There is indeed another important calling between whose professional work and this work a great gulf is fixed; namely, the immeasurable difference between the supernatural and the natural. And yet the priests of some creeds make the singular mistake of illustrating their duties by comparing them to ours; nay, they go beyond comparison in declaring positively that sin is spiritual disease, and that they are physicians of the soul. It behoves us to look to this; for it cannot be said that the priest and the physician are very much alike, especially the priest. Comparisons are commensurate, and by as much as the priest is like the physician, by so much is the physician like the priest. If sin is disease, disease is sin; and if the priest is a physician, the physician is a priest. I desire punctiliously to guard myself, in the following remarks, from the expression of any theological opinion whatever, and especially from any opinion which may give offence to our most respected fellow-members who belong to the communion of the Roman Catholic Church. I believe they will be among the first to agree with me that the functions of the physician and those of the priest are essentially unlike, and that it is most desirable to avoid any misleading analogies between them. The Roman Catholic honestly expresses his belief that the functions of the priest are divine, and that confession is a sacrament ordained by God. That is a definite position which we can understand, and which in this place it would be improper to dispute. But within the Protestant Church of this country a very different position has been assumed, against which, I think, the medical profession will do well to protest. I well remember that at the meeting of this Association which was held at Torquay, the chancellor of the diocese presented himself as the ambassador of his bishop, with the proposal that priests should be admitted within the ranks of the medical profession, in order that they might practise medicine in conjunction with their clerical duties. I observe that a certain school or sect of divines within the State Church of this country are diligently employed in the dissemination of the doctrine that the priest is a physician; that sin is disease, and that the confession of sin to the priest is as natural and necessary as the communication of the causes, history, and symptoms of disease made by a patient to his medical adviser. If we allow this doctrine to pass unquestioned, there may perhaps be little danger that priests will really seek to practise as physicians; but there is a likelihood that the public estimate of the functions of the physician will be unsettled and confused, and that the avowal of the history and causes of disease will not escape from that suspicion and repugnance which, in this country, is so widely attached to the confession of sins to the priest. I have found the doctrine to which I refer expressed in many works of English divines. Often, no doubt, it is used oratorically as a mere metaphor, as by Bishop Hooker, who said that "priests are spiritual and ghostly physicians in the private particular case of diseased minds"; but of late, in that section of the English Church which mimics the Church of Rome, the doctrine seems to be definitely taught that sin is disease and the priest a physician: and, under cover of this doctrine, so-called patients or penitents

are exhorted to the confession of their symptoms or sins, in order that they may be cured and absolved. To establish this assertion, I shall only quote from one book, which, however, is the accepted manual of confession among this mimic priesthood.

The author of "The Priest in Absolution" speaks of the subject of his manual as "this subject of spiritual pathology." He says: "The qualification of a priest binds him to the acquisition of sound morality as a judge, and of great skill as a physician" (part 1, page 4). He speaks of "the duty which devolves upon a priest, in his character of a physician, to probe the spiritual wounds of his patients" (page 5). "The priest must have the knowledge of a physician, in order to direct the moral knowledge of which it is the strength" (page 10). "For the priest should as a judge punish offences, but as a physician heal the sick so far as he can prevent a relapse" (page 41). "He [the priest] is nevertheless, as a physician, obliged to warn them and rebuke them according to their needs" (page 49). In the second part, he says: "A surgeon may do many things else indecent for the sake of curing disease; a confessor may study cases of conscience" (page 20). In his directions "How to deal with shame-faced penitents," he says: "The priest should kindly remind them that they do not shrink from revealing their bodily diseases to friends and physicians; and that, as the soul is of more consequence than the body, they should not shrink from disclosing the diseases of the soul to its physicians" (page 189). He says that it is sometimes the priest's duty to delay absolution, "advising him [the penitent or patient] to come back on a fixed day within eight or ten days, adding that any relapse within that period should cause no discouragement, but rather urge him all the more to resort to the physician" (page 195). "If absolution be delayed, etc., it is good for the patient who is very ill to see his doctor frequently" (page 235). "A priest is said to have cured one patient by telling him to come to him for confession as soon as he had fallen into sin, and not to wait for a second fall. By absolving him and giving him the same penance, he was cured in a few months" (page 236). "We must distinguish between what is a proper disposition to receive absolution and what is its fruit; else we may act like doctors who content themselves with purges without ordering the supports needful to sustain the effects thereof, and so kill their patient" (page 237). "Like medicines after which the patient seems to be better, though the fever recur afterwards, so with confession, which, though it blots out all sins of which a person accuses himself with sincere grief, does not remove all subsequent evils" (page 240). "Different people require different treatment. The phlegmatic, the melancholy, the choleric, and the sanguine, must not be dealt with in the same manner" (page 268). This work, "The Priest in Absolution," has been severely criticised both in Parliament and the press on account of its obscenities; and it has been defended from the pulpit of this very city by the Rev. Knox Little, from whose sermon I quote a passage from the *Pall-mall Gazette* which directly affects us. "There are," says this priest, "many books of medical science just as bad; but they are not flung into society from the House of Peers, nor are their authors called corrupters of society." I am not aware whether the books of medical science referred to by this reverend gentleman are the poisonous pamphlets of the manly-vigour quacks; but with regard to books of real medical science his comparison invites the obvious retort that the badness or goodness of anything is relative; and that the shrewd saying of Lord Palmerston, that dirt is matter in the wrong place, applies with undiminished force to thoughts and words, so that language which may be wise and good and pure in a medical treatise may be dirt in its worst sense elsewhere. Let us pass, however, this comparison with our books, to follow that drawn with ourselves. Is the priest a physician? Is sin disease? Is sacramental confession the avowal of symptoms, penance treatment, and absolution cure? In the interests of society and our profession, I must emphatically deny not only the identity of these things, but that there is any real analogy between them. I assert that the physician is a naturalist, the priest a super-naturalist; and that no sophistry can bridge the abyss between them. The physician works by natural means upon natural conditions to produce natural effects within and upon the bodily organisation. In the pursuit of his calling, he only differs from other men by the possession of superior knowledge and skill acquired by labour. He is the successor of Hippocrates and Harvey, but only in the same sense that Whitworth and the village blacksmith are successors of Tubal Cain. He pretends to no supernatural power acquired by mystic ceremonial, and he is content to do that which any other human being can do who has taken the trouble to learn his art. That art is the correction of deviations in the organism of men's bodies, which disturb the ease with which it works in health; that is to say, the removal of bodily disease, which in itself has no necessary connexion with disobedience of God's laws, and is no more sin than health is virtue. To the physician's idea of disease, an organisation—that is to say, a complication of parts—is essential, and is diametrically opposed to the theologian's idea of sin as an affection of the immaterial soul, which has no parts.

