which they will have to appear as witnesses in a court of law: the trial over, then only to discover beyond doubt that, had they accepted the offer made to them, in every sense, pecuniary included, they would indeed have been gainers.

THE WHITECHAPEL TRAGEDY:

REPORT OF THE POST MORTEM EXAMINATION OF THE REMAINS.

By F. G. LARKIN, M.R.C.S. Eng.

ON Saturday, September 11th, 1875, I was called to the Stones End Police Station, about 5.30 P.M., where I was shown two parcels wrapped in American cloth. On opening them, I found one parcel to contain the trunk, and the other bundle the remaining portions, which collectively were the remains, beyond doubt, of a human female about five feet high, and about twenty-five years of age, and those of a thin person. The body had been very recently and most unscientifically dissected. It was in a very stinking and decomposed condition; some parts were more or less "mummified", whilst other portions were in a state tending to "adipocere". I have examined the remains several times, at first by myself, and subsequently assisted by Mr. Bond of Westminster Hospital. The body was, roughly speaking, divided into ten parts, as follows: two hands; two arms; two legs and feet connected (the left leg included part of the patella); two thighs, including portions of the pelvis (the right thigh included the patella, the left thigh included part of the patella); one trunk, excepting the front of the pelvis; one head and neck.

Hands.—The left hand (or rather the bone) had been broken off just above the wrist-joint; the right hand had been removed more carefully through the same joint; otherwise, both hands were entire. There were no signs of a ring having been worn, the decomposition having advanced so far as to prevent the possibility of such evidence (moreover, it is a known fact that these rings had been in pawn some months before death). The nails were easily removed.

Arms.—The head of the left humerus had been cut through. The limb was entire, excepting a small portion which was attached to the hand. The right arm was broken off just above the middle of the humerus, the upper part of which was still connected with the trunk; the remainder of the limb was entire down to the wrist-joint.

Legs and Feet.—The knees were smashed about, especially the right. A wedge-shaped piece had been cut out of the back of the left knee-joint. The left great toe was broken at the extreme joint. The nails were easily removed. A pair of boots proved to have been worn by the missing woman, I found to correspond to, and they could have been worn by, the feet of the deceased. The length of the feet was 8½ inches, and that of the boot 9 inches. There was an oblique scar from a burn, about one inch long, and three-quarters of an inch wide, very

much puckered, thickened, and fibrous, on the outer side of the right leg, somewhat in front, and about four inches below the centre of the knee-joint.

Thighs.—These were very much hacked about in severing them from the pelvis, fragments of which were attached; together with portions of the labia vaginae, which, with much difficulty, I managed to place *in situ*.

Trunk.—The upper part was more or less mummified; at other places, tending to adipocere. The mammae were quite invisible, the regions being flattened level with the remaining surface of the body. The head and neck had been separated between the sixth and seventh cervical vertebrae. The cartilages of the ribs were easily cut with a knife. The ossification of the sternum had advanced to such a degree that the third and fourth pieces were nearly united. The pelvis had been smashed up into innumerable pieces, especially in front; the sacro-iliac synchondroses were dislocated on both sides. The labia vaginae were lacerated in all directions, and very little hair was to be seen; it had the appearance of having been shaven off, but was probably removed by the lapse of time, etc.

Head and Neck.—The colour of the hair was light auburn; it was tied up with a piece of black velvet, half a yard long, and one and three-quarter inches wide, which was rotten. All features of the face were quite gone, a considerable portion of the flesh having been removed; there was, however, some remaining, on the right cheek more especially, but too decomposed to be of any use in identification. The cheek-bones were rather prominent. The eyeballs were in a very shrivelled-up condition, and retracted into the back of the orbits. The scalp was all torn off, excepting at the posterior and left side of the head. The ears were all gone, with the exception of a small portion of the left, which gave evident signs of having worn an ear-ring. The teeth were perfect, excepting the two central incisors and left canine of the upper, and the central incisors of the lower, jaw, which had been removed since death. The left upper and the right lower incisors, together with the left upper canine, having been found and replaced, the only missing teeth were the right upper and left lower incisors. All the wisdom-teeth were perfect, excepting the left upper, which was being cut. The front right upper bicuspid was decayed down to the gum, and it was the only decayed tooth, so far as it was possible to say in the absence of the two missing incisors. There were large quantities of congealed blood and dirt about the head generally, but more especially in the neighbourhood of the wounds, one of which, that of the cut throat, was a wound two inches in length, which extended from the *right* side of the median line, just above the thyroid cartilage backwards, and slightly upwards to opposite the angle of the lower jaw on the *left* side, and had divided all the structures in front of the third cervical vertebra. This wound must have been inflicted during life or immediately after death, as evidenced by the congealed blood on its surface, and also in the immediate neighbourhood, especially in the direction of the ear on the same side. This wound appeared to have been continued into the body of the third cervical vertebra, and extended in a straight line across the same, including the transverse processes, cutting it nearly half through. This injury to the bone appeared to have been more recent: its surface was fresher: which fact might be accounted for by the comparative absence of atmospheric influence by the closing of the incision into the vertebra, thus pointing to the probability of its having been done at the same time as the division of the softer structures. The frontal suture was absent, all others perfect. On the right temporo-parietal suture, posteriorly, there was a fracture about three-quarters of an inch long, and three-eighths of an inch wide, with its posterior part more depressed than its anterior; its direction was obliquely backwards and upwards. On the inner surface of the scalp in the immediate neighbourhood, there was a smooth layer of congealed blood, about two inches in diameter, and about one-sixteenth of an inch in thickness. On removing the skull-cap, I found a wound in the dura mater corresponding to the above fracture, in which were imbedded spicula of bone and slight hæmorrhage. Finding the brain in a fluid and pulpy condition, I deemed it prudent to desist from any further interference in removing it; for, had I done otherwise, my evidence would have been unconfirmed in reference to the finding of any bullet; but subsequently, with the assistance of Mr. Bond of Westminster Hospital, I found two bullets at the base of the brain; one, which had entered by the fracture already described, had lodged itself (after having struck the posterior portion of the occipital bone) in the base of the cerebellum on the opposite side; the other bullet found within the skull was lodged in the sella Turcica, the clinoid processes of which had been broken by it; then, in following its course outwards, we found it had entered by an opening or fracture, just above and in front of the root of the right zygomatic arch. Here, also, there

was a considerable quantity of congealed blood and dirt. I also found, in the padding at the back of the head, a third bullet, very flattened, and which had evidently not entered the skull, its progress having been arrested by the innumerable hair-pins and padding. These hair-pins were bent and broken in all directions, some having been broken a long time, as evidenced by the rust.

Viscera.—These were in a very decomposed condition, with the exception of the uterus, which was very thin and wasted in substance, like all the other organs, but in a good state of preservation. The lungs were in a very small shrivelled-up state, almost as if they had never been inflated. The heart, also, was shrunken up into a very small mass, enclosed in a fair-sized pericardium. The liver was very distinct; likewise the stomach, which, on being opened, was found to be empty, with the exception of its surface being covered with what appeared to be decomposed blood, but which gave very doubtful evidence under the microscope: indeed, the time that must have elapsed, together with the action of the gastric juice, would go far to disintegrate the corpuscles; the colour, however, was very marked to the naked eye. The intestines were in a very different condition—viz., a confused mass, glued, as it were, together, so that it was perfectly impossible to separate one coil from another. I placed each viscus (with the exception of the brain, for the reason above stated), for subsequent inspection, in a separate glass jar of the purest quality, specially washed out with distilled water. The general appearance of the uterus was most inconsistent with virginity, which fact, also, was to a great extent borne out by the appearance of the skin of the lower part of the abdomen, which here and there amidst the decomposition showed one or two white lines in the hypogastric region, and other marks nearer to and in the inguinal region, of a darker colour, apparently the remains of the peculiar violet lines which, together with the above-mentioned *lineæ albicantes*, are peculiarly characteristic when taken in conjunction with other evidence of delivery having taken place at some more or less remote period; and what seems to bear out this idea in my mind more strongly, is the fact that the decomposition had progressed more rapidly with the little *raisal* portions of integument between the cicatrix-like lines than at any other part of the whole trunk, or upper part of thighs, where the surface of the skin is *even*. The dimensions of the uterus were in every way enlarged; its measurements, as near as possible, were: extreme length, 3 inches; width at fundus, $2\frac{1}{2}$ inches; cervix, upper part, $1\frac{3}{8}$ inches; lower part, $1\frac{1}{2}$ inches; thickness, $\frac{5}{8}$ inch; cavity, length, $2\frac{1}{2}$ inches; breadth between Fallopian tubes, $1\frac{1}{2}$ inches; centre, 1 inch; lower orifice, $\frac{1}{2}$ inch; cervix thickness, $\frac{3}{8}$ inch; width, $\frac{1}{2}$ inch; weight of uterus, 12 drachms.

This subject of pregnancy constituted the only point of difference in the medical evidence given by myself on behalf of the prosecution, and that given by Dr. Meadows for the defence. Dr. Meadows spoke of two things which guided him more especially in coming to an opposite opinion to that given by myself. In the first place, he commented on the *shape* of the uterus. Now, it is a singular thing that, when I first examined the organ, I was struck by the very opposite shape to that which he described in the witness-box; the uterus was so flaccid that, by the most trivial ingenuity, it might be altered in this respect; and I confess I did not think it worthy of any reliance whatever in this case. Next, he spoke of the thinness of the walls. He said "the walls were unusually thin"; I agree with him, as will be seen by my measurement, which coincides with what Dr. Meadows said ($\frac{5}{8}$ inch). Now, this "thinness", I will show, goes very far to prove, in this unparalleled case (and taken in conjunction with the other evidence, on which I rely as a whole, the appearance of the abdomen, the uterine measurements, and weight as given above), will suffice to convince any reasonable mind that this uterus was not nulliparous.

I cannot do better than quote from a letter which I wrote to Sir John Holker, the Attorney-General, on behalf of the prosecution.

"Dr. Meadows gave as one reason that the walls were very thin. We agree; but calm reflection reminds me of a most remarkable fact in reference to the walls of the bladder, which was as thin as or thinner than this paper (foolscap). Now, the bladder has been subject to the same influence as the uterus; and I should like to know why the muscular walls of the one organ should not follow the same rule of atrophy as the other. The stomach, too, and the other viscera, had also wasted in thickness; and why should the uterus be the only exception? True it is, that the uterus lasts longer than any other viscus; but that does not alter the possible fact of getting thinner in proportion with other organs; and, if my argument be sound, such a fact strengthens my undisputed evidence as to weight. Of course, the uterus would be heavier; and it now is inconsistent with virginity, as are the measurements; and I certainly observed the converse as to the shape of the uterine cavity as stated by Dr. Meadows; but this point, I confess, might vary in the present case."

THE WHITECHAPEL TRAGEDY:

NOTES OF A REPORT TO THE SOLICITOR TO THE TREASURY ON
THE POST MORTEM EXAMINATION OF THE REMAINS.

By THOMAS BOND, F.R.C.S.,

Assistant-Surgeon to the Westminster Hospital, and Lecturer on Forensic
Medicine.

50, Parliament Street, S.W., Sept. 16th.

SIR,—According to your request, I beg to report that I received this day from Inspector Fox the remains of a human body in a sealed coffin. I received, also, from Dr. Larkin, the pelvic viscera of the same body in a closed jar. The body was divided into ten pieces; and, when fitted together, proved to be the complete body of an adult female, in an advanced stage of decomposition. The length of the body was just under five feet. The woman had evidently been dead many months; but certain parts were well preserved where they had been exposed, apparently, to the action of chloride of lime. The division of the body was undoubtedly of recent date, as proved by freshly cut bone and muscle. The division appeared to have been accomplished in an unskilful and bungling manner, by an adze or chopper, and was probably done by the hatchet in possession of the police.

The face was decomposed, and all trace of features lost. The scalp was partially separated from the skull, especially on the right side; and, attached to it, was a quantity of curly auburn hair at the back, fixed with hair-pins to a pad; and, on the left side of the head, clotted with a dark substance resembling dried blood. The sutures of the skull were very distinct, with the exception of the frontal, which was obliterated. On the right side of the head, at the junction of the inferior and posterior angle of the parietal bone with the squamous portion of the temporal, there was a depressed fracture, of the size of a sixpence; and, at the back part of the depressed bone, there was complete penetration of the skull by a hole large enough to admit a small bean. The fracture must have been caused by a hard blunt substance striking in a direction obliquely backwards and inwards. The fracture was not of recent date, the broken surface being of a dark colour, and similar in appearance to the exposed portion of the skull. The scalp was detached over the fracture and around for a distance approximately of three inches, exposing the skull. There was a penetrating wound of the scalp, which, when drawn forward, corresponded to a point on a level with, but an inch posterior to, the fracture. The scalp around the wound was dark-coloured, and its substance infiltrated with blood to a depth of one-sixteenth of an inch on its under surface. The uninjured portion of the scalp was of a pale brown colour.

The dura mater was detached from the skull-cap, and entire at the upper part, and of a light grey colour; but exactly opposite the fracture it was torn through, and of a dark brown colour around the puncture, from infiltrated blood. The above injuries were, I have no doubt, inflicted during life. On passing my finger into the hole in the dura mater, I found two spicula of bone. On opening the dura mater and removing the decomposed brain, I found a flattened bullet lying in the left hemisphere of the cerebellum, and in the direct axis of the hole through the skull. This bullet, I have no doubt, caused the injuries I have described. On removing the dura mater and the soft pulpy brain-substance, I discovered a second bullet lying on the posterior clinoid processes of the sphenoid bone. This bullet was flattened on the top only, and appeared to have entered the skull by direct impact. Both spinous processes were fractured; and, on further examination, I found a hole in the skull exactly above the base of the zygomatic process of the right temporal bone, passing directly inwards along the base of the brain, in a line with the petrous portion of the temporal bone, to the position of the bullet on the sphenoid bone. In the substance of the brain, and in the axis of the wound, I found a large spiculum of bone, but observed no effused blood. I cannot say if this wound was inflicted during life; but, if so, it was sufficient to cause death.

The head was severed from the trunk between the sixth and seventh cervical vertebræ. A cut two inches long extended from the angle of the thyroid cartilage upwards to the left angle of the lower jaw, dividing the tissues down to the vertebræ. The surface of the wound was retracted and dried, and not flaccid and soft like the cuts separating the body. It must have been inflicted from the front upwards and backwards. At the bottom of the wound, there was a cut nearly dividing the body of the third cervical vertebra. I am of opinion that the wound was inflicted during life, or directly after death; but cannot say positively, as the cut in the vertebra appeared to have been done

recently. The hair over the left ear was much clotted with a substance like dried blood.

The teeth remaining in the jaws were perfect, with the exception of the first bicuspid of the right upper jaw, which was decayed to the root. The third molar of the upper jaw on the left side was still uncut. Four teeth were missing, having fallen out since death. The cartilages of the ribs were not ossified, and the bones of the skeleton were light and small. The cartilaginous ends of the bones were abundantly covered with articular cartilage. I am of opinion that the age of deceased was from twenty to twenty-five years.

I examined the uterus, which was much decomposed, and found the cavity large, but the walls thin; the os was transverse and broad, and the neck projected very little into the vagina. In my opinion, the deceased had borne children.

THOMAS BOND, F.R.C.S.

September 24th.—I re-examined the remains, by request of solicitor for the defence, in the presence of Mr. Aubin, who attended on behalf of the prisoner. It had been stated by Mr. Lane that his daughter had a scar on one of her legs, but he could not recollect on which one. I, therefore, examined each leg very carefully; scraping away the chloride of lime and earth which thickly covered most of the body. I first scraped the left leg completely, but discovered nothing except eroded patches on the skin, one of which Mr. Aubin cut out subsequently, under the impression that it was a scar. On scraping the right leg, I found an undoubted scar, exactly over the fibula, about four inches below the point of the knee. It was about the size of a shilling rather elongated, downwards and backwards. It was a hard fibrous scar, and one-eighth of an inch in depth. In front, the skin was healthy, but very much puckered; at the back, the skin was white, similar to the ordinary appearance found around the scar of a burn or scald. The epiphyses of the shoulder, thigh, and knee-joints, had united.

ON INFUSION OF MATICO AS AN INTRA-UTERINE INJECTION.

By W. DRAPER, M.R.C.S., &c.,

Surgeon to the York Dispensary.

IN THE BRITISH MEDICAL JOURNAL of November 13th, Dr. Spender of Bath has a note on infusion of matico as an intra-uterine injection in cases of uterine hæmorrhage. Dr. Spender asks whether such an injection "has ever been tried in *post partum* hæmorrhage". In 1868, I published, in the BRITISH MEDICAL JOURNAL, some cases of hæmorrhage treated by intra-uterine injection; and I then mentioned strong infusion of matico as having been employed by me. Again, as recently as July of last year, I communicated to the *Obstetrical Journal*, a paper on intra-uterine injection in hæmorrhage. In this paper, a case, illustrating the use of infusion of matico as a styptic injection, was given. Some years ago, when, as resident obstetric officer to the Middlesex Hospital, I had ample opportunity for testing the relative value of different forms of intra-uterine injections, I gave infusion of matico a fair trial; but, after due observation of its action in several cases of *post partum* hæmorrhage, of which cases, unfortunately, I have no record beyond that which my memory retains, I could not consider it, or, indeed, any other injection which I tried, so prompt and decided in action as the solution of perchloride of iron, used after Dr. Barnes's method. In other forms of uterine hæmorrhage, I found strong infusion of matico a valuable hæmostatic.

I can hardly think with Dr. Spender that, in the use of intra-uterine injection, it is sufficient to inject the fluids into the vagina; for, although I do not deny that, when both the internal and external os uteri happen to be very patent, some fluid may find its way into the cavity of the uterus, still I think that one could hardly rely upon sufficient entering to act with certainty. The plan I have usually adopted in cases not connected with the puerperal state, has been to pass into the uterus a small silver tube perforated in all directions, and having a little plate at its proximal extremity. The plate prevents the tube from passing too far into the cavity of the uterus, and it also acts as a rest for the directing finger. This small tube is fixed to one end of a gum elastic catheter, to the other end of which an elastic bottle is attached. This simple little apparatus has always answered satisfactorily. I may here repeat what I have recorded in previous communications, that I have never experienced any accident from the use of iron injections; but in their use in *post partum* hæmorrhage, as Dr. Barnes has recently observed, it is highly essential to preserve a passage by the side of the injecting tube, sufficient to allow the free outflow of the injected fluid from the uterine cavity.

CLINICAL MEMORANDA.

THE USE OF ANÆSTHETICS IN EXTRACTION OF TEETH.

DR. J. LAUDER BRUNTON'S "Remarks on one of the Causes of Death during the Extraction of Teeth under Chloroform" in the *JOURNAL* of December 4th, resting on a sound basis of careful physiological research, are of the utmost value to the now anxious administrators of chloroform. For "the extraction of teeth", however, surely chloroform is a thing of the past; its successor, nitrous oxide, carefully prepared and administered, being equal to every requirement, and having almost a blameless reputation. My experience in the extraction of teeth extends over many years; and, till the introduction of nitrous oxide, I was daily extracting while chloroform was being administered. I therefore feel warranted in giving my opinion that, happily, chloroform is no longer necessary in any case for the painless extraction of teeth; and I am anxious lest it should be inferred from the title of Dr. Brunton's paper that its employment in such cases is still not unusual, and lest any should be led, because familiar with its use, to advise the inhalation of chloroform, rather than the nitrous oxide, by those patients. In every respect but one, nitrous oxide seems to me preferable to chloroform in the extraction of teeth; the exception being that, under the oxide, the operation must be over in one minute, while, under chloroform, it may occupy many minutes. But sixty seconds suffice to remove several ordinary teeth; and as cases of acute suffering seldom, if ever, arise from more than two teeth or roots, ample time is afforded for their extraction. When many teeth or roots have to be extracted to prepare for artificial teeth, as convenience alone urges their extraction at one visit under chloroform, the operator should not hesitate to object to its administration, insisting on their being extracted at sufficient intervals under the nitrous oxide.

A. STEWART, F.R.C.S.E., Surgeon-Dentist.

EXTRACTION OF TEETH UNDER CHLOROFORM.

DR. LAUDER BRUNTON has, no doubt, made out a case in support of the rule which he lays down for preventing death during the extraction of teeth under chloroform. I say rule; because the second of the rules which he mentions has been, I believe, long recognised and acted upon in the administration of chloroform. It has been the custom of most experienced chloroformists to administer the anæsthetic, in all but exceptional cases, to the patient in the recumbent position; but it has certainly not been usual in dental operations to render the patient so deeply insensible as to produce *total abolition of reflex action*. Although Dr. Brunton has made out a case in favour of his rule, still there is much to be said against it; and not the least objection consists in the fact that, in operations about the mouth, the more profoundly unconscious the patient, the greater the danger of entry of blood or foreign bodies into the glottis, and the less the power of the patient to resist their effects and to expel them. For Dr. Brunton's words of advice to those about to give chloroform in dental operations, I should like to substitute the one word—don't. Chloroform, undoubtedly, at the present state of our knowledge of its mode of action and our means of combating its deadly effects when they appear, is always dangerous to life; and the danger is so insidious in most cases, that it is impossible with certainty to guard against it. Now, the instances in which it is justifiable to risk life in an operation like tooth-extraction, are extremely rare; and even if no safer anæsthetic were available, the employment of chloroform would be, in my opinion, indefensible. But we have now an agent, the nitrous oxide gas, which, by physiological and practical experiment, has been demonstrated—to say the least—to be much less dangerous to life than chloroform; besides which, it possesses advantages over every other agent for the production of insensibility during tooth-extraction. It is extremely rapid in its action, and transient in its effect; from sixty to eighty seconds of inhalation sufficing to produce complete anæsthesia, and less than a minute being enough to allow complete recovery. It produces no excitement or struggling during exhibition, neither is it followed by nausea, vomiting, *malaise*, headache, depression, or any of the common distressing sequels of chloroform-anæsthesia. With it, also, it is always possible to fix the patient's mouth easily, safely, and firmly open, before the administration by the mere insertion between the teeth of a simple prop; whilst with chloroform, unless a cumbrous gag be used, or unless the patient be profoundly narcotised, the opening and fixing open of the mouth are frequently to be accomplished only with extreme difficulty.

HENRY SEWILL, M.R.C.S., Surgeon-Dentist.

REVIEWS AND NOTICES.

ZIEMSEN'S CYCLOPEDIA OF THE PRACTICE OF MEDICINE. Vol. X: Diseases of the Female Sexual Organs. By PROFESSOR CARL SCHROEDER. The English Translation edited by ALBERT H. BUCK, M.D. Pp. 575. Illustrated. London: Sampson Low and Co. 1875.

To all interested in the study of gynecology, the present volume, which forms one of Ziemsen's valuable series, will prove of much interest. It appears somewhat earlier than was originally intended, "in consequence of its great interest and importance, and in compliance with the expressed wish of many subscribers". It will doubtless be a source of regret to many that they cannot procure the work without subscribing for all the volumes, sixteen in number. For the comfort of those thus circumstanced, we may assure them that the recent works of Barnes, Graily Hewitt, Thomas, etc., which can be obtained separately, will amply compensate them for the loss of Schroeder, which, although a work of surpassing merit, is less calculated to supply the wants of the practitioner than either of the works we have indicated.

It is needless to speak of the general "get up" of the volume. It does credit to the publishers. The translation into English from the original has been undertaken by men fully competent for the task, and leaves little to be desired.

The illustrations—147 in all—are engravings from electrotypes of the originals, and are clear and distinct, although the figure of the outline is stiff and unnatural, and the illustrations in many cases purely diagrammatic.

The index at the end is of little use for reference, being chiefly occupied by proper names, which would have been far better grouped by themselves as an index of authorities. Some little ingenuity is necessary to find the name of any subject that may be desired. Dysmenorrhœa, for instance, has no place except as a subheading under Menstruation. Endometritis has to be sifted out of a long list under the head of Inflammation of the Mucous Membrane—a subheading of "Uterus, Diseases of the". The arrangement is inconvenient and irritating.

The bibliographical references at the heads of chapters are of much service, and in most cases very complete. German authorities naturally preponderate; but English are fairly represented.

The author, well known to us by his *Manual of Midwifery* and by his researches in the domain of gynecology, has endeavoured to make the work as comprehensive as possible, describing, and in many instances figuring, the most unusual forms of congenital defects and malformations: a veritable chapter for the curious in these matters, showing much literary research, and evidently the result of much labour. Hypertrophy of the cervix, in all its different phases and portions, is described at length, most elaborate diagrams being given to show the difference between supravaginal, median, and infravaginal hypertrophy.

The arrangement of the work will scarcely find much favour with the student or young practitioner, who is perforce obliged to start from the symptomatology of disease. Wishing, for instance, to determine the most frequent causes of menorrhagia, he will turn in vain to Schroeder, either to the index or to the heading, if he be lucky enough to find it, for any information on this subject. He must first learn gynecology thoroughly; a single page and a quarter is all that the author devotes to the subject of menorrhagia, and the student will turn from it disheartened. Again, take the subject of sterility. We find no notice of it anywhere, not even in the index, and it is scarcely even mentioned as a symptom under the various disorders that usually produce it. This is clearly a great defect. The majority of those who subscribe for the complete set are probably men who have no special training in gynecology, or whose opportunities of studying the subject are few and far between. They will naturally be disappointed in not being able to see at a glance the usual causes producing sterility, the means adopted for diagnosing the particular cause of the case in question, and in not finding any indications for treatment. It may be well to ignore symptomatology; but the mass of practitioners, we believe, will regret its absence in the present volume.

Nearly one hundred pages are devoted to diseases of the ovaries, including ovariectomy. The whole subject is treated very exhaustively, and we complete the perusal of it with much satisfaction, feeling that we have learned much from the systematic way in which the differential diagnosis of abdominal tumours has been presented to us, and the various methods of operating discussed.

Respecting the treatment of uterine diseases generally, the method suggested is essentially German in many of its peculiarities. Intra-

uterine injections, in place of applications, whether solid or liquid, filling the vagina with fluid through a speculum, so as to bathe the cervix or vaginal walls as the case may be, and other similar methods seldom employed in this country, are recommended. Few practitioners, we imagine, will be satisfied with the seven lines devoted to the treatment of acute vaginitis at pages 493-94.

The author, speaking of Graily Hewitt's cradle-pessary, asserts that "it is not only incorrect in principle, but experience shows that it is not well borne". He regards the method of treatment by intrauterine pessaries as very efficient in appropriate cases, and not particularly dangerous. He removes them during the catamenial flux, to avoid the risk of inflammation. The use of the chain-*lérascur* for the removal of intrauterine polypi "is by all means and altogether to be prohibited"; for "it is difficult of application, and is liable to amputate a considerable area of uterine mucous membrane". The single wire *lérascur* is the one recommended.

No mention is made of vascular growths in the urethra.

We have pointed out what appear to us a few defects in the volume; but, apart from these, the work is one of great merit, and does the author much credit. It is evidently the outcome of much honest and laborious work, and we have no wish to prejudice the professional public, who will not fail to appreciate its intrinsic merits. It is wonderful what an amount of information the author has succeeded in compressing into the space at his disposal; and, considering the rapid strides that have recently been made in the study of diseases of women, the reader will find that justice has been done to the subject regarded from a pathological point of view, and he will be glad to avail himself of the opportunity of making himself acquainted with the clear and concise view of these which the author has presented.

SELECTIONS FROM JOURNALS.

SURGERY.

REMOVAL OF OMENTAL TUMOUR.—Two cases of removal of omental tumour from the scrotum are reported by Dr. J. F. Miner in the *Buffalo Medical and Surgical Journal* for August 1875. The first case was that of a healthy young man, who from youth had been troubled with a scrotal tumour, which had been supposed to depend upon some affection of the testicle. When an attempt was made to remove the tumour, it was found to be omental. The omental mass had probably descended with the testicle in youth, and had increased in size as the patient had grown fleshy. It was firmly adherent on all sides to the inguinal canal. A short ligature was thrown around the mass at the lower end of the canal, and the omentum cut away with scissors. The mass when removed weighed two pounds and a half. The patient, after a somewhat troublesome convalescence, returned home in about a month. The second case was less successful. It was that of a man, sixty-five years old, who weighed three hundred and twenty pounds. Eight years before he consulted Dr. Miner, he began to notice an enlargement of the scrotum. The various physicians whom he consulted seemed to arrive at no satisfactory diagnosis. At the time of the surgical operation, the mass was found, as in the previous case, to be enclosed in a peritoneal envelope, and to be firmly adherent to the margin of the inguinal canal. A ligature was applied as high up as possible. The removed mass was several inches in length and width, and weighed three pounds and a half. In five days, the patient died of peritonitis. Dr. Miner remarks that it is frequently the case that large portions of omentum have to be removed in operations for hernia, but he is not aware of a report of similar cases to the two which he describes.

EXCISION OF A GALL-STONE.—Dr. A. Mödel describes in the *Ärztliches Intelligenz-Blatt*, No. 41, 1875, the case of a man aged about 50, who had for a year and a half suffered from pain in the abdomen, at first coming on at rare intervals, but afterwards more frequently and severely. There was no hernia. He was habitually constipated, and his skin was rather sallow. On examination, some swelling and redness were found in the right hypogastric region; and a little more than an inch and a half below and to the outer side of the umbilicus, in the centre of the redness, was a minute opening, from which a small quantity of yellowish viscid matter escaped on pressure. A small sound introduced into the opening came into contact with a rough gritty substance at the depth of about seven-eighths of an inch. The opening was dilated with a scalpel, and the substance was removed. It was a calculus of the size and shape of a nutmeg, with a rough crumbly surface, of a dark brown colour; its outer layer, which

was comparatively soft, presented numerous fine fissures. On physical and chemical examination, it was recognised to be a gall-stone, containing, *inter alia*, 47 per cent. of cholesterine. It had become encysted in the abdominal wall, lying in a cavity nearly as large as a walnut, lined with a smooth membrane, which contained also an abundant thin, fibrous, yellowish, nearly transparent secretion. No connection with the gall-bladder could be traced. The wound was dressed with charpie, and subsequently touched with nitrate of silver, and was quite healed in ten weeks. The patient has since continued in perfect health.

AMPUTATION AT THE ELBOW-JOINT.—Dr. George W. Say (*Boston Medical and Surgical Journal*, September 16th), alluding to amputation at the elbow-joint, says that two considerations have probably deterred surgeons from performing this operation: fear of ulceration of the cartilages, and a long, club-shaped, unwieldy stump. The first has been proved to be groundless. In many, if not in most cases, the flaps unite as readily over cartilages as over the sawn extremity of bone. Whether the second objection is of sufficient importance to overbalance the increased danger of higher amputation, is by no means proven. It is asserted by good surgical authorities, that the redundant size of the end of the bone becomes in time reduced, and leaves a very comely and useful stump. It is admitted by every one, that the less the part removed, the greater the chances for the patient's recovery. It is also admitted, that the more the sheaths of the muscles and the medullary cavities of the bones are interfered with, the greater are the dangers of pyæmia, osteo-myelitis, necrosis, profuse suppuration, etc. These are certainly strong reasons in favour of joint-amputations.

MEDICINE.

ECZEMA PRODUCED BY TINCTURE OF ARNICA.—Dr. Whittaker has (*Ohio Clinic*) lately encountered several cases illustrating the evils of the local application of tincture of arnica. One young man with orchitis applied it, and came to Dr. Whittaker with an extensive and profound eczema, which lasted for three weeks. Another man, having let a tenpin-ball fall upon his toes, applied it to relieve the pain, and had a violent eczema, which was not cured for two weeks. At the society at which this communication was read, Dr. Longworth mentioned the fact as something peculiar about this drug that the majority of persons may use it with impunity, but it will now and then act as a virulent poison producing an eczema, not limited to the seat of its application, but which becomes universal, and is often very obstinate to treatment.

HÆMATURIA.—Dr. David Choate (*Boston Medical and Surgical Journal*, September 16th) reports the case of a man aged 40, who was affected with what seemed to be a purely idiopathic hæmaturia, the effect of the changes induced in the system by the lack of proper nutriment and excess of alcohol. Albumen was present, but only in quantity proportioned to the amount of blood, which was always intimately mixed with the urine, and was never passed by itself, either in liquid or in coagula. There was neither mucus nor pus present, and no casts could be discovered. The loss of blood continued for about seven months, the patient finally becoming excessively weak and anæmic. All the ordinary astringents were administered; the only one which had even a temporary effect being gallic acid in doses of from five to seven grains every two hours. Hypodermic injections of one-fifth to one-fourth grain of ergotin were commenced, and were continued for five days, when the stomach became irritable, vomiting occurred, and they were stopped. At this time, the urine suddenly became clear, and continued so. Twenty-four hours later, the patient had a sharp attack of pain in the course of the right ureter, followed by the passage of a small coagulum, apparently moulded by the ureter. The patient gradually recovered from the condition of extreme anæmia into which he had sunk.

MATERIA MEDICA.

FORMULA FOR THE COMBINED ADMINISTRATION OF COD-LIVER OIL AND PHOSPHORUS.—Dr. Edward C. Mourn (*New York Medical Record*, September 18th) has employed the following mixture with the happiest results, patients taking it readily who could not bear the plain cod-liver oil at all. R Yolks of three eggs; cod-liver oil, 8 ounces; sherry wine, 4 ounces; phosphoric acid, simple syrup, of each an ounce; bitter almond water, 8 ounces; rectified spirit, a drachm. Rub the eggs up in a mortar, adding the oil spoonful by spoonful. Last of all, add the phosphoric acid.

BRITISH MEDICAL ASSOCIATION:
SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, DECEMBER 11TH, 1875.

THE WAINWRIGHT CASE IN ITS MEDICO-LEGAL ASPECTS.

THE trial of the Wainwrights, which occupied the Central Criminal Court for the long period of nine days, adds another *cause célèbre* to the criminal records of England. For the intense public interest excited by this trial, we can find no parallel except in that of William Palmer, who was convicted in 1856 of murdering his friend, John Parsons Cook, by poison. Although these cases differ from each other in the mode selected for the destruction of life, they bear a strong resemblance in the cunning and treachery displayed by the criminals, as well as in the efforts made to conceal the crimes and defeat the ends of justice. Palmer and Wainwright were not of the ordinary class of criminals; they had planned the act of murder with coolness and premeditation, and each had taken, as he believed, such precautions as to render detection difficult, if not impossible; yet a small matter betrayed both, and brought their crimes to light. An ill-packed parcel of mangled human remains in the one case, and a missing pocket-book in the other, were the accidents by which their crimes were revealed. In the case of Wainwright, the murder was actually concealed for a year. The trials of the two criminals occupied the Central Criminal Court for an unusually long period; but there was not in the trial of Wainwright that conflict of scientific evidence which imparted such a great professional interest to the trial of Palmer. Although two medical witnesses were on the recent occasion called for the defence, their evidence was not such as to throw any doubt on the guilt of the accused, or to influence in any way the verdict of the jury.

We may here note another point in which these cases bear a strong resemblance, namely, that both criminals, in spite of the clearest proofs against them, strenuously denied their guilt. The criminal Palmer did not go so far as Wainwright in calling God to witness that he had not committed an act of murder. He refused to make any confession, and merely contented himself by saying, on his way to the scaffold, "Cook did not die from strychnia". The minds of some persons were no doubt influenced at the time by this stern refusal on the part of the criminal to admit his guilt, and they were inclined to take this reticence as a proof of his innocence. The fallacy of accepting any statement made by a convicted criminal as a proof of his innocence, is plainly illustrated by the case of Wainwright. This man, in the face of the most complete proofs of his guilt, from the medical and circumstantial evidence, and standing, as he said, "on the brink of eternity", affirmed in the most positive manner that he did not commit this act of murder, and that he neither buried nor exhumed the remains which were found in his possession!

The facts of this remarkable case have been brought so fully before our readers, that we need only refer in this place to the salient points of general interest, and to the medico-legal evidence on which the prosecution relied for conviction.

Henry Wainwright was indicted for the murder of a woman with whom he had for some time cohabited, Harriet Louisa Lane; and his brother, Thomas Wainwright, was indicted for aiding and abetting in the commission of this murder, and as an accessory after the fact. It may suffice, with regard to the last-mentioned prisoner, to state that

the jury upon legal grounds, properly convicted him as an accessory after the fact, so that his case will require no further notice here.

The evidence leading to a motive for an act of murder, showed that the prisoner, Henry Wainwright, a married man with a wife and five children, had formed a secret connection with the deceased Harriet Lane, and had had by her two children. He paid for their support, but with difficulty, as he was in embarrassed circumstances. In the autumn of 1874, this led to quarrels between the prisoner and the deceased. He became indifferent to her, and she fell into great distress. She was moved by the prisoner from one lodging to another, passing under a false name as the wife of the prisoner, who had also assumed another name. By an arrangement with the prisoner she left her lodging on September 11th, 1874. He had provided her with means to discharge all her debts, and she was then in good health and spirits. From that date she was never afterwards seen alive. Application was made to the prisoner by her friends for information respecting her, but his answers were not satisfactory. By his statements, and by the use of false letters and telegrams, he led the friends to believe that the woman had gone away with another man whom he named. This also was proved to be a falsehood, and the matter dropped, until September 11th, 1875, exactly a year after the disappearance of the deceased.

At this date, the prisoner was found removing from a grave on premises in the Whitechapel Road, of which he had the key, the remains of a body, which proved to be the body of a woman, and was alleged to be that of the missing Harriet Lane. It was further alleged, that, when she left her lodging on September 11th, 1874, she went in a cab to the premises in the Whitechapel Road where this body was found. She took leave of her friend and her children, and made a statement which, owing to the strict rules of evidence, was not admitted at the trial. It has now transpired, that she went directly by an appointment with the prisoner to these premises, and was never again seen alive. Other facts led to the conclusion that the prisoner had met her there, murdered her, and buried her body in a grave dug beneath the floor of one of the rooms.

In September 1875, these premises were likely to pass into the hands of others. This would have led to a discovery of the remains, and it rendered their removal a necessity. It was in thus transferring them to another hiding-place in Southwark belonging to his brother, that he was found in possession of parts of a mangled human body for which he could not reasonably account, and concerning which he made what was proved to be a false statement.

The body had been recently cut up, and when taken possession of by the police, the pieces were packed in two parcels of American cloth and corded. It was proved that, on September 10th, 1875, the prisoner had employed his brother to purchase for him a spade and a small chopper or axe. These articles were found on the premises, and had evidently been recently used. The chopper had upon it putrescent animal matter, and the spade clay mixed with lime. On the same day, Wainwright himself had purchased three yards of American cloth and a quantity of cord, similar to that used in tying up the remains.

The medical evidence given at the trial by Mr. Larkin and Mr. Bond was directed (1) to the cause of death, and (2) to the identity of the body as that of the missing woman, Harriet Lane. The cause of death was sufficiently obvious. It is thus concisely stated by the learned judge from the evidence given by these two medical witnesses.

"The woman was found with two bullets in her brain, and a third was found in a hair-pad at the back of the head. Besides that, there was a cut extending from the centre of the throat to the angle of the lower jaw, which had severed all the tissues, and which must have been inflicted with very considerable force. Such were the appearances; and, from them, there could not possibly be a doubt that the woman had been deprived of life by pistol-shots. There was reason also to think that the first shot was just behind the right ear; and the bullet was found to have caused extravasation of blood to three inches in circumference. Another bullet was found in the brain; and there was a cut in the throat; the other bullet having probably been fired when life was ebbing; and another had been flattened against a mass of hair-

pins which had no doubt prevented it from going into the head. Therefore, we have a fact beyond all doubt, that this poor woman, whoever she was, came to her death in that way; and the probability is, that the murderer came up from behind and fired the first shot from the back of the head. It is probable, also, that, finding the first shot had not taken effect, the person using the pistol had brought it round and fired it just behind the right ear; and then, not certain it would answer the purpose of destroying life, the third shot was fired. My own impression is, that the attack was made from behind."

In reference to the cut in the throat, it is important to state that, it was a cut of old date, *i. e.*, it had clearly not been produced in the recent mutilation of the body; but, in the cautious words of Mr. Larkin, it must have been "inflicted immediately before or immediately after death". As the principal arteries of the throat were divided, it would have been sufficient of itself to cause death. It is probable, however, as the learned judge remarked, that the bullets were discharged first, and while the woman was dying from the effect of the shots, the throat was cut to make sure of her speedy death. It is most improbable that, with a severe cut of this kind in the throat, an assassin should have taken the trouble to fire three separate shots into the head.

The cause of death, therefore, although a year had elapsed, was clearly proved by the medical evidence. Then came the question, Could this have been an act of suicide on the part of the deceased while with the prisoner? Had the throat alone been found cut, and no bullet-wounds on the head, there might have been a difficulty in answering this question; but, taking these wounds together, the answer given by Mr. Larkin to a question put by the Attorney-General was perfectly justified by the medical facts. "It is perfectly impossible for the woman to have inflicted the wounds upon herself."

In referring to the theory of suicide, which was made a part of the elaborate defence, it was truly described by the Lord Chief Justice as a vague and even a wild suggestion; and, as he well observed, it involved the supposition that the deceased had dug her own grave. The propounding of a theory of this kind to account for the facts simply proved that there was no reasonable ground of defence. With such an admission, there would be no difficulty in allowing full credibility to the miracle ascribed to St. Denis.*

The cause of death, and the fact that it was an act of murder, were therefore clearly established.

We now come to the question of *identity*. Were these the remains of the missing woman, Harriet Lane? The answers to this part of the case were based partly on medical facts, and partly on the discovery of certain articles of dress in the grave from which the body had been removed. The features were not recognisable. The body had been irregularly cut up into ten pieces, and much mangled. It was decomposed; but, as a quantity of chloride of lime had been used in the burial of it, putrefaction had been in some degree retarded. Nevertheless, the medical witnesses agreed that the appearances were such as might be consistent with a twelvemonths' burial superficially in the earth.

The relatives could only speak generally to the slender form and stature of the body, and the smallness of the hands and feet, as points in which it resembled that of Harriet Lane. The colour of the hair (a light auburn), the absence of a tooth in the upper jaw on the right side, and the presence of a scar or cicatrix from a burn received many years before, and still remaining on the right leg below the knee, were also circumstances which strengthened their opinion. We may add to these proofs the discovery in the grave of some buttons and other articles of dress, such as those which were actually worn by the deceased on the morning on which she left her lodging to meet the prisoner on the premises. These were clearly identified by the relatives. The greater part of her dress had been destroyed by burning, and the ashes were found in the grate.

* This stupendous miracle, as it is described by Mrs. Jameson, consisted in the body of the martyr rising up on its feet after decapitation, taking up the head in his hands, and walking the space of two miles to a place called the Mount of Martyrs, known in the present day as Montmartre. (*Jameson's Legends*.)

The direct proofs of identity were: 1. The *age*. The age of the deceased was twenty-four. Judging by the wisdom teeth, three of which had appeared, this corresponded with the age assigned to the body. 2. *Stature*. It was inferred, but by no means directly proved, that the deceased was five feet and a quarter of an inch in height. The remains, when put together, represented a stature of four feet eleven inches and one-eighth of an inch. This made about an inch difference, which was accounted for by one of the medical witnesses, as a result of the shrinking of the intervertebral substance. This slight difference in measurement was made a strong point in the defence; it gave rise to much discussion, and, as it appears to us, much unnecessary cross-examination. Had the body been entire, there might have been some reason for dwelling upon this difference; but there would always be a great difficulty in taking the exact length of a dead body cut into ten pieces, and no two persons would be likely to agree in the measurement. A difference of an inch in such a case, assuming that the stature of the deceased had been accurately determined just before her disappearance, would be really unimportant in itself.* When the stature so nearly corresponded, a medical witness would be justified in saying that, considering the mutilated state of the remains and the date of interment, there was nothing inconsistent with the body being that of the deceased. 3. The *colour of the hair*. This is stated to have been slightly different; but the difference was consistent with the hair of the remains having been buried for a year in the earth, and exposed to the action of chloride of lime. Apart from this consideration, there are so many women in the world with hair of a similar shade or colour, that no great reliance can be placed on a resemblance of this kind in a disputed question of identity.

The medical points upon which the question turned were chiefly the presence of a scar or cicatrix from a burn in the right leg below the knee, and the state of the uterus as indicative of a woman having borne a child or children. With respect to the cicatrix of a burn, it is a significant fact that its existence was mentioned by the father of Harriet Lane before its presence had been discovered by the two medical witnesses. They removed the adipocere and other matter on the body which concealed such superficial marks, and then readily found it in the part indicated. It was distinctly puckered, and presented all the usual marks of a scar produced by a burn from a red-hot poker. The sister who dressed the burn, which had occurred many years previously, described the nature of the accident; and her evidence was corroborated by that of several relations and friends.

A medical witness, Mr. Aubin, who had examined the remains as an expert on the part of the defence, admitted the existence of a scar on the right leg, but stated that, on a subsequent examination, he discovered another scar on the left leg. In what way this discovery could have helped the case of the prisoner we do not quite see. It could not neutralise the positive evidence afforded by the cicatrix on the right leg, or have shown that this was not the body of Harriet Lane. It might well have happened that she had more recently met with another slight accident, of which the relatives were not aware. All doubts and difficulties on this point were, however, satisfactorily removed by the witness himself. He found the body much decomposed, and he would not swear positively that the dark mark which he described as a "scar" was not the effect of decomposition.†

* The stature of Harriet Lane was merely a matter of inference from a photograph taken of herself and a sister now living. They were taken side by side when girls, or at any rate some years before the date of Harriet's disappearance. The living sister, as a grown woman, measured five feet and one-eighth of an inch. Upon the basis of this photograph an additional eighth was assigned to the stature of Harriet. This is surely a very flimsy ground upon which to base a difference of eighths of an inch in comparing the statures of two grown women. Had the missing woman been measured shortly before her disappearance, and a difference of five or six inches found, there would have been some reason to argue from this that the proof of identity failed in one important particular.

† It is the first time that we have heard of a dark mark in the skin, such as might result from putrefaction, being mistaken for a cicatrix resulting from a wound or a burn. With any ordinary examination of a dead body, we believe such a mistake to be impossible. When the portion of skin was handed by Mr. Aubin to the Lord Chief Justice, he asked "Where is the scar?" It was then handed to the jury and Attorney-General. The latter tried to find the scar by the aid of a magnifying glass; but, judging by his cross-examination of this witness, he does not appear to

The other medical facts connected with identity referred to the condition of the uterus of the woman whose remains were found; *i. e.*, whether the appearances which it presented were such as to indicate conclusively that she had borne children. The missing Harriet Lane had had two children by the prisoner, the last having been born some time before Christmas 1873; therefore about nine months previous to her disappearance. From their examination of the uterus, Mr. Larkin and Mr. Bond came to the conclusion that this woman had borne a child. On the other hand, Dr. Alfred Meadows, who appeared as an obstetric expert for the defence, stated that, in his opinion, the woman of these remains had never borne a child. He qualified this opinion, however, by stating that he believed it to be impossible to decide this question in any case with absolute certainty. If this witness had been able to swear positively that the indicia of childbearing were absolutely certain, and could never be mistaken for a virgin or unimpregnated state of the uterus, his evidence would have gone far to show that this could not have been the body of Harriet Lane. The numerous facts establishing identity in other respects would have gone for nothing. He felt, however, he could not carry his evidence to such an extent, and the effect of it simply amounted to this: "I differ in opinion from the witnesses for the prosecution on the answer to this question. Nevertheless, those witnesses may be right, for I well know that there are no certain criteria by which the question can be positively answered in the affirmative or negative." This material qualification of his opinion was all that was really necessary to sustain the case for the prosecution. Mr. Larkin and Mr. Bond might be right in their conclusion. There was nothing to show that they were wrong.*

Another point, which scarcely requires notice, was whether, Harriet Lane having worn a wedding-ring and keeper like a married woman, there would not be some mark or furrow on the ring-finger. It is stated that there was no appearance on the fingers of the woman whose remains were found, to indicate that she had worn a wedding-ring. The learned judge, however, remarked that, as the fingers were small, slender, and not full, they would not be likely to show any mark or depression. There was, in fact, a similar condition of the fingers of Harriet Lane.† We may add to this observation, that the production of such marks will depend greatly on the length of time during which the ring had been worn, and the evidence left it clear that Harriet Lane had but for a short time before her death passed for a married woman. Besides, after the dead body of a woman of slender form had been buried for a year, there would be a shrinking or desiccation of the fingers, which might remove such an appearance even had it at any time existed, of which there was no evidence.

There was practically no defence to the great questions at issue in this case—the act of murder—the perpetrator and the identity of the murdered woman. That the crime had been carried out with premeditation, precaution, and some attempt at concealment, was amply proved. On September 11th, 1874, the prisoner had in his possession a revolver, which the bullets found in the head would fit. On September 10th, 1874, the day before he had made the appointment for her to go in a cab to his premises in Whitechapel Road, he caused to be purchased half a hundredweight of chloride of lime; this substance had been largely used in disposing of the remains; it was found in the grave and scattered over the body. Whether it was intended to accelerate decomposition of the dead body, or to destroy the effluvia likely to arise from it, does not appear. If with either object, it failed. The use of this substance appears to have somewhat retarded decomposition, and not to have prevented the escape of offensive effluvia. The

have been successful. Testimony like this—for it does not amount to evidence—should not have been given. Its tendency could only be to mystify the case, and raise a false issue. If the witness were not able to distinguish a mark from the effects of putrefaction from one resulting from local injury, he was not justified in describing it as a scar.

* The special reports of Mr. Larkin and Mr. Bond are published in another part of this JOURNAL. The reader will there find a full description of the appearances presented by the uterus.

† Harriet Lane did not wear a ring for some months before her death, as it had been pawned.

chloride of lime was provided, the joists of the floor cut, and a grave was dug beneath ready to receive the body of the woman before she had left her lodging! A year afterwards, when the necessity for its removal came, the prisoner caused to be purchased a spade, a chopper, American cloth, and cord, for cutting up and packing the remains. Yet this is the man who boldly stated, after his conviction, that he did not commit this act of murder, and had had nothing to do with the burial and exhumation of the body!

In our judgment, the defence set up for Henry Wainwright is beneath criticism. If, instead of dwelling upon trivial discrepancies in the evidence of the non-medical witnesses, as to their remembrance of persons whom they had casually seen, and events which had occurred a year before, the colour of a man's whiskers and moustache, etc., the learned counsel for the defence had been able to give a reasonable explanation of the purchase of chloride of lime in 1874, and of the spade, axe, and other articles in 1875, the jury might have been induced to take a different view of the case.

So, again, if he could have satisfied them on the medical evidence that suicide might have been committed by the woman first discharging the bullets into her head, and then cutting her throat, or *vice versa*, with a possible purchase of chloride of lime and the digging of her own grave, the verdict might have been different. He dealt, however, with what lawyers call the fringe of the case, and not its substance. The main facts, pointing to a most deliberate murder by the prisoner, were either not noticed, or in a manner to render the case against him more conclusive. Medical science was of great service on this occasion, and the two witnesses for the crown who conducted the examination of the body, acquitted themselves creditably. The witnesses for the defence were really, so far as their evidence went, witnesses for the prosecution; for there was no substantial point on which they could either contradict or nullify the medical evidence given on the part of the Crown. The only real approach to a conflict, was in reference to the opinion of Dr. Meadows, who, as an obstetric expert, could find no proof of child-bearing; but the summing up of the judge, and the unanimous verdict of the jury, can now, we should think, leave no doubt either on his mind or that of any man capable of estimating and weighing evidence, that the ghastly remains taken from the grave of the dark room in the Whitechapel Road were, beyond any reasonable doubt, those of the missing woman Harriet Louisa Lane, and that Henry Wainwright has been justly convicted of a foul and premeditated act of murder.

THE MEDICAL DEFENCE ASSOCIATION.

THOSE who, during the last twelve or fourteen years, have interested themselves in medical politics, must have noticed a deep and widespread desire on the part of medical practitioners to be protected from those who practise without legal qualification. It was hoped that the Medical Act of 1858 would be a very efficient agent in putting a stop to unqualified practice; but it has been found to fail in several instances, and its penal clauses are now rarely put into operation. Although the Medical Act is thus practically inoperative, the Apothecaries' Act remains in force, and supplies a comparatively summary and inexpensive mode of proceeding against those who illegally practise as apothecaries. Proceedings under this Act must be taken in the name of the Society of Apothecaries, and the consent of the Society must be obtained before an action can be brought against an unqualified practitioner for the recovery of the penalty of £20, to which such unqualified practitioners render themselves liable.

The Society itself never takes proceedings against unqualified practitioners; but it allows its licentiates to do so in certain cases in its name, provided that the action is brought without any expense to it. For obvious reasons, individual practitioners naturally shrink from incurring the expense and odium which attach to the prosecution of persons who are practising without legal qualification, and thus the Act has practically remained a dead letter. Pending an alteration of

the Medical Act, and the appointment of a public prosecutor, the only practicable plan of dealing with the question appears to be the formation of an association of registered medical practitioners, whose function shall be the prosecution of all clear cases of illegal practice that are brought under their notice. The formation of such an association was proposed several months ago in the columns of this JOURNAL by Mr. George Brown; and we are pleased to learn, from the large and successful meeting that was held at the rooms of the Medical Society of London last week, that the idea has met with a large amount of support from the members of the medical profession, and that there is every prospect of the Association being established on a firm basis.

From the report of the Provisional Committee, we learn that the primary object of the Association is "the suppression by every legitimate means of the practice of medicine and surgery by unqualified persons". This is an useful and a laudable object, and one that not only commends itself to the whole medical profession, but is also deserving of the sympathy and support of the public. The profession, doubtless, suffers somewhat from illegal practice, but this is an insignificant consideration in comparison with the injury that is done to the public by the ignorant and designing persons who assume the position and functions of medical practitioners. Numerous cases might be gleaned from the records of our coroners' courts where life has been sacrificed through persons having been called in to attend cases of severe illness who have had no professional education, and consequently have been unable to diagnose the disease or prescribe the proper treatment, while others show a course of life-long fraud and black mail.

The Defence Association has shown that it can accomplish some good. Already it has, we understand, prosecuted in three cases of illegal practice in the East End of London, and in each instance has recovered under the Apothecaries' Act a penalty of £20. Other prosecutions are being proceeded with, which will, we hope, be attended with similar success.

We shall watch the proceedings of the Defence Association with much interest; and, as long as it continues to use its influence in the exposure and punishment of imposture and deception, it will give us pleasure to extend to it our cordial support.

THE next International Medical Congress is to be held in Geneva in 1877.

M. DENUCE communicates to the Académie de Médecine of Paris, a case in which he successfully performed external hysterotomy on a woman, whose life was endangered by excessive hæmorrhage due to old-standing irreducible inversion of the uterus.

THE Academy of Medicine at a recent sitting, voted for a foreign corresponding member; the ballot showed 53 votes for Dr. Swann of Liege, 24 for Dr. Faget of New Orleans, 2 for Dr. West of London. Dr. Swann (a well-known histologist) was therefore elected.

THE Wainwright case is one which has involved some important questions in medical jurisprudence; and it will remain a leading case in the books. We publish an analysis of the evidence from the pen of an eminent authority; and furnish, also, by the courtesy of Mr. Larkin and Mr. Bond, the text of their reports, as well as some comments by Dr. Meadows at the Obstetrical Society, on some points raised by the evidence which he tendered to the defence.

THE announcement of the death of Mrs. Palmer from enteric fever in Grosvenor Square has naturally attracted attention, and caused some anxiety as to the sanitary condition of that wealthy quarter. We are glad, therefore, to be able to state, on the authority of Dr. Corfield, the medical officer of health of the district, that the disease was not contracted in that locality. Mrs. Palmer contracted the fever in the country, and was brought home ill with it. The proper sanitary precautions have been adopted.

FOOT-AND-MOUTH DISEASE.

WE are happy to be able to announce that the negotiations to which we recently referred as being in progress between the Royal Agricultural Society and the Committee of the Brown Institution, have been brought to a successful termination: the Council having, at their meeting on Wednesday last, agreed to devote a sum of money, not exceeding £500, for the carrying out of researches, under the direction of Dr. Burdon Sanderson, on the etiology, nature, and properties of pleuropneumonia and foot-and-mouth disease. Of these two epizootics, the former has a remarkable pathological interest as an infective, and, in all probability, communicable disease, localised in an important organ, and producing lesions which, although very characteristic, have been as yet very imperfectly investigated. The other disease derives its interest from its very extensive prevalence, and the great losses which it has recently occasioned in this country. We confidently anticipate that the Royal Agricultural Society, which has, in taking this step, exhibited an enlightened appreciation of the practical value of knowledge, will find themselves justified by the result. It is not, of course, to be expected that any new methods of cure will be discovered, but we believe they will find their reward in the greater efficiency of practical measures for the prevention of these plagues. We have had in the past examples enough to prove that whatever may be the value of the general principles of so-called "sanitary science", the only certain guide in the prevention of epizootic and epidemic diseases is the knowledge of the nature and tendency of the particular disease to be prevented.

SUPPLY OF SUBJECTS FOR DISSECTION.

IT will be some consolation to those interested in medical education to learn that the serious deficiency in the supply of subjects at the metropolitan schools, to which we called special attention last week, has not extended to at least one of the leading provincial schools. A correspondent informs us that the dissecting-room of the Liverpool Royal Infirmary School of Medicine continues to receive the usual ample supply of subjects which it has hitherto obtained. During the present session, the number of bodies sent for dissection since October 1st is fourteen, which, with one body preserved during the summer recess, makes a total of fifteen subjects for distribution amongst seventy students, the number actually engaged in dissection up to the present date.

PATRIOTISM *versus* HUMANITY.

THE *Allgemeine Medicinische Central-Zeitung* publishes the following letter to show that there are still some with whom hatred of Germany is a stronger feeling than even life itself, or at least regard for the lives of others. "Ingrande, October 29th, 1875. Gentlemen,—I have this morning received a printed circular, in which the use of the natural bitter water of Friedrichshall is recommended to me. In my beloved country, France, we have everything that we want—and everything much better too; mineral waters among the rest. Moreover, I would much rather let my patients die than order them to use anything whatever which your country produces. With best respects, Dr. F. Lannelongue, Doctor of Medicine." It might be hoped that there is some mistake about this.

THE RAINFALL AND PUBLIC HEALTH.

IN almost all parts of England, the rainfall during the eleven months of the present year already elapsed has been excessive. The year 1872 was one of the wettest years on record, but, at Oxford, the rain which had fallen before November 15th of this year exceeded the fall there in 1872. The rainfall in September, October, and the early part of November, was reported from nearly all recording stations as excessive. At Bristol, during the nine weeks ending November 20th, the total rainfall was 15.942 inches, the average quantity for the same period being 6.200 inches; consequently, the excess above the average was 9.742 inches in the nine weeks. In other localities the down-pour was equally great. The result has been a series of disastrous floods in all the low-lying districts of the central parts of the country,

the nearest parallel to which occurred as far back as November, 1852, during the lying-in-state of the Duke of Wellington. Where drainage is good, wet seasons appear to be generally healthy; at any rate, in large towns, where some of the principal causes of disease and death are impurities in the atmosphere, drains, etc. And the reason of this is obvious. The rain in descending first washes the atmosphere, from which it doubtless carries off zymotic particles, and then mechanically cleanses the streets and sewers; consequently, an abundant rain usually coincides with a low death-rate in town districts. But, in low-lying and badly drained localities, where the water rises and enters the basements of houses, especially when the surface-water is added to the sewage of overflowing drains, diseases are wont to be rife. It is to be feared that the present wet season will not prove an exception to the rule. But for the statistics which will show the exact effect of the rains and floods upon the public health, we must wait until the Registrar-General furnishes his next valuable quarterly report. The weekly returns of deaths in the eighteen largest English towns do not as yet apparently exhibit any marked feature due to the prevailing wet. It is certain, however, that in many of the flooded districts, in which the houses have for days, and even weeks, had water lodged in the lowest rooms, much sickness will prevail, since the walls and floors will remain damp and unwholesome for weeks to come. To add to the misery of the inhabitants, who in the flooded districts almost all belong to the poorer classes, they have, by reason of the flood, lost in many instances a considerable part of their property; whilst the extreme cold which has set in at this early period of the winter, will greatly aggravate their troubles (at a time when they cannot afford to pay for extra coals), produce disease, and augment the death-rate. Under these circumstances, we are extremely glad to find the new Lord Mayor inaugurating his term of office by raising a national subscription for the relief of the sufferers; and we feel confident that nothing further is required to produce a sum sufficient for the relief of the distress and disease which are likely to prevail still further, than a true appreciation upon the part of the public of the really urgent need there is for help. We are pleased to observe, that the sum already subscribed exceeds £16,000.

TWO DEATHS FROM THE ADMINISTRATION OF CHLOROFORM.

MR. CHESHIRE of Birmingham favours us with the following report. An inquest was held on Saturday last, at the New Inn, Union Street, Smethwick, before Mr. E. Hooper (coroner), on the body of Evan Miles, aged 42, gardener, in the employ of Captain Thurston, Targate Hall, parish of Towyn, Merionethshire, who died on Tuesday, from the administration of chloroform. The deceased received a gunshot wound in his right eye, while beating for game, on the 16th ult.; and, the sight being endangered, he came from Wales to Smethwick, to the house of a man named Hughes, for the purpose of having an operation performed. Some time previously, the gamekeeper at Targate Hall had gone through an operation at Mr. Hughes's house for a similar accident. Mr. Cheshire of Birmingham, and Mr. W. F. M. Jackson, surgeon, of Smethwick, performed the operation upon Miles, who died from the administration of the chloroform. After Mrs. Miles and Mrs. Hughes (who had witnessed the operation) had given evidence, Mr. Jackson was examined. He said that he was asked to be present at the operation of taking out the eyeball of Miles, which Mr. Cheshire considered necessary for the safety of the sight of the other eye. He accordingly met Mr. Cheshire at the house of Mr. Hughes. Mr. Cheshire brought with him a two-ounce bottle, containing chloroform, quite full. While Mr. Cheshire was administering the chloroform, witness felt the pulse of the deceased, and found it quiet and regular. Miles was perfectly free from excitement. Mr. Cheshire examined the heart of the patient, and pronounced it sound. Altogether, the conditions appeared to be favourable to the administration. Mr. Cheshire poured forty or fifty drops of chloroform on a towel, and the deceased immediately became semi-unconscious. He then commenced the operation; but the deceased not being sufficiently under the influ-

ence of the chloroform, about forty or fifty drops more were administered, and the operation was resumed. Almost immediately that the operation began, witness noticed a failure in the patient's pulse. He at once seized the patient by the feet, and lowered his head for the blood to run through the heart. He afterwards practised artificial respiration, with the view of restoring him. Mr. Cheshire assisted him as much as possible, and applied a piece of wood from the fire to his breast, with the hope of producing animation. Other means were adopted, but all in vain. The patient died in about half an hour after the chloroform was administered. His own opinion was that Mr. Cheshire had administered the chloroform in a particularly careful manner, and every precaution had been taken with the view of ascertaining whether the deceased was in a condition to be subjected to chloroform. He had seen hundreds of cases in which chloroform was given, but had never before seen a case in which death had resulted. Mr. Cheshire informed him that, in all his experience, he had only known one death from chloroform.—The coroner remarked that there was little doubt that every precaution had been taken by the medical men, who were both practical surgeons, Mr. Cheshire being one of the most eminent oculists in the midland counties.—The jury returned a verdict of "Death from the effect of the administration of chloroform".—We hear of another death recently in London in the practice of a metropolitan hospital surgeon, on which no inquest has been held, and of which we have seen as yet no public notice.

THE SICK AND WOUNDED IN WAR.

THE Society for the Relief of Sick and Wounded Soldiers is about to send representatives to Cetigne, with the sanction of its patroness, the Empress of Russia, to relieve Bosnian and Herzegovinian families which have suffered from the effects of the insurrection. The Society is preparing a hundred beds for the sick, and will send four physicians, together with some Sisters of Mercy, apothecaries, and field-surgeons, for the care of the wounded. The monthly expenditure for the above hospital purposes is estimated at 10,000 roubles.

THE CHILDREN'S HOSPITAL.

WE have on several occasions drawn the attention of our readers to the important reforms which have been introduced into the out-patient department of the Children's Hospital. The following extract from the *Charity Organisation Reporter* shows what have been the results of the inquiry system during last quarter.

The Secretary read a summary of returns of Children's Hospital cases during the three months ending September 30th. He stated that 3,498 cases had been registered at the Hospital during that time; that was to say, 3,498 patients had received letters, and had been told that before a second attendance they must get a district committee to stamp them, in proof that the statements they had made as to earnings were correct. It appeared from the returns that 1,487 letters only were brought to the offices; of these, 1,213 were stamped, and in the case of 266 the stamp was refused.

MEDICAL PRACTICE IN SIBERIA.

THE *Gazette Médicale de Paris* extracts from the *Courrier Médicale Russe* an interesting description of the life of some practitioners in Siberia. Dr. N., says the narrative, having arrived at the shores of the Lena, applied himself to the discharge of the duties devolving on him. In the province where he was located—Yakutsk—the practitioner has to act as a hospital, district, town, and village medical officer, and even to compound his medicines. Very frequently he has also to act as director, *feldcher* (a sort of barber-surgeon), and steward of the hospital, although the names of persons supposed to perform these duties are borne on the official lists. In the course of ten months, Dr. N. travelled, in his professional visits, over 5,000 versts (about 3,385 miles); the weather being sometimes so cold that the spirit of wine froze in the thermometer. In travelling, he was obliged to carry provisions with him; for it was very often impossible to get any others. The warmest clothing is not always sufficient, and two of Dr. N.'s predecessors died of frost-bite of the lower limbs. At night, Dr. N. was obliged to rest

in the *iurtas*, a kind of hut having the walls and roof covered with dung, which freezes and produces so great a lowering of temperature in the *iurta*, that the air within is as cold as that without. Dr. N. has been unable to continue his nomad life, in consequence of the insufficiency of his pay. Besides attending to numerous patients, Dr. N. has published an excellent description of the medical topography of the country, and has described the pathogeny and symptoms of two diseases called in Siberia *prokava* (probably a modification of elephantiasis) and *miriatshilitshestvo*.

PRIZES OF THE ROYAL COLLEGE OF SURGEONS.

SOME of our readers may care to be reminded that the time for sending in essays for the Jacksonian Prize of the Royal College of Surgeons has been altered from Christmas Day to Friday, the 31st instant. The subject for the present year is the Use of the Galvano-caustic in the removal of Morbid Growths; and for the succeeding year, the subject is the Treatment of Cancer of the Rectum, particularly as regards the possibility of curing or relieving the patient by excision of the affected part. Essays for the Collegial triennial Prize are not due until December 1876; the following is the subject, viz., the Radicles of the Lymphatic System in relation to the external and internal surfaces of the body. This prize consists of the John Hunter medal, executed in gold, to the value of fifty guineas; or, at the option of the successful author of the dissertation, of the said medal executed in bronze, with an honorarium of £50.

ROYAL COLLEGE OF SURGEONS.

IN addition to the names already published in this JOURNAL of the candidates for the new Board of Examiners in Anatomy and Physiology, the following gentlemen, already members of the Court of Examiners, were nominated at a meeting of the Committee on the 2nd instant, viz., Messrs. John Birkett and John Cooper Forster, of Guy's Hospital; Luther Holden and William Scovell Savory, F.R.S., of St. Bartholomew's Hospital; and Timothy Holmes, of St. George's Hospital; and we understand that Messrs. Arthur Trehern Norton, of St. Mary's Hospital; Henry Power, of St. Bartholomew's Hospital; and William Thomas, of Queen's College, Birmingham, have also been nominated. We share the opinions, and add our wishes to those of many of our correspondents, that a provincial representative may be added to the Board of Examiners. A meeting of the Committee was held on Thursday, the 9th instant, for determining the list of Fellows to be recommended to the Council, which, we believe, will meet shortly.—In last week's JOURNAL, the date of Mr. Edward Bellamy's Fellowship was by error stated to be 1870 instead of 1867.

THE LATE MR. ACTON.

WE regret to announce the death of Mr. Acton, which occurred suddenly, at his residence in Harley Street, on Tuesday morning last. The deceased gentleman occupied a prominent position amongst London practitioners in his special department. He was the author of numerous well known works concerning the diseases of the urinary and generative organs, prostitution, and allied subjects. He had lost his father and his wife this year, and spent the early part of the late vacation in Scotland, where he seemed to be in tolerably good health, except that he complained of pain at the lower part of the sternum upon taking exercise. At the end of September, he was seized with faintness in Bond Street: and was then seen by Dr. Murchison and Sir James Paget, who found him suffering from feebleness of the heart's action. Mr. Acton, at various times, consulted also Dr. Quain and other physicians. His principal symptoms were the sternal pains produced by exercise, and great flatulence after taking food. He saw his patients as usual on Monday, and entertained some guests at his house at dinner that evening. Next morning, as he did not make his appearance at his usual hour at the breakfast table, his family became alarmed; and he was then discovered in his bath-room, lying against the outside of the bath, and dead. A *post mortem* examination revealed the fact that death had resulted from fatty degeneration of the heart,

the muscular fibres of which were found, beneath the microscope, to be largely replaced by fat. There was also extensive atheroma of the aorta and larger vessels.

THE CORONER FOR CENTRAL MIDDLESEX.

IN connection with the death of Mr. Acton, we hear of an unnecessary display of energy upon the part of the coroner for Central Middlesex. It appears that Dr. Hardwicke decided to hold an inquest upon the body, and communicated notice of his intentions at once to the family of the deceased gentleman. Dr. Quain and Dr. Murchison both expressed the opinion that an inquest was quite unnecessary, as the death was exactly such as might be anticipated from the symptoms exhibited during life. Dr. Murchison further made, in conjunction with Dr. Cayley, a *post mortem* examination of the body, and found the fatty condition of the heart and atheromatous state of the large vessels which might have been expected, and which fully accounted for the mode of death. He then wrote a certificate to the effect that he had attended Mr. Acton, that he had seen him for the last time on October 4th; and that he had died suddenly on Tuesday morning of fatty degeneration of the heart, as verified by *post mortem* inspection. This report, however, was not sufficient to stay the proceedings of the coroner, who held his inquest on Thursday morning, when a verdict of death from natural causes was returned. We believe that the affair is likely to be made the subject of complaint to the Home Secretary.

THE HARVEIAN LECTURES.

NOTWITHSTANDING the severity of the weather, a large number of members of the Harveian Society, and others interested in the subject, assembled on Thursday, the 2nd instant, to hear the delivery of the first Harveian Lecture by Dr. Sibson at the rooms of the Harveian Society. The lecture was principally devoted to the consideration of arterial tension in Bright's disease, and will shortly be published in its entirety in these pages.

AMERICAN OTOLOGICAL SOCIETY.

AT the last meeting of this Society, held in Newport, Rhode Island, July 21st, 1875, it was voted, that the Committee on an International Congress, be empowered by this Society to issue a call for an International Otolological Congress, at such time and place as they shall see fit. In accordance with this vote, the Committee have called a Congress, to be held in New York City, on Friday, September 15th, 1876, at 10 o'clock, A.M., the place of the meeting to be announced later. Members of the medical profession who take an active interest in aural surgery, are cordially invited to be present, and take part in the Congress.

RECENT URBAN MORTALITY.

DURING last week, 5,085 births and 3,899 deaths were registered in London and twenty other large towns of the United Kingdom. The mortality from all causes was at the average rate of 26 deaths annually in every 1,000 persons living, and in the various towns was as follows:—Norwich, Portsmouth, and Hull, 22; Sheffield and Nottingham, 23; Sunderland, 24; London, Birmingham, and Manchester, 25; Dublin and Leeds, 27; Newcastle-upon-Tyne, 28; Edinburgh and Liverpool, 29; Glasgow, Bradford, and Bristol, 30; Wolverhampton, 31; Leicester, 33; Salford, 34; and Oldham, 35. Scarlet fever showed fatal prevalence in Bristol, Salford, and Bradford; measles in Portsmouth, and fever in Sheffield. In London, 2,072 births and 1,628 deaths were registered. The births were 262, and the deaths 85, below the average of the week. The annual death-rate, which in the two previous weeks had been equal to 24.3 and 22.8 per 1,000, rose last week to 24.7. The 1,628 deaths included 59 from measles, 104 from scarlet fever, 16 from diphtheria, 54 from whooping-cough, 29 from different forms of fever, 13 from diarrhoea, and not one from small-pox: in all, 275 deaths, or 6 below the average of the week. No death from small-pox was recorded in London during the last twenty weeks. During the fifteen days ending last Saturday, cold

weather continuously prevailed; the mean temperature during that period being but 33.7 deg., and 8.0 deg. below the average. Notwithstanding this low temperature, the fatality from diseases of the respiratory organs continues comparatively low. The deaths referred to this class of diseases were 391, or 74 below the average of the week; 228 resulted from bronchitis, and 111 from pneumonia, numbers differing but slightly from those in each of the two previous weeks. In outer London, the general and zymotic death-rates were 16.7 and 2.5 per 1,000 respectively, against 24.7 and 4.2 in inner London. At Greenwich, the mean reading of the barometer last week was 29.72 inches. The mean temperature of the air was 30.9 deg., or 10.9 deg. below the average of the week; it was lowest on Saturday, when the mean was 27.5 deg, a defect of no less than 14.4 deg. The general direction of the wind was north-east and north. Melted snow was measured to the amount of .41 of an inch.

WESTMINSTER HOSPITAL.

THE long talked-of improvements in the sanitary condition of this hospital have at length assumed a definite form. On the 16th of March last, a subcommittee, consisting of Sir Rutherford Alcock as Chairman, Dr. Basham, Mr. Brooke, Mr. Cowell, Mr. Davy, Dr. Dupré, Dean Stanley, Mr. Charles Hood, Mr. Helmore, and Mr. William Gilbert, was appointed to consider the whole question. This Committee has, with the valuable assistance of Mr. Hunt, C.B., and of Mr. Stephen Salter as architect, recently presented a full and exhaustive report, which was on Tuesday last accepted by the House Committee, and will be finally considered by a general board of the governors in January next. The recommendations of the subcommittee are briefly as follows: the addition of octagon towers in front, and angle buildings behind, by which the whole of the sculleries and water-closets will be placed outside the building, with a connecting lobby entered from the several wards and cross-ventilated; the addition of consultation and retiring rooms to the operation theatre; the erection externally, so as to be entered from each ward corridor, of bath and lavatory rooms; the addition of a new floor to part of the building to provide wards for the accommodation of infectious and delirious patients; a complete system of ventilation by perpendicular tubes in each ward; besides many other improvements, such as alterations in the out-patient department, painting and colouring the hospital throughout, improving the mortuary, etc. These important alterations are estimated to cost nearly £8,000, and will, it is hoped, be carried out next summer. The towers and buildings outside can be constructed first, so that the hospital will not require to be closed for more than six or eight weeks.

THE BROWN INSTITUTION: LECTURES.

DR. BURDON SANDERSON announces as the subject of the annual course of lectures, which will this year be delivered at the University of London, the Pathology of Inflammation. The course will consist of two parts. The first lecture (December 15th) will be devoted to the development of the doctrine of inflammation, with particular reference to the influence exercised by the observations and writings of John Hunter. In the succeeding lectures, an account will be given of recent researches relating to the three great phenomena of inflammation; viz., determination of blood and congestion, exudation, and textural changes as exhibited in non-vascular structures. The lectures will be given, as before, on alternate days, at five o'clock.

ANGLO-SAXON SKELETONS.

AN Anglo-Saxon burial place has been discovered on the banks of the Avon, about a mile from the town of Warwick. The indications from the remains at present exhumed seem to show that it was not a place of regular interment, or a Saxon cemetery, but a somewhat hurried burial after a battle or skirmish in the immediate neighbourhood; for though some of the bodies were laid east and west, with their heads eastward, others were not so. Many of the skeletons were found indiscriminately upon the others—a circumstance which in other cases has given rise to the supposition that these were either prisoners taken

in battle, or slaves sacrificed as a propitiation to the gods. With respect to the bodies themselves, one of the most perfect of the skeletons was that of a powerful young man, who was upwards of six feet high, and about twenty-three or twenty-four years of age. His teeth were perfect, and the chin was somewhat more pointed than usual. This pointed chin marked all the lower jaws of which there was an opportunity for examination, for many of the skeletons fell into dust, or were broken by the workmen, in removing them.

SCOTLAND.

DR. JAMES A. SIDEX has been elected Medical Officer to the Edinburgh County Prison, vacant by the resignation of Dr. James Simson. There were eleven candidates.

THE number of students matriculated at the University of Edinburgh is 13 more than last year, reaching the high figure of 1,884. Of these, 744 are medical, 758 arts, 325 law, and 57 divinity students.

THE first case heard at Dumbarton under the Food Adulteration Act of 1875, came up in the Sheriff Court on the 20th ult. A dairyman was charged with having sold sweet milk adulterated with 30 per cent. of skimmed milk. He pleaded not guilty, and the Sheriff dismissed the case as not proven, but refused costs.

CRIEFF DRAINAGE AND HOSPITAL ACCOMMODATION.

AT a special meeting of the Crieff Local Authority, the Committee appointed to make arrangements with the several landowners in regard to outlets for the sewage of the borough, reported that they and their engineer had had a meeting with the landowners in question, and that all parties were prepared to give outlets on their respective lands. The engineer was instructed to prepare plans and specifications, with the view of proceeding with a thorough drainage scheme for the borough. A letter was read from Lord Aveland, in which he stated that the Baroness Willoughby and he, seeing that a general wish was expressed for the erection of a hospital for infectious diseases only, would give their donations for that purpose, but wished that accommodation should be provided for the parishes of Crieff-Conine, Mongiessair, and Nuthill.

MEMORIAL TO THE LATE DRs. ADAMSON AND BELL OF ST. ANDREW'S.

AN influential meeting was recently held in the Town Hall, St. Andrew's, to consider a proposal to erect a memorial to perpetuate the memory of the late Drs. Adamson and Bell. The chief speakers were Principal Tulloch and Principal Shairp; and resolutions were passed to the effect that some permanent memorial should be proceeded with at once, taking the form either of placing the Cottage Hospital on a more permanent basis, or carrying out some other useful and appropriate object. A Committee was appointed to collect subscriptions, and take all necessary steps.

ROYAL COLLEGE OF PHYSICIANS IN EDINBURGH.

ON Thursday, December 2nd, at the usual meeting of the Royal College of Physicians of Edinburgh, the following office-bearers were elected for the ensuing year. *President*: Dr. Alexander Keiller. *Vice-President*: Dr. Robert Paterson. *Council*: Dr. Halliday Douglas, Dr. Paterson, Dr. Matthews Duncan, Dr. Rutherford Haldane, Dr. George W. Balfour, Dr. Douglas Maclagan. *Treasurer*: Dr. J. A. Smith. *Secretary*: Dr. John Wyllie. *Librarian*: Dr. George W. Balfour. *Curator of Museum*: Dr. T. A. G. Balfour.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

THE following gentlemen were elected office-bearers for the ensuing year, at the meeting on Dec. 1st. *President*: Dr. Gillespie. *Vice-Presidents*: Dr. G. W. Balfour, Dr. Littlejohn, Dr. Keiller. *Councillors*: Dr. Clouston, Mr. G. H. Gilruth, Dr. Moinet, Dr. P. A. Young, Dr.

Batty Tuke, Dr. James Carmichael, Dr. Hardie, Dr. Affleck. *Treasurer*: Mr. Joseph Bell. *Secretaries*: Dr. Muirhead, Mr. Chiene.

GLASGOW LYING-IN HOSPITAL.

At the annual meeting of the directors of the Lying-in Hospital of Glasgow, the medical report was read, stating that the number of women confined there during the year was 304, and the number attended at their own homes 927, making a total of 1,231. The hospital during the year had been in a healthy condition, though there had been two fatal cases of fever. A large number of medical students had attended the hospital during the year. The financial statement showed that the income for the past year was £807, and the expenditure £683. The directors are anxious to secure sufficient funds to build a new hospital, and are hopeful of success.

ILLEGITIMACY IN SCOTLAND.

THE Registrar-General's Report for the last quarter shows, as usual, a very great difference existing in different parts of Scotland with regard to the proportion of illegitimate to legitimate births: thus while over the whole country the percentage of illegitimacy is 8.75, in the large towns it is only 7 per cent., but rises in the mainland rural districts to 10 per cent. The difference between counties in this respect is very peculiar; thus Ross and Cromarty show the rate as low as 3.5, Fife to 6.5, Inverness 10, Aberdeen 13.7, and so on in gradation, until the list culminates in Wigtownshire, with the very high rate of 18.8. This is not a solitary instance, as the county of Wigtown is usually at or near the head of the list. The *Scotsman* thus comments on the fact: "The returns show that in the county . . . almost every fifth child is born out of wedlock. If to that were added the number of children, the first of each marriage, who escape that category only by a few weeks or days, the proportion would be largely increased. In one of every four of such cases, which registrars must enter as legitimate births, there is said to be in Wigtownshire justification for O'Connell's cruel and clever parody directed against the South of England peasantry:

'The marriage baked-meats do coldly furnish forth the christening tables.'

THE WEATHER AND THE DEATH-RATE IN EDINBURGH.

THE death-rate of Edinburgh has risen during last week to an annual mortality of 30 per 1,000; this great rise being due to the continued severity of the weather, and its variability, there having been constant variations between frost, snow, sleet, and hail. The increased mortality is most marked among persons over sixty and under five years of age, the intermediate ages remaining near the average. The number of deaths from zymotic diseases is rather less than for the three previous weeks; but scarlatina is still prevalent, being credited with twelve out of the twenty-one deaths due to this class of disease.

IRELAND.

DR. MILLER has been re-elected, without opposition, Mayor of Londonderry.

THE WATER-SUPPLY OF LUGAN.

At a special meeting of the Lurgan Town Commissioners held last Monday, the question of a proper supply of water for this town was under discussion. The report of the committee appointed for the purpose of considering the matter stated that the Government were agreeable to lend the sum of £10,000, payable by a sinking fund in fifty years by an annuity of 5 per cent. interest and principal, if application were made before the termination of this year. Some difference of opinion exists as regards where the water should be obtained from, one authority suggesting Lough Neagh, whilst two others recommend that it should be taken from wells sunk in limestone in a locality adjacent to Lurgan. It was moved that the conditions mentioned by the Government should be accepted, which was carried by the casting vote of the chairman.

ZYMOTIC DISEASES IN DUBLIN.

A PARLIAMENTARY paper moved for by Sir Arthur Guinness furnishes a return of the number of deaths caused by zymotic or preventable diseases, during the ten years ended December 1874, in those urban sanitary districts in Ireland which have a population of 10,000 inhabitants and upwards. The deaths in the Dublin District from these affections amounted to 16,412, or upwards of six in every 1,000 of the population. The most fatal was fever, which caused 3,215 deaths, then scarlatina, to which 2,793 were ascribed, while to diarrhoea 2,410 were attributed, and to small-pox 1,562 persons fell victims.

HEALTH OF IRELAND: QUARTERLY REPORT.

DURING the quarter ending September, there were registered in Ireland 32,585 births, being equal to an annual birth-rate of 24.5 in every 1,000; and 19,289 deaths, representing an annual mortality of 14.5 per 1,000. The birth-rate was somewhat under, and the death-rate slightly over the average for the corresponding quarter of the past five years. The deaths from scarlatina, though numerous, continue to decrease, and there has been a considerable decline in the mortality from small-pox. The deaths from scarlatina occurred principally in Ulster, and small-pox was almost entirely confined to Connaught. The deaths of nine persons stated to have been 100 years old and upwards were registered during the quarter.

THE MEDICAL COMMISSIONSHIP OF THE IRISH LOCAL GOVERNMENT BOARD.

WE understand that this office, which is now vacant by the resignation of Dr. John McDonnell, will be shortly filled up, and that the Government have wisely decided not to make any attempt to abolish it. The report that Dr. McDonnell's resignation would be taken advantage of to abolish the office was not without substantial foundation, as many attempts have been made in non-medical circles to underrate the importance of the office. We think it not improbable that, in the working of the new Sanitary Act, the Government have found the necessity of a medical head for the Public Health and Poor-law Medical Service of Ireland. We have good reason to know that, had the Government relied upon, and in some instances sought the advice of, the Medical Commission, fewer mistakes would have arisen, and many medical grievances would have been avoided. In the determination of the Government to fill Dr. McDonnell's office, we see a step in a direction which, if followed up, will lead to important results not only to our profession, but also to the Irish public.

THE MAYORALTY OF DUBLIN FOR 1876.

DR. OWENS, J.P., who was nominated in July last Lord Mayor of Dublin, has unanimously been elected Chief Magistrate of the City of Dublin for 1876. Dr. Owens has been for many years a member of the Municipal Council, and has shown himself to be a gentleman of the highest principle and integrity. He is Chairman of the Dispensary Committee of the South Dublin Union Board, in which position, "so far as in him lies", he acted in the most kindly and considerate manner to the members of the profession who serve as dispensary medical officers. We congratulate Dr. Owens upon the honour the citizens of Dublin have conferred upon him, and upon his opportunity for promoting much needed reforms.

THE DUBLIN BARRACKS.

WE regret that, owing to a statement which appeared in the *Times* of Saturday last, it is our duty again to refer to the question of the sanitary condition of the Dublin barracks. The Dublin correspondent of the *Times* accuses us of inaccuracy. The statement in the *Times* implies ignorance on the part of the gentleman who furnished us with the information we published on the 27th instant; and takes a great deal of trouble to contradict statements about the unhealthiness of certain barracks which our informant did not describe as unhealthy. There was no charge of *general* unhealthiness made against the Dublin barracks; on the contrary, our informant specially mentioned the

healthiness of Portobello, Aldborough, and Pigeon House. The *Times* Dublin correspondent also implies that our informant is ignorant of the fact that Linen Hall and Aldborough are not usually occupied by troops; whereas our informant specially stated that "Linen Hall is not much used, and unfit for use as a barrack". The *Times* correspondent seems to have forgotten, in great part, the well known fact of the unhealthiness of Beggar's Bush Barracks, which had to be emptied and overhauled. There can be no doubt that a number of cases of enteric fever occurred at Beggar's Bush; an attempt was at first made to deny that these were connected with the barracks; then a further attempt was made to gloss the matter over; finally, the authorities gave up, and admitted that the place was unhealthy, and reconstructed all the sanitary arrangements. The drainage of Beggar's Bush barracks was not "remedied twelve months ago", as stated by the *Times* correspondent, but only at the end of April last. All details with reference to Beggar's Bush will be found in the *Sanitary Record* for April 17th of the present year; in which journal a very disgraceful state of things is shown to have prevailed in those barracks. With reference to the Royal Barracks, we have to state that, on careful inquiry, we find that, in October, a patient was admitted into Cork Street Fever Hospital, suffering from enteric fever; and that, when admitted, the military authorities informed the resident medical officer of the hospital that the girl contracted the fever from the family of an officer in the Royal Barracks suffering from the disease. The case was a severe one; and the patient died in the hospital ten days ago. The military authorities, on the 30th of November, applied to the Government to have a better water-supply for Island Bridge barracks, on the ground of "numerous cases of enteric fever having taken place among the troops there stationed". We do not think that the term "numerous cases", as used by the military authorities, is consistent with the term "two cases", used by the *Times* correspondent. With reference to the Richmond Barracks, we believe, if it do not now drain into a cesspool, it did very recently. The *Times* correspondent can hardly have inspected the Carnac (not Carnac) stream, or he would know that it is not a "natural and effective sewer". It is a filthy open river, which receives the drainage of the district in the neighbourhood of the Richmond Barracks; it has been much complained of by the inhabitants; and its state was even the subject of a Local Government Board inquiry. Our informant made all due allowance for the filthy and unhealthy state of Dublin; but the *Times* correspondent gives us no credit for our informant's statements on this head, while quietly adopting it, and using it as if it were original, and then as quietly makes use of it against us and our informant. Every statement our informant made is substantially correct, including those with reference to the treatment of cases of enteric fever from, not in, barracks, and that about the Lord-Lieutenant's household. It must be remembered that our statements refer to matters which have existed, in varying degrees, for about two years. It is quite possible that it is the unhealthiness of Dublin that causes unhealthiness of the troops there stationed; but this is a cause for increased alarm, not for congratulation, as the *Times* correspondent seems to imagine.

MANAGEMENT OF PREMATURE CHILDREN.—Dr. Ahlfeld, in the *Archiv für Gynäkologie*, Band viii, says that cases occurring in the practice of others and in his own have proved to him that premature infants ordinarily regarded as non-viable may, under favourable circumstances and assiduous care, live and thrive. He gives examples in which children born at the twenty-sixth week were preserved alive. Immediately after birth, the child must be wrapped in cotton and placed in a warm bath, so as to impart to it the heat which it is unable to produce in sufficient quantity. The baths, which should be somewhat warmer than usual, must be frequently repeated. Great importance is attached to awaking the child regularly every one or two hours in order to feed it. As long as it does not suck, milk (woman's milk is the best) must be given to it by a teaspoon. With a view to the better development of the lungs and the movement of the thoracic muscles, it should be excited to cry by slight irritation. It is dangerous to bring such children into the open air for several months after birth, as their air-passages are readily affected.

NEW BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

WE have the pleasure to announce that a preliminary meeting of the members of the Association residing in Edinburgh and the district was held on the 30th ult., with a view to forming a Branch of the Association for Edinburgh and the Lothians. A resolution was passed to the effect that it was desirable that a Branch should be formed; and a Committee was appointed, with Dr. Matthews Duncan for its Chairman, to draw up a code of laws and report to an adjourned meeting. The meeting was well attended.

THE CONJOINT SCHEME.

THE members of the conference whose names have been announced in former numbers of the BRITISH MEDICAL JOURNAL, held a meeting at the College of Surgeons on Friday last, for the further consideration of some modifications in the proposed conjoint scheme. We understand there was an unanimous feeling on the part of all the delegates as to the importance of taking such steps as will be necessary for bringing the scheme into operation. The meeting was adjourned until the 23rd instant.

ACCIDENTS CAUSED BY THE FROST IN LONDON.

THE dangerous condition of the streets of the metropolis during the recent frost is painfully exemplified by the following reports from the various hospitals kindly furnished by the house-surgeons of the respective institutions.

ST. BARTHOLOMEW'S HOSPITAL.—Mr. J. Macready (House-Surgeon) observes that the following is the list of the injuries treated in this hospital that occurred in consequence of the frost. No mention is made of the numerous sprains of the wrist and ankle that were treated in the out-patient department, for none of them were severe. *Cases of Fracture treated as In-Patients.*—Fracture of thigh in lower third in a man; fracture of both bones of the leg in lower third, two males; fracture of the tibia in lower third in a man; Pott's fracture in two males, and Pott's fracture in a woman, with Colles's fracture on the same side (left); fracture of fibula in lower third in a woman; fractured patella, one man and one woman. *Cases treated as Out-Patients.*—Fracture of upper third of the humerus in a man; two Colles's fractures; fractured clavicle in a man.

CHIRING CROSS HOSPITAL.—Mr. James Cantlie (House Surgeon) reports that, during the first and second days of the frost, a great number of accidents were brought in; during the last few days, however, the number of accidents has decreased to a minimum. The following is a list of the more important casualties. Two cases of sprained wrist, with effusion into the sheaths of the flexor tendons; two cases of fractured radius (Colles). These four cases were all treated between 5.30 and 6.30 P.M. on December 1st; one fracture of the acromion; a lacerated wound over the patella; a fracture of the humerus in the upper third; sprained ankle; separation of the epiphyses at the lower end of the humerus; dislocation of the little finger; dislocation of the shoulder (subcoracoid); fracture of the pelvis, with effusion into the hip-joint; compound comminuted fracture of tibia and fibula; fracture of fibula (Pott's); compound fracture of radius and ulna, and temple, fracture of the upper third of humerus, also a wound on the temple in a man whose horse had fallen and rolled over him; extensive scalp-wound, with concussion. No deaths occurred from any of these accidents, and the patients were all doing well on December 8th.

GUY'S HOSPITAL.—Mr. J. Farrant Fry (House-Surgeon) reports, that the accidents due to the recent frost admitted were—five cases of simple fracture of tibia and fibula, all of which were treated with a back and two side splints, and swung in a cradle; two cases in which the fibula alone was fractured. In these cases, the limb was kept between sandbags a day or two until the swelling had disappeared, and then put up in the Bavarian splint. One case of fractured thigh, which was transverse just above the condyles, with a vertical split through them—a back splint was put on to get a fixed joint, the patient being old and infirm; one case of fractured patella, treated by the back splint and raising the limb; one case of concussion, in which unconsciousness lasted three days. In the surgery, there were four Colles's

fractures, two fractures of the olecranon, two fractures of the radius, two of the humerus, and very many lesser injuries.

ST. GEORGE'S HOSPITAL.—Mr. William H. Bull (House-Surgeon) sends the following list of the accidents brought to the hospital between November 29th and December 7th, which were caused by the state of the weather: fracture of the forearm, 8; fracture of the arm, 1; injury to the shoulder, 8; injury to the arm, 3; injury to the hand and fingers, 5; injury to the thumb, 3; sprained wrist, 6; sprained thumb, 1; scalp-wound, 5; fractured nose, 1; injury to ribs and side, 5; fractured ribs, 4; injury to back, 3; injury to hip, 2; sprained knee, 7; injury to the leg, 2; fracture of the leg, 5; injury to the foot and ankle, 3.

UNIVERSITY COLLEGE HOSPITAL.—Mr. Taunton reports that there was, during the past week, a considerable increase in the number of fractures treated, especially those of the upper limb; six cases of Colles's fracture headed the list. One of the most troublesome cases was that of an old woman, aged 82, who was admitted with subcoracoid dislocation of the humerus and fracture of the surgical neck. The dislocation was reduced under chloroform by Mr. Bayly, one of the house-surgeons; the fracture was then treated with a shouldercap in the usual manner.

MIDDLESEX HOSPITAL.—Nothing very unusual occurred here. Mr. Scott treated four cases of transverse fracture of the patella, and five or six of Colles's fracture.

ROYAL FREE HOSPITAL.—Mr. F. G. Hamilton writes, that fractures of the forearm and dislocations of the humerus were, surgically speaking, the most serious results of the frost in the neighbourhood of Gray's Inn Road.

ST. MARY'S HOSPITAL.—Mr. Gawith (Senior House-Surgeon) admitted a compound fracture of the leg, two simple fractures of the leg and one of the thigh, besides treating several fractures of the forearm and minor casualties as out-patients.

GREAT NORTHERN HOSPITAL.—Mr. Herbert F. Chapman (Junior House-Surgeon) states, that the following accidents treated in this hospital were the result of the frost: fracture of the surgical neck of the humerus, put up in a gutta-percha shield; dislocation of the foot backwards without fracture, reduced under chloroform and admitted; two sprained ankles; eye bruised by a snowball; four contusions; one scalp-wound.

THE WAINWRIGHT CASE:

DR. MEADOWS ON THE POST MORTEM DIAGNOSIS OF A MULTIPAROUS UTERUS.

DR. ALFRED MEADOWS, in a communication to the Obstetrical Society at their last meeting, remarked upon the extreme importance of being able to diagnose *post mortem* whether or not an uterus had borne a child; and on this point he invited the opinion and experience of the Society. In the case referred to (that of the woman for whose murder Wainwright is to be hanged), he thought it was not too much to say that, if any absolute test existed whereby a positive opinion in the negative could have been given, the whole case for the prosecution must have failed on the first indictment; for it was well known that the person alleged to have been murdered had borne children. He, however, knew no such test; nor did he think it could be affirmed, on the contrary, that the uterus had ever been gravid, so far as appearances went. The thinness of the uterine wall, which in this case barely exceeded a quarter of an inch, and the distinctly convex shape of the internal aspect of the uterine wall, induced him to the opinion that it was a nulliparous uterus. Accordingly, the evidence which he gave at the recent trial was to the following effect. 1. As a general rule, no absolute certain opinion can be given by *post mortem* examination only, even under the most favourable circumstances, on the question whether or not a woman has borne a child. 2. On the question of probability, some reliance may be placed on the internal appearance of the uterine walls, especially with reference to their convexity. 3. So far as this particular uterus was concerned, there was certainly no proof that it had borne a child; but, on the contrary, the evidence, doubtful and unreliable as it was, tended rather in the opposite direction, and justified an expression of opinion to that effect. Dr. Meadows then referred to a very delicate question of a medico-ethical character; viz., as to whether a scientific witness is at liberty to allow his private judgment on the general merits of a case to influence his opinion on a purely scientific question. Upon this point also he invited the opinion of the Society. The discussion was adjourned to the following meeting.

SPECIAL CORRESPONDENCE.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

M. Broca's Essay on Craniology.—Clinical Teaching in Paris.

THE last volume of the *Mémoires* of the Anthropological Society of Paris, which has just been published, is one of the most interesting volumes the Society has been favoured with since its foundation. Out of deference to M. Broca, the Society has exclusively devoted the volume to his "Instructions Craniologiques et Craniométriques". The memoir is, in short, an *exposé* of the principles of craniology and craniometry, and constitutes a most valuable contribution to these branches of science. It would be invaluable alike to the anatomist as to the anthropologist. In order to give an idea of the comprehensiveness of the subjects of which it treats, I may mention that forty-two pages are devoted to the osteology alone of the skull, and a complete index of seven pages of small print shows the extensive scope of the work. There are two exceedingly good articles on the determination of the age and sex of the skull, which would deeply interest the medical jurist. The distinction of the male and female skulls in the dry state is, according to M. Broca, not so easy to determine as would at first sight appear, as the distinctive characters do not belong more absolutely to one than to the other skull. "There is," adds the author, "in every race a masculine and a feminine type, which any observer even of limited experience can distinguish at first sight, and which may be found depicted on the skull; but there will always be found a certain number of individuals whose skulls partake of the characters of both the types". Even in the living subject, this confounding of the sexual characters may be observed; for, setting aside the genital organs, the various external characters which distinguish man from woman are different only in degree, for many women may be seen who present the masculine type, and men who are more or less effeminate.

M. Broca's instructions for measuring the capacity of the cranial cavity are not the least interesting part of the work, and he applies the term "stéréométrie" to this branch in contradistinction to "craniométrie". He obtains this by ascertaining the quantity or volume of the liquid or solid substance with which he fills the skull, and then taking the cubic measure of that substance. Different substances are employed in the stereometric measurement of the skull, such as an emulsion of lime, gelatine, water, mercury, sand, seeds or grain, shot, etc.; but M. Broca prefers No. 8 shot, as affording the most correct results. For fragile skulls, however, he employs mustard-seeds, and gives the preference to the white mustard, owing to its hardness and more perfect roundness.

In treating of the deformities of the skull, M. Broca divides these into pathological, artificial, and posthumous. The first of these forms may be produced by causes to be found in the brain ("encéphaliques"), or in the cranial bones themselves ("ostéologiques"). The encéphalique causes may produce either an increase or a diminution of the size of the skull, and the deformities of osteological origin are attributable to disturbance in the development or in the nutrition of the osseous tissue. M. Broca's remarks on hydrocephalous heads are extremely interesting; and, in reference to microcephalia, he states that this deformity is owing to some defect in the development of the brain, and not, as taught by Virchow, to the premature union or obliteration of the sutures. This condition, however, is sometimes met with in these deformities, in which case M. Broca looks upon it as the effect, and not the cause of microcephalia. At the last meeting of the Anthropological Society of Paris, M. Broca presented a living specimen of this deformity, in the person of a female child four months old, the youngest microcephale on record; and the condition of this child's head fully corroborated the statement made above, that the premature obliteration of the sutures in microcephalous heads is the exception, and not the rule. In the case under notice, the sutures and fontanelles were normal; but the size of the head, and indeed of the whole body, was not greater than that of a child a few days old. The child weighed only 1,800 grammes, or a little over 2½ lbs. Another peculiarity about this child was, that its anus was imperforate, and the intestinal dejections passed through the vagina. M. Broca stated at the meeting that he proposed to remedy this infirmity by an operation, to which M. Giraudeau, whose death is noticed in the last number of the *JOURNAL*, made the following remark: "If you operate, the child is sure to die." M. Broca did operate—that is, he perforated the anus, and closed the recto-vaginal fistula—and, when I last saw the child, two days ago, it was in a dying state, and is perhaps now dead.

In speaking of plagiocephalous heads, M. Broca stated that this deformity may be produced spontaneously or artificially, and he referred

to an observation made by M. Guéniot a short time ago, that infants made to lie always on the same side, or carried always on the same arm, are subject to the deformity in question, which is produced by the flattening of the parietal protuberance of the corresponding side of the skull. Generally speaking, the deformity is not of a permanent character; the head recovers its normal condition soon after the child begins to walk, though it may persist until adult age, or as a permanent deformity, as has been met with in some rare cases. This ought to be a good lesson to mothers and nurses; and obstetric practitioners would do well to bear this circumstance in mind, so that, by their timely advice, they might prevent a deformity which may have serious consequences in after-life.

With reference to the remarks made in my last letter on the inefficiency of clinical teaching in Paris, that measures were in contemplation to effect a reform in this direction, I have now to inform you that the committee that was appointed to investigate the subject has since sent in its report, and the following is a summary of its conclusions:—New chairs to be created for the following special subjects: syphilis, diseases of the skin, ophthalmology, otology, mental diseases, and odontology, which will be established at the different general hospitals already in existence, and be placed under the direct control of the Faculty, which will have the right to appoint its own professors. These latter may be selected not only from the list of *agrégés*, but from that of all the hospital physicians and surgeons. The appointment is for ten years, with the power of re-election, and the salary attached to it to be 5,000 francs (£200) *per annum*. For the Odontological Chair, however, all doctors of the Faculty are eligible. Thus it will be seen that specialism is now officially recognised by the Faculty of Paris; and indeed it could hardly be otherwise, when it is considered that it is simply impossible for any clinical professor to do justice to these various branches of medicine and surgery. It has been remarked that diseases of the throat and urinary organs have not been included in the schedule; but it is anticipated that ere long the utility of these branches will also be officially recognised.

ASSOCIATION INTELLIGENCE.

WITH a view to giving increase of prominence to the scientific proceedings of Branches, and to the improved classification of matter, we propose henceforth to report only the official and administrative business of Branches under the head of Association Intelligence, and to transfer their medical and scientific reports to the columns in which are recorded the proceedings of Societies generally. We shall be much obliged if the Honorary Secretaries will kindly arrange their MSS. accordingly.

SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT MEETINGS.

A MEETING of the members of this district was held at the Royal Pavilion, Brighton, on Wednesday, November 24th, Dr. HENRY MOON, in the Chair. Twenty-six members present and two visitors.

Dr. MOON gave an introductory address.

Communications.—Sir CORDY BURROWS related a Case of Hip-joint Disease occurring in a young lady. The most remarkable feature in the case was the passage of urine through a fistulous opening resulting from the formation of an abscess which had formed below the trochanter margin. Perfect recovery ultimately ensued.—Mr. HOLMAN of East Hoathly and other members mentioned cases of fecal matters passing *per urethram*.

Mr. F. WALLIS, of Bexhill, related the case of a Most Severe and Extensive Burn in a young lady aged 23. His object was to elicit the opinion of members as regarded some dressing which, while it checked the profuse discharge, would relieve the extreme pain.

New Member.—Mr. F. Dulton of Newhaven was proposed for membership of the Association and of this Branch.

Notice of Motion.—Mr. BRANWELL of Brighton gave notice, "That, in view of the very inadequate results arising from the working of the British Medical Association, he would move at the next meeting, that a committee be appointed to inquire into the objects, organisation, policy, and measures of the Association, and into the general plan and conduct of the JOURNAL."

The Dinner took place at Markwell's Hotel under the presidency of Dr. Moon. Twenty-two sat down.

The Next Meeting was appointed to be held at Tunbridge Wells on March 9th, 1876; Mr. W. Wallis of Hartfield to be invited to take the Chair.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT MEETINGS.

THE fifty-eighth meeting was held in the Library of the County Hospital, Canterbury, on Thursday, November 11th; FRANK WACHER, Esq., in the chair. Seventeen members and visitors were present.

Next Meeting.—Dr. WILKS of Ashford was chosen Chairman for the meeting at Ashford on March 9th, 1876.

Ethical Committee.—The SECRETARY reported that he had received from the Secretary of the Branch the following resolution, which had been carried at the last meeting of the Executive Council.

"That the communication on the subject of the formation of an Ethical Committee in East Kent be acknowledged."

Mr. REID brought up a report from the Ethical Committee, in which the following resolutions were embodied.

1. "That it be recommended that the tariff of the Shropshire Ethical Branch be adopted for the guidance of the members of the East Kent District meetings, and that copies be purchased and issued to the members of the district."

2. "That it be recommended that the medical men of the East Kent District should, as far as may be, discountenance the conventional custom of attending funerals of deceased patients; and let it be known in their neighbourhood that they do not attend funerals except in their private capacity as friends, nor accept the usual complimentary gifts."

These recommendations were carried unanimously.

Papers.—1. Mr. CLEMENT WALTER read a paper on Diabetes.

2. Mr. RIGDEN read a paper on the Comparative Birth-rate and Number of Conceptions at different Periods of the Year at Canterbury.

3. Mr. RIGDEN also read a paper upon the possibility, and therefore the advantage, of Turning in Extreme Cases of Shoulder and Arm-Presentation by means of the Craniotomy Forceps, in preference to Eviscerating the Thorax.

4. Dr. HORNSBY WRIGHT read a Case of Empyema treated by Aspiration.

Dinner.—The members afterwards dined at the Fleur-de-Lis Hotel.

THAMES VALLEY BRANCH: ORDINARY MEETING.

THE first meeting was held at Richmond on November 17th; Dr. LANGDON DOWN in the Chair.

Five New Members joined the Branch.

Next Meeting.—It was decided to hold the next meeting at Surbiton in February 1876.

Papers.—Papers were read by Dr. Milner Fothergill, Dr. Donkin, and Dr. Wiltshire. On account of shortness of time, Dr. Fenn's paper was postponed till the next meeting.

Dinner.—The members and visitors, to the number of eighteen, dined at the Greyhound Hotel. The numbers attending the meeting and dinner would, no doubt, have been greater but for the badness of the weather.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, DECEMBER 7TH, 1875.

G. D. POLLOCK, F.R.C.S., President, in the Chair.

Molluscum Contagiosum.—Mr. JONATHAN HUTCHINSON showed some drawings illustrative of this disease, the peculiarity in each case being the copiousness of the eruption, and the fact of its occurring in adults. No history of contagion could be got at, though carefully inquired for. In one case, that of a man aged 50, the eruption was over the whole body. It resembled lichen at first sight, the spots being very small; but on the back it was more typical, and the true nature of the disease was at once apparent. Mr. Tay had seen a case at the Skin Hospital, Blackfriars, some time since. In this instance, the eruption had come out gradually, and had occurred over the whole body, except the face and scalp. There was no history of contagion, and no tendency to disappear spontaneously. In reply to Mr. Pollock, Mr. Hutchinson stated that the usual treatment was to excise them; but, in these cases, the eruption had been too extensive to allow this treatment. In one case, however, at the patient's own request, he had snipped off upwards of two hundred of these tumours. Microscopically, they consisted of collections of sebaceous material in hypertrophied sebaceous glands.—Dr. COUPLAND drew attention to two memoirs in which the authors, Boeck and Lukomsky, working separately, had

arrived at the conclusion that these cysts were due to alterations in the upper layer of the rete Malpighii, and consisted of so-called molluscous bodies within the epidermic cells, which had been by some mistaken for spores and by others for altered sebaceous products.

Dilatation of Bile-Ducts.—Mr. MORGAN showed a liver with its bile-ducts considerably dilated. There was a perforating ulcer of the duodenum, to which the bile-duct was adherent; and at this point was an inflammatory thickening, with stricture of the duct. The liver was large and distended; its surface was marked by a number of projecting cysts, but between these it was quite smooth. There was also extensive fatty degeneration of the heart.

Congenital Deficiency of Common Bile-Duct.—Dr. WICKHAM LEGG brought forward a case. The child was brought to St. Bartholomew's Hospital. It was 7 weeks old; was jaundiced, and had been so since birth. There had been no hæmorrhage from the navel when the cord dropped off. It died five months later, its liver and spleen having meanwhile considerably increased in size. At the *post mortem* examination, the portal vein, round ligament, and hepatic artery were found to be natural. The cystic and hepatic ducts opened into a cyst of the size of a marble, between which and the duodenum passed a membranous band. Followed up to the liver, the right duct was found much dilated and then thickened. The left duct was thickened throughout, and almost impervious. The liver was granular on its surface, and of a dark olive-green colour. The spleen was very large, and the Malpighian bodies prominent. Dr. Legg considered that the cirrhosis was secondary to the dilatation, because of the rarity of cirrhosis in children, and because ligation of the bile-duct in animals led to similar changes. There were only eleven recorded cases: two in the *Transactions of the Society*, one by Dr. Wilks and one by Dr. Nunneley. Dr. Nunneley's case lived seven months, Dr. Legg's case five months. He believed that a similar condition probably existed in cases where there was hæmorrhage from the umbilicus, though, of the eighty-four recorded cases, only in seven or eight was there any mention of this circumstance. Dr. West had also adopted this view, and pointed out the hereditary tendencies of this malformation.

Aneurism of the Aorta.—Dr. ROBINSON showed a case of aneurism situated just about the central cusp of the aortic valves, and pressing on the pulmonary vein. It was taken from a soldier, aged 46, who had seen eighteen years' service. It was not suspected during life. There had been a soft systolic *bruit* over the aortic valves, which at times was so low as to be almost inaudible. He seemed to improve under treatment, but died suddenly one night. On *post mortem* examination, the aneurism was found; its walls were thin, and it contained layers of decolorised clot. There was no communication between the aneurism and the pericardium; the latter, however, contained some blood-stained fluid. It was interesting clinically, from the absence of all those symptoms which suggest aneurism. The man had had a slight attack of syphilis twelve years previously, but appeared to have recovered completely. Dr. Robinson believed in several exciting causes rather than dogmatically in one, and placed intemperance as the most important of all.

Obliteration of the Superior Vena Cava.—Dr. HABERSON related the case. It occurred in a coalwhipper, who had appeared quite well until about 30 years of age, and had been doing very hard work. At this time, about seven years before his death, great swelling of the face, and congestion of the face and upper extremities, with distension of the superficial abdominal veins, came on. Some intrathoracic tumour was suspected. He ultimately died from dropsical effusion into the abdomen. At the *post mortem* examination, the superior cava was found obliterated, its entrance into the right auricle being marked by white puckering of the endocardium; the innominate veins ended in a *cul-de-sac*, and large compensatory veins passed in front of the pericardium into the mammary and azygos veins, through which the blood passed into the inferior cava. The pulmonary valves were imperfect, there being but two; the third, which was rudimentary, was placed on a lower level. Dr. Habershon considered the obliteration to be congenital, and thought that the condition of the pulmonary valves rather supported this theory. Had it not been congenital, there would also have been more evidence of an opening into the auricle. In reply to Dr. Douglas Powell, he stated that there was no history of cyanosis in early life.

Chronic Ulcer in Duodenum.—Dr. HABERSON exhibited a case of ulcer in the first part of the duodenum. The patient had died of hæmatemesis, and *post mortem* it was found that the ulcer had opened into the vena porta. There were evidences of inflammation in the course of this vein, and abscesses in the liver. The gall-duct was partially destroyed, and opened into the abscess cavity.

Disease of the Pulmonary and Tricuspid Valves.—Dr. ALEXANDER MORISON related a very interesting and rare case, in which the disease

was confined entirely to the right side of the heart. A man, aged 20, though known to have heart-disease, had enjoyed fair health until 13 years of age. At this time, a medical man had allowed him to play cricket, shortly after which his troubles began. He had a systolic *bruit* close to the left side of the sternum, not traceable towards the left side; there was also a harsh grating double murmur audible in the second left intercostal space, close to the junction of the third rib to its cartilage. There was bulging in the precordial region, with a visible systolic pulsation, especially in the second and third left spaces; and tactile *frémissement*. Respiration was hurried. There was albuminuria, with granular casts and blood in the urine. There was also well marked angina pectoris of the right side. At the *post mortem* examination, there were found valvular obstruction and regurgitation through the pulmonary semilunar valves, which were altered and distorted by warty growths. The tricuspid valves were also altered from the same cause. Both the right ventricle and auricle were hypertrophied and, the former especially, dilated. On the suggestion of Dr. Greenfield, the specimen was referred to the Morbid Growths Committee.

Cirrhosis of Liver in a Child.—Dr. GRIFFITHS showed a liver taken from a child aged 10. She came of healthy parents. There was no suspicion of syphilis. She came under his care four years ago, at which time the liver was greatly and uniformly enlarged, reaching as low as on a level with the umbilicus. The heart and lungs appeared healthy. There was no albumen in the urine; no dropsy nor anasarca. The child was not rickety or tubercular, and she had not taken alcohol. At the necropsy, the liver was found hard and tough; it weighed 15 ounces. Microscopically, it consisted chiefly of areolar tissue with atrophied liver-cells.—Dr. MURCHISON looked on the case as interesting, not only on account of its rarity, but also as showing that true cirrhosis may occur without alcoholism. In a case that had been under his own care, he finally found out that the child had a craving for drink, which it had been able to satisfy, as its father was a publican. He then referred to the danger of taking alcohol in small quantities, as being more liable to produce cirrhosis.—Mr. PARKER said that a boy, aged 9 years, had been in the Hospital for Sick Children, in whom this condition was diagnosed by Dr. Dickinson. The lad had been accustomed to take his father's dinner to a cab-stand, and had regularly partaken of his father's glass of grog. The symptoms in this case were ascites and a retracted liver.

Syphilitic Gummata in Spleen, Kidneys, &c.—Dr. GREENFIELD exhibited fresh specimens which had been removed from a woman who had died in St. Thomas's Hospital rather suddenly, after an attack of left hemiplegia, with spasm in the affected muscles. There was disease also in the cerebral arteries, which he proposed to describe at a future meeting of the Society.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

WEDNESDAY, NOVEMBER 10TH, 1875.

D. RUTHERFORD HALDANE, M.D., President, in the Chair.

Treatment of Nevus.—Dr. JOHN DUNCAN read a paper on the treatment of nevus, of which the following is an abstract. The "natural history" of nevus was interesting. It was not always congenital, but might make its appearance a few weeks after birth. The after-growth was characterised by fits and starts. Thus, at the first dentition, about one-third of all these cases retrogressed, either disappearing, degenerating, or becoming cystic. Two-thirds, or fewer, increased at the second dentition, and at puberty more diminished, either by the *vis medicatrix nature*, or by the efforts of the surgeon. In the former case, the port-wine stain was left, and likely to remain. Those left now become deforming to the patient, or they might ulcerate or bleed. There was little alarming in the two last-mentioned results. In the former, a cure generally resulted; and, in the latter, any hæmorrhage could easily be controlled. In those causing deformity, the two classes of stationary and spreading could be recognised. In the former, puncture with a needle dipped in nitric acid was the best plan. Pressure might be applied, but it did little good. Painting the nevus with collodion was one means of doing so. In the spreading navi, the remedies could be divided into those avoiding, and those leaving, a scar. The first should be used in prominent situations; the second in places that were covered. Dr. Duncan then considered the various methods, showing where each was most applicable, and where any special method was contraindicated. The best coagulating fluids were perchloride of iron and carbolic acid. They should, however, never be used unless the part treated could be isolated. It was difficult so to regulate the dose as to avoid sloughing, and yet not do too little. In electrolysis, he used three to twelve cells of Weiss's Smees' battery, and insulated needles. The conclusions at which he had arrived as to

this method were the following. 1. In a large number, there was no untoward result. 2. In two cases, alarming pallor was probably due to chloroform. 3. There was never sloughing nor suppuration. 4. With perseverance, a cure was always obtained. 5. It was extremely tedious.—The PRESIDENT expressed his opinion that the Society were much indebted to Dr. Duncan for his excellent paper. He admired the account given of the natural history of the disease, and of the rules deduced therefrom as to the propriety of interference. Dr. Duncan had given a choice of treatment, and clearly laid down the reasons of selection.—Mr. JOSEPH BELL supposed it was because nævus was a surgical, and not a medical disease, that the physicians present did not rise to express their views on the subject, and thus commence the discussion. Dr. Duncan had, indeed, left little scope for criticism; for when a man who was thoroughly master of the subject—indeed, an acknowledged authority on it—had taken the trouble to arrange his ideas with accuracy, to go over the whole subject concisely and without redundancy, what more could be said except to thank him? His own experience had taught him much the same lesson as that of Dr. Duncan. He found the ligature almost universally applicable in parts not exposed to view; and, even in the face, a properly applied ligature left very little mark. He described a case of nævus under the eyelid, of the size of a fourpenny piece, cured by ligature, in which, six months afterwards, no trace of a scar could be found. On the whole question of electrolysis as a mode of treatment of large nævi, Dr. Duncan could say of it, “Cujus pars magna fui”; as he was not only a great authority on the subject, but he put his advice and assistance at the service of his colleagues. He believed the members of the Society would be able to appreciate the value of the paper when it was published, as it soon would be.—Mr. CHENE thought that Dr. Duncan had hardly laid sufficient stress on, or done sufficient justice to his use of, the elastic subcutaneous ligature in the treatment of nævi. His use of a metal button was most original and valuable.—Dr. G. W. BALFOUR, though a physician, and not much in the way of treating nævus, had listened with much pleasure to Dr. Duncan's paper. The logical deduction as to the treatment of nævi from a consideration of their natural history, would have delighted a former president of the Society, whose loss they all deplored. He thought, as this was the first occasion in which the Society had met since the death of Professor Ilughes Bennett, they should record on their minutes the profound sense of the great loss they had sustained by his removal from amongst them.

External Uses of the Hydrate of Chloral.—Dr. CRAIG read a paper on this subject. After a brief note on the discovery and chemistry of chloral, he alluded to Keen's experiments on it as an antiseptic for dissecting-room purposes; and then detailed a series of experiments he had made in preserving tumours, organs of animals, fishes, etc. He then detailed cases illustrating its value as an antiseptic dressing for wounds, ulcers, and skin-diseases. He concluded by reading a letter from Dr. Heron Watson, who had used chloral as a dressing in various ways in his wards during six months, and has been much satisfied with the results. He believed it to be superior in its antiseptic properties to carbolic acid, and less irritating; and, by its absorption by wounds, it deadened pain. Dr. Watson used it in four forms as a dressing: 1. In a solution of five or ten per cent. in water for cleansing wounds, sponges, instruments, etc.; 2. As an ointment made up with paraffin, wax, and almond-oil, spread on linen cloth, and applied to wounds or ulcers; 3. Lint soaked in a solution of chloral (one drachm to one ounce) in water; 4. Lint soaked in a solution of chloral in olive-oil of due strength. This made an excellent material for stuffing cavities after resection of bones or joints. Dr. Watson had never met with any disagreeable results from absorption of the remedy.—The PRESIDENT felt sure that the Society were much indebted to Dr. Craig for his important practical paper, and much credit was due to him for his experiments. The specimens showed the advantages possessed by chloral-hydrate in not hardening the tissues, as was done by spirit, or removing the colour.—Dr. JOHN DUNCAN remarked on the practical nature of the paper, and related an experience of his own as to the use of chloral-hydrate as an antiseptic dressing. He had tried it as a dressing in the manner described in Dr. Watson's letter, in the hope that it might prove less irritating than carbolic acid; but found, with a twenty per cent. solution as dressing, and used as spray, that the wound did not remain sweet. He tried, next, a twenty per cent. solution of chloral as a spray, which proved exceedingly pungent and disagreeable, causing both himself and his dressers to sneeze violently. He then dressed the wound with lint soaked in a saturated watery solution of chloral. The patient was very comfortable after the operation; in the evening, he was drowsy; and, next morning, was found in a state of absolute narcotism, from which it was impossible to wake him for twenty-four hours. The state was a most alarming one; and though the patient eventually came out of it, it was only

after the use of various stimulants, injections of strychnia, etc. He believed that if chloral were used in sufficient strength to be a reliable antiseptic, it would prove a dangerous narcotic; while, in less strong solution, it was not reliable as an antiseptic, and would do more harm than good.—Dr. CRAIG replied that he had always found that it removed putrescence in the surgical cases in which he had tried it, but that he had had no experience in major operations.

Jaborandi.—Dr. CRAIG read a paper entitled notes on jaborandi. After a note on the history of its introduction into Europe, Dr. Craig alluded to an experiment he had made on himself in January 5th, 1875, the first in Scotland; and then proceeded to give the general results of a number of other experiments he had recently made on the drug. The strained infusion of one drachm of the leaves produced, in twenty minutes, a salivation which lasted from five to six hours, and which was very profuse, but attended by no pain in the salivary glands, with a profuse perspiration, which passed from the forehead to the trunk and limbs, and also was lasting. The same effects followed its use as an enema. The active principle of the drug seemed to be an alkaloid, which had been named pilocarpine; and did not reside either in the volatile oil which gave its characteristic odour, nor in an acid also present in the leaves. One grain of pilocarpine seemed to equal in power the infusion of one drachm of the leaves. Dr. Craig had tried the effects of the drug against the dry tongue and mouth of fever with good result. It had also been of use in removing pleuritic effusion. The author concluded by a disquisition into the botanical source of the drug.—The PRESIDENT, after thanking Dr. Craig for his paper, said that as yet no sufficient experiment had been made to determine the therapeutic value and application of this interesting drug.—Dr. BRAKENRIDGE stated that he could, from experience, confirm Dr. Craig's opinion as to the value of jaborandi in pleurisy. In one case, a single dose had removed a pleuritic effusion; and, on its returning, a second dose had again removed it. He had tried it, also, in post-scarlatinal nephritis, and also in a case of post-scarlatinal dropsy, with anasarca, ascites, and albumen in the urine. Digitalis, purgation, and local applications, had failed to remove it; œdema of the lungs came on, followed by numerous convulsions. Jaborandi, first in ten-grain, and afterwards in thirty-grain doses, during fourteen days, gradually overcame the anasarca, and now the boy was quite well. The urine steadily increased during its use, diminishing again when it was stopped.—Dr. MUIRHEAD related three cases in which he had used the drug with no good result; but in none of them had its physiological effect been obtained.—Dr. CRAIG briefly replied.

SOUTH OF IRELAND BRANCH.

SECOND GENERAL MEETING, SATURDAY, NOVEMBER 20TH.

W. J. CUMMINS, M.D., President, in the Chair.

Extroversion of the Bladder and Epispadias.—Dr. R. ATKINS exhibited a specimen of extroversion of the bladder and epispadias taken from the body of a man, aged about 53, a patient in the District Lunatic Asylum. The parts presented the characteristic appearance of this peculiar species of defective development; the anus was situated in the perineum about one inch behind the posterior surface of the scrotum.

Chronic Phthisis.—Dr. R. ATKINS showed the thoracic viscera from a case of chronic phthisis. The left lung was almost completely destroyed, while the right organ, although infiltrated with tuberculous matter, had not yet commenced to break down. The heart was exceptionally small, measuring on its anterior surface from the root of the aorta to the apex $3\frac{1}{2}$ inches, in the transverse direction at the broadest part $3\frac{1}{4}$ inches, circumference $7\frac{3}{4}$ inches, and it weighed $6\frac{3}{4}$ ounces. The veins on its surface were dilated, and its valvular apparatus and substance were perfectly healthy.

Scirrhus of the Pylorus.—Dr. CREMEN exhibited a specimen of scirrhus of the pylorus. Although the patient, a female, had presented the symptoms of the disease, yet vomiting was often absent for several days together.

Traumatic Tetanus.—Dr. GREGG read the report of an interesting case of traumatic tetanus which occurred in a lad, aged 13, after a lacerated wound of the finger, who had been treated successfully under his care in the South Infirmary, with Calabar bean and subcutaneous injections of morphia. The total quantity of Calabar bean administered amounted to 180 grains of the extract, extending over a period of twenty-five days, while only four injections of morphia were given of one-eighth of a grain each. The tetanic symptoms were well marked; the temperature never rose higher than 99 degs., and usually stood at 98.5 degs. The pulse came down under the influence of the drug from 104 on October 14th (the day of admission), to 40 on November

1st. The pupils were affected very slightly on October 20th, and he was discharged cured on November 7th, 1875.

Accidental Concealed Haemorrhage.—Dr. CREMEN read the report of a rare case of accidental concealed hæmorrhage which had occurred in his practice. He was called to see a multipara, and, from the size and shape of the abdomen, diagnosed twins. The os was slightly dilated, and the pains weak. About an hour afterwards she fainted, and looked blanched. Fearing internal hæmorrhage, he summoned a consultant, who agreed with him that such was the case, and, in view of the undilated condition of the os uteri and the weakness of the pains, a stimulating and expectant plan of treatment was adopted. Soon afterwards, however, she again became faint, was seized with a convulsion, and almost immediately expired. He at once laid open the cavity of the uterus through the abdomen, and found the diagnosis correct. The womb was full of blood, and contained two children, females. The placenta were placed laterally; one was completely separated; the other was still adherent. He removed the children, and found the one which had been attached to the separated placenta dead and blanched; the other breathed for a few seconds. This was the only case of this nature that he had seen, and if he were to meet another similar he would adopt the following plan of treatment; dilate the os with Barnes's bags, and deliver as speedily as possible, avoiding the rupture of the membranes until he was in such a position as to be able to apply the forceps immediately. Dr. Cremen brought forward some statistics regarding this form of hæmorrhage, and remarked that the complication of twins added to the difficulty of the case.

SOUTH-EASTERN BRANCH: WEST KENT DISTRICT.

WEDNESDAY, NOVEMBER 10TH, 1875.

ROBERT ROSS BROWN, Esq., in the Chair.

Excision of the Elbow.—Mr. A. W. NANKIVELL related a case of excision of the elbow in a lad aged fifteen, for compound comminuted fracture of the humerus involving the joint. The patient was exhibited to the meeting. The skin and soft parts were extensively lacerated, causing sloughing; and severe bleedings occurred from the granulating surfaces, endangering the safety of the limb. The hæmorrhages were subdued by the application of the undiluted tincture of ergot of the *Pharmacopœia*. A woman, whose elbow had been excised for disease by Mr. Nankivell eight years ago, was also exhibited. The elbow was freely movable, and the arm strong and useful.

Abscess of Thigh: Extension: Rupture of Artery.—Mr. A. W. NANKIVELL related a case of recent abscess of the thigh and ham in a boy aged 8, in which extension was made to rectify malposition, and in which rupture of an artery occurred (deep branch of anastomotic?). Immediate amputation was found to be necessary, after the failure of exploratory incisions. The blood-vessel was supposed to be in a diseased condition, through sloughing of the adjacent tissue. The popliteal artery appeared to be intact.

Neuro-hæmatic Lesion.—Mr. ROBERT COBB related a case of neuro-hæmatic lesion running a protracted course (five months), and presenting great variations of temperature (low evening, high morning). Recovery took place under the use of eucalyptus globulus and physostigma.

Central Placenta Prævia.—Mr. ROBERT R. BROWN related a case of placenta prævia centrally implanted, that terminated fatally. The patient, aged 41, in her ninth pregnancy, declined the use of the plug in the initiatory stages. On attempting delivery, the placenta was found to be so much separated as to come away entirely on endeavouring to clear the front portion. The head came down with the pains, but receded soon afterwards, and allowed the elbow to protrude, together with gushes of blood. Turning was immediately performed. There was no more hæmorrhage; but collapse occurred, and the patient died in one hour and fifty minutes after delivery. The uterus continued firmly contracted for eighty minutes, then became rather flaccid, and some external hæmorrhage took place. The restlessness of death set in before the uterus lost its tone. This case was attended by Drs. John and Frederick Brown, in connection with the narrator. Death must be attributed to excessive loss of blood in the initiatory stages, and to trusting to the pains after the removal of the placenta for ten minutes, without immediate turning. Chloroform was used on commencing delivery, and ergot was given. The pains improved under these agents.

Intermittent Fever.—Dr. JAMES V. BELL reported a case of intermittent fever with paroxysms every fifth day, complicated with lung-congestion, diarrhoea, vomiting, and petechial-looking erythematous rash. The patient recovered under the use of quinine.

Stomatitis, etc.—Dr. JAMES V. BELL narrated a case of stomatitis followed by obscure symptoms of enteric fever (without rose-spots),

with erythema nodosum, pericarditis, and double pleuropneumonia. There was apparent recovery; but, after six weeks' abeyance of symptoms, cerebral disease became developed, and proved fatal in three weeks.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT MEETING.

THURSDAY, NOVEMBER 11TH, 1875.

F. WACHER, Esq., in the Chair.

Comparative Birth-rate and Number of Conceptions.—Mr. RIGDEN read a paper on the comparative birth-rate and number of conceptions in Canterbury at different periods of the year, showing that the highest average birth-rate, viz., 35.65 per 1,000 inhabitants, was in December, and consequently the greatest number of conceptions occurred in March; the lowest birth-rate, viz., 30.27 per 1,000, was in June, and, consequently, the least number of conceptions was in September. Also, when the birth-rate was at the lowest, the male births were in excess of the females; while, in December, when the birth-rate was high, the females were in excess. April and May also produced an excess of conceptions, while comparatively few conceptions occurred in October and November. The excess did not seem to be determined by the marriage-rate, inasmuch as the excess of marriage-rate in Canterbury was in October, November, and December. He suggested that the excess appeared to depend upon increased vitality in the spring months of March, April, and May.

Turning in Shoulder and Arm Presentations.—Mr. RIGDEN read a paper upon the possibility, and therefore the advantage, of turning in extreme cases of shoulder and arm presentations by means of the craniotomy forceps in preference to eviscerating the thorax. This might be effected by grasping the foot with the forceps, while the left hand might be used to lift up the shoulder. The paper was illustrated by a case in which the right arm had been prolapsed for fifteen hours at the least. The foot, and if possible the opposite foot to the arm, might often be reached by the forceps, but could not be held by the hand of the surgeon, and room might yet remain in the vagina for his left hand.

CORRESPONDENCE.

CLINICAL TEACHING.

SIR,—A few days ago, I met a once active member of our profession, now retired on a competence obtained by well directed industry and intelligence. Among other subjects of conversation, he made some remarks on the general condition of professional knowledge at the present time compared with that of his own day. He is not an unfair *laudator temporis acti*, and I thought much that he said was true. There is one point on which it would be interesting to hear the opinions of some of the readers of the JOURNAL, and that is the general state of practical knowledge among the rising generation. To go to this point at once, we may ask whether there is any substitute for that kind of instruction which, under the old system of apprenticeship, was afforded by good general practitioners to those placed under their care as apprentices. There is, no doubt, a system of teaching the elementary branches of medical education which is decidedly superior to that of the past; but this has been brought about by the effect of examinations. So far, of course, as a knowledge of chemistry, botany, anatomy, and materia medica is concerned, an examination is the best test; but we all know that, when we use the term "a practical knowledge" of our profession, we mean something more than our present system of examination can secure, and, indeed, which is not to be obtained by such a system.

Now it appears to me that, if we are to look to anyone in particular to supply the place of the practical teaching to which I have alluded, it is undoubtedly to the clinical teachers at our schools of medicine. There is no doubt we shall in time have some change in this branch of medical education; but those changes will be brought about by external influences, and not by internal efforts. Such is always the case, and there is no reason to believe that the eminent men who are now engaged nominally as the teachers of clinical medicine and surgery in London will resist the reasonable demands of those who are interested in this subject; and I would ask whether it is not one of the greatest importance to society and to our profession.

There are some who would take a commercial view of this subject. They would say it is unjust that the teaching of medicine and surgery, or, as it is usually called, hospital practice, should be the most expen-

sive part of medical education, and, as a rule, the worst attended to. A free-thinking and independent student might say to the dean of his school: "I paid you fifty guineas to be taught the most useful part of my profession—that by which I hope to live and support myself some day. But, as far as teaching goes, I am indebted very little to you. The hospital provides the patients and everything else, and you take fees for allowing me a privilege that is not really yours to give." And it would not be easy to reply to this charge. It is undoubtedly a difficult thing to define the liabilities of an indefinite bargain of this kind; but there are moral responsibilities involved in it which cannot be avoided. If we take only a superficial view of this question, it is unlikely to lead to any results. Suppose we assume that there is truth in the statement that clinical teaching is very insufficiently carried on, considering the price which is paid for it. There is some reason why that attention which ought to be given to it by every member of a hospital staff is not given, and why those responsibilities are not properly recognised. There are indeed some examples in London of unselfish devotion to the teaching of clinical medicine and surgery, and the reward obtained is by no means what would be expected. Labour and thought, and neglect of practice, are necessary for such instruction; and when those who neglect their duties share equally with those who perform them, there is more loss than gain by devotion to them.

It might be asked whether an appointment to the full staff of a hospital is regarded by some as a reward for past services; for such an idea might justify the neglect of those duties imposed on clinical teachers. If this be so, nothing more can be said. The system must be altered entirely before improvement can take place. It may be replied that clinical teaching is more systematic now than it ever was, and that regular lectures are given by each of the staff. Such lectures do not supply the place of bedside instruction; they are not an equivalent in any sense, and ought not to be considered so. The remarks I have made may, I hope, be so favourably received by you as to be brought under the notice of the readers of the JOURNAL. Some advantage must follow from the consideration of the subject, and will be appreciated by many an one who is, like myself,

AN OLD STUDENT.

SUGAR IN URINE.

SIR,—In his brevity, your reporter has conveyed an incorrect representation of my communication to the Royal Medical and Chirurgical Society on the 23rd inst. I made the remark, as given, that sugar is found to occur in urine as a transitory condition more frequently than is generally supposed; but this referred to sugar present to such an extent as to be at once recognisable by the copper-test, and to amount, as quantitative examinations have shown me, and as I mentioned, to some few grains to the fluid ounce. The product exhibited at the meeting of the Society was not obtained from urine of this description, but from urine which failed to give a reaction on being tested in the simple and ordinary way. I took scrupulous care to state that every sample of urine, before being treated for obtaining the product, was tested with the copper-solution, and was only employed when found to give a negative reaction. The object I had in view in exhibiting the product was to carry conviction throughout the profession that sugar must be ranked as a constituent of healthy urine, although such urine may not betray its presence (from the minute extent to which it exists) under the ordinary mode of testing. I was led to adopt the course I took from the unsettled state of opinion upon the subject. In the interest of medical science (for the question, I consider, has an important bearing in this direction), I should be glad if you would make the correction, so that the readers of your JOURNAL may not remain under the impression that the sugar exhibited had anything to do with a transitory condition.

Nov. 30th, 1875.

Yours faithfully,

F. W. PAYE.

EXTRACTION OF TEETH UNDER CHLOROFORM.

SIR,—In his able paper on "One of the Causes of Death during the Extraction of Teeth under Chloroform", Dr. Brunton has shown his usual acumen both in interpreting the intricate physiological processes which may induce death by shock, and in his plausible hypothesis *ex hypothesi* to account for death during a minor operation under chloroform, by supposing that, in such cases, too small a quantity of the anæsthetic has been given. We have, alas! too many well authenticated cases of death after small doses of this dangerous agent, wherein "shock after operation" could not possibly form a factor in the case. (Only last week, we see recorded the death of a lady in her bed after a comparatively small dose of chloroform.) That shock may, in a few isolated cases, be the cause of death after a minor operation, I do not deny, although I have never heard of a case of even temporary stoppage of the heart's

action after the extraction of a tooth; but it would lead to a very dangerous course of practice were we to assume that, in cases of death after the administration of chloroform, too small a quantity of the anæsthetic had been used. I am, etc., A. H. H.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

THE Town Council of Southampton have increased the salary of Dr. Henry Palk, Medical Officer to the Borough Police, from £50 to £100 *per annum*.

POOR-LAW MEDICAL APPOINTMENTS.

GREEN, Edward F. S., M.B., appointed Medical Officer and Public Vaccinator for the Bentham District of the Settle Union, *vice* E. Tatham, M.B., deceased.
HYATT, James T., L.R.C.P.Ed., appointed Medical Officer for the First Division of the Shepton Mallet Union.
M'KELVIE, Robert B., M.D., appointed Medical Officer to the Lorne Combination Poorhouse, and Medical Officer for the Parish of Kilmore and Kilbride, Argyllshire, *vice* G. M'Gillivray, M.D., deceased.
MARKBY, Thomas, M.R.C.S.Eng., appointed Medical Officer for No. 5 District of the Royston Union, *vice* J. Balding, M.R.C.S.Eng., resigned.
MAYBURY, William A., M.D., appointed Medical Officer and Public Vaccinator for the Second Ward District of the Colchester Union, *vice* G. Brown, M.D., resigned.

MILITARY AND NAVAL MEDICAL SERVICES.

DR. ANDREW H. LEITH, of H.M. Bombay Medical Service, late Inspector-General of Hospitals, and President of the Government Sanitary Commission in that Presidency, has lately died at Etherton Lawn, near Tunbridge Wells.

LOSS OF STORES AT ALDERSHOT.—We understand that the Board, whose recent appointment to adjudicate a disputed point in connection with loss of stores at Aldershot, have recommended that the deficit shall be borne by the public. We are not in a position at present to say more than a word of congratulation to the Army Medical Department on this satisfactory decision, which we hope may be fully endorsed by the Horse Guards and Secretary of State for War.

FORAGE ALLOWANCES.—A War-Office circular has just discontinued the customary allowance of forage to officers as an allowance according to rank. Forage allowance is only to be given in future on condition that the keeping of a horse or horses is absolutely necessary for the performance of the officer's duties, and that the horses used are *bonâ fide* the property of the officers using them. This circular will materially curtail the allowances hitherto given to all the higher grades of army medical officers by virtue of their relative rank.

OBITUARY.

WILLIAM RAWLINS BEAUMONT, M.D., F.R.C.S.Eng.

THERE are many members of the profession in this country, especially old Bartholomew's men, who will regret to hear that this distinguished and estimable surgeon died on October 12th last, at Toronto, Canada, where he obtained the highest appointments and had practised for many years.

Dr. Beaumont was born in London in 1803. After a sound preliminary education, he entered on his professional studies at St. Bartholomew's Hospital, where he soon became a great favourite, especially with his illustrious teacher, Abernethy, who testified that he "did very assiduously prosecute his professional studies, for a more than ordinary length of time"; he completed his anatomical studies in Paris, under Amussat, who recognised in him "un zèle et une aptitude rare". On his return to England, he presented himself for examination, and obtained the diploma of membership of the Royal College of Surgeons on December 22nd, 1826. In 1844, the College recognised his claims for the honorary fellowship, which was conferred on him August 26th of that year. He commenced the practice of his profession in this metropolis, and for some time was surgeon to the Islington dispensary. He proceeded to Toronto in 1841, and soon afterwards graduated as M.D. in the university of that city. In 1843, he was elected Professor of Surgery in the University of King's College (now the Uni-

versity of Toronto), an appointment he held for ten years. His clinical lectures on surgery, at the Toronto General Hospital, were greatly appreciated. In 1872, he was elected Emeritus Professor of Surgery in the University of Trinity College, Toronto. He invented, and himself made, several surgical instruments of great ingenuity and utility; one of which, an instrument for passing sutures in deep-seated parts, as in the operation for cleft palate, which was examined and admired by Brunel, the great engineer, and was considered by Tirmann, the surgical instrument maker in New York, to have been the origin of the Singer sewing machine, an opinion shared by Sir James Paget and communicated by him to the late Dr. Fraser of Toronto. An account of this invention was published in the *Medical Gazette* of 1836, and also in the *Medico-Chirurgical Transactions*. Our friend, Mr. T. M. Stone, of the Royal College of Surgeons, who was a frequent correspondent of Dr. Beaumont, claims this discovery for his friend, stating that long before the sewing machine was known, Dr. Beaumont had shown, and subsequently presented to him, the instrument which he gave a few years ago with others to the College of Surgeons, in furtherance of the wishes expressed by Sir William Ferguson to form a collection of surgical instruments for the museum of that Institution. It may be there seen, described in the catalogue by Professor Flower as "D 11A. Another instrument for applying sutures to cleft palate. Mechanism resembling modern sewing machine. Presented by Mr. T. M. Stone." Other instruments illustrating the great mechanical skill of Beaumont were presented by him to the same collector, to which he was a valuable contributor. The *Canada Medical and Surgical Journal* deservedly states that Dr. Beaumont was a gentleman of a quiet and retiring disposition, a sound surgeon and an instructive lecturer, and his memory will be held in veneration by all with whom he came into contact.

MEDICAL NEWS.

UNIVERSITY OF LONDON.—M.D. Examination, 1875.

Crocker, Henry Radcliffe, B.S., University College
Duncan, Andrew, King's College
Eastes, Thomas (Gold Medal), Guy's Hospital
Philpot, Joseph Henry, King's College
Sturge, William Allen, University College
Yeo, Isaac Burney, King's College. (Obtained the Number of Marks qualifying for the Medal.)

Logic and Moral Philosophy only.

Hoar, Charles Edward, King's College
Houghton, Walter Benoni, B.S., University College
Leech, Daniel John, Manchester Medical School
Lewtas, John, University of Edinburgh and Netley Hospital
Lowe, Walter George, St. Bartholomew's Hospital
Nicholson, Arthur, King's College
Rigby, James Arthur, Guy's Hospital
Taylor, Herbert, St. Bartholomew's Hospital

M.S. Examination.—Logic and Moral Philosophy only.

Gould, Alfred Pearce, University College

B.S. Examination. Pass List.

First Division.

Hullard, Jean Arthur, B.Sc., University College
Maclean, Thomas Edwin, University College
May, Bennett, Birmingham General Hospital

Second Division.

Hobson, Lewis John, University College
Jameson, Leander Starr, University College
Rose, William, King's College
Voelcker, George Henry, University College

Examination for Honours.

First Class.

Hullard, Jean A., B.Sc. (Gold Medal), University College
May, Bennett, Birmingham General Hospital } equal
Rose, William, King's College }

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, December 2nd, 1875.

Broome, Stephen Bernard, 89, Camden Street, N.W.
Elcum, Donald, Warwick House, Cheltenham
Houchin, Edmund King, 12, High Street, Steppay
Whitfield, William Clarke, St. Owen Street, Hereford

The following gentlemen also on the same day passed their primary professional examination.

Bailey, Henry Frederick, University College
Gairdner, John, University College
Rean, William Henry, London Hospital

MEDICAL VACANCIES.

THE following vacancies are announced:—
ADDENBROOKE'S HOSPITAL, Cambridge.—Dispenser. Salary, £60 per annum. Applications on before December 15th.

ARDWICK and ANCOATS DISPENSARY, Manchester.—Resident House-Surgeon.
BERKS COUNTY ASYLUM, Moulsoford.—Assistant Medical Officer. Salary, £80 per annum, with board, lodging, and washing.
BOOTE BOROUGH HOSPITAL.—House-Surgeon. Salary, £80 per annum, with board, furnished apartments, and washing. Applications to the Honorary Secretary.
CARMARTHEN UNION.—Medical Officer.
CHORLTON-ON-MEDLOCK, RUSHOLME, and MOSS SIDE DISPENSARY, Manchester.—House-Surgeon.
DENBIGHSHIRE INFIRMARY.—House-Surgeon. Salary, £85 per annum, with board, washing, and residence.
DUMFRIES and GALLOWAY ROYAL INFIRMARY.—Assistant House-Surgeon. Board and washing. No salary. Applications to the Treasurer.
GENERAL HOSPITAL and DISPENSARY FOR SICK CHILDREN, Penlebury, near Manchester.—Superintendent. Salary, £100 per annum, with everything found.
GLOUCESTER INFIRMARY.—Surgeon and Assistant-Surgeon. Applications before January 27th, 1876.
HAMBLEDON UNION, Surrey.—Medical Officer. Salary, £53 per annum, with extra fees. Applications on or before December 15th.
HUDDERSFIELD INFIRMARY.—Physician.
INFIRMARY FOR CONSUMPTION, Margaret Street, Cavendish Square.—Visiting Physician. Applications on or before December 16th.
LEEDS UNION.—Medical Officer. Salary, £300 per annum, with unfurnished residence, coals, gas, water, and rates. Applications on or before Dec. 29th.
MOFFAT HYDROPATHIC ESTABLISHMENT.—Medical Man to take charge. Applications to Messrs. Bruce and Kerr, W.S., Edinburgh.
PARISH OF LISMORE AND APPIN, Lettermore.—Medical Officer. Salary, £100 per annum. Applications to the Rev. D. Dewar, Manse, Appin, Argyll.
ROTHERHAM HOSPITAL.—Resident House-Surgeon. Salary, £120 per annum, with board and furnished apartments. Applications on or before December 23rd.
ST. PANCRAS and NORTHERN DISPENSARY.—Resident Medical Officer. Salary, £100 per annum, with residence, and £20 for servant's wages.
SHEFFIELD GENERAL INFIRMARY.—Physician. Applications on or before January 5th, 1876.
STROUD GENERAL HOSPITAL.—House-Surgeon. Salary, £60 per annum, with board, furnished rooms, attendance, and washing.
THARSIS MINES, Province of Huelva, Spain.—Medical Practitioner. Salary, £250 per annum. Applications to the Secretary, 136, West George Street, Glasgow.
TONGUE and FARR, District of, County of Sutherland.—Medical Officer. Salary, £150 per annum, and house.
TRINITY COLLEGE, Dublin.—Professor of Botany. Applications on or before January 22nd, 1876.
WANDSWORTH and CLAPHAM UNION.—Resident Medical Officer. Salary, £250 per annum, with furnished apartments, rations, washing, gas, and coal.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

BARLOW, Thomas, M.D., appointed Assistant-Physician to Charing Cross Hospital, *vice* G. V. Poore, M.D.
BOOBLE, Robert M., M.R.C.S. Eng., appointed House-Surgeon to the Rochdale Infirmary, *vice* W. H. E. Burke, M.R.C.S. Eng., resigned.
CRESTON, John, M.R.C.S. Eng., appointed Resident Medical Superintendent of the Hoxton House Asylum, *vice* W. J. Hunt, M.D., deceased.
HAYWARD, W. T., L.Q.C.P.I., appointed House-Surgeon to the Liverpool Infirmary for Children, *vice* A. James, M.B., resigned.
***JACIELSKI, A. V., M.D.,** appointed Physician to the Margaret Street Infirmary for Consumption, *vice* Gilbert Smith, M.D., resigned.
JUMEAUX, Benjamin, L.R.C.P. Ed., appointed House-Physician to the North Staffordshire Infirmary.
MILNER, E., M.R.C.S. Eng., appointed Surgeon to Out-patients at the Lock Hospital, *vice* B. Shillitoe, F.R.C.S. Eng., appointed Surgeon.
PURCELL, Ferdinand A., M.D., appointed Physician to the Westminster General Dispensary.
QUINTON, R. F., M.D., appointed Resident Medical Officer and Secretary to the Newark-on-Trent Hospital, *vice* W. A. Maybury, M.D.
***SHEWEN, Alfred, M.D.,** appointed Assistant-Physician to the Metropolitan Free Hospital.
***SHILLITOE, Buxton, F.R.C.S. Eng.,** appointed Surgeon to the Lock Hospital, *vice* J. R. Lane, F.R.C.S. Eng., resigned.
WALTER, William, M.B., appointed House-Surgeon to the North Staffordshire Infirmary.
***WINSLOW, LITTLETON S. F., M.D.,** appointed Lecturer on Psychological Medicine at the Charing Cross Hospital, *vice* W. J. Hunt, M.D., deceased.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTH.

BARNES.—On December 4th, at 45, Lowther Street, Carlisle, the wife of *Henry Barnes, M.D., of a daughter.

MARRIAGE.

WILSON-COWAN.—At 13, Mount Street, Aberdeen, on December 7th, by the Rev. Matthew Galbraith, M.A., John S. Wilson, M.R.C.S. Eng., L.R.C.P. Ed., F.R.G.S., Greenock, to Isabella Henderson, daughter of William Cowan, Esq., Locomotive Superintendent, Great North of Scotland Railway.

DEATH.

***DANIELL, William Cole, M.R.C.S. Eng.,** of Calverton Limes, Stony Stratford, son of the late Edward Daniell, Surgeon, of Newport Pagnell, Bucks, aged 40, on December 6th.
GRAHAM, George Young, Esq., Surgeon, at Stockport, aged 71, on December 2nd.