For the removal of disease, the physician employs the forces of nature aided by abstention from its causes. Beyond such curative abstention, he asks for no repentance and he imposes no penance. Nor does he postpone his beneficent action as we have heard that the priest is instructed to do, telling his patient to come again in eight or ten days; nor when he has alleviated disease, or even removed it, does he perform any incantation or ceremonious declaration of health. There is absolutely nothing in medical practice corresponding to absolution, which is the very essence and acme of the priest's proceedings. With this profound difference between the function of the priest and that of the physician, it would, indeed, be surprising if we found that the questioning of a penitent, which is called confession, bore any real resemblance to the questioning of a patient as to the history and symptoms of disease. The first obvious difference is that the physician does not assume that all men are diseased, needing his recurring aid and imprimatur of recovery; while all men are said or known to be sinners whose peril can only be averted by periodical confession and absolution. The second is that in a vast number of instances the doctor's patient makes no confession whatever, the physician seeing, or hearing, or feeling the symptoms, and proceeding with his remedies; while without confession the penitent receives no priestly benefit and no taste of absolution. A third difference is, that the confessions of patients to their medical men are purely voluntary, and the omission of them in no way penal; whereas absolution from priestly confession is in itself an offence only to be condoned by special repentance and penance. The physician looks upon confession as a painful necessity, and avoids it to the utmost of his power; he recognises the danger which lurks in spoken thought reacting upon bodily function; his experience telling him that the surest method of avoiding many symptoms of disease is not to think of them, and that the best means of escape from the thought of them is to avoid speaking of them. Therefore, the physician will often endeavour to obtain the history of those diseases of the nervous system which most seem to justify confession from a near relative rather than from the patient himself; or if from the patient himself, and the history having once been obtained, he will discourage its repetition, and thus he will avoid incurring the mischief of that hypochondriasis of sentiment to which patients and penitents are alike liable.

> "Whatever hypocrites austerely talk
> Of purity, and peace, and innocence,
> Defaming as impure what God declares
> Pure, and commands to some, leaves free to all,"

the physician believes sexual pleasure within rational and legal bounds to be wholesome and right, but that to think of it unseasonably, and far more to converse about it, leads to excess, debility, and disease; and, therefore, he is most chary of encouraging the confidences of his patients on this protean subject of priestly confession.

Finally, the physician restricts his attention to the present condition of his patient, and whatever inquiries he may make as to the past history of the case are directed solely to such facts as bear upon the present. The attention of the priestly confessor, on the other hand, is directed mainly to past time, when the soul of his penitent was in a sinful state, but which has already changed to a condition of repentance, or he would not be at the confessional. I have little more to add, except that the aim and results of the priest's and physician's activity are as different—nay, as antagonistic—as possible. The guidance of the physician, and especially of the mental physician, is towards reticence and restfulness, and the repression of that self-examination which leads to hyperæsthesia of sentiment. The guidance of the confessor, if we still follow "The Priest in Absolution," is towards what he calls "*supernatural* recollection," and three kinds of union with the Lord, namely—1. Simple union; 2. The union of *espousals*, which is

preceded by *substantial dryness*. 3. The union of *consummation*, called *spiritual marriage*. In these unions there are three degrees, those of *Ecstacy*, *Ravishment*, and *Spiritual Flight*. "In the simple union the soul's powers are suspended, but not the body's." "In Ecstasy, the body is lost; one sees not, hears not, feels not." "In Ravishment, the soul is carried away suddenly and violently." "In Spiritual Flight, the soul seems carried out of the body, and Ecstasy and Ravishment are included" (page 319). I think that now, if not before, mental physicians will be disposed to take a lively interest in the 700 clergymen of our State Church who are the believers and followers of this "Priest in Absolution."