OPERATION DAYS AT THE HOSPITALS.

- MONDAY**Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.
- TUESDAY**Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.
- WEDNESDAY** ..St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaitan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.
- THURSDAY**St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 3 P.M.
- FRIDAY**.....Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.
- SATURDAY** ...St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M. and 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

- MONDAY**.—Medical Society of London. Dr. Henry Lawson will exhibit M. Hayem's new mode of estimating the amount of Blood-Corpuscles. Dr. Alfred Freer, "A Case of Impalement, with *post mortem* Results four years and a half afterwards".
- TUESDAY**.—Royal Medical and Chirurgical Society. 8 P.M.: Ballot. 8.30 P.M.: Mr. Marsh, "Case of Abdominal Section for Intussusception in an Infant"; Dr. Fage and Mr. Howse, "Case of Abdominal Section for Intussusception in an Adult"; Mr. J. Hutchinson, "Case of Operation for Intussusception into the Colon".
- FRIDAY**.—Quekett Microscopical Club (University College), 8 P.M. Mr. Henry Davis, F.R.M.S., "On a Larval Cirripede"; Mr. John E. Ingpen, "On the Measurement of Angular Aperture";—Medical Microscopical Society, 8 P.M. Dr. U. Pritchard, "A New Form of Freezing Microtome"; Mr. J. Needham, "Specimens".

NOTICES TO CORRESPONDENTS.

- CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.
- PUBLIC HEALTH DEPARTMENT**.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.
- AUTHORS** desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.
- CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.
- WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**
- COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

MEDICAL EDUCATION.

SIR,—Will you kindly allow a senior student space for a few words on this subject? I have read with interest the letter of a Graduate in Medicine. His remarks and suggestions are admirable, and evidently result from careful and impartial observation on medical education; but is he not mistaken in saying that at most schools the lecturers are paid at fixed stipends? I strongly agree with your correspondent, that compulsory attendance at lectures is, under any circumstances, bad. Nearly all students with whom I have conversed on this subject—and their name is legion—agree that the majority of students learn little or nothing from lectures, but derive the knowledge necessary for their examinations entirely from other sources. Now, if this be the case, there must be something radically wrong. Is the fault in the students? Is it in the lecturers? Is it in the system? Perhaps in all three: certainly in the last. I am afraid that medical men are often induced to lecture more to further their own interests than from any disinterested conviction of their fitness for teaching. Many lecturers fail to acquire, and few possess naturally, that clear, explanatory, fluent address, which is a *sine quâ non* in a good teacher. There are, I fear, more lectureships than men well qualified to fill them. Practical work is most important; but the more time students spend in attending lectures, the less they have in the wards or dissecting room. It is hard for students who are devoting all their energies to preparation for one examination to be compelled at the same time to attend lectures on subjects for another and more distant examination; yet this often happens. If the compulsory system were abolished, good lecturers would not find the students' attendance seriously diminished, while students would be spared the humiliation (which I have undergone for a certificate, forsooth) of hearing a man blunder and stammer through a so-called course of lectures with an oratory that would disgrace a nursery governess.—I am, etc.,

GLYNN WHITTLE.

Liverpool, November 29th, 1875.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

ANESTHETICS FOR THE MILLION.

WE have seen with regret Mr. Ellis's letter in the *Times* on the case of Mrs. Childers. The main lesson which was taught by that sad event is the danger of the self-administration of anaesthetics. Their danger is not to be overcome by the use of any known mixtures. All tend to produce delirium and drowsiness, and to render the patient more or less unfit to take care of himself. We know of nothing which authorises Mr. Ellis to represent his mixtures as anaesthetic, and we can but regret that he should have taken the occasion of a very sad calamity to enforce a moral which is not, we think, conducive to the public safety, or in consonance with skilled opinion in the profession.

DR. M. (Royal Navy) makes a suggestion that recipients of the gold medal of Sir Gilbert Blane, being members of the London College of Surgeons, should have some distinguishing mark in the calendar of the College, similar to that in the Navy List. This seems to us deserving of notice by the authorities. No doubt the Calendar might be made still more valuable and interesting by publishing the honours obtained by so many of its Fellows and Members, as M.P., J.P., Vict. Cross, Jacksonian and Collegiate Prize Essayists, F.R.S., B.A. or M.A. Oxon., Cantab., or Lond., Graduates in Medicine of Universities in the United Kingdom, etc.; but this might possibly involve official difficulties.

LEITER'S HYPODERMIC SYRINGE.

SIR,—In to-day's JOURNAL, under the heading of New Inventions, appears Leiter's Hypodermic Syringe. We beg to inform you that we have for some time past made hypodermic syringes with spring, etc., as therein described, but possessing the additional advantage of injecting the solution immediately after the puncture. By simply pressing a small trigger, the spring is released, the needle inserted, and solution injected simultaneously. The instrument is known as Arnold's self-acting hypodermic syringe.

Apologising for trespassing on your valuable space, we remain, sir, your obedient servants,

35 and 36, West Smithfield, November 27th, 1875.

ARNOLD AND SONS.

* * * We have seen one of the syringes in action, and it seems to us a very neat and satisfactory instrument. Messrs. Milklin inform us that they have made for some time a similar instrument.

PROFESSIONAL ETIQUETTE.

SIR,—I should feel much obliged if you will let me know your opinion of the following case in your next issue, if possible. One of the surgeons of this town had a patient living in the country, who went on a visit to a friend, a patient of mine. While there, she was taken seriously ill. I was sent for, and attended, with the parents' consent, and also met their family medical man in consultation, who approved of my treatment, and left the case in my hands. In the course of some weeks she was sufficiently recovered to be removed home, where I was given to understand that I should continue my attendance; but it happened that the family medical man was attending on others in the same street, so the parents called him in as he was passing, and he took on the case without letting me know. Was that professional? and, if not, how should I act?—I am, sir, yours truly,

Frome, December 1st, 1875.

L. D. V.

* * * We think the natural course of events was followed, and see no ground of complaint against the family medical attendant. The parents may have shown some want of courtesy.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE following is a copy of the paper on pathology, therapeutics, and surgery, submitted to the candidates at the written examination for the Fellowship on Saturday, Nov. 27th. It was necessary to answer all four. 1. Describe minutely all the changes observed in the vessel, its branches, and its contents during the repair of a large artery after ligation. 2. What are the causes of non-union after fracture of a long bone? Describe the treatment you would adopt to obtain union. 3. Mention the conditions, local and general, coexistent with fracture of the skull which would guide you to a decision as to the propriety of trephining. 4. A man is the subject of strangulated inguinal hernia, with well marked symptoms. Taxis is applied, and the rupture passes back into the abdomen. Four hours afterwards, when the man is seen again, there is still urgent vomiting, and no relief to the other symptoms. Explain fully the view you take of the probable nature of the case, and the treatment you would adopt.

A MISPLACED ANNOUNCEMENT.

A CORRESPONDENT forwards the following from the *Belfast News Letter* of Thursday, November 4th, which we read with regret.

"The *Belfast Hospital for Sick Children*, 25, King Street.—Yesterday, a child, sixteen months old, was brought to this institution in the most dreadful agony, and evidently at the point of death. After a rapid examination, Dr. Fagan operated for lithotomy, successfully removing a foreign substance of remarkable size, and affording immediate relief to the poor infant. The case is very unusual in its own young, and reflects the greatest credit on Dr. Fagan's promptitude and skill."

MEDICAL PRACTICE IN HAMBURG.

M. B., L.R.C.S.E., writes:—I have an inclination to practise my profession on the continent, in either Hamburg or Bremen, both free towns. I want to know if I can go there and begin at once? If not, what examinations are necessary? Are the fees in general above or below those in Scotland?

ABSORPTION OF THE LUNG.

SIR,—I am able to corroborate the statement of Dr. Cotter regarding the occasional occurrence of entire absorption of one lung, without binding down or flattening against the vertebral column. Many years ago, I made a *post mortem* examination of a young male epileptic patient, an inmate of the old St. Peter's Lunatic Asylum, Bristol. In this case, the right cavity of the thorax was filled with perfectly limpid straw-coloured serum, entirely unmixt with purulent matter or shreds of lymph. All the tissues of the right lung had undergone absorption under pressure of the fluid gradually effused into the sac of the pleura. The shrivelled remnant of the lung hung free on the apex of the cavity of the pleura. At the time, I remarked to my pupils that all that remained of the lung was about the size of, and much resembled in appearance, a black kid glove, partially inflated, and afterwards crumpled and compressed.—I am, sir, yours obediently,

HENRY OXLEY STEPHENS, M.D., M.R.C.P., etc.,

lately Medical Superintendent of the Bristol Lunatic Asylum at Stapleton.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

FROGS IN SANDSTONE.

At the Shieldmuir pit, near Motherwell, Airdrie, belonging to the Summerlee Iron Company, an extraordinary discovery, says the *Scotsman*, has been made. Mr. Wilson, manager, while superintending the driving of a mine through sandstone, was surprised to find from thirty to forty live young frogs issue from the centre of a mass of the stone that had been dislodged. The level in which the frogs were found is three hundred and thirty feet under the surface, and the mass of stone was fully a hundred yards from the pit bottom. No crevice or fissure could be observed in the stone; and all who were present are positive that the frogs came from a cavity in the centre of the block. The frogs, apparently quite fresh after their imprisonment, at once made for a pool of water, in which element they were of course quite at home.

MODERN CURIOSITIES.

J. M. H. forwards us two cuttings from the advertisements of a medical contemporary, which, placed in juxtaposition, he not unnaturally describes as "really curious." One runs:—"To Medical Practitioners.—Female Dispenser.—A young woman, aged thirty, is desirous of securing a situation in a private surgeon's as dispenser." The other:—"Special.—Wanted, by a Gentleman, a situation as Companion to a single Medical Gentleman. Can dispense, keep books, knows the regular routine of surgery work; can attend an ordinary midwifery case. Could, if required, take the entire domestic management. Salary not so much an object as a comfortable home."

MIDWIFERY ENGAGEMENTS.

SIR,—I am a young country practitioner, and most of the confinements I attend are half-guinea and guinea cases. I have been very much annoyed for some time past by women engaging me to attend them, and then getting it over with the aid of a nurse without sending for me. I have several times been afraid to take a couple of days' holiday, as I had so many engagements; and perhaps only two out of a dozen have sent. In this way, one gets little money, none of the easy, and all the bad cases. Can you, or some of your readers, inform me, through the *JOURNAL*, whether I can make these people who do not send for me pay? Is it not a contract binding on both parties?—Yours truly,
H.

. It has, we believe, been decided more than once that, under such circumstances, the practitioner can recover his fee.

THE EDUCATION OF DEAF-MUTES.

We have before given an account of the very valuable exertions made by Mr. Van Praagh in this country to perfect the methods of instructing the deaf and dumb; they have been largely carried out under the auspices of benevolent members of the Jewish community. New and spacious buildings for the Jews' Deaf and Dumb Home have been opened in Walmer Road, Notting Hill. The institution was originally founded by the Baroness M. de Rothschild, and the success which attended the system of lip-reading practised in it was so great as to lead to the establishment of the Association for the Oral Instruction of the Deaf and Dumb of all classes and creeds. The association has its school for daily tuition in Fitzroy Square, under the management of Mr. Van Praagh. The Home in Walmer Road is under the direction of Mr. Schonherr, from the great institution of a similar kind in Vienna, where a hundred and fifty children are educated together. In Walmer Road, children born without the sense of hearing, or deprived of it by illness, are taught to read and speak not only English, but Hebrew, and to gather from the movements of the lips, unassisted by gestures or alphabetical signs, all that is said to them. Great care is also bestowed upon teaching them drawing. The girls learn needlework and help in preparing meals. It was part of the proceedings at the opening of the Home that two little pupils—Phebe Solomon and M. Jacobs—should recite addresses; and it was easy to catch the meaning of the words they uttered, though spoken in a foreign accent, and without the light and shade of expressional intonation. It was evident, from the manner of the children, that their intelligence had been remarkably brought out by good training; and they could be seen, and sometimes heard, chattering to each other by means of their lips with great volubility. The Chief Rabbi and the Rev. I. Samuel consecrated the building by prayer; and addresses were delivered by Mr. F. D. Mocatta, Professor Marks, Dr. Hermann Adler, the Rev. P. Magnus, and the Rev. Llewelyn Bevan. Dr. Richardson said, on the point of hygiene, that he had been through the Home, and could testify to its excellent sanitary arrangements. Mr. H. L. Cohen bore witness to the exertions of the Countess d'Avigdor and other members of the Ladies' Committee. Mr. Isaac Seligman, the treasurer, announced a deficit of £1,600, which was afterwards considerably lessened. Among the original subscriptions were £250 from Sir Francis Goldsmid, M.P., on condition of three like amounts being found; an anonymous gift of the required £750, through the Rev. Professor Marks; £500 from Baron Lionel de Rothschild; donations from Mr. Samuel Montagu; Mr. Lionel L. Cohen, and others.

A THEORY CONCERNING SLEEP.

OUR existing knowledge about the physiology of sleep does not go much beyond the fact, that the phenomenon in question is invariably associated with a comparatively bloodless condition of the brain. Pflüger attempts to take us a step farther by constructing an elaborate hypothesis of a physico-chemical order (Pflüger's *Archiv.*, vol. x, quoted in *Dublin Medical Journal*, November 1875). Starting from the view that the functional activity of any organ, and more especially of a nerve-centre, depends upon a dissociation of living matter, which is itself only a modified form of albumen, the author goes on to speculate that the chemical potential energy which is used up in the formation of every molecule of carbonic acid is transformed into heat. In other words, the atoms of which this molecule consists are thrown into a state of very active vibration. These intramolecular explosions are propagated in all directions along the nerves to the muscular and glandular systems, which are in structural continuity with the nerve-centres. Frogs, deprived of oxygen, are thrown into a state of apparent death, precisely similar to sleep: from this they may be roused by a fresh supply of oxygenated blood. A certain proportion of intramolecular oxygen in the nerve-centres is thus essential to the waking state, since it enables a given number of explosions to occur in an unit of time at a given temperature. But, during the waking state, the energy of chemical affinity is used up much faster than the intramolecular oxygen of the grey matter of the brain can be replaced; consequently, the formation of carbonic acid steadily diminishes; and when the number of explosions per unit of time sinks below a certain minimum, sleep ensues. The entire energy of the brain is never really used up; but it sinks to a point at which, in the absence of all external stimuli, it is incapable of maintaining functional activity. This theory may be so developed as to explain most of the phenomena of ordinary sleep, such as its periodicity, etc.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, no later than *Thursday*, twelve o'clock.

MR. F. H. WARD (Springfield).—"Universitat, Ber'in", is a sufficient address.

A HOSPITAL SLATE.

MR. W. MACKISON, C.E., Burgh Surveyor of Dundee, makes a novel suggestion. He says:—"Were a large board or slate fixed in a protected and conspicuous place at the entrance-gates of infirmaries and hospitals, containing the names of the patients, and after these (at least once a day), in few words, the condition of their health, I feel confident that greater interest would not only be taken in these institutions, but that more confidence would be placed in them by the general public."

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The *Hastings* and *St. Leonard's News*; The *Belfast News-Letter*; The *Sheffield Daily Telegraph*; The *Chester Guardian and Record*; The *Hereford Times*; The *Bristol Daily Post*; The *Statesman*; The *Birmingham Morning News*; The *Cork Constitution*; The *Newcastle Weekly Chronicle*; The *Worcester Journal*; The *Hobart Town Mercury*; The *Weekly Times*; The *Mid-Weekly Hampshire Independent*; The *Lincolnshire Herald*; The *Sunderland Daily Echo*; The *Co-operative and Financial Review*; The *South Wales Daily News*; The *Macefield Courier*; The *Glasgow Herald*; The *Croydon Advertiser*; The *Glasgow News*; The *Hastings and St. Leonard's Chronicle*; The *Metropolitan*; The *Londonderry Sentinel*; *Saunders's News-Letter*; The *Tenby Advertiser*; etc.

. We shall be greatly obliged if correspondents forwarding newspapers will kindly mark the passages to which it is desired to direct attention.

COMMUNICATIONS, LETTERS, ETC., have been received from:—

Dr. George Johnson, London; Dr. Southey, London; Mr. Christopher Heath, London; Mr. Spencer Watson, London; Mr. Morgan, London; Dr. Wilson, Edinburgh; Dr. J. Sawyer, Birmingham; Dr. Percy, London; Dr. Macleod, Glasgow; Mr. George Brown, London; Our Vienna Correspondent; Dr. Jefferies, Lochmaben; Dr. Ball, Blaenavon; Mr. F. Jordan, Birminghams; Dr. J. Coats, Glasgow; Mr. J. Croft, London; Dr. Fialayson, Glasgow; Dr. Mackey, Birmingham; Dr. Durrant, Ipswich; Dr. Eraxton Hicks, London; Dr. R. J. Lee, London; Mr. Cheves, Devonport; Dr. McKeown, Belfast; Mr. Henry Sewill, London; Mr. A. Stewart, London; Mr. Craigie, Lyme Regis; Dr. Fleming, Netley; Mr. J. R. Lane, London; Mr. J. T. CLINICAL LECTURE

ON

THE SCOPE OF DENTAL SURGERY.

Delivered at King's College, London.

By HAMILTON CARTWRIGHT, M.R.C.S.,

Professor of Dental Surgery at King's College, and Lecturer at the London School of Dental Surgery.

THE duty which devolves upon me of giving you a course of clinical lectures and demonstrations on dental surgery is a peculiarly pleasant and congenial one, inasmuch as I have to address a body of gentlemen who are studying medicine and surgery in a general hospital, upon a subject which has been looked upon too much in the light of a specialty, more separate than other specialties from medicine, and which I fear, as a rule, does not meet with that measure of attention which is its due; although, if you would give even a very small proportion of your time, in comparison with that allotted to your other studies, to its consideration, I am certain that you would thereby render yourselves good service in a future day. I fear that there are too many not only of those who are without the ranks of that branch of surgery which I profess, but also of the less highly cultivated practitioners within them, who seem to think that the practice of dentistry merely implies the filling or extraction of teeth; and I must confess that I have often been surprised at the ignorance of intelligent members of our profession in relation to diseases of these organs. Feeling strongly as I do, as a surgeon, the *rapproch* existing between this specialty and general surgery, I shall attempt to show you to-day, in this Introductory Lecture, the necessity, on the one hand, that the dental practitioner should not only be a fully qualified but also an intelligent surgeon, and, on the other, that the general surgeon, aye, and the physician too, may derive some benefit from studying those diseases, direct or indirect, which have their origin in morbid or abnormal conditions of the dental structures. You all recollect the fable of Menenius, wherein he pointed out to the dissident plebeians the harmony existing between the various parts of the human frame, applying the moral of his story to their divisions with the patrician body of the state. Now, the teeth are in as intimate relation with the body generally as is the eye or ear, and their morbid conditions can only be treated rationally upon such acknowledgment. The oculist and the aurist are fully qualified practitioners. The dentist should be so also, and it seems to me ridiculous that men should cavil about their status and position in the social scale, if they do not choose to educate themselves as other specialists are educated. The teeth must not be looked upon as mere pegs or nails inserted into living structure, but as organs having the most important relation to the whole system; and I think that I shall be able to prove to you that there is not a period in life when some knowledge concerning their development and condition may not be of service to you in any branch of practice, whilst the special objects of my future demonstrations will be to give you practical illustration of the treatment and diagnosis of cases quoted here, and to show you those operations which, having for their object the relief of pain or the arrest of disease, may be especially useful to those in country practice, or to those about to be engaged in the naval and military service of their country.

Firstly, consider, with me, the position of the maxillary bones, in which the teeth are implanted. Consider with how many nerves, with their attendant ganglia and plexuses, those teeth have connection. On each side, the oral cavity is in close proximity to the internal and external ear. Above, it is in near relation to the orbits and that oft-troublesome cavity the antrum, which is again in contiguity with the nasal fossae, the contents of which are frequently affected as a result of dental disease; whilst, finally, the continuation of the oral aperture leads to the stomach, in which arise, should assimilation be imperfect, the first causes of faulty structural development, or in which are produced, if dyspepsia exist, those acids which, being eructed into the mouth, constitute a local source of dental lesion; whilst the unhealthiness of the mucous membrane of the gums may serve as a valuable means of diagnosis in various morbid conditions of the gastro-intestinal mucous track.

The necessity of some knowledge of dental surgery to the general surgeon, and of medicine to the specialist, is shown from the earliest period of existence. Caries and imperfection of tooth-structure are to a very great extent, I regret to say, diseases of civilisation; and my

experience as a traveller in many parts of the world has taught me how much influence climate and *modus vivendi* have, not only upon the condition of the teeth, but upon the body generally.

As a rule, the savage or aborigine scarcely suffers from dental lesion, save in those instances where the conditions of his life are peculiarly adverse to constitutional integrity. The freedom of the aborigine from disease undoubtedly depends, to a great extent, upon the healthy life he leads. His hours are regulated by the rising and setting sun, whilst his occupations all conduce to health; but, when the country is notoriously unhealthy, his system is affected by the existing factors of disease; thus it is remarked that, on the eastern side of the Rocky Mountains, where the climate is healthy and bone-forming food abundant, caries is unknown; whereas, on their western boundary, where animal food is very scarce, and the vegetable diet deficient in those elements which are the chief ingredients of osseous tissue, disease is not unfrequent. Mine has been the same experience in relation to the Zulu and Bosjesman tribes in Africa, and also with regard to various parts of China. If you ever happen to be near Hythe, in Kent, and will visit the old church there, you will see hundreds of the skulls of our Anglo-Saxon progenitors, and will find that their maxilla are well developed and firm in structure, with not a tooth decayed in young or old; and in this specimen, at least two thousand years of age, found in a sarcophagus during excavations made at Cumæ some short time since, you see another proof that the changed conditions of modern life present important factors in the induction of disease. If you will examine more modern skulls, a very different story will present itself, decay revealing its ravages on every side. The causes of this disintegration of tissue are numerous. Change of climate may alike produce or arrest disease; thus when the healthy Irishman or Scotsman quits his home for another habit, where potatoes and oatmeal, rich in bone-material, are not abundant, in a few years he suffers from disease alike with those amongst whom he has sought another home; whilst, on the other hand, another person may regain new health in another clime, and the tendency to disease may cease. The argument from these facts is that, inasmuch as it is proved that a constitutional condition can exist in which the teeth may be free from caries, there is no reason why, if we discover the conditions of this immunity, we should not be able, in the course of a generation or two, to bring about a like result; for all evidence tends to prove that there are constantly recurring changes of waste and repair taking place in the dental tissues as in other parts, though naturally their structure forbids these being as rapid as in other tissues. I am confident that the prevalence of dental disease in the present day is in no small proportion of cases a direct consequence of the way in which our food is overrefined and prepared, so much so, that it is too frequently almost entirely deprived of those elements which are most requisite for the formation of firmly knit bones and healthy muscle; and I fear that parents will never be taught to understand, until they are instructed in the elements of physiology and hygiene as a part of their education, how often they are unwittingly responsible for the sufferings of their offspring. The bread of our Anglo-Saxon progenitors was prepared of crushed meal, in which the husk and the flour were mixed up together, so that all the necessary constituents for tissue-formation were retained, with such results as those to which I have alluded. The pregnant mother should be enjoined to make use of food containing an excess of nitrogenous material, so as to counterbalance the extra demands upon her blood for those inorganic particles which are necessary to build up the framework of her child. The child being born—and it is after birth that the greater portion of the bony framework is deposited—its digestion and its powers of assimilation must be carefully considered in determining the character of its food; whilst, in later years, it should be amply supplied with ossific material, such as eggs and potatoes, and, above all, if its assimilative powers be intact, bread made with the bran. But the treatment of the child ought to commence with that of the parent during her pregnancy; and, to make her submit to this, she must be taught the responsibility which her condition imposes upon her in regard to the welfare of future generations. Could this be done, in a generation or two, many constitutional defects might be blotted out, and notably diseases like rickets, scrofula, and caries. I have had the good fortune to have some few children under my care from early childhood; and, by judicious attention to their digestive and assimilative powers, I have been enabled to arrest those ravages which, I am convinced, would otherwise have maintained their sway until nearly every tooth had been destroyed.

Let me next consider the subject of teething, a period so fraught with danger to the child, that no less than 5 per cent. of the deaths under one year, and 7 per cent. of the deaths between that period and three years, are ascribed to dentition. At this epoch, when the spinal predominates over the cerebral system, the slightest sources of irritation may lead to fatal results; for that which causes a shud-

ler in a man may produce a convulsion in the infant. The symptoms of dental irritation may be confounded with congestion or inflammation of the brain and its membranes, and in some cases a mistaken diagnosis might be of serious import. Whilst cursorily alluding to the maladies which are dependent upon, or synchronous with, the eruptive stage, I cannot but draw your attention to the empiricism often exhibited in lancing the gums, that favourite method of treatment for actual or supposed dental irritation. There is little doubt that the gums are not only lanced during those periods of repose which characterise evolution, or when the osseous structure of the maxilla still remains unabsorbed over the advancing tooth, but that, as a rule, this operation is performed simply because, in a few cases, the relief of tension in congested tissue has sufficed to relieve an attack of convulsions. Where the tooth is just beneath the gum, or where there is manifest congestion, the incision of the parts may be productive of much benefit, but otherwise it is a procedure not only useless but barbaric. Retardation in development of the teeth is also a means of indicating future disease; for example, when their eruption is delayed beyond nine months, there is every reason to suspect that the child is suffering from rickets, a valuable means of diagnosing that disease for which we are indebted to Sir William Jenner. Next I must mention some of those diseases connected with the teeth which characterise a later period in life, than which none is of greater importance to the practitioner than neuralgia. If you will recall to mind the extensive sympathetic connections of the trigeminal or fifth nerve, it will not seem strange to you that the teeth should be often connected with reflex phenomena leading to simple spasm, neuralgic pain, or even epilepsy, whilst, in nine cases out of ten in which neuralgia attacks the upper extremity, a dental lesion will be found to be the exciting cause of irritation. This disease has the epithet "idiopathic" far too often applied to it; for in nearly every case a cause exists, though it may be concealed from us, whether it has its origin in the filament of nerve ensheathed by cicatrix, in a hidden splinter or a lurking parasite. Doubtless, you are all familiar with a case quoted by Sir Thomas Watson, of a well known physician who was forced to relinquish an extensive practice and a distinguished position through the terrible agonies he suffered as a consequence of tic douloureux. Every remedy was tried in vain, until death revealed the cause, which existed in a small osseous excrescence upon the falciform process of the dura mater. If I could lay down an axiom with regard to the treatment of neuralgia, it would be, "Never rest until you have found the cause"; for it will often discover itself when least expected.

[Mr. Cartwright here related a case under his care, in which he found severe neuralgia of the parts supplied by the cervical and brachial plexuses to be due to the presence of a small piece of glass in a swelling over the third phalanx of the second finger of the right hand; the removal of which permanently cured the neuralgia.]

Like sources of irritation exist very frequently in diseased or abnormal conditions of the structures of the teeth, and my experience teaches me that this is a fact not sufficiently appreciated by medical men. The ordinary treatment of neuralgia is far too often empirical. One specific is tried after another with varying success, until all fail, whilst the oral cavity, so rich in explanations of reflex pain, is quite forgotten or overlooked. Caries is by no means the most frequent source of neural pain; for it is often to be found in exostosed cementum, or as a result of secondary dentine formed within the pulp; whilst, yet again, an osseous excrescence growing from the dentinal wall may, by its pressure on the nerve, be an exciting cause, as in the case of this beautiful and unique specimen prepared and kindly lent to me with others by Mr. Salter. It is sometimes difficult to discover the offending member; but a gentle tap, the alternate use of hot and cold water, or, if the pulp be sphacelated in a non-carious tooth, the appearance of opacity on exposure to a strong light, will make the culprit doff its disguise, and reveal a traitor in the camp.

Amongst my notes, I have recorded the case of another patient who had long been the subject of intractable neuralgia in the head and face. She had been in the hands of celebrated physicians, of quacks, of homœopaths and hydropaths, but with no relief. The pain invariably had its origin on the left side of the face, just over the malar bone. On examination, all her teeth seemed perfectly sound, and the tests mentioned above suggested no intimation of disease. One day, knowing my suspicions that the teeth might be the source of her trouble, she told me that she had an "undefined sensation" in one of the teeth, but she could not point out whether it was the canine or the bicuspid on the left side of the superior maxilla; but the renewal of the tests gave no sign of pain. After various experiments, I resorted to the use of a galvanic current, which made her say that she was certain that the canine was the tooth which had a different feeling from the others. Warned that the loss of the tooth would very probably not effect a

cure, she begged me to extract it on the chance of relief being afforded thereby. I did so, and, if you will examine this preparation of the tooth under the microscope, you will see that the cause existed in an almost total ossification of the pulp. After a week, her pain entirely ceased, and not long since she described herself to me as sitting at an open window on a cold day at the seaside—a thing which she had not dared to do for several years. Of such cases I have seen many; and the immediate relief which occurs upon the removal of the exciting cause of pain makes me somewhat question the correctness of the late Dr. Anstie's view in relation to neuralgia, that the seat of pain is invariably situated in the posterior roots of the spinal nerves, and that an essential condition of the tissue of those roots is atrophy. Then, various diseases of the ear, the nose, and antrum, and even amaurosis, have had their origin in diseased conditions of the teeth, so that an oversight as to the source of mischief might lead to the loss or impairment of the functions of at least three of the organs of special sense. Mr. Hancock, of Charing Cross Hospital, mentions a very remarkable case of amaurosis dependent upon nothing more than an overcrowded condition of the teeth. Four of these were removed with such good effect, that the sight, which was nearly entirely lost, improved at once, and was again perfect within ten days. I could quote many similar cases, many of which have occurred in my father's practice, some few in my own, but would refer all of you who are interested in the subject to Mr. Salter's valuable work on *Dental Pathology and Surgery*.

It must not be forgotten that the teeth are not only the sources of, but that they are not unfrequently the objects of, sympathetic irritation themselves, and have, doubtless, in the absence of adequate knowledge as to the cause of pain, been often condemned for the faults of other members, like certain unfortunate officers in a recent naval inquiry. Thus I have frequently seen a constipated condition of the bowels induce pain in the teeth; and in another case an attack of gout is always ushered in by intense dental suffering, which a dose of colchicum relieves at once; whilst I have long had a patient under my observation, who, suffering from hæmorrhoids, always has acute pain in his upper molar teeth when these become congested, which invariably ceases when an attack of hæmorrhage relieves the engorged vessels. Many of the tumours which afflict the maxilla have their origin in a diseased root or an impacted tooth, these varying from the simple abscess to the cyst or odontome, in which latter tumour an appreciation of its character renders its removal the simplest of operations. A swelling occurring in connection with the unexplained absence of a member of the normal dental series should always suggest a hint in such cases, and it will be found that this class of tumour is invariably encysted, so that the removal of a little superficial bone will permit these growths to be enucleated with little loss of tissue.

Again, in a very large proportion of examples of abscess or neuroses connected with the maxilla a local source of irritation exists, such as may be found in a wisdom tooth attempting fruitlessly to take its position where there is want of space, or, more often still, in the remnant of a fang over which the gum has grown. Such errors in diagnosis are frequently made with regard to patients of strumous and scrofulous diathesis, in whom the history of the case and the swollen glands too frequently mislead the unwary practitioner. Wherever there are sinuses in connection with the glands about the jaw, search for an errant root. You may have much trouble in discovering it; but, if you be successful, its removal will not only instantly cure the patient, but prevent that terrible disfigurement which is a result of abscesses in this position. I have witnessed the cure of long-standing suppuration diagnosed as scrofulous again and again by the extraction of a root, the presence of which was unsuspected by patient or practitioner.

Finally, every surgeon practising in the country or abroad, in places where special aid is not at hand, should be able to arrest pain and disease in the teeth, at least temporarily, whilst he should have some knowledge of the treatment of the milk-teeth, which he is often called upon to remove; indeed, with regard to the latter subject, his appreciation of the simple rule, never to remove a temporary posterior molar or canine without urgent reason, would alone prevent many subsequent deformities of the permanent denture.

Think how many teeth might be saved by the aid of a little special knowledge concerning their diseases. Such knowledge would be useful to all, but especially to those who are about to devote themselves to the preservation of the health of those who maintain England's glory and good name *per mare, per terras*. The agony which I have seen soldiers, and especially sailors, suffer from their teeth has been terrible, and in too many cases without a chance of satisfactory aid, unless it be by the extraction of the offending organs. By such unnecessary losses men are incapacitated before their time, and it is from a feeling of pure humanity that I would insist upon the necessity of army and naval officers devoting a short period to the study of diseases

of the teeth, thereby arming themselves with another weapon with which to combat pain and suffering. In future lectures, I shall hope to have opportunities of showing you examples of those direct and indirect results of dental lesion to which I have alluded to-day, whilst I shall especially demonstrate to you those operations necessary to alleviate pain or to arrest disease, whether temporarily or permanently, by more complicated means. My task will be a labour of love, if I can impress upon you the importance of my subject when considered in its highest *rapports*; whilst I shall feel that, in disseminating amongst you what little knowledge I possess, I shall be contributing in some small way towards the lightening of those burdens, and the assuagement of those many ills to which flesh is heir.

CASE OF GRAVE LESION OF BOTH CORPORA STRIATA;

RECOVERY FROM HEMIPLEGIA; EXTENSIVE CEREBRAL DEGENERATION; DEMENTIA; DEATH TWELVE DAYS AFTER RUPTURE OF INTRATHORACIC ANEURISM.

By W. JULIUS MICKLE, M.D.,

Medical Superintendent, Grove Hall Asylum, London.

E. B., a private in the 19th Regiment, was admitted into Grove Hall Asylum on May 10th, 1873, having previously been under treatment in India and at the Royal Victoria Hospital, Netley. He was single, aged 37; had seen eighteen years' service, sixteen of which had been passed in India. The attack of insanity for which he was admitted was stated to be the first, to be of about six months' duration, and was supposed to be the result of hereditary predisposition and tropical climate. A brother had been insane, and formerly under care in the lunatic wards at Netley. While still serving in India, E. B. suffered from an attack of hemiplegia in March 1872, but was said to have "recovered" from that, and to have subsequently become the subject, in succession, of rheumatism, of debility, and of mental derangement. Previously to his admission here, he had been fussy, childish, forgetful, demented, and, at times, confused.

On admission, his height was 5 ft. 5 in., his weight about 10½ stones. He was much bronzed by exposure to sun; the skin of the face was of a greasy parchment-like appearance; his hair was short, thin, and streaked with grey. The pupils were slightly irregular, the ocular fundus hazy. There was faintly marked right facial paralysis, and occasional very slight dragging of the right heel in walking; the grasp of the hands was about equal. His speech was low, mumbling, indistinct, but not stammering or tremulous. There was the scar of an old bubo in the right groin. The mental symptoms enumerated above still continued; there was great loss of memory, and the manner was childish and silly. He did not at all know how long he had been here, stated that he was forty-five years of age, and that his father had died two years before at the age of forty-six, and so on.

Double ophthalmia appeared during the earlier period of his residence here; but, after a few months, the traces of hemiplegia became even still less, and he seemed rather brighter, took exercise regularly, played interminable games of cribbage, etc., with his intimate companions; and his general health seemed to improve for a time under tonics. He made no special complaint of pain, or of any chest trouble, or of any symptom which might give rise to a suspicion of aneurism; but, on December 24th, 1874, it appears to have been noted that there was some cough, that the vesicular murmur generally was defective, that laterally there were large sonorous *râles*, and posteriorly some dulness. He was as usual until December 29th, when sudden profuse hæmoptysis occurred after he had retired to bed. The pulse was rapid, and there was irritable hacking cough. Absolute quietude was ordered; and ergot, gallic acid, and small doses of Dover's powder were administered. Profuse hæmoptysis recurred the same night at 3 A.M.; and, next day, there were dulness on percussion, distant respiration, and indistinct crepitation over the back of the left lung, and, in front, dry *râles* and feeble respiratory murmur, followed on the ensuing day by cooing expiratory *râles* at the front and side, and distinct crepitation and dulness posteriorly. On January 2nd, decided pleuritic friction-sound replaced the latter sign, and the dulness about the base and back was increased. Pleuritic creaking and percussion dulness continued to increase over nearly the whole posterior and lateral surfaces of the left lung, where, also, vocal resonance and fremitus were diminished or lost. But not only was there large effusion evidently present in the left pleural cavity; much of the lung, also, was consolidated; in various parts over the upper and anterior portions were increased vocal

resonance and fremitus, blowing, bronchial, or tubular breathing, with occasional large sonorous *râles*. There were exaggerated respiration and compensatory expansion on the right side; and, throughout, the measurements of the halves of the thorax were about equal. The urine became dark and smoky; dyspnoea came on, and gradually increased; the temperature was high throughout, the sweating profuse, the mind of its usual degree of clearness. The respiratory symptoms became more urgent day by day, and he gradually sank and died on January 10th, 1875. During this illness, the pulse and respiration on the successive days were: Pulse, 92, 100, 105, 114, 100, 108, 110, 120, 120, 128; respirations, 22, 25, 25, 30, 34, 32, 44, 42, 54, 60; temperature (third day), 102 deg.; last two days, 102.8 deg., and 103.6 deg.

NECROPSY, twenty-one hours after death.—*Head*: The vessels at the base were healthy. Much serum drained away during removal, etc., of the brain. The arachnoid and pia mater were thickened; the latter was oedematous. There was a considerable amount of sub-arachnoid serum over the frontal and parietal lobes, especially on the left hemisphere, filling up the wide and rounded sulci, and more particularly collected about the sulcus præcentralis, sulcus interparietalis, and fissure of Rolando. The membranes were but very slightly opaque, stripped off readily, and left scarcely any shreds in the sulci. There was moderate atrophy of the frontal and of the parietal gyri, with grooved indentation, and some wasting, of the inferior surface of the right occipital lobe. The cortical grey matter was rather thin, and of ordinary consistence and colour; its stratification was fairly marked, and its minute vessels unusually obvious. The medullary substance had a cribriform appearance from numerous dilated vascular channels; its consistence and sanguineous points were ordinary. The specific gravity of many of the convolutions was tested; but it need only be stated here that the departure from health in this respect was in two directions: firstly, the specific gravity, generally speaking, was .001 to .002 lower in the left than in the right hemisphere; and, secondly, the specific gravity of the posterior region more nearly approximated that of the middle and anterior than is usual in the healthy brain. The fornix was firm. The ventricles contained a moderate amount of serum; their ependyma was thick and firm. The choroid plexus and velum interpositum were adherent to the optic thalami; the third ventricle was dilated; the grey commissure absent. Certain areas of the intraventricular aspect of both corpora striata were softened, collapsed, shrunken, and of a drab yellowish or greyish tint. This change was more extensive in the left corpus striatum, the upper surface of which presented a patch of it, coarsely triangular in shape, of about the size of a sixpence, commencing a quarter of an inch behind the anterior border of the corpus; behind this, again, was a rounded and smaller area of *ramollissement*. There was, also, a patch of the same change on the intraventricular aspect of the right corpus striatum, similar in extent to the larger of those just described in the left ganglion, but placed more posteriorly and externally. On section, the softening and disintegration in the left corpus striatum were found to extend throughout the whole length of that body, and passed half an inch behind the level of the posterior border of the obvious change upon the superior surface: the two portions of softened, atrophied, and discoloured tissue, above described, jutting upwards, as it were, from the main body of the lesion, and cropping upon the intraventricular surface. On transverse section, the depth of the naked-eye change was found to be half an inch in the inner and middle thirds, and a quarter of an inch in the outer third. On section of the right corpus striatum, a similar lesion was seen, half an inch in depth, but less extensive, and situated slightly further back than that of the left side. In both, there appeared to be many vascular connective tissue-bands, the interstices of which were filled with diffuent material, which exuded on pressure. The optic thalami were slightly shrivelled. There were two small, firm-walled, cavities in the medullary substance, containing fluid *débris*, and traversed by minute bands, the larger of which lay immediately above the body of the left lateral ventricle, and the smaller above the anterior horn of the right. The average specific gravity of right corpus striatum was 1032½. The weight of the entire encephalon (*i.e.*, with two innervated, etc.) was 43 ounces; of the right cerebrum, 18½ ounces; of the left, 17¾ ounces; of the cerebellum, 4½ ounces; of the pons Varolii and medulla oblongata, ¾ ounce.

Microscopical Examination.—The vessels of the right optic thalamus, examined when fresh, were fatty, and the right corpus striatum was strewn with oil-molecules and large granular cells; there were granular and fatty deposits on its vessels. Prepared sections of the left corpus striatum exhibited fatty molecules, amyloid bodies, granular masses, and *débris*, twisted and broken nerve-fibres, fatty vessels, and points of much wavy connective tissue. In other sections, fatty-like molecules were still more prominent, and occurred either in aggregations, or widely strewn, or in fat-laden cells. The vessels of this corpus striatum pre-

sented a variety of alterations; such as the walls thickened, or covered by fatty molecules, or with dark granular intramural deposits. In places, there was bulging of the walls where they were thickened or replaced by the granular or the fatty deposits. The lumen of some was blocked by *débris*, others were tortuous, or kinked, or presented deposits at the bifurcations. In the fresh cortical substance, the capillaries were thickened, and dark granular masses were apparent in their walls; their outlines were irregular, and, at points, very slightly moniliform. In prepared sections from the left ascending parietal convolution, were rounded compound granular masses. The pyramidal nerve-cells were small, some granular; their fine angular outlines had disappeared, and their nuclei were rounded. There were also small round or oval cells containing granular matter, and some of the vessels were fatty or tortuous. In the first left frontal gyrus, were granular degeneration of the nerve-cells; granular collections on, and fatty like degeneration of, the walls of some of the vessels, whose outlines were thereby rendered irregular; some dilated perivascular spaces and points where shrunken vessels lay within their sheaths. In the tip of the left occipital lobe, the nerve-cells were small and granular; the vessels tortuous, thickened, or their walls bulging with deposits, mainly of a granular character.

Thorax.—The feature of great interest here was an aneurism of the descending aorta, where its coats were extensively atheromatous. The aneurism was of the size of a large orange, was situated just below and behind the root of the left lung, and had grown forwards and to the left side; it had ruptured and still contained loosened masses of firm laminated fibrine covering its walls, and projecting at the rent. The sac was adherent to the spine, to the root and internal surface of the left lung, and was surrounded by large dark clots. The lower half of the internal surface of the lung was hepatised, and was deeply burrowed into, and irregularly excavated, by the aneurism and by the extravasated blood, which latter had passed through the disintegrated pulmonary tissue, and opened into some of the bronchial ramifications. The rest of this lung was inflamed; it was hepatised in parts, and was gorged with blood, and hæmorrhagic nodules were found here and there throughout its substance. It weighed $35\frac{1}{2}$ ounces, and rode upon blood-clot. Thirty-four ounces of fluid blood and of clot, mingled with some lymph, from acute pleurisy set up by the extravasation, were removed from the left pleural cavity, the walls of which were also thickened by old pleuritic membranes. The bronchi were deeply congested. The right lung weighed 17 ounces; there were emphysema and some old pleuritic adhesions; two-and-a-half ounces of fluid were contained in the pleural cavity. The heart weighed $10\frac{1}{4}$ ounces; the left ventricle was contracted; the mitral valves and aortic arch slightly atheromatous.

Abdomen.—The cones of the kidneys were deeply injected; the cortices granular and mottled; the capsules adherent. The right kidney weighed $4\frac{3}{4}$ ounces; the left, $5\frac{1}{4}$ ounces. The spleen was firm, pale, and weighed nine ounces. The liver weighed 65 ounces; it was pale and flabby; there were a cicatrix on the upper surface, and starred depressions on the upper and lower surfaces near the anterior border, connected with each other by septa of firm white fibrous bands traversing the gland.

REMARKS.—1. The absence of any noteworthy symptoms of aneurism was due to the partial filling of the sac with laminated firm clot, and to the situation of the tumour at a point of the descending aorta, where it did not implicate the pulmonary plexus to any marked extent. If, however, perception and sensation had not been blunted, the relation of the sac to the bronchus and vessels would probably have induced E. B. to complain of his chest. The patient survived twelve days after the rupture of his thoracic aneurism. The lung immediately adjoining the sac received the first brunt of the hæmorrhage; it was extensively inflamed, and the hepatised and engorged tissue was made ragged by the burrowing blood, which had found its way into the bronchi, on the one hand, and had caused profuse hæmoptysis; and, on the other had escaped into the left pleural cavity, and had set up acute pleurisy, with fibrinous effusion. The cause of the aortic atheroma was not clear. How far the influences of tropical climate, strain of the circulatory organs arising from the exigencies of a soldier's life, or syphilis, were engaged in producing it, cannot now be ascertained. Certain it is that the chronic cirrhosis of the kidneys found after death was only of moderate degree, had given rise to no special symptoms during life, and had not induced cardiac hypertrophy. The weight of the heart was quite within the normal range for a healthy man of his size and time of life, and was about one ounce less than the average found in cases of similar brain-disease in males of a corresponding age. (Burman, *West Riding Reports*, 1873, p. 232.) It is true the hair was prematurely thinned and tinged with grey, the features withered, and of parchment hue; and there was arcus senilis; but these indications are not characteristic

of renal degeneration alone. (Fothergill, *BRITISH MEDICAL JOURNAL*, January 9th, 1875.)

2. From the existence of atheroma and of aortic aneurism, one was led to expect that probably the small military aneurisms described by Bouchard and Charcot existed in the minute vessels of the brain; and that the attack of hemiplegia was caused by a blood clot, resulting from the rupture of one or several of these little aneurismal dilatations, which are not infrequently found in cases resembling the one described above. But this anticipation was not verified by the necropsy; the large vessels at the base appeared to be healthy; and numerous sections, from various parts of the brain, presented, under the microscope, no change of the character specified by the above writers, notwithstanding that the minute cerebral vessels were extensively diseased, and that certain changes on, or in, their walls were revealed; such as granular and fatty molecules, thickening, bulging, or twisting from intramural deposits, occlusion, etc. The microscopical appearances of the vessels resembled rather those observed by Major in senile atrophy of the brain (*West Riding Reports*, 1873 and 1874) than in chronic brain-wasting (*Ibid.*, 1873), differing from the latter mainly in the absence of any marked proliferation of the nuclei of the vascular walls. The changes in the minute vessels and cells were, in some respects, not unlike those found in certain cases of general paralysis. L. Meyer has described alterations analogous to some of those present in the above case, as being merely "characteristic of retrograde metamorphosis of tissues". (Abstract in *Journal of Mental Science*, October 1872.)

The cerebral degeneration was, in all probability, largely due to the abnormal state of the nutrient vessels, aided by the influence of the lesions of the corpora striata. No doubt the hereditary inclination to nervous disease made the cerebral tissues the more ready prey to the general departure from health, and to the premature senility; and there was the further stress of a long residence in the east. Degeneration had advanced to a greater degree in the left than in the right cerebral hemisphere; the weight of the left was the lesser, and the specific gravity of its cortex was lower than that of the cortex on the right side. Moreover, the under surface of the right occipital lobe was rather wasted, and there was not the normal difference of .002 to .003 between the specific gravity of the posterior and of the antero-median convolutional regions. (Bastian, *Journal of Mental Science*, January 1866, p. 493.)

3. But the principal gross lesions found in the brain of E. B. were those affecting both corpora striata. It has been seen how extensive was that of the left corpus, how the greater portion of this ganglion was implicated, especially in its deeper aspects; and how the tissue in the area of morbid change was completely broken down and almost reduced to mere *débris*; while a portion of the medullary substance immediately above the body of the lateral ventricle was converted into a minute cavity containing turbid fluid detritus. It has been seen, also, how, in the right corpus striatum, the complete *ramollissement* was confined to more narrow limits, especially in front, and, as on the left side, was associated with a minute cavity in the medullary substance—in this instance, situated above the anterior horn of the ventricle. Though one could not positively assert the contrary, there seemed to be no proof that the patches of *ramollissement* marked the sites of former hæmorrhages from ruptured vessels. Judging from the vascular condition, the portions of limited softening were probably due to thrombosis of the minute degenerated vessels supplying these regions; thrombosis which occurred long before he came under care here, and of which no noticeable trace might remain in the vessels after the lapse of so long a period. The portions of softened tissue were those mainly supplied by twigs from the middle cerebral artery to the corpora striata; and, on the right side, by those twigs, also, which pass onwards to the anterior and external portion of the optic thalamus. There was no history of the mode of onset of the attack of hemiplegia, from which he virtually recovered; and, therefore, no data for a clinical diagnosis of the particular lesion which produced it primarily. The average specific gravity of the various portions of the striate body was $1032\frac{1}{2}$, or considerably below the standard, which is about 1038 to 1039 .

It was a feature of interest that, while so much of both his corpora striata were destroyed for all practical purposes, this man's hemiplegic symptoms were only slight when he was admitted, and scarcely continued beyond the earlier months of his residence in this asylum. True he was inert, indisposed to move, and walked slowly; but this, though partly from feebleness, was mainly the result of his mental condition. Part of the routine of his life here was to fall into the ranks, and march in the grounds with his fellow-patients. The only history of palsy to be obtained was that of an attack of hemiplegia about three years before his death—of which side not stated, the patient himself said it was of the right—and slight dextral hemiplegia existed when he was admitted. No history of symptoms due to the lesion in the right corpus striatum was known, and no symptoms of this character were observed while he

was here, unless, indeed, it aided in causing his inaptitude for exertion.

Finally, there was no aphasia. Speech was low and mumbling, he was disinclined to converse, his replies were usually nearly monosyllabic; but, when urged, he could, and often would, speak more fully to the point, and used his limited vocabulary without hesitation or mistake. The use of language was partly restricted by his mental condition; and the impairment of articulation was merely of a paretic nature, and the essential characters of aphasia proper were absent.

HYDATID DISEASE:

AS ILLUSTRATED BY SPECIMENS CONTAINED IN THE PATHOLOGICAL MUSEUMS OF THE METROPOLIS AND IN OTHERS ELSEWHERE.

By T. SPENCER COBBOLD, M.D., F.R.S., F.L.S.,
Correspondent of the Academy of Sciences of Philadelphia.

IV.

BEFORE concluding my summary of the human hydatids contained in the metropolitan and certain other museums, there is in this connection an interesting literary contribution that I cannot pass unnoticed. In the November number of the *Indian Medical Gazette* for 1870, an article occurs in which it is stated that the Calcutta Medical College Museum contains eighteen specimens of hydatid cysts of the liver. This fact was, it seems, originally adduced to show not the frequency, but rather the rarity, of the occurrence of hydatids in India. However, from a valuable communication by Dr. James Cleghorn, which was published in the same periodical for the following March, it appears that hydatids of the liver are much more common in India than is generally supposed. This, according to Cleghorn, is owing to the circumstance that many of the so-called cases of tropical abscess are neither more nor less than examples of hydatid cysts that have suppurated.

I now turn to a phase of the subject from which much practical instruction may be gathered. The consideration of the pathological phenomena of hydatid disease as it affects the lower animals is of high interest, and no prejudice should induce any medical man from accepting such useful data as may be gathered from this source. The facts of hydatid parasitism in animals, though often peculiar, are, for the most part, of an order similar to those presented in the human subject. If any practitioner think it beneath his dignity to study the pathology of the lower animals, the conduct of John Hunter in this respect is a standing protest against such narrowness.

The museum of the Royal College of Surgeons of England contains some of the finest specimens of hydatids from the lower animals that are to be seen anywhere; the very choicest of them having been selected by Hunter himself. That distinguished man sought information from every available source; and hydatids were for him of almost equal interest, whether found in the body of a human being or in the carcass of an ox or an ass. Now, at all events, neither pathologists nor sanitarians can well afford to neglect comparative pathology; and, for myself, I am free to say that the yearly exposition to the students of the Royal Veterinary College of the phenomena of parasitic life amongst animals has brought with it an ever increasing knowledge of the most curious and often unlooked for information. Some of the data thus supplied are quite remarkable. Let me also add that my studies of the entozoa of wild animals have put me in possession of particulars of the highest value in regard to the larger question of the origin of epidemics. Beasts, birds, reptiles, and fishes of every description are liable to succumb to internal parasites, and there is practically no end to the variety of useful information to be obtained from this source. I have collected materials for a large treatise on this department of the subject, but I fear I shall never have either the means or opportunity of giving the facts due publicity. Here, for obvious reasons, I restrict myself to the hydatids, more or less properly so-called.

Referring, in the first instance, to those true hydatids of animals that have the same mode of origin, and that exhibit the same general characteristics as those found in man, I notice that four of the museums exhibit nine examples of liver echinococci. The Hunterian collection shows specimens of this kind from the pig, monkey, zebra, and lion. The museum at St. Bartholomew's Hospital contains two examples from the pig and one from a cow; whilst the animal liver-hydatids preserved in the King's College and Guy's Museums, respectively, are from the pig and sheep. That from the latter is partly calcified. Respecting animal hydatids affecting the lung, the Cambridge Museum exhibits a simple acephalocyst from a monkey, and the Guy's Hospital Museum shows a pulmonary hydatid from the kangaroo. In the museum at Oxford, Dr. Acland's (pathological) department shows a preparation of

"one large echinococcus cyst from the abdomen of a baboon", whilst Dr. Rolleston's department (anatomical) displays the echinococcus itself from the "cavity of the abdomen of the same animal". The collection also contains a variety of other bladder worms from different animals. The Hunterian Museum, Lincoln's Inn, exhibits four or five alleged examples of hydatids from the kidney of the sheep, besides another from the spleen. Some of these are very doubtful in character. A cystic kidney from the sheep, preserved in the London Hospital Museum, and originally supposed to have been due to hydatids, is (as hinted in the MS. catalogue) certainly not of parasitic origin. In regard to the occurrence of hydatids in the heart of animals, the Hunterian series shows two good examples from cattle, whilst the collection at University College exhibits one taken from the wall of the left ventricle of a sow. This was presented by Dr. Elliotson.

In the museum of the Royal Veterinary College, Camden Town, there are a number of excellent preparations of true hydatids taken from various animals, especially from cattle, swine, and sheep; and there are also many kinds of bladder-worms which, though often called hydatid by veterinarians, have a totally different origin from that of the true echinococci. The so-called gid-hydatids (*canuri*) and slender necked hydatids (*cysticercus tenuicollis*) are of this description. Specimens of the polyccephalus brain-hydatid, or *cenurus*, also exist in the museums connected with St. Bartholomew's, Guy's, and St. Thomas's Hospital Medical Colleges, as well as in both the anatomical and pathological departments of the Oxford Museum. Specimens of large *canuri* occurring in the soft parts of rabbits may be seen in the Guy's Museum (presented by Mr. Carpenter). Similar characteristic specimens exist in the Oxford collection, labelled *C. cuniculi*, obtained from the "mas-seter and infraspinatus" muscles of a rabbit. My private collection also contains a recent addition of this remarkable hydatid, sent to me by Mr. Alston from Ayrshire. It is the only one I have seen from Scotland. Three examples of the slender necked hydatid (from a monkey and two sheep, respectively) may be seen in the Guy's and University College collections, and several are preserved at the Royal Veterinary College.

I cannot go out of my way to speak of other bladder-worms, except so far as to call attention to the heart of a bear preserved in the museum at Guy's, the walls of which are crowded with cysticerci. That unique preparation ought to be more carefully examined and described. Lastly, in this immediate connection, I have only to call attention to the fact that the Hunterian Museum contains two really magnificent specimens of hydatids affecting the bones of cattle. In the one case, a large solitary vesicle occupies the shaft of the humerus; whilst in the other, several "acephalocysts" have taken up their residence within the cancellous structure of the ilium. These facts are of high interest when taken along with certain others of a like character, already adduced in connection with hydatid parasitism as it affects the osseous system of man.

INJECTION OF PERCHLORIDE OF IRON IN *POST PARTUM* HÆMORRHAGE RESULTING IN RECOVERY.

By H. ERNEST TRESTRAIL, F.R.C.S., Aldershot.

IN considering cases in which death has followed the injection of perchloride of iron in *post partum* hæmorrhage, we should be careful not to attribute more of the result to the perchloride, *per se*, than actually belongs to it. In the case reported in the *JOURNAL* by Mr. Boddy, I cannot avoid the conviction that the manner in which the iron was used was the cause of death. I observe that from the commencement there was decided contraction of the os uteri, requiring "dilatation for the passage of the tube", and also that subsequently "the uterus was so firmly contracted around the tube that some little force was required for its withdrawal". It is evident, therefore, that there could not have been sufficient passage for the free exit of the solution—a point of very great importance. The pipe being introduced to the fundus, the nurse worked the syringe, and sixteen ounces were forced in. The question immediately suggests itself, what became of this fluid? Doubtless, it dilated the uterus, and at the same time escaped at the weakest points. Mr. Boddy contends that fluid could not pass through a contracted uterus, but it certainly might through the placental site of a forcibly distended one, especially if introduced in the jerking manner essential to the working of an "ordinary enema-apparatus". Then, again, why should not some of the solution have escaped through the Fallopian tubes?

In my experience, the two most essential points in the use of the perchloride of iron are—first, to see that there is a free passage

for the exit of the injection; and, secondly, not to use too strong a solution. I may mention that I do not consider one and three a safe strength. The liquor ferri perchloridi fortior thus diluted is a very different thing from a solution of perchloride of iron in water; the former is very strong in acid, and more caustic and irritant in its action. There can, however, be no doubt that the injection of styptics in severe cases of *post partum* hæmorrhage will save life after every other means have failed, but there is no reason why we should confine ourselves to the iron solutions; on the other hand, there are remedies equally efficacious and open to less objections; one of these, which I have used successfully, is chloralum. The following is a brief outline of a case in which I used iron.

August 8th. Mrs. C., primipara, was taken suddenly, whilst asleep, and prior to the commencement of labour, with copious hæmorrhage; and, being consumptive and very anæmic, was reduced to a state of the greatest prostration. To add to her danger, severe *post partum* hæmorrhage took place. I first injected vinegar and water; but, this failing, I used one part of liquor ferri perchloridi fortior to ten of water, which immediately stopped all hæmorrhage; and, although my patient suffered much from the extreme loss of blood, she had not a bad symptom in any way attributable to the iron injection; in fact, to it alone she owed her life. I should be happy to send full particulars of this case to anyone interested in the subject.

CLINICAL MEMORANDA.

TINEA CIRCINATA OCCURRING IN VERY NUMEROUS PATCHES, AND WITH UNUSUAL RAPIDITY.

HAVING lately seen a case of the above, similar in detail to that described by Mr. Nettleship in the JOURNAL of November 27th, I will briefly give a few particulars concerning it. Beatrice D., aged 10 years, the subject of strumous ophthalmia and other evidences of the strumous diathesis, was noticed, early in September, to have a red patch upon the neck, immediately above the right clavicle, about the size of a crown-piece. The surface was covered with minute branny scales, and gave rise to occasional itching. One or two small spots, similar in appearance, were noticed a few inches distant, the remainder of the surface being quite free. The parasitic nature of the disease being suspected, tincture of iodine was freely applied to the larger patch, with the effect of altering its character, and producing some irritation. The affected part then put on an eczematous appearance, discharging, for a few days, a thin serous fluid, and rapidly healed. About a fortnight afterwards, the child was again brought by its mother with ringworm, situated in patches, ten to fifteen in number, varying in size from a pin's head to that of a crown-piece, and scattered over both the trunk and extremities. Several of these had assumed a well marked circinate form, the larger being found upon the thighs and pubic region, and in the axillæ. Notwithstanding the thorough and constant application of remedies, including warm baths, etc., fresh patches continued to make their appearance, until as many as from twenty-five to thirty existed on the body at the same time, the former gradually dying away as the latter became more pronounced. The child was closely watched, but six weeks or more elapsed before she was entirely free from the disease. A microscopical examination showed nothing unusual either in the size or shape of the numerous mycelia, and spores, which were present, of the well known vegetable parasite the trichophyton tonsurans. A younger sister, during this period, exhibited a small patch of the same upon the forehead, which was effectually destroyed by one application of the solid nitrate of silver. This case occurred during an unusually prolonged wet season; and it seems very probable, as Mr. Nettleship suggests, that the atmosphere, when charged with an excessive amount of moisture, has the effect of favouring the rapid development of vegetable fungi.

JAMES H. STOWERS, L.R.C.P. Lond., M.R.C.S.

IDIOPATHIC OR PROGRESSIVE PERNICIOUS ANÆMIA.

HAVING, during the last eighteen months, met with five cases of this disease, I was much interested in an able article on the subject by Dr. William Pepper, Professor of Clinical Medicine in the University of Pennsylvania, which appeared in the October number of the American Journal of Medical Sciences.

Dr. Pepper describes minutely three cases which occurred in his own practice. The chief symptoms were: insidious and apparently causeless development of languor, debility, and pallor of the surface; palpitation; hæmic murmurs; passive œdema; a progressive reduction in the mass of the blood, and especially of the red blood-corpuscles; irregular fever; absence of emaciation in any marked degree; wandering delirium; coma; and death.

All three cases proved fatal. In two, the diagnosis was confirmed by *post mortem* examination. Fatty degeneration of the heart, liver, and kidneys was found. In one case, the only one in which the medulla was examined, "there was a profound hyperplasia of the marrow of the bones, with production of lymphoid cells, constituting a change similar to that described by Neumann, Ponfick, Mosler, and others as found in leucæmia". Dr. Pepper thinks progressive pernicious anæmia is simply the medullary form of pseudo-leucæmia. The truth of this view, he says, will be established, if it be shown that, in progressive pernicious anæmia, the lesion of the medulla be a constant one.

At the commencement of the article, the author quotes Addison's description of idiopathic anæmia, and refers to the contributions of Corrasco, Gussierow, Biermer, and other recent writers on the subject. He comes to the conclusion that the affection, as described by these recent authors, is not a new disease, but is one and the same as the idiopathic anæmia of Addison.

He then goes on to say: "It is not a little melancholy, if this conclusion be correct, to find that, in the native land of that great clinical master, one of the leading journals (*Medical Times and Gazette*, November 21st, 1874) accepts progressive pernicious anæmia as a disease *sui generis*, and observes that no case has as yet been reported in Great Britain."

In making this statement, Dr. Pepper has surely overlooked a communication from Dr. Wilks on the subject, which appeared in the BRITISH MEDICAL JOURNAL of November 28th, 1874. Dr. Wilks, referring to the supposed discovery of progressive pernicious anæmia as a new disease by Drs. Biermer and Immermann, says: "As foreigners are not so well acquainted with English literature as they should be, and as these two physicians may gain the credit of introducing a new disease into our nosology, I beg leave to remind your readers that the disease is well known in England, and that fatal anæmia is alluded to by most authors. I heard a lecture on it by Addison in 1843, and I myself published several fatal cases of the disease in the *Guy's Hospital Reports* for the year 1847-49." Dr. Wilks then quotes Addison's description of the disease; and gives the following extract from his own *Lectures on Pathological Anatomy*, published in 1859. "We occasionally meet with cases of fatal anæmia where no disease is found in the body; patients after being in an almost bloodless condition for some months, die, and all the organs are found pale, and some of them in a commencing state of fatty degeneration. There is, also, generally some exudation of serum into the serous cavities, as well as œdema of the lungs and other parts. I have now seen several of these cases (*Guy's Hospital Reports*, vol. iii): the blood resembles pink water, containing no coagula in the vessels or the heart; and the latter organ exhibits the form of fatty degeneration, where the internal surface, especially the left ventricle, presents the peculiar mottling from change in the muscular fibre."

At a recent meeting of the Northumberland and Durham Medical Society, I showed a patient suffering from the disease. I intend shortly publishing this and my other cases in detail.

BYRON BRAMWELL, M.B.

Physician and Pathologist to the Newcastle-upon-Tyne Infirmary

OBSTETRIC MEMORANDA.

CONJUGATE CONTRACTION: VERSION: DEATH FROM EMBOLISM.

ON September 8th, 1871, at 1.40 A.M., I saw Mrs. J., of Reigate, then in labour for the third time. The patient was a fat pale woman, whose circulation was feeble. She had given birth to two living children by a former husband after severe labours, the latter of which occurred in 1861. On examination, I found the head presenting in the first position, above a pelvic brim shortened in its conjugate diameter by a projecting sacral promontory. At 3.30 A.M., the pains, which were regular, failing to advance the head, I sent for Dr. John Walters of Reigate, and, on his arrival at 4.15 A.M., the patient being put under chloroform, I applied the long forceps. Traction was made well backwards, with the view of bringing the head round and under the false sacral promontory into the cavity of the pelvis. The forceps, after a patient trial, proving useless, I passed my left hand into the uterus, and turned. Every effort to deliver the head entire being unsuccessful, and the cord ceasing to pulsate, the skull, which was much ossified, was perforated through the occipital bone, and delivery completed at 6.45 A.M. The woman died on the sixth day after delivery, having suffered acute pain beneath the sternum and very urgent dyspnoea. Dr. Walters and I were of opinion that death was caused by embolism of the pulmonary artery. Most unfortunately, no *post mortem* examination could be obtained.

JOHN CRAIGIE, M.B., Lyme Regis.

BRITISH MEDICAL ASSOCIATION:
SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, DECEMBER 18TH, 1875.

"SEASONABLE" WEATHER.

UNTIL the stubborn figures of the Registrar-General rendered it no longer tenable, it was a favourite theory that "seasonable" weather was good for mankind. By seasonable weather was meant hot summers and cold winters. It must be acknowledged that it is a somewhat unwelcome discovery, that cold wet summers and warm muggy winters are not only innocuous, but actively favourable to the public health; whereas fine hot summers and bracing cold winters invariably produce excessive rates of mortality. In England and Wales, the excess of deaths during a hot summer, as compared with a cold one, is to be numbered by tens of thousands, consisting for the most part of infants. The excess of deaths due to a long and severe winter, like that of 1874-5, reached a far more formidable total, and is shared, though unequally, by persons of all ages. These facts notwithstanding, it is still difficult to persuade the hale, the hearty, the well-fed, the well-clothed, and the well-housed, of the fatal results which follow a week or two of that frosty weather which gives them so much pleasure. Those who live under the above mentioned fortunate circumstances form so small a section of our communities, that it is next to impossible to judge of the real effect of extreme cold upon them. We know, however, that as we descend in the social scale, this effect becomes rapidly magnified. Hence it is that what may be called the excess death-rate due to cold becomes a sensitive test of sanitary condition in the broadest sense of that term.

Although we have arrived at the inevitable conclusion that, as the thermometer falls below a certain point, so surely will the rate of mortality within a brief period show a corresponding increase, we at present neither know the exact point at which the temperature becomes too low for human health, nor the exact period which elapses between the incidence of the low temperature and the commencement of its effect upon the death-rate. The returns of the Registrar-General only record the dates of registration, which vary principally between one and six days after the dates of death. In order to be able to make accurate observations as to the effect of temperature on the rate of mortality, it would be necessary to have a daily return of deaths, tabulated according to the date of occurrence, instead of registration. Until this information is made available, we have to content ourselves with such observations and conclusions as can be derived from the weekly returns of deaths as registered. Although falling short of that precision which in such matters is so desirable, we have already, however, derived considerable information from the study of these weekly returns.

The Registrar-General, in his weekly return relating to the seven days ending the 4th instant, although reporting an increase in the death-rate, published a more favourable return than might have been expected, considering the fact that in the preceding fifteen days the mean temperature had been so low as 33.7 deg., and 8.0 deg. below the average. The rate of mortality in the six-and-a-half millions of persons estimated to be living in eighteen of the largest English towns was remarkably stationary during the five weeks ending November 27th, and averaged 24.1 per 1,000. The influence of the cold weather during the fifteen days above mentioned caused the death-rate in the

week ending the 4th instant to rise to 25.9 in the eighteen towns, showing an increase of 7.4 per cent., or 239 deaths. In London, the increase due to the cold was equal to 5.2 per cent.; whereas in the seventeen provincial towns it was 9.6. This increase in the death-rate was remarkably small, when compared with the increase which has resulted from previous cold periods. The return for the week which has since elapsed, ending 11th instant, showed a considerable further increase of mortality; and the death-rate rose to 28.1 per 1,000 in London, which corresponded with the average rate in the eighteen large towns. In the same week of last year, following weather less severely cold than what has recently been experienced, the death-rate in these towns rose to 33 per 1,000. Without accurate information as to the daily occurrence of deaths, it is next to impossible to decide whether the recent cold weather has really been less fatal than usual, or whether, in consequence of an increase in the average interval between death and registration, due to recent changes in the law of registration, the real effect of the cold upon the death-rate is longer appearing in the returns. It may, in the meantime, be useful to recall some of the results of previous observations upon the effect of extreme cold upon mortality.

The cold winter of 1874-5 consisted principally of two long periods of low temperature; the one before, and the other after Christmas. With reference to the cold period before Christmas, the Registrar-General published some interesting figures showing its effect upon the mortality. The results were compared with those of a still more strongly defined cold period ending February 24th, 1855. During the five weeks ending December 19th, 1874, 9,871 deaths were registered in London, against 6,967 in the five preceding weeks of moderate temperature. Thus the excess of deaths due to cold in the five weeks was 2,904, or equal to 42 per cent. The percentage of increase at the five vicennial periods of life ranged from 38 per cent. between 20 and 40 to 175 per cent. among persons aged upwards of 80 years. In order to show how the effect of cold upon mortality increases with the ages of those exposed to its influence, or, in other words, how the power of resistance against this effect of cold declines with age, it will be useful again to refer to these calculations of the Registrar-General. Calculating the rate of mortality due to the excess deaths caused by cold, it was found to be 2.2 per 1,000 between 20 and 40 years, 9.4 between 40 and 60, 46.9 between 60 and 80, and 218.3 at 80 years and upwards. Thus what may be called the cold-mortality increased about 8 per cent. for each year of age over twenty years, and doubled every nine years. These figures, interesting in themselves, acquired a greater value from the fact that they corresponded almost identically with similar figures calculated for the six weeks ending February 24th, 1855, when it was also found that the excess death-rate from cold doubled every nine years; and, taking the excess rate at 20-40 years to be one, the excess at each of the three succeeding vicennials was equal to two, four, and eight respectively. Thus it would appear that the excess of mortality from cold at different ages has a well-defined law, although this law is only applicable to a population living under the at present unsatisfactory sanitary condition of a large proportion of the people of England. It should, above all things, be fully recognised by sanitarians, that the excess death-rate from cold is not beyond control. In November and December, 1874, the excess death-rate due to cold was far more severe in the east than in the west group of registration-districts: a result of more unsatisfactory sanitary condition, including housing, feeding and clothing.

Dr. Griffiths, the Medical Officer of Health for Sheffield, in his excellent report upon the sanitary condition of that borough during 1874, embodied some facts and calculations showing the effect of the same period of cold weather (that in November and December last) upon the rate of mortality in Sheffield. These figures agreed with those published by the Registrar-General for London in a remarkable manner. The excess rate due to cold at all ages averaged 8.2 per 1,000 persons living in Sheffield, against 8.6 in London. At the first period of life—0-20 years—the cold appeared to be more fatal in Sheffield than

in London; whereas in each of the four subsequent vicennials the figures showed an opposite result. The increase of the effect of cold in regular geometrical proportion after twenty years of age was, however, as strongly marked in the Sheffield calculations as they were in those for London, in the two cold periods of 1855 and 1874.

There appears to be no means for satisfactorily distinguishing that portion of the excess of mortality directly due to diseases produced by the cold, and that probably still larger portion indirectly caused by the effect of cold upon invalids suffering from various forms of chronic disease. In the latter case, the undue number of deaths registered after cold weather may be said to have been hastened rather than caused by the cold. In this way, there is probably a considerable tendency to overrate the effect of cold upon the mortality. In London, during the five weeks showing the effect of the cold weather in November and December last year upon the mortality, it has been stated that the deaths from all causes showed an increase of 42 per cent. The increase in the mortality from diseases of the respiratory organs was, however, equal to 138 per cent.; and in that from heart-diseases, 56 per cent. It follows, therefore, that though by far the larger proportion of this excess was returned under the head of lung-diseases, there was a considerable remainder which appeared under other classes of disease. In London, of the annual excess rate of 8.6 per 1,000 from all causes during these five weeks, 5.9 was returned as due to diseases of the respiratory organs. In Sheffield, however, while the total excess rate was 8.2 per 1,000—nearly identical with that in London—only 3.8 was attributed to lung-diseases. Such a difference cannot, to any considerable extent, be due to variation in the manner in which the causes of death are certified; and it would be interesting to know under what classes of disease cold was more fatal in Sheffield than in London, which balanced the far lower fatality from diseases of the respiratory organs.

A more accurate knowledge of all the various aspects of the influence of cold upon mortality would be the first step towards rendering this excess more amenable to control. While we may venture to hope that the Registrar-General will contribute further towards our fund of information on this point, we must look to medical officers of health to furnish materials in greater detail relating to the effect of cold on different classes of the community and in different localities, which are essential to supplement the generalisations which have been furnished to us from the General Register Office.

THE young Rajah of Kolapore intends to devote from £20,000 to £30,000 to build a hospital at his capital, to be called the Albert Edward Hospital.

ACCORDING to the Italian journals, the Duke di Galliera has made the munificent donation of fifteen million *lire* (£600,000) for the erection of a model hospital in Genoa.

THE Berlin medical papers announce the death, at the age of 30, from blood-poisoning contracted in the discharge of his duties, of Dr. Paul Samt, senior assistant in the department for nervous diseases in the Charité Hospital.

PROFESSOR EDWARD MARTIN, director of the Royal Lying-in Institution and of the Obstetric Clinic in Berlin, died on the 5th instant, after suffering for several months from pyelitis.

THE Royal Commission to inquire into the practice of subjecting live animals to experiments for scientific purposes, met on Saturday, Monday, and Wednesday last; all the members being present.

WE deeply regret to announce the death of Dr. Desmond of Liverpool, an able, kindly, and public-spirited member of this Association, whose loss will be widely felt and deeply deplored. We shall publish an obituary next week.—We see also with regret the announcement of the death of Dr. Hassall of Richmond.

THE Committee of the Council of the Royal College of Surgeons have selected the names of the examiners whom they propose to recommend to the Council, who will meet on Monday for the purpose of electing. It is, we understand, desired that we should not meantime make public the names of the recommended candidates.

WE find we had omitted to notice that Dr. Carpenter had been gazetted "C.B." Dr. Carpenter must accept our apologies; this he will do the more readily, that he has many titles which to a man of science are so much the better worth having.

THERE will, we hear, in all probability, be four vacancies declared in the Council of the College of Surgeons next July, caused by the retirement in the prescribed order of Mr. John Simon, F.R.S., of St. Thomas's Hospital; Mr. Luther Holden, of St. Bartholomew's Hospital; Dr. Humphry, F.R.S., of Cambridge; and Mr. Southam, of Manchester. These gentlemen are all eligible for re-election; but a rumour has reached us that three will decline being nominated for re-election.

A "DEATH from tight lacing" is recorded in the papers. As, however, the subject of the story was seventy-seven years of age, and was ascertained to have died from the rupture of an aortic aneurism, the moral is not so impressive as it might be. It appears, however, that in addition to the ruptured aneurism, *post mortem* examination revealed a very sad state of things. The lower ribs were tightly jammed together, the sides nearly touching each other. The liver, intestines, stomach, and other organs were all jumbled up together, and were remarkable for their smallness. The kidneys, etc., were all drawn up in a frightful manner. Deceased was a tall, and had been a very beautiful woman; and this was caused by former tight lacing.

LUNACY APPOINTMENT.

THE Lord Chancellor has appointed Dr. Crichton Browne, Superintendent of the Yorkshire West Riding Asylum, to be a Visitor of Lunatics, in the place of Dr. Bucknill, who has resigned, owing to ill health. The appointment had been foreseen, and will be entirely ratified by the voice of the profession. It is a just recognition of the singular energy, skill, and ability with which Dr. Crichton Browne has conducted the administration of a great curative establishment, and of the scientific zeal and initiative power which he has shown in making his asylum a notable centre of clinical, pathological, and psychological investigation of nervous diseases. To the asylum itself, and to the scientific organisation which he had created, and which is still in its early youth, this appointment indicates a probable and very serious loss. We should rejoice for the sake of both to hear that Dr. Crichton Browne had been induced to decline the appointment, though it be the blue-riband of superintendents of asylums. The West Riding Asylum has, under his management, rapidly assumed a foremost position in the country; and to lose his services, then, at this juncture, would endanger the fruits of his successful labours just when they promised most highly.

MURDERS BY A LUNATIC AT NORWICH.

ROBERT EDWARDS, a labourer, aged 42, was admitted an in-patient of the Norfolk and Norwich Hospital on Saturday. On Sunday, he exhibited symptoms of nervous disorder, and was restless during the night. About five on Monday morning, the nurse in charge of the ward missed him, and communicated with two other nurses, and likewise reported the circumstance to Mr. Baumgartner, the house-surgeon. While searching for Edwards, they heard a noise below, and found one nurse talking with a boy, who said some one was killing the boys in his ward. Mr. Baumgartner went into one portion of the ward, and saw Edwards beating a boy, who was in bed, with a pair of tongs taken from the fireplace. Edwards turned upon him (the doctor) with a poker, but he parried the blow; and, with the assistance of a porter, the madman was secured. It was then found that

Edwards had murderously assailed five boys. William Martin, aged 11, was killed, John Lacy, 10, killed, Joseph Colman, 11, was killed. Lacy's and Colman's brains were dashed out. Martin lived only an hour after receiving his injuries. Alfred Clarke, aged 9, is not likely to recover. These four boys were inmates of one ward; and, while Edwards was attacking Clarke, the nurse, who slept in an adjoining room, was aroused, and, looking out to see what was the matter, Edwards levelled a murderous blow at her with the tongs, which she avoided by closing and barring the door. He then went across a passage to the other portion of the ward, where he was assailing Edward Lubbock, aged 9, when Mr. Baumgartner came in. The police were called, and he was removed to the station.

LUNATICS IN HOSPITALS.

THE shocking occurrence at the Norwich Hospital reveals, in the most appalling form, the weakest point of our hospital administration. It is an event from the recurrence of which no hospital can safely assert itself free of apprehension. That the hapless inmates of a sick-ward should be subjected to the rabid attacks of a maniac, and that he should be permitted to continue his savage onslaught until three or four innocent victims were slaughtered, argues either a deplorable helplessness on the part of the immediate attendants, a want of due surveillance, or a serious error with respect to the laws regulating the admission of patients. It appears that the patient, in this unfortunate instance, showed no premonitory symptom of insanity, and that the medical officer, by his promptitude and courage in encountering and disabling his antagonist, did all that a medical man could do under the circumstances; but there remains the important question, whether it is possible to prevent or to mitigate the liability to such accidents. Granted that, in a very small minority of cases, the homicidal impulse is exhibited without warning, and that the previous history of the case discloses no reason to apprehend untoward results, there still remain the necessary precautionary arrangements in dealing with doubtful cases of mental aberration, which no hospital which values its reputation can afford to overlook. But of all places used for the treatment of incipient mental disease, the wards of hospitals are probably the worst adapted. In many, though not in all, rooms are set apart, usually in the basement of the building, where refractory patients are sent till the attack of delirium tremens passes away, or it may be to remain under observation prior to being transferred to the workhouse, which, as the law at present stands, is the only passport to the lunatic asylum. Probably, no hospital would admit a lunatic with the knowledge that he is such, but every hospital is subject to the inconvenience of admitting patients suffering from cerebral disease, and accidental cases in which delirium tremens may sooner or later supervene. There appears no alternative with regard to cases of delirium tremens but to secure them in a separate room apart from the wards, and, if necessary, to employ physical restraint, as it is out of the question to place a patient with broken limbs in a padded room; but in cases of sudden impulse, emanating from a disordered condition of the intellect, it is important that the patient should be removed at once from the custody of the hospital authorities. Experience teaches us that, both suicidally and homicidally, the dangers to be apprehended from the presence of lunatics are in the earlier stages of the malady, before the symptoms are sufficiently marked to justify their detention; and it is in this condition that they readily gain access to the hospital. As a rule, they are placed in wards appropriated for medical cases, under the custody of women, who, whatever may be their merits in other respects, have a strong instinct of self-preservation, and who naturally rush away for assistance on the first outburst of fury on the part of the lunatic. It will probably be said that much danger might be avoided by the substitution of male for female nurses, and there are, no doubt, times in all hospitals when it is found necessary to secure the services of men to grapple with violent cases, but in no civil hospital in this country are male nurses specially retained for the purpose; and, considering the desultory nature of the employment, it is doubtful whether they should

be placed on the permanent staff of attendants. We have said that the most satisfactory method of dealing with cases of doubtful lunacy is to remove them from the hospital out of the reach of harm, to a place of safety, where they may be placed under medical observation prior to their transfer to a lunatic asylum. Unfortunately, the difficulties in the way are very great; and the daily press teems with reports of suicides and homicides, committed while their perpetrators were suffering from "a fit of temporary insanity". Admission to lunatic asylums, perhaps rightly, is hedged round with so many checks of a technical and medico-legal nature, that it is the next thing to an impossibility for a medical man to obtain admission for a patient at the time when restraint is most urgently required, and removal to the parish workhouse can hardly be looked on as an agreeable alternative. It is now some years since the Local Government Board expressed a wish to legislate on the subject, and made overtures to the Metropolitan Sick Asylums Board respecting it; but the matter, from some cause or other, remains in abeyance. Can nothing be done to rearouse the authorities to a sense of its importance?

DEATHS FROM CHLOROFORM.

A CORRESPONDENT writes to us:—The death from chloroform in the practice of a metropolitan surgeon, to which you last week referred as not having been made the subject of an inquest, or of any public notice is, I presume, the one which occurred on November 26th, in the Kensington district. The particulars of registration are as follows: "Nov. 26th, 1875. A female, aged 48, wife of a major-general, H.M.C. Cause of death. From a surgical operation during the inhalation of chloroform. Certified." We refer to this matter in virtue of the conviction which we have long since and repeatedly expressed, that the circumstances and *post mortem* appearances in every such case of death under the use of anaesthetics should, in the interests of humanity and of the advancement of the medical art, be fully placed upon record, in such a manner as to be brought under the notice of the profession. At the present time, when the relative value and comparative danger of anaesthetics are under active discussion, it is extremely desirable that all the contemporary and home facts should be impartially and accurately stated. We hope, therefore, to see the record of this in some one or other of the medical journals. We hear, also, of a recent death from chloroform at Glasgow, of which we expect next week to be able to publish particulars.

THE GREAT NORTHERN HOSPITAL.

A LETTER was read at the Council Meeting of the Charity Organisation Society, on the 6th inst., from the Hon. R. Capel, Honorary Secretary of the Great Northern Hospital, describing the system adopted at the hospital for checking misuse of out-patient relief.

"Perhaps it is the only hospital", wrote Mr. Capel, "that has upon its staff an officer whose sole duty it is to register the out-patients, to inquire into their circumstances, and to report monthly to the Executive Committee. This inquiry is made as inoffensively as possible, and I am assured by him that he is almost invariably well received, and is often asked to come in and sit down. Personally, I am disposed to think that a Provident Dispensary should be part and parcel of every hospital. I believe that a great number who now come for gratuitous relief would, if they could rely upon having the medical advice of the staff attached to such hospitals, be quite ready to pay the fees which are paid at Provident Dispensaries; but then arises the question, whether any should be attended to without payment? I would not shut the door of gratuitous relief, nor draw too hard-and-fast a line; but I would have a register, to prevent those in really good circumstances from becoming members of such Provident Dispensaries, and, on the other hand, to admit those a shade above the pauper class to relief without payment. I believe such a system would work well, though, like all changes, it might provoke opposition. It is doubtful, perhaps, whether our hospital has benefited by the system in a pecuniary point of view, but it is satisfactory to myself at least to know that a discriminating element has been introduced in the selection of the out-patients."

Mr. Bosanquet said that it was satisfactory to find that the Great Northern Hospital had a registrar. Mr. Fairlie Clarke had pointed

out, in an article in *Macmillan* some years ago, that every hospital ought to have such an officer. It was essential that there should be some person at the hospitals competent to judge what inquiries it was necessary to make, and how different applicants should be dealt with.

ANTIVACCINATORS IN BERLIN.

AN active agitation, says the *Berliner Klinische Wochenschrift*, has commenced in Berlin, having as its object the repeal of the compulsory vaccination law enacted about a year and a half ago; and a petition for this, with many thousand signatures, has been presented to the *Reichstag*. No new grounds nor any facts worth notice have been adduced; on the contrary, the old well known motives, based on gratuitous assumptions and false interpretations, have been brought into the field. It appears that this petition, which is accompanied by numerous pamphlets (mostly a *réchauffé* of old productions), has produced no small impression on some of the members of the *Reichstag*, so that it is possible that it may receive more consideration than it deserves. It can, however, scarcely be believed that the *Reichstag* can be induced to repeal the law, which has been generally hailed as an important step; but it would be to be lamented if even only a minority supported the petition. At a recent meeting, the Berlin Medical Society, at the suggestion of Dr. B. Fränkel, decided to throw the weight of its influence into the scale. Not one of its members supported the petition; on the contrary, the following resolution was passed unanimously: "The Berlin Medical Society, after consideration of all the objections raised in recent times against compulsory vaccination and revaccination, which objections it regards as feeble, considers that it is an essential step in the progress of public sanitation, and would regard it as a lamentable misfortune if the German empire should be again deprived of the benefit of the vaccination law of April 8th, 1874." A resolution to the same effect was passed at a meeting of the Public Health Society in Berlin on November 29th, and has been transmitted to the *Reichstag*.

MARRIED SOLDIERS' QUARTERS.

CONSEQUENT upon the fearfully fatal outbreaks of fever and diphtheria which attracted much public attention many months ago, the Woolwich cottages for married soldiers were cleared, and plans were then prepared by which ample accommodation would be secured for more than sixty families. The number of women and children there is unusually great, and much inconvenience was necessarily felt by those married men who were compelled, by want of room in barracks, to take their scanty lodging-money and pack their families into some unwholesome dwelling in the town far removed from their daily work. Under these circumstances, not only do they lose their allowance of coal and candles, as well as the advantage of a common laundry and bakehouse, but the actual pecuniary recompense received by them in lieu of these solid benefits is very insufficient, and they are deprived also of the wholesome discipline and restraints imposed on those who live more immediately under the eye of their superiors. Some years ago, a benevolent lady sought to alleviate this state of affairs by building a number of cottages in the immediate neighbourhood of the common, to be used as married quarters; but these, having now fallen behind modern sanitary standards, recently gave rise to the well known scandal in connection with an epidemic of diphtheria. There was little doubt, however, that the defects of these structures was very considerably exaggerated at that time, and, although they are at present unoccupied and somewhat decayed from neglect, we are informed that rectification of their drainage, and some slight structural alterations, are all that is necessary to render them fairly eligible habitations. In connection with them, schools and lavatories have lately been built on the most approved principles; and, when Government has made up its mind to sanction the expense attending the building to which we have already referred, we understand that its erection will take place on a piece of ground adjoining the cottages. One of our contemporaries ascribes the delay which has taken place in commencing operations to the necessity for utilising the ground now actually occupied by these

"condemned" structures, and to some difficulty with reference to the freehold, which prevents its being employed for this purpose. We are informed, however, that no such difficulty stands in the way, but that Government not unnaturally prefers to build on adjoining ground with equally good exposure and surroundings, and not involving the necessity for sweeping away the already existing quarters, which may not impossibly be yet turned to good account. We should be glad, however, to hear that there is some reasonable prospect of action being taken in this matter. The disgraceful and degrading accommodation too often provided in former years for the wives and children of the married soldier was a scandal to any civilised country, and an insult to respectable women. Nothing used to be more common at Aldershot than for five or six families to be put up in one hut, the only semblance of partitions being extemporised from rugs suspended here and there by some rudely constructed appliance. Under such conditions, cleanliness and morality must suffer, epidemics make rapid progress, all sense of home comfort be rapidly destroyed, and that gradual hardening process exist which made these unfortunate women soon sink into the worst form of slatternly domestic drudge. If we wish to encourage recruits to enter our ranks, and hope to compete on any equal terms with the present prosperous state of the labour market, we must put our soldier's house in order, and endeavour to secure for him something like order and decency in his domestic life.

EPIDEMIC OF FEVER IN SHEFFIELD.

ENTERIC fever is now fatally prevalent in the borough of Sheffield. The deaths referred to typhus, enteric, and simple fevers in that town averaged five per week during the first six months of this year. In the three months ending September, this weekly average rose to seven; and, in his last weekly return, the Registrar-General calls attention to the fact that the deaths referred to this cause were 10, 11, and 18, respectively, in the three weeks ending on the 11th instant. In order to show the exceptional fatality from fever in Sheffield last week, it is stated that the 18 deaths were equal to an annual death-rate of 3.5 per 1,000; whereas, in the seventeen other large towns, the fever-rate last week did not exceed 0.4 per 1,000. The workhouse at Sheffield is overcrowded with fever-patients, many of whom are not admitted until past hope of recovery. The responsibility for this fever-epidemic would appear to fall in great measure upon the Town Council, as the urban sanitary authority for the borough of Sheffield, if, as we are informed, it is a fact that they have neglected to provide any hospital accommodation for the isolation and treatment of infectious diseases, notwithstanding remonstrances both from the Local Government Board, and from their own medical officer of health, Dr. Griffiths. In spite, too, of the admittedly wretched condition of a large proportion of the houses inhabited by the working classes in Sheffield, there appears to be no alacrity upon the part of the Town Council to take advantage of the powers they possess under the Artisans' Dwellings Act of last session.

UNQUALIFIED MEDICAL ATTENDANCE.

OUR attention has been attracted by the report of an inquest held on a child whose death occurred under the following circumstances. It appears that in Bethnal Green there is established a mission-hall devoted to preaching the Gospel and alleviating the sufferings of the poor. On week-days, a woman attends there, and assumes the duties of a medical man; and relief in that respect is afforded poor people who are unable to pay a doctor, or who are unwilling to apply to the parish. The mother of the deceased child took him to the mission-hall, as he was unwell. She there entered a room fitted up like a doctor's shop, and received from a woman a bottle of medicine and some cod-liver oil. The deceased not getting better, she went to the woman and asked her whether, in the event of his dying, she would give a certificate, to which she replied that she could not. The mother then took the deceased to Mr. Schmidt of Bethnal Green Road, but he died at four o'clock the same day. Mr. Schmidt deposed that, when the child was brought to him, it was in a sinking condition. He had since

made a *post mortem* examination, and found the immediate cause of death to be bronchitis. From the conditions of the lungs and general appearance of the internal organs, he was of opinion that the deceased had needed the most skilful treatment. He was unable to say positively that, had the deceased been attended by a medical man, he would have recovered; but its chance of living would probably have been greater. The jury returned a verdict of "Death from natural causes"; but the verdict might not improbably have been one of manslaughter. At any rate, much blame attaches to those who promote and support an establishment of the kind, where responsibilities are assumed which are not warranted by the possession of the necessary medical skill and qualifications. In view, too, of the extensive provision made for the sick poor by hospitals and dispensaries in all parts of London, such a course of proceeding is as unnecessary as it is manifestly dangerous.

THE DEATH-RATE IN LONDON.

LAST week, 1,856 deaths were registered in London, which number exceeded by 117 the average of the week, and was equal to a death-rate of 28.1 per 1,000, a higher rate than in any previous week since the end of March last. There were 303 deaths from the seven principal zymotic diseases, or 17 above the average. This excess of zymotic deaths was principally due to the fatal prevalence of scarlet fever (which caused 103 deaths) and whooping-cough (to which 75 deaths were referred). During the twenty-two days ending last Saturday, the mean temperature was continuously below the average; the mean for this period was 33.6 deg., and the average deficiency 8.0 deg. The deaths referred to diseases of the respiratory organs, which in the eight preceding weeks had slowly increased from 194 to 391, rose last week to 536, and exceeded the corrected average number of the week by 71; 342 resulted from bronchitis, and 132 from pneumonia.

BRITISH MEDICAL DEFENCE ASSOCIATION.

AT a general meeting of the members of the British Medical Defence Association held on the 10th inst., Dr. B. W. Richardson was elected President for the ensuing year; Dr. Alfred Meadows and Mr. James R. Lane, F.R.C.S., were elected Vice-Presidents; and Mr. George Brown was elected Honorary Secretary. The Council and remaining officers of the Association are to be appointed at an adjourned meeting, to be held at the Guildhall Tavern, Gresham Street, on Tuesday afternoon next.

THE MEDICAL USE OF ALCOHOL.

DR. DIPLOCK, the coroner for West Middlesex, lately held an inquiry at the Royal Eagle Tavern, Keppel Street, Chelsea, touching the death of Sarah Bull, the infant daughter of a labourer. The father of the deceased stated that she appeared a little poorly on Saturday morning last. He sent to a chemist for a cough mixture, which was given to her. On the Monday, she having become worse, he went to Mr. Woolrych of the King's Road, who advised him to give her brandy and milk. He refused to give the child brandy, as he was a total abstainer, and did not believe it would do any good. Mr. Woolrych then told him to call in another medical man. Witness went for Dr. Scatliff, but the child died before he arrived. Mr. Woolrych deposed that, when called to see the child, he found it suffering from a lung disease. Its life could be saved only by the administration of a stimulant, and he ordered brandy because it was the most easily to be obtained. The father was very rude, and said that he would not give the child brandy. In reply to the coroner, the witness stated that he did not suggest any other stimulant, such as ether or chloroform. He could not positively say that, if the brandy had been given, the child would have lived. Undoubtedly brandy or some other stimulant was necessary. The coroner told the jury the case was a parallel one to that of the Peculiar People. The law in their case had been held to be that if a man acted *bonâ fide* and to the best of his conscience—but this must be conclusively proved—then he was not criminally responsible. The medical man could not say in this case that the brandy would

probably have saved the child's life, but if he had, he should have told them it was their duty to return a criminal verdict against the father. He should ask them to consider whether there was culpable negligence or not. The jury returned a verdict of "Death from natural causes". Our comment upon this case is that, if the medical man thought and declared brandy essential to the child's life, the culpability of the father in declining to obtain it is clear. On the other hand, fair allowance should be made for the conscientious scruples which many persons entertain against the use of alcoholic stimulants in the forms in which they promote drunkenness, and thus become the dread source of immeasurable crime and misery. We do not easily figure to ourselves any such case in which a diffusible stimulant of a strictly medicinal character might not, under pressure of such scruples, be advantageously employed.

NEWCASTLE-UPON-TYNE WORKHOUSE INFIRMARY.

AT the meeting of the Newcastle-on-Tyne Board of Guardians on November 26th, a report upon the workhouse infirmary, from Dr. Mouat, her Majesty's Local Government Board Inspector, dated Nov. 20th, was read by the chairman. The report spoke in very high terms of the infirmary. The building was erected four or five years ago under the superintendence of Mr. Septimus Oswald of Newcastle, architect. The above report is not the first official commendation which the building has received, the Lunacy Commissioners having reported upon it when near completion as "incomparably the best accommodation for the sick poor anywhere known to them, creditable to the humanity as well as public spirit of those who have provided it, and a honour to the town".

HOSPITAL SUNDAY FUND.

A MEETING of the managers of this fund was recently held to appoint a day for considering the date of the Hospital Sunday Collection in 1876; and a notice was prepared convening such a meeting for the 22nd inst. Though this was the main business of the day, some other subjects were incidentally discussed; among these, two are of sufficient importance to call for a passing notice. Mr. Hogg drew attention to the fact, that several hospitals had been assisted out of the fund, of the usefulness of which the profession entertained grave doubts. It is well that this fact—for a fact it is—should be plainly stated, and carefully considered by the manager. No doubt it is delicate ground to tread upon; but the first report of the fund led us to believe that some censorship would be exercised, and the need for it has certainly not diminished during the last few years. It would have a very damaging effect upon the fund, if it were found by experience that it tended to encourage such undesirable institutions as those to which Mr. Hogg alluded. Canon Miller moved for a committee to inquire into the question of the distribution of tickets, and urged that hospitals receiving grants should be required to give tickets in return for the same. This would surely be to aggravate and perpetuate an evil. Among all the moot points connected with hospital reform, there is scarcely one upon which there is so much agreement as upon the evils of the ticket system. As upwards of 890 churches and chapels gave last year less money than in 1874, it is not wonderful that the managers of the fund should cast about for means to increase their popularity. But nothing will be gained in the long run by descending from a higher line of action to a lower. No ultimate benefit will arise from encouraging those hospitals which are of most questionable utility, or from trying to please those persons who cannot give a guinea for charitable purposes without demanding a *quid pro quo*.

IRREGULAR PRACTICE IN BAVARIA.

A MINISTERIAL order, dated July 1873, provides that, before the first of March in each year, a tabular return shall be made of persons practising medicine without due authority in the kingdom of Bavaria. The table for the present year is published in a recent number of the *Ärztliches Intelligenz-Blatt*. It shows that there were, on January 1st, 1,156 illegal practitioners—911 men and 245 women—in the kingdom: and gives

statistics as to the nationality, social condition, and calling of the various persons, and the department which they practise. There are 106 homœopaths—99 males and 7 females; 39 bonesetters—28 males and 11 females; 15 rheumatism and gout doctors; 2 hydropaths; while 4 gave their special attention to skin-diseases, 2 to cancer, 2 to syphilis, 7 to hernia, 4 to whitlow, 1 to toothache, etc., and in the list are 396 *chirurgen*, barber-surgeons and dentists, and 40 apothecaries. Medicine in general is practised by 464; internal medicine by 112; and surgery by 50.

SCOTLAND.

THE Police Commission of Dundee have resolved to appoint a public analyst, and have remitted to the Sanitary Committee to recommend a suitable person for the office, and to report upon the amount of remuneration which should be attached to it.

THE Queen in Council has approved of the alterations made by the Aberdeen University Court on the ordinance which regulates the number of examiners in medicine in that University; and in future six medical examiners will be appointed by the Court, instead of three, as at present.

It was stated to the Dundee Parochial Board last week, that three foreign seamen who had arrived at Dundee on board a vessel from Calcutta, and who had become insane, had been sent to the asylum at the expense of the parish. The clerk said he had written to the members of Parliament for the town, asking them to ascertain from the Government whether the parish could not be relieved in the matter. It was agreed to communicate with the Boards in Aberdeen, Glasgow, Greenock, and Leith, on the subject.

THE MONTROSE ASYLUM.

AT the meeting of the Montrose Asylum and Infirmary Board, a report was read from Sir James Cox, M.D., in which he drew attention to the desirability of having the proposed extensions to the asylum proceeded with. It was stated that the extensions would cost about £5,000. The matter, as well as the plans of the architect, stand over for further consideration.

EDINBURGH OBSTETRICAL SOCIETY.

ON Wednesday, the 8th instant, the Edinburgh Obstetrical Society held a meeting, to which all the members of the profession in Edinburgh and the neighbourhood were invited, to hear an introductory address from Professor Simpson, the newly elected President. The address was on the subject of Menstruation, and was a masterly sketch of what is known on the subject and its connection with utero-gestation. A vote of thanks to the lecturer was proposed by Dr. Matthews Duncan, and seconded by Dr. Moir. There was a large attendance of Fellows of the Society and others.

THE CHAIR OF PHYSIOLOGY IN GLASGOW UNIVERSITY.

DR. ANDREW BUCHANAN has intimated his intention to resign the Chair of Physiology or Institutes of Medicine in Glasgow University at the end of the session. This step has immediate reference to an article and correspondence in one of the daily papers, in which it is alleged that this class has been for some time in an unsatisfactory state. We understand that the University Court were about to inquire into the condition of the class when they received the intimation of Dr. Buchanan's intention to resign, which caused them to suspend the inquiry. Dr. Buchanan has sent an exceedingly intemperate letter to the newspapers, the publication of which, we are sure, his friends will regret. The appointment to the Chair is in the gift of the Crown. It is understood that Dr. McKendrick of Edinburgh intends to become a candidate. Dr. McKendrick's claims to such a position are of the highest order. As an original investigator, he has few rivals; as a teacher, his

power of lucid exposition and brilliant demonstration are widely recognised; and his tutorial powers and capacity of managing a large class are proved. Dr. McKendrick's services would be valuable to any University, and the University of Glasgow is fortunate in the conjunction of circumstances which has set them free at a period when its physiological chair is vacant.

AN EXTRAORDINARY CASE OF POISONING.

AN extraordinary case of poisoning occurred in Lochmaben last week. On Thursday, the assistant in a druggist's shop in the town had occasion to leave the shop for a short time, and, on his return, he found a woman in the shop drinking from one of the bottles, which contained tincture of cantharides. Remedies were immediately used, but the woman died in a few hours from the effects of the poison. She was a confirmed laudanum-drinker, and had been in the habit of watching when no one was in the shop, and entering and taking laudanum. On this occasion, she had mistaken the bottle. We should be glad to hear the symptoms and course of this case from the medical men who saw her, as the drug has been rarely used as a poisoning agent.

IRELAND.

IT is commonly reported, that Dr. Burke will be the medical member of the Local Government Board in the vacancy caused by Dr. McDonnell's resignation. Mr. Rawdon Macnamara has received a very strongly worded testimony, supporting his claims, from a number of the leading medical men of the city.

DAMAGES FOR INSUFFICIENT RESTRAINT.

A CASE of considerable interest to the managers of public or private hospitals has just been tried at the Court of Queen's Bench, Dublin. The following is a statement of the case: *Denis Morrissey v. James Duncan and others*.—This was an action to recover damages, laid at £4,000, for injuries sustained by the plaintiff through the alleged negligence of the defendant. The plaintiff was a dealer in whiskey, carrying on business in Dublin; in the year 1871, in consequence of a family affliction, he became addicted to intemperate habits, and, in the year 1872, he had an attack of delirium tremens. He was removed to the Maison de Santé Hospital—a private hospital conducted by the defendants—in order that he might receive the care and comforts of a hospital, as well as the medical attendance suitable to his malady. He was at that time three weeks in hospital, and returned home perfectly cured. In August, 1874, he again fell into habits of intemperance, and was again attacked with delirium tremens. He was again taken to the Maison de Santé, and, in addition to the ordinary charges, he paid a sum of £1 5s. per week for an attendant who was expected to keep a constant watch upon his movements. It appeared that there was a room on the ground floor set apart for delirium tremens patients; but for some reason the plaintiff was removed to a room on the third story, and after he had been for some time under treatment, he took advantage of the absence of his attendant and jumped out of the window, the result of which was that he received a compound fracture of the leg, which was successfully amputated on September 22nd. The plaintiff's case was, that proper care had not been taken to prevent him doing a dangerous act when suffering from delirium tremens; that the attendant was improperly absent when the plaintiff jumped from the window, which was not properly secured. The defence was, that the attendant was careful and attentive; that all precautions had been taken to secure the patient against injury; that when he was in a dangerous condition he was placed in a room on the ground floor specially provided for delirium tremens cases, and only placed upstairs when it was considered safe to do so; that he was convalescent when he jumped from the window; that the patient had been insane and confined in a lunatic asylum before admission to the Maison de Santé. This fact had not been communicated by the pa-

tient's friends to the managers of the Maison de Santé, and therefore arrangements had not been made to treat a person liable to maniacal attacks apart from delirium tremens, and that it was in one of such attacks that he jumped from the window. The jury were unable to agree to a verdict, and were accordingly discharged. We understand that a new trial will take place shortly, so for the present we abstain from remark upon the case.

TYPHOID FEVER IN DUBLIN GARRISON.

A PAPER by Dr. Albert A. Gore, Surgeon-Major to the Military Prison (read before the Medical Society of the College of Physicians of Ireland, on the 8th instant) contains the following statement with reference to the recent prevalence of fever in the Dublin garrison, by which it will be apparent that quite sufficient ground existed for recent rumours and for our statements. In former days, the Irish command was unpleasantly notorious for the production of all forms of febrile disease. The military records of the seventeenth and eighteenth centuries, show that continued fevers, called by Boate the "Irish ague", was very prevalent, but the history of the disease is so mixed up with that of epidemic dysentery, an acute specific disease, thought by Dr. Marchison, in our own time, to be very closely allied to typhoid, which stood next in order of frequency of occurrence, that to differentiate the two is not always easy. Between the years 1837-46, continued fevers of all kinds, including typhoid, accounted for an annual ratio per 1,000 *per annum* among the troops in the United Kingdom as below :

	Admitted.	Died.
Dragoon Guards and Dragoons	51.9	1.36
Royal Artillery	50.065
Foot Guards	77.7	2.44
Infantry Regiments	69.9	2.45

Since that period the Foot Guards have always shown the highest ratio of admissions. In 1859, the annual ratios had fallen with improved sanitation.

	Admitted.	Died.
In Dragoon Guards and Dragoons to	27.837
Royal Artillery	26.035
Foot Guards	32.284
Infantry Regiments	24.066

The minimum was reduced in 1867, when there were among

	Admitted.	Died.
Dragoon Guards and Dragoons	9.052
Royal Artillery	14.200
Foot Guards	16.672
Infantry Regiments	15.596

From that year until the present, there has been, on the whole, a gradual rise or increase in the admissions from these various forms of fever, the ratios being, in 1872, among

	Admitted.	Died.
Dragoon Guards and Dragoons	17.019
Royal Artillery	22.538
Foot Guards	25.549
Infantry Regiments	18.038

In the Dublin garrison alone, the ratio per 1,000 *per annum* of admissions and deaths from continued fevers from among all arms was as below:

Year.	Admitted.	Died.
1860	27.4737
1861	32.8041
1862	29.1000
1863	13.1065
1864	14.7085
1865	15.0068
1866	13.6060
1867	21.40	2.97
1868	20.60	2.24
1869	24.6070
1870	19.4022
1871	19.0087
1872	29.9040

According to Dr. Grimshaw, fever among the civil population of Dublin steadily decreased from 1866 to 1869, since which last year it has been rising again. If the army medical returns are referred to, it will be seen that the admissions from typhoid have followed much the same course; the fall and rise in the military statistics corresponding on the whole with the fall and rise in the admissions into the civil hospitals of the Irish metropolis. In 1871, the excess in typhoid admissions occurred at Aldershot and Mullingar—twenty-eight cases and seven deaths at the first; eighteen cases and two deaths at the last station. In 1874, outbreaks of this fever occurred at the military prisons of Limerick and Dublin, traced also to faecal poisoning, and in the present year at Duncannon Fort, where it had been for some years since epidemic. Fever is never absent from Dublin. It seems to be an endemic and epidemic disease, and appears to depend especially upon the weather, presenting a tendency to prevail in the first quarter of the year. It becomes very fatal in the autumn, when the mean temperature falls below 54 deg., the mortality beginning to rise with the falling temperature. As the summer goes on, typhoid shows, according to the tables published by Dr. Moore, a decided tendency to increase at an earlier period than typhus. There is a striking increase in the percentage of the amount of typhoid towards the close of the year, while the highest percentages of typhus are met with in the contrary seasons of winter, spring, and early summer. According to the Registrar-General's returns, Dublin, with a population of 314,666, yielded during 1837-74, the following number of deaths from fever :

Typhus.		Typhoid.		Simple Continued Fever.	
1873	1874	1873	1874	1873	1874
54	103	144	182	53	61

It will be seen from these figures that not only was the febrile poison more active in 1874, but that this increase was spread over all the forms of fever, and not confined exclusively to typhoid. Among the troops, however, the admissions were almost confined exclusively to typhoid, owing probably to the fact that some of the essentials to the production of typhus—viz., want of food, proper clothing, *plus* undue exposure to wet and cold and overcrowding—were entirely absent, whereas the defects in the mode of getting rid of the excretions were many and apparent, for, wherever it appeared among officers or men, the subsequent investigation brought to light some defects in the mode of getting rid of the excretions. The exact number admitted into the General Hospital of Dublin garrison were : In 1868, 2; in 1869, 4; in 1870, 7; in 1871, 3; in 1872, 11; in 1873, 15; 1874, 29; all cases of typhoid. As has been frequently noticed by those who have had much experience of fever, the type of the disease, and even the symptoms and complications, varied according to the source of the poison, and where the source of the poison was evidently the same the symptoms and duration of the disease varied immensely, one member of a family having rose-coloured spots and diarrhoea, and a prolonged fever of eight or nine weeks' duration, while other members of the family would have neither diarrhoea nor eruption, and the duration of the disorder would be ten to twelve or twenty-one days. Dr. Gore has observed this also among soldiers. In the garrison of Dublin, the disease, in 1874, appeared amongst the men in the form of a series of small local outbreaks, solitary cases being the exception. For instance, we had in January two cases admitted from among the men of the Royal Artillery quartered in Portobello Barracks; in March and April, four cases from among the Guards, stationed at Beggar's Bush; next, three cases from the 17th Lancers, at Island Bridge, in May; and sixteen cases from the military prison—one in August, the remainder in November and December—isolated cases occurring in September, November, and December. In fourteen admissions to hospital, the ultimate results are stated. Of these, seven, or fifty per cent., were sufficiently recovered on leaving hospital to resume their duties in the ranks after intervals varying from thirty-two to seventy-four days, according to the severity of the symptoms; five required sick furlough before joining, and one was invalided for phthisis, and one case terminated fatally.

ASSOCIATION INTELLIGENCE.

BATH AND BRISTOL BRANCH.

THE next meeting of the above Branch will be held at the York House, Bath, on Thursday, January 20th, 1876, when a discussion on Cerebro-spinal Meningitis (based on Dr. Cole's paper, printed at page 667 of the JOURNAL) will be opened by Dr. Brabazon.

R. S. FOWLER, Bath. } *Honorary Secretaries.*
E. C. BOARD, Clifton. }

Bath, December 15th, 1875.

UNIVERSITY INTELLIGENCE.

UNIVERSITY OF CAMBRIDGE.

DR. HERBERT DAVIES is appointed Assessor to the Regius Professor of Physic in the place of Dr. J. W. Ogle, resigned. Mr. B. Anningson of Cains is appointed a member of the Board of Medical Studies.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen of the College, having undergone the necessary examinations, were admitted Licentiates in Midwifery at a meeting of Board on the 15th instant.

Messrs. Edward John Burgess, Brentwood, Essex, diploma of membership dated July 24th, 1873; Samuel Beuton, Waking Hall, Essex, July 27th, 1874; and Thomas James Pickburn, M.D. & C.M. and L.S.A., Sydney, New South Wales, not a Member of the College (Students of St. Bartholomew's Hospital) Andrew Henry Blake, Drury Lane, July 20th, 1875 (of the Middlesex Hospital); Thomas Stroud Hosford, Mrnington Road, May 5th, 1866 (of the London Hospital); and Eyre Jevers, M.D. & C.M. Dub., Tonbridge, not a Member of the College.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, December 9th, 1875.

Bickford, William, Ashburton, Devon
Carey, John Thomas, 47, Trinity Square, S.E.
Cross, Philip Henry Eustace, Lancaster Road, Notting Hill
Henbeck, Frederick Emanuel, Westbourne Terrace North

The following gentlemen also on the same day passed their primary professional examination.

Batchelor, Henry Thomas, London Hospital
White, Robert Godfrey, London Hospital
Hamp, John Walter, Queen's Hospital, Birmingham
Marsh, Joseph Henry, St. Thomas's Hospital
Turner, Alfred Moxon, Guy's Hospital
Welchman, Walter H. Lawson, Guy's Hospital

MEDICAL VACANCIES.

THE following vacancies are announced:—

ARDWICK and ANCOATS DISPENSARY, Manchester—Resident House-Surgeon.
BELHELVIE, Parish of—Medical Officer.
BERKS COUNTY ASYLUM, Moulsoford—Assistant Medical Officer. Salary, £80 per annum, with board, lodging, and washing.
BOOTLE BOROUGH HOSPITAL—House-Surgeon. Salary, £80 per annum, with board, furnished apartments, and washing. Applications to the Honorary Secretary.
CARMARTHEN UNION—Medical Officer.
CHORLTON UNION—Medical Officer. Salary, £250 per annum, with fire, light, attendance, and furnished apartments. Applications on or before the 30th instant.
CHORLTON-ON-MEDLOCK, RUSHOLME, and MOSS SIDE DISPENSARY, Manchester—House-Surgeon.
DARLINGTON HOSPITAL, and DISPENSARY—House-Surgeon. Salary, £50 per annum, with board, rooms, and attendance in the Hospital. Applications on or before the 22nd instant.
DENBIGHSHIRE INFIRMARY—House-Surgeon. Salary, £85 per annum, with board, washing, and residence.
DUMFRIES and GALLOWAY ROYAL INFIRMARY—Assistant House-Surgeon. Board and washing. No salary. Applications to the Treasurer.
EVELINA HOSPITAL FOR SICK CHILDREN—Registrar and Chloroformist. Salary, £30 per annum. Applications on or before the 22nd instant.
GENERAL HOSPITAL and DISPENSARY FOR SICK CHILDREN, Pendlebury, near Manchester—Superintendent. Salary, £100 per annum, with everything found.
GLOUCESTER INFIRMARY—Surgeon and Assistant-Surgeon. Applications before January 27th, 1876.
HUDDERSFIELD INFIRMARY—Physician.
KENT and CANTERBURY HOSPITAL—Assistant House-Surgeon and Dispenser. Salary, £50 per annum, with board, lodging, and washing. Applications on or before the 31st instant.

LEEDS UNION—Medical Officer. Salary, £300 per annum, with unfurnished residence, coals, gas, water, and rates. Applications on or before Dec. 29th.
LIVERPOOL DISPENSARIES—Assistant Resident House Surgeon (unmarried). Salary, £108 per annum, with £5 additional each year till the salary reaches £128, furnished apartments, coals, gas, and attendance. Applications on or before the 20th instant.
MALE LOCK HOSPITAL—House-Surgeon.
MOFFAT HYDROPATHIC ESTABLISHMENT—Medical Man to take charge. Applications to Messrs. Bruce and Kerr, W.S., Edinburgh.
PARISH OF LISMORE AND APPIN, Lettermore—Medical Officer. Salary, £100 per annum. Applications to the Rev. D. Dewar, Manse, Appin, Argyll.
RIPON DISPENSARY—Resident House-Surgeon. Salary, £100 per annum, with furnished apartments, attendance, coals, and candles. Applications on or before January 1st, 1876.
ROTHERHAM HOSPITAL—Resident House-Surgeon. Salary, £120 per annum, with board and furnished apartments. Applications on or before December 23rd.
ST. PANCRAS and NORTHERN DISPENSARY—Resident Medical Officer. Salary, £100 per annum, with residence, and £20 for servant's wages.
SHEFFIELD GENERAL INFIRMARY—Physician. Applications on or before January 5th, 1876.
STROUD GENERAL HOSPITAL—House-Surgeon. Salary, £60 per annum, with board, furnished rooms, attendance, and washing.
TIARSIS MINES, Province of Huelva, Spain—Medical Practitioner. Salary, £250 per annum. Applications to the Secretary, 136, West George Street, Glasgow.
TONGUE and FARR, District of, County of Sutherland—Medical Officer. Salary, £150 per annum, and house.
TRINITY COLLEGE, Dublin—Professor of Botany. Applications on or before January 22nd, 1876.
WANDSWORTH and CLAPHAM UNION—Resident Medical Officer. Salary, £250 per annum, with furnished apartments, rations, washing, gas, and coal.
WESTMINSTER GENERAL DISPENSARY—Honorary Surgeon. Applications on or before the 30th instant.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

BARTLET, George, M.R.C.S. Eng., appointed Medical Officer to the Morrison Infirmary, Forgue, Aberdeenshire.
DALE, William, M.D., appointed Physician to the West Norfolk and Lynn Hospital, *vice* T. Cossar, M.D., resigned.
MAPLES, Rec., M.R.C.S., appointed House-Surgeon to St. Thomas's Hospital.
NEWBY, Chas. Henry, M.R.C.S. Eng., appointed House-Surgeon to St. Thomas's Hospital.
POTTER, H. Percy, M.R.C.S., appointed House-Physician to St. Thomas's Hospital.
ROSSITER, George F., M.R.C.S., appointed Resident Accoucheur to St. Thomas's Hospital.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

MARRIAGE.

GANDY—WORSLEY.—On the 9th instant, at St. John's, Hackney, by the Rev. R. Allen, M.A., Vicar of Christ Church, Gipsy Hill, William Gandy, Esq., M.R.C.S., Parkstone House, Gipsy Hill (late of the Peninsular and Oriental Company's Service), to Julia Matilda, youngest daughter of the late Charles Worsley, Esq., of Upper Clapton.—No cards.

MR. VALENTINE STONE, F.R.C.S. Ed., has been appointed a Justice of the Peace for Kincardineshire.

TESTIMONIAL.—On December 9th, Dr. F. D. Jones of Washington, county of Durham, was presented with a testimonial by the inhabitants of that place, where he has been located in his professional capacity for upwards of a quarter of a century. The testimonial consisted of an illuminated address, a silver salver, gold pencil, and cameo ring. The presentation was made by S. B. Coxon, Esq., of Ilsworth, Hull.

LONDON HOSPITAL MEDICAL SOCIETY'S SOIRÉE.—The microscopical *soirée* of the London Hospital Medical Society was held on Friday, the 10th inst., in the Medical College. By the kind permission of the Council, the greater part of the ground floor was in use. The anatomical, pathological, and materia medica museums, which were used as a general promenade, had numerous curiosities and objects of interests displayed in them. The reading-room was devoted to microscopes, stereoscopes, and photographic views. In the anatomical theatre, a good collection of gleans and solos were admirably performed, and some recitations given with great success. A number of lime-light views were shown in the chemical theatre, thanks to the kindness of Dr. Tidy, who placed his instruments unreservedly at the disposal of the Committee. Refreshments were provided in the lecturer's room, and done due justice to. The rooms were crowded; many strangers and neighbouring medical men being present, together with a large number of the members of the Society, and all seemed much pleased and interested by the entertainment, which lasted from seven to half-past ten; the only cloud upon which was the serious indisposition and consequent absence of the President, Mr. Mercier.

OPERATION DAYS AT THE HOSPITALS.

- MONDAY**Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.
- TUESDAY**Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.
- WEDNESDAY** ..St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.
- THURSDAY** ...St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 3 P.M.
- FRIDAY**.....Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.
- SATURDAY** ...St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M. and 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

- MONDAY**.—Medical Society of London, 8.30 P.M. Mr. Maunder, "Excision of the Elbow-joint" (discussion on case of). Dr. T. Lauder Brunton, "On the Physiological Action of Alcohol".
- TUESDAY**.—Pathological Society of London, 8.30 P.M. Mr. Thomas Smith: Haemorrhagic Periostitis. Dr. Gowers: Fatty Tumour of Spinal Cord. Mr. Nunn: Injury to Radius from Fracture. Mr. Nunn: Deformity from Rheumatic Gout. Mr. Goodie: Recurrent Epithelioma. Dr. Greenfield: Cancer of Heart and of Suprarenal Capsules. Dr. Greenfield: Cancer of both Breasts and of Right Ovary. Mr. Walsham: Tumour of Clavicle. Dr. Frederick Taylor: Aneurism of Aorta. Mr. Alban Doran: Arrest of Development of both Forearms. Mr. Spencer Watson: Report of Sequel to Dr. Walker's Case of Recurrent Sarcoma of Leg. Dr. Goodhart: Embolic Infarct in Heart-Muscle. Dr. W. Legg: Aneurism of Heart. Dr. W. Legg: Aneurism of Mitral Valve. Dr. W. Legg: Displaced Kidney. Mr. C. Heath: Epithelioma of Chin (living specimen). Mr. C. Heath: Epithelioma of Tongue. Mr. D. Baiding: Sarcoma of Sciatic Nerve. Dr. Coupland: Cancer of both Breasts and of Ovaries.

NOTICES TO CORRESPONDENTS.

- CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.
- PUBLIC HEALTH DEPARTMENT**.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.
- AUTHORS** desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.
- CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.
- WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**
- COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

ERRATA.—In the notice of Crief, p. 741, BRITISH MEDICAL JOURNAL, read, at end of paragraph, "the parishes of Crief, Comrie, Monzievard, and Muthill".

MIDWIFERY ENGAGEMENTS.

SIR.—The practice of which H. complains is not uncommon. Although I have attended a large amount of cheap midwifery, I rarely get cheated. I advise H. when a woman engages him, to tell her it is a contract, and that he shall expect his fee, whether called in or not, and to ask her if she wish to engage him on those terms. If she consent, and do not send for him, he is at liberty to sue her husband for his fee, and I believe would recover. With a little tact and firmness, I think he would soon get over his difficulty. He would find a good deal of worry in going to law—more than it is worth.—I am, etc.,

December 1875.

AN OLD PRACTITIONER.

ARE YEW-LEAVES POISONOUS TO PHEASANTS?

MR. M. A. KENNY (Holme-on-Spalding Moor) asks whether the leaves of the yew-tree are poisonous to pheasants, and, if so, in what way do they act? He has lately examined a pheasant, and found yew-leaves in the gullet and a few in the stomach. There were no signs of irritation. He tested for metallic poisoning, but found no trace.

ERRATA.—In Mr. Christopher Heath's clinical lecture in last week's JOURNAL, p. 725, first column, last line but one, for "continued", read "confirmed"; p. 726, first col., line 20, for "was", "were"; line 19 from bottom, for "vertical", read "vertebral"; line 3 from bottom, insert "of" between line and force; 11 lines from end of lecture, for "no", read "a".

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

MISPLACED ANNOUNCEMENT.

SIR.—In the last issue of your JOURNAL, under the heading "Misplaced Announcement", a correspondent has furnished you with a notice that appeared in one of our local papers, in which my name appears in a most erroneous light. That paragraph, I need not say, appeared without my knowledge or sanction. A member of the Hospital Committee, in his zeal for the interests of the institution, had it inserted. I refrained, on the advice of several of my professional brethren, from noticing it in the paper, inasmuch as we considered it would be only giving the matter undue publicity, and would not be understood by the reading public. I brought the matter before the next meeting of the Ulster Medical Society, as I felt it was due to the members and myself to explain the facts of the case.

I am happy to state that no member of the profession to whom I am known would for a moment attribute any connection on my part with so unworthy and unprofessional a proceeding; and I am sorry to find your JOURNAL made the medium of placing members of our profession in a false light before their brethren. I would respectfully suggest your observing greater caution for the future before inserting, without inquiry, communications from your Belfast correspondent, who, if he belong to our profession, must have been actuated by other than honourable motives.—I am, sir, your obedient servant,

December 14th, 1875.

JOHN FAGAN, F.R.C.S.I.

* * The paragraph was transferred to our columns without any comment except the obviously just one implied in the head. Mr. Fagan's highly satisfactory explanation would have been better without the tag. In noticing such "misplaced announcement", the JOURNAL fulfils an important function. Not every such announcement—and there are only too many of them—can be as satisfactorily explained and as promptly disavowed.

L. M. D.—Mr. Pillischer, New Bond Street, London.

THE HOSPITAL SATURDAY FUND.

SIR.—I am requested by the members of the Hospital Saturday Board, who met last evening, to beg you to state, in contradiction to an announcement which, we are informed, appeared in your columns, that there is no intention whatever to transfer the functions of the Hospital Saturday Fund to the Sunday Fund; on the contrary, every arrangement calculated to ensure a successful collection for next year is in active preparation. It being the intention of those earnest members of the industrial classes who have devoted their energies to the good work to still persevere, it will be satisfactory to the public to know this, and that the distribution of the amount (£4,000) available of this year's collection has been completed, the principal hospitals participating being King's College (£158 1s. 9½d.), London (£26 8s. 3d.), Metropolitan Convalescent (£228 12s. 3½d.), Middlesex (£206 17s. 8d.), Seamen's (£148 17s. 6½d.), and University College (£159 16s. 3½d.).—I am, sir, your obedient servant,

CHAS. MERCIER, Chairman.

28, Leicester Square, W.C., December 9th, 1875.

DR. ROGERS.—We will draw attention to the subject next week.

WHOOPING-COUGH.

In the course of a case lately tried before the Vice-Chancellor's Court, "The Atorney-General v. the Hyde Chemical Company", an affidavit was put in deposing that the medical men in the neighbourhood of Hyde, a town in Cheshire, had within the last month sent about forty children suffering from whooping-cough to the manufactory to inhale the fumes of pitch.

MESSRS. WEISS and Co. forward us a letter from Mr. Barr of Northampton, stating that more than a year ago they made for him a spring hypodermic syringe similar in principle to that of Leiter's of Vienna, but, in his opinion, superior in construction. Leiter's syringe is, however, by no means of recent invention, and was described by us chiefly because we have found it useful.

SO-CALLED INQUESTS.

We have before us, cut from the *Eccles Advertiser* of November 13th, 1875, the following report of what appears on the face of it to have been a monstrous farce, though called an inquest.

"*Inquest on the Body of a Child found in the Truwell*.—Inspector John Henderson deposed that on Sunday, the 7th November, about twelve o'clock at noon, he was in a field near the boat-house, at Irlam, when his attention was drawn to an object on the opposite side of the river. The object was about fifty yards past the boat-house on the Flixton side of the river, floating in the stream, but entangled in some willows. He got a man to take a boat and fetch it across for him, and he did not lose sight of it while the man was fetching it across. When he got possession of the object, he washed it; found it to be the body of a full grown male child. It had apparently been in the water some weeks. The skull was open in the middle, and there were no brains in it. The navel-string appeared to have been rudely broken asunder without being tied. No medical man had seen it; he thought it would be difficult for a medical man to say whether it had been born alive or not. There was a wrapping round its loins—a coarse old apron. The water was half way up the towing-path, and had been five feet higher than it then was during the night. No information had been obtained respecting the mother of the child. A verdict was returned to the effect that the child was "Found dead, and that there was no evidence to show that the child was born alive."

Thus one of the most important and nicest questions in jurisprudence is described as having been settled on the off-hand dictum of a police-inspector, that he thought it would be difficult for a medical man to decide it. We need not point out the crass ignorance involved, or the certainty that such a mode of proceeding must, in the end, facilitate crime, and defeat the ends of justice. It is desirable at this time to collect such flowers of justice from the inquiries of legal coroners, and we shall be obliged if those of our readers under whose notice they may come in the columns of local papers will have the goodness to mark them and forward the papers to us.

ERRATA.—In the list of candidates who passed their examination on November 16th (JOURNAL, November 20th, page 660), the name "Whitley, E. E.," should be "Whitby, E. V."

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

MEDICAL EDUCATION.

SIR.—I own the letter of your correspondent K. N. M. on the subject of medical education generally, and the course of education in Edinburgh specially, has occasioned me much surprise. To make a few remarks on his letter is perhaps allowable to an old graduate who has been unable, from many years' absence in the East, and pressing engagements since his return, to revisit, for more than twenty years, the scene where some of the pleasantest, and, he would hope, the most profitable, years of his life were passed. His only regret then was, and still is, that he could not, after graduation, spend another session there to allow more perfect assimilation of the "food" he had received.

First, it may be well to say but a few words as to some of the teachers who then filled the professorial chairs. Their names together are surely sufficient to refute K. N. M.'s idea, that "the success of Edinburgh as a seat of learning is to be as much attributed to political considerations as to the wisdom and greatness of its professors"—Good, Sir, Alison, Syme, Miller, Simpson, Christison, Bennett, Balfour, and Jamieson. Is there one of these names that is not well known over Europe or America? The writer went to modern Athens when over twenty-one years of age, and knowing nothing whatever of medicine or medical practice, and so his impressions may be taken as illustrating the effect of the system. The only prior assistance he had was, that for some years he had studied chemistry under an old pupil of Liebig.

Naturally, the study of the bones, as the framework of anatomy, was the first. Does not the study of the bones at first suggest the parallel of the generals of medical subjects being studied before the particulars? My course of study was entirely that recommended, except that I attended Syme's clinical surgery from my first session, and nearly every session afterwards. Yet I differ from K. N. M., as I can now recall many of Alison's remarks, and turn up my note-books for confirmation. Syme's lectures I can scarce imagine any one forgetting, his remarks were so terse, frequently so scathing in verbiage, and yet so filled with instruction. Some of Christison's clinical lectures are now vividly present to my mind, and many of Simpson's and Bennett's. Yet why should I go on with such reminiscences, when I wish to defend the system in vogue, which I believe is right, and more likely to produce a class of medical men with a breadth of view, as contradistinguished from the routine practice likely to be engendered by such a process of educational cramming, combined with two hours' practical instruction, as is recommended by K. N. M.? What more likely to induce a true practical knowledge of the body than lectures giving a general knowledge of anatomy, combined with practice at dissection, followed by the institutes of medicine, showing the intimate structure and function of each part, and then their diseased conditions? then medicine proper giving a general view, clinical medicine a particular, and general pathology and practical pathology completing (as far as we can) our natural history of the body in health and disease? Side by side with these we naturally have chemistry, botany, natural history, and materia medica; and, except of the last, no very deep knowledge is required at examinations. Hospital practice is combined, and illustrates what the student has heard in lectures, and what he must supplement by reading, as various classes of disease come before him. Medical education is only the framework of knowledge; on practice and thought of one's own labours, and comparing these with the works of others, must hang the wisdom of the experienced physician.

Many medical students fail from not devoting a certain portion of time day by day to completing the work of the day. Lectures are attended but not listened to, not being considered to have a distinct place in the medical curriculum. The subject is not read after lecture, and so it goes on till the crammer has in a few weeks to try to get his pupil to remember what requires mouths and years to master and digest, and even then imperfectly.

That lectures are most useful is, to my mind, abundantly proved by the lectures in the extra-academic school in Edinburgh, which are numerous, and much resorted to; and the lecturers themselves act as no mean stimuli to exertion in their academic brethren.

There was one most important matter which distinguished, or did in my day distinguish, the Edinburgh Infirmary medical officers, which was the daily visit, and its absolute punctuality. The arrival of Syme, Miller, Spence, Alison, Christison, and Bennett, was absolutely to the time, and it was only the most pressing emergency which prevented the daily round from being made. When in Paris, I found the same punctuality; and it is a most important matter to teach the student, that the medical men in charge of important cases should see them daily.

I have not specially alluded to surgery and midwifery; the lectures on both had a high degree of interest as well as instruction.

So much for the University and its maligned lectures. Then, what pleasant evenings were Fridays at the Royal Medical Society, venerable in a green old age, dating from 1737; proving, by the roll of attendance, that the students were not so overburdened with academic work but that they could devote some of their spare time to write each in his turn a paper on some medical or scientific subject, to be circulated in duplicate for a fortnight, and then discussed. Surely, earnestness in work may be claimed for such a society, and the work was all that of volunteers. Meeting in their own hall, the Society had in my day a library of 14,000 volumes; and, if I remember rightly, about £2,000 of accumulated funds. The story of that Society has, I think, much to do with the eminence of the University, and shows that the University teaching of medicine bore such fruit in generations long gone by as could be shown by no other British school of medicine.

I have most pleasant memories of the years I passed and the agreeable society I enjoyed, procured by a few letters of introduction. It is, I think, no mean item in the advantages to a student that he should have good society occasionally.

As a place for study, I need scarce say aught of the physical features or the surroundings of Edinburgh; but as to the basis and plan of medical education pursued, I would say with the old Roman, "Hanc retinet quæso, Quiritis, quam vobis tanquam hæreditatem majores vestri reliquerunt.—Your obedient servant,
November 8th, 1875. M.D. EDIN.

MR. MALCOLM.—The following are the correct lines.

"How "D.D." swaggers, "M.D." rolls;
I dubb them both a brace of noddies;
Old "D.D." takes the cure of souls,
And "M.D." takes the cure of bodies.

Between them both, what treatment rare
Our souls and bodies must endure;
One takes the cure without the care,
T'other the care without the cure."

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, no later than *Thursday*, twelve o'clock.

ROYAL COLLEGE OF SURGEONS.—The half-yearly examination of candidates for the diploma of Fellowship of the College was brought to a close on Saturday, November 27th.

THE EXAMINATION OF M.R.C.P.L.

SIR.—Can any one who has recently passed the final examination for the M.R.C.P. kindly give me some information as regards the best works in which to study the prescribed subjects? These are: Medical Anatomy, Principles of Medicine, Practice of Medicine, Principles of Public Health, and Psychological Medicine. Moreover, one has previously to translate a passage from a Latin author, and have the opportunity of showing a knowledge of Greek, or of one or more of the European languages (Rule 13). This looks very simple; but I should like the opinion of a recent candidate as to the security or otherwise of the examination. In the bustle of general practice, it is not many who keep up their classical studies; and what might have been easy fifteen years ago, may perhaps be formidable now. Any information will be very acceptable to yours, etc.,
December 1875.

IGNORAMUS.

ONLY A DOCTOR.—As showing how members of our profession were appreciated by the upper classes a few years ago, Mr. Greville, in his *Memoirs of George and William IV.*, states that on dining one evening at Lord Holland's, he found himself between Sir George Robinson and a common looking man in black; and, as "he did not open his lips, except to eat, I settled that he was some obscure man of letters, or of medicine—perhaps a cholera doctor". To his great astonishment, he found him able to carry on a conversation on every subject started; and it was not until Lord Auckland respectfully addressed the supposed "cholera-doctor" as "Mr. Macaulay", that he became aware of the genius seated by his side, when he sabbirily observes, "I thought I should have dropped off my chair; the perspiration burst from every pore of my face".

We would suggest to Mr. T. P. Lucas to submit his "doubts" direct to Dr. T. L. Brunton.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Hastings and St. Leonard's News; The Belfast News-Letter; The Sheffield Daily Telegraph; The Chester Guardian and Record; The Hereford Times; The Bristol Daily Post; The Statesman; The Birmingham Morning News; The Cork Constitution; The Newcastle Weekly Chronicle; The Worcester Journal; The Hobart Town Mercury; The Weekly Times; The Mid-Weekly Hampshire Independent; The Lincolnshire Herald; The Sunderland Daily Echo; The Co-operative and Financial Review; The South Wales Daily News; The Macclesfield Courier; The Glasgow Herald; The Craydon Advertiser; The Glasgow News; The Hastings and St. Leonard's Chronicle; The Metropolitan; The Londonderry Sentinel; Saunders's News-Letter; The Tenby Advertiser; etc.

AN ADDRESS

ON

THE EFFECT OF THE ANTISEPTIC TREATMENT
UPON THE GENERAL SALUBRITY OF
SURGICAL HOSPITALS.*Being the Address delivered in opening the Surgical Section of the British Medical Association in Edinburgh, August 4th, 1875.*

By JOSEPH LISTER, F.R.S.,

Professor of Clinical Surgery in the University of Edinburgh; President of the Section, etc.

GENTLEMEN,—I believe I can hardly more profitably occupy the time allotted to me for an address in opening this section, than by bringing before you some facts illustrative of the effect of antiseptic treatment, when strictly carried out, upon the general salubrity of surgical hospitals.

Six years ago, when writing on the very remarkable improvement which had been brought about by "enforcing strict attention to the antiseptic principle" in the wards of which I had charge in the Glasgow Royal Infirmary, "converting them from some of the most unhealthy in the kingdom into models of healthiness", I ventured to express myself thus. "Considering the circumstances of those wards, it seems hardly too much to expect that the same beneficent change which passed over them will take place in all surgical hospitals, when the principle shall be similarly recognised and acted on by the profession generally."* That prediction, I think I may say, is now in course of fulfilment.

I shall speak first of what has come to my knowledge with regard to some foreign hospitals, and I will begin with Copenhagen, where Professor Saxtorph long ago introduced antiseptic treatment; indeed, I believe he was the first to bring it into operation on the continent. The large hospital of which he had the charge used to be a very unhealthy one. Pyæmia was extremely frequent, even after very small operations, such as amputation of a finger. Pyæmia has vanished ever since the antiseptic treatment was introduced, hospital gangrene has almost entirely disappeared, and erysipelas is nearly unknown except as imported from the town. Professor Saxtorph writes to me as follows: "If you ask me what I have observed respecting the effects of antiseptic treatment, I may say that it has not modified, but completely changed my principles of pathology and my surgical practice." "The word *hospitalism*, which some years ago found its way from Edinburgh to the continent, no longer terrifies us; it no longer keeps us from performing operations in the infirmary, and you seldom meet with a case that could be called a case of hospital disease." After going into details regarding the various forms of hospital disease, he proceeds to describe the greatly increased success that now attends the treatment of some injuries. "As to accidental deep wounds, large lacerated wounds of the scalp, contused wounds with smashing of hand or foot, compound fractures or wounds of joints, I almost invariably have them heal without any bad symptoms, by means of antiseptic dressing and drainage-tubes. Any case of this sort will almost certainly recover if there is no complication of shock, or gangrene of the limb, or contusion of internal organs." He next speaks of the change which has taken place in the results of operations, such as amputations and excisions, and adds, "In short, I think I am right in saying that patients very seldom die from an operation. If they do die, it is not the operation that kills them, but the disease that existed previously to the performance of the operation." Lastly, he alludes as follows to abscesses connected with diseased bone. "What until the last few years proved the most difficult to deal with, are the abscesses which are connected with bone-disease. But now I think we may safely cut into them, if we only persevere in the antiseptic treatment for a sufficiently long time. By means of careful dressing, drainage-tubes, and the antiseptic spray whenever the dressing has to be changed, we get over those accidents of septicæmic poisoning which formerly almost invariably followed incision into these collections. But I am equally sure that, if I do not carry out the antiseptic treatment to its full extent, it is of no use whatever to apply carbolic acid to a wound, at least as regards the dangers that always accompany putrefaction."

I come now to what I witnessed in the course of my recent travel in Germany, and I shall speak only of those hospitals into which antiseptic treatment has been introduced. Of these, the first I saw was Munich. The large Allgemeines Krankenhaus there has been until

lately increasingly unhealthy; pyæmia was very frequent; and hospital gangrene, which made its appearance in the year 1872, had become annually a more and more frightful scourge, until last year it had reached the astounding proportion of 80 per cent. of all wounds that occurred in the hospital, whether accidental or inflicted by the surgeon. And not only was it thus extremely frequent, but was in a very severe form, produced frightful ravages, often caused death, and led to patients who recovered being retained an inordinately long time in the hospital. But, from the time when, at the beginning of the present year, efficient antiseptic treatment was brought into operation by Professor Nussbaum, they have not had one single case of hospital gangrene. At the time when I was at Munich, they were doubtful whether they had had one case of pyæmia; erysipelas, formerly very prevalent and severe, was rare, and, when it did occur, was in a very mild form; and I saw the convalescent wards—which previously had always been filled and overflowing—standing one after another empty, because the patients, no longer affected with hospital gangrene, recovered much more rapidly."

I next proceeded to Leipzig, where Professor Thiersch is clinical teacher. He has three hundred beds under his own charge, of course seconded by able assistants. Professor Thiersch was the first to introduce antiseptic treatment on scientific principles into Germany. His results, as regards the general salubrity of the hospital, have been, on the whole, progressively more and more satisfactory, and in the present year he was able to state that he had only had one case of pyæmia in twelve months; and that, you will observe, in a service of three hundred beds. Hospital gangrene, also, had almost disappeared. There had been in 1871 a curious attack of that disease in two barrack wards, which seemed to be due to old hospital furniture piled up in an empty space under those apartments; but of late this also has vanished. Professor Thiersch has of late used, instead of carbolic acid, salicylic acid as an external dressing; but he still employs carbolic acid for the spray and lotion. Salicylic acid, as he uses it, certainly works very well; but that his increasingly satisfactory results are due to any special virtues of that agent, cannot be maintained.†

From Leipzig I passed to Halle, where I found Professor Volkmann carrying out antiseptic treatment just in the same way as we do here. He gave an antiseptic demonstration, to which he invited professors from various parts of Germany; and he certainly showed us a magnificent set of cases. It was, I confess, somewhat gratifying to me, that Professor Volkmann had obtained his results without any of his assistants having visited Edinburgh. Seeing the importance of the subject, he had worked in good earnest at the system, in accordance with what he had read of my writings. He told me he had only gradually got into the way of carrying out the system properly; but I had the satisfaction of seeing everything done exactly as we do here, and with results of the most brilliant kind. That hospital was previously an extremely unhealthy one. The wards are small and overcrowded; each one has a water-closet opening into it, and a large drain of the city runs under the wards. Indeed, the building is so confessedly bad, that it has been condemned to demolition. Pyæmia used to be exceedingly common there; but, since the introduction of

* Since the delivery of this address, I have received from Professor Nussbaum a pamphlet entitled *Die Chirurgische Klinik zu München im Jahr 1875. Ein Andenken für seine Schüler*. Published by Ferdinand Enke, Stuttgart. The subject of this work is the complete revolution brought about in the salubrity of the hospital by antiseptic treatment, and the means by which this result has been attained. One passage from the first chapter seems to me to demand reproduction here. After describing the previous frightful state of unhealthiness, he says: "Every thing that we had tried against the above-mentioned horrors had proved unsuccessful. The open treatment, the occlusion dressing, the continuous water-bath, irrigation with chlorine water or with carbolic acid solutions, salicylic acid in powder and in solution, the putting on of Lister's antiseptic materials—carbolic paste, etc.—all, were unable to combat hospital gangrene and pyæmia. But when in the course of a single week, with great energy and industry, we applied to all our patients the newest antiseptic method, now in many respects improved by Lister, and did all operations according to his directions, we experienced one surprise after another. Everything went well; not a single other case of hospital gangrene occurred. Pyæmia and erysipelas were observed a few times at the very beginning; but only, as the result proved, because we did not yet possess the necessary practice in the carrying out of Lister's directions. We took pains, as you know, and learned from day to day more exactly how to comply with his instructions. Our results became better and better, the time of healing shorter, and pyæmia and erysipelas completely disappeared." (*Op. cit.*, page 6.)

† The true explanation of the improved results is given by Professor Thiersch himself in the following passage in a work which he has recently published on this subject—a statement characterised by the usual perfect candour of the distinguished writer: "Our results have constantly improved in proportion to the perfecting of the method and our own practice in carrying out its details. They are, indeed, not so good as those of Lister himself, or of Volkmann, etc." (see *Klinische Ergebnisse der Lister'schen Wundbehandlung*, etc., one of the *Klinische Vorträge* edited by Volkmann; Leipzig, 1875, page 645). To the same cause, I have little doubt, is to be attributed the fact that erysipelas was considerably less ("bedeutend geringer," *op. cit.*, p. 676) in the year 1874 than in the previous year. Professor Thiersch himself believes that erysipelas is not influenced by antiseptic treatment; but this view is entirely opposed to the experience of Saxtorph and Nussbaum already mentioned in the text, and to that of others to be alluded to in the sequel.

* See the *Lancet*, January 8th, 1870.

antiseptic treatment, a change has taken place which I can best describe by a quotation from a paper by Professor Volkmann himself.

"I had hoped to have been able to publish before now the communication which I made on the antiseptic treatment and Lister's mode of dressing, on the occasion of the third Congress der deutschen Gesellschaft für Chirurgie; but as this has, unfortunately, not been the case, I may, perhaps, be allowed to mention here a few facts for the purpose of showing how greatly the danger of some forms of injury, which were formerly followed by a very high rate of mortality, is diminished by this procedure.

"Since the introduction of the antiseptic method into my *clinique*, now exactly two years ago (at the end of November 1872), no single patient suffering from a compound fracture, in which conservative treatment was attempted, has died. Amongst this number are included even those cases in which conservative treatment was only resorted to because the patients would not give their consent to amputation, and also those in which we at first underestimated the severity of the injury, and afterwards intermediate or secondary amputation had to be undertaken on account of hæmorrhage or gangrene. The number of compound fractures successfully treated without a single fatal result in our hospital, which is old and always overcrowded, and offers the most unhealthy hygienic conditions, amounts at present to thirty-one. Amongst these were as many as nineteen compound fractures of the leg, in several instances much comminuted, and often complicated with most severe bruising and laceration of soft parts. There were also two compound comminuted fractures of the patella, both of which recovered with movable joints. No case of pyæmia has occurred for a year and a half—*i. e.*, since July 1873—although during this period alone about sixty major amputations have taken place." (See Professor Volkmann on Antiseptic Osteotomy, translation in the *Edinburgh Medical Journal*, March 1875.)

I also learn that hospital gangrene is now entirely unknown in that hospital. Erysipelas likewise is extremely rare; and, where it does appear, it is of a superficial and mild type: and Professor Volkmann told me that his experience of the effects of antiseptic treatment in diminishing the amount and severity of that disease was so striking, that he entirely differed from the opinion of Professor Thiersch on this matter.*

Amongst the cases brought before us in Professor Volkmann's demonstration was one of excision of the hip-joint, where putrid sinuses had existed before the operation. About a week had passed since the operative procedure, but there was no purulent discharge whatever; and no fluid even of a serous character could be pressed out from the small spot that alone remained unhealed, and the use of a drainage-tube had been already given up. In short, the case had followed the typical course we expect under antiseptic treatment when we operate with an unbroken skin. This is a kind of result I myself had never yet obtained, and it filled me with astonishment. I inquired how it had been arrived at, and I found it was as follows. Professor Volkmann several years ago strongly advocated the application to diseased soft parts of "the sharp spoon" which had been introduced into German surgery by Bruns of Tübingen for scraping carious bone. Thus, supposing a strumous abscess to be opened, instead of leaving the degenerated textures around to come away by a tedious process of suppuration, or to be removed by slow absorption, he scraped it all out at once with the sharp spoon, and thus greatly accelerated the recovery. Being thus accustomed to the use of this instrument, he applied it to clear out the pyogenic membrane of putrid abscesses and sinuses, and all granulations around the diseased bones after excision. For my part, I have always, after operating upon such a case, treated the cut surfaces with solution of chloride of zinc, and injected the sinuses with the same, in the faint hope of exterminating existing putrefaction; but I have practically never succeeded. The failure was always readily intelligible to me, on the ground that I could never get the antiseptic to penetrate all the recesses of the sinuses and the lymph or sloughs lying among the granulations. But here Professor Volkmann had cleared out the offending substances altogether, and then introduced an antiseptic lotion; and he told me, to my amazement, that it was the rule with him to attain results of the character I then witnessed. If my journey on the Continent had been one of unmixed labour, I should have thought that labour well rewarded by this circumstance in my visit to Halle. I have already put this plan in operation in my own practice since my return, and I hope to show you some of the results to-morrow, at a demonstration in the operating-theatre of the Royal Infirmary. Whether I can obtain such frequent success as Professor Volkmann, I do not know; but I have already succeeded in some cases.

In Berlin, Professor Bardeleben, with one hundred beds under his care at the Charité Hospital, has long introduced the antiseptic system. The hospital used to be a very unhealthy one. Pyæmia was so fre-

quent, that amputation in the lower limb was almost certain death to the patient; but, through antiseptic treatment, this has for a long time past been entirely changed. Professor Bardeleben informed me, at the time of the meeting of this Association in London, that pyæmia was practically abolished from the wards, without any other change than the introduction of antiseptic treatment; and I found that this same satisfactory condition of things continued at the time of my visit this year. Erysipelas was also rare, and of a mild type; and hospital gangrene very uncommon. At the same time, I feel bound to express my conviction that Professor Bardeleben would get still better results had he not been led, on the score of economy, to substitute for our antiseptic gauze unprepared gauze soaked with a watery solution of carbolic acid; for here, the carbolic acid being dissolved in a liquid, instead of being stored up in an insoluble medium, the antiseptic and its vehicle are both displaced together by the discharge which soaks into the dressing, and this involves great additional risk. In fact, Professor Bardeleben told me that for very special cases he still used our antiseptic gauze.

In the other great clinical hospital of Berlin, the renowned and veteran surgeon Von Langenbeck had not until the present year seen his way to adopting antiseptic treatment. He had professed admiration of various results he had heard of; but, as Professor Bardeleben said, it had been barren admiration. But it was a singular coincidence, and one very gratifying to me, that, when I called upon him, I found him preparing to perform his first operation according to strict antiseptic principles. The case was one of tumour of the upper end of the fibula; and, considering the possibility of the wound communicating with the knee-joint, he felt himself bound to use antiseptic treatment. This he did with perfect faithfulness, in spite of the serious inconvenience of a most unnecessarily wetting spray; and, when the operation was concluded, he did me the honour to ask me to put on the dressing.