I have only one word further to say, namely, that however the above remarks may apply to general physicians, they apply still more emphatically to us as mental physicians, seeing that the peculiarities of our specialty compel us, far more than our brethren, to inquire into the state of men's minds, and into the hidden circumstances and conditions which lead to them. The symptoms of the diseases with which we deal being far less obvious to the senses than the symptoms of other diseases, we are correspondingly compelled to occupy a position which carries with it a greater danger that we shall be compared with spiritual confessors, and which needs the greater caution that we should walk with prudence and circumspection in the well-trod paths of medical reticence and forbearance.

ORIGINAL COMMUNICATIONS.

REMARKS ON

UNUSUAL SLOWNESS OF THE PULSE,

FOUNDED UPON A CASE ILLUSTRATING THAT FORM OF DISEASE.

By JAMES RUSSELL, M.D., F.R.C.P.

(*Concluded from page* 60.)

WHATEVER be the value attached to the evidence afforded by the large cardiac element in the cases on which I am commenting, it must be added that there were at least six in which nothing occurred in the history of the case to prove that the heart was otherwise than healthy.

Now, with reference to such cases as these, and indeed to some others in which valvular disease was present, the question has arisen as to the probability of some condition of the nervous centres, especially of the cervical cord or medulla oblongata, or of the pneumogastric nerves having constituted the agency through which the frequency of the heart's action had been reduced.

The well-known influence of certain poisons, such as digitalis —and, according to Dr. Brunton, casca (*British Medical Journal*, vol. i. 1877)—to inhibit the action of the heart, lends countenance to the suggestion. A curious case of the kind, involving doubtless some idiosyncrasy in the patient, was mentioned by Mr. Times at a meeting of the Harveian Society (*Medical Times and Gazette*, vol. ii. 1864, page 607), in which vinum colchici in five-minim doses reduced the patient's pulse to 20, the natural frequency returning after the withdrawal of the medicine. Again, the well-known effect of depressed cerebral power, but especially of certain injuries to the cervical cord, affords further support to the hypothesis of direct nervous influence in the cases in question. Sir Benjamin Brodie, in his paper on Injuries to the Brain, in the *Medico-Chirurgical Transactions*, mentions a case of compression of the brain in which the pulse was reduced to 40; and Mr. Hutchinson (*London Hospital Reports*, vol. iii., page 365) notices an instance of reduction of the pulse to 48 after an injury to the cervical spine. But one remark appears to be applicable to the different instances of slowing of the pulse which I have just quoted: that the inhibitory influences, to which analogy leads us to attribute the retardation of the heart's action, is of very temporary duration; hence, whilst they may serve to account for the production of slowness when induced suddenly, and existing but for a short time, the analogy fails in affording a reply to the question when it relates to cases in which the same condition has been permanent or has been maintained for a considerable period, especially in the absence of any evidence of disease in the nervous centres.

Still more does the analogy fail in relation to the instances —of which I have noticed several at the beginning of this paper—in which the pulse has been long preternaturally slow, without the presence of evidence of any disease whatever in the individual who manifested the peculiarity; in such cases it would seem impossible to refer the condition of the pulse to any other circumstance than to some change in the special endowment of the heart itself.

But probably the strongest argument in favour of supposed nervous influence as having been specially concerned in these cases is derived from the peculiar attacks, of very sudden character and brief duration, which appear to occur in the majority of the reported instances of extreme slowness of the pulse of morbid character. They have, indeed, been present in twenty-nine at least out of my thirty-eight cases—probably in a larger proportion had full details been given in all.

In a considerable number it was the occurrence of these fits which first drew attention to the state of the circulation. In many of the cases they have occurred frequently; in two, at least, even thirty or forty times in a day; sometimes they have been suspended for some time, even for many months, again to return. One of the earliest occasions on which this association was made the subject of comment was the often quoted case by Mr. Holberton, in which a change connected with the medulla oblongata had occurred, as reported already. The author's conclusion, connecting the slowness of pulse with the state of the medulla oblongata, was disputed at the time by high authorities; and Dr. Peacock adds the just remark that instances of remarkable compression of the medulla oblongata have occurred without the pulse becoming slow.

M. Charcot, in one of his admirable lectures ("Sur les Maladies du Système Nerveux," 2me série, page 137), when speaking of the consequences of gradual compression of the spinal cord, specially dwells upon permanent retardation of the pulse as constituting one of the most interesting, though least remarked, circumstances in the symptomatology of certain lesions of the cervical spine. He clearly and succinctly reviews the whole subject of slowing of the pulse, noticing the symptoms in connexion with fracture of the cervical vertebræ, especially of the fifth and sixth, adding, however, that, as a rule, the slowness is essentially transitory. But in continuation he quotes a case from Rosenthal of a child injured in the region of the sixth cervical vertebra, in whom, besides dilatation of the pupil, the pulsations of the heart oscillated between fifty-six and forty-eight per minute during four weeks, at the end of which period a complete cure had been effected.