At Magdeburg, I found a great hospital, containing, on the average, one hundred surgical patients. This hospital used to be noted for its unhealthiness; but I learned that, since the introduction of antiseptic treatment, an entire change had come over it in this respect. Pyæmia has almost entirely disappeared, hospital gangrene has gone, and erysipelas, when it occurs, is of a very mild type.*

At Bonn, also, I heard similar testimony. I learned from Professor von Busch, who introduced antiseptic treatment into the clinical hospital last year, that some previously unhealthy wards had since quite changed their character; and that in some fine airy wards, which were always very free from hospital disease, the mode of healing of the wounds was something altogether different from what it used to be.

So much, then, gentlemen, for my continental experience. And now I wish to say a few words as regards the Infirmary here, where I have now been at work for about six years. And, first, as to the conditions under which I am working. The wards, as some of you have seen, are small and overcrowded. These wards were never so severely tested as they have been since I came here. There used to be, in the old High School building, two reserved wards kept ready for the reception of erysipelas or other peculiar case; but, at the time when I was appointed, twenty beds were taken off from the clinical surgical department for the purpose of creating a new surgeoney; and, at the same time, the two reserved wards previously kept empty were filled with patients. That particular block of building has, therefore, been more severely tried than ever it was before. The number of beds is so limited that there is always great pressure upon them. When I came to Edinburgh from Glasgow, seeing the beds so close, I had several of them cleared out; but the result was, I found, that the same number of patients were admitted; and there always being a considerable proportion who could walk about during the day, they were put down on mattresses on the floor at night, so that the number of patients remained as before; and, as the wards continued perfectly healthy, I had the beds reintroduced. But, more than this, I have still the mattresses on the floor. If you were to go into these wards sometimes at night, you would be surprised to see how many "shake-downs" there are. We have, also, often two or three children in one bed; and altogether by these means, while I have fifty-five beds, I have lately had seventy-one patients. During the time I have been here, there has hardly been a day on which there have been as few patients as beds,

* Dr. Hagedorn, the chief surgeon, was absent at the time of my visit; but in a letter, which, through accidental circumstances, I did not receive till after this address was delivered, he describes in full detail the change that antiseptic treatment has effected. From this letter I must content myself with quoting two short passages. "I have now been for twelve years chief surgeon to the hospital, and I had to do battle on a large scale with pyæmia and septicæmia, till in May 1872 I introduced your antiseptic method." "Since that time we have constantly practised it with excellent results, which, in truth, have been constantly improving; for at first the procedure does not always succeed, and every man must pay for his schooling (musz Lehrgeld geben). Now I have arrived at the conviction that your procedure is unconditionally secure, and that in every failure the surgeon himself is to blame, and not the method."

* See note at the foot of last page.

although any of you can see those beds are not as distant from each other as they ought to be, according to modern notions of what is requisite for the salubrity of an hospital.

Then there is another important respect in which my wards have been more severely tried than before. There had previously always been an annual cleaning of the wards of our infirmary. Now, this involves considerable inconvenience. The patients had to be transported to another part of the hospital, and some cases were liable to be injured by this transport. Therefore, when the annual cleaning came about, I used to consider whether the patients would get more harm from the want of the cleaning of the wards, or from the transportation. I thought they were more likely to get harm from the transport; and this being year after year my conviction, it is now three years since any cleaning took place in these wards of mine. The year 1872 was the last in which it was practised, except in the case of one individual ward where a sore throat prevailed last summer, which seemed to be of the nature of scarlatina, and on that account the ward was emptied and purified. I have sometimes observed remarks made with regard to the results of treatment in my wards, to the effect that I work under superior hygienic conditions. It is, in truth, exactly the opposite. My wards, in these respects, are more severely tried, I believe, than those of any other surgeon in the kingdom.

Then it is said that greater cleanliness is involved in the antiseptic treatment. This, again, is an entire mistake. If we take cleanliness in any other sense than antiseptic cleanliness, my patients have the dirtiest wounds and sores in the world. I often keep on the dressings for a week at a time, during which the discharges accumulate and undergo chemical alteration, probably from oxidation and the action of the resin of the gauze upon them; and, when the wounds are exposed after such an interval, the altered blood with its various shades of colour conveys often both to the eye and to the nose an idea of anything rather than cleanliness. Aesthetically they are dirty, though surgically clean.

There is yet another way in which my wards have been unusually tried—namely that I now perform operations which, without antiseptic means, I should not have considered justifiable, some of them being of a character which used to involve especially the risk of pyæmia, such as cutting down on ununited fractures of the femur, and removal of the ends of the fragments.

Yet, in these circumstances, if I have had one case of pyæmia where I have operated myself, it is the only one I know of; and that was a spurious form of the disease. It occurred in a patient from whom I had removed the mamma, and, at the same time, cleared out all the axillary glands; and putrefaction took place in the axilla, in consequence, as we had reason to believe, of mismanagement of the spray. Of hospital gangrene we have not had one single case during these six years. As regards erysipelas, our experience has been various. As a rule, it is very rare in many wards. I have been two entire years without a single case of it; but, on the other hand, there was a time when it was frequent. This was during a concurrent epidemic of small-pox and erysipelas in Edinburgh two years ago. The erysipelas was of a very virulent type, and some patients in private practice in the city died of erysipelas affecting the puncture of revaccination. At this time, we had several cases of erysipelas admitted into my wards from the town, and several, also, took origin within the hospital. But the constitutional rather than the local cause of these cases was shown in several instances by the disease occurring not in or near the wound, but at some remote part, as in the head after an operation upon the penis. And it was somewhat remarkable that in no case did the disease as it originated in the hospital assume the malignant form which it sometimes exhibited in private practice.

Tætaus also appears to be rendered much less frequent by antiseptic treatment. Far be it from me to say that putrefaction is the only cause of it; we all know it is otherwise; but when I say that, in six years, with an average of sixty severe surgical cases, I have only had two cases of the disease, and those both of them in connection with septic wounds, I show strong grounds for believing that, if we exclude putrefaction, we exclude one—and the most common—exciting cause of tetanus.

One objection that has been urged against my treatment is the inordinate length of time patients remain in hospital. No doubt it is so in some cases; but, as a rule, these are instances in which we expect to cure otherwise incurable cases, such as spinal abscess. But, on the other hand, on comparing Mr. Syme's case-books with my own, during two periods of three years, the unexpected result has lately been arrived at that, in proportion to my number of beds, I have had a larger number of operations than Mr. Syme; showing that, while some patients, kept alive by antiseptic treatment, have remained long in the hospital, this was more than counterbalanced by the rapid cure of others.

I trust, gentlemen, that the facts which I have now had the honour

to bring before you will be considered pretty strong proof of the value of strict antiseptic treatment in promoting the general salubrity of surgical hospitals.

FURTHER OBSERVATIONS ON HARE-LIP AND CLEFT PALATE.

BY SIR WILLIAM FERGUSSON, Bart., F.R.S.,
Surgeon to King's College Hospital, etc.

IN the BRITISH MEDICAL JOURNAL of March 28th and April 4th, 1874, I ventured to write on these topics, under the impression that, in regard to both, I had something new, and therefore original to state. On hare-lip I trod on ground which to many might seem so trifling and so exhausted that I could scarcely expect attention to what I stated, excepting from those who might have special interest in such cases; or who might, like myself, have devoted more than forty years of careful study to matters in surgery and abnormal development, which, in the estimation of many, have been considered of minor importance.

Within these two years, my experience on such malformations and their treatment has been considerably increased; and, at the risk of being considered prolix, I venture to give the results of that experience in the hope of making additions to our knowledge in this department of professional study.

At this date in surgery, it is not easy to imagine how any novelty in regard to hare-lip could be announced. In the paper above alluded to, I described a practice in the operation which I thought likely to be advantageous in certain examples. In some cases of single fissure, I had learnt from experience that failure of the usual operation was induced by the projection of the intermaxillary bone on that side, and I had long been in the habit of removing such projection previously to bringing the edges of the gap into approximation. This removal was readily accomplished, in the majority of cases, by the scalpel or scissors. Preferring, as I do, to perform the operation in the early months of infancy, the tissues are then so soft that they can be readily cut by these instruments. At an older date, the cutting forceps was sometimes applied to divide the narrow part of the intermaxillary bone where connected with the vomer. For many years in early life, a scalpel can readily be passed between the intermaxillary bones in the mesial line; and it was my custom in many instances to so use the blade as to effect the separation. But even here, in the course of time, I learnt to apply conservative surgery; and, instead of taking away bone, tooth, and mucous membrane, I so managed by cutting and raising the mucous membrane that I could cut away tooth and bone, and leave the membrane as a soft cushion and a more complete covering to the side not interfered with. The object here was to keep a natural surface of mucous membrane, instead of exposing a considerable portion of raw surface. Within these two years, I have frequently acted on these views, and have every reason to be well satisfied with the results. In some instances, I have been content with gouging out the tooth only; but in others, where the prominence has been of considerable bulk, I have clipped away the whole bone, leaving, however, the whole mucous membrane, and probably most of the periosteum. By such a plan, I feel confident that union of the gap in the lip has been rendered more certain. An objection, and seemingly important one, to this plan is, that it costs the milk incisor, and possibly the permanent one. I have long been convinced, however, from experience, that these teeth are rarely of much value. Occasionally, some good teeth are met with in the intermaxillary bone, but so rarely, that their preservation is of small consequence as compared to the result of a well designed and perfect operation. Whilst advocating the sacrifice of teeth, or even of an intermaxillary bone in single hare-lip, where the bone happens to project, I feel equal confidence in recommending free work with the two intermaxillaries when they happen to be very prominent in double hare-lip. In many instances of double hare-lip, as in single, the alveoli are not involved in the fissure; but usually there is the complication of cleft-palate, and the intermaxillary bones are left so isolated, being attached by a slender neck to the vomer, that in subsequent years their value is questionable, even when preserved in a satisfactory operation for the double gap. It does in some instances, even after years have passed, fill up a gap that might otherwise be in front of the mouth; but it has often appeared to me that it would have been better away, so as in due time to permit the closer approximation of the lateral portions of the jaws. Where, however, the intermaxillary bones do not project, so as to endanger the success of an operation on

the lip, I am not disposed to urge their removal; but, where they project so as to interfere with the satisfactory treatment of the lip, I earnestly recommend the removal of the projecting and nearly isolated mass. From time to time, I have met with cases where I have been reluctant to meddle with this projection; and, with a conservative motive, have even been content to do one gap first, and the other in a few weeks afterwards. I cannot say, however, that this plan has given me so much satisfaction as taking away the whole, and effecting junction in the two gaps at once, whether the intermediate portion of skin has been worked into the lip or made to represent the columna only.

It is often a puzzle what to do with the central portion of the lip in front of the intermaxillary bones. It is rare to find it so long and the nostrils so perfect that it can be associated with the lip—particularly to bring its free margin down to the level of the lateral portions of the lip by however small a strip. It more frequently is so short that the surgeon may be well pleased if he can, by paring its extremity into a wedge, incorporate it into the upper portion of the lip. In the majority of cases, he may be well content if he can shape it into a respectable columna; and in some instances it will puzzle his ingenuity even to accomplish this. Some of the most troublesome cases I have met with have been those where the difficulty has been how to dispose of this bit of lip—it might have been called skin—so very short has it been. Some writers on this subject have gone so far as to question the presence of this intermediate portion of lip or skin, as if to show that the gap in the human subject may take place in the mesial line, as in the hare. This, I contend, never happens; but, in some instances, the intermediate portion may be so short as to appear wanting altogether. There are specimens of this kind in the museum of the Royal College of Surgeons of England; but a fissure in the mesial line in the human subject, with the nostrils perfect, has never to my knowledge been seen. It would be to me as unprecedented as to see a fissure in the upper lip under each nostril in a hare. So far as I am aware, no such specimen has ever been seen.

In general, if I have the opportunity of treating a case *de novo*, I try to join the apex of this intermediate portion with the sides of the lip at the first operation, but occasionally union fails. I have tried again months or years afterwards, and usually succeeded. Sometimes I have met with instances where the junction in the mesial line has been effected by others, and I have been in doubt whether a bit of the mesial soft substance has or has not been cut away. I fancy that in some cases a portion has actually been cut away. If anyone who reads these lines should ever think of cutting a portion of the intermediate soft slip away, I earnestly urge him not to do so—at first at any rate. Sometimes, in my own practice, I have left this portion so long and broad as to make it appear far too big for a columna; but that is a fault which can easily be remedied, whilst the surgeon with all his skill may be foiled in closing the opening into the nostrils, left either by the natural shortness of this intermediate portion, or in consequence of its abbreviation by his own hands.

Since I last wrote on the intermaxillary bone in the human subject, illustrative of hare-lip, the most notable case I have met with in practice is to me unique, and, in my opinion, specially worthy of record. In April 1875, I was consulted regarding the case of a young lady, six years old, who had been born with double hare-lip and cleft palate, each of the worst kind. The operation for hare-lip had been performed in early infancy, and union had ultimately been accomplished after several failures, chiefly attributable to the prominence of the intermaxillary bones. To facilitate matters, these had been bent backwards towards the gap in the palate. The whole condition of the upper lip and mouth was most unsatisfactory, both regarding appearance and comfort. There was still a projection in the middle line, caused by the intermaxillary prominence, which was but scantily covered by the sides of the lip and a portion of soft material extending partially from the columna. Being requested to improve if possible, I decided to remove the intermaxillary mass entirely, bring the lateral portions more extensively into apposition, and to raise the columnar portion more into the normal position. These views were most satisfactorily realised. The friends and I were gratified; but, for myself, further matter of interest remained regarding the condition of the intermaxillary bones and the teeth. Prior to the present generation of surgeons, the idea of bending back the projecting central portion had been entertained. Mr. Samuel Cooper described an interesting case of the kind, wherein, by means of a kind of truss, this was accomplished by a slow process of pressure. Some thirty years ago, it was not uncommon to push the projection back by means of rapid force. The slender neck was bent, or rather broken, the mass was carried backwards and held there by the completion of the operation for the clefts in the lip. I performed the operation repeatedly, but was never specially well satisfied with it, nor had I ever an opportunity of examining the parts anatomically

afterwards. Before doing so, the death of the patient was to be implied. Here, however, in the young lady's case above referred to, was an opportunity never presented to me before. So I had the intermaxillary projection macerated with care, and found the slender neck bent upon itself. The bone or bones were thickened somewhat, as if there had been a fracture. The symphysis between the bones had closed by bone, an early period for this, and probably caused by the exalted action subsequent to the bending or breaking action. But the state and position of the teeth chiefly interested me, as I had for the first time ocular proof of what I had long conjectured, and considered a serious objection to this mode of preserving the intermaxillary bones. I doubted the wisdom of thrusting this wedge between the side portions of the jaws, and placing the part so much in the horizontal plane as to make the front surface the under one. Moreover, I fancied that probably the most desired object of this plan, viz., that of preserving the teeth, would so place them that, in the event of their acquiring to even tolerable development, they would grow horizontally backwards instead of downwards, as in the usual direction. Before I removed this intermaxillary process, I could feel the margin of the left front incisor, as if it were coming in this fashion; and, on macerating the specimen, I found such to be the case. Here is a sketch of the specimen, of normal size. It is placed in the line of the alveoli as it was in

Sketch showing Intermaxillary Portion, with Teeth Horizontal.

life. The right, which had not yet come through the gum, besides having its horizontal direction, has its margin where the flat surface should be; and the left, whose edge had protruded, is nearly parallel with the horizontal palate plates of the upper jaw, instead of being at right angles with the roof of the mouth. This specimen I believe to be as unique as were those, now preserved in the museum of the Royal College of Surgeons, when they were first depicted in some of the early editions of my work on *Surgery*, about thirty years ago, and displayed at the College of Surgeons, where I gave lectures on the Progress of Surgery in the Nineteenth Century, in 1864.*

But I fear those matters may appear too minute, and possibly trifling, to those who read them; yet they are of palpable value to the practical surgeon, and this comparatively substantial aspect may possibly prove refreshing to some who feel themselves bound to read up to the day about organisms, anatomies, and atomies which seems so transcendental and subtle as to reach beyond ordinary comprehension and demonstration.

The object of this paper is more with reference to cleft palate than hare-lip. To some it may appear that the latter is a worn out subject, but I believe there are many to whom cleft palate is still an abstruse subject, and for further elucidation I venture to continue the theme which formed the principal feature of the communication in 1874, above referred to. At that date, my experience of the operation for the defect extending to between two and three hundred cases, had led me to the conclusion that operative interference with cleft in the hard palate was rarely followed by satisfactory results. I had resorted to most of the plans familiarly known, likely to prove successful, and was occasionally much pleased, but failures were so frequent that in many instances I made no attempt to close such gaps at all, and was content if I got fair union in the greater extent of the soft velum. The subject had long engaged my attention in every aspect I could think of, and at last I resolved to adopt a plan which in my estimation held out the greatest chance of success. This plan consisted mainly in dividing the hard palate about midway between the margin of the fissure and the alveoli, with a sharp chisel, so as to set a portion of the hard palate on each side free, thereafter paring the edges and uniting them in the middle line by means of stitches. Particulars of the operation were given in the paper in the BRITISH MEDICAL JOURNAL, already referred to, and in the concluding remarks I ventured to say that I had touched new ground in surgery. In this, however, I soon found that I was mistaken, for my friend Mr. Hulke, of the Middlesex Hospital, within a few days pointed out to me that Diesffenbach, more than forty years ago, had made a proposition of the kind. The subject was further made public by my friend Mr. Mac Cormac of St. Thomas's Hospital, in a

* See *Lancet*, 1864; also *Lectures on the Progress of Surgery during the Nineteenth Century*. Churchill.

communication to this JOURNAL, of date June 20th, 1874, and I found that I had been in a manner anticipated in what I had considered an original idea. In several of my first trials of this process on the living body, I carried the threads through the holes or slits made by the chisel, but I found that on drawing the noose there was great tendency to bring the palatal mucous surfaces of the flaps into apposition instead of the pared edges; in other words, to throw the two flaps into a vertical position in the roof of the mouth. Here I fancied that I had hit on a remedy for this also, which was to bore one or two holes, according to the size of the flaps, through which I could pass the needles and threads, and so approximate the pared margins without upsetting the horizontal position of the flaps. This plan answered my expectations, but here again I found that the original record of the great German surgeon had anticipated what I had found in practice. Dieffenbach had also suggested these punctures. It seems doubtful whether or not this operation had been done by Dieffenbach; and it is curious that no trace on the subject is to be found in any English surgical writings on cleft palate during the last forty-five years. I myself had not met with any suggestion in regard to division of bone until my attention was called to it by my two friends above referred to. Within the last thirty years much has been said and written by Mason Warren, myself, and others regarding cutting and tearing the soft parts from the hard, and bringing them down in hope of getting union in the middle line, but the proposal with the chisel seems to have been overlooked or ignored by all who have worked at the subject. I shall, however, be well content to have followed in the wake of Dieffenbach, whose proposal to divide the internal rectus of the eyeball for ordinary strabismus gave me the key to my own practice of dividing the levatores palati in ordinary cases of cleft palate.

I shall now proceed to give the results of my experience in regard to the supposed addition to the operation in certain cases of cleft palate, which I described in this JOURNAL of date April 4th, 1874.

(To be continued.)

CLINICAL LECTURE ON WINTER PRURIGO.

By JONATHAN HUTCHINSON, F.R.C.S.,

Senior Surgeon to the London Hospital, and to the Blackfriars Hospital for Skin-Diseases; Surgeon to Moorfields Ophthalmic Hospital.

GENTLEMEN,—I wish to describe to you this evening a certain group of well marked cases in which the skin is made irritable by cold. A man who has gone about through the summer with his skin quite comfortable finds himself, as soon as the first threatenings of winter weather occur, troubled by irritation in various parts, often of a very severe character. Year after year, the same thing happens, until he begins to expect his tormentor, or possibly has learnt how to anticipate and prevent it. This form of prurigo usually affects first and most severely certain special parts: the calves of the legs, the out-sides of the thigh, the forearms, and the outer parts of the upper arms. It usually attacks the trunk last, and but slightly. It is not, in the first instance, attended by any eruption, but only by a general tendency to *cutis anserina*. If, however, the sufferer give way to the temptation to scratch, he will be able to find certain isolated points which itch intolerably; and on these, after use of the nails, little pimples appear. Sometimes I have been told that these points felt like little seeds in the skin, which it was absolutely necessary to dig up with the nail. These are the true prurigo-papules, and possibly are developed in connection with nerve-papillæ. In addition to them, there is often more or less tendency to roughening of the surface by lichen-spots (thickened orifices of hair-sacs). Ultimately, in bad cases, the skin becomes rough and harsh, and there are seen a number of little blood-stained crusts; but in a majority of cases, in comparison with the patient's loudness of complaint, there is surprisingly little to be found. Now and then, patches of eczema are produced, or a porrigo or ecthyma rash may result. Perhaps I shall, however, best convey a good idea of the malady, or rather of the liability, by relating to you some cases; and I will select first a mild one.

W. T. aged 45, is a London collector in good health, but thin and rather bilious. He has all his life suffered from that kind of feeble circu-

lation which allows the extremities to become very cold. He never has chilblains or chaps; but his hands and feet are usually dry, somewhat shrivelled, and very cold. His feet, he says, are often icy. He scarcely ever perspires, and can take vigorous exercise with much pleasure and advantage. In boyhood, he did not ail anything from his skin; and it was, indeed, not until about fifteen years ago that he first began to suffer. He then, in winter weather, found the calves of his legs very irritable, and affected by spots which were aggravated by scratching. Afterwards, his thighs, in their outer and posterior parts, became affected; and then it spread in greater or less degree to the entire surface. From that time to the present, he has suffered with varying degrees of severity every winter. He assures me that in summer he is perfectly well, but he dreads the first advent of cold weather. It is not always the coldest weather which makes him worst; for, if it be cold, dry, and clear, without wind, he does not suffer so much. Wind and draught are his chief enemies, and they make his skin creep and itch all over. He has been obliged to adopt all sorts of precautions to diminish the influence of cold; wears washleather next his skin and woollen over it, and high Wellington boots for the protection of his calves. He sleeps between blankets, fearing lest the cold sheets might induce the prurigo and keep him awake. By these expedients, he keeps himself in a state of tolerable comfort, and has usually very little to show on his skin. When seen in March 1873, we noted that there were a few scattered black blood-crusts, but no papules, and no long excoriations from scratching. The same was the state of things in December 1875. During the intervening summers, he had been perfectly well. I must ask you to keep in mind, as to this patient, who is a good example of the class which affords the subjects of winter-prurigo, that he is thin, chilly, bilious, and has a feeble circulation. With the exception of advising the use of a tar-wash to all affected parts, I was unable to do more than counsel, in the way of precaution, sedulous attention to the class of expellents which he was already in the habit of using. He had previously consulted several specialists, but with no definite result. It was clearly a case for management, rather than for drugs.

The severe and lifelong form of prurigo described by Hebra, and for which he has claimed the name to the exclusion of all others, has the peculiarity of being made worse by cold. It is not impossible but that the severe Vienna winters, and the biting character of the winds to which the Austrian capital is liable, may account for the apparent fact that prurigo assumes there features much more formidable than those which attach to it in London. In another lecture, I shall show that we do not in English practice meet with many cases which fit well with Hebra's descriptions. Our chronic cases either are made better by winter, or, if the reverse, have not begun in childhood; two points which are amongst the more distinctive features of Hebra's disease. In this instance, you will see that the man, now forty-five, began to suffer for the first time in his life at the age of thirty. Nor have his sufferings from the disease ever in the least approached Hebra's description; nor, although his tendency still persists, does there seem reason to apprehend its increase.

The case which I will next read to you corresponds very closely to the Vienna type, except in its minor degree of severity.

Prurigo in an Old Man more or less since Childhood: the Eruption aggravated by Cold.—James Colebrook, aged 66, was under care at the Hospital for Skin-Diseases for a year and a half in 1872-73, on account of prurigo of varying severity. The parts affected were the sides of the neck and insides of the thighs, with a few spots at times on the fore-arms. The eruption was not copious at any time while under observation. At one time, there was an eczematous patch above the ear. On inquiring as to the duration of his malady, he told us that from early life he had had an irritable skin. In boyhood, he often used to scratch the insides of his thighs till they bled, and also frequently suffered from what he thought was nettle-rash; the latter form of eruption he used to attribute to bites of fleas, gnats, etc. He never could bear flannel next his skin. His prurigo had always been worse in winter than summer, and was worst of all during one winter that he spent in Quebec, where the cold was intense. With regard to time of day, he stated that his itching was generally worst just after getting up in the morning. In respect to treatment, he said he had once derived some benefit while under medical care in Belgium. He had often suspected that he had lice, and had looked for them repeatedly without success; and there seemed no reason for suspecting their presence while he was under care. He said that bugs did not annoy him particularly. It seemed probable that he had transmitted an irritable condition of skin to some of his children, for two of them were said to have had bad "scald-heads" at the age of two or three years. The treatment used for this old man did not have much effect on his very troublesome

skin-disease. Temporary improvement was followed by fresh crops of papules; and at his last visit in October 1873, it is noted that a fresh outbreak had occurred. I have not been able to learn anything about him since then. It is probable that the prurigo on the thighs was aggravated, and to some extent kept up, by the presence of large varicose veins in that part; but this condition had not been present until long after his disease had become established. The treatment was much varied, the most constant element being the lotio sulphuris, which was continued throughout the greater part of the time. The tar-lotion was tried for a short time, but apparently did not suit, as it was soon changed again for the sulphur.

Winter-prurigo in its milder forms is, I suspect, a very common affection; and not a few who read this lecture will probably, from personal experience, be able to confirm my description of it. It is not, however, very often that it rises to such a degree of severity as to induce its subject to seek medical advice. In certain cases, it acquires a very troublesome complication in a tendency to eczema, as well as in liability to irritation, not only from cold, but from the very measures likely to prevent its influence. When a prurigo-patient is unable to wear flannel on account of the aggravation caused, and unable to come near a fire for fear of exciting eczema, his case becomes very difficult to manage. Such a case is at present under my observation. The gentleman who is its subject tells me that in boyhood he suffered from somewhat irritable skin, and that he well recollects having the popliteal spaces cracked and sore every winter. He believes, however, that this was caused rather by standing with his back to the fire, than by cold. His mother had psoriasis, and at least one brother suffered severely from eczema; whilst several of his children have had slight forms of the latter. He is himself, like the subject of my first narrative, thin, bilious, of feeble circulation, and liable to suffer much from cold extremities. In boyhood, the change from summer to winter clothing always annoyed his skin, but it was not till middle life that the cold itself began to cause prurigo. For the last five winters, he has been liable, with the first onset of cold, to prurigo on the legs and some other parts, and with gradually increasing severity; and during the last two he has been obliged to keep at a distance from fires, on account of the smarting and tendency to eczema which fire-heat always causes. Formerly, he used to roast himself with impunity. Being engaged in avocations which compel him to mix much with the poor and dirty, he has once at least had scabies, and on several occasions been temporarily troubled by lice. Although these have always been quickly got rid of, yet they have occasioned extreme irritation; and he believes that these accidents have had their effect in augmenting the permanent irritability of his skin. He is always quite well in summer, with the exception that now and then, in consequence, apparently, of excessive perspiration, he has had eczema between the nates and on the inner sides of the thighs. There appears reason to fear that, in his case, both the eczematous and the pruriginous liabilities are likely to increase, and that the utmost care will be requisite to prevent his becoming severely affected. Washing with the tar-lotion, applications of boracic acid ointment, and the use of abundant warm clothing (from the irritation of which the skin is protected by silk or some soft material), seem to be the most helpful measures.

I have been careful to mention to you all the little details of the symptoms and supposed causes at work in these cases, because it is only by the correct appreciation of these that we can in any degree understand them. Winter-prurigo is not so much a disease as a liability. It is by a susceptibility to annoyance from slight and common sources of cutaneous irritation, which do not hurt the majority, that its sufferers are characterised; and it is by obviating these that we must hope to cure them. As to the efficiency of any internal remedies, I really have nothing that I can say with any confidence. Several of my patients have thought themselves better whilst taking arsenic; but, as one of those who spoke most definitely on this point afterwards told me that the homœopathic "*arsenicum*" suited him yet better than my prescription, I felt obliged to distrust his evidence. Let me insist that the utmost care is necessary in accepting conclusions on this point; for the disease varies with every change of wind, and may sometimes disappear spontaneously when mild weather suddenly succeeds to cold. As regards tonics and dietetic measures, I have but to say that the more you can invigorate your patient, and especially the more you can fatten him, the less will he suffer from cold and the prurigo which it induces.*

* Since this lecture was in the printer's hands, I have been informed by my friend Dr. Hilton Fagge that Dr. Dühring of New York has carefully described the same malady. I have not had time yet to seek Dr. Dühring's paper; and prefer, with this acknowledgment of his priority, to leave my statements just as they had been written. He has proposed for it, I believe, the term winter-pruritus, or pruritus hyemalis.

ABSTRACT OF NOTES OF A CASE OF REMOVAL OF THE ENTIRE OF THE RIGHT PARIETAL AND HALF THE FRONTAL BONE.*

By JOHN R. HAYES, M.D., Tralee, co. Kerry.

On the night of May 24th, 1874, Mrs. S., aged 32, was found insensible, lying on her right side, with her face and head on the hearth, in which there had been a turf fire, then nearly extinguished. How long she had lain there no one could tell. She had been seen under the influence of drink about seven o'clock P.M. She is supposed to have sat on a low seat near the fire, and to have fallen off insensible. She was found in the above-mentioned position about eleven o'clock, when I was called to see her.

I found her unconscious, with a quick weak pulse, about 120. The upper and centre parts of the right cheek were of a yellowish grey colour, and quite callous; both eyelids of the same side were reddened and vesicated. The eschar extended upwards between the ear and eye, involving the parietal and frontal bones. The integument was charred, the bone appearing without any covering to an extent of an inch square; half the forehead was also covered with an eschar; and the entire scalp from before backwards was extensively burned. Part over the parietal bone remained adherent; posteriorly there was a charred surface extending to the lambdoid suture. I cleaned off the ashes which covered the injured parts, removing the hair; administered a stimulant, and had the burned parts dressed with Carron oil. During this time she remained unconscious.

The following morning, consciousness had returned. I found her greatly depressed, the pulse quick, but small and weak; she was free from pain. I renewed the stimulants cautiously. About the third day, reaction set in, and the pain increasing rendered her sleepless. I gave occasional doses of opium, allaying the pain. Gradually she became calmer, and the stimulants were omitted.

In about ten days the inflammatory symptoms subsided, her appetite improved, and the pain entirely left her. Her pulse was 80. A slough appeared all round the edges of the eschar. I had this dressed with carbolic oil. The discharge decreased, and the vesicated parts began to cicatrise.

In about sixteen days, she suddenly became delirious, with nausea and occasional vomiting. Paralysis set in on the left side, the arm and leg only being affected; the face was not engaged. The pulse became weak and quick. She could take no food, but was able to

Fig. 1.—Appearance after removal of bone.

retain her drinks. These symptoms slowly passed off, in about ten days her strength returned, and her appetite improved.

On July 1st, about five weeks after the receipt of the injury, the upper part of the ear had sloughed away; the vesicated portions were

* Read before the South of Ireland Branch.

nearly cicatrised. A line extended round the entire lateral portion of the scalp, from the mastoid portion of the temporal bone to the posterior angle of the parietal, and upwards along the lambdoid suture, from the inner angle of the superciliary ridge of the frontal, outwards to the external angle; the centre within this line continued quite hard and immovable. Not knowing how long she might continue in that state, and having no one to nurse her, I recommended her to go into hospital. She became dissatisfied in the County Infirmary, and left it in about a fortnight. I saw her some time afterwards, on August 1st, when a part of the frontal bone, about two inches square, was exposed. The bones were slightly movable, as if they had separated at the sagittal suture. The eschar on the cheek had separated. The eyelids were contracted, the conjunctiva everted, dragging the eye outwards. Her general health appeared good; she was able to take plenty of nourishment. To counteract the foetid odour, I applied a lotion of carbolic acid. She continued going about doing her household duties; and I did not again see her until she sent for me on October 1st. She complained "that the bones of her head were falling off". I found the right parietal and half the frontal separated from those of the opposite side, to the extent of about an inch, and slightly movable. I did not like to interfere with them then, fearing some serious result; but on October 3rd, the bones having separated a little more, I removed the whole parietal and half the frontal. The inner surface was covered with

Fig. 2.—Portion of bone removed: outer surface.

a thick curdy matter, and the depressions for arteries, etc., obliterated; the surface of the dura mater was covered with florid granulations, and a quantity of foetid pus came away. I could neither see nor feel any pulsation in the meningeal arteries. On making slight pressure on each side of the head, a quantity of pus welled up from between the

Fig. 3.—Portion of bone removed: inner surface.

hemispheres. She felt no inconvenience, neither headache, nor any other cerebral symptoms. Her appetite continued good; she said "she could eat a pound of chop for dinner, and take two pints of porter in a day". I washed the surface with a weak carbolic acid lotion, after which I applied water dressing, and kept it covered with gutta-percha paper, in lieu of oiled silk, which gave the surface a clean healthy granular appearance. In ten days, I changed it for zinc dressing, which I still continue to use. It was slowly healing from the margins; no pus escaped now from the situation of the superior longitudinal sinus; it was healed over to the extent of three quarters of an inch in width. The surface occasionally bled from the slightest touch. She complained of pain and soreness through the eye, but none in the head.

On December 2nd, I grafted skin on the surface of the granulation on four different places; three became attached, the other fell off.

Only once since writing the above notes (December 7th, 1874) did she have any symptoms of an urgent nature, when she became feverish, vomited, and was slightly delirious (December 9th, 1874). These symptoms, however, quickly subsided; and, from that date to the present, she has continued in good health. I exhibited the patient at the South of Ireland Branch of the British Medical Association on January 9th, 1875, when she accurately described her state from the time she recovered consciousness after the injury, and did not appear in the least to have suffered from any mental impairment. She then remained in Cork, at the Ophthalmic Hospital, under Dr. H. M. Jones's care, for about three weeks, during which time she enjoyed excellent health. It was while in the hospital that the photograph (Fig. 1) was taken. On the day I write this postscript to the case (April 13th, 1875), she is quite well. The new skin has grown nearly over the entire of the exposed surface. It was astonishing how successfully the grafting acted in this instance. She goes about at her ordinary duties, complaining of no pain or any ill effects from the terrible accident. I am not aware that any case has ever been put on record in which recovery took place, when, from any cause, such complete destruction of the cranial bones and extensive exposure of the brain has ensued.

A CASE OF DIABETES INSIPIDUS TREATED BY (1) JABORANDI AND (2) ERGOT.

By SYDNEY RINGER, M.D., F.R.C.P.,

Professor of Materia Medica in University College, and Physician to University College Hospital.

THIS was a well marked case of this disease. The patient was for some time under the care of my friend Mr. William Murrell, who has kindly supplied me with the following notes.

William S., aged 38, has been under occasional observation since May 1874. The intermittent nature of his treatment was owing to the fact that he resided some miles from town. Notes of his condition were taken at every visit. It would be tedious to give the notes in full, and a classification of the chief points has, therefore, been attempted. The patient's own expressions have in most instances been used in the description of his symptoms. Respecting his paternal grandparents, the patient knew nothing. His maternal grandfather died at the age of 82 of consumption. He used to spit up a "good quantity" of blood every morning. The patient remembered him well, and had often seen the blood in his chamber utensil when he washed it out. His maternal grandmother was always very healthy, and lived to the age of 92. The patient did not think that either of his mother's parents passed an unusual quantity of urine. The patient's mother was subject to cough, with expectoration. When from 40 to 41 years of age, she commenced passing large quantities of urine. The patient was sure that she habitually passed more than he had ever done. He did not think that she passed urine quite so frequently as he did; but she used to make more at a time. This lasted about four years, when she died. She never received any treatment, and the patient could not say whether her urine contained any sugar or not. The patient's father died, aged 60, from a "bad leg". He never suffered in any way from his urine.

The patient was the eldest of a family of seven, four girls and three boys. He was apparently not very clear as to their relative position as regards age, but remembers each individual perfectly. His eldest brother was now about 30, and, for the last three years, he had spat blood in considerable quantities. He was formerly in the army, but was discharged on account of bad health. He was described as being a "drunken beggar"; but was not known to suffer in any way with his urine. His youngest brother was "taken bad" when he was about 21. He had a cough, and spat a good deal of blood, and was said by the doctor to be in a decline. He only lasted six months or so, and was quite a skeleton when he died. The patient had three sisters living who were said to be well and strong. They had no cough, did not spit blood, and did not pass an unusually large quantity of urine. The youngest sister died when she was about 20. About two years before her death, she began passing large quantities of urine, often a pint or more at a time. The ordinary chamber-utensil "was not a bit of good to her", and she was always obliged to have a big pail kept in her room. She had a nasty cough, but the patient thought she never spat any blood. Respecting his cousins, the patient could not say much; two or three of them on his mother's side died of "decline", but were not known to have suffered from diabetes.

Place of Birth.—The patient was born at Aberdeen. His

was a soldier, and they were constantly changing their quarters, so that the patient never remained long at any one place.

He was a private gardener, and had always lived in good families. He could not say that he had ever been particularly overworked.

Habits.—He had lived well; rather better, he supposed, than most people. He had been a strong healthy man, accustomed to boxing, wrestling, and active out door exercise. He had never been a drinker; had, in fact, always been rather careful in what he took in the way of stimulants, seldom exceeding a pint of half-and-half in the day.

Temperament. He was of a strikingly lively temperament. It was rare to see him "out of sorts"; even when he knew that he was steadily progressing downwards, he exhibited no despondency.

Social Condition.—He had been married fourteen years. He had had seven children; they were all living with the exception of one which died from whooping-cough. The youngest, a girl, had been born since the patient had suffered from diabetes, and was now four months old. When six or seven weeks old, she began passing large quantities of urine—"twice as much as she ought to"—but this condition, after lasting seven weeks, passed off, much to the relief of the parents. The other children suffered from wheezing on the chest, but not in any way from their urine.

Previous Illnesses.—The patient had measles and scarlet fever when a child, and small-pox when about 13. He had no recollection of any blow or fall upon the head or abdomen.

Mode of Origin.—About Christmas 1873, the patient was told to go after a carriage, and give the occupants some money which had been accidentally forgotten. He ran as hard as he could for four miles before he came up with them. He was, he says, dripping wet, and the perspiration was "regularly running off him". Before he had time to get cool, he was asked to drive a pony-chaise home, a distance of six miles. It was a bitterly cold day, with a nasty east wind blowing, and, before he had gone far, he felt all of a shiver. He was so bad that he had to pull up and get some ginger brandy; but that had no effect, and he kept on "in a regular tremble" all the way home. For a fortnight after this, he "felt very queer"; had no appetite; could hardly keep about, and was always very drowsy and sleepy. At the expiration of that fortnight, his excessive thirst commenced. He drank then more than he has ever done since. He used to drink "a good gallon in from two to three drinks". For the first three days, he passed hardly any urine; but, on the morning of the fourth day, he awoke with a strong desire to urinate, and got up and passed "the best part of a pot full". From that time to this, he had passed large quantities of urine. Four or five months later, he suffered from cough, and for the first time spat blood, on one occasion nearly half a pint. In about ten months from the commencement of his illness, he noticed that he was losing flesh. His weight had always been about 9 st. 2 lb.; but, in a few months, he had lost nearly two stones. About a year later, his appetite fell off considerably. The excessive dryness of the skin had troubled him from the time he commenced passing the large quantities of urine.

A detailed description of the patient's symptoms will now be given.

Urine.—The quantity of urine passed in the twenty-four hours when not under active treatment varied from nine to twenty-two pints. The average quantity passed during five days in May 1874, when he was under constant supervision, was twelve pints five ounces; the largest quantity being fifteen pints, and the smallest nine pints five ounces. About a year later, the patient was habitually passing twenty-two pints in the twenty-four hours. He usually passed urine two or three times during the hour, and was on this account unable to go to church or to any place of amusement. It may be mentioned that the diagnosis of the case was first made by observing that the patient had a slop-pail under his bed, in addition to two ordinary chamber utensils.

Characters.—The urine was examined at frequent intervals, but varied little in its characters. It was usually of a light straw colour, clear, with no deposit; odourless, very faintly acid, and of a specific gravity ranging from 1,002 to 1,005. It contained no albumen and no sugar. It decomposed very rapidly, and became extremely offensive after standing for even a short time. An estimation of the urea showed that it contained, on an average, about $\frac{1}{4}$ per cent.

Thirst.—This was one of the patient's most distressing symptoms. During the first year of his illness, he used generally to drink about six quarts of water in the day, in addition to tea and coffee. He had drunk as much as twenty-two quarts in the twenty-four hours. He had measured it on several occasions when this had been the quantity. He seldom drank less than a quart at a time. He went out as much as possible, to "keep away from the water". He generally kept a little pebble in his mouth to check the sensation of thirst. His sufferings when he was unable to get water were very great. He said he should never forget one day, when he was left alone in the house without any-

thing to drink. He was laid up at the time, and too weak to get about. For about an hour, he was pretty comfortable, but then became very thirsty. He bore his thirst as well as he could, hoping that some one would come to him; but it finally became so intolerable, that he suddenly caught up his chamber-utensil and took a long deep draught of his urine. During the day, he drank the urine he passed seven times. It was at last so salt, that it hardly quenched his thirst at all.

Appetite.—The appetite was extremely poor. The patient often went for days together without touching meat. Whilst under treatment in a hospital, he had so little appetite that he obtained permission to stay in his ward during the dinner hour, instead of going to table with the other patients. On one occasion on which he was seen, he stated that he had had nothing to eat but half a halfpenny biscuit for four days. He had money in his pocket, and could get anything he wanted in the way of food; but "he had no appetite, and could not eat anything".

Bowels.—The patient was usually a week or more without having a motion, and had sometimes gone from a month to six weeks. The feces were extremely hard, and were passed with the greatest difficulty. There was occasionally a little blood in the motions.

Skin.—The skin was very dry, with the exception of the feet. The patient said he could walk as fast as he liked, even in the hottest day in summer, without perspiring about the body. The feet, however, were constantly damp, and the secretion from them was so exceedingly offensive, that he had to change his socks two or three times a day. The feet itched very much, and were often "almost raw". He was never troubled with the dryness of skin or offensive secretion from the feet before this illness. For the last two years, he had suffered greatly from boils at the back of the neck "each spring and fall". With this exception, he had had no cutaneous eruption. The patient's hair was always "very dry and crisp".

Pain.—The patient had not suffered much pain during his illness. He had at times complained of pains in the legs and loins; but these had usually been of short duration.

Cold.—He was always cold. As soon as he got away from the fire, he came over all of a shake.

Loss of Flesh.—As already stated, the patient very rapidly lost flesh, and in a few months was reduced from 9 st. to 7 st.

Cough.—The cough had never been a prominent symptom. It had troubled him chiefly in winter, and was seldom accompanied by much expectoration.

Hæmoptysis occurred on some half a dozen occasions, but never whilst he was actually under observation. It was stated to have been once about half a pint, but was ordinarily, judging from the patient's description, from three to four ounces.

Physical Examination.—There was nothing very striking in the patient's appearance; nothing, at all events, which would excite a suspicion of the disease from which he was suffering. A physical examination of his chest showed nothing abnormal. The temperature was taken in the mouth and rectum and under the tongue; but there was no fever.

Previous Treatment.—The patient had had a great deal of general treatment—quinine, cod-liver oil, etc.—without deriving any benefit.

Treatment by Ergot.—The ergot was first tried in June 1874. The dose was twenty minims of the liquid extract taken in water three times a day. In a fortnight, the urine was reduced from fifteen to eight and a half pints, and in six weeks to between six and seven pints. The medicine was then discontinued, but the urine passed did not exceed seven pints daily for four months. It then increased in quantity; in January, it had returned to the old amount. The ergot was given for the second time in July 1875, the dose being on that occasion fifteen minims of the liquid extract every three hours. In a fortnight, the urine fell from twenty-two to twelve pints. The thirst was less troublesome, and the patient said "the medicine had made a good two quarts difference in his drink". The appetite was improved, and the patient was able to get about better. The bowels were opened more frequently, and the motions were softer. The medicine was discontinued in consequence of his admission into the hospital.

On the publication by Dr. Laycock of two cases of diabetes insipidus successfully treated by jaborandi, Mr. Murrell sent this patient into University College Hospital, that we might test this drug.

The man was very thin. His thirst was most distressing. He would drink three to four pints of water at a time. His skin was very dry, except his feet, which, strange to say, perspired profusely, enough to annoy and trouble him. He was easily tired. His mouth was generally distressingly dry. In other respects, he was fairly well, and no disease could be detected in any of his organs. His temperature varied between 98 and 99 Fahr. His appetite was bad; his bowels obstinately confined; his sexual powers were not diminished. We kept him some days without any treatment. He

was then put on infusion of jaborandi (one drachm to six ounces), and this treatment was continued for forty-four days. The dose was from time to time increased till he took several times daily a dose enough to produce in healthy people very profuse perspiration and salivation. As will be seen, the jaborandi had no effect on the quantity of urine; but his mouth was moister and more comfortable, and, though the jaborandi never produced copious perspiration, it kept the skin comfortable, and, after exercise or eating, or hot drinks, he perspired rather freely. The sweating of the feet soon ceased after taking jaborandi. The medicine did not make him spit. After it had been clearly proved that the jaborandi was useless, he was put on ergot for the third time with considerable success. The results of the treatment will be seen in the following table.

Date.	Quantity of urine in litres.	Treatment.	Date.	Quantity of urine in litres.*	Treatment.
Aug. 12	9.0600		Aug. 30	10.0600	
" 13	10.0600		" 31	10.0500	Four drachms every 3 hours.
" 14	8.0500		Sept. 1	11	Five drachms every 3 hours.
" 15	11.0		" 2	10.0500	Six drachms every 3 hours.
" 16	10.0250		" 3	11	Five drachms every 3 hours.

" 19	11.600		" 6	10	One ounce every 3 hours.
" 20	11		" 7	11	
" 21	10.0100	Two drachms of iofusion of jaborandi every 4 hrs.	" 8	10	
" 22	11		" 9	10.0500	
" 23	10.0600	To be given every 3 hours.	" 10	11	
" 24	10.0250		" 11	11	
" 25	11		" 12	10.0500	
" 26	10.0600	Three drachms every 3 hours.	" 13	11.0500	One ounce every 2 hours.
" 27	10.0600				
" 28	11.0250				
" 29	11.0600				

From the 14th to the 30th inclusive, the amount varied between 10.0500 and 9.0250

Oct. 1	10	One ounce and a half every 2 hrs.	Oct. 16	6.0300	
" 2	11		" 17	6.0600	
" 3	11		" 18	6.0500	
" 4	11		" 19	5.0800	
" 5	11	Ergot begun.—30 minims of liquid extract of ergot every 3 hours.	" 20	6.0200	
" 6	12.0800		" 21	6.0200	
" 7	12		" 22	5.0900	
" 8	11.0800		" 23	5.0700	
" 9	11.0500		" 24	5.0400	
" 10	11.0500		" 25	3.0500	
" 11	11		" 26	2.0800	
" 12	7.0900		" 27	1.0600	
" 13	7.0700		" 28	1.0100	
" 14	6.0500		" 29	0.0700	He left the hospital, and the ergot was discontinued. He came as an outpatient in a week. The urine had not increased.
" 15	6.0400		" 30		

When he was in the hospital, the urine was free from albumen or sugar. The specific gravity varied between 1000 and 1006; but as the quantity became less, it rose to 1017.

It will be seen from the foregoing notes that this well marked case of diabetes insipidus was uninfluenced by jaborandi, whilst on three occasions the quantity of urine was very greatly reduced by ergot.

CHLOROFORM AND ANÆSTHESIA.

By JOHN SMITH, M.D., F.R.C.S.E.,
Surgeon-Dentist to the Queen for Scotland.

SINCE the publication of Dr. Lauder Brunton's communication, in which he alludes to the administration of chloroform in insufficient quantity as a cause of danger, some attention seems to have been drawn to the subject in respect to this and other points.

I wish to make a few additional remarks on the matter; and that I am so far qualified to do so, will perhaps be admitted from the fact of an experience in the use of chloroform ever since its introduction in 1847, and a practical acquaintance with it, more or less, in every variety of case in which it ever has been given—over and above that of between three and four thousand times administering it in my own department of surgery. I trust my making such a statement may not be set down to any other motive than to show that I do not speak without sufficient data to entitle me in a certain measure to do so.

First of all, I entirely agree with Dr. Lauder Brunton's views regarding the degree of anæsthesia required for operating safely. In a

communication read by me before the Medico-Chirurgical Society here ten years ago, and published in the *Edinburgh Medical Journal* for 1866, I make the following remarks, which will be seen closely to coincide with those of Dr. Brunton.

"In all cases, anæsthesia, to be either satisfactory or safe, should be complete. I have repeatedly noticed patients, who have had chloroform on different occasions for such operations as came under my own department, express themselves as much less uneasy after a full dose—much less exhausted; and I may mention my own personal experience of this agent to bear out such a statement. So far it is more satisfactory; but it is also more safe. We know that one of the benefits of anæsthesia is the prevention of shock during an operation. We know also that shock tends to interfere with the heart's contractions, by the influence of the cerebro-spinal system on the cardiac ganglia through the par vagum. And this tendency does not always depend on the magnitude or importance of the operation. The operation may be a minor one, and the suffering inflicted very slight. The patient may be unconscious of pain, and yet the heart may, through the ganglionic system, be affected by the operation, and syncope result. . . . There can be no reasonable doubt that, of two patients equally under chloroform, if one be operated on in any way worthy of the term, and the other not, although neither has actually experienced pain, yet the one wakens up in a very different condition from the other: the one has suffered more or less from shock, the other has not."

In the same paper, allusion is made to the fact of the sudden diminution of the heart's action, on the operation being commenced, even during the state of anæsthesia. This I have myself frequently remarked even in tooth-extraction, and the fact has been over and over again observed in the greater operations. It is this tendency to sudden syncope which indicates the necessity for all operations being, if possible, performed with the patient in the recumbent position. In my lectures at Surgeons' Hall here in 1854 and subsequent years, and in the *Handbook of Dental Surgery* published as my class-book, this was, so far as I am aware, inculcated for the first time as applied to dental surgery; while, again, in the paper I am now quoting, I find it stated that "syncope during anæsthesia, as at all other times, is most apt to occur when the patient is in the upright or semi-upright position; and it need scarcely be here said that, in order to diminish the chances of a complication so serious, the horizontal posture should in all cases be the one adopted during the exhibition of chloroform. Such, however, is far from being the position generally chosen for minor operations. The preponderance in these operations of death associated with chloroform is, no doubt, attributable in a great measure to a contrary practice, it being very generally considered not worth while in such cases to make a patient lie down."

With regard to the subject of death from the administration of chloroform, much has been stated calculated to create a very unfair prejudice against it. No agent possessing such power of abrogating sensation can possibly be free from a certain amount of risk in its employment. Thus much, therefore, is to be understood as admitted in speaking of chloroform. But a great deal beyond this has been attempted to be made out. Every death now occurring during an operation in which chloroform has been given is set down to its effect, and sensational paragraphs too often appear in our daily press spreading such ill-authenticated reports. In fact, no deaths under such circumstances are now-a-days attributed to "shock" and other causes which used, before the days of anæsthesia, to be set forth in explanation of such cases, which, by the way, were far more numerous than they now are. But these cases, although fewer, still do occur; and that chloroform is unwarrantably blamed in them is, I fear, equally true.

Dr. Brunton mentions a case where chloroform was to have been given, and in which the patient suddenly died during the operation without its use. As I happened to have been present on that occasion, I may mention that the non-administration of the anæsthetic was not due to the bottle being broken, but to Professor Simpson, who was to have administered the chloroform, not arriving in time. Here the patient died on the first incision being made through the skin over the hernial sac. Shortly before this, again, Dr. John Argyll Robertson here had met with a similar case—strangled hernia—where the patient died while the groin was being shaved, and where no anæsthetic had been given. And, since the introduction and general use of chloroform, did time and space permit, many such cases could be cited where circumstances rendered the administration of any anæsthetic impossible. Even in tooth-extraction, this has occurred; and Mr. Holmes mentions the case of a patient whom the dentist found dead in the chair on returning from a side table, where he had been selecting the instrument to be used. There is very little doubt that, had chloroform been employed

* A litre is = 35½ fluid ounces.

in these cases, it would have been subject to strong suspicion, if not to actual blame, as the cause of death.

Lastly, there is an important point connected with the numerous alleged deaths from chloroform which seems to be overlooked or set aside, as undeserving of notice; and that is the extreme discrepancy prevailing in the account of *post mortem* appearances. In the case of any other poison producing death, we find certain specific and uniform indications of its peculiar toxic action; whereas in those ascribed to chloroform the *post mortem* appearances range from those presented by death from syncope, on the one hand, to those produced by asphyxia, or those of the very opposite characters to syncope, on the other; arguing it to be extremely probable that one or other of them was during, and not owing to, anaesthesia from this agent. I will add a single other quotation on this topic from the paper to which I have so largely ventured to refer. It is as follows.

"In the fifty cases collected by the late Dr. Snow, the condition of the heart was very various. In nearly twenty, it was either gorged or tolerably filled with blood. In others, it was empty, but stained with blood, showing that probably it had been emptied only at the *post mortem* examination. Dr. Berend of Hanover details, among others, ten cases, in all of which the heart was empty, flaccid, collapsed, and doubled upon itself. In other cases from time to time recorded, the heart was firmly contracted. In many it was diseased, and in not a few the cause of death was found in some other organ altogether, such as the spinal cord. Again, the opinions as to the mode of death are not less various. Dr. Silson, in 1848, attributed the fatal result to death of the heart; Dr. Snow, to what he termed cardiac syncope; Dr. Black, to asphyxia; Caspar, to neuro-paralysis; Sansom, to both syncope and asphyxia, etc. A conflicting mass of evidence, from which it appears impossible to derive any other conclusion than that the deaths described were due to no one cause, but had been produced in a manner widely different, according to the circumstances of the case."

A word here may be said regarding nitrous oxide as an anæsthetic. Although in the daily use of this agent, I fear that we can scarcely yet place it in comparison with chloroform, allowing that its mode of action were similar, which is very doubtful. The limited sphere of its application in medicine and surgery, the condition of patients under its influence, and some of its possible bad effects not being immediate, but more likely to show themselves at an after date, preclude its being used as anything like a fair standard by which to judge of chloroform. It is an excellent, an invaluable agent in its own place; but neither in medicine nor surgery is it ever likely to supersede such anæsthetics as ether or chloroform. In fact, if such were attempted, it seems very doubtful whether its present small rate of mortality would not increase in rather a startling manner; while its efficiency as a substitute would be found at fault in many ways.

CASE OF ACUTE POISONING WITH CHLORAL-HYDRATE.

By DAVID YOUNG, M.D., Florence.

A FEW days ago, I was called to see a gentleman who had just recovered from an attack of delirium tremens. He was feeble looking and nervous, and wished me to prescribe for persistent sleeplessness. For many months previously, he had taken chloral-hydrate in doses of twenty-five grains, with excellent results; but, since his last attack, the medicine had failed to act as before. I suggested a slight increase of the dose, and ordered the following mixture.

R Chloral hydrat. ℥ij; glycerini ℥ij; syrupi ℥ss; aquæ q. s., ad ℥iv. Misc.

A sixth part to be taken at bedtime, and half a dose more in two hours, if necessary. I was hastily summoned in the night; and, when I reached the hotel, found the patient in a deep stupor, the breathing slow and difficult, and the surface of the body, especially the extremities, very cold. In reply to my question if he had taken the medicine as ordered, his wife told me that he had come home about three hours before, and had apparently been drinking. He said, just before he went to bed, "I will now take the doctor's draught", and poured out, as she thought, one dose. Shortly after taking it, he became very restless, complained of being breathless, and of severe cramps in the legs. On attempting to get up for a drink of seltzer water, he staggered and fell on the floor. His wife became alarmed; and, after lifting him up, discovered that the bottle which had contained the chloral was empty; he had taken the whole—180 grains.

I was immediately sent for; and, on arriving, found him as above

stated. Acting on the suggestions given by my friend Dr. Lauder Brunton for the treatment of this accident, I ordered blankets and hot bottles to be procured at once. In the brief interval which elapsed before they were got ready, I noticed the following points in the condition of the patient. His breathing was slow and difficult; respirations 11 in the minute. Pulse 76, feeble and irregular. The temperature in the axilla was 35.6 deg. C. (96.08 Fahr.). The first sound of the heart was indistinct, and its action feeble. The eyelids were opened with difficulty. The conjunctiva was deeply injected, and the pupil firmly contracted. The surface of the body was very cold.

The lower limbs were wrapped in warm flannel, and hot bottles applied to different parts of the body; and a gutta-percha water-bag was filled with hot water, and laid over the cardiac region, and the patient carefully covered with blankets. The effects of the warmth were decided, and soon apparent. The temperature slowly rose, the breathing improved, and the heart regained its power. Half a teaspoonful of Darby's extract of meat, with a teaspoonful of brandy in a small cupful of hot water, was now ordered to be given every two hours.

Six hours after the application of the warmth, and nine after the taking of the chloral, the patient's condition was noted as under. Breathing was tranquil; respirations 16 per minute. The heart-sounds were distinct; its action was somewhat tumultuous. Pulse 92, full and soft. The pupil was contracted. The conjunctiva was injected, and he complained of muscular pains in the arms and legs. The patient continued in a state of great drowsiness for fifteen hours. He was easily roused, but immediately went off again to sleep.

In two days, he was quite well. I have no doubt that the effect of the application of the warmth, in this case, was to prevent another being added to the list of those whose death has been caused by chloral injudiciously taken.

A NOTE ON ANGINA LUDOVICI.

By F. MURCHISON, M.A., M.B. Edin.,
Assistant-Physician to the Crichton Royal Institution, Dumfries, N.B.

Two years ago, during my residence as medical officer in Harris, in the Hebrides, some cases of what I now believe to have been the *Angina Ludovici*, occurred among the natives of the island. The disease was different in its symptoms and peculiarities from any throat-affection that either my experience or reading had brought under my notice. I vainly tried to diagnose the malady, and as vainly read whatever medical literature of the past and present I had access to; but I could find nothing, having a name, similar to it. It attacked children and young persons of various ages. The youngest patient under my care might have been three years of age; the oldest was not certainly over thirty. The symptoms were uniformly of the same type, save that they were modified according to the diathesis and idiosyncrasy of the individual invaded. As a rule, the older the patients, the more intense were the sufferings, and the better developed were the throat-tumours that occasioned them. It is worthy of mention that the anæmic, pale, and pasty fair-haired, suffered in the proportion of six to one of the plethoric and healthy-looking; and that the disease among the latter did not occasion the prostration which it did among the former. Indeed, the cases among the absolutely robust were so few and far between, that I was induced—in the absence of a more plausible one—to adopt the theory that the sickness was one of the numerous manifestations of a scrofulous habit of body, incited into activity by the prevalence of very cold weather, insufficient clothing, want of cleanliness, and inappropriate food. All the cases were purely idiopathic, and independent of any local lesion. They all occurred in winter, and in close succession; but they were not confined to one isolated locality. One island seemed to favour the growth and development of the affection more than any other situation; but the six cases that occurred in it seemed to have arisen independently of infection for their origin, and rather to have commenced in an unhealthy locality, destitute of proper sanitary arrangements. No two cases occurred in the same family, although isolation of the sick from the healthy was not enforced; so that I am induced to believe that the disease was occasioned by climatic and insanitary influences rather than by contagion.

The disease began with a chill, a stiffness of the muscles that move the tongue and throat, a feeling of general *malaise*, discomfort and prostration, loss of appetite, and, in a word, with the feelings that are frequently the precursors of the specific fevers—symptoms which preceded the development of the disease in every instance. This incipient stage was followed by another of much distress and discomfort to the patient. The vicinity of the submaxillary gland, the gland itself, and

the entire floor of the mouth, became the seat of a hard swelling that seriously interfered with the functions of mastication, deglutition, and respiration. From this centre, the disease gradually extended, till, in its course, it involved the parotid and thyroid glands in the morbid action. The mouth was left half open; the voice became much modified, either existing only as a whisper, or being altogether inaudible. The patient was a spectacle of real suffering, and, in some instances, feverish and delirious. His countenance bore the expression of intense anxiety. The saliva dribbled from the mouth, which performed its functions imperfectly or not at all, according to the severity of the case. It was impossible for the sufferer to move his lower jaw without great pain. The entire constitution became involved. The bowels were constipated, the urine scanty and high-coloured, the tongue furred and enlarged from sharing in the contiguous inflammatory action. The local tumour became gradually harder, and imparted the sensation of a board. It pressed the tongue upwards, so that there was scarcely any passage left open to feed the patient, who now lived entirely on slops and stimulants. This state of matters continued for a varying period, which never exceeded twelve days, and terribly exhausted the patient, who passed day and night sleepless, and in despair of relief from pain so insupportable. The tumour was now much larger, but its colour was not characteristic, and differed little from that of the parts in their healthy state. In a short time, redness and, in the worst cases, lividity marked the seat of the inflammation, and the whole throat bulged out as if an immense goitre had attacked the neck. Some of the cases ended in resolution; others in the formation and discharge of pus; but none in gangrene nor in death. Such as were subjected to early treatment got on best, and ended most frequently in resolution; but, in each case, a marked hardness, which proved intractable to every remedy, save time and iodine, remained.

The treatment I adopted was very simple. The bowels were relieved by a saline draught; while the strength of the patient, who was not allowed to leave his bed, was kept up by stimulants administered at stated intervals in a diluted form, as well as by slops and chicken-broth. The local treatment consisted of fomentations and poultices made with a drachm or two of tincture of opium superadded. When fluctuation pointed out the necessity of making an incision, I resorted to the knife to get rid of the pus. This treatment was adopted with few variations, in every case with the best results; and, when convalescence fairly set in, the patient went on uninterruptedly from good to better, till every trace of the disease disappeared.

OBSTETRIC MEMORANDA.

ON THE VALUE OF NITRIC ACID IN THE TREATMENT OF DISEASES OF THE NECK OF THE WOMB.

I FULLY endorse Dr. Braithwaite's recommendation of the use of nitric acid in affections of the cervix uteri. He seems, however, to have overlooked the fact that this agent had been previously recommended by others in such cases. Had he referred to my *Lectures on Diseases peculiar to Women*, he would have found (page 84, 3rd edition) that I say "brushing the part lightly over with nitric acid may (if the unhealthy condition of the mucous membrane does not extend very high) be sufficient"; and again, pp. 154-5: "My usual treatment has been to apply the strong nitric acid freely to the whole interior of the cervical canal." Dr. Braithwaite is, therefore, mistaken in supposing that the value of nitric acid in affections of the cervix uteri has been overlooked.

LOMBE ATTHILL, M.D., Master of the Rotunda Hospital, Dublin.

I AM happy in being able to add my testimony to that of Drs. Braithwaite and Churchill, the result of considerable experience, as to the value of nitric acid as an uterine caustic, which I have found especially useful in cases of chronic endocervicitis, induration and intractable abrasions about the neck of the uterus; and its value appears to have been greatly enhanced, in many cases, by previous depletion of the part affected. Lately, I have been in the habit of applying the anhydrous nitric acid, which, from its rapid effects upon the tissues, occasions little or no pain; and I find a piece of porous ordinary fire-wood, cut to the requisite size and shape, a convenient method of application.

R. GREENHALGH, M.D., Physician-Accoucheur to and Lecturer on the Diseases of Women, etc., at St. Bartholomew's Hospital, etc.

MY desire for brevity in the paper kindly read for me at Edinburgh by Mr. Cullingworth, as I infer from Dr. Tilt's criticisms, has unfortunately led to some ambiguity. It was not my intention to recommend the use of nitric acid as a caustic in all cases of disease of the neck of the womb requiring such an application; the expression used was "generally, but not invariably, the most suitable". Nor did I aim at embracing the whole subject of treatment of the disease in question; but only at pointing out the superiority of nitric acid in cases of "ulceration or erosion of the os and cervix uteri" and "endocervicitis". But I expressly stated that, "if the canal be not open, the case is not one suitable for this treatment". This disposes of Dr. Tilt's objection to the use of nitric acid in comparatively recent cases of endocervicitis. I did not intend to recommend it; for in these cases, the canal is not open. Dr. Tilt again demurs to my "recommendation to leave the patient without examination for a month, unless the os uteri be patulous, and the calibre of the cervical canal such as to render its contraction rather an advantage than otherwise". But this sentence (the words are Dr. Tilt's) does not correctly state my views. For "unless", read "provided that", and it would be correct; but the meaning of the sentence is reversed.

I quite see the value of the classification of cervical diseases requiring a caustic given by Dr. Tilt; and our want of accord as to the treatment is more apparent than real. In his first class—recent cases of endocervicitis—I did not recommend its use. His third class is more strictly inflammatory hypertrophy of the cervix, with hard and fissured lips. These cases, Dr. Tilt regards as originally inflammation of the mucous membrane spreading to the surrounding tissues; and this view naturally leads him to classify them with endocervicitis. On the other hand, I do not so regard them; but believe them to arise from direct injury to the structure of the parts, generally from crushing or laceration during delivery, either by the head of the child or the finger of the accoucheur. Nothing conduces more to this than the practice of rupturing the membranes before the os has attained its full size, especially if it be thick and fleshy. Whatever the origin of these cases, I quite agree with Dr. Tilt as to the value of potassa cum calce in their treatment; but I have certainly, in some cases, been able to avoid the use of that remedy by a free application of nitric acid to the eroded surfaces of the everted lips. But, in a bad case, I should precede this by the use of potassa cum calce, and then after a time use the nitric acid, with the view of producing a healing surface. A sore resulting from the application of potass has little healing power; it is pale and watery in appearance. To sum up, I should use nitric acid in all cases of erosion or ulceration of the os uteri, and in all cases of inflammation or ulceration of the cervix in which the canal is open. I should not use nitric acid in any case in which the canal is closed; and in cases of great induration and hypertrophy of the lips, its use should be preceded by that of potassa cum calce. I cannot admit that it produces more pain than nitrate of silver, nor that it has "an ugly tendency to run"; for there should never be enough on the cotton-wool to do so. Nor can I admit that there is much analogy between the action of nitrate of silver in morbid conditions of the fauces and in the cases in question. A tannin gargle is often very efficacious in the former, but it would be quite useless as a lotion in the latter. The reason is that, from the capillary vessels of the womb running perpendicularly to the surface, there is a strong tendency for the whole thickness of the structures to become implicated; whereas, in the case of the fauces, the vessels run in the mucous membrane, and are amenable to the action of astringents, such as nitrate of silver and tannin. No doubt much of the inefficacy of nitrate of silver as a caustic is from the film of chloride preventing its deeper action. Next to nitric acid in value, I should place nitrate of mercury. Nitric acid, in the words of Dr. Churchill, "does just what we want, and no more". It is a clean and handy remedy in the possession of every medical man in country places, and all are familiar with its action in other diseases; but its great recommendation is that the frequent use of the speculum can, by its aid, be avoided; and nothing, to my mind, is so repulsive in the treatment of these diseases.

JAMES BRAITHWAITE, M.D. Lond., Lecturer on Diseases of Women and Children at the Leeds School of Medicine.

PUERPERAL STATISTICS.

As a small contribution to puerperal statistics from private practice, I beg to send the following for publication. Out of 216 consecutive cases which I have attended and noted down, I find the following; forceps used once in 14, breech once in 36, footling, hand with head, hands and feet, arm, each once; *post partum* hæmorrhage 1 in 54; retained placenta once. I have lost no mother, although several have suffered from considerable fever with tenderness in the abdomen, etc.,

beginning about the third day after confinement, and continuing in some cases for three weeks.

J. HADDON, M.A., M.D., Monk's Hall, Eccles.

THE DIMENSIONS OF A MULTIPAROUS UTERUS.

THE Whitechapel murder will, for some time to come, cause much thought to the medical jurist. Any evidence which can be brought to bear upon the several medico-legal questions involved in it must be of value.

Dr. Meadows questions the opinions of Messrs. Bond and Larkin as to whether the uterus in this case had ever been gravid. I find, in Beck's *Medical Jurisprudence* (5th edition, 1836), at page 161, article "Delivery", a foot-note taken from Velpeau's *Midwifery*, p. 61, in which that distinguished physician gives the dimensions of the womb after several pregnancies. I place side by side with it those given by Mr. Larkin as found in the womb of the supposed Harriet Louisa Lane.

VELPEAU.	LARKIN.
Total length..... 2½ to 3 ins.	Extreme length..... 3 inches.
" of neck..... 1½ to 1½ ins.	Width of neck (upper part)..... 1½ "
" of body..... 2 ins.	" (lower part)..... 1½ "
Breadth of neck..... 18 lines.	" at fundus..... 2½ "
Thickness of neck..... 8 to 10 lines.	Thickness of walls..... ⅝ of an in.
" of uterine walls..... 6 lines.	Cavity:—length..... 2½ inches.
Weight..... 1½ to 2 ozs.	" breadth between Fallopian tubes } 1¼ inches.
	" breadth of centre..... 1 inch.
	" breadth of lower orifice..... ½ an in.
	Thickness of cervix..... ⅜ of an in.
	Width of cervix..... ⅜ of an in.
	Weight of uterus..... 12 drachms.

A line is 1-12th part of an inch.

After a careful comparison of these two tables, we find how closely they correspond in all the principal measurements, and bear out the opinion expressed by Messrs. Bond and Larkin. Let us take, for instance, the following :

VELPEAU.	LARKIN.
Length..... 2½ to 3 inches. 3 inches.
Breadth of neck..... 18 lines (1½ inches)..... 1½ inches. 1½ inches.
Thickness of walls..... 6 lines (½ an inch)..... ⅝ of an inch. ⅝ of an inch.
Thickness of neck..... 8 to 10 lines..... ⅝ of an inch. ⅝ of an inch.
Weight..... 1½ to 2 ounces..... 12 drachms. 12 drachms.

With regard to the womb retaining its preservation, and being of a bright red colour, long after the other organs have decomposed, many months after death, Casper gives several cases in vol. i, pp. 52, 53, 54.

H. C. STEWART, F.R.C.S., etc.

THERAPEUTIC MEMORANDA.

ASCITES SPEEDILY CURED BY THE RESIN OF COPAIBA.

GEORGE B., aged 38, recently came under my care in Guy's Hospital. He was admitted with ascites and slight anasarca of the leg on October 13th, and was discharged on October 21st. On October 14th, he was ordered the *mistura resinæ copaibæ*, but did not commence it on that day. On October 15th, the amount of urine passed was found to be 3 pints. On October 16th, it was a little more than 6 pints. On October 17th, it was a little over 8 pints, and the dropsy was fast disappearing. On October 18th, it was 6½ pints, and the swelling of the abdomen much less. On October 19th, the urine passed was 7½ pints; the ascites was considerably diminished. On October 20th, the urine was 7 pints. On October 21st, he left the hospital, as the dropsy was nearly gone. The rapid disappearance of the dropsy, combined with the increased flow of urine, was very striking.

It is now more than two years since I first suggested the use of the *simple resin of copaiba* as a diuretic, and my further experience of it has more than confirmed my early opinion of its great value. I believe that, with the exception of digitalis, it is a far better diuretic than any which is at present found in the *Pharmacopœia*. The old objection to the use of the ordinary *copaiba* is entirely got rid of by making use of the simple resin after the removal of the nauseous oil. The formula of the Guy's dispensary is as follows: *Copaibæ resinæ* ʒj; *sp. rectificat* ʒiiss; *spir. chloroformi* ʒj; *syrup. zingiber.* ʒss; *macilaginis acaciæ* ʒj. *aq. ad* ʒvj. A sixth part three times a day. It is, however, a troublesome mixture to compound; and Mr. Probyn (Hooper, Grosvenor Street) informs me that it is necessary to triturate the dry resin thoroughly in a mortar; and then, by adding the gum, an emulsion can easily be made. The mixture is not nauseous, and should have scarcely an odour of *copaiba*. The remedy has now been so long in use, that its efficacy is undoubted both in hepatic and cardiac dropsy. It is more especially in the former case that its great value has been

seen; although, in some of the worst examples of dropsy arising from heart-disease, where the ordinary remedies have failed, its diuretic effect has been equally striking. In the case of a private patient, when the well-known pill of digitalis, squill, and mercury had ceased to be beneficial, the *copaiba*, taken in doses of fifteen grains (made into pills) three times a day, removed all the dropsical fluid in a few days.

There is this excellent property of the drug, that, if it act on the kidney at all, it acts at once. The first or second dose displays its diuretic effect; and, should this not be the case, there is no use in persisting in it, as it is not a medicinal remedy in the strict sense of the term.

Copaiba has long been known as a remedy in bronchitis, and in inflammations of the bladder and urinary passages. It is most probable that the oil is the ingredient which acts beneficially on the mucous membrane of the bronchial tubes and other organs. In the case of gonorrhœa, the mixture made of the ordinary balsam appears to be most efficacious, for therein we have the diuretic properties of the resin combined with the more specific ones of the oil.

It remains to be seen whether other resins might be substituted for that of *copaiba*. I have tried common resin or rosin without success.

SAMUEL WILKS, M.D., F.R.S., Physician to Guy's Hospital.

CLINICAL MEMORANDA.

DETECTION OF ALCOHOL IN URINE.

I WOULD call attention to the fallacy of the bichromate of potassium and sulphuric acid-test for the detection of alcohol in the urine, as recommended in several works on the science and practice of medicine, and originally proposed by the late Dr. Anstie. The test may certainly be used for the detection of alcohol in urine, but not by simply heating a little of the test fluid with the urine. The fallacy consists in the reduction of the bichromate into a green oxide of chromium, not by alcohol singly, but by reducing agents present in the urine of persons who are even total abstainers from alcoholic liquids. But the test is still of use to detect the recent introduction of any considerable amount of spirit into the system by distilling the urine, and applying the test in the usual manner to the distillate, if any considerable, but doubtful, amount have been recently taken. The characteristic green colour of the reduced oxide of chromium will be produced by the alcohol acting as a reducing agent; but this reaction will not be obtained in similarly treating the urine of an abstainer.

F. CRESSWELL HILWETT, Southampton.

CHLOROFORM IN DENTAL EXTRACTION.

THE value of Dr. Lauder Brunton's paper on the Cause of Death during the Administration of Chloroform cannot, I think, be over-estimated. It goes far to explain the fact for which it has hitherto been difficult to account, that the proportion of deaths during the administration of this anæsthetic is greater in England, where small doses are given, and apparently greater precautions used, than in Scotland, where, following the original practice of the late Sir James Simpson, it is given fearlessly and in large unmeasured doses.

There is undoubtedly some truth in Dr. Brunton's belief that comparatively few of the deaths occurring during the administration of chloroform are directly the result of its use. It would be interesting to know, in statistics of operations in the Edinburgh Infirmary, whether the proportion of deaths during operation—*i. e.*, on the table—has been greater or less since the introduction of chloroform. For practical purposes, it may be said, death from chloroform-poisoning is caused by either syncope or asphyxia, the latter probably being more common. Excluding the reflex causes, of which Dr. Brunton endeavours to prove the existence, death always appears to begin either at the heart or lungs. Chloroform, after having abolished consciousness and motor power, then paralyzes the medulla oblongata. The respiratory, as well as the cardiac and vaso-motor centres, are very near one another, and closely connected in the medulla. Any agent applied through the medium of the blood to the medulla must act on all these centres simultaneously; yet how does it happen that in so many cases the respiration stops before the heart's action? Doubtless, because the heart, by virtue of its own inherent nervous arrangements, is so far independent of the nervous centre. If Dr. Brunton's reflex theory turn out correct, it comes to be a question whether, in the absence of some reflex cause, the heart's action is ever likely to stop before the respiration. Many practical questions hinge on this, and I sincerely trust a point so important may be definitely settled by the labours of such painstaking observers as Dr. Lauder Brunton and others.

JAMES CARMICHAEL, M.D., Edinburgh.

REPORTS OF MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN.

CHLOROFORM AND ETHER AS ANÆSTHETICS.

WE have once more thought it our duty to test the prevailing opinion, and to ask for the experience of the leading practitioners engaged in the administration of anæsthetics, as to the relative value and uses of chloroform and ether.

We have now for many years drawn attention to the duty of publishing records of all facts bearing upon the relative mortality from the administration of surgical anæsthetics; and the number of fatal accidents put on record from chloroform in our pages has surprised the most experienced observers; although there is reason to believe that some surgeons and administrators of anæsthetics are still so ill-advised as to conceal their fatal or serious mischances. Our records for a long time have showed an average of one fatal case per month. We have felt bound now, since 1870, to press upon the profession the propriety of giving a full trial to ether, as being, according to a great bulk of evidence, the safer and more reliable anæsthetic. It may be convenient to preface the following reports by a summary of our former conclusions and those of our correspondents in 1870-73. For this purpose, we reprint here an article from the pen of the late Dr. John Murray, containing such a summary, for which we are indebted to the *London Medical Record* of May 7th, 1873.*

"The persistent efforts of the editor of the BRITISH MEDICAL JOURNAL, in advocating increased attention to anæsthesia and the claims of ether, have at length aroused the attention of the profession to the statements made in America and France of this anæsthetic; and, at the present moment, its claims to general recognition are being practically investigated in London and the provinces. The editor of the BRITISH MEDICAL JOURNAL (November 10th, 1872) says that, 'in the face of the great mortality from chloroform, and of the almost deathless record of ether, it has become our duty to interpose, to call the urgent attention of professional men throughout the country to the claims which ether has upon their confidence; and to urge that the anæsthetic which was thrust out of repute by the ready and convenient fluid introduced by Simpson, shall have an extended and a fair trial'.

"It will be well to record some of the recently published opinions on which the present advocacy of ether in this country is mainly based.

"In America, ether has been for twenty-five years generally but not exclusively employed in preference to chloroform. Mr. Ashhurst, one of the leading authorities in America, says (*Principles and Practice of Surgery*, 1871): 'I prefer ether in a very large majority of cases; it is sufficiently convenient for almost every case that the surgeon is called upon to treat.' At the Massachusetts Hospital, a resolution was passed (*Neligan's Medicines*, by Macnamara) to the effect that the exclusive use of ether should be an absolute law of the institution. The Société de Médecine de Lyons have pronounced three times in favour of ether in preference to chloroform. M. Diday (*Gazette Hebdomadaire*, November 29th, 1872), says that chloroform has for a long time been abandoned in Lyons for ether; and that the latter has been found to answer very well, while the patients prefer it. He invites the surgeons of Great Britain to listen to the appeal made to them, and to furnish to the already convincing Lyonese statistics counterproofs which would give them their full value. Dr. J. H. Packard of Boston says (*Boston Medical Journal*, April 12th, 1873) that, until 1864, his custom was to

* Since May 1873, the following communications on this subject are to be found in the pages of the BRITISH MEDICAL JOURNAL. In the second volume for 1873, by Mr. Clover, Mr. McGill, Mr. W. Brown, Dr. Bigelow, and Mr. J. Morgan. That number also contains a report of the discussion on the comparative advantages of ether and chloroform, which took place at the meeting of the British Medical Association in London. In the first volume for 1874, are notices by Mr. Clover, Mr. R. Davy, Dr. J. Carmichael, and Dr. W. Munro; in the second volume for 1874, by Sir J. R. Cormack, Dr. Marion Sims, and Mr. Clover; and in the first volume for this year, by Mr. Clover, Dr. Hoggan, Dr. Fifield, Dr. Skinner, Dr. Schiff, Dr. Blackwood, Mr. S. M. Bradley, Dr. W. Munro, Mr. F. Jordan, and Dr. T. Keith. There are also reports of deaths by anæsthetics in all the above volumes, which are to be found duly tabulated in the index of each under the heads "Anæsthetics," "Chloroform," and "Ether".

employ ether or chloroform indifferently. Now he believes ether to be not only perfectly safe, but wholly satisfactory as an anæsthetic. 'My firm conviction is that, if the profession in England give ether a fair trial as an anæsthetic, they will agree with the majority of the physicians in this country that it is as economical and efficient as its more dangerous rival. We have no right to imperil our patients' lives by the use of an agent which has slain over a thousand persons, if other and safer means are available.' The editor of the *American Quarterly Journal of Medical Sciences*, says that it is surprising that so many surgeons in England should have obstinately persisted in preferring the use of chloroform, notwithstanding the numerous deaths which have followed its use, and the strong array of evidence which has been adduced of the superior safety of ether. Dr. Joy Jeffries of Boston, in a paper which he contributed to the *Boston Medical and Surgical Journal* of October 3rd, 1872, relates his experience of ether inhalation as demonstrated by him in London during the meeting of the Ophthalmological Congress, and says that he 'foresaw the day when our English brethren would awaken to the danger of chloroform and safety of ether'. The editor of the *Boston Medical Journal*, October 3rd, 1872, commenting on Dr. Jeffries' paper, maintains that, in the legitimate use of ether by inhalation, no *bonâ fide* case of death is on record, or ever has taken place, and that it is absolutely safe. He asserts that the complaints against ether made by English operators, that it produces insufficient relaxation of the muscular system and but partial insensibility, can only be explained by want of knowledge.

"Dr. Thomas Jones (BRITISH MEDICAL JOURNAL, November 23rd, 1872), after very long experience in ether and chloroform inhalation, thoroughly believes in the superior claims of ether as an anæsthetic; and is quite sure that, if fairly tried, ether will soon replace chloroform in this country as the anæsthetic in general use. Mr. Thomas Green of Bristol (*Ibid.*, December 7th, 1872) feels so convinced as to the superiority of ether that nothing shall ever again induce him to give chloroform. Dr. William Alexander (*Ibid.*, December 14th) thinks that, by the late ventilation of the subject, ether has been restored to its pristine position. Mr. Frank Underhill (*Ibid.*, November 9th, 1872) is persuaded that the advantages which our American brethren assert ether to possess are fully proved by facts; and he believes the time to be close at hand when chloroform, except on special occasions, will be considered a thing of the past, and that the advantages of ether will be every day more conclusively demonstrated. Dr. J. Morgan of Dublin (*Ibid.*, October 12th, 1872) has used it all ages, from three to seventy-one years, from amputation to the most delicate operations on the eye; and ether has proved itself both most convenient and efficient, while it has been proved to be the safest of all anæsthetic agents. The arguments which have been urged against its use have been those only of its being inconvenient, and these have arisen from want of a perfect means of application."

The information contained in the following reports is principally given under four heads, and has been elicited in order to ascertain the following points. 1. What anæsthetics are now in use; and for what cases is either anæsthetic preferred? 2. What methods of administration are employed? 3. Has any change been made within the last four or five years in the anæsthetic used, or its mode of administration? and, if so, what were the reasons for the change? 4. Can any suggestions be made by the adoption of which the safety of the anæsthetised patient might be more completely secured, or any improvement in the production of anæsthesia for surgical operations be effected?

ST. BARTHOLOMEW'S HOSPITAL.—Mr. Joseph Mills (Chloroformist to the Hospital) reports as follows. The anæsthetics now in use at St. Bartholomew's Hospital are ether, chloroform, and nitrous oxide gas; ether preceded by nitrous oxide gas is used in by far the greater number of cases. Chloroform is used for very young children, and in operations about the mouth and nose which are likely to last some time. Nitrous oxide gas is employed for short operations, such as extraction of a tooth or opening an abscess. Nitrous oxide gas and ether are administered by means of Mr. Clover's apparatus, which is admirably adapted for the purpose. Chloroform is given on lint, from a drop-bottle. Until January 1875, chloroform was used for nearly all cases; but I found that, while chloroform frequently depresses the heart's action in long operations, ether stimulates it. It rarely happens that there is any persistent sickness after the inhalation of ether; I have met with but one instance in nearly nine hundred administrations, and in that case it lasted about twelve hours, at the expiration of which time the patient was able to take food well. Ether does not appear to be much less likely to cause vomiting at the time of the operation than

chloroform, but it certainly causes much less after-sickness. Chloroform is used in long operations about the mouth and nose, because : 1. The narcosis of chloroform lasts longer than that of ether ; 2. In many operations, as for cleft palate or removal of the tongue, it is necessary to keep a gag in the mouth, which comes very much in the way of a face-piece, such as is necessary for the administration of ether ; while chloroform can very conveniently be given on a piece of lint ; 3. In operations for cleft palate, too, there is another objection to the use of ether, in the fact that it excites a flow of viscid saliva, and is apt to induce coughing. In delicate operations about the eye, I prefer chloroform, as it causes less congestion. In cases of fracture which require an anæsthetic whilst the parts are being placed in apposition during the time the muscles are relaxed, chloroform is preferable, because patients recover from its effects quietly, the inhalation of ether being generally followed by a state of noisy delirium and struggling, which would be likely to displace the fractured ends and necessitate their readjustment.

GUY'S HOSPITAL.—Mr. Frederic Durham (Surgical Registrar to the Hospital) replies to the queries as follows.—1. In the surgical wards and surgery of Guy's Hospital, chloroform is the anæsthetic which is almost invariably administered ; occasionally only, the mixture of alcohol, ether, and chloroform, as recommended by the Committee of the Royal Medical Chirurgical Society, and, more rarely still, ether alone. In some cases, anæsthesia first produced by chloroform, is continued by "the mixture" or by ether alone ; this especially in cases in which chloroform does not appear to be well borne.—2. Chloroform is given from a piece of lint, fitted into a metal nose-piece for convenience sake alone, a few drops being poured from a stoppered bottle as often as required. The mixture is generally given on flannel, adapted as the loose lining of a cylindrical paste-board or leather inhaler ; and ether on a sponge at the bottom of a deep cylindrical leather inhaler fitting closely round the mouth.—3. During the last four or five years, all the anæsthetics, old and new, ether, chloroform, nitrous oxide, bichloride of methylene, the mixture of alcohol, chloroform, and ether, etc., have been used to a very considerable extent at Guy's ; but, chloroform being found much the most convenient in administration, and, as a rule, well borne in surgical operations, and much less frequently followed by the disagreeable after-effects—headache, vomiting, etc.—which were observed to be especially severe and prolonged in the case of ether, it has again become the anæsthetic in common use. In the eye wards, however, "the mixture" is still generally administered.

Mr. Bader (Ophthalmic Surgeon to the Hospital) sends the following replies. 1. For the last two years, I have been using as an anæsthetic a mixture of alcohol one part, chloroform two parts, ether three parts. This mixture I have been using in all cases, both private and in the hospital.—2. It is given in a card-board cylinder, covered with flannel.—3. I have changed the anæsthetic, because I wished to make an experiment.—4. In many cases where the least sign of danger appears, we put from six to ten drops of the nitrite of amyl on a piece of lint, place it on the patient's nose and mouth, with the instantaneous effect of restoring the action of the heart and lungs.

LONDON HOSPITAL.—Mr. Lewis Mackenzie (late resident medical officer) sends the following replies. 1. The anæsthetic chiefly employed at the London Hospital is ether ; it was introduced into this hospital in the early part of the year 1872, and has since been used in by very far the majority of cases requiring the production of complete anæsthesia. Some surgeons make exception to ether in certain cases. Mr. Jonathan Hutchinson prefers the use of chloroform in old people with rigid or brittle arteries, as he considers the arterial tension produced by ether a condition very likely to give rise to cerebral hæmorrhage. It will be remembered that Mr. Hutchinson reported a case of this nature when ether was recently reintroduced. Chloroform is more used in the maternity department than any other of this hospital ; but, in obstetric operations, ether has been chiefly given. Whilst resident accoucheur, I repeatedly used chloroform, and to the full surgical extent in cases of obstructive and operative midwifery. There never seemed any danger ; and one has such a powerful reflex stimulus always ready to be acted upon in this class of cases, that it is very rare to hear of any death from chloroform-administration during labour. In a severe case of *post partum* hæmorrhage, ether seemed to improve circulation, and did not increase the bleeding. In cases requiring the application of the actual cautery about the face, the patient is generally placed under the influence of ether, and anæsthesia is kept up by the use of chloroform. In the eye department, in a few cases, ether has seemed to produce so much venous congestion of the eyeball and orbit that, in some of them (notably cataracts in plethoric old people), chloroform is here preferred. In the dental department of this hospital, nitrous oxide

gas has been very freely given, and with great success ; but the writer is acquainted with one case in which the inhalation of this gas for tooth-extraction was followed by a very painful, intermittent, and irritable action of the heart, extending over a period of one year and more ; and, again, of another in which auditory vertigo and tinnitus followed the use of this gas, and remained for some months without any cause being discovered by aurists to explain the symptom. Bichloride of methylene was used for a short time in our ophthalmic department, but was abandoned in consequence of its acquiring a bad reputation in other hospitals.—2. It has been the invariable rule at the London Hospital to have as little apparatus in the administration of anæsthetics as possible : this rule has been maintained because so many gentlemen have to give these agents that it was thought more desirable they should not have each to overcome the difficulties of the various forms of inhalers, etc. ; but should rely on their own judgment and knowledge, and watch for symptoms of danger unfettered. Ether is administered in cones, made with new stiff towels, with sponges in them. Chloroform is always given with a simple Skinner's inhaler ; nitrous oxide gas is given with the usual apparatus ; and when bichloride of methylene was given, it was measured from a drop-bottle on lint. I may mention that it has never been the custom at this hospital to measure the amount of chloroform used. I need hardly add that ether is not measured in quantity before administration ; several leathern inhalers have been tried with the ether, but the towel, in form of a cone, seems still most popular.—3. A great revolution in the administration of anæsthetics took place in this hospital in 1872 ; at that time, ether became almost universally substituted for chloroform. Since the introduction of ether, the hospital has not contained any case in which death has resulted from its use nor during its administration. Cases of death have occurred whilst patients have been under the influence of chloroform ; but none of these could in any sense be classed under the head of "death from chloroform" ; they were such cases as hernia, in which the patients were moribund when put on the table, and died during the operation : one was a case of an aneurism bursting whilst the patient was under the influence of chloroform for compression-treatment. It would be quite useless to deny that ether was adopted in this hospital, and readily so, in consequence of several deaths having taken place during the preceding few years from chloroform-administration. I myself, as a student, had the good or bad fortune to see three deaths from chloroform ; two of them, however, were from the introduction of vomited matters into the trachea and bronchi. This raises the important question as to whether it is justifiable to give any anæsthetic when a person is in the last stage of an abdominal obstruction or hernia with fecal vomiting, etc. Having witnessed several deaths from suffocation by such vomited matters, I should myself be very loath to administer any anæsthetic to patients in this last stage of abdominal collapse. On *à priori* grounds, ether is a more suitable agent in such cases ; and I personally have never seen death from this cause with ether-administration. It has always appeared to me that, in hospitals, sufficient importance is not paid to the danger of anæsthetics ; fully recognising and believing that there is never any carelessness in the administration of them, I still hold that often the operation is performed without the precautions which experience should guide us to use. An unseemly haste is a common fault ; everyone seems to want the patient to be under the influence in a minute or two ; the operator looks at the chloroformist as much as to say, "When are you going to get the patient under ?" I think, too often, no examination of viscera by any competent physician is made. Chloroform has been given, and a patient operated on who had acute pericarditis (as was proved *post mortem*) ; and it teaches its own lesson. Again, how often has chloroform been given without good light in the patient's face, and with an inefficient assistant, when the delay of only a few minutes could have procured good help and sufficient light, etc. Moreover, when possible, galvanic batteries should be at hand, injections of brandy ready, etc. In the case of chloroform, I should attach great importance to the fasting of the patient for four or five hours previously, and the administration of a small quantity of brandy about half an hour before the operation ; for want of the former precaution, several people have suffocated under chloroform. Thus it appears to me that, if we thoroughly examine our patient's "clinical pathology" (as Dr. Hughlings Jackson calls it), if we employ the anæsthetic we consider safest (which in ninety-nine times out of a hundred is ether) ; if we commence to place our patient under its influence quietly, cautiously, and surrounded by skilled assistants, and such instruments as galvanism at hand, we shall do all that at present lies in our power ; and I very firmly believe that it is only by insisting strongly on the maintenance of these rules, rather than by adding fresh ones to them, that we shall bring the mortality from anæsthetics to its minimum.

[To be continued.]

REVIEWS AND NOTICES.

A TREATISE ON SURGERY: ITS PRINCIPLES AND PRACTICE. By T. HOLMES, M.A. Cantab., Surgeon to St. George's Hospital. London: Smith, Elder, and Co. 1875.

THIS book has been long looked forward to, and, for two reasons, with considerable interest. On the one hand, there has been a natural curiosity to see a work which comes from a writer of such acknowledged repute as Mr. HOLMES; who, by his writings, has proved himself to be familiar with the surgical literature of the past, as well as of the present day. On the other hand, as those who see much of students can abundantly testify, there has been a need of a thoroughly good text-book on surgery. The student now-a-days makes his selection from the following books, viz., Druitt, Fairlie Clarke, Pirrie, Erichsen, or Bryant. Putting aside the first two as insufficient in quantity, whatever their quality may be, the student (we mean one who is not content with a bare minimum) is left with three books; of these, it is scarcely to be expected that he will trust himself for his London examinations to a book written in Aberdeen, though it may present him, as Pirrie undoubtedly does, with some particularly good chapters. We fear due justice will never be done to Mr. Erichsen's book, in spite of its great worth and the special merit of such chapters as those on aneurism, for to many it is undoubtedly heavy reading. Mr. Bryant's book failed signally to supply the want above indicated; partly because it dealt only with the practical side of surgery; partly because, throughout the book, there was evidently a lack of culture and an inability to write correctly, even on subjects on which the writer was authorised to speak. Taking, then, for granted, the want of a thoroughly reliable text-book on surgery, we propose to see how far this is supplied by Mr. Holmes's book.

First, while we believe it to be by far the best surgical text-book that we have, inasmuch as it is the completest, and the one most thoroughly brought up to the knowledge of the present day, we cannot but regret one or two serious shortcomings and blemishes, not only because they detract from the great value of the book, but because they might have been easily prevented. We allude to the shortness with which some important subjects are treated, and to the inferior value of many of the original illustrations, notwithstanding there has evidently been a great expenditure of time and money on them. We are here especially disappointed, for two reasons. Anyone who has read carefully through the *System of Surgery* must have been struck by the articles which are written by surgeons connected with St. George's and Guy's Hospitals, not only because they are amongst the fullest, but also because of the illustrations which they contain. We allude more particularly to the articles by Mr. Pollock and Mr. Holmes, Mr. Birkett, Mr. Durham, and the late Mr. Poland. When Mr. Bryant's *Surgery* appeared, one of its few indisputable merits was the fact of its being well and largely illustrated from drawings and preparations in Guy's Hospital Museum. Mr. Holmes's book is liberally illustrated with several hundred new drawings; but we have no hesitation in saying that a great many of the drawings of specimens are nearly useless; and in this we meet with our second disappointment. Most students will pay some attention to surgery in the wards and in the out-patients' rooms, but the museum shelves are practically never touched. If, in the book before us, the quality of these illustrations had only been equal to their quantity, so many well-selected drawings must have been a great help to the reader; whereas, at present, not a few of them only serve to puzzle him.

The book opens with a short but clear sketch of the chief symptoms of inflammation, and an outline of the changes to which the process is believed to be due; a sketch doubly valuable to the student, as hitherto he has too generally been deterred, by the size of the *System of Surgery*, from seeking in the articles of Simon and Burdon Sanderson the best account that we have of the process as it bears upon surgery. Then follows early an account of the dressing of wounds, in which due attention is paid to the value of that *questio vexata*, antiseptic dressing. The opinion of Mr. Holmes on this subject will be read with great interest. After speaking of the want of agreement on this point, and having alluded to the practice of Dr. Humphry, who prefers uncovered wounds, and to that of Sir W. Fergusson, who, as a rule, relies on water-dressing, Mr. Holmes goes on to say: "I cannot but express my own strong conviction of the value of Mr. Lister's method. I have frequently ascertained, by thermometric and other observations, and pointed out to others, the perfect immunity from traumatic fever which in some cases follows even the gravest injuries

or operations thus treated" (a very striking instance is given); "and though I quite admit that a similar immunity follows after other methods, yet I think that it is more common after the antiseptic system than any other; and on that account I advocate the use of that system, as well as on account of its utility in hospital practice, as necessitating the dressing of important cases by the surgeons and house-surgeons themselves, and almost excluding the possibility of any subsequent inoculation....."

Passing on, we would recommend to the student's notice the account of pyæmia; and we would only remark that it is to be wished that Mr. Holmes had given more importance to this great pest of surgery by giving a fuller account of the cases and conditions in which it is most likely to appear; and if to the mention of bacteria he had added a short account of what bacteria are believed to be.

Before leaving the account of the complications of wounds, we would draw attention to the very helpful thermographs (rather unusual in a treatise on surgery) which are found here; also to Mr. Holmes's advice as to amputation in traumatic gangrene. The greater number of authorities seem now to be in favour of early amputation, though this question will probably not be settled till we know how far the gangrene is due to inflammation arising from the injury, or from some as yet unknown constitutional cause. The account of the treatment of tetanus is interesting, as Mr. Holmes thinks that, in the present condition of our knowledge of this disease, early amputation may be often advisable; for, though irritation may have reached the central organ, yet "this may be capable of recovery if only the peripheral excitement be removed". As to medicines, Mr. Holmes, after condemning the use of certain remedies which tend to constipation, or which are highly poisonous, thinks aconite the most promising.

The chapter on hæmorrhage and wounds of arteries is written, as might be expected, with especial clearness and fulness; the account of the value of carbolised catgut-ligatures is a proof how the book is brought up to date, the way in which torsion and acupressure are spoken of is an instance of the author's candour, while the mention of the "uncipression" of Professor Vanzetti shows the wide scope of his reading. The "foreipression" of M. Vermeil appears to us to be merely an old method under a new name. In the account of transfusion, no mention is made of the saline solution of Dr. Barnes.

In the chapter on fractures, we should take exception to two statements; one in which the author implies that the American method of treating fractured femur by an extending weight has not been successfully introduced into English practice; the other, where he speaks of the operation of refracture of a bone, e.g., the femur, as "a very simple one". In one case which is especially in our mind, where the patient was fully under ether—and the operator, for physical power, might have taken the first place amongst London surgeons—it was only after three prolonged attempts that the bone gave way at the seat of fracture, though it was only three months after the accident.

The chapter on injuries of the head is one of the best. It opens with a warning instance of the danger of touching with the knife sebaceous tumours of the scalp, and an account of the anatomy of this region. In the treatment of scalp-wounds, we are glad to see Mr. Holmes speaking unhesitatingly of the value of sutures. At one time, when we had an extensive opportunity for testing their value, we thought that catgut-sutures were superior to those of silver mentioned by the author. Sufficient prominence does not appear to us to be given to the frequent occurrence of pyæmia after injuries to the head. Pott's "puffy tumour" is fully described, and the question of trephining is gone into. We cannot leave this chapter without drawing attention to the two characteristic thermographs of compression and traumatic encephalitis; and, as an instance of the carefulness with which the book is written, to the directions for finding the middle meningeal artery when it is necessary to apply the trephine over it. At the close of the chapter on injuries to the back, some helpful remarks will be found as to the diagnosis in that now-a-days too common class of cases known as "railway injury".

In the account of injuries of the face, the reader will find an interesting mention of the two views held as to the mechanism of dislocation of the jaw.

In the chapter on injuries of the neck, we come early upon two very inferior illustrations, viz., figs. 64, 65. In his treatment of scalded larynx, Mr. Holmes writes, "some surgeons prefer tracheotomy to laryngotomy.....but the operation of laryngotomy is sufficient". This may be right as far as the œdema goes; but, considering the early age at which this accident usually occurs, surely the size of the parts calls for tracheotomy, or at least laryngo-tracheotomy.

In the account of injuries of the pelvis, we doubt if anyone would recognise fig. 71 as representing the parts taken from a child aged 5. Further on is an interesting account of ruptured bladder, and a novel

suggestion to open the abdomen, sew up the wound in the bladder, and wash out the peritoneal cavity.

Chapters xiv and xv, on injuries of the extremities, are for the most part very comprehensive. The account of dislocation of the thumb, where Mr. Holmes puts forward very clearly Professor Fabbri's view and treatment, and that of the dislocations of the hip, are especially interesting. We regret that two amongst the most important of the above injuries are very briefly treated, *e.g.*, compound dislocation of the knee, and compound fracture of the patella. In the latter case especially, Mr. Holmes might have transferred to his pages the short rules laid down by the late Mr. Poland in his paper in the *Medico-Chirurgical Transactions*, which is only just mentioned in a note. Throughout these chapters, illustrations are profusely given; but this liberality loses much of its value from the defective character of too many of them, such as those of fractured patella, or of the valuable specimen of subastragaloid dislocation.

Chapter xvii, on the other hand, presents some very capital drawings of sections of tumours copied mainly from the Pathological Society's *Transactions*, and, by way of contrast we suppose, such illustrations as figs. 155 and 156.

The account of syphilis, which is very clear, is clinically the best we know. In the chapter on gonorrhœa, we find a short but interesting notice of gonorrhœal or urethral rheumatism; on the other hand, amongst the complications, cystitis is not given; and we are surprised that Mr. Holmes even mentions a very nasty way which some patients have of giving relief to a chordee.

The chapter on aneurism speaks for itself, based as it is on the admirable essay by Sir J. Paget in the *System of Surgery*.

On diseases of the bones, Mr. Holmes writes, as might be expected, *currente calamo*: we have only space to draw attention to the account of osteomyelitis, the peculiarities of the different forms of ulceration, and the advice as to the diagnosis of tumours of bone. Here, as elsewhere, such illustrations as figs. 202, 204, and again 213-216, of caries of the spine, are only blemishes to the book.

What Mr. Holmes says on diseases of joints is very clear, but rather scanty; especially as regards treatment. At p. 442, there is a very interesting note as to the causes of the apparent lengthening or shortening in hip-joint disease; but the reader will look in vain here or elsewhere in this book for a discussion of the merits of excision and amputation respectively.

The chapter on aneurism sustains the reputation of the writer on this subject. Some clear diagrams illustrate the nomenclature used, but the illustrations farther on of ligature of the various arteries, though evidently intended to be as simple and uncomplicated as possible, appear to us insufficient and meagre.

In treating of varicose veins, no mention is made of a method which promises to be useful in these cases. We refer to that brought forward by Mr. Marshall, though previously, we believe, used by Mr. Davies-Coley, tying the dilated vein in two places with catgut ligatures, and removing it antiseptically.

Our space will not permit us to do more than allude most cursorily to the remaining chapters of the book. Having wondered at the illustrations which are allowed to mar the chapter on hernia, which is otherwise well worth studying, the reader comes next to the malformation of the lower bowel. This account is abbreviated from that by the author in the *System of Surgery*. Its value, therefore, needs no comment from us.

The completeness of the book is added to by chapters on the eye and ear. The former, by Mr. Brudenell Carter, is especially clear and comprehensive, and more particularly so on recurrent vascular ulcer of the cornea, glaucoma, and intraocular growths. On the other hand, while the question of a "rheumatic" iritis is practically omitted, we think it a mistake that in a treatise like this on general surgery, no fewer than seven pages should have been taken up by the discussion of squint.

The chapters on the urinary organs are full of interest—Mr. Holmes will excuse us if we point out one or two omissions; thus, there is no adequate account of "surgical kidney", nor of the parts cut through in lithotomy. In the treatment of stricture, there is no mention of that form of perineal section which goes by the name of Cock's operation. Again, in his account of puncture *per rectum*, Mr. Holmes does not appear to be familiar with the proper instruments; thus he speaks "of a long curved trocar and cannula", and of a "loose piece of gum catheter to retain the cannula". Surely the long trocar must be more difficult of manipulation in the rectum than the proper one of about six inches, and the cannula more easily kept *in situ* by the other retaining and expanding cannula than by a gum-catheter. Where removal of the penis is described, there is not a word about the galvanic cautery, nor of Mr. Hilton's modification of this operation by which the urethra is cut long.

The affections of the testis, the breast, and notably those of the thyroid body, are rather briefly treated—all that is said is very clear; but on each of these subjects we should have been glad to have had more from the author, and perhaps we might have done so, if nearly seventeen pages had not been devoted to diseases of the skin.

In the section amputations the reader will find very clear accounts, and many useful hints, though he cannot but be surprised at the admission of such drawings as those which are supposed to represent stumps after amputation at the shoulder and hip, and also by Mr. Teale's method. If, moreover, the large illustrations showing the various incisions, and which must be of very little use, had been omitted, Mr. Holmes would have been able to give his opinion as to the value of amputation through joints, and to make due reference to the papers of Pollock and Stokes.

In the section on excisions will be found by far the best existing account of each operation; but the fact that the author is known to have paid much attention to, and done much for the advancement of, excisions of joints, makes us regret the more that in this book he scarcely gives any directions as to when to perform them, and we have alluded before to the absence of any discussion as to the contrasted value of amputation and excision.

Before taking leave of the book, we must not omit to mention the excellent index, the pleasant type and paper, and, above all, the luxury of marginal references.

While with all respect to the author we have pointed out a few shortcomings, we are sure that this book supplies a longfelt want. Hitherto students have been in the habit of saying, "we do not know what is the best book to read for the College"; or, again, "in beginning to work for the second fellowship, what is the best book to begin with?" They have now a book ready to their hand, though we would not be understood to say that the highest inducement to read it lies in the fact that it is written by one who will probably be for some time an examiner. All who will give this book the careful perusal that it deserves and requires, whether student or practitioner, will agree with us, that from the happy way in which equal justice is done both to the principles and to the practice of surgery, from the care with which its pages are brought up to modern date, from the respect which is all along paid to the opinions of others, it deserves to take the first place amongst our best text-books of surgery.

When a new edition is called for—and the author, from the care which he has bestowed upon this, deserves that this should very soon be the case—we trust that Mr. Holmes will replace many of the illustrations, and amplify some of the sections, to which, considering his justly high repute as a surgeon and a writer on surgery, he has scarcely done justice.

THE SURGEON'S POCKET-BOOK: being an Essay on the best Treatment of Wounded in War. By Surgeon-Major J. H. PORTER, Assistant-Professor of Military Surgery, Army Medical School, Netley. London: Griffin and Co. 1875.

It may be remembered that, on the occasion of the International Exhibition of 1873 at Vienna, the Empress of Germany, after visiting the large collection of objects connected with the transport of wounded soldiers in time of war, and their hospital treatment, exhibited in the Sanitary Pavilion, placed a sum of two thousand thalers in the hands of the Central Committee of the German Societies for aid to wounded soldiers at Berlin, to be offered as a prize for the best practical manual of military surgery. Eventually, Professors von Langenbeck, Billroth, and Socin, were constituted a jury to determine the respective merits of the essays which were sent in by the several competitors for this prize, and their decision was published in October 1874. They considered the worth of three of the essays to be so great as to induce them to recommend a division of the prize among them; and to this recommendation the Empress gave her assent. The three selected prizemen, on the sealed packets containing the names of the authors being opened, were found to be Professor Esmarch of Kiel, Dr. Landsberger of Posen, and Surgeon-Major Porter of Netley. Each author had the right to publish his essay; but, if he did not avail himself of it within six months, the essay became the property of the Central Society of Berlin. Surgeon-Major Porter has availed himself of his right, and the book the title of which stands at the head of these remarks is his treatise to which the prize above mentioned was awarded.

It would be superfluous to discuss the professional merits of this manual, after the decision upon them of three such eminent and competent judges as Professors Langenbeck, Billroth, and Socin. All three are surgeons who not only hold the very highest position in surgical science and practice, but who have had also a very large experience in the special requirements of military surgery. Their report on

the value of the work as a manual of military surgery must, therefore, be accepted as final. We shall confine ourselves to indicating the materials which the work contains, merely premising that they are all laid before the reader in a short and concise form, as is suitable to a "pocket-book"; and that they are copiously interspersed with excellent woodcut illustrations.

After a few general remarks on hygienic regulations, the subject of the conveyance of wounded men from fields of action to the dressing-stations and field-hospitals, is considered, and numerous means of forming extemporary litters, in the absence of regular stretchers, are described. A description is then given of various extemporary appliances to be used as supports for broken limbs; and this is followed by instructions on several modes of forming and applying plaster-of-Paris bandages, and on the uses and manipulation of a variety of surgical apparatus, such as splints of different kinds, irrigating appliances, and others. The modes of examining gun-shot wounds, extracting foreign bodies, and their general treatment, follow. Gunshot wounds of special regions are next described in systematic sequence. Operative surgery succeeds, and the modes of performing amputation in different situations, and excision of joints, are described. Each description in the text has its accompanying explanatory drawing. Hæmorrhage; the operations for tying arteries; the principal complications which are from time to time met with in the hospital treatment of wounded men—viz., local gangrene, bedsores, tetanus, hospital gangrene, erysipelas, phlebitis, pyæmia, septicæmia, osteomyelitis, and scurvy—are the subjects which occupy the remaining pages of the strictly professional portion of the work. The construction of latrines, field-ovens, and of extemporary water-filters, scales of diets, classifications of wounds and injuries, a formulary of prescriptions, and a copious index, complete the work.

It will be thus seen that the contents of the *Surgeon's Pocket-Book* are of a very comprehensive character; that they form, indeed, a complete *vade mecum* to guide the military surgeon in the performance of duties which may devolve upon him at any moment in the field. Extensive and numerous as the subjects treated upon are, however, owing to the conciseness of the language in which the descriptions are expressed, and by judicious management of the typography, the whole are compressed into a small book less than an inch in thickness and about four inches square. It can thus, with the aid of its limp leather cover, be carried, like Sir Garnet Wolseley's soldier's pocket-book, in an ordinary pocket, without any inconvenience. Bound up with the book are a dozen blank pages of writing-paper for notes and memoranda, which may prove to be a very convenient appendage under many circumstances in field-practice.

In conclusion, we do not imagine that the author intends his "pocket-book" to take the place of larger and more systematic works on the subjects treated in it; but, these having been studied, as they should be, as a regular part of surgical education, there is no surgeon, especially no surgeon who is liable to be called upon to engage in field-duties, but will find Surgeon-Major Porter's work a no less handy than valuable remembrancer and guide. We can strongly recommend it as one of the most useful companions that a medical officer in any branch of the public service can have with him on active service.

NOTES ON BOOKS.

DR. AVELING'S *Memorials of Harvey* (Churchill) is a pamphlet including some rather interesting letters from and relating to Harvey. These fragments, Dr. Aveling suggests, "will be found useful in compiling that larger and more complete memoir of Harvey which is much needed and must some day be written".

MILNE'S *Materia Medica* (Edinburgh, E. and S. Livingstone). This little handbook is so very skillfully condensed, and presents in so small a compass information often given more diffusely, though not more perfectly, that we are not surprised to find that it has reached a third edition. In this edition, it has been carefully revised and rearranged by Dr. William Craig. Part II, Medicines arranged according to their Uses; and Part III, on Particular Forms of Medicines; with the subsequent sections, including posological tables; a list of poisons, their effects, tests, and antidotes; and the chapter on Prescription-writing,—are all good. The therapeutical part of the book is weak. As examinations go just now, it is a good students' book.

LETT'S *Diaries* retain the characteristics which have given them their world-wide reputation. Among the most useful for medical men will be found the Office Diary, No. 45, interleaved with blotting-paper; No. 8 also, an excellent cloth-bound diary; and for pocket, the well-known Medical Diary, bound in a Russia wallet. This is especially

handsome and serviceable. The Medical Diary is particularly well arranged and well printed, and contains much useful information. These publishers issue a catalogue of a great variety of note-books and diaries for every kind of use.

SELECTIONS FROM JOURNALS.

THERAPEUTICS.

EXTERNAL USE OF TURPENTINE IN THE TREATMENT OF TONSILLITIS.—In the *Leavenworth Medical Herald*, Dr. S. H. Roberts strongly recommends the use of turpentine externally in tonsillitis. He folds the flannel to four thicknesses, wrings it out in hot water, and pours oil of turpentine over a spot of the size of a silver dollar. The flannel is then applied over the subparotid region, and the fomentation is continued as long as it can be borne. After removal, a dry flannel is applied, and the same region is rubbed with turpentine every two hours. This application is continued daily till resolution occurs. He believes, from the evidence of his long experience, that, thus applied early in the disease, the oil of turpentine has almost a specific effect in tonsillitis. That its action is not simply that of an irritant, he has proved by employing mustard, croton-oil, tincture of iodine, etc., in the same class of cases. They always failed to diminish the inflammation of the tonsils, while the turpentine succeeded.—*Philadelphia Medical Times*.

THE TREATMENT OF CHRONIC DYSENTERY.—Mr. R. Donaldson, writing from Rangoon to the editor of the *Indian Medical Gazette*, June 1st, recommends the compound tincture of benzoin as a most efficacious remedy in dysenteric affections. He says that, in Barmah, dysentery is a very common affection, and in the European, as well as in the native, exhibits a marked tendency to become chronic. In many of these cases, ipecacuanha appears to have little or no effect; and persistence in the treatment by large doses of this drug, far from being productive of good, is fruitful of positive mischief. The stomach is rendered so irritable by it, that the patient is unable to retain nourishment; and he then suffers from exhaustion, the combined effect of the disease and innutrition. In these cases, the tincture of benzoin, given in combination with astringents—notably with logwood—has been found extremely useful; often, indeed, acting like a charm; and it may be truly said of it, that its powers of healing diseased mucous membranes equal its performances when applied externally to wounds. The formula recommended is: Compound tincture of benzoin, half a drachm; compound tincture of catechu, one drachm; tincture of opium, ten minims; extract of hæmatoxylin, ten grains; water, to one ounce; for a draught to be given three times a day. If necessary, the remedy may be administered by the rectum. It would appear that the compound tincture of benzoin is an old, and at one time a well known, remedy in dysentery, as well as in simple mucous diarrhoea and in chronic infantile inflammatory diarrhoea, in which the evacuations always contain mucus, and sometimes a little blood.

CHLORAL AS AN ANTIDOTE AGAINST SEA-SICKNESS.—At a recent meeting of the Paris Société de Médecine Pratique, M. Guyot stated that he had in his own person tried the efficacy of chloral as an antidote against sea-sickness. He took two fluid-drachms of a French preparation known as the cream of chloral mixed in half a glass of water before going on board the steamer, and felt no disposition towards sea-sickness, from which he had always suffered severely on other occasions.

THE THERAPEUTIC ACTION OF COTO BARK.—Professor von Gietl writes on this subject in the *Archiv für Pharmacie*, September 1875 (abstract in *Allgemeine Medicin. Central-Zeitung*, November 20th). Coto bark is obtained from a tree in the interior of Bolivia. It is there used in the form of powder or of alcoholic extract in cases of diarrhoea, colic, and neuralgic toothache; also in tincture in rheumatism and gout. The description of it apparently indicates that it does not belong to the cinchona class (though growing in the district where these trees flourish), but that it is probably one of the *Lauraceæ* or *Terebinthinaceæ*. Wittstein finds its chief constituents to be, an ethereal oil; a fluid alkaloid, having a smell of herrings and urine, and thus resembling propylamin or trimethylamin; and hard and soft woody matter. It also contains starch, gum, sugar, oxalic acid, tannic acid, etc. Sixteen patients were treated with it—fifteen males and one female. It was given sometimes in fine powder, sometimes in the form of tincture made with one part of coarsely powdered bark and nine parts of spirit of 85 per cent. The powder was given in eight cases, the tincture in seven; both together in one case. The dose of

the powder was $7\frac{1}{2}$ grains four or six times daily; of the tincture, 10 drops every two hours. The cases in which it was given were, two of diarrhoea in pulmonary phthisis; five of diarrhoea from cold and hospital diarrhoea; six of non-febrile gastro-intestinal catarrh with diarrhoea; three of febrile gastro-intestinal catarrh with violent diarrhoea. The powder and tincture were given together in one case of diarrhoea with phthisis. In one case only, neither the powder nor the tincture could be continued, as both produced severe burning pain in the abdomen and vomiting; the patient was phthisical. In another phthisical case, the powder produced much distress, while the tincture was easily borne. Dr. von Gietl believes that the coto bark is a remedy of very great value in the various forms of diarrhoea.

INTESTINAL OCCLUSION CURED BY ELECTRICITY.—In a case of intestinal occlusion supervening in a washerwoman aged 74, and having lasted fifteen days, during which injections and purgatives had been ineffectually employed, Dr. Dal Monta obtained a cure by electricity. The author employed the electro-magnetic apparatus, introducing one pole into the rectum, and applying the other over the abdomen by a wet *plaque*. After the first application, lasting ten minutes, there was an abundant emission of gas. On the following day, the second application produced the expulsion, first of gas, and then of fecal matters. (*Movimento Medico*.) The *Bulletin de Therapeutique*, in commenting on this case, recalls an analysis which it gave of a work by Dr. Fleuriot (p. 4, vol. lxxxix), who has collected a number of similar facts, and expresses the opinion that, before having recourse to an operation, it will always be a duty to have recourse to this treatment, which presents no danger.

PHYSIOLOGY.

THE TRANSFERENCE OF MATTERS FROM MOTHER TO FŒTUS.—At the recent meeting of the Association of German Naturalists and Physicians (*Allgemeine Wiener Medizin. Zeitung*, No. 40, 1875), Dr. Benicke described the results of some experiments which he had made by administering to twenty-five pregnant women salicyl in doses of half a drachm shortly before labour. The newly born children and the mothers were catheterised, and the urine examined for salicyl. The results were the following. 1. The interchange between mother and fœtus was very rapid. The salicyl was always given as soon as labour-pains began. In two cases, where the birth took place at the end of ten and fifteen minutes, no salicyl was found in the children. In two other cases, where the children were born forty and eighty-five minutes after the commencement of labour, no salicyl was found at first, but it was present in the urine examined some hours afterwards. In all the other cases, salicyl was found in the children's urine immediately after birth; in these cases, the shortest duration of labour was two hours. Thus salicyl had passed into the organism of the fœtus in forty minutes, and had appeared in the urine in two hours. 2. The tissue-change in the child was more active immediately after birth than in the uterus. This was shown by the stronger evidence of salicyl in the urine obtained a few hours after birth than in that removed immediately after birth. 3. Salicyl ceased to be found in the mother's urine at the end of twenty-four to thirty-six hours; in the child's urine, it was found up to the third or fourth day. The liquor amnii was obtained in a pure state in four of the cases, and was found to contain no salicyl; nor was salicyl found in the liquor amnii of several women to whom it was given for six to fifteen days before labour, although it was detected in the urine of the children.

REPORTS AND ANALYSES

AND

DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

THE FLUID EXTRACTS OF THE UNITED STATES PHARMACŒIA.

WE have received from Messrs. Ferris and Co., of Bristol, lists and samples of a large series of fluid extracts of the United States of America, of which they keep a stock. Some of these preparations are beginning to be well known here; others which have a high reputation there have yet hardly, if at all, been tested by British practitioners. Among these are *extractum cimicifugæ fluidum*, considered to be a valuable remedy in chorea; *extractum cornis Floridæ fluidum*,

an antiperiodic and tonic; *extractum gelsemini fluidum*, recommended in our columns by Dr. Wickham Legg, Dr. Sawyer, and others, as a febrifuge and nervous tonic, and especially as having valuable odontalgic properties; *extractum pruni Virginianæ fluidum*, extensively employed in America to relieve the anorexia, cough, and debility of phthisis; *extractum spigeliæ fluidum*, almost universally employed there as an anthelmintic; together with many other preparations, with some of which it might be advisable for our practitioners to make acquaintance. They have also a fluid extract of coto bark, imported from Bolivia, which is recommended by Professor von Gietl of Munich, as having something like specific qualities in many troublesome forms of diarrhoea.

PESSARY OF PERMANENTLY ELASTIC RED INDIA-RUBBER.

THE pessary, of which an illustration (three-quarter size) is here given, is the invention of Mr. William Donald Napier.

Mr. Napier's attention was some time ago directed to the subject of pessaries by Dr. Lee and Mr. Henry Lee of St. George's Hospital; the latter having suggested a form of pessary similar to that which Mr. Napier was working out. The result has been the introduction to the profession of an instrument well calculated to serve the purpose for which it is intended.

The principal advantage which this pessary possesses over others is due to the fact, that it is constructed of a permanently elastic substance, and, like Mr. Napier's catheters, is made in a mould, by which perfection of form, combined with an absolutely smooth surface, is obtained.

The introduction of this pessary into the vagina may, if required, be facilitated by its being drawn, like the catheters alluded to, within a tube from which it is afterwards expelled. An ordinary tubular speculum serves the purpose. The actual means by which the uterus is supported, is (as will be seen by the opening in the stem) through the medium of broad bands placed round the waist or over the shoulder, no resistance being required from the soft parts or pelvic walls. This pessary can be made of any size, and may be obtained from Messrs. Maw and Co., Aldersgate Street, or any surgical instrument maker. The manufacturers are Messrs. Warne and Co., Tottenham.

VENTILATION OF HOSPITALS.

A VERY efficient apparatus for supplying hot air in sick rooms or wards has lately been made for the Hospital for Sick Children in Great Ormond Street by the Messrs. Benham of Wigmore Street, under the direction of Dr. Robert J. Lee. By its means, a continuous stream of mixed hot air and steam may be kept up at a temperature of over 120 deg. Fahr., as it issues from the jet; this can be conveyed by means of a tube to any part of the apartment where specially heated air is required. The obvious advantages of this apparatus are, that the combined stream contains so much atmospheric air as to render it continuously and easily respirable with comfort at quite a short distance from the mouth of the tube; and that by its means the temperature of the air of a small apartment can be considerably raised without causing an undue amount of moisture. These will be great gains in the treatment of cases of tracheotomy and other operations which now call into use the boiling kettle, and will be felt as such not only by the patient, but also by the attendant nurse, a much greater heating effect being brought about with far more comfort and less trouble than by the old method.

This machine acts on the same principle as that lately recommended by Dr. Lee for small "inhalers", enabling patients to breathe continuously heated or medicated vapour uninterrupted by periodic respiratory efforts, which other apparatus generating steam only renders necessary. By the addition, of course, of the various substances used in inhalation, this machine readily impregnates the air of the room with their vapours. It is set going by simply filling the boiler and lighting a small gas-burner, and will then work for ten hours without further attention.

BRITISH MEDICAL JOURNAL.

SATURDAY, DECEMBER 25TH, 1875.

THE ASSOCIATION AND THE "JOURNAL".

IN this, the last number of our volumes for 1875, we may content ourselves with a brief retrospect of a year which has been one of continued prosperity and activity for the Association and the JOURNAL. It has seen a great and in every respect a successful gathering of our members on Scottish soil. The Edinburgh meeting showed how complete is the fraternity of feeling between the practitioners of medicine in Scotland and the other parts of Great Britain, how largely all are interested in a common scientific and professional progress, and how completely great public and professional interests may assist to combine us all in a broad platform, aiming only and by a common effort to "advance medical science and to promote the interests of the medical profession". Upwards of a thousand English, Scottish, and Irish members met there, under the presidency of the chieftain of Scottish medicine, supported by representatives of the most brilliant achievements of British medical science and practice. The moral and political interests of the profession and the public were not forgotten; and two of the Committees then formed—those, namely, for the amelioration of the position of the Poor-law medical officers of Scotland, and the furtherance of legislation for the restraint of uncontrollable inebriates—are now in action, and will no doubt yield good results.

The Scientific Grants of the Association have produced a highly valuable series of reports of original investigations in medicine and the allied sciences, which are in course of publication in our pages, in a form which will allow of their being bound so as to form a separate volume. The full amount granted has not yet been applied for either this year or last. As applications on behalf of suitable researches by skilled observers increase, the means will be at hand to supply them; for, thanks to the continued growth of our numbers (reaching this year to 6,500 members) and the prudent administration of finance, the modest annual subscription of a guinea begins to suffice not only to furnish each member with his JOURNAL weekly free by post, and to meet the demands of organisation, but to furnish the scientific grants, and to leave annually a respectable surplus.

The work which the Association has in hand for the year includes not only the two subjects mentioned, of amelioration of the Poor-law Medical Service of Scotland, and legislation on drink-craving, but also the provision of an adequate standard of qualification in State Medicine, on which subject the Association first moved three years since in a direction which has been followed by many of the Universities and examining bodies, and on which the Committee of Council has now further sent a communication to the General Medical Council. The work of the Association embraces also the further investigation of the question of hospital abuse, which has been referred to the Committee of Council, in virtue of a memorial signed by many hundred leading practitioners.

The programme of action of its Parliamentary Committee includes an effort on behalf of the surgeons of the convict service; the better regulation of the status of ship-surgeons in the mercantile service; and the reform of the present system of sale of dangerous and secret "patent medicines", a prolific cause of injury and of fatal poisoning, especially of children. It is further the duty of this Committee, to which every Branch of the Association sends a representative, to watch over medical interests in relation to Bills introduced in either House of Parliament which may seem to affect those interests.

The number of Branches of the Association has been increased this year by two more Branches in Scotland, now in process of organisa-

tion, having Edinburgh and Glasgow as their respective centres. These Branches will afford to our Scottish members resident in those parts their adequate influence and initiative power in the councils and affairs of the Association, and furnish them with a powerful means of making their wishes known on all public questions affecting their interests, as well as promoting, in many districts now unprovided, the means of frequent scientific and fraternal intercourse.

The JOURNALS of the last year are before our members, and we need say nothing of their contents: the most competent critics at home and abroad have stamped them with the highest meed of approbation. We can but feel encouraged, by the repeated expressions of confidence and satisfaction which reach us on all sides, towards further exertions to make the JOURNAL in every respect worthy of its great constituency, and the faithful representative of the high objects of the Association. We are doubly gratified that the voice of foreign critics ratifies the pleasing verdict, and that the most eminent of French medical journals, the *Archives Générales de Médecine*, recognises the BRITISH MEDICAL JOURNAL as being at the head of English medical periodical literature. Our programme, printed elsewhere, speaks of the principal arrangements for the next year. The JOURNAL now enjoys, we are informed, a considerably larger circulation than any other medical paper in the kingdom; and this, joined to our other resources, places at our disposal a great amount of valuable material, from which we endeavour to select the most important elements for publication. We hope to be able to add to the papers announced some valuable contributions from eminent foreign savans, for which arrangements are now in progress. The first of these is an address by Professor Marey, of the Collège de France, on the Applications of the Graphic Method to the Study of Medicine. It will appear, fully illustrated, in early numbers in January.

It remains only to speak of our next annual meeting at Brighton. The arrangements for this are not yet complete; but we may note the inherent natural attractions of this great marine suburb of London; the admirable buildings which are liberally placed at the service of the Association by the Corporation, and which are unequalled for the purposes of meeting and entertainment; the fact that the municipal authorities of Brighton have already intimated to Sir Cordy Burrows, the President-elect, that they will be prepared to do due honour and show public hospitality to the Association; and that provision is in progress for filling agreeably all the evenings of the meeting. Eminent orators have been selected, as will be seen in the programme. The South-Eastern Branch, in whose territory Brighton is situated, is one of the largest and best arranged in the Association, and will certainly spare no pains to assist in making the reception worthy of it, of Brighton, and of the profession. There is every reason, therefore, to hope that the meeting will be not less scientifically interesting than agreeable.

Closing the year 1875 with a satisfactory retrospect, we enter also upon the year 1876 with pleasing and auspicious prospects and with earnest wishes of increased usefulness and prosperity for the British Medical Association and its associates.

THE COST OF MAINTENANCE OF HOSPITAL PATIENTS.

AN important question of hospital administration has arisen at the Metropolitan Asylums Board regarding the different costs of the maintenance of patients at the fever hospitals or "asylums" at Homerton and Stockwell, the cost *per diem* at the latter being nearly half the cost at the former, and the detention of the patients at Homerton being considerably longer than at Stockwell. The matter has come before the Board at several meetings lately, and was discussed on Saturday last, when the reply of the medical officers at Homerton was in the hands of the managers.

The question originally arose on the report of the Finance Com-

mittee, who stated that the cost of provisions *per diem* at Homerton, for each patient, was 7d. a head, and at Stockwell 6¼d., while the cost of medical extras at Homerton was 6d. a head *per diem*, and at Stockwell 1½d.; making the total cost of each patient at Stockwell for food and medical extras 7¾d., and at Homerton 1s. 1d. On the motion of Dr. Curtis, reports were demanded from the two asylums as to the number of days' residence of those who died and of those who recovered, and the answer was that, at Stockwell, the average duration of residence of those who died was 8.8 days, and of those who lived 38 days. At Homerton, the average days' residence of those who died was returned as 12.5, and of those who recovered 58. It was then referred to the committee to report upon the causes of these differences, and the report was presented on Saturday last.

The Committee said that, after consideration of the respective references and of the order of the Local Government Board, stating that "the paupers shall be dieted in such manner as the medical superintendent shall in writing direct", and that "when any pauper has recovered, and the medical superintendent is of opinion that such pauper may leave the asylum without risk of communicating infection or contagion, he shall be discharged",—they came to the conclusion that the medical officers were alone responsible; and they had called upon Drs. Collie and Gayton, in whose medical skill and science the Committee had every confidence, to report, and the Committee had formed the conclusion that the replies were satisfactory. With regard to the concluding paragraph in Dr. Collie's report, and to the question of the time patients should be retained in the hospitals, the Committee had directed the medical superintendents to conform to the regulations of the Local Government Board relating to the discharge of patients.

The report which Dr. Collie presented was of considerable length. As, however, it discusses matters of great medical interest, we abstract it fully.

"The difference in the cost of maintenance of patients at Homerton and Stockwell is considerable, and is explained by the more liberal diet and the more liberal use of stimulants at Homerton. Full diet at Homerton contains seven ounces of cooked meat, and at Stockwell six ounces; but, as during the last half-year not a single full diet has been used at Stockwell, the ordinary diet at Stockwell, which contains four ounces of meat, corresponds to the full diet at Homerton. That the full diet in use at the Homerton Fever Hospital is more liberal than that in use at Stockwell is perfectly correct, and the medical officer of the Homerton Hospital thinks it superfluous to prove that seven ounces of cooked meat is not too much for an adult recovering from an attack of fever, just as he thinks it superfluous to attempt to prove that four ounces is too little. A reference to the children's diet at Homerton will also aid in explaining the difference in cost between the two hospitals; for at Homerton each child has two eggs daily, two pints of milk, and four ounces of meat, whereas at Stockwell they have no eggs and little over half a pint of milk, and only three ounces of meat. The medical officer of the Homerton Hospital is of opinion that the dietaries in use at this hospital are not only not too liberal, but are sometimes found inadequate, and have to be supplemented by extras. As compared with Stockwell, the medical extras appear large; but, deducting fish and a proportion of the eggs, the cost falls from 6d. to 3½d. There still remains a difference to be accounted for, arising from the more liberal use of stimulants at Homerton. The use of stimulants in disease is a question on which there is some diversity of opinion; but there are considerations which lead us to expect that alcohol will prolong the life of patients. At Homerton, where stimulation forms an important element in the treatment, the average duration of residence of those who die is 12.5 days; while at Stockwell, where a contrary plan of treatment is adopted, it is 8.8 days: apparently showing that, by the treatment adopted at Homerton, cases which prove fatal are kept alive just one-half longer than at Stockwell. At the London Fever Hospital, the cost of stimulants per patient daily is 2d.; at Homerton Fever Hospital, it is 2½d. This slight excess in the cost of stimulants at Homerton might be explained by the fact that the patients in the Homerton Fever Hospital, being paupers, and therefore in a more deteriorated condition, require a greater amount of stimulant. That the cost of maintenance of patients at Homerton is not excessive is shown by the fact that, in other institutions, for instance, Poplar and Stepney Sick Asylum, the cost of maintenance for each patient per day is 1s. 1d., being the same as at

Homerton; while at Bow Infirmary it ranges from 11d. to 1s. As regards the residence of patients, the practice here has been to retain them, they being paupers, until such time as they might be able to resume their employment immediately on their discharge from the hospital. If, on their discharge, they are unable to work, it is impossible for them to obtain the means wherewith to purchase suitable food, and consequently, with meagre and insufficient nourishment, their constitutions, weakened by an attack of fever, might be impaired for life. As to children, the more delicate nature of a child's constitution, its greater susceptibility to succumb to disease in general, and, in particular, to diseases due to defective nourishment, make it a matter of the first importance that children, on recovering from an exhausting disease, should not be discharged to the custody of poor parents until they are in good physical condition. If it be the opinion of the managers that patients should be discharged so soon as they have recovered from fever, and are unable to communicate infection to others, the cost of maintenance would be reduced to some extent; but, if the method be adopted, the medical officer feels that he cannot accept the responsibility of discharging patients in this state without distinct instructions."

After some conversation, in which the report was adversely criticised, it was agreed that the reports from Dr. Collie and Dr. Gayton (the latter being in most respects like the former) should be adjourned until the next meeting, and that they should not appear on the minutes.

DR. NEVINS' STATEMENTS ON THE CONTAGIOUS DISEASES ACT.

We have, as requested, carefully looked into the Parliamentary Paper (No. 266, June 1875) criticised by Dr. Nevins in a printed paper of which he has forwarded a copy to us. It is signed W. M. Muir, Director-General; and it relates, solely to the "working of the Contagious Diseases Acts as regards the Army". Dr. Nevins's description of it, therefore, as a statement on "the influence of the Contagious Diseases Acts upon venereal diseases", is incorrect and misleading. Still more so, following upon this incorrect description, is his complaint that a paper which relates to disease in the army contains no contradiction of the alleged increase of disease in the navy; and that the navy is given up as indefensible. How entirely this is contrary to the fact will be apparent by reference to the Report on the Health of the Navy for 1874, just published as a blue-book, which we elsewhere notice.

His next complaint is that "it contains no contradiction whatever of the alleged increase of secondary syphilis in the army. The increase of this most serious form of disease is therefore admitted." The paper contains no such admission. It does not allude to secondary syphilis at all; for the reason that it was, at the outset, found impossible to frame returns which would show the comparative frequency of secondary disease at protected and unprotected stations; for, in consequence of the interval required for the development of this form of disease, it will constantly be contracted at one station, and not make its appearance till the soldier has been removed to another. There is no reliable proof that secondary disease has increased at the stations under the Acts; on the contrary, there is abundant testimony from military surgeons that they have found it not only less frequent, but also much less severe.

The only point on which we are able to agree with Dr. Nevins is with reference to gonorrhœa: for the statistics shew, and the paper states, that "the Acts have not reduced the prevalence of gonorrhœa amongst soldiers materially".

There remains the question of primary venereal sores, the improvement in which Dr. Nevins has alleged to have been checked since the passing of the Acts. Instead of this being the case, the following are the facts set forth in the paper in question. For the four years 1860 to 1863, before any Act was passed, the average of primary sores per 1,000 of strength was 130 at the group of stations which have since been placed under the Acts, and 116 at the stations which have never been placed under the Acts. In 1869, by which time the Acts had

been brought into tolerably efficient operation, the ratio had fallen in the protected stations to 66 per 1,000, while it had risen to 128 per 1,000 at the unprotected stations. In 1873, after four years' efficient working, the ratio was 50 at the former as compared with 102 at the latter, or, taking the average of the four years ending 1873, 52 to 108.

The returns for 1874 are characterised by Dr. Nevins as fallacious and of no value; because an order was issued in October 1873, punishing men who became diseased, and they were therefore induced to conceal their complaints. Probably the order had this effect, for less disease is recorded at both sets of stations; but, as it operated equally on both, we find, as might have been expected, the comparative rate remaining as before, the figures being respectively 42 and 88.

How is this striking difference to be accounted for, if not by the operation of the Acts? Let Dr. Nevins, instead of ignoring it as much as possible, explain, if he can, why this form of disease is less than half as prevalent at the protected as at the unprotected stations. This would be more to the purpose than dwelling, as he does, almost exclusively on variations in the comparative rate of decline at the two sets of stations. It is idle to argue that the Acts are a failure because the rate of decline has occasionally been greater at the unprotected stations, when, comparing the average of the four years 1860-63, without any Acts, with that of the four years 1870-73, with the Acts in full operation, the total decline has been from 130 to 52 per 1,000, or 60 per cent., at the protected stations; and only from 116 to 108, barely 7 per cent., at the unprotected. We believe, moreover, that even this 7 per cent. is mainly, if not entirely, the result of the Acts, being, in fact, caused by the constant transfer of healthy troops from protected to unprotected stations; while the former are subject to the disadvantage of an equivalent influx from the latter of men with a high rate of disease.

In commenting upon the tables framed to show the ratio of men constantly in hospital for primary sores, Dr. Nevins says, "the absence of any benefit from the Acts in the subjected stations when compared with the unsubjected ones, as shown by this paper, is somewhat remarkable". To demonstrate this, however, he can only point out that, in 1870, the number constantly sick at the protected stations was 4.46 per 1,000, and, at the unprotected, 9.74 per 1,000; whereas, in 1873, the corresponding numbers were 4.45 and 8.86, thus showing a fractionally greater decrease of about seven-eighths of a man per 1,000 for that particular year at the unprotected stations. But he is obliged to admit that the average of the four years 1870-73 was 1.34th below 1870 at the protected, and only 1.37th below 1870 at the unprotected, stations, the difference being, therefore, slightly in favour of the former; a difference, however, as he truly says, "so small as to be without weight in deciding upon the alleged sanitary value of the Contagious Diseases Acts". The same remark might be made about the decrease of seven-eighths of a man in 1873, which is all Dr. Nevins has to rely upon to establish the "remarkable absence of any benefit from the Acts".

All this is mere trifling with the question. We say, again, let Dr. Nevins explain, if he can, why the number of men constantly sick at the protected, is less than half that at the unprotected, stations; the average for the four years 1870-73 being 4.33 per 1,000 at the one, and 9.48 per 1,000 at the other.

The parliamentary paper says: "It is believed that the two groups of stations are fairly comparable". Dr. Nevins says that there is a "difference of every description between the circumstances of the towns and garrisons in the two sets of places". The difference is, however, entirely in favour of the Acts and against Dr. Nevins' arguments: for, before any Act was passed, the ratio of disease was considerably higher at the now protected, than at the unprotected, stations; the average of the four years 1860-63 being 130 per 1,000 at the former, against 116 at the latter, which, therefore, started with the advantage in the rate of disease of 14 per 1,000.

HYPODERMIC MEDICATION.

M. VIBERT (*Journal de Thérapeutique*, 1875, No. 4, et seq.) has studied this interesting subject practically, and his observations are worthy of note. He commences by observing that the state of the pupil may be considered as a manometer which should be at every instant consulted. The contraction of the pupil has nothing in it peculiar or capital, that is to say, it does not prove a toxic effect. It shows itself as soon as there is a happy modifying influence under the influence of morphia; but once this contraction has commenced, its degree is proportionate to the quantity of morphia injected, at the same time that its impressionability by light will diminish more and more, and the contracted pupillary circle will end by being immobilised even in case of passage from full light to darkness. Hence, as long as complete pupillary atresia with immobilisation is not obtained, a further dose of morphia may be injected, if no relief from suffering have been obtained; and, on the other hand, farther morbid phenomena, such, for example, as vomiting, occurring after injection, if this pupillary atresia be wanting, need not be attributed to the injection, and are not, therefore, contra-indications to a new injection. M. Vibert, indeed, as has been noted, goes not only as far as pupillary atresia, but, if necessary, as far as pupillary atresia persisting in darkness. This action on the pupil is produced at the end of about fifteen to twenty minutes. The desideratum wanting here is the previous knowledge of the relative impressionability of the subject to morphia. In the absence of information on this subject, not more than two to three *milligrammes* (0.03 to 0.45 grain) should be injected; then a quarter of an hour should be allowed to pass, the pupil interrogated, and the second injection made if there be ground for it.

Subcutaneous injection of morphia can cure almost instantly an access of asthma, during which the pupil is dilated. It was moreover, indeed, this pupillary dilatation which led M. Vibert to try hypodermic injections of morphia, and the cases which he cites are very conclusive. However serious the case, relief always ran parallel with the progress of the pupillary contraction. The relief commenced at the end of ten to twenty minutes, by an agreeable sensation of interstitial, general, and internal warmth. Here morphia thus employed realised the author's ideal of a diffusible stimulant.

Cardiac lesions, the complication of anasarca, and pleural effusions, are not, in his experience, contraindications to the employment of the endermic use of morphia against the oppression, although they would be generally considered to be so.

Injections of morphia are very efficacious against delirium tremens, but the dose must be considerable, up to eight *centigrammes* (1.2 grains) in a few hours by successive injections. In acute mania the author has failed three times, succeeding twice. It is in the form of delirium, called by M. Gubler asthenic, in which there is a defect of incitation (eye pale and pupil large), and which indicate excitants, that morphia injections succeed. In the second form, hypersthenic irritation, delirium, with congestion of the eye and contraction of the pupil, blood-letting, digitalis, quinine, and bromide of potassium are indicated.

The great power with which morphia in injection manifests its effects as a diffusible and anodyne excitant, induces the author to recommend it as sovereign against sporadic choleric with violent colic; and he has obtained from it also the best results in dysentery. To arrest a miscarriage, injections of morphia are preferable to opiate potions or enemata, by reason of the facility with which the dosage of the medicament is obtained.

The employment of subcutaneous injections of morphia against nephritic and hepatic colic, against pleurodynia and all portal pains, symptomatic or not of pleurisy or pneumonia, is already well known. It succeeds admirably against lead-colic; but the dose must be strong enough—about two to three *centigrammes* (0.3 to 0.45 grain). It is capable of favouring the reduction of strangulated hernia.

Although lauding highly injections of morphia in cases of neuralgia,

the author insists on the point that here they constitute a treatment which is simply symptomatic; the neuralgia of zona yields very well to this mode of treatment. Hysterical crises are curable by this treatment; the author has injected as much as seven *centigrammes* of morphia in the space of five to six hours. M. Vibert relates the case of a young lady in whom he has for seven years injected an average of twenty to twenty-five *centigrammes* of morphia for a horrible anguish experienced in the epigastrium. The failure of the treatment in tetanus is complete; and in paralysis agitans very nearly so.

M. Vibert supplements morphia injections by the endermic application to a blistered surface of the size of a sixpence of four to eight *centigrammes* of morphia. The morphia plaster should be left on for several days. He insists on the advantages to the digestive canal of the hypodermic injection rather than the internal administration of opiates. He employs a solution of acetate or hydrochlorate of morphia, of 1 part in 20; prefers an India-rubber cork to the bottle, and hollow steel to gold needles; he pierces the skin perpendicularly, and, before throwing in the injection, he separates the syringe from the needle in order to see that no blood flows, so as to avoid direct injection into the circulatory system. He considers the injection of some bubbles of air as insignificant; he desires local action of the drug, and chooses, therefore, as the spot for injection, the subcutaneous abdominal tissue, the skin of the belly being the least sensitive, and especially the cicatrices which it may present as the traces of pregnancy. M. Vibert cites two unfortunate cases: the lesson which he draws from them is, that cyanosis with pronounced venous stasis annuls the action of morphia on the phenomena of oppression. Finally, he rejects from antineuralgic medication subcutaneous injections of atropine.

FURTHER investigations of Sir William Gull and Dr. Sutton on the subject of arterio-fibrosis are, we believe, nearly ready for publication, and we expect shortly to be able to present to our readers the papers from those authors on this subject which have been previously announced.

SIR ROBERT CHRISTISON was, at a recent meeting of the Academy of Medicine in Paris, elected a corresponding member by forty-six votes, against sixteen given for M. Donders, the celebrated ophthalmologist of Utrecht.

THE Council of the Pathological Society of London has decided, with justifiable and gentlemanly good feeling, that Mr. Pollock shall not be the first victim of his proposition to abolish the biennial tenure of presidency, and have arranged to nominate him again for the office in the ensuing year.

A BIRMINGHAM correspondent informs us that the Rev. George Inge has given a freehold site for the Medical Institute, and a donation of £100 to the Building Fund.

THE *Times* mentions that, last week, Miss Isabel Clark passed the major examination of the Pharmaceutical Society of Great Britain, and received the diploma of Pharmaceutical Chemist. It states that there are several ladies on the official register as chemists and druggists, but that this is the first lady who has been placed on the roll of Pharmaceutical Chemists.

THE newly enrolled Pharmaceutical Society of Ireland has also unanimously resolved to admit ladies to the examination for the diploma of Pharmaceutical Chemist in Ireland.

THE Royal Commission to inquire into the practice of subjecting live animals to experiments for scientific purposes, met at 13, Delahay Street, on Monday. It is understood that the examination of witnesses is now concluded, and the Commission have now nearly completed their report. It is not, however, expected that it will be issued before February.

MEANTIME, some vivid reports of vivisection in sport have occupied a prominent place in the daily papers, whose special correspondents have sent home descriptions of encounters between wild animals of various sizes and descriptions, presented as spectacles on occasions graced by the presence of a Royal Prince.

NOTICE is given that the Senate of the University of London have appointed a Meeting of Convocation to be held on Tuesday, January 18th, 1876. Members of Convocation who may wish to bring forward any business at the meeting are to give to the clerk specific notice in writing of such business, not later than the 28th instant.

M. TARDIEU has resigned his office of President of the General Medical Benevolent Society of France. This step, which is rendered indispensable by the necessity for cessation from too much work felt by M. Tardieu, is much regretted by the Association generally, to which his lucid intellect and excellent conduct of affairs have rendered essential service.

OUR number for January 1st will include lectures by Professors Marey and Macleod, the conclusion of Sir William Fergusson's paper, and an important paper by Dr. George Johnson. The immediately succeeding numbers will contain lectures by Drs. Broadbent, Southey, and John Duncan, and Mr. Christopher Heath; the Harveian lectures of Dr. Sibson, and original papers by Mr. W. Adams, Mr. Lund of Manchester, Dr. Otis of New York, etc. Most of these papers will be fully illustrated.

EVERY one must have been deeply concerned to see that the misbehaviour of certain London "medical students" at a music hall has once more come under notice at a police-court. However small a minority may be concerned in such degrading displays of misconduct, the disgrace is reflected upon the whole body to which they belong. The school authorities will not fail to notice this misbehaviour with the proper severity; but it is to the students themselves that we must look to mark, by the most distinct disapproval and condign contempt, the conduct of those who have dragged in the mixe the honourable name of London students of medicine. Above all things, students must be gentlemen. Persons worthy of that name do not take part in low broils and pot-house quarrels. The man who does such things is unworthy of the fraternity of medicine, and should be treated by his fellows as what he has shown himself to be.

WE learn, with sincere regret, the death of Professor Boeck of Christiania, the eminent syphilographer, whose visit to this country many will remember, and whose ardent labours in the prophylaxis and cure of syphilis were inspired by an unselfish devotion to what he believed to be a labour useful to science and humanity. His suggestions, fairly tried here, yielded no good result; and his travels throughout the world left him many friends, but few followers.

THE MANCHESTER MEDICO-ETHICAL ASSOCIATION.

THIS Association has just issued a report upon the working of the Manchester Provident Scheme, which has lately been the subject of a correspondence in our columns. When this scheme was started, nearly three years ago, the Medico-Ethical Association regarded it favourably, and co-operated with it. According to the present report, it still holds that the scheme, as originally proposed, was sound, and, if thoroughly carried out, would be beneficial to the poor and satisfactory to the profession; but it maintains that the scheme has not been carried out in its entirety. In particular, it says that the necessary checks and safeguards against the admission of unsuitable members have not been applied; that the inquiries are not genuine; that an objectionable system of canvassing and advertising has been used; and that much has been sacrificed to an over-eager desire to make the scheme self-supporting. If these points be rectified, and if the charities which have not yet joined in the scheme be induced by the pressure of public opinion to submit their out-patients to an efficient system of inquiry, the Medico-Ethical Association "still believes that the good elements

will preponderate; and, instead of falling (as seems now to be threatened) into a worse evil than the one it was intended to remedy, the scheme will be a boon to the mass of the poorer people, and a relief to the routine labours of the public charities".