He then makes the inquiry whether it be not very probable that the phenomenon of a permanent slow pulse may not be observed, with all its consequences, in certain circumstances after irritative lesions of the cervical cord, even irrespective of injury having been inflicted. He observes that beyond traumatic lesions of the cord, "le pouls lent," in the opinion of the few authors who have studied this condition, is only observed in connexion with certain diseases of the heart; and he adds that he has three times observed this symptom in its most marked form, lasting through several years, in old men at the Salpétrière, in whom the heart was found perfectly healthy after death, except for certain customary changes belonging to the period of life. A fourth case is also quoted in a note. With reference, however, to the main question, the remark which I have made already, in relation to the large majority of the cases I have quoted, applies to these cases also—viz., that there does not appear to have been any evidence of disease of the nervous centres; and it may be added that the age of the patients, with the presence of senile changes in the heart itself, directs attention to that organ as the more probable seat of the lesion causing the slow pulse, in the absence of any evidence to the contrary. M. Charcot candidly states that anatomical investigations which he had undertaken with reference to this subject had been fruitless in results.

In a note, M. Charcot refers to an observation on slowing of the pulse during diphtheritic paralysis, made by Dr. Greenhow at a meeting of the Clinical Society. Dr. Greenhow says (*Transactions*, 1872, page 192)—"The slowness which set in about the seventh day of the illness, when the throat affection was subsiding, is another symptom which has been observed in many cases; and in several of these I have seen the pulse has become slower and slower from day to day, until at length the patient has died, apparently from failure of the heart's action." The nature of diphtheritic paralysis is at present too little understood to admit of a safe analogy being drawn from its phenomena; it may, however, be observed that in diphtheria we have to do with an altered condition of blood, which may exert its influence directly upon

the cardiac fibre or upon the cardiac ganglia. Moreover, late observations have tended to suggest that the changes in the nerve-tissue commence at the periphery; nor must it be forgotten that, in by far the majority of cases of diphtheria, there is no paralysis, yet that the liability to death from failure of the heart may be equally pronounced.

It is unnecessary to remark that attacks, not only of syncope, but also partaking more or less of what is termed the epileptic character, occur in connexion with cardiac failure alone. In cases of degeneration of the heart we find mention, not only of apoplectic and of comatose attacks, and of attacks of syncope, but also of convulsive movement, of tongue-biting, and even of actual epileptic fits, with lividity.

In one of the foregoing cases of degeneration an aura was present; a lump passed up the right side of the neck into the head, and there exploded, the patient becoming stupefied and occasionally biting his tongue. Looking at the cases I have collected, there is certainly a greater diversity in the character of the attacks in those instances not of degeneration, with or without cardiac symptoms, as compared with those in which degeneration of the heart was present; but although, so far as the limited number admit of a judgment, there is a larger admixture of questionable, or of unquestionable, epileptic seizures, yet, taking the majority, the group has a very close resemblance, so far as the fits are concerned, to that composed of cases of degeneration pure and simple. M. Charcot's description of the attacks is very succinct and accurate:—"Sometimes they present themselves with all the characters of syncope; sometimes they participate in the symptoms of syncope, and of the apoplectic condition; lastly, there are cases in which epileptiform movements are superadded, especially marked in the face, with discoloration of the face, foaming at the mouth, etc."—(Page 140.)

With regard to the special conditions under which these sudden attacks occur, there is nothing in the phenomena they present, nor in the analogy with other forms of disease, to forbid the supposition that they themselves may be sometimes produced by sudden inhibition of the heart's action; whether or not we accept a similar explanation for the condition of the pulse with which they are connected. On the other hand, the hypothesis which connects the slowness of pulse with an altered condition of the irritability of the heart, would also intimate that the heart itself was morbidly subject to any sudden influence exerted upon it through inhibition, whether directly or by means of reflex action propagated from the periphery. This I believe to have happened in the case at present under my own observation. The patient did not regard himself as ill until he became subject to faints four months before I saw him, although his pulse was ascertained by a medical man to be remarkably slow seven or eight years before. During that time he worked as an engineer without any trouble and without believing himself ill. The faints were coincident with the occurrence of epigastric pain (from which he has suffered during the whole time of his attendance, now eighteen months), the nature of which is quite inexplicable. A certain form of this pain, beginning under the edge of the right ribs, and passing towards the apex of the heart, was particularly dreaded by the patient, from its being the certain precursor of a faint, though a large proportion of the faints took place without the occurrence of any symptom sensible to the patient. In this patient, as in some others, suspension of the heart's action coincided with the commencement of the fit. In Mr. Holberton's case, again, the fits were more especially induced by costiveness, by disorder of the stomach, or by gout. A case was briefly described by Dr. Addison, in which it would appear that the slowness of the pulse occurred only in paroxysms together with epileptic symptoms. The patient was subject to a kind of epileptic fit in which the pulse was only 23 or 24; it then "gradually acquired number until it reached 68 or 70, when it would become perfectly still, and in a very short time the convulsive fit came on" (*Lancet*, vol. i., 1840-41, page 892). Here it would be allowable to suspect an inhibitory influence to have produced the entire group of symptoms.

I conclude my notice of the cases I have collected with briefly detailing the particulars of another, which differed from the general type, and, like the one just described, may have been occasioned by exceptional circumstances. It is also one of Mr. Mayo's cases. The patient had been much lowered in consequence of mismanagement during illness, but had recovered, and had remained well for a year; his pulse being 72. He then had suddenly in his chest a sensation of something turning over, and his pulse was found at 30, stimulants having no influence in increasing its frequency. On the third evening, after vomiting, the uneasy sensation passed off, and the pulse regained its normal standard. A similar occurrence took place six months afterwards, on his rising one day from bed, and three or four weeks elapsed before the patient recovered; he then felt all at once that he was well, and his pulse beat at 68. Again, a year afterwards, slowness of pulse recurred one evening after exposure to fatigue, and the pulse remained slow, sometimes falling to 22 at the date of the report. The probable explanation of this singular series of phenomena was that the circumstances at the beginning of his illness had produced a permanent change in the condition of the heart's fibre, which had left it open to be acted upon by accidental influences of a depressing or of an inhibitory nature.

Although the foregoing observations do not afford demonstrative evidence in favour of any theory to explain the slowness of the pulse to which they have related, they yet, I think, afford strong presumption on the side of the hypothesis which assigns to the heart itself the seat of the change, be it what it may, on which the peculiarity of the pulse depends. The prominence in the histories of the cardiac element, as opposed to the deficiency of any evidence in favour of disease of the nervous centres, strongly supports this conclusion, which is further strengthened by the analogy specially derived from the effect upon the pulse of diseases tending to induce degeneration of the heart's fibre, and is not inconsistent with the presence of such nervous symptoms as have been reported. This statement by no means excludes the theory of nervous influence as being operative in certain exceptional cases, in which the change in the pulse is of temporary duration, and is accompanied by symptoms of depressed circulating power; nor does it refuse to accept nervous influence as being concerned in the production of certain attacks which occur in the course of many cases. As to the precise nature of the change in the heart, it does not appear to be indicated by any specific organic disease, although allied with several, and chiefly, if not entirely (so far as anatomical evidence goes), with changes of a degenerative character. It seems capable of being induced under certain conditions by circumstances which have a direct tendency to depress the nutritive power of the heart.

Case.—The principal particulars of the case which has given occasion to these remarks have been already stated. The patient's age was thirty-eight when admitted to the Birmingham General Hospital, April 13, 1876. As already stated, he was aware of slowness of pulse for seven or eight years, but was not conscious of suffering in consequence from any incapacity. It was only at Christmas, 1875, that he applied to Dr. Parkes on account of the faint attacks, which began to occur about that time at the rate of two or three in the day, but increased in frequency until, soon after admission, they were sometimes computed at fifty or sixty in the day. Further observation of the patient's symptoms taught us that these faints were attended with momentary insensibility, followed by immediate return of consciousness. In some of the fits the eyes were staring, the face somewhat flushed; in others the face was unchanged, the patient appearing as if asleep. The attacks took place whether he were recumbent or erect: they were preceded by a kind of numbness. The patient believed that brandy lessened the liability to their occurrence.

About the same time with these fits he began to suffer from pain across the epigastrium, sometimes passing up each side of the sternum, sometimes lying under the edge of the ribs on the right side, and once described as starting from the region of the gall-bladder. The pain occurred generally quite irrespective of food, sometimes relieved by the presence of food in the stomach. There was neither sickness nor pyrosis; sometimes an acid taste concurred with the pain. The saliva was found acid on some occasions, on others neutral. The pain has continued unexplained to the present time. Bismuth and potass, with opium, was the only medicine which afforded any relief, and that for a time only. I have mentioned that this pain when occurring under the right ribs preluded a faint; at other times before a fit he experienced an indescribable feeling at the epigastrium, as though vomiting would relieve him, and sometimes after a fit a sense of something moving in the epigastrium.

The pulse through the eighteen months which have elapsed has varied little from 32; taken for seventy days in succession, with one interval (for thirty-two of these days night and morning), it was twice at 24, once at 19, twice at 26, ten

times at 28, but it more than once was found at 20 after a faint. Nine times only did it exceed 34, once rising to 43.

The rate was not affected by exercise, nor was it increased by bending down so as to bring the head near the ground. Respiration, taken night and morning for twenty-one days, was very constant at 20.

The accompanying tracings indicate sufficiently the character of the pulse. I regret I had no means of testing the force required to extinguish it; its resisting power was low. As regards the physical signs, on one occasion only, the pulse being 22 to 26, a second faint beat was heard after each distinct beat. This was never heard again, but still, to the eye, there is a kind of reduplication of the apex impulse, to which no sound corresponds. A loud bruit follows the first sound, heard most loudly in the lower half of the sternum below the level of the fourth cartilage, but also up the course of the aorta and in the carotids; it is distinct at the apex, faint in the lateral and posterior regions. Both cardiac sounds are faint; the impulse is feeble, dulness not extended.