THE NEW EXAMINING BOARD OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE following is an alphabetical list of the candidates for the Board of Examiners in Anatomy and Physiology for the Fellowship and Membership of the Royal College of Surgeons. The gentlemen whose names appear in italics and marked with an asterisk were recommended by the Committee appointed for that purpose, and were duly elected at a meeting of the Council on the 20th instant. Messrs. J. E. Adams, London Hospital; W. M. Baker, St. Bartholomew's Hospital; T. H. Bartleet, Queen's College, Birmingham; R. Barwell and E. Bellamy, Charing Cross Hospital; **J. Birkett*, J. N. C. Davies-Colley, A. E. Durham, and **J. C. Forster*, Guy's Hospital; **G. G. Gascoven*, St. Mary's Hospital; **C. Heath*, University College Hospital; **L. Holden*, St. Bartholomew's Hospital; **T. Holmes*, St. George's Hospital; H. G. Howse, Guy's Hospital; J. Langton, St. Bartholomew's Hospital; B. T. Lowne, Middlesex Hospital; J. McCarthy, London Hospital; F. Mason, St. Thomas's Hospital; H. Morris, Middlesex Hospital; A. T. Norton, St. Mary's Hospital; T. W. Nunn, Middlesex Hospital; **H. Power*, St. Bartholomew's Hospital; U. Pritchard, King's College; W. Rivington, London Hospital; **W. S. Savory*, St. Bartholomew's Hospital; W. Thomas, Queen's College, Birmingham; W. W. Wagstaffe, St. Thomas's Hospital; **J. Wool*, King's College. In the above list, the following gentlemen retain their seats as members of the Court of Examiners; Messrs. Birkett (Chairman), Forster, Holden, Holmes, and Savory.

THE EFFECT OF COLD ON CHILDREN.

THE atmospheric changes which have lately occurred, and which have occasioned a great reduction of temperature, succeeded by excessive humidity, will produce distinct effects as usual upon the mortality of those who are most sensitive to the influence of cold. The old and the young, whose health and even existence depend very much, if not entirely upon others, are the chief sufferers at this period of the year. The nervous system in old age and in infancy is similarly affected by the depressing influence of cold. It is important, therefore, that those who have the care of either young or old should consider their responsibilities, and endeavour to carry out judiciously such precautions as may oppose the dangers of our winter season. It is more particularly to the important question of the care of the young that we think attention should be directed, for the moral responsibility which attaches to the duties of those who have such care is greater than in the case of the aged. The notions which prevail about some of the most simple means which may be used to protect children from the effects of cold are singularly at variance. We hear, for example, the satisfaction with which an English mother tells us that her infant of three months old has been out every day, except, perhaps, once or twice, when the weather was really too bad for the nurse to take it. The English mother has a love of hardy children, and thinks fresh air, or even the atmosphere of London streets, is of vital importance to their health. The idea of having no fire in the bed-rooms is another of her favourite maxims; and amongst the wealthier classes the luxury of seeing the arms, neck, and legs of those just commencing to practise the art of progression in the erect position seems to be peculiarly delightful. We find no other country where these ideas exist. We do not certainly desire to see the system of swaddling introduced into England which prevails in France, nor that our young ones should, like those of Northern Europe, resemble little round bundles of clothes more than anything else. But we seriously think that many lives are sacrificed to ignorance and erroneous ideas. Amongst the poor, the scantiness of children's clothing is quite remarkable. Winter and summer are not distinguished by any change of dress;

short sleeves, bare necks and legs, are not the exception, they are the rule; cotton or thin stuffs are not changed for woollen or flannel; and so in all other respects; beyond a shawl or some such addition, there is very little difference between their clothing in summer and winter. And yet this system is not the result of carelessness. It has become a custom, and one that has many supporters. There is no doubt that, if used to test the character of the child, very much as we see a boy holding up a terrier by its tail or its ear to show its pluck by its silence, it has certain advantages. "Would you keep the child indoors all the winter?" is the question that is asked in somewhat an aggrieved tone, when the opportunity of reading a lecture presents itself to the medical man after just seeing a victim of this system suffering with acute bronchitis. It does not occur to most people that the air inside their houses, if they are properly ventilated, is as pure as the air outside. We should say that no child too young to walk or run should be taken out when the external temperature is below 50 degs.; that the rooms in which they live and sleep should never be below 58 degs.; and the day room should be three or four degrees warmer. The practice of wheeling children about in perambulators, sitting or reclining in one position without exercise, is particularly harmful. We would earnestly appeal to mothers to put aside all feelings of vanity, or what is sometimes miscalled natural pride, and cover the arms, neck, and legs of their children as a simple sanitary precaution. High frocks, long sleeves, and warm stockings should be worn out of doors; hats which cover the head, and boots which keep the feet as dry and warm as possible. On coming in from our streets, nearly always damp, both boots and stockings should be changed; and if the feet be cold, a warm foot-bath should be used for a few minutes. The exquisite pain of chilblains could be saved to many children by this use of hot water for hands and feet. We see that flannel has yielded to merino, chiefly on account of the greater convenience of ready-made under clothing; but there is nothing equal to flannel in the property of preserving warmth. There is one important point which is the question of the day with mother and nurse, and that is, the morning bath. It requires a strong mental effort to recall those sad scenes of early life, when the battle of the bath was fought out in the cold and gloomy nursery. Resolute, not unkind determination, struggled too successfully with vociferating opposition, and all this trouble was for nothing but harm. Let the room be well warmed before the child is taken out of bed, and let those who think a cold bath an absolute necessity, remember that on a summer morning their children enjoy it; and if they keep the temperature of the water the same all the year round, that is, about 55 or 60 degs., they may obtain all the benefit possible. Let them think how unreasonable it is to take water not much above freezing point, and attack the nervous system already depressed, by a shock which is followed by a reaction which requires the whole morning to recover from. We have no hesitation in recommending a warm bath early in the day, followed by a simple douche of cold water, as far preferable to the cold bath; or a warm bath at night for the sake of cleanliness, and none at all in the morning. It may be taken as a rule that, in the case of children, sudden changes of temperature are dangerous, and that 58 to 60 degs. may be taken as the safe average temperature in which they should be constantly kept. We feel certain that the members of our profession could soon remedy some of the evils to which we have referred, not dogmatically, but by availing themselves of those physiological principles, which they generally apply to therapeutic good. There are few subjects more important to society, or more satisfactory in its results, than that of the prevention of many of the effects which arise from the climatic influence peculiar to this country, and which are so fatal in their character.

POPULATION STATISTICS OF THE GERMAN EMPIRE.

THE official returns for 1873 show that in that year there were 416,048 marriages in the German empire; 252,567 being in Prussia. The births were 1,715,132; viz., males, 882,945; females, 832,186; one child is described as asexual. There were 67,165 still-births. Of the

living children, 768,890 males and 729,393 females were born in wedlock; and 76,570 males and 93,527 females were illegitimate. The proportion of illegitimate to legitimate children was thus about 1 to 10. Among the still-born children, the proportion of illegitimate children was much greater than of legitimate; the number of the former was 59,337, of the latter 7,827; the latter being in proportion to the legitimate still-born children as 13 to 100. Including the still-births, the deaths were 1,241,120; 647,206 males and 593,913 females. The births exceeded the deaths by 473,012.

THE HEALTH OF THE NAVY.

DEPUTY INSPECTOR-GENERAL MACKAY prefaces the statistical report of the health of the navy for the year 1874, just published, with the following statement.

"The advantages derived from the operation of the Contagious Diseases Act continue to be maintained. On referring to the remarks on the station, a table will be found showing the decrease in the ratio of cases of those diseases against which the Acts are more particularly directed from the year 1864, when they came into operation, to the year 1874, as compared with the ratio of the three years preceding; viz., 1861 to 1863 inclusive. From this table, it will be seen that the ratio has been reduced from 104.4 per 1,000, the average which obtained from the year 1861 to 1863 inclusive, to 56.0 per 1,000, the average ratio for the years 1866 to 1874 inclusive. In 1874, the ratio of disease was 48.6 per 1,000, as compared with 104.4, the average ratio for the three years before the Acts came into force.

"On the Mediterranean Station, cases of enteric fever, although not very numerous, occurred in the squadron, and, as heretofore, were mainly contracted at Malta. The general and comprehensive scheme of sewerage of the principal towns surrounding Malta Harbour, which has been submitted to and approved by Government, is to be carried into effect at once, and will, doubtless, prove an inestimable boon to the island, as well as to the naval force on the station, of which Malta Harbour is the head-quarters.

"The comparative absence of yellow fever from the North American and West Indian Station caused a reduction in the death-rate of the station, compared with the previous year, to the extent of 7.6 per 1,000. The sanitary condition of the force on the station was good.

"On the South-East Coast of America Station, however, an outbreak of yellow fever of a fatal character caused an increase in the death-rate, compared with the preceding year, to the extent of 26.1 per 1,000. The cases were almost entirely confined to the receiving ship permanently stationed at Rio de Janeiro, and in some respects the character of the fever was such as to induce the belief that it was of a malarious origin, and not what is recognised as specific yellow fever. The details in connection with the fever will be found on referring to the report on the station.

"The operations on the West Coast of Africa and Cape of Good Hope Station in connection with the Ashantee Campaign were productive of much invaliding; the ratios of cases entered on the sick list, and of mortality, were, however, lower than in the preceding year. The duties devolving on the Naval Brigade and Marine Battalion employed on shore on the Gold Coast are fully detailed in the reports on the station.

"On the East Indian Station, the sanitary condition of the squadron was comparatively good, although cases of remittent fever were of somewhat frequent occurrence among the crews of ships employed on the East Coast of Africa, where there is much boat and river service in connection with the suppression of the slave trade. Cases of sunstroke and heat-apoplexy were also rather numerous.

"There was nothing calling for particular notice in connection with the China or Australian Stations, or the Irregular Force. An interesting report on the Physical Geography and Climatology of the Fiji Islands, which are within the boundary of the Australian Station, will be found in the appendix.

"Upon the whole, the sanitary condition of the service afloat in the year 1874 may be considered very satisfactory. The ratio of cases of disease and injury entered on the sick list was below that of the preceding year, and, although there was an increase in the ratio of invaliding to the extent of 2.0 per 1,000, it was attributable altogether to the exceptional character of the duties devolving on the squadron on the West Coast of Africa. There was also an increase of 1.1 per 1,000 in the death-rate, mainly due to the fatal outbreak of yellow fever on the South-East Coast of America; but the ratio of mortality of the total force for 1874 was below that of the average taken for eleven years by 1.5 per 1,000."

THE DEANSHIP OF THE FACULTY OF MEDICINE IN PARIS.

OUR Paris correspondent writes:—"The Faculty of Medicine of Paris has at last found a successor to the deanship vacated by M. Wurtz. Professor Vulpian, well known as an experimental physiologist and pathologist, has, at the unanimous recommendation of his colleagues, been appointed to the post, and was officially installed on the 9th instant. Professors Broca and Sappey are designated as assessors, but their appointment is not yet officially announced."

OPPOSITE EXTREMES.

WE have expressed ourselves strongly as to the great want of judgment, common sense, and propriety, which Dr. Hardwicke has shown on the recent occasion in holding an inquest on the remains of the late Mr. Acton, when there was medical evidence and a medical certificate at hand, showing that the cause of death had been ascertained to be fatty disease of the heart. The following extract, however, exemplifies a practice prevalent among non-medical coroners far more dangerous and far more common, of which examples constantly recur, and to which it is desirable that the attention of the Lord Chancellor should also be directed, that of holding inquests and directing verdicts without any adequate or skilled evidence as to the cause of death. We reported lately an inquest on an infant found in the water, at which the sole evidence as to the cause of death was that of a police-constable, who stated that he imagined (!) that a medical man would find it difficult to say whether the infant had breathed or not. In the following case, the verdict is given on a verbal expression of probability. The case might well be one either of suicide or poisoning, so far as the evidence goes. We quote the report from the *Western Daily Press*.

"*Peculiar Death at the Hotwells.*—Yesterday afternoon, the coroner, Mr. H. S. Wasbrough, held an inquest at the Stork Hotel, Hotwells, on the body of Louisa Newman, aged 40, who was found dead under rather peculiar circumstances. She was the wife of a hotel-keeper living at Cardiff, but had been separated from her husband for some time, and had been employed as barmaid at the Stork. Deceased was to have left her situation on Monday morning, and went upstairs about nine o'clock to pack up her box. She had occasionally been the worse for liquor, but when last seen alive was perfectly sober, and appeared to be in good health. A servant who went into her room about a quarter-past nine, found deceased lying on the floor, with her chin resting on the edge of an open box, quite dead. Mr. Grier, surgeon, was sent for, and, on his arrival, pronounced life to be quite extinct. Mr. Grier, who was examined by the coroner, said he could not form any opinion of the cause of death. There was no trace or indication of poison, the face was very pallid, and death must have been sudden. Deceased might, therefore, have died from heart-disease, but he could not say so with any certainty. A juryman said that the deceased came to his shop a few days since, and then complained of heart-disease. She was then so affected that she had to sit down in the shop. The coroner said he would adjourn the inquest if the jury wished. There was no evidence at present to show how death had occurred, but the circumstances made it very probable that it was from heart disease. The jury returned a verdict of 'Found dead in her room, probably from an affection of the heart.'"

OXFORD EXAMINATIONS.

WE have received copies of the very excellent papers of questions set for the first and second examinations for the degree of M.B. at the University of Oxford. The examination is searching, not only in the scientific but in the practical and clinical departments of study. We note with pleasure in the second examination for the degree of Bachelor of Medicine, a paper on Practical Hygiene, containing the following two questions.

"1. The city engineer, or a person appointed by him, will accompany you to portions of the drainage works. Make any observations or notes you think fit, and return to the Museum at 1, to write an account of what you have seen. (Note-books and pencils will be furnished.)

"2. Make a written report on one of the substances marked *A, B, C, D*, with reference to the adulterations, if any, they might be expected to contain. Examine *A* microscopically, and state if there is any obvious or readily detectable foreign matter in *B, C, D*. If there is, prove it."

EXTRACT OF MEAT.

OUR Paris correspondent writes:—In a recent lecture at the School of Medicine, Professor Bouchardat addressed his audience on the hygienic and therapeutic use of the so-called extract of meat. He stated that those who laud the extract assume that it fully represents the nutritive properties of meat, whilst its detractors look upon it as of doubtful utility as an aliment, and allege that, in certain conditions and exaggerated quantities, it may, after long-continued use, become injurious to the constitution. After describing the immediate principles of the extract, M. Bouchardat went on to say that the nutritive qualities of this substance can on no account be compared to those of the expressed juice of raw meat. The latter contains the albuminoid substances in a form which renders it more favourable for assimilation, and hence its great utility in those cases in which raw meat is refused. With fresh vegetables, however, the extract of meat would make excellent soup, and, as it contains the salts necessary for the reconstitution of muscle, it might, to a certain extent, be usefully substituted for meat in the soup. It may constitute an useful addition to sailors' rations, as the latter consist almost exclusively of salt meat, which is deficient in the very salts which the extract of meat contains.

THE MEDICO-CHIRURGICAL TARIFFS.

WE observe with pleasure, that at the last East Kent District Meeting of the South-Eastern Branch held at Canterbury, the recommendation of the Committee that a copy of the Shropshire Ethical Branch tariffs should be issued to each member, was unanimously adopted. Indeed, as we remarked when reviewing them in the JOURNAL of November 28th, 1874, it would be much for the advantage of the profession if the tariffs were in the hands of every general practitioner in the kingdom. We shall be glad to see other Branches adopt a like course.

SIR THOMAS WATSON ON DR. LATHAM.

IN the new volume of *St. Bartholomew's Hospital Reports*, vol. xi, Sir Thomas Watson contributes a biographical notice of the late Dr. Peter Mere Latham, which will be widely read, both for the sake of the subject and of the writer. It has many passages of scientific interest apart from its literary value and from its beauty as a sympathetic study of the high type of intellectual morality, of which Dr. Latham appears to have presented an example. We select the following, as illustrating certain gains to medicine from the growth of precise knowledge.

"*Treatment of Continued Fever.*—Dr. Latham's first project, in the publishing way, after the commencement of his work at St. Bartholomew's, proved abortive. For ten years he had been collecting and arranging materials for, and was about to put forth, a book on continued fever. His clinical clerks had been chosen with care, his case-books had, by them, been regularly and accurately kept, and their contents analysed and digested by himself. It appeared that he had bled from the arm one in every four of his fever patients, and leeches nearly all of them, with a mortality of seven in the hundred. All that died of the fever were found to have ulcerated bowels. Then, suddenly—it was just after the first invasion of the cholera—a startling change took place. He no longer dared to bleed any of his fever patients; on the contrary, he was obliged to uphold them. Their skins were mottled with an eruption, and often spotted with petechiae. So numerous became the deaths, that time could not be found for examining many of the dead bodies. I think he told me that the mortality was doubled.

"We know now the solution of this perplexing change. The fever which he had been so long watching was typhoid, or enteric fever; the new cases belonged to a severe epidemic of typhus. At that time, the distinction between these specifically different forms of continued fever had not been recognised. His intended book never saw the light."

And we also quote this weighty and ponderable sentence on our modern methods of medical education.

"I (Sir Thomas Watson) would refer to one paper in particular, on medical education, in the first volume of the BRITISH MEDICAL JOURNAL for 1864, because it contains an admirable exhibition of the doctrine, always strenuously maintained by him, that we attempt to teach

our students too much science, to the displacement of practical knowledge. 'The practice of physic', I have heard him say, 'is jostled by quacks on the one side, and by science on the other.'

DEATH FROM ETHER.

THE *Boston Medical and Surgical Journal* for November 25th, 1875, contains the following statement abridged from the *New York Herald* of November 22nd. A man, aged 54, went to the homœopathic college in New York, on Saturday, November 20th. "He was complaining of pain in the left upper jaw extending to the head, with great nervous prostration. There were four openings in the jaw, all discharging fetid pus. On introducing a probe, caries of the upper jaw was found, and the patient was advised to have the bone removed." "He was placed under the influence of ether, and *laid on the table*" (the italics are ours). "A physician was constantly feeling the patient's pulse while the ether was being given." An "incision was made into the upper jaw, and four teeth extracted". The operator was "about to extend the incision, when he noticed the face of the patient become blue. Artificial respiration and the galvanic battery were applied, but they were unavailing; he was dead". The editor of the Boston journal makes the following comment on the case. The reputation of ether, in doses even of a pound or two, has been hitherto pretty good. It has been tried on patients with hearts variously fatty. It will be difficult to persuade us that two and one fourth-ounces of this hitherto beneficent agent proved so suddenly fatal, without any previous gradual diminution of the pulse. It should be conclusively shown that the patient died of nothing else. This patient, so far as we can judge, died of asphyxia from blood in the trachea. In the first place, after he was etherised, he was laid on his back. An "incision" was made in the jaw, and time enough elapsed to extract four teeth. Dead bone always makes the soft parts vascular. There was ample time for blood to fill the trachea. Until it is shown that there was no blood in the fauces and trachea, this must stand as the cause of death. The necropsy is silent on this point. The suddenness and the lividity both belong to asphyxia and neither to etherisation. In the Massachusetts General Hospital, operations on the mouth are usually done in the erect posture, with special attention to keeping the fauces clear of blood.

HUMAN ANATOMY AT CAMBRIDGE.

THE Board of Natural Sciences Studies has issued a report recommending that human anatomy should occupy a more prominent and definite position in the examination for the natural sciences tripos. The reasons assigned for the proposal are, first, that medical students who are candidates for the tripos, find it necessary to relinquish the study of human anatomy till after the examination for the tripos; and many are therefore deterred from making the attempt to obtain a degree with honours. Secondly, the more distinct recognition of human anatomy in the examination for the tripos cannot fail to elevate the character of the teaching and study of it in the University as a branch of science, especially as it is contemplated by the Board that the subject of human anatomy shall include the mechanism of the human body, the comparison of its parts with those of lower animals, its development, etc. Thirdly, the addition would also help to maintain the connection between the schools of natural science and medicine. In the discussion which took place on the subject in the Arts Schools, it was objected by Dr. Bradbury, that human anatomy, especially relational anatomy, is not a good subject of education, though it might be necessary to instruct in it students who were preparing to be physicians and surgeons. To this it was replied by Professor Humphry, that, if taught simply as a collection of facts, and with reference only to the requirements of the medical examination, he quite admitted that it did not constitute a good educational subject. The object of the report was to redeem it from this position, to associate it with the thoughts and views which properly belong to it, and to maintain its study in a manner worthy of the University. If studied as it ought to be, and as it could only be by being made a subject in the tripos, it was an excellent medium of education, combining, in as great a degree as any other

study, the exercise of thought with the observation of facts. Encouragement would thus be given to the students to pursue it in a higher and better manner. Mr. Trotter also thought human anatomy, in the wider sense in which the term was used in the report, was a very fair subject for examination, and he wished to see the connection between the medical and natural science schools kept up.

FOREIGN CRITICS OF THE BRITISH MEDICAL ASSOCIATION.

DR. NOEL GUENEAU DE MUSSY has recorded his impressions of the meeting of the British Medical Association at Edinburgh in a series of brilliant *feuilletons* published in successive numbers of *La France Médicale*. He notes with gratification the appreciation accorded to the labours of the French physicians and surgeons, and regrets that his colleagues, Claude Bernard, André Bouillaud, Duchenne de Boulogne—the two latter of whom have since passed away—could not have been present to enjoy the warm reception with which they would have been welcomed at Edinburgh. He then proceeds to speak of the pleasure he felt in hearing justice done by the eminent surgeons present at the meeting to the labours of Chassaignac, and the valuable methods with which he had enriched the art of surgery. Dr. Gueneau de Mussy remarks on the importance of the part played by the British Medical Association as compared with any medical society in his own country, and notes the utility of the Association in amicably bringing together all the strength of the profession at some given city of Great Britain, there to report the progress of medical science and its latest discoveries; and to discuss the most important questions of State Medicine and of professional interest. Hence, writes Dr. Gueneau de Mussy, the eminent men who preside over the great centres of medical education are brought yearly into contact with their colleagues, whose duties place them in a more restricted sphere; and from these meetings there result a considerable spread of enlightened opinion, and the formation of a firm bond of fellowship. Dr. Gueneau de Mussy, who was also present with Mr. Gladstone at the London meeting, attributes to the British Medical Association a considerable influence with the ruling authorities of the State, and traces to its efforts a large share in the improved sanitary legislation and organisation of the country, in the reform of the educational establishments, and the formation of the General Medical Council. He has not failed to appreciate the successful exertions of the British Medical Association on behalf of the Military, Naval, and the Poor-Law Medical Services; whilst the British Medical Benevolent Fund also receives its meed of approval from our kind and able critic. The *Archives Générales de Médecine*, the leading medical periodical of France, also reviews at length the proceedings of the Edinburgh meeting, gives a brief summary of the organisation of the Association, and flatteringly places the BRITISH MEDICAL JOURNAL at the head of the medical periodicals of Great Britain; a complimentary judgment which we are proud in any degree to have merited, and shall do our utmost to deserve.

SCOTLAND.

MR. JAMES M. MILNE of Glasgow has been appointed Public Analyst for Dunfermline.

AT the annual meeting of the subscribers to the Kilmarnock Fever Hospital and Infirmary, the report was read, stating that 291 patients were admitted during the year, of whom 26 died. The total income was £1,615, while the amount actually expended was £983.

THE scheme of Mr. Gale for supplying Mid-Lanarkshire with water may be now said to be practically rejected. The boroughs of Wishaw and Motherwell prefer supplying themselves to joining in the undertaking; and the Local Authority of Cambusnethan, a large centre of population, refuse to entertain Mr. Gale's scheme.

IT is stated that the total expenditure on the New Infirmary, Edinburgh, will not be less than £300,000, of which about £140,000 has already been spent, including the purchase of the site.

AN Edinburgh tobacconist was last week fined in the mitigated penalty of £50 for having in his possession tobacco which, on examination, was found to contain sugar and liquorice. The full penalty for the offence is £200.

AT a recent meeting of the Royal College of Surgeons of Edinburgh, Dr. Joseph Bell was appointed Secretary and Treasurer of the College, and Dr. J. Blair Cunynghame Conservator of the College Museum. We understand that it is intended to make more use than has hitherto been done of this magnificent collection, in the interests of medical science, and for the instruction of medical students.

PROPOSED HOSPITAL ACCOMMODATION FOR DUMBARTON.

A CONFERENCE was held last week, between the Dumbarton Local Authority and the representatives of the Bonhill and Cardrop Local Authorities, for the purpose of considering the propriety of uniting to provide hospital accommodation. After a long discussion, it was agreed that an arrangement should be come to, whereby the Dumbarton Local Authority might retain the management of the hospital, and, by the payment of a certain sum, the other parishes could obtain the right to a certain number of billets; and a committee was appointed to draw up a basis of agreement.

BIRTHS AND DEATHS IN SCOTLAND.

FROM the Registrar-General's return for the past month, we learn that there had been registered in Scotland the births of 3,545 children, 1,866 being males, and 1,679 females. Of these births, 305 were illegitimate—that is to say, 8.6 per cent. of the whole, the rate ranging considerably in the large towns, from 5.8 per cent. in Paisley to 13.4 in Perth. The deaths of 2,465 persons were registered, being 27.0 below the average. The highest rate of mortality was in Greenock, being there equal to an annual mortality of 36 per 1,000; the lowest among the large towns was Perth, with 20 per 1,000. In Greenock, 64 per cent. of the persons who died were under five years of age. Zymotic diseases constituted 23 per cent. of the total mortality; this rate was exceeded in Edinburgh owing to the prevalence and fatality of scarlet fever; and, in Greenock, from the simultaneous presence of scarlet fever, measles, and whooping-cough. Scarletina alone caused 7.2 per cent. of the whole mortality; while in Edinburgh, 16.9 per cent. of the registered deaths were ascribed to this cause. Of the whole mortality, 21.5 per cent. was due to inflammatory affections of the organs of respiration.

VENTILATION OF DRAINS AND SEWERS.

AT a recent meeting of the Royal Scottish Society of Arts, Dr. Stevenson Macadam read a paper on the Ventilation of Drains and Sewers, and the Cleansing of House Cisterns. The water-carriage system of disposing of sewers he thought pernicious; it poisoned the streams and the air above them, and promoted disease in households. He drew attention to a mode by which the evils of the present system might be lessened or modified. In order to prevent the return of foul gases from the main sewer, he suggested, in addition to the ordinary syphon-trap at the water-closets, there should be an U-shaped trap between the main sewer and the house, from which trap a fine clay pipe should lead to the air with a charcoal absorbent cage at the top. There followed upon the paper a discussion on the general subject of sanitary arrangements, in which the Liernur system found pretty general approbation.

THE MILK IN FOOT-AND-MOUTH DISEASE.

AT a meeting of the local authority for the parish of Cambusnethan, the sanitary inspector gave in a report which stated that, on November 18th, Dr. Millar, of New Mains, had called the attention of the in-

spector of poor and himself to the cases of a number of children in the village of Waterloo who, he thought, had been made ill with milk supplied by a dairyman in Carluke. He had visited seven different families at Waterloo who had been supplied with the milk, and found that all who had used the milk had been taken ill. Altogether, about thirty persons had been affected; but none of the cases ended fatally. Samples of the milk had been sent to Dr. Wallace, of Glasgow, for analysis; but he could find no poisonous substance in it. It was not known at that time, however, that the dairyman's cattle were affected with foot-and-mouth disease. After a discussion, the Board came to the conclusion that it could do no more in the matter than had been done already.

UNIVERSITY OF ST. ANDREW'S.

AT the last meeting of the General Council of the University of St. Andrew's, Dr. Benjamin Ward Richardson, F.R.S., was unanimously appointed Assessor to the University Court, in place of Patrick Anderson, Esq., resigned. Dr. Richardson was proposed in an appropriate speech by Dr. Archibald, and seconded by Mr. Robb, M.A. This is the second time that Dr. Richardson has had the honour of being elected Assessor.

IRELAND.

THE deaths in Dublin for the week ending December 11th, exceeded the average by 35, which was attributable to the low temperature, the mean for the week being 9.2 degrees under the average for the corresponding week of the years 1865-74.

SCARLATINA NEAR LURGAN.

AT the present time, scarlatina is exceedingly prevalent about Lurgan, and a number of deaths are daily taking place from this malignant disorder. On last Saturday, within a short distance of the town, seven deaths took place, and such an outbreak has not been remembered for many years.

LUNATIC ASYLUMS.

THE Report of the Inspector of Lunatic Asylums in Ireland for 1874 is an interesting one, and from it we learn that the number of lunatics in Ireland was increased by 80 over that of the preceding year. The number of registered lunatics had increased, and that of the unregistered—those at large—had diminished. The slight increase is explained by the fact that more extended views of lunacy now exist, and many mental conditions are now placed under the head of insanity which formerly were not; besides this, asylum accommodation has greatly increased, so that more patients have been able to avail themselves of the advantages of seclusion and proper treatment. The average number of lunatics has been placed at 2.14 per 1,000 of the population, and it is remarkable that in Ireland the married bear to the single the proportion of 2 to 5; the exact reverse, we believe, taking place in England. The accommodation of the district asylums is at present insufficient for existing wants, the inmates being about 1,000 in excess of what the number ought to be. Attached to the various asylums are small farms, which are cultivated by the lunatics; and the Inspectors recommend the enlargement of these farms when practicable, as no curative agent or sanitary treatment is more calculated to benefit the patients than outdoor exercise combined with employment. The inspectors draw attention to the inconsiderate and unreflecting way in which magistrates commit lunatics to asylums as dangerous, without taking the proper and necessary precautions to ascertain the true facts of the case. As regards the curability of insanity, it may be confidently stated, that the sooner the treatment is commenced, the greater will be the ultimate restoration to reason. Out of 1,176 patients discharged from the asylums cured or improved, 429 were sent out within four months, 339 in less than eight months, whilst 361 were discharged in perfect health under the age of 30, and 569 between the ages of 30 and 40.

TESTIMONIAL TO PROFESSOR APJOHN.

ON last Wednesday, the 22nd inst., a portrait in oil painted by Mr. Jones, P.R.H.A., was presented to this gentleman at the College of Physicians, Kildare Street, Dublin. The likeness is an admirable one, and bears on a plate attached to the frame the following inscription:—"Presented to Professor Apjohn, M.D., by a few of his friends and former pupils, December, 1875."

THE MEDICAL COMMISSIONERSHIP OF THE IRISH LOCAL GOVERNMENT BOARD.

UNPLEASANT rumours as to the probable suppression of this office are still afloat in Dublin, but we believe we have good grounds for holding to the opinion expressed some time since, that the Government has no present intention of abolishing the office. It may be well to remind our readers, that the Irish Government has only two medical officers employed in its executive departments in Dublin, namely, the Medical Commissioner of the Local Government Board, and the Medical Superintendent of Statistics at the General Register Office. In short, upon these two gentlemen alone can the Government rely for official medical advice. To abolish either office at the present time would be most inopportune; especially to abolish that office upon which, it may be said, the efficiency of the whole sanitary and civil medical service of Ireland depends. We understand that Dr. McDonnell has not yet resigned his Commissionership, and, until his resignation has taken place, it would be useless to state in any authoritative manner who will be his successor. We may, however, mention that the question has been much discussed in Dublin, and that by general consent Dr. Burke of the General Registry Office is admitted to be the most likely successor to Dr. McDonnell. Of other candidates, there is one in the field of unusually high qualifications; but, unquestionably, should the Government decide to select Dr. Burke, they will secure an active, able, and highly experienced head for the most important medical department in Ireland.

SURGEONS' FEES IN DUBLIN.

A CASE, not only of very considerable interest, but also of professional importance, has just been decided in the Dublin courts. Mr. Croly, the well known surgeon to the City of Dublin Hospital, was consulted by a wealthy country gentleman with regard to a disease of the rectum. Mr. Croly found that operative interference was necessary. The patient, accordingly, acting on Mr. Croly's advice, took lodgings in Dublin, and placed himself under Mr. Croly's care. An operation was performed, and the patient progressed favourably; but, being of a nervous and hypochondriacal disposition, he was not satisfied with the amount of attention Mr. Croly gave him, and was constantly and unnecessarily sending for Mr. Croly to attend him at all hours of the day and night. Not only did the patient himself demand all this excessive, and in Mr. Croly's opinion unnecessary, attention, but on many occasions he requested Mr. Croly to prescribe for members of his family. The result was, that Mr. Croly paid the patient and his patient's family over four hundred visits; many of these visits were at night, and many of them included advice to several patients. Mr. Croly, not having been paid his proper fees, made a demand for the very moderate sum of £300 for this laborious attendance, the operation included. Mr. Croly was refused this fair demand, and brought an action for the amount claimed. The defendant paid £200 into court, but the jury awarded the full amount claimed, apparently on the ground that a demand for one guinea for each ordinary visit, and two guineas for each visit at night, were not excessive charges, and that Mr. Croly had made a very moderate charge. Many members of our profession would shrink from running the risk of the "uncertainties of the law" in such a case, and would rather take what they could get than enter upon litigation. We think Mr. Croly was right in submitting his case to a jury; and, while we congratulate him on his success, we have to thank him for fighting out at great risk and inconvenience a battle, the result of which will be a lasting benefit to our profession in Dublin.

THE NEW EDINBURGH, FIFE, AND LOTHIANS BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

THE adjourned meeting of the new Branch of the Association, which is to include the members residing in Fife and the Lothians, took place in Edinburgh, on Friday, December 17th. In the unavoidable absence of Sir Robert Christison, Dr. Matthews Duncan took the chair; and the meeting passed, with some modifications, a code of laws which had been drawn up by the committee appointed for that purpose at a previous meeting. The following gentlemen were elected office-bearers—*President*: Sir R. Christison, Bart. *Vice-Presidents*: Dr. Matthews Duncan and Professor Lister. *Treasurer*: Dr. Coghill. *Council*: Dr. Begbie, Dr. Keiller, Dr. Macrae (Penicuik), Dr. Gillespie, Dr. Ballantyne (Dalkeith), Dr. McKendrick, Dr. Gordon (Juniper Green), Dr. J. W. Moir (St. Andrew's), Dr. Tuke, Dr. Constable (Leuchars), Dr. James (Dunbar), Dr. Hunter (Linthgow). *Secretary*: Dr. C. E. Underhill (Edinburgh). All members of the Association residing in the above-named counties are invited to join the Branch. The secretary will be glad to receive the names of those who intend joining.

THE NEW GLASGOW AND WEST OF SCOTLAND BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

AT Glasgow also, as we last week announced, it has been resolved at a special meeting of the profession to form a Branch of the British Medical Association, respecting which our Glasgow correspondent writes to us this week as follows.

We believe that, with the simultaneous formation of Branches in Edinburgh and Glasgow, the British Medical Association will greatly increase its membership and strength in Scotland. From anything we can learn, the Glasgow and West of Scotland Branch is likely to meet with very general and extensive support. Of course, little can be said about this till after the next general meeting; but there are signs which seem to indicate a much greater amount of sympathy with its objects than could almost be looked for. To the members of the Association living in large towns in the West of Scotland, or in populous country districts, we would point out a means by which this Branch might be made peculiarly useful to them. That is by forming district societies under the Branch. This is done in connection with the South-Eastern, Southern, and other Branches in England, and we can conceive that societies of this kind would be a very useful means of drawing the profession closer in our larger towns, where they might take the form of mutual improvement societies, for reading papers, showing cases and specimens, and so on. We would commend this to the attention of members outside of Glasgow. As to Glasgow itself, it is clear to everyone that it has enough of purely medical societies already. There is undoubtedly abundant room for a Branch of the Association, but it will probably confine itself, so far as Glasgow is concerned, to occasional special meetings, and an annual gathering or congress of the profession, at which subjects of general professional interest may be discussed, and, if necessary, special committees appointed to report. We conceive that such a meeting and organisation will be of the greatest use; it will help to elevate the profession, and draw closer the bonds of professional brotherhood. We have no doubt that the Branch will be a thorough success.

THE ROYAL COLLEGE OF PHYSICIANS.

A MEETING of the Comitia Majora of the Royal College of Physicians was held on Monday last, the Treasurer of the College (Dr. Farre) being in the chair, in the absence of Sir George Burrows, who was suffering from indisposition, and was unable to attend. After the transaction of some formal business, such as the granting of licenses, fixing the seal of the College to the diplomas of Fellows, and receiving a communication from the General Medical Council, formally applying for a return of qualifications granted by the College during the year, a report was presented from the Leprosy Committee, in answer to a communication received from the Colonial Secretary, Lord Carnarvon, in which he called the attention of the College to some statements made in the *British and Foreign Medico-Chirurgical Review*, and asked the College whether the opinion already expressed by it on the subject would be influenced by the statements contained therein. The Committee recommended the College to express as its opinion that there

was nothing sufficiently definite in the statements to justify the Committee in recommending the College to modify its opinions formerly expressed. The report further recommended that it should be suggested to the Colonial Secretary that, in any case where it was necessary to report on the occurrence of disease and other professional matters in the colonies, an effort should be made to obtain comprehensive and precise statements of the conditions upon which an opinion could be formed. The report was adopted; and it was ordered that a communication in accordance therewith should be addressed to the Colonial Secretary.

A Report from the Committee appointed to inquire into the regulations of the College on the use of the title of "doctor" by persons not being graduates in medicine of an University, was read and ordered to be considered at the next meeting. It was desired that the report should be regarded as confidential until after its discussion by the College. We feel at liberty, however, to say that, in our opinion, the report of the Committee will be alike satisfactory to the College and to the profession.

AMERICAN CENTENNIAL CELEBRATION: INTER- NATIONAL MEDICAL CONGRESS.

WE are requested to publish the following, which will commend itself to the attention of our readers.

The Medical Societies of Philadelphia, animated by a just spirit of patriotism, and an earnest desire to unite with their fellow-citizens in celebrating the Centennial Birthday of American Independence, have taken the initiatory steps for the formation of an International Medical Congress, by the appointment of delegates from their respective bodies, who were empowered to organise and perfect a scheme for the above purpose. In accordance with the authority thus given, the delegation has organised "The Centennial Medical Commission", with the following officers—*President*: Samuel D. Gross, M.D., LL.D., D.C.L. Oxon. *Vice-Presidents*: W. S. W. Ruschenberger, M.D., U.S.N., and Alfred Stillé, M.D. *Recording Secretary*: William B. Atkinson, M.D. *American Corresponding Secretaries*: Daniel G. Brinton M.D., and William Goodell, M.D. *Foreign Corresponding Secretaries*: Richard J. Dunglison, M.D., and R. M. Bertolet, M.D. *Treasurer*: Caspar Wister, M.D.

Arrangements have been made for holding the Congress in the city of Philadelphia, to begin on the 4th and to terminate on the 9th of September, 1876. The Commission propose the following general plan for the organisation and business of the Congress.

I. The Congress shall consist of delegates, American and foreign, the former representing the American Medical Association and the State and Territorial Medical Societies of the Union; the latter the principal medical societies of other countries.

II. The officers shall consist of a president, ten vice-presidents, four secretaries, a treasurer, and a committee of publication, to be elected by the Congress at its first session, on the report of a committee of nomination.

III. The morning sessions of the Congress shall be devoted to general business and the reading of discourses; the afternoons to the meetings of the sections, of which there shall be nine, viz: 1. Medicine, including Pathology, Pathological Anatomy, and Therapeutics. 2. Biology, including Anatomy, Histology, Physiology, and Microscopy. 3. Surgery. 4. Dermatology and Syphilology. 5. Obstetrics and Diseases of Women and Children. 6. Chemistry, Toxicology and Medical Jurisprudence. 7. Sanitary Science, including Hygiene and Medical Statistics. 8. Ophthalmology and Otology. 9. Mental Diseases.

IV. The language of the Congress shall be the English, but not to the exclusion of any other language in which members may be able to express themselves more fluently.

Gentlemen intending to make communications upon scientific subjects, will please notify the Commission at the earliest practicable date, in order that places may be assigned them on the programme.

In order to impart to the Congress a thoroughly international character, invitations to send delegates will be extended to all the prominent medical Societies in Europe, Mexico, the British Dominions, Central and South America, the Sandwich Islands, the East and West Indies, Australia, China, and Japan. Invitations will also be tendered to medical gentlemen of high scientific position; and distinguished visitors may be admitted to membership by a vote of the Congress.

Among the advantages arising from such a convocation as this, not the least important will be the opportunity afforded its members for the interchange of friendly greetings, the formation of new acquaintances, and the renewal and cementing of old friendships.

The Centennial Medical Commission tender in advance to their brethren in all parts of the world a cordial welcome, and a generous hospitality during their sojourn in the "Centennial City".

The Congress will be formally opened at noon, on Monday, the fourth day of September, 1876. The registration book will be open daily from Thursday, August 31st, from twelve to three P.M., in the Hall of the College of Physicians, north-east corner of Thirteenth and Locust Streets. Credentials must in every case be presented.

Gentlemen attending the Congress can have their correspondence directed to the care of the College of Physicians of Philadelphia, north-east corner of Locust and Thirteenth Streets, Philadelphia, Pennsylvania.

There is every reason to believe that there will be ample hotel accommodation for all strangers visiting Philadelphia in 1876. Further information may be obtained by addressing the corresponding secretaries.

All communications must be addressed to the appropriate secretaries (all in Philadelphia): William B. Atkinson, 1400 Pine Street, *Recording Secretary*; Daniel G. Brinton, 2027, Arch Street, and William Goodell, Twentieth and Hamilton Streets, *American Corresponding Secretaries*; Richard J. Dunglison, 814, N. Sixteenth Street, and R. M. Bertolet, 113, S. Broad Street, *Foreign Corresponding Secretaries*.

SPECIAL CORRESPONDENCE.

BIRMINGHAM.

[FROM OUR OWN CORRESPONDENT.]

The Queen's Hospital.

THE following is an abstract of the regulations adopted by the Committee of the Queen's Hospital, Birmingham, for the working of the non-privileged system of admission. This is the first instance of a large general hospital adopting the free system controlled by inquiry and selection. The regulations, therefore, are offered subject to modification and correction by experience. It is further premised that the hospital is designed to deal with two classes of cases: 1. Those who, from accidents or attacks of acute disease in a serious form, must pass at once into the wards; and 2. Those who, not needing in-door treatment, need the advice of skilled consultants or specialists.

As regards the former, the sole consideration for admission must be physical necessity, and no inquiry or payment is proposed; as regards the latter, many trivial cases now treated at the hospitals ought to be left to dispensaries, sick clubs, and private practitioners; so that the staff of the hospital may have leisure to deal effectually with cases of a more serious character. The operation of a registration fee, combined with inquiry into circumstances, will, it is believed, lessen the number of such cases, and promote a reform urgently needed. Those patients also for whom provision is made out of public rates must be regarded as unfit for hospital treatment, unless specially recommended by the parochial medical officer. With regard to the inquiry, it is obvious that other than pecuniary circumstances must sometimes be taken into account, such as the nature of the case, previous efforts to obtain relief, etc., regard being always had to the essential feature of hospital charity; namely, that no applicant whose necessities entitle him to assistance shall be denied access to the best means of advice or restoration which the hospital can afford.

The following are the regulations. No further tickets of admission will be issued, excepting (if they desire it) to life-governors. On and after January 1st next, patients will be required to apply to the secretary between the hours of 9 and 10 A.M. for town patients, nine and eleven for country patients, for orders of admission; and, on receiving such order, each applicant shall pay one shilling as a registration fee, such fee to cover the whole period of attendance. Serious accidents and urgent medical cases, *i.e.*, acute disease of recent origin, will be at once admitted to the wards without inquiry or payment, subject only to the available beds and the judgment of the medical staff as to necessity. In all cases other than accidents or emergencies, inquiry shall be made into the fitness of the applicant for hospital relief; inquiry as to available income, number and ages of family, nature and duration of ailment, and any special circumstances. In ordinary cases, an income of thirty-five shillings a week, with not more than four children, or six persons, in a family, will be regarded as the limit of pecuniary fitness. If satisfied as to such fitness, an admission to be given.

Any special case, having been under the care of a qualified medical man, and recommended by him, is to be received.

Those in receipt of parish relief are to be received only on the recommendation of the parochial surgeon.

Appeal in all cases is to lie to the House Committee, who will have general superintendence of the carrying out of the above regulations.

MANCHESTER.

[FROM OUR OWN CORRESPONDENT.]

Proposed Removal of the Infirmary.—The Manchester Medical Society.

THE question whether it is desirable to remove the Infirmary is still left unanswered; and the result of the quarterly meeting held last Monday (December 20th) is that the whole question will have to be gone into again. At a meeting of trustees held at the Town Hall in October, the original motion, "that it is advisable to dispose of the Infirmary site, and remove the institution", was passed, with the proviso that, in any negotiations for the sale of the property, due regard shall be had to the preservation of an open area of land not materially less than that which at present exists. The effect of this amendment was to so seriously interfere with the plans proposed, that they had to be abandoned. At the last quarterly meeting, it was moved and seconded, that the minutes of the special boards held during the quarter be confirmed. To this, the ex-mayor submitted an amendment, to the effect that the proceeding of the weekly board be confirmed, with the exception of that relating to the sale or disposal of the Infirmary site. The amendment was passed. The ex-mayor also moved, and his proposition was carried, that the weekly board be requested to summon a special general meeting of trustees for the purpose of appointing a Committee to consider: 1. Whether it is desirable to change the site of the Infirmary; 2. If so, to determine what steps to be taken for the disposal of the property; and, 3. As to the application of any moneys which may be obtained. We shall anxiously look forward for the answers of the Committee to the above questions. It has been unanimously decided by the medical staff that the removal of the Infirmary would be to the advantage of the classes for whom it was established; that the present building is utterly insufficient and bad in construction. The objectors to the scheme speak of the central position of the building; but a receiving house, with about fifty beds, in the immediate vicinity, would have been provided had the proposition of the weekly board been adopted; so that this objection at once falls to the ground.

The library of the Medical Society, consisting of about twenty thousand volumes, has been safely deposited in the new medical school building connected with Owens College; and the meetings of the Society will henceforward meet in a room provided by the College. The microscopical section will hold its meetings in the Physiological Laboratory, where plenty of microscopes are kindly lent for the use of the members.

GLASGOW.

[FROM OUR OWN CORRESPONDENT.]

Glasgow University and the Recognition of Andersonian Lectures.—The Chair of Physiology.

A RECENT action of the University Court of Glasgow University has, perhaps, hardly received so much attention as it deserves. This body has, for the first time since its constitution, recognised the lectures of one of the teachers in Anderson's University. Those who know the history of Anderson's University, have not been surprised that Glasgow University has withheld recognition from its lecturers. It was founded according to the will of a professor in Glasgow University. This learned gentleman, having quarrelled with his own school, resolved to found one which should rival and ultimately eclipse the national institution. His will bears the impress of hatred towards the University, and the resolve to do his best to supplant it. No one having the remotest connection with the old University is to be allowed to hold office as one of the eighty trustees of the new. It was natural that the University should have scruples in recognising an institution whose foundation was a menace to itself. But there were other reasons for being chary in giving this recognition. The chief of these was the name assumed by the institution, which, according to the will, was called Anderson's University. Now, we state no more than what has come under our own personal observation repeatedly, when we say that this name has been the means of misleading students. We can well suppose that a student in the South of England or in Wales will hardly understand the difference between Anderson's University in Glasgow and the University of Glasgow, especially when he finds the advertisement of the former occupying half a page of the weekly medical journals, and that of the latter half a column. We know of several who have joined the Andersonian, expecting to get a degree there; and who only learnt, too late, that their classes would not count for Glasgow University. We believe that even some of your readers are not aware that the Andersonian is a purely private institution, having

no royal or other charter. A short time ago, it was reported that some one interested in the Andersonian, but somewhat ignorant of its true position, while in conversation with a well known member of the profession, spoke of the advisability of trying to get powers by which they could grant degrees in medicine. In order to this, he thought they might apply for a new charter. "Faith," was the answer, "you had better get an old one first." We have mentioned these facts to show that, in recognising a teacher in this institution, the University Court have given evidence of their intention to admit free trade in teaching. So long as there was no medical teaching outside the University, except in the Andersonian, they seemed to hesitate to recognise teachers there, because it would be like recognising the institution, and it would be encouraging the idea of a corporate body of teachers. But now, when there seems a likelihood of numerous teachers springing up in connection with the Royal Infirmary, they seem to be prepared to recognise all. This is a most important step, and one likely to give a great impetus to medical education in Glasgow.

The note in your pages of last week concerning the vacancy in the Chair of Physiology has taken some of the Glasgow people rather aback. Some have felt that the strong advocacy of one of the candidates at this early date is rather premature, especially as there is a well known Glasgow man in the field. Dr. Eben Watson will, no doubt, be a candidate; and he is recognised as a man of very decided ability and attainments. It is not for us to speak of the respective merits of the several candidates; but it seems a pity to prejudge the case at once, and your observations should not be read in that sense.

ASSOCIATION INTELLIGENCE.

BATH AND BRISTOL BRANCH.

THE next meeting of the above Branch will be held at the York House, Bath, on Thursday, January 20th, 1876, when a discussion on Cerebro-spinal Meningitis (based on Dr. Cole's paper, printed at page 667 of the JOURNAL) will be opened by Dr. Brabazon.

R. S. FOWLER, Bath. } *Honorary Secretaries.*
E. C. BOARD, Clifton. }

Bath, December 15th, 1875.

SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT MEETING.

A MEETING was held on December 9th, 1875, at the Greyhound Hotel, Croydon; T. R. ADAMS, M.D., in the Chair. There were present, thirty members and six visitors.

Perforate Bronchia.—Dr. HOLMAN stated, that the second attempt by actual cautery to close the still perforate bronchia, mentioned by him at the last meeting, had succeeded.

Papers were read by Dr. Wiltshire, on Puerperal Hyperpyrexia treated by Dry Cold; by Dr. Tilbury Fox, on Lichen Planus or Ruber; by Mr. C. Heath, on a Case of Suppression of Urine for Calculus in the Urethra; by Dr. Duncan, on various Forms of Apoplexy, with reference to Prognosis; by Dr. Holman, on a Case of Partial Placental Presentation with Contracted Os. Mr. Christopher Heath exhibited specimens of Cystine Calculi.

Next Meeting.—It was agreed that the next meeting should be held at the Crystal Palace Hotel on March 9th; J. H. Galton, Esq., in the Chair.

Dinner.—Twenty-seven members and five visitors sat down to dinner.

BATH AND BRISTOL BRANCH: ORDINARY MEETING.

THE second ordinary meeting of the session was held at the College Green Hotel, Bristol, on Thursday, December 9th, at half-past seven o'clock; W. M. CLARKE, Esq., President, in the Chair. There were present thirty-nine members and five visitors.

New Members.—Dr. James Stewart, Dr. E. Markham Skerritt, Dr. Donald Campbell of Calne, and Mr. W. H. Marsant, were duly elected members of the Association and of this Branch.

Communications.—1. Dr. SWAYNE read a case of Thrombus of the Vulva during Labour, and also a case of Inversion of the Uterus.—Mr. BAKTRUM made some remarks; and Mr. J. PARSONS mentioned two cases of thrombus which had occurred in his practice.

2. Mr. THOMPSON brought before the meeting the case of a Female Lunatic who had swallowed thirteen Iron Screws, each weighing upwards of 700 grains, the patient being still alive, and having passed five of the number.—Dr. MARSHALL read a record of the case of a

Sailor who had swallowed forty Clasp Knives in ten years, and who died soon after swallowing the last six or seven.—Dr. SWAYNE, Dr. CADDY, Dr. EAGER, Mr. TIBBITS, and Mr. W. M. CLARKE, also mentioned similar cases.

3. Dr. MARTYN read an interesting case of Double Thrombosis of both Middle Cerebral Arteries in a Syphilitic Patient, and exhibited the specimen. This led to a lively discussion on the connection between syphilis and arterial disease, in which Dr. Fyffe, Dr. Beddoe, Dr. Spender, Mr. Lansdown, and Mr. W. M. Clarke, took part.

4. Mr. R. M. STONE exhibited two large Calculi spontaneously expelled by an aged female.

The attention of the meeting was called to the fact that, at the next meeting, the discussion would be on cerebro-spinal meningitis.

CORRESPONDENCE.

PREVENTION OF PYLEMIA IN HOSPITALS.

SIR,—I wish to suggest two methods of ventilating wards that would prove effectual against those scourges, erysipelas, pyæmia, etc.

1. To drive pure warm air twice or oftener daily through the wards by a portable engine constructed with a stove and air-chambers, and a supply-pipe passed out of a window. The windows would be opened, and the engine would be worked after the manner of a fire-engine.

2. Free exposure to pure cold air twice or oftener daily, by all the windows being fully opened, whilst the patients are enveloped in tar paulins or impervious bed-clothing.—I am, sir, your obedient servant,
FREDERICK J. BROWN, M.D.

Rochester, December 11th, 1875.

HOSPITAL ABUSES.

SIR,—The enclosed letter, which by an accident only reached me to-day, puts in a very clear light the injury which our present hospital system does to many of our provincial brethren, and entirely supports the statement made by Mr. Wordsworth a few months ago in the JOURNAL, that the abuses connected with in-patients are quite as great as those connected with out-patients. Can anything be more absurd than that people moving in good society in the country—one "the aunt of a banker", another a gentleman "worth thousands"—should, upon a question of the amount of fee arising between them and their surgeon, be able to say, "Very well, we shall go to London, and get it done for nothing; and the surgeon there will not only raise no objection, but most likely will solicit us to come into his hospital"; and, alas! be able to say this with truth? The cool impudence of the thing strikes one at once; and, did we not know it for a fact, we could hardly believe that a system which rendered such imposition possible would be upheld by any man belonging to the same profession as the surgeon, and, least of all, under the sacred name of charity.

December 7th.

I am, etc.,

H. NELSON HARDY.

"Dear Sir,—I was pleased to see your letter in the BRITISH MEDICAL JOURNAL; but I do not think you see quite the spirit of the motion. It was particularly directed to the great encouragement given by hospital surgeons to cases of operation, which they only too willingly take as *in-patients*, and thus rob their country medical brethren. It is the old dog-and-manger system. If the person cannot pay the regular fee of the London hospital surgeon, the system is to do it for nothing, rather than the provincial general medical man shall do it for a fee that will quite remunerate him. Of late, it has been getting so bad, that people coolly tell country surgeons that, unless you do it on their terms, they will go to London and get it done for nothing. At this present time, I have a patient the aunt of a banker, who moves in the best society, but has the impudence to tell me that, if a large fee be charged, she will go to a charitable institution. She has been operated on before. This lady positively looks down on the medical profession as being a grade beneath her.

"I could tell you of dozens of cases; in fact, it is getting most monstrous. Even to-day, a man worth thousands is threatening similarly, unless the operation is performed at his price. A patient the other day told me that the London surgeon begged her to come into the hospital, although she was quite willing, as she said, to pay a fair fee, and had agreed with a surgeon for that fee. Some of the surgeons of Moorfields perhaps sin in this way more than any other surgeons; but almost all London operating surgeons do it more or less. No wonder we have so many starving members in our profession, when the big fat fish in our community think it honourable thus to swallow the small fish. If you can do anything to lessen this increasing evil, you will deserve the thanks of all the country general practitioners."

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, DECEMBER 21ST, 1875.

G. D. POLLOCK, F.R.C.S., President, in the Chair.

Hæmorrhagic Periostitis.—Mr. THOMAS SMITH exhibited drawings, and gave an account of a case of this nature. He gave it this name because he could not find a more appropriate one for it. It occurred in a female child, twenty-three months old, which was brought to the Children's Hospital. It was a hand-fed child, free from syphilis. It had never walked alone. Eleven months before admission, its feet had swelled without redness; in the summer, it quite recovered. Two months before admission, its feet again swelled. On admission, it was found pale and rickety; its bowels loose; urine red; a bad cough; œdema of the lower extremities; and at its knee-joints could be heard crepitation at the epiphyses. Its abdomen was natural; temperature 101.4 deg. Several epiphyses were loose. Steel wine and iodide of potassium were given, but the cough continued; and the child died seven days after its admission. A *post mortem* examination was made twenty-four hours after death. Extravasation of blood was found in the muscles of the lower limbs. The periosteum of the femur was quite loose all over, and thickened. The shaft of the bone was also loose from its epiphyses, and surrounded by a maroon coloured clot. There was no suppuration. In the left tibia, the same condition was found, but less marked. There were also in the leg extravasation of blood and loose epiphyses, with detached periosteum. The left fibula was in a like condition; the ankle was healthy. The right side was much the same. There was crepitus at the shoulder. The abdominal viscera were healthy, and so was the heart. In the lung, there was a patch of congestion.—Mr. WAGSTAFFE asked if there was any hæmorrhagic diathesis.—Mr. SMITH replied none that could be made out. The periostitis came first, and the hæmorrhage after.—Dr. GOODHART said that a similar case occurred at Guy's Hospital some time ago. The left leg was amputated, and the periosteum was found detached.—The PRESIDENT agreed with Mr. Smith's view, that the hæmorrhage was secondary to the periostitis and the detachment of the epiphyses. He had seen a case lately at St. George's Hospital, a boy aged 10, who had disease of the hip-joint, and an abscess had formed. There was bleeding into the abscess from some accidental condition.—Mr. MAUNDER said he had had two cases where pus was supposed to be under the periosteum, but a red fluid escaped.

Fatty Tumour of the Spinal Cord.—Dr. GOWERS showed a spinal cord, with a fatty tumour upon it, from a man who had empyema, and also locomotor ataxy. There was sclerosis in the posterior columns of the cord. The tumour was half an inch long, and a third from side to side, and of crescentic form. Some of the nerves of the cauda equina were embedded in the tumour. The tumour consisted of cells about a two-hundredth of an inch in diameter, amidst fluid. There were also found in the front of the tumour fibres about a two-hundredth of an inch in diameter, which possessed transverse striæ. The striæ varied somewhat in the distance betwixt them. These were striated muscular fibres, and betwixt them was loose fibrous tissue. He had not been able to find a similar tumour in the London museums—at least, one with the dura mater sheath of the cord. There was no degeneration of the cord from pressure. The coincidence of the sclerosis and the tumour was accidental.

Epithelioma of the Chin.—Mr. CHRISTOPHER HEATH showed a case of epithelioma of the chin following epithelioma of the lip four years ago. The man was shown. He was fifty-five years of age. His lip was removed in 1872. In September 1874, a lump was felt in the chin. It became a tumour six inches by five and a half. The skin was adherent to the bone. There were ulcerated openings. The chin was first sawn off, and then the galvano-caustic *crasseur* applied. As the operation did not open into the mouth, there was no difficulty in feeding him. The gap was well filled up, and there was no appearance of a return of the disease; but, whether the cure would be permanent or not, could not be said.

Epithelioma of the Tongue.—Mr. HEATH also exhibited a case of epithelioma of the tongue, which had been shown to the Society in November last. The patient was now quite well.

Tumour of the Thyroid.—Mr. LENNOX BROWNE described a case of tumour of the right lobe of the thyroid pushing the trachea to the left, and interfering with its form. Some derangement of the sympathetic nerve had ensued, and the right side of the face did not perspire.

The right pupil was contracted. Both optic discs were anæmic. Vision was unaffected. There was a difference of 1 deg. in the temperature of the axilla; the left axilla being a degree higher than the normal. The pulse was 100, and weak. There was increased tension in the right radial pulse. The patient first felt unwell at Luton fifteen years ago. Goitre is common at Luton. There was considerable shortness of breath, so that she had to sit up in bed; but there were no attacks of dyspnoea. She had right ptosis, and was menorrhagic. The pressure on the trachea caused the difficulty of breathing. No treatment had been adopted as yet. It would be interesting to see if the sympathetic disturbance was affected by any local treatment.

Recurrent Epithelioma.—Mr. GODLEE brought forward a case of recurrent epithelioma from a man aged 56. He was a strong man, and had a tumour of the tongue. It had formed rapidly, so an attempt was made to reduce it by puncture, which failed. It was an oval tumour, covered with epithelium over its inner surface. Mr. Erichsen operated upon it; and the hæmorrhage was so great that tracheotomy had to be performed and the blood sucked out of the air-passages. The case made a good recovery. The man next presented himself for a tumour upon the middle toe of the right foot. The tumour was of the size of a hen's egg, and had a granular surface. The man at the same time suffered from an attack of jaundice, and was yellow and weak. There was also an enlarged gland in the right groin. There were great cough and pain in the chest, with a tumour in the right side. There was expansile pulsation in both tumours at each heart-beat. On the *post mortem* examination, there were found a tumour of the chest, and another in the right lung. There was a mass of enlarged glands in the mediastinum. There was adherent pericardium, with several nodules of similar character on it. There was no recurrence of the disease in the tongue. The interest of the case lay in the question, How did the recurrence take place? Was it before or after the removal? If the view of after was espoused, it would seem that there was a constitutional tendency to cancer—and to one form of cancer too. If before, then the constitution was implicated without the glands being affected. Or was it that pieces of cancer had been drawn into the lungs and thus infection produced? A similar case had been recorded by Dr. Moxon, where the lungs were secondarily affected. There was a close analogy betwixt such a process and the establishment of diffuse cancer of the peritoneum after the rupture of a cyst.

Tumour of Clavicle.—Mr. WALSHAM showed (for Mr. HANCOCK) a case of tumour of the clavicle. It occurred in a girl aged 14, at Leicester. She had suffered from a dull aching pain locally, and noticed a tumour forming. It was about the size of a hen's egg at its greatest diameter. The family history was good. The tumour, the clavicle, and some glands, were all removed together. The patient made a good recovery. The tumour was periosteal. On microscopic section, small cells were found in a finely granular fibrillated substance. It was a case of round-celled sarcoma of malignant character.—The PRESIDENT asked for the case to be submitted to the Morbid Growths Committee.

Aneurism of the Aorta.—Dr. FREDERICK TAYLOR brought forward a case of aneurism of the aorta. It occurred in a man aged 53, a pipe layer of good health, but who had a cough for some years. For five months he had suffered from much cough and tightness of chest, together with shortness of breath and dysphagia. Very little food could he take, and it often regurgitated. The heart was displaced outwards and downwards. The pulse was alike in both radial arteries. The respiration was bronchial at the right apex and diminished at the left apex. There was pulsation at the right side of the sternum. After being in hospital ten days, the man was sitting up in bed, when he fell back and died. On *post mortem* examination, a large aneurism was found in the third part of the aortic arch. The stomach was found distended by a two-pound clot of blood. Near the œsophageal end of the stomach was a smooth ulcer, with a nipple-like projection. This led to a channel which ran up by the side of the gullet, formed by the ploughing-up of the muscular wall of the œsophagus. At the top of the channel was an opening, which would admit a cedar pencil. There was also some hæmorrhage into the subpleural tissue with openings therefrom. There was a large aneurism six inches by two. The aorta below was normal.—Dr. CRISP asked if the man had had syphilis. The answer was in the negative.

Arrest of Development of both Forearms.—Mr. ALBAN DORAN showed a case of arrested development of both forearms from an old pauper woman aged 54. All that could be learnt was that this deformity had always been so. There were no scars; all the articulations were freely movable. The hands were well formed. The synovial cartilages were normal; the bone was friable. There was no rickets. The radii were four and a half inches long. The lower ends were softened and disintegrated. There were senile changes. The arrest could

scarcely be due to infantile paralysis, as there was no atrophy of the muscles; while there were no traces of rickets, and the tibiae were straight and slender. The probability was the arrest was congenital.—Mr. WAGSTAFFE asked if there were any history of "maternal impressions". The answer was in the negative.—The PRESIDENT asked if the movement of the elbow was free.—Mr. DORAN replied that it was quite free.

Recurrent Sarcoma of the Leg.—Mr. SPENCER WATSON related the sequel to the case of Mr. Walker's, related in the twenty-second and twenty-fourth volumes of the Society's *Transactions*. The patient, a lady aged 30, had had five operations performed; after each the wound healed, and she got well. In September 1873, she noticed a little enlarged gland in the groin, about the size of a walnut. Her health was deteriorated, and she wished the tumour to be removed. An operation was discontinued. The swelling suppurated and a slough escaped. Severe hæmorrhage followed, which, though temporarily checked by styptics, returned, and she sank in a few days; three years and eight months from the commencement of the case. The growth was spindle-celled sarcoma. The tying the femoral artery in the last operation had retarded the growth of the tumour.

Embolic Infarct in Heart-Muscle.—Dr. GOODHART gave an account of a case of a girl with presystolic bruit and dropsy, who died at the age of 15, with the usual symptoms of mitral disease. On the *post mortem*, the usual changes were found, and along with them an extravasation of blood into the structure of the left ventricle. Was it an embolism? No plug was found; but there was discoloration of the outer surface of the clot, and other points of hæmorrhage to be found. The next point was the bearing of such infarct on the formation of a fibroid condition of the heart-wall. There was fibrous tissue betwixt muscular bands in such cases. Was the embolism primary here, and the fibrous condition secondary? If so, the muscle had wasted, and a fibrous condition was left. Or was it that blood was effused into the changing muscle? In a like case of sudden death, where there was found empyema at the necropsy, there was a similar extravasation into the structure of the heart.—In answer to a question from Dr. GOWERS, Dr. GOODHART said that the infarct had probably existed three or four days ere death.—A discussion then took place as to the occurrence of sudden death during the washing out of the chest, in which Messrs. Butlin, Heath, Morris, Doran, and Drs. Godlee and Douglas Powell took part.

The PRESIDENT announced that a discussion on Syphilis would take place in February, which would be opened by Mr. Jonathan Hutchinson. The heading of the discussion would be furnished before the discussion took place. The meeting then adjourned.

MEDICAL SOCIETY OF LONDON.

MONDAY, DECEMBER 20TH.

C. H. F. ROUTH, M.D., President, in the Chair.

On the Physiological Action of Alcohol. By T. LAUDER BRUNTON, M.D., F.R.S.—The author observed that alcohol in small quantities increases the secretion of gastric juice and the movements of the stomach, and thus aids digestion. Although unnecessary in health, it is useful in exhaustion and debility. It increases the force and frequency of the pulse by acting reflexly through the nerves of the stomach. In large doses, it impairs digestion by precipitating pepsin and over-irritating the stomach. It may produce death reflexly by shock. After absorption into the blood, it lessens the oxidising power of the red blood-corpuscles. This property renders it useful in reducing temperature. When it is constantly or very frequently present in the blood, it causes accumulation of fat and fatty degeneration of organs. It undergoes combustion in the body, maintains or increases the weight of the body, and prolongs life on an insufficient diet. It is, therefore, entitled to be reckoned as a food. If large doses are taken, part of it is excreted unchanged. It dilates the blood-vessels, increases the force and frequency of the heart, imparts a feeling of comfort, and facilitates bodily and mental labour. It does not give additional strength, but merely enables a man to draw upon his reserve energy. It may thus give assistance in a single effort, but not in prolonged exertion. The same is the case with the heart, but in disease alcohol frequently retards instead of quickening this organ, and thus economises instead of expending its reserve energy. By dilating the vessels of the skin, alcohol warms the surface at the expense of the internal organs. It is thus injurious when taken during exposure to cold, but beneficial after the exposure is over, as it tends to prevent congestion of internal organs. The symptoms of intoxication are due to paralysis of the nervous system, the cerebrum and cerebellum being first affected, then the cord, and lastly the medulla oblongata. The apparent immunity which

drunken men enjoy from the usual effects of serious accidents is due to paralysis by the alcohol of the nervous mechanism through which shock would be produced in the sober condition.—Drs. Broadbent, Drysdale, Edmunds, Sansom, Symes Thompson, and Bartlett took part in the discussion, which was adjourned until January 10th, 1876, when Dr. Milner Fothergill will reopen the subject.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

WEDNESDAY, DECEMBER 1ST, 1875.

T. GRAINGER STEWART, M.D., in the Chair.

Operations for Relief of Extensive Destruction of the Vesico-Vaginal Wall.—Mr. JOSEPH BELL read a paper on this subject. After referring to a previous paper which he had read some years before, in which he gave the results of a number of cases of vesico-vaginal fistula cured by the usual operation of bringing the edges of the fistula together by silver wire passed by means of small curved needles welded on to the wire, he gave an account of various plans adopted by Herrgott of Nancy, Vidal, Wützer, Beraud, Bozeman, Simon, and others, in which they endeavoured to remedy more severe cases of destruction of parts by operations involving partial or complete closure of the vagina; he discussed the points connected with the relations, social and domestic, of the sufferers both before and after such operations, and then detailed three cases in which he had performed operations of this kind. In the first case, other surgeons had failed in five operations to close an extensive fistulous opening between the upper part of the vagina and bladder, from the complete denudation of the vagina up to the anterior lip of the os uteri. Mr. Bell determined to utilise the posterior lip, and after denuding it, brought it into connection with the lower edge of the fistula, thus making an artificial retroversion of the uterus, and shutting up the os uteri into the bladder. The first operation succeeded only partially, as, after the patient had been dry for seven days, a small opening resulted. This was completely cured by a second operation, and the patient remained quite dry. The operations were both extremely difficult and tedious, as a Marion Sims's speculum could not be used. The result was excellent; a tolerably capacious vagina being left, though of course the patient was sterile, as the uterus opened into the bladder, through which menstruation took place with wonderfully little pain. In the second and third cases, the destruction of parts was so great that no attempt could be made to re-establish the vesico-vaginal septum, so the operator and the patient had to face the question of almost complete closure of the genital fissure. To this both patients consented. Mr. Bell, without removing any mucous membrane whatever, split the labia on each side, so as to enable him first to bring into accurate connection the edge of mucous membrane, by numerous closely set catgut sutures. He then, by means of deep stitches of silver secured by buttons or quills, brought the broad surface of each labium into accurate apposition, after which, the actual skin edges were to be secured by sutures of fine silk or horsehair. A small opening was left as close up to the mons Veneris as possible, in which was placed a lead catheter, bent so as to fit the curve of the orifice and pubes. This was retained till the wound is soundly healed, after which a silver one is made, and fitted to the ordinary boat-shaped urinal, by which means the patient could be kept perfectly dry, and in a condition of comparative comfort. Both cases were successful. One required two operations, as the first one did not close the lower or posterior angle of the fissure, as the patient had suffered from a perinæum split almost into the anus; one operation sufficed for the other case.—The PRESIDENT said, that the relief afforded to the unfortunate sufferers must have been indescribable, and the plan adopted by the operator seemed to commend itself as being simple and satisfactory.—Dr. A. R. SIMPSON said that, though cases of vesico-vaginal fistula were much rarer now than in former days, still many were seen. Most of these could be cured easily enough, if not at the first, yet generally at the second or third trial. He had now operated pretty frequently, but had not as yet met with cases so severe as those reported by Mr. Bell. He had, however, seen one in his uncle's practice in a girl of sixteen; there had been so much sloughing of the vaginal septum, that the only chance of relief was by closing the genital fissure, by making the labia raw, and uniting them with iron wire. She wore a boat-shaped shield only, but he thought that the catheter as suggested by Mr. Bell was an improvement. He had lately seen a case somewhat like Mr. Bell's first case. In it, the os uteri had by cicatrices been so tilted forward as to be concealed in the bladder, and at first the state of affairs was puzzling, the uterus being enlarged. An abortion at the third month threw light on it; and after she had fairly recovered, he united the fistula in such a way as to put the uterus into the bladder, and to leave a vagina only long

enough to admit the forefinger to the second joint. He found that he could not use the speculum, and felt that there was a considerable risk of opening into the peritoneum in Douglas's space; no bad results followed, the aperture was healed, and the patient menstruated twice by the bladder with ease. He related another case, in which the operation was rendered very difficult by the extreme narrowness of the vagina. All these operations required patience, but gave most excellent results and great satisfaction, as Mr. Bell had often experienced. He thought such cases encouraged the performance of similar operations in cases where no other means of damming up the flow of urine remained.—Dr. JOHN DUNCAN thought that there was one point in Mr. Bell's paper which deserved more than a passing notice. He had himself only a single experience of the operation for vesico-vaginal fistula, and he had never met with cases of such severe destruction as Mr. Bell's. But he believed the method described of not removing any tissue when paring the labia, was one deserving greater extension, and might be employed, not only in all cases of vesico-vaginal fistula, but in other surgical proceedings. He himself, in a case of preternatural anus after a hernia, found that, after various plans had been adopted for destroying the septum, a plastic operation was still necessary to close the wound. Most of these operations had been unsuccessful; but he, instead of merely exposing a raw surface of skin to the irritation of the feces, managed, by splitting up the bowel all round the orifice, to bring from it a surface of mucous membrane, which he secured by catgut stitches, and on these brought the edges of skin in contact by iron wire. The result was a cure, except one small aperture, which eventually yielded to a touch with wire at a white heat.—Mr. BELL had little to add in reply. He was interested in Professor Simpson's case, in which retroversion had followed the cicatricial displacement of the uterus. In his own case, the chief difficulty had been to get the uterus so to tilt as to undergo the partial retroversion necessary in the new position of the cervix, and he was glad to find that Professor Simpson had experienced the same difficulty he had in the use of the speculum, as he had feared it might have been due to his own awkwardness. He had a distinct recollection of Dr. Duncan's case, and had used the same splitting plan in many cases of ruptured perineum, harelip, and the like. He referred to a note lately published by Mr. Maunder on the use of a similar method in the operation for ruptured perineum. He himself had used it at least ten years ago.

Persistent Constipation in a Child.—Dr. CUTHBERT read a paper on a case of torpor of the liver and bowels from birth. The patient was a boy, six years of age, troubled with obstinate constipation only relieved by purgatives, such as aloes, etc. There was, when he came under Dr. Cuthbert's charge, enormous distention of the abdomen, so that no organs could be defined; and there was also alteration of the apex beat of the heart. Liquorice powder and oatmeal diet, along with occasional enemata, had no effect. But by removing fecal masses from the rectum, injections of olive-oil, and the internal use of gray powder and Easton's syrup, frequent stools were produced, blue in colour at first, but ultimately natural. He thought that the case was interesting as a complaint rare among children. It was most probably due to torpidity of the liver, and therefore the beneficial action of mercury on this organ was shown. The good general health enjoyed by the boy was also worthy of note.

PATHOLOGICAL SOCIETY OF DUBLIN.

SATURDAY, NOVEMBER 27TH, 1875.

ROBERT McDONNELL, M.D., F.R.S., President, in the Chair.