Temperature at admission, taken in the axilla, was 98° to 98·4°. At a later period, taken in the cheeks, on three occasions it was—right cheek, 97·4°, 97·8°, and 98·4° respectively; left cheek, 97·8°, 98°, and 97·5°. Once, during a feverish attack, attended with profuse sweating, the temperature attained 103° in the morning, being 101° the same evening, and on the third morning afterwards reaching 98° again. The fundus oculi was quite normal. The pupils were below the average size, but dilated freely under atropine. When the ciliary muscle was paralysed, Mr. Priestley Smith discovered a high degree of hypermetropia. For the rest, the man's health was fairly good; his nutrition moderate; face fairly coloured; he was markedly indisposed for exertion, and much wanting in physical and mental energy; there was no œdema; his urine was normal. He had no headache; lately he has found himself disposed to keep near a wall, but he has no positive giddiness. He does not suffer from cold.

No cause for the illness can be discovered. His family history is healthy; there is absence of all nervous disease. He has been temperate, and active in his habits; has not been exposed to anxiety; nor has he committed sexual excesses, nor suffered from emissions. He has not lost sexual passion.

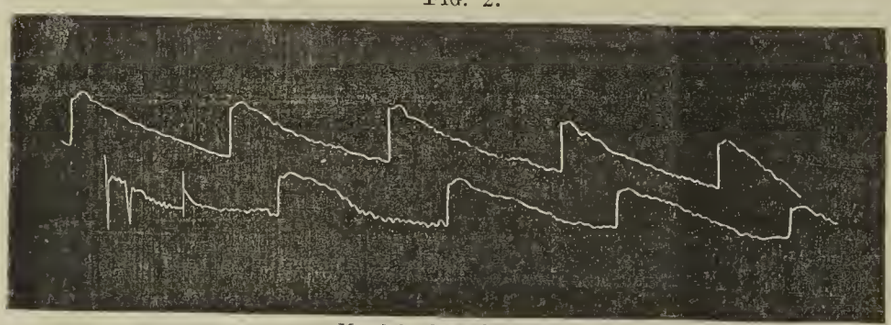
Fig. 2.



March 3, 1877.—Pulse 36.

All treatment employed was utterly fruitless. Digitalis not only failed, but produced marked uneasiness. I regret not to have had a tracing made at the time of the failure. Belladonna, given till vision was affected, equally failed in influencing either the pulse, the frequency of the occurrence of the fits, or the epigastric pain. Bromide fared no better. I tried phosphorised capsules fully, rising to the rate of six a day. The continuous current along the region of the cord and between the region of the medulla oblongata and that of the heart's apex gave no result; with sixty cells from the Muirhead battery the pulse-rate was unchanged; this remedy had a very full trial, but without effecting any improvement. He went through the various tonics, steel and strychnine in particular; cod-liver oil could not be taken. The total result is, that having been in the hospital for four months, without improvement, he went to the Convalescent Institution, and, having been there five weeks, was able to walk five or six miles. He has since, however, declined in vigour, and still attends, with little encouragement to himself or his doctor.

Note.—Since the former part of my paper appeared, my friend Mr. Crompton has reminded me that the late Mr. Hodgson, who suffered from cardiac degeneration, had a pulse of 40, and that he referred the diminution in frequency to overwork in connexion with an important public office which he held. Mr. Crompton has also mentioned to me the case of a patient of his own who has had a notably slow pulse for many years, but is, and has long been, an enthusiastic salmon-fisher and sportsman. It is an interesting fact that the pulse of this gentleman's son, on one occasion when accidentally felt, was found remarkably slow. He is now in Australia.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

HEAD INJURIES.

UNIVERSITY COLLEGE HOSPITAL.

Case 1.—*Depressed Fracture of the Skull—Meningitis on the Tenth Day—Recovery in Twenty-five Days.*

(Under the care of Mr. BERKELEY HILL.)

[Reported by Frank Davies, F.R.C.S., House-Surgeon.]

Alfred ——, aged five, was admitted into University College Hospital on February 21, with a history of having fallen off a horse on to some rough pitching-stones.

On Admission to the hospital, half an hour after the accident, he was conscious, but in a drowsy condition; answering questions put to him, but doing so in a peevish, irritable manner, flexing the upper extremities, and drawing up his legs, while he querulously asked to be let alone. His face was pale; his eyelids were half-closed. The surface of the body was cold. There was no motor or sensory paralysis of either limbs, nor any irregularity about the angles of the mouth. The pupils were moderately contracted, but contracted still more on exposure to light. There was no sub-conjunctival hæmorrhage. His pulse was 82 per minute, very small, weak, and markedly irregular, intermitting about every five beats; his respiration was 27, sighing in character. He had not vomited. On examining the head, a soft, fluctuating prominence was felt over the left parietal region, and in the centre of this a most distinct depression of the skull. This appeared to be one-eighth of an inch deep, and extended in a direction horizontally backwards for one inch and a quarter. There was no bleeding from the mouth, ears, or nose, nor any other injury elsewhere. The little patient was put to bed, and ordered milk diet only. During the day his pulse varied between 100 and 108; but by 7.30 p.m. it had fallen to 88. He slept a great deal, and when awaked up to take milk he rapidly dropped off again. His breathing was quiet, not stertorous, while he was asleep.

For the next few days the patient continued much in the same condition, his temperature being normal, and pulse varying from 70 to 90.

On the 26th, patient appeared much better, laughing and noting all that was going on in the ward. The swelling had nearly all gone, and allowed of the fracture being more clearly defined. He was calling for food, which it was not deemed advisable for him to have. His bowels being constipated, he was ordered by Mr. Hill half a drachm of compound jalap powder; and this not acting, it was followed up by one teaspoonful of castor oil, with good effects. His temperature

was normal, and his pulse had now risen to 120. He continued to improve until March 1, but was not allowed to get out of bed.

On the morning of March 1 it was found that the patient had passed a restless night and had been sick twice. He complained of severe pain in his head, and pointed with his hand to the left side to indicate the point where "it hurt." The swelling at this part was not increased, neither was there any local heat or tenderness. There was great intolerance of light, the child keeping the lids forcibly closed, and struggling freely when any attempt was made to open them. His pupils were moderately dilated, the left more so than the right; both reacted to light. He lay on his side curled up in a state of general flexion, and was very irritable when interfered with. Abdominal walls not retracted, nor any twitching of muscles generally. His temperature had risen to 101°, and his skin was dry and hot; pulse 120; respirations 36; bowels constipated. Mr. Hill ordered five grains of calomel with half a drachm of compound jalap powder immediately, and an ice-bag to his head.

For the next few days the child's condition continued much the same, he being drowsy, and complaining of great pain in his head, the intolerance of light also persisting. His temperature varied from 102° to 99°, and his pulse fell to 64. Ice-bag continued, and one drachm of the compound jalap powder given.

On the afternoon of the 6th the child appeared very much depressed, his skin being cold and pulse only 52, weak and irregular. Mr. Hill ordered the ice-bag to be discontinued.

The next few days there was no change of importance, further than that the child's pulse rose to 70 and 100. On the 10th, however, he was very much better, the intolerance of light having disappeared, and the child being quite cheerful, clamouring for food. The pain had gone from his head, his temperature had fallen to normal, and pulse risen to 100, regular in beat and rhythm. From this date up to the time he left the hospital he continued to improve, and on March 18, when he left, he was quite well, though his parents were warned to keep him very quiet for some weeks. Later on he was brought as an out-patient, but was quite well when last seen.

LONDON HOSPITAL.

(Under the care of Mr. RIVINGTON.)

Case 2.—Compound Fracture of the Skull—Depression without Symptoms—Convulsions on the Fifteenth Day—Secondary Removal of Bone—Death.

John C., fifty-two, a strong, powerful-looking man, and a beer-drinker, was admitted about midnight on November 23, 1872, with a lacerated forehead. There was a wound an inch in length about an inch above the outer part of the left eyebrow. On inserting the finger, Mr. Cooke, the House-Surgeon, could feel a broad fissure in the bone, about an inch long and nearly a quarter of an inch broad; it appeared to be a fracture of the external table only. No loose fragments were to be felt, and no depressed bone was detected by Mr. Cooke and others. The patient, who was drunk on admission, subsequently stated that he was struck by a pint pewter pot. He did not become insensible or fall. The wound bled very much.

November 24.—No bad symptom whatever. Temperature 97·9°; pulse 56; respirations 28. He was seen by Mr. Rivington, who considered the question of trephining him in order to ascertain the state of the internal table. The patient, however, was so well, and had been so free from symptoms calling for interference, that it was thought better to leave him alone.

25th.—Slept fairly, although frequently interrupted by startings.

The temperature went up suddenly on the afternoon of the 24th to 103°; on the 25th it reached 103·4°, and then began to fall again. On the 26th it was normal in the morning; in the evening 100·4°. On the 27th, 99·4° and 100·2°; on the 28th, 100·4°; 29th, 99·6°; and on the 30th, 99° and 98·2°.

During the first few days he complained of a shooting pain, located three or four inches higher than the external wound, but it did not become severe till December 8. By that time the wound had filled in with granulations, and had nearly healed.

From December 1 to 8 his temperature was normal; his pulse ranged from 54 to 64; his respirations from 24 to 30. There were no symptoms to occasion any anxiety, and it was thought that he would recover perfectly.