Enteric Fever.—Dr. WILLIAM MOORE submitted an example of the intestinal lesions of enteric fever in a child, aged 10, in whom death was caused by a perforation situated a little above the ileo-cæcal valve, and capable of admitting a goose-quill. The temperature never ranged very high, but rose-spots, diarrhoea, and tympanites were present, and the child screamed incessantly.

Large Gall-Stones.—Mr. F. T. PORTER exhibited two large gall-stones, each weighing one hundred and twenty grains, from the body of a man who was both very fat and the subject of great muscular development.

Uterine Myoma.—Dr. MCCLINTOCK showed a tumour which weighed nine ounces, and which had almost destroyed the patient's life by hæmorrhage. It was removed with a wire *céraseur* under chloroform.

Transverse Fracture of the Patella.—Mr. H. G. CROLY showed a specimen, dating back to 1854, which was united partially by bone and partially by ligament. During his life, the man enjoyed free motion in the injured knee. On removing the fractured patella after death, the first thing that Mr. Croly noticed was that the cartilage was eroded on

the external condyle of the femur. On looking at the patella, a line was seen where the fracture ran, and corresponding with that line below there was an osseous deposit. Then there was a very narrow line of ligament, not as wide as appeared when the bone was examined in front. The line between the fragments was extremely small, and filled with ligamentous tissue. There was a considerable deposit of bone above and below the seat of the fracture.

Calculi of the Urates.—Mr. STOKES laid on the table a cluster of calculi of urates, which he had removed by Allarton's median operation from the bladder of a man, aged 45.

MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS OF IRELAND.

WEDNESDAY, DECEMBER 8TH, 1875.

SAMUEL GORDON, M.B., President, in the Chair.

Cases of Continued Fever of Unusually Long Duration.—Dr. JAMES LITTLE read notes of four cases, in which for more than forty days pyrexia existed, although, as far as he could make out, it was not symptomatic of any local inflammation, or due to any of the acknowledged types of essential fever. He had seen three other cases very similar in character during the past five years. The patients were obliged to keep their beds for three or four weeks, during which time the temperature of their bodies was higher and the pulse more frequent than in health. They were all depressed and apathetic, and very weak, but presented no symptom or physical sign which justified a precise diagnosis, and ultimately recovered without the development of chronic, thoracic, or abdominal disease. All the persons in whom the author had observed this state appeared to him to be of the lymphatic diathesis, and the pyrexial condition, he considered, was associated with some general irritation and overgrowth in the lymphatic glands.—Dr. GRIMSHAW thought that the true explanation of these cases was, that a comparatively slight attack of enteric fever set up a lymphatic glandular inflammation, which produced a fever of the subtypical character described by Dr. Little. His note-books contained many cases of this sort, and he had put them all down as cases of enteric fever. He had always looked on them as rather serious; and, if the patient had chronic lung-disease, they were very likely to terminate in some form of phthisis.—The PRESIDENT said that within the last few months he had seen several cases bordering somewhat on those described by Dr. Little. He considered them to be all more or less typhoid, although for a considerable time, at all events, there had been little if any diarrhoea, and in very few cases rose-coloured spots.—Dr. DOYLE asked Dr. Little if cases of typhus fever of a bad type had occurred in the vicinity of any of the cases which he had described. In the *Medical Times and Gazette* of February 1874, a translation was given of some cases described by Professor Jürgensen of Tübingen, under the term of continued fever, and he accounted for them by supposing that the patients had received the secretions of typhus fever, and had become affected with a fever of a modified type.—Dr. G. F. DUFFEY said that during the five years he was in Malta he saw a large number of cases of an anomalous form of fever, commonly called "Maltese fever", which were entered in the official returns under the head of Common Continued Fever, but which he believed to be enteric fever. The type of this fever was essentially what Dr. Little had described.—Dr. J. W. MOORE gave the particulars of a recent outbreak of fever in Dublin, which was traceable to infection of a dairy by the poison of enteric fever. Several of the cases were treated in the Meath Hospital, to which they were admitted from the house in which the enteric fever first appeared, from a dairy infected from that house, and from a large girls' school in turn infected from the dairy. The cases presented marked varieties, and some of them closely resembled the nondescript fever described by Dr. Little. Others were unequivocal examples of severe enteric fever.—Dr. LITTLE, in reply, said that the suggestion of Dr. Doyle commended itself to him more than any of the others that had been thrown out, because he could hardly believe that his were cases of true enteric fever, unless that expression were used in a sense so vague as to deprive it of very much significance. In the instances he had recorded, he could not ascertain that any other persons in the families had fever of any kind, and he should have expected, if those were cases of slowly developing enteric fever, that some other members of the family would have exhibited the disease in a more typical form. In several of the cases, he had ascertained that the persons had been exposed very much to fecally contaminated air. In two cases, of which he had given no record, this had happened. Therefore, he was disposed to think that the disease was not true enteric fever, but some modified form of fever arising from the absorption of fecal emanations.

Typhoid Fever in the Dublin Garrison.—Surgeon-Major GORE read a

paper on this subject. It was given in abstract in the BRITISH MEDICAL JOURNAL, December 18th (p. 765).—Dr. H. KENNEDY made some remarks on the bearing of the amount of intestinal lesion on the duration of enteric fever, on the occurrence of this fever in the presence of a strumous diathesis, and on the morbid anatomy of enteric fever and of scarlatina (*psorentic*).—Dr. GRIMSHAW said that enteric and typhus fevers had been on the increase during the latter end of last year and the beginning of this. It was also evident that there had been an increase in enteric fever lately. He did not think there was evidence to prove that the troops of the Dublin garrison were more unhealthy than troops similarly situated in towns where the sanitary condition of the population was the same and the death-rate so high as in the city of Dublin. It could scarcely be expected that troops introduced into Dublin would not fall into the same condition of health as the rest of the population. Dr. Grimshaw referred at length to the sanitary conditions of the barracks of Dublin, and particularly of Beggar's Bush Barracks, which he had minutely inspected, and reported on in April last. The Constabulary Depôt in Phoenix Park, a well drained and healthy locality, also furnished constant cases of enteric fever. In the treatment of this disease, his practice was to leave the patient as much as possible alone. Unless the diarrhoea were excessive, we should be cautious about checking it; but, in the recent cases of enteric fever he had seen, the bowels were usually confined. He had tried the cold water treatment, and he did not intend to try it again. Temperature could be more safely reduced by quinine, which would also act as a tonic, and he found it of the greatest possible value in most cases of enteric fever. He believed the mortality in the hospitals in which cold water had been tried was much higher than in the Dublin hospitals. He had not seen any patients that he would be inclined to bleed.—Surgeon-Major LAWRENCE (Grenadier Guards) said that there had been only two cases of enteric fever, both among officers, in Beggar's Bush Barracks since April 1874, and it was a moot point whether in these cases the disease had not been contracted out of barracks. They had had six or eight cases among the men, every one of which, however, came from the Pigeon House Fort. The situation of Beggar's Bush Barracks was low, and when the tide was out a quantity of gas collected in the drains, which was afterwards driven back into the barrack by the flow of the tide. He did not, however, believe that the drainage of the barrack was in such a deplorable state as they had been led to believe.—Dr. GRIMSHAW said that an engineer officer in charge of the barrack at the time he visited it pointed out to him four places where the drains were choked, at the rear of premises where an officer had died of typhoid fever. He was shown where new ventilating shafts had been erected, and he reported that the arrangements appeared to be such as would prevent anything of the sort from occurring in future. What he stated was, that the conditions which existed previously to the improvements were such as, if there were any truth in the ideas with regard to the cause of enteric fever, would give rise to it. He did not say that they did give rise to it in Beggar's Bush Barracks.—Surgeon-Major GORE approved of the use of milk and the employment of very little medicine in the treatment of enteric fever, the idea being to guide the disease in its course. In one case in which the diarrhoea was interfered with, the disease terminated fatally. The Registrar-General's returns did not show an increase of fever in the present year. In the beginning of the present year, the number of zymotic cases was 323, as against 510 in the same quarter of 1874; for the July quarter the numbers were 166 less; and the numbers for the October quarter were 366, as against 540 for the same quarter of last year. It was believed that the Dublin garrison was worse off as regarded disease than civilians; but he found, from military returns, that zymotic disease during the quarter ending the 1st of October was, for civilians, 5 per 1,000, and for the garrison only 1.7 per 1,000. As to the tide driving the gas of sewers upwards, the same thing occurred at the Royal Barracks.

OBITUARY.

LORENZO EDWARD DESMOND, M.A., M.D., LIVERPOOL.

DR. DESMOND died on December 10th, after a few days' illness, from an attack of bronchopneumonia, brought on by exposure to cold and fatigue in his professional duties; and he may thus be truly said to have died in harness. He was a native of Ireland, studied and graduated in Dublin, and, after a short time spent in India, practised in Liverpool for upwards of a quarter of a century. His high professional character, great urbanity, geniality, and gentlemanly bearing, had won the respect and regard of his professional brethren.

Although actively engaged in an extensive practice, chiefly as an

obstetrician and gynaecologist, he took a prominent and eminently useful part in all professional movements and institutions. As a member of many years' standing, he had done good service to our Association, having with much credit served as President of the Lancashire and Cheshire Branch, and for several years was a regular and faithful representative of his Branch on the Parliamentary Bills Committee of the Association. He was also an active and influential member of the Liverpool Medical Institution; and, had his life been prolonged, would no doubt, at no distant period, have been chosen as its President. He was also a member of several local scientific institutions, a Fellow of the Obstetrical Society of London, and had filled successively the offices of Honorary Surgeon and Consulting Surgeon to the Liverpool Dispensaries, and Surgeon to the Lying-in Hospital, and at the time of his death was Assistant-Surgeon to the 4th Lancashire Artillery Volunteers. He was followed to the grave by a numerous gathering of his professional brethren, including nearly every one of the leading practitioners of Liverpool and the neighbourhood, as well as a large number of grateful patients and sorrowing friends, thus testifying to the high esteem in which he was held while living, and the profound and widespread grief his premature and unlooked-for death had occasioned.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

THE POOR-LAW MEDICAL OFFICERS' ASSOCIATION.
OF ENGLAND.

At the meeting of the Council of this Association, held on October 14th last, it was resolved—that a letter signed on behalf of the Council by the President, Dr. Lush, M.P., should be forwarded to all medical gentlemen holding office under the Poor-Law Department of the Local Government Board, inviting their support, and soliciting their co-operation in one more vigorous effort, to remove the anomalies and redress the grievances of the service. We call attention to it, and heartily support its avowed objects.

MORTUARIES FOR THE METROPOLIS.

We have recently made application to the medical officers of health of the various district boards in the metropolis as to how far the 27th and 28th clauses of the Sanitary Act (1866), permitting such boards to construct mortuaries and rooms for *post mortem* purposes, have been complied with; and we now lay before our readers a tabular statement of those boards which have established them, and those which have failed to do so, together with the population of each district, so far as the returns have reached us.

District.	Population.	Medical Officer of Health.	Mortuary Accommodation.	Post Mortem Room.	Remarks.
Battersea . . .	65,220	Mr. Kempster	Ooe projected for 6 bodies	There is to be	
Bermondsey ..	80,413	Mr. Oakman	For several	Yes	
Poplar	112,001	Dr. Parker	For 40	No	
		Dr. Elhson			
		Dr. Talbot			
Hackney	142,300	Dr. Tripe	For 8	Yes for 4	
Lambeth	208,342	Dr. McCormack	For 12	Yes	Just built
Lewisham	56,000	Dr. Wilkinson	For 4 or 5	Yes	A small building, with lean-to roof
St. Saviour's ..	39,253	Mr. Bianchi	For 3	No	
St. Mary, New-	99,000	Dr. Iliff	For a large	Yes	Isa railway arch
ington			number		
City of London	113,239	Dr. S. Saunders	18	Yes	The best building of the kind in London
St. Olave's . . .	14,873	Mr. Viney	No proper place	No	
Eltham	4,528	Dr. King	No	No	Only the work-house
Hampstead ..	38,710	Mr. Lord	No	No	Dead-house
St. George's-in-	47,709	Dr. Rygate	No	No	Ditto
the East					
Kensington ..	146,000	Dr. Duffield	No	No	
Mile End, Old		Dr. Corner	No	No	Only the work-house
Town					
St. Paneras ..	230,000	Dr. Stevenson	No	No	Dead-house
Whitechapel ..	76,573	Mr. Liddle	No	No	Ditto
Holborn	43,116	Dr. Gibbon	No	No	Ooe in construction for 12, etc.
St. George's, Southwark ..	56,083	Dr. Bateson	No	No	There is to be a post mort. room
St. Luke, Middlesex	54,969	Dr. Pavy	For 12	No	Accommodation in building

From the medical officers of health of the other districts we have received no reply; but having had the opportunity of examining the abstract of the answers to a circular letter addressed to the clerks of the various boards, on the motion of Dr. Joseph Rogers, member of the Strand Board of Works, we find that no mortuary accommodation exists in St. James's, Westminster, nor in the Strand, except the mortuary in Dean Street, belonging to the parish of St. Anne's, Soho, which was built twenty years ago; nor is there any in Greenwich, with some 105,000 inhabitants; nor in Bethnal Green, with 120,213. In St. Pancras, with its 230,000 inhabitants, spreading over an area three miles long, there is only the dead-house of the workhouse; and several of the so-called mortuaries are, as regards site and construction, totally unfitted for the purpose, and calculated to deter the poor from temporarily depositing their dead therein. We hope to return to this important public question before long. It concerns the provinces not less than London.

POOR-LAW MEDICAL APPOINTMENTS.

BOAST, Boanerges R., L.R.C.P.Ed., appointed Medical Officer for No. 3 District of the Henstead Union, Norfolk, *vice* A. M. F. Morgan, M.R.C.S.Eng., resigned.

DAVIS, David, M.R.C.S.Eng., appointed Medical Officer and Public Vaccinator for the No. 4 or Leigh District of the Martley Union, Worcestershire.

DONOVAN, John I., M.D., appointed Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Ballinacoly Dispensary District of the Cork Union, *vice* G. A. Rountree, M.D., deceased.

FOWLER, Trevor, L.K.Q.C.P.I., appointed Medical Officer for the Thoydon Garnon District of the Epping Union, Essex.

GRAY, John R., M.B., appointed Medical Officer for the Borrowby District of the Northallerton Union, Yorkshire, *vice* J. H. Buchanan, M.D., resigned.

GOVETT, Philip W., M.R.C.S.Eng., appointed Medical Officer and Public Vaccinator for the No. 5 District of the Plympton St. Mary Union, *vice* J. E. Adkins, M.R.C.S.Eng., resigned.

HARRISON, Thomas W., L.R.C.P.Ed., appointed Medical Officer for the Doneraile Dispensary District of the Mallow Union.

WILLAN, Reginald M., M.R.C.S.Eng., appointed Medical Officer and Public Vaccinator for the No. 4 District of the North Witchford Union, Cambridgeshire, *vice* J. M. Wilson, M.B., resigned.

MILITARY AND NAVAL MEDICAL SERVICES.

SURGEON-MAJOR STANHOPE H. FASSON, M.D., vacates his appointment as medical officer of the Royal Military Academy, Woolwich, on being promoted to the rank of Deputy Surgeon-General. Dr. Fasson, who has held the appointment since July 1872, is succeeded by Surgeon-Major Edmund H. Roberts, late of the 9th Regiment.

THE ALDERSHOT INQUIRY.

WE have been for some time prepared to announce to our readers the decision of the Board recently assembled at Aldershot for the purpose of assessing loss of stores in connection with the first station hospital, but have waited until we could ascertain whether their recommendations had been fully endorsed by head-quarter authority. Nothing, however, has transpired beyond the bare fact that Major-General Primrose and his colleagues have recommended the deficiency to be made good by the department, and that Sir Thomas Steele has most strongly supported their views.

We trust that the Commander-in-Chief and Secretary of State for War will concur in this recommendation, and thus prevent the saddling of a meritorious medical officer with a liability which was, so to speak, forced upon him, and the responsibility for which was weakened, if not destroyed, by informality in the documents submitted to him by the Control. Others, however, may not be so strong in their defence; and we would point out the gross injustice of holding surgeons in charge of station hospitals individually liable for deficiencies which they are merely expected to assess on the Army Hospital Corps. Our combatant brethren would, no doubt, consider it strange were the colonel of a regiment called upon to pay the entire barrack damages committed by his officers and men during their occupation of a particular station. But here is a precisely similar case; and, even as the commanding officer distributes these charges equitably among the companies under his jurisdiction, so is the surgeon expected to transmit the damages to those with whom he is most immediately concerned, *i.e.*, the Army Hospital Corps; and it is absurd, and probably illegal, to hold him individually responsible for one penny beyond his proper share. The department have clearly taken up a false position in this matter. For some unexplained reason, they took over the charge of hospital stores from the Control, who were by no means anxious to relinquish it, and have given it to their own staff, without any counterbalancing indemnity either in money or position.

A good opportunity of retrieving their error is now afforded them, and we hope to see this cumbrous appendage of medico-military duty finally swept away.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen were admitted Licentiate on December 20th, 1875.

Atkinson, Francis Edward, 32, Regent Square
 Bartlett, Henry, 153, Great Dover Street
 Barton, James Kingston, 12, Doughty Street
 Birch, Philip, Lichfield
 Cadge, William Hotson, 23, Woburn Place
 Cobb, Robert, St. Bartholomew's Hospital, Chatham
 Crétin, Eugène, M.B.Lond., St. Bartholomew's Hospital
 Foley, Samuel, St. David's
 Harper, Robert Russell, Holbeach

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following members of the College, having undergone the necessary examinations for the Fellowship, on November 25th, 26th, and 27th, were reported to have acquitted themselves to the satisfaction of the Court of Examiners; and at a meeting of the Council on the 20th instant, were admitted Fellows of the College.

Messrs. Thomas Jones, M.B.Lond., L.S.A., Royal Infirmary, Manchester, diploma of membership dated May 17th, 1870, of Guy's Hospital; Robert Lyell, M.D.Lond., L.S.A., Penge, January 25th, 1871, of the King's College and Middlesex Hospitals; William Thomas Law, M.D.Edin., L.S.A., Seamen's Hospital, Greenwich, May 16th, 1871, of the Guy's and Edinburgh Schools; William Garton, M.B.Edin., L.S.A., St. Helen's, Lancashire, July 26th, 1871, of St. Thomas's Hospital; Lewis Mackenzie, L.R.C.P.Lond., Tiverton, Devon, November 15th, 1871, of the London Hospital; Walter Hamilton Acland Jacobson, B.A., M.B.Oxon., November 13th, 1872, of Guy's Hospital; Augustus Winterbottom, Chelsea, November 13th, 1872, of St. George's Hospital; Albert Boyce Barrow, Newmarket, January 24th, 1873, of King's College.

Six candidates, having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their professional studies for twelve months.

The following gentlemen, elected Fellows at previous meetings of the Council, were admitted as such.

Messrs. Thomas Bruges Flower, F.L.S., Bath, diploma of membership dated July 9th, 1841; and John Briscoe, L.S.A., Oxford, August 15th, 1842.

At the same meeting, the following members were elected Fellows of the College.

Messrs. James Bratton, L.S.A., J.P., Shrewsbury, diploma of membership dated May 20th, 1836; and William Nash Spong, L.S.A., Faversham, Kent, August 1st, 1842.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, December 16th, 1875.

Buckell, Ernest Hook, University College Hospital
 Haselden, Robert, Bolton, Lancashire
 Macintire, John Henry Lee, 95, Gower Street, W.C.
 Reeve, Henry, Victoria Park, Hackney
 Richardson, Arthur, Rusholme, Lancashire

The following gentlemen also on the same day passed their primary professional examination.

Dalton, C. J., London Hospital
 Gay, C. W. E., King's College
 Morgan, John, Guy's Hospital
 Prior, E. T., St. Bartholomew's Hospital
 Rigley, W. B., St. Bartholomew's Hospital
 Scallon, E. O., King's College
 Symons, J., King's College
 Walsh, W. A. S., King's College
 White, W. R., King's College
 Whitley, F. G. H., St. Bartholomew's Hospital

UNIVERSITY OF OXFORD.—The following candidates have passed the First Examination for the Degree of Bachelor in Medicine in Michaelmas Term, 1875.

Enn, Stacey Southernden, B.A., Corpus Christi College
 Cottle, Ernest Wyodham, B.A., St. Alban Hall
 Kidd, Percy, B.A., Balliol College
 Moulán, James Alfred, M.A., Pembroke College

OPERATION DAYS AT THE HOSPITALS.

MONDAY	Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.
TUESDAY	Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.
WEDNESDAY	St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.
THURSDAY	St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 3 P.M.
FRIDAY	Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.
SATURDAY	St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M. and 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

UNDERGRADUATE should apply to the Deans of the respective Universities. The examinations must be passed on the spot and in the language of the country.

MIDWIFERY CONTRACTS.

SIR,—In reply to your correspondent H. in last week's JOURNAL, in reference to midwifery engagements, I beg to say that county court judges hold different views on the subject. I determined some time since to try a case in the county court, and very sorry I was for doing it, as the judge laughed me to scorn, and, in fact, kept the whole court amused for about ten minutes with his remarks on the absurdity of a medical man expecting to be paid for work he had not done. In short, he ruled that the contract was not binding on either side. I replied that, in case of a doctor being engaged to attend a woman, and not doing so when sent for, he would be liable for damages (in the event of accident). The judge said no; a doctor can only be expected to use due diligence in attending any case to which he is called, whether he has been previously engaged or not.

My object in troubling you with this long letter is to prevent other medical men from placing themselves in such a humiliating position as I found myself on the occasion mentioned above.—Yours truly,
J. WILLIAMS, M.B., M.A.

Barrow-in-Burness, December 14th, 1875.

MR. G. C. STURT (Hampstead).—See BRITISH MEDICAL JOURNAL, May 21st, 1870, and May 11th, 1872; also *London Medical Record*, January 20th, 1875. Our correspondent will also very probably find information on the subject in the pages of *Nature* and the *Pharmaceutical Journal*.

CROTON-CHLORAL.

A. C. D.—According to Liebreich (BRITISH MEDICAL JOURNAL, December 20th, 1873), croton-chloral administered internally rapidly produces sleep, but without (as is the case with chloral) lowering the pulse and respiration. It is especially successful in cases of facial neuralgia, according to German reports, and to the reports of correspondents of the BRITISH MEDICAL JOURNAL, whose notes have appeared in past volumes. It is, however, far from being so generally tolerated as chloral. It may be given dissolved in half an ounce each of glycerine and water, with two or three drops of oil of peppermint and some syrup.

WHOOPING-COUGH.

The Attorney-General v. the Hyde Chemical Company.

SIR,—Among notices to correspondents in your last issue, an affidavit is quoted in which it is deposed that the medical men here had within the last month sent about forty children suffering from whooping-cough to the above manufactory, to inhale the fumes of pitch. Permit me, for myself (and, I think, I may safely say also for the four qualified gentlemen in practice here), to contradict the flattering imputation. But as there are at least five unqualified men in extensive practice in the town, an equal number of prescribing druggists, and still more numerous body of bone-setters, herbalists, and other irregular aspirants to medical fame, the novel method of treatment may have emanated from some of the latter body of practitioners.—I am, s. r., yours respectfully,
THOS. C. LEAH.

Hyde, near Manchester, December 18th, 1875.

E. T.—"Après la soupe, une coupe d'excellent vin
Tire un écu de la poche du médecin."

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

THE QUESTION OF THE ADMISSION OF LADIES TO THE MEMBERSHIP OF THE BRITISH MEDICAL ASSOCIATION.

SIR,—Referring to the appeal recently put forth to the members of the above-named Association, for their decision as to the expediency and the rightfulness of admitting women as members of that Society, I venture to submit that a more preposterous notion than the one here suggested cannot be brought under the consideration of professional men. I quite concur with Mr. Lindsay, who, in this day's JOURNAL, in sustaining his answer "No", gives, as his first ground of objection, the indisputable fact, that a professional union and fellowship with women would at once weaken or destroy that influence and power hitherto possessed by the British Medical Association, in respect of governing bodies, and even legislative assemblies. I go further, and say that such an amalgamation would probably at no distant period lead to subversion of the policy and general objects of the Association, and all this through the presumption of women, as abandoning their natural sphere of life and taking upon themselves duties proper only to men, for connected with this Association is a fund for the relief of widows and orphans of medical men. Let ladies come amongst us, and thus assert an equality with men in this striving world, and then we may reasonably be called upon to act upon one of two suggestions—either to abolish the fund already established, or to institute a second fund for the relief of widows and orphans of medical women. This action may appear absurd enough to some readers; but when women take upon themselves the functions of the medical profession, and for themselves the revenues of that profession, they and we may contend that women are no longer of the weaker sex. In looking, however, at Mr. Lindsay's second reason for opposing the admission of women, I confess that I am not prepared to believe, as he seems to believe, that a female practitioner may, as well as a male practitioner, contribute "to the advantage of the science of the profession". And here we are led from the one question of eligibility of women as members of our Association, to the other question of their fitness for the exercise of the medical profession. I at once affirm their incompetency, and say that their assumed position as church preachers, lawyers, or auctioneers, would be far less offensive to common sense and decorum than is their determination for the medical profession. It is true that a woman may vaccinate, open an abscess, do the operation of tapping, or read a compilation on some medical subject, and call it her paper, but we can never expect to find her in the practice of really serious and important operations, or adding to the science and practical skill of surgery or medicine. Then, with respect to her physical powers for the discharge of professional duties, I say there is not a woman in England who could endure for six months the fatigue necessarily connected with country medical practice; but perchance she soars above that, and lays herself out for town practice, to the expulsion, perhaps, of good men for country districts. As, however, we now cannot know what a woman may prefer, let us suppose her selecting a rural district for practice. Will she ride on horseback, or will she drive her carriage? and, taking to the vehicle, will she also take the whip, or employ a driver? Adopting the latter course, will she patronise a woman or a man? A man, to be sure; for a man has more strength than a woman, more presence of mind, and more self-reliance—qualities, indeed, which are especially required in the practice of the medical profession.

For these reasons, then, and for others not here stated, I in my answer to the question of "Yes" or "No", have written the words "No, most positively"; and at the bottom of the paper I have taken the liberty of making the gratuitous declaration: "When women are admitted as members of the British Medical Association, I go out of it"; and by way of justifying such determination, it seems to me that I cannot do better than quote the language of Copland's edition of Richerand's *Elements of Physiology*: "The reproduction of the species is, in woman, the most important object of life; it is almost the only destination to which Nature has called her, and the only duty she has to fulfil in human society. Wherever the earth is fruitful, and furnishes man with abundant means of providing for his wants, he dispenses with the services of woman in obtaining from it means of subsistence; he releases her from the burthen of social obligations. Whatever withdraws woman from this primitive destination, whatever diverts her from this end, is to her injury. It is the scope of all her actions and habits; everything in her physical organisation has evident reference to it."—I am, sir, your obedient servant,
WILLIAM MOORMAN.

Saint Columb, Cornwall, December 4th, 1875.

STUDENT.—*Part. Vic.*: Partitis vicibus, in divided doses. *Hora decub.*: Hora decubitus, at bed-time. But every student should have a Latin dictionary, and know how to use it.

THE DISPENSING OF MEDICINES.

SIR,—I am surprised that the subject of general practitioners dispensing their own medicines has not been taken up with the spirit that the subject of medical titles was a short time ago, and discussed with much vigour week after week in the columns of the JOURNAL, as it is one of very great importance to the welfare of the profession. Either the principle of general practitioners dispensing their medicines is right or wrong. If right, why should it not be continued? or if wrong, let it be given up. The general practitioners of the present day are much more highly educated men than their predecessors of even twenty or thirty years ago, and the tendency of the age in almost everything is division of labour; and the time, no doubt, will come, if we continue to increase and prosper as a nation as we have done during the last half century, when pharmacy and dispensing will be entirely relegated to chemists and druggists. Still, for a young man commencing practice as a general practitioner, it is a great mistake for him not to dispense his own medicines, which, with coated pills, and concentrated infusions, etc., can be easily done, and without much expense. Giving a prescription, and charging a fee of 2s. 6d. or 3s. 6d., especially in chronic cases, is ruinous practice to a young general practitioner. By so doing, he plays into the hands of his patient and the druggist, who are the real gainers, whilst he and his wife and family, should he possess such blessings, may starve at home; and did not midwifery come to the rescue, many a young general practitioner must pay the penalty of such folly by going to the wall.

The very sensible letter of A Junior Member in your impression of October 23rd I fully endorse, and should advise all young general practitioners to follow his example. The contrast of M.D. Edin. is most remarkable. I never heard of such ruinous practice as an M.D. visiting a patient and prescribing for him for 1s. 6d. I cannot but deeply commiserate such a poor brother, and advise him to follow some such plan as that of a Junior Member.—I am, yours faithfully,
November 29th, 1875.
A SENIOR MEMBER.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

PERCHLORIDE OF IRON IN POST PARTUM HÆMORRHAGE.
 SIR,—Dr. Weir's case of *post partum* hemorrhage was, no doubt, simply a case of inertia uteri, from defective power; and had he used, as contemplated, the forceps, I feel sure it would not have taken place; if so, to a much less extent: at any rate, it shows how necessary in these cases it is to be energetic. I quite agree in the recommendation not to pull too much at the cord, but rather to give the placenta good time, as I can well recollect a case wherein hemorrhage was increased, if not induced, by such. I have always found it better to allow the uterus to expel the hand, as Gooch says, instead of frequently introducing, as contraction is then better, and of longer duration.

As to the second case of "chronic hemorrhage", it is not stated if it were due to fibroid of the uterus, which is possible. In that case, no doubt, the perchloride solution would stop it for a time; but inasmuch as there is (this case) a foreign body already *in utero*, which of itself would retain secretions that must decompose, and give rise to all the fatal symptoms of purulent infection, I for one fail to observe the great benefit of filling the uterus with perchloride of blood-clots, setting aside the tanning of the muscular walls. We know the perchloride of iron is not the safest remedy for removing *navi*; and in wounds where it is used, very often great sloughing results, as much from the agent as from the injury. These cases we can see; in the partially closed uterus it is more difficult—I am, sir, your obedient servant,

November 23rd, 1875.

Late House-Surgeon Lying-in Hospital.

PUBLIC VACCINATOR.—A very good statement of the subject is to be found in Ross's *Vaccinator's Handbook*, p. 44. "In regard to insusceptibility, it will be observed that no medical practitioner is justified in giving a certificate to that effect, unless he has at least three times unsuccessfully vaccinated the child (30 and 31 Vict., c. 84, sec. 20), and that the form of certificate provides for the insertion of the number of times the child has been so unsuccessfully vaccinated, and also for the operator's opinion that the child is insusceptible. A certificate omitting either of these particulars should be rejected by the vaccination officer, and not registered; for the fact of numerous unsuccessful attempts is not of itself evidence of insusceptibility, nor is the statement of the operator's opinion to be accepted as conclusive, unless he states, as the basis of such opinion, the number of attempts he has made. The statement of having had small-pox in the old form of certificate—that under the Act of 1867—(30 and 31 Vict., c. 84, schedule, Form C) was followed by an expression of the medical practitioner's opinion that the child was 'insusceptible'. This, however, it will be seen, is otherwise in the new form; and it appears to be intended that the receipt by the vaccination officer of a certificate that the child has had small-pox will justify him, after recording such certificate in his report, in treating the case as finally disposed of, without any reference to the medical practitioner by his opinion as to the child's susceptibility or insusceptibility of the vaccine disease. It is desirable to mark this distinction between the old certificate and the new, though even under the Act of 1867 the mere fact of having had small-pox was recognised as an excuse for non-vaccination." (See secs. 20 and 31.)

SUPPRESSED MENSTRUATION FROM RESIDENCE AT THE SEA-SIDE.
 EARLY in the month of June, Mrs. H., aged 31, the mother of three children, the youngest of whom is three years old, left her home in Northumberland for the purpose of visiting her parents in the Orkney Islands, where she remained for five weeks, the menstrual flow being regular as to time and quantity up to the date of her leaving home. The next "show" ought to have appeared during her residence there; but though it was irregular, she satisfied herself that it would appear at the next monthly period. Being disappointed in this, however, I was asked to visit her, and, on careful inquiry into the history of her case, could find no satisfactory explanation for this sudden cessation, as she was in the normal standard of health, and gave the assurance that there was no reason for her thinking herself pregnant. The only thing of which she complained was a slight discharge at the regular monthly period, which continued for a few days, and was attended with the same kind of local and general disturbance that we see associated with the proper uterine discharge. The case did not seem to me, therefore, to call for any very active line of treatment, and the patient was asked to wait, in the confident assurance that times all would come right with her. The following month, however, proved only to be like the previous, though she complained more of the discharge, and, in addition, a little pain, when it occurred to me that there might be some ulceration to account for this; but, on examination, it was found to consist of only a little leucorrhœa, which seemed an attempt on the part of the uterus to furnish the true sanguineous secretion. The saccharine carbonate of iron was now prescribed for her, in the form of two five-grain pills three times a day, the use of the ordinary remedies usually applied in such cases being advised a day or two before the next period, when, much to her satisfaction, the catamenial flow appeared. It appears, therefore, that this cessation of menstruation was altogether unconnected with any pathological condition, and could only be accounted for from the effects of the marine atmosphere during her stay in the north.

Matfen, November 29th, 1875.

ROBT. TORRANCE, L.R.C.S.E.

L. M. A.—The Midwifery Board met on the 15th instant, only the second time in this year. The following gentlemen are members of the Board—viz., Mr. Prescott Hewett, chairman, and Drs. Arthur Farre, Robert Barnes, and W. O. Priestley.

CHLORAL AND CHLOROFORM.

SIR,—May I direct your attention to an oversight which occurs in a paragraph at p. 710 of this week's *JOURNAL*? Chloral is there twice referred to as "solidified chloroform", and as chloroform "in the solid state". With the general intention of the notice in question every one must cordially agree, and on this account it is the more to be regretted that it should be complicated with a scientific inaccuracy such as that quoted. The formula for chloral is C_2HCl_3O ; that for chloroform is $CHCl_3$; from which it will be seen that the latter contains no oxygen, and only half the amount of carbon contained by the former. The physiological effects are, I think, as different in the two cases as is the chemical composition. The practical danger to be apprehended from considering chloroform and chloral as identical is this: a person who had acquired the habit of taking chloral with apparent impunity might naturally, under this impression, think it equally safe to inhale chloroform, so incurring a risk the magnitude of which could scarcely be exaggerated.—I am, sir, yours truly,

December 6th, 1875.

CHAS. ELAM.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the *BRITISH MEDICAL JOURNAL*, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, no later than *Thursday*, twelve o'clock.

BOGUS DIPLOMAS.

SOMEWHERE (says the Paris correspondent of the *Times*) there would seem to be a great trade in what the Americans call "bogus" diplomas, for, since the recent exposures in the *Times* and other papers, the dealers in these distinctions have hit upon a plan for obtaining vouchers, about whose authenticity there can be no doubt. Several Parisian doctors have been the victims of these speculators under the following circumstances. Not long ago, this advertisement appeared in several French papers:

"1,000 to 2,000 francs lent to every doctor in medicine or health-officer on the simple presentation of his diploma.—Address M., etc."

Several young men who had just taken their degrees, and whose practice was as yet not equal to their wants, were entrapped by this tempting bait, and hastened to the address given. They were most politely received, and asked to leave their diplomas for verification with the affable gentleman who was to make the loan, to return in a week; but, on revisiting the house, the victims found that money-lender and paper had both disappeared. Doubtless at the present moment the writing on these documents has been carefully erased, and some impudent quack is practising as a licentiate of the Sorbonne.

1876.

THE BRITISH MEDICAL ASSOCIATION.

President.—SIR ROBERT CHRISTISON, Bart., M.D., D.C.L., LL.D., F.R.C.P.Ed., F.R.S.Ed., Professor of Materia Medica in the University of Edinburgh.

President Elect.—SIR JOHN CORDY BURROWS, F.R.C.S.Eng., Brighton.

President of Council.—R. WILBRAHAM FALCONER, M.D., D.C.L., F.R.C.P., Senior Physician to the Mineral Waters Hospital, Bath.

Treasurer.—WILLIAM D. HUSBAND, F.R.C.S.Eng., Senior Surgeon to the County Hospital, York.

Editor of Journal.—ERNEST HART, Esq.

General Secretary.—FRANCIS FOWKE, Esq.

The ANNUAL MEETING of the Association for 1876 will be held in BRIGHTON under the Presidency of

SIR JOHN CORDY BURROWS, F.R.C.S.Eng.

The ADDRESS in MEDICINE will be delivered by EDWARD H. SIEVEKING, M.D., F.R.C.P., Physician to St. Mary's Hospital, and Physician Extraordinary to the Queen.

The ADDRESS in SURGERY will be delivered by C. G. WHEELHOUSE, F.R.C.S.Eng., Senior Surgeon to the General Infirmary, Leeds.

The ADDRESS in PUBLIC MEDICINE will be delivered by ALFRED CARPENTER, M.D., Croydon.

THE HASTINGS GOLD MEDAL, Value Twenty Guineas,

Will be awarded for the best Essay "On Diphtheria: its Pathology, Diagnosis, and Treatment".

THE WOOD PRIZE of Twenty-five Pounds,

Will be awarded for the best Essay "On Pyæmia".

The objects of the Association are—the promotion of Medical Science, and the maintenance of the honour and interests of the Medical Profession. The Subscription to the Association is One Guinea annually; and each Member on paying his Subscription is entitled, in addition to the other advantages of the Association, to receive weekly, post free, the "BRITISH MEDICAL JOURNAL: BEING THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION". The Subscription is payable, in advance, on the 1st January in each year.

Gentlemen desirous of becoming Members of the Association should communicate their wish to the HONORARY LOCAL SECRETARIES, or to the General Secretary, F. FOWKE, Esq., 36, Great Queen Street, Lincoln's Inn Fields, London, W.C.

For the Annual Subscription of One Guinea, paid in advance, the BRITISH MEDICAL JOURNAL is forwarded weekly to Members, free by post. Orders enclosing remittances should be addressed to FRANCIS FOWKE, Esq., at the Office of the Journal, 36, Great Queen Street, London, W.C.—For persons not Members of the Association, the Annual Subscription is Twenty-eight Shillings.

GRANTS in AID of ORIGINAL RESEARCHES in MEDICINE and the ALLIED SCIENCES.

Applications, stating the nature and objects of the intended research, should be sent before the 29th day of DECEMBER instant, to the General Secretary, at the Office of the Association, 36, Great Queen Street, London, W.C.

THE BRITISH MEDICAL JOURNAL for 1876,

Edited by ERNEST HART, Esq.

The JOURNAL includes the earliest scientific, social, and political information on all subjects interesting to the Profession; LEADING ARTICLES and Editorial Comments on the Subjects of the Week; ORIGINAL ARTICLES and LECTURES by the most eminent authorities; MEMORANDA and RECORDS of DAILY PRACTICE by Hospital and General Practitioners; Extracts from BRITISH and FOREIGN JOURNALS; Reports of the Practice of the HOSPITALS and ASYLUMS of Great Britain and Ireland; Full Reports of the Proceedings of the BRITISH MEDICAL ASSOCIATION and of its BRANCHES and Committees; SPECIAL CORRESPONDENCE from the principal cities and localities of Great Britain, Ireland, and the Continent; REPORTS of the PRINCIPAL MEDICAL SOCIETIES in SCOTLAND, and IRELAND; REPORTS on NEW INVENTIONS; SPECIAL REPORTS on SANITARY and MEDICO-LEGAL QUESTIONS; ENGLAND, REVIEWS OF BOOKS; a Department devoted to the PUBLIC HEALTH and POOR-LAW SERVICE; a Department devoted to the MILITARY and NAVAL MEDICAL SERVICES; University Intelligence; Lists of Vacant Appointments; Obituaries of Medical Men; NOTICES and ANSWERS to CORRESPONDENTS.

The arrangements for reporting the proceedings of the MEDICAL SOCIETIES in the United Kingdom are very complete, and include the transactions of Societies in London, Edinburgh, Dublin, Manchester, Glasgow, Leeds, Bradford, &c., together with abstract Reports of the Papers read, and the Cases and Specimens exhibited, at the Meetings of the Twenty-nine Branches of the BRITISH MEDICAL ASSOCIATION.

The Department devoted to the interests of the PUBLIC HEALTH and POOR-LAW MEDICAL SERVICES has been largely developed, and the services of gentlemen of the highest authority and largest experience have been obtained. The Department includes notices and answers to questions from Medical Officers of Health and Poor-Law Medical Officers, and is intended to assist and support them in the performance of their difficult duties.

The Department devoted to the interests of the **ARMY and NAVY MEDICAL SERVICES** is intended to fulfil similar functions in respect to those services.

Arrangements have been made for a complete **SPECIAL CORRESPONDENCE** from **SCOTLAND, IRELAND, and the PROVINCES of ENGLAND**, as well as from **THE CONTINENT**.

In the forthcoming volumes will be published—

THE HARVEIAN ORATION delivered at the Royal College of Physicians of London. By **Edmund A. Parkes, M.D., F.R.C.P., F.R.S.**, Professor of Hygiene in the Army Medical School, Netley.

THE LUMLEIAN LECTURES, delivered at the Royal College of Physicians of London, on the Pathology of the Pneumogastric Nerve. By **Samuel O. Habershon, M.D., F.R.C.P.**, Senior Physician to and Lecturer on Medicine at Guy's Hospital.

THE CROONIAN LECTURES, delivered at the Royal College of Physicians of London, on the Pathology and Relations of Albuminuria. By **W. H. Dickinson, M.D., F.R.C.P.**, Physician to and Lecturer on Materia Medica at St. George's Hospital.

THE GOULSTONIAN LECTURES, delivered at the Royal College of Physicians of London, on the Natural History of Pulmonary Consumption. By **A. B. Shepherd, M.D., F.R.C.P.**, Assistant-Physician to St. Mary's Hospital.

TWO HARVEIAN LECTURES delivered at the Harveian Society of London, on Bright's Disease, and its Treatment, considered mainly in relation with Arterial Tension from Blood-contamination. By **Francis Sibson, M.D., D.C.L., F.R.C.P., F.R.S.**, Consulting Physician to St. Mary's Hospital.

THE LETTSOMIAN LECTURES at the Medical Society of London, on the Influence of Climate on the Treatment of Pulmonary Consumption. By **C. Theodore Williams, M.A., M.D., F.R.C.P.**, Physician to the Hospital for Consumption and Diseases of the Chest.

SELECTED LECTURES on the Practice of Medicine. Series I. **FEVER**. By **T. Clifford Allbutt, M.A., M.D.**, Physician to the Infirmary, and Lecturer on Medicine in the School of Medicine, Leeds.

LECTURES on Electrolysis: with Illustrations. By **John Duncan, M.D.**, Assistant-Surgeon to the Royal Infirmary, Edinburgh.

AN ADDRESS on the Practical Application of the Sphygmograph. By **M. Marey**, Professor in the College of France.

REPORT of Experimental Observations on the Effects of certain Drugs in Diseases of the Chest By **R. Douglas Powell, M.D., F.R.C.P.**, Physician, and **Reginald E. Thompson, M.D., F.R.C.P.**, Assistant-Physician, to the Hospital for Consumption and Diseases of the Chest at Brompton.

REPORTS presented to the Scientific Grants Committee of the British Medical Association.—

II.—Contribution to the Life-History of Contagium. By **P. M. Braidwood, M.D.**, and **F. Vacher**, (continued).

III.—The Physiological Action of the Chinoline and Pyridine Compounds. By **J. G. McKendrick, M.D.**, Lecturer on Physiology in Edinburgh.

IV.—The Treatment of Pyrexia by the Gradual Abstraction of Heat: the Action of Uranium Salts in Diabetes: the Action of Trimethylamine (pure) and its Alkaline Products distilled from Herring-Brine, in Rheumatism and Gout. By **W. H. Spencer, A.M., M.B.**, Physician to the Bristol Royal Infirmary, and Lecturer on Medicine at the Bristol Medical School.

V.—The Antagonism of Aconite and Digitalis. By **J. M. Fothergill, M.D.**, Physician to the West London Hospital.

VI.—Investigations of the Electric Currents of the Brain. By **Richard Caton, M.D.**, Lecturer on Physiology in the Liverpool Royal Infirmary School of Medicine.

VII.—On Albuminuria. By **F. A. Mahomed, M.D.**

VIII.—On the Restoration of Life in Cases of Apparent Death from Chloroform. By **W. Munro, M.D.**

These Reports are paged separately, and may be cut out and preserved for binding, if desired, in a separate form.

Lectures and other Contributions from the following Members of the Profession.

WILLIAM ADAMS, F.R.C.S.Eng., Surgeon to the Great Northern Hospital.—The **TREATMENT of BURN-CICATRICES**.

JULIUS ALTHAUS, M.D., Physician to the London Infirmary for Epilepsy and Paralysis.—The **SEVERER FORMS of EPILEPSY**, and their **TREATMENT**.

T. McCALL ANDERSON, M.D., Professor of Clinical Medicine in the University of Glasgow.—**LECTURES on CLINICAL MEDICINE**.

THOMAS ANNANDALE, F.R.C.S.Edin., F.R.S.E., Surgeon to the Edinburgh Royal Infirmary, and Lecturer on Clinical Surgery.—**OBSERVATIONS and CASES in CLINICAL SURGERY**.

LOMBE ATTHILL, M.D., F.R.C.C.P., Vice-President of the King and Queen's College of Physicians in Ireland; Master of the Rotunda Hospital.—Contributions in **MIDWIFERY and UTERINE SURGERY**.

THOMAS H. BARTLETT, F.R.C.S.Eng., Joint Professor of Anatomy and Physiology in Queen's College, and Surgeon to the General Hospital, Birmingham.

H. CHARLTON BASTIAN, M.D., F.R.C.P., F.R.S., Professor of Pathology in University College, and Physician to University College Hospital.

JOHN BARCLAY, M.D., Banff.—An **ACCOUNT** of interesting and unusual **CASES** occurring during the past year's **PRACTICE**.

RICHARD BARWELL, F.R.C.S.Eng., Surgeon to the Charing Cross Hospital.—**CLINICAL LECTURES on LOOSE CARTILAGES in the KNEE-JOINT**.

W. R. BASHAM, M.D., F.R.C.P., Senior Physician to the Westminster Hospital.—**CLINICAL LECTURES on GOUTY DISEASE of the KIDNEYS**.

E. BUCHANAN BAXTER, M.D., Professor of Materia Medica in King's College, London, and Assistant-Physician to King's College Hospital.—**PAPERS on THERAPEUTICS and CLINICAL MEDICINE**.

LIONEL S. BEALE, M.B., F.R.C.P., F.R.S., Physician to King's College Hospital, and Professor of Pathology in King's College.—**PAPERS and CLINICAL LECTURES**.

JOSEPH BELL, F.R.C.S. Ed., F.R.S.E., Surgeon to the Royal Infirmary, Edinburgh.—**CONTRIBUTIONS on SURGICAL PATHOLOGY and OPERATIVE SURGERY**.

EDWARD BELLAMY, F.R.C.S.Eng., Assistant-Surgeon to, and Lecturer on Surgery at, the Charing Cross Hospital.—**1. SHORT CLINICAL LECTURES. 2. CONTRIBUTIONS on the SURGERY of the NASAL PASSAGES**.

HERMANN BEIGEL, M.D., Vienna.—On CHOREA.

J. B. BRADBURY, M.D., F.R.C.P., Linc. Lecturer on Medicine in the University of Cambridge, and Physician to Addenbrooke's Hospital.—1. CANCER of the CEREBELLUM & LEFT LUNG. 2. The TREATMENT of PSORIASIS.

DAVID J. BRAKENRIDGE, M.D., Assistant-Physician to the Royal Infirmary, Edinburgh.

JAMES P. BRAMWELL, M.D., Surgeon to the Infirmary, Perth.

MESSENGER BRADLEY, F.R.C.S. Eng., Senior Assistant-Surgeon to the Manchester Royal Infirmary.—The SURGICAL TREATMENT of TUMOURS of the LYMPHATIC GLANDS.

P. M. BRAIDWOOD, M.D.—SEVERE CEREBRO-SPINAL SYMPTOMS produced by a FALL AT FOOTBALL.

BYRON BRAMWELL, M.B., Physician to the Newcastle-on-Tyne Infirmary.—1. CASE of OBSCURE ABDOMINAL TUMOUR. 2. CASE of INTRATHORACIC TUMOUR (LYMPHOSARCOMA) with SECONDARY DEPOSIT in SUPRARENAL CAPSULES. 3. CASE of UNILATERAL CONVULSIONS and HEMIPLEGIA, depending upon a LESION of certain CEREBRAL CONVOLUTIONS.

GEORGE BUCHANAN, A.M., M.D., Professor of Clinical Surgery in the University of Glasgow.—CLINICAL LECTURES on SURGERY.

GEORGE W. CALLENDER, F.R.C.S. Eng., F.R.S., Surgeon to and Lecturer on Surgery at St. Bartholomew's Hospital.—LECTURES on CLINICAL SURGERY.

S. HAMILTON CARTWRIGHT, M.R.C.S., Professor of Dental Surgery in King's College.—CONTRIBUTIONS to ORAL SURGERY.

JAMES P. CASSELLS, M.D., Surgeon to the Dispensary for Diseases of the Ear, Glasgow.—OTOLOGICAL MEMORANDA; being CLINICAL OBSERVATIONS, illustrative of the DISEASES and INJURIES of the EAR.

JOHN CAVAFY, M.D., Assistant-Physician and Lecturer on Physiology at St. George's Hospital.—A CASE of GRAVES' DISEASE.

M. CHARTERIS, M.D., Physician to the Royal Infirmary, Glasgow.—CASE of GONORRHOICAL RHEUMATISM and PYÆMIA.

W. B. CHEADLE, M.A., M.D., F.R.C.P., Senior Assistant-Physician and Lecturer on Pathology at St. Mary's Hospital, Assistant-Physician to the Hospital for Sick Children.—1. On CERTAIN VARIETIES of EPILEPTIFORM DISEASE in CHILDREN (Eclampsia Nutans = Eclampsia Loquax). 2. A CASE of EXTREME HYSTERICAL AFFECTION in a BOY.

JOHN CHENE, F.R.C.S. Ed., Lecturer on Surgery, and Assistant-Surgeon to the Royal Infirmary, Edinburgh.

ANDREW CLARK, F.R.C.S. Eng., Assistant-Surgeon to the Middlesex Hospital.—SURGICAL CASES.

J. LOCKHART CLARKE, M.D., F.R.C.P., F.R.S., Physician to the Hospital for Diseases of the Nervous System.—CLINICAL OBSERVATIONS on the TREATMENT of DISEASES of the NERVOUS SYSTEM.

W. MICHELL CLARKE, M.R.C.S., Consulting Surgeon to the Bristol General Hospital.

THOMAS CLOUSTON, M.D., Physician-Superintendent of the Royal Asylum, Morningside, Edinburgh.

JOSEPH COATS, M.D., Pathologist and Lecturer on Pathology in the Western Infirmary, Glasgow.

T. SPENCER COBBOLD, M.D., F.R.S., Professor of Helminthology and Botany in the Royal Veterinary College.—SPURIOUS PARASITISM, or PSEUDHELMINTHOLOGY.

J. G. SINCLAIR COGHILL, M.D., F.R.C.P. Ed., Lecturer on Midwifery, Edinburgh.—On UTERINE DISPLACEMENTS.

ALEXANDER COLLIE, M.D., Medical Officer to the Fever Hospital, Homerton.—HOSPITAL DIETARIES and the COST of PATIENTS.

R. PAYNE COTTON, M.D., F.R.C.P., Consulting Physician to the Hospital for Consumption at Brompton.—NOTES on HÆMOPTYSIS.

EDWARD COPEMAN, M.D., F.R.C.P., Senior Physician to the Norfolk and Norwich Hospital.—THERAPEUTICAL and OBSTETRICAL MEMORANDA.

GEORGE COWELL, F.R.C.S. Eng., Surgeon to the Westminster and the Royal Westminster Ophthalmic Hospitals, and Lecturer on Surgery and Ophthalmic Surgery at the Westminster Hospital.—OPHTHALMIC CASES.

GEORGE CRITCHETT, F.R.C.S. Eng., Surgeon to the Royal London Ophthalmic Hospital.—PAPERS on the DISEASES and INJURIES of the EYE.

JOHN CROFT, F.R.C.S. Eng., Surgeon to, and Lecturer on Practical Surgery at St. Thomas's Hospital.—CLINICAL LECTURES on DISEASES of the JOINTS.

J. HALLIDAY CROOM, M.B.—MELENA in the NEWBORN CHILD.

JAMES CUMMING, M.D., F.R.C.P. Ed., Extra Physician to the Royal Hospital for Sick Children, Edinburgh.—NOTES on SKIN-DISEASES.

W. JACKSON CUMMINS, M.D., Physician to the South Infirmary, Cork.—1. CASE of PUERPERAL SCARLATINA. 2. CASE of PUERPERAL TYPHUS. 3. CASE of DIABETES, presenting unusual Symptoms.

A. DYCE DAVIDSON, M.A., M.D., Lecturer on Ophthalmic Surgery in the University of Aberdeen, and Ophthalmic Surgeon to the Aberdeen Royal Infirmary.—CLINICAL CASES.

W. HENRY DAY, M.D., Physician to the Samaritan Hospital.—On TUBERCULOSIS in CHILDREN, and the CONDITIONS which RESEMBLE it.

WALTER DICKSON, M.D., R.N., Medical Inspector of H.M. Customs.—The NUMERICAL RATIO of DISEASE in the ADULT MALE COMMUNITY, deduced from the SANITARY STATISTICS of HER MAJESTY'S CUSTOMS, London, for the year 1857-1874.

A. SCOTT DONKIN, M.D., Assistant-Physician to the Westminster Hospital.—CLINICAL OBSERVATIONS on the INFLAMMATORY FORM of CHRONIC BRIGHT'S DISEASE.

J. LANGDON DOWN, M.D., F.R.C.P., Physician to the London Hospital.—The PHYSICAL DIAGNOSIS of MENTAL FEEBLENESS in CHILDREN and YOUTH.

THOMAS S. DOWSE, M.D., Medical Superintendent of the Central London Sick Asylum, Highgate.—1. SPINAL SCLEROSIS. 2. BULBAR PARALYSIS.

ALFRED B. DUFFIN, M.D., F.R.C.P., Physician to King's College Hospital.

C. M. DURRANT, M.D., F.R.C.P., Senior Physician to the East Suffolk and Ipswich Hospital.—HOSPITAL REPORTS and CLINICAL JOTTINGS.

PETER EADE, M.D., F.R.C.P., Physician to the Norfolk and Norwich Hospital. On BOILS and CARBUNCLES.

ARTHUR W. EDIS, M.D., Assistant Obstetric Physician to the Middlesex Hospital.—DEFECTIVE and DECAYED TEETH a CAUSE of IMPERFECT MASTICATION, INDUCING MUCH NEEDLESS and UNSUSPECTED SUFFERING.

ROBERT FARQUHARSON, M.D., Physician to the Belgrave Hospital for Children, and Lecturer on Materia Medica at St. Mary's Hospital.

SIR WILLIAM FERGUSSON, BART., F.R.C.S. Eng., F.R.S., Surgeon to King's College Hospital.

JAMES FINLAYSON, M.D., F.F.P.S.G., Physician to, and Lecturer on Clinical Medicine in the Western Infirmary, Glasgow.—PORTIONS of CLINICAL LECTURES on MEDICAL DIAGNOSIS.

BALTHAZAR FOSTER, M.D., F.R.C.P., Physician to the General Hospital, Birmingham, and Professor of Medicine in Queen's College.—LECTURES on CLINICAL MEDICINE.

J. MILNER FOTHERGILL, M.D., Physician to the West London Hospital.—1. The USE of DIGITALIS in DISEASE of the AORTIC VALVES. 2. The EFFECT of DRUGS upon the INTRACRANIAL CIRCULATION.

TILBURY FOX, M.D., F.R.C.P., Physician to the Skin Department, University College Hospital.—On HYDROA.

ALFRED L. GALABIN, M.D., Assistant Obstetric Physician to Guy's Hospital.—On COMMON CAUSE of DYSENTERICÆ.

SAMPSON GAMGE, F.R.S. Ed., Surgeon to the Queen's Hospital, Birmingham.—The TREATMENT of INDOLENT ULCERS of the LEG.

HENRY GERVIS, M.D., F.R.C.P., Obstetric Physician to St. Thomas's Hospital.—PUERPERAL SEPTICÆMIA.

THOMAS R. GLYNN, M.B., Physician to the Liverpool Royal Infirmary.—CASE of SUDDEN DEATH after THORACENTESIS.

CLEMENT GODSON, M.D., Assistant Obstetric Physician to St. Bartholomew's Hospital, and Physician to the Samaritan Hospital.—CASES with REMARKS.

WILLIAM R. GOWERS, M.D., Assistant Physician to University College Hospital, and to the National Hospital for Epilepsy and Paralysis.—1. The CLINICAL HISTORY of CHOREA. 2. FACIAL PARALYSIS.

ROBERT GREENHALGH, M.D., Physician-Accoucheur and Lecturer on Midwifery at St. Bartholomew's Hospital.—CASES with CLINICAL COMMENTS.

WILLIAM C. GRIGG, M.D., Assistant Obstetric Physician to the Westminster Hospital.—The MORTALITY of LYING-IN HOSPITALS.

S. O. HABERSHON, M.D., F.R.C.P., Senior Physician and Lecturer on Medicine at Guy's Hospital. CLINICAL CASES of DISEASE of the ABDOMEN.

GEORGE HARLEY, M.D., F.R.C.P., F.R.S.—MEDICAL PAPERS.

ISAAC HARRINSON, F.R.C.S.—On a FORM of UTERINE HÆMORRHAGE accompanied with WATERY DISCHARGE.

ALEXANDER HARVEY, M.D., Professor of Materia Medica in the University of Aberdeen.

JOHN HADDON, M.A., M.D.—INTemperance in WOMEN: with SPECIAL REFERENCE to its EFFECTS on the REPRODUCTIVE SYSTEM.

JOHN HARKER, M.D., Surgeon to the Lancaster Infirmary.—SUCCESSFUL CASE of TRACHEOTOMY with ARTIFICIAL RESPIRATION, in a CASE of APPARENT DEATH from CHOKING.

CHRISTOPHER HEATH, F.R.C.S. Eng., Surgeon and Holme Professor of Clinical Surgery in University College Hospital.—CLINICAL LECTURES and SURGICAL CASES.

GRAILY HEWITT, M.D., F.R.C.P., Professor of Midwifery in University College Hospital, and Obstetric Physician to University College Hospital.—1. The VOMITING of PREGNANCY. 2. The TREATMENT of CHRONIC FLEXIONS of the UTERUS.

J. BRAXTON HICKS, M.D., F.R.C.P., F.R.S., Physician-Accoucheur to, and Lecturer on Midwifery at, Guy's Hospital.—CONTRIBUTIONS in OBSTETRICS and OBSTETRIC MEDICINE.

MATTHEW HILL, M.R.C.P. Ed.—A New OPERATION in CASES of UNUNited FRACTURE.

T. HOLMES, M.A., F.R.C.S. Eng., Surgeon to, and Lecturer on Surgery at, St. George's Hospital.—CONTRIBUTIONS to CLINICAL SURGERY.

CARSTEN HOLTHOUSE, F.R.C.S. Eng.—SKETCHES illustrative of SOME of the VARIETIES of DIPLOMANTIA.

W. H. JALLAND, F.R.C.S. Eng.—TRANSVERSE FRACTURE of the UPPER END of the TIBIA from INDIRECT VIOLENCE.

WALTER R. S. JEFFERISS, M.D.—Three CASES of LIGHTNING STROKE.

FREDERICK B. JESSETT, F.R.C.S.—On OSTETIS and PERIOSTITIS.

GEORGE JOHNSON, M.D., F.R.C.P., F.R.S., Professor of Medicine in King's College and Physician to King's College Hospital.—CLINICAL LECTURES on VARIOUS PRACTICAL SUBJECTS.

SYDNEY JONES, M.B., F.R.C.S. Eng., Surgeon to, and Lecturer on Surgery at, St. Thomas's Hospital.—NOTES of CASES in SURGERY.

- THOMAS JONES, M.D.**, Senior Assistant-Physician to the Victoria Hospital for Sick Children.—CLINICAL OBSERVATIONS ON SOME OF THE DISEASES OF CHILDREN.
- FURNEAUX JORDAN, F.R.C.S.Eng.**, Surgeon to the Queen's Hospital, and Professor of Surgery in Queen's College, Birmingham.—OBSERVATIONS ON JOINT-DISEASES.
- H. MACNAUGHTON JONES, M.D.**, Surgeon to the Ophthalmic and Aural Hospital, Cork.—OPHTHALMIC OBSERVATIONS IN EPILEPTIC and INSANE CASES.
- PETER W. LATHAM, M.D., F.R.C.P.**, Downing Professor of Medicine in the University of Cambridge, and Physician to Addenbrooke's Hospital.—CONTRIBUTIONS IN CLINICAL MEDICINE.
- GEORGE LAWSON, F.R.C.S.Eng.**, Surgeon to the Middlesex Hospital.—OPHTHALMIC and OTHER SURGICAL CASES.
- RT. J. LEE, M.A., M.D., F.R.C.P.**, Assistant-Physician to the Hospital for Sick Children.—1. REMARKS ON WHOOPING COUGH and on its TREATMENT with CARBOLIC ACID VAPOUR. 2. CASES SELECTED FOR THE OUT-PATIENT DEPARTMENT OF THE CHILDREN'S HOSPITAL, with REMARKS.
- J. WICKHAM LEGG, M.D.**, Senior Casualty Physician to St. Bartholomew's Hospital.—AN EXAMINATION OF THE VIEWS held as to the CAUSES OF JAUNDICE.
- ROBERT LIVING, M.A., M.D., F.R.C.P.**, Physician to the Middlesex Hospital.—CLINICAL REMARKS and LECTURES ON DISEASES OF THE SKIN.
- R. CLEMENT LUCAS, M.B., F.R.C.S.Eng.**, Assistant-Surgeon to Guy's Hospital.—CHLORAL-HYDRATE as a LOCAL APPLICATION IN SURGICAL CASES.
- EDWARD LUND, F.R.C.S.Eng.**, Surgeon to the Royal Infirmary and Professor of Surgery in Owens College School of Medicine, Manchester.—ON A SECOND CASE OF OPERATION FOR ADAMS'S SECTION OF THE NECK OF THE FEMUR FOR DOUBLE STRAIGHT ANKYLOSIS OF THE HIP JOINT.
- GEORGE MAY, jun., F.R.C.S.Eng.**, Surgeon to the Royal Berkshire Hospital.—A CASE OF DISLOCATION OF THE JAW, reduced after an interval of thirty-three days.
- ALFRED H. McCLINTOCK, M.D.**—A LIFE OF SMELLIE.
- WILLIAM MAC CORMAC, F.R.C.S.Eng.**, Surgeon to, and Lecturer on Surgery at, St. Thomas's Hospital.
- ROBERT McDONNELL, M.D., F.R.S.**, Surgeon to Dr. Steevens's Hospital, Dublin.—THE TREATMENT OF CHRONIC CYSTITIS in the FEMALE.
- W. A. McKEOWN, M.D.**, Surgeon to the Ulster Eye, Ear, and Throat Hospital.—THE EXTRACTION OF STEEL and IRON from the INTERIOR OF THE EYE; with PARTICULAR REFERENCE to the USE of the MAGNET.
- EDWARD MACKAY, M.D.**, Physician to the Queen's Hospital, and Professor of Materia Medica in Queen's College, Birmingham.
- GEORGE H. B. MACLEOD, M.D.**, F.R.S.E., Regius Professor of Surgery in the University of Glasgow, and Surgeon to the Glasgow Royal Infirmary.—SURGICAL CLINICAL LECTURES.
- HENRY M. MADGE, M.D.**—On SYPHILIS in the FETUS.
- EDWARD MALINS, M.D.**, Honorary Medical Officer to the Birmingham Lying-in CHARITY.—FUNCTIONAL DERANGEMENT OF THE UTERUS.
- HOWARD MARSH, F.R.C.S.Eng.**, Assistant-Surgeon to St. Bartholomew's Hospital and to the Hospital for Sick Children.—LECTURES ON THE CLINICAL SURGERY OF CHILDHOOD.
- JOHN MAR-HALL, F.R.C.S.Eng., F.R.S.**, Professor of Surgery in University College and Surgeon to University College Hospital.
- SAMUEL MARTYN, M.D., F.R.C.P.**, Senior Physician to the General Hospital and Lecturer on Medicine in the Medical School, Bristol.—SYMMETRICAL THROMBOSIS in SYPHILITIC ARTERITIS.
- FRANCIS MASON, F.R.C.S.Eng.**, Senior Assistant-Surgeon and Lecturer on Anatomy at St. Thomas's Hospital.—CASES in HOSPITAL PRACTICE.
- C. F. MAUNDER, F.R.C.S.Eng.**, Surgeon to the London Hospital.
- JOHN E. MORGAN, M.D., F.R.C.P.**, Professor of Medicine in Owens College, and Physician to the Royal Infirmary, Manchester.—On SOME OF THE FUNCTIONAL DISORDERS OF THE NERVOUS SYSTEM.
- J. MORTON, M.D.**, Surgeon to the Royal Infirmary, Glasgow.—CASE OF SPINA BIFIDA.
- EDWARD NETTLESHIP, F.R.C.S.Eng.**, Surgeon to the South London Ophthalmic Hospital.—UNUSUAL DISTRIBUTION OF RETINAL VESSELS; THREE CASES.
- ALEXANDER OGSTON, M.D.**, Surgeon to the Royal Infirmary, Aberdeen.—On DISLOCATIONS OF THE ELBOW-JOINT and FRACTURES OF THE LOWER END OF THE RADIUS.
- FRANCIS OGSTON, jun., M.B.**, Assistant-Professor of Medical Jurisprudence in the University of Aberdeen.—The NOURISHMENT OF THE HEAD OF THE FEMUR after INTRACAPSULAR FRACTURE.
- MARTIN G. B. OXLEY, L.R.Q.C.P.I.**, Physician to the Liverpool Infirmary for Children.—CASE OF LYMPHADENOMA in a BOY aged SIX YEARS, AFFECTING THE KIDNEYS, LIVER, LUNGS, and BRAIN.
- GEORGE H. PHILIPSON, M.A., M.D., F.R.C.P.**, Physician to the Newcastle-on-Tyne Infirmary, and Lecturer on Medicine in the University of Durham College of Medicine.—On the TREATMENT OF RHEUMATIC FEVER. 2. On the TREATMENT OF DIABETES MELLITUS.
- W. S. PLAYFAIR, M.D., F.R.C.P.**, Professor of Midwifery in King's College, and Obstetric Physician to King's College Hospital.—CLINICAL LECTURES ON DISEASES OF WOMEN.
- JAMES EDWARD POLLOCK, M.D., F.R.C.P.**, Physician to the Hospital for Consumption at Brompton.—The PROGNOSIS in CERTAIN VARIETIES OF HEART-DISEASE.
- JOHN POPHAM, M.D.**, Physician to the North Infirmary, Cork.
- JOHN B. POTTER, M.D.**, Obstetric Physician to, and Lecturer on Obstetric Medicine at, the Westminster Hospital.—REMARKS ON DISEASES OF WOMEN.
- HENRY A. REEVES, F.R.C.S.Eng.**, Assistant-Surgeon to the London Hospital.—1. SURGICAL RABBITES. 2. OBSERVATIONS IN AURAL SURGERY. 3. SURGICAL DISEASES OF FEMALES.
- WALTER RIVINGTON, M.S., F.R.C.S.Eng.**, Surgeon to, and Lecturer on Anatomy at, the London Hospital.—1. A CASE OF PARTIAL RUPTURE OF THE POPLITEAL ARTERY and COMPLETE OF THE POPLITEAL VEIN, TREATED BY PRIMARY AMPUTATION OF THE THIGH; with REMARKS. 2. CLINICAL LECTURES ON INTRAORBITAL ABSCESS.
- D. LLOYD ROBERTS, M.D.**, Physician to St. Mary's Hospital, Manchester.—CLINICAL PAPERS ON THE DISEASES OF WOMEN and CHILDREN.
- FREDERICK T. ROBERTS, M.D.**, Assistant-Physician to University College Hospital, and to the Hospital for Consumption at Brompton.
- ALEXANDER ROBERTSON, M.D., F.F.P.S.G.**, Physician to the Town's Hospital and Asylum, Glasgow.—CONTRIBUTIONS ON DISEASES OF THE NERVOUS SYSTEM.
- D. ARGYLL ROBERTSON, M.D., F.R.S.E.**, Ophthalmic Surgeon to the Edinburgh Royal Infirmary.—THE TREATMENT OF INFLAMMATORY & ULCERATIVE AFFECTIONS OF THE CORNEA.
- JAMES ROUSE, F.R.C.S.Eng.**, Surgeon to St. George's Hospital.—SURGICAL CONTRIBUTIONS.
- JAMES RUSSELL, M.D., F.R.C.P.**, Physician to the General Hospital, Birmingham.—CLINICAL REPORTS.
- A. ERNEST SANSON, M.D.**, Assistant-Physician to the London Hospital, Physician to the North Eastern Hospital for Children.—INFECTED and DISINFECTED.
- JAMES SAWYER, M.D.**, Physician to the Queen's and Children's Hospitals, and Professor of Pathology in Queen's College, Birmingham.—NOTES ON PHTHISICAL LARYNGITIS.
- GEORGE SHANN, M.D., F.R.C.P.**, Physician to the County Hospital, York.—A CASE OF FRACTURE OF THE PTEOUS PORTION OF THE TEMPORAL BONE from a SLIGHT FALL WITHOUT EXTERNAL MARKS OF VIOLENCE; MENINGITIS; PECULIAR THERMAL PHENOMENA.
- J. SHAW, M.D.**, Assistant Medical Officer to the Norfolk County Lunatic Asylum.—CASES OF SOFTENING OF THE BRAIN.
- PROTHEROE SMITH, M.D.**, Physician to the Hospital for Women.—OVARIAN DROPSY, SOME POINTS in its PATHOLOGY and TREATMENT.
- REGINALD SOUTHEY, M.D., F.R.C.P.**, Physician to St. Bartholomew's Hospital.—ORATORICAL LECTURES ON TUBERCULAR MELITIS and other SUBJECTS.
- W. H. SPENCER, A.M., M.B., F.L.S.**, Physician to the Bristol Royal Infirmary, and Lecturer on Medicine at the Bristol Medical School.—1. SCIENTIFIC METHOD in DESCRIPTIVE MEDICINE—THEORETICAL and PRACTICAL. 2. ILLUSTRATIONS OF THE ADVANTAGE OF SCIENTIFIC METHOD in the DESCRIPTION OF DISEASES.
- W. STEPHENSON, M.D.**, Professor of Midwifery in the University of Aberdeen.—PAPERS and LECTURES ON SUBJECTS in MIDWIFERY.
- T. GRAINGER STEWART, M.D., F.R.C.P.Ed.**, Physician to the Royal Infirmary, Edinburgh.—CLINICAL CASES.
- OCTAVIUS STURGES, M.D., F.R.C.P.**, Physician to, and Lecturer on Medicine at, the Westminster Hospital.—The TREATMENT OF EMPYEMA in CHILDREN; with Statistics.
- WILLIAM P. SWAIN, F.R.C.S.Eng.**, Surgeon to the Royal Albert Hospital, Devonport.—CLINICAL CASES.
- W. F. TEEVAN, F.R.C.S.Eng.**, Surgeon to the West London Hospital.—An IMPROVED METHOD OF PERFORMING THE BUTONNIERE OPERATION.
- E. SYMES THOMPSON, M.D., F.R.C.P.**, Physician to the Hospital for Consumption, Brompton.—THE VARIATIONS OF CARDIAC RHYTHM in PULMONARY and HEPATIC DISEASES.
- Sir HENRY THOMPSON, F.R.C.S.**—Surgeon Extraordinary to the King of the Belgians, late Surgeon to University College Hospital.
- JOHN THORBURN, M.D.**, Professor of Midwifery in Owens College, and Obstetric Physician to the Royal Infirmary, Manchester.
- H. M. TUCKWELL, M.D., F.R.C.P.**, Physician to the Radcliffe Infirmary, Oxford.—On the TREATMENT OF CHOREA by ARSENIC and OTHER MEDICINES.
- J. BATTY TUKE, M.D., F.R.C.P.Ed.**, Metropolitan Lecturer on Insanity to the Royal College of Physicians of Edinburgh.—CONTRIBUTIONS ON CEREBRAL PATHOLOGY, INSANITY, &c.
- JOHN R. WARDELL, M.D., F.R.C.P.**, Senior Physician to the Tinsbridge Wells Infirmary.—REMARKS ON ENTERIC FEVER.
- W. SPENCER WATSON, F.R.C.S.Eng.**, Surgeon to the General London and Royal South London Ophthalmic Hospitals.—The DIAGNOSIS, PROGNOSIS, and TREATMENT OF SEVERE INJURIES OF THE EYE.
- SPENCER WELLS, F.R.C.S.Eng., F.R.C.P.L.**, Surgeon to the Samaritan Hospital.—LESSONS FROM MISTAKES and FAILURES.
- C. G. WHEELER, F.R.C.S.Eng.**, Senior Surgeon to the General Infirmary, Leeds.—1. PERINEAL SECTION, as PERFORMED in LEEDS. 2. HOSPITAL CASES.
- EDWARD T. WILSON, M.B., F.R.C.P.**, Physician to the Cheltenham General Hospital.—A CASE OF DISSEMINATED INSULAR SCLEROSIS.
- W. BATHURST WOODMAN, M.D.**, Physician to the North-Eastern Hospital for Children, and Assistant-Physician to the London Hospital.—Some DISEASES OF CHILDREN, especially those of a PARASITIC CHARACTER.
- STRETHILL H. WRIGHT, M.D.**, Physician to the Barrow Hospital, Glasgow.—THE TREATMENT OF THE SICK FOOT in SCOTLAND.
- I. BURNEY YEO, M.D.**, Senior Assistant-Physician to King's College Hospital.—THE THERAPEUTICS OF PHTHISIS.