On the 8th, however, at 1 a.m. he became unconscious, and he had a fit of an epileptiform character. Mr. Drew, one of the House-Surgeons, saw him about the termination of this fit, when both his legs and arms were convulsively moving. His jaws were fixed, and he was bleeding from his mouth, having evidently bitten his tongue. (The cause of the fit was considered to be a free imbibition of gin. An empty gin-bottle was found in his bed.) The fit lasted about fifteen or twenty minutes, and he vomited during its continuance. Another fit followed at 10 p.m. He was unconscious, and the arms and muscles of his face were twitching and moving convulsively. During the morning he had been very restless and ill-tempered, finding fault with different things, and rushing about the wards in an irritable condition. He was removed to the attics. A consultation on his case was held with Mr. Hutchinson, but as it was thought that his fits were most probably due to drink, it was decided not to trephine.

December 10.—Slept well. His face was pale; his tongue was steady, but covered with a brownish fur. He had neither headache nor pain. At 8 p.m. he was seized with another fit. He was seen by Mr. Todd, who stated that at the commencement he was lying on his right side. There were convulsive movements of the left side occurring at intervals, and there was hemiplegia of the right side. There was a convergent squint of the left eye, and a divergent squint of the right eye. Mr. Drew saw the patient after Mr. Todd, at about 9 p.m., and stated that he had convulsive movements of the right side occurring at intervals, and none whatever on the left side. Of the latter point he was most positive. There were no less than six convulsive paroxysms in five minutes. His head was turned, and his eyes were directed to the right side during the fit. During the fits the breathing was very difficult and laboured. At 10 p.m. he was seen by Mr. Cooke. He then had hemiplegia of the right side; the breathing was stertorous, and he was perspiring freely; when touched he would moan and weakly raise his left arm. At 11 p.m. he was seen by Mr. Tay and Mr. Reeves. The breathing was easier, without stertor; the hemiplegia continued. By testing with the point of a pin, pulling the whisker, and pinching, it was found that the right half of the face was insensible, but that a similar proceeding on the left side produced moans and an irritable movement of the left arm. There was ptosis on the left side, and the conjunctiva was quite sensitive. The conjunctiva of the right eye had lost its sensibility, and could be touched without causing reflex action of the orbicularis. The surface of the cornea was dull, and covered with a mucoid secretion. At 12 p.m. he was in the same condition, and was seen by Mr. Rivington, who decided on trephining. A T-shaped incision was made, the flaps were dissected up, and two small thin pieces of bone about half an inch long and some spicula of the external plate were removed. These pieces were depressed to the extent of about one-eighth of an inch. The aperture was then enlarged, and two loose pieces of the internal table were extracted. The dura mater was thus exposed; but no pus or blood was found on its outer surface. It was not depressed, or lacerated, or inflamed, although a little rough at one spot. No serous fluid therefore escaped from the arachnoid cavity. The pulsations of the brain underneath the dura mater were perceptible. There was no bulging or fluctuation, nor any indication of pus inside. Nothing further was done, but the wound was closed. The temperature before the operation was 102°.

11th.—Hemiplegia continued, and there was no abatement of the symptoms. At 5.30 p.m. he died.

Autopsy (December 12).—The skull was thin. Although the internal table had been fractured, there were no spicula to cause irritation. There was no inflammation of the dura mater, nor any pus between the dura mater and the bone. The dura mater was entire. On opening the dura mater, about two ounces of a puriform serum escaped. The parietal arachnoid in the neighbourhood of the fracture retained its polish. The visceral arachnoid was a little dull. The pia mater which covered the left hemisphere was more congested than that covering the right hemisphere. There was increase of vascularity of the brain-substance, more marked on the left side. The ventricles did not contain serum.

The case baffled pathological acumen. Death was accounted for by cerebritis. The other viscera were healthy.

Case 3.—Laceration of Scalp—Thirty Hours' Unconsciousness and Cerebral Irritation from a Fall on the Head.

James N., aged fifty-nine, was admitted at 2.30 p.m. on October 23, 1872. He had fallen off a cart, and pitched on his

head and right shoulder. On admission the scalp was found lacerated just over the middle of the posterior border of the right parietal bone. There was no bare bone. The laceration was about two inches long. There were no symptoms of concussion or compression. The patient was very sullen and irritable. He would not speak or answer questions that were put to him. He resisted examination, would not be undressed, and had a great desire to walk out of the ward. He was neither intoxicated nor sleepy. One pupil was contracted and the other dilated. Whilst he was being examined he muttered in a peevish way, "I wish to God you would leave me alone." Four grains of calomel were ordered, and an ice-bag was applied to his head. When seen at 8 p.m. he was groaning and sighing frequently. He lay on his side in a state of general flexion, his body bent forwards, his legs drawn up, and his forearm bent. Then he became very restless, and frequently shifted his position, but never extended himself. He had great difficulty in raising his eyelids, and when raised his pupils were seen to be equally contracted and inactive. The nurse had not been able to give him the pill, as he vomited it the moment it was administered. His pulse was compressible. He had marked arcus senilis, and symptoms of atheroma. His wife stated that he was a sober man, and was quite well before the accident. A hypodermic injection of morphia (a quarter of a grain) was administered by Mr. Cooke because he was restless. He passed an uneasy night, sleeping at intervals. The next day he was in much the same condition. There were frequent bilious vomiting, snatches of sleep at intervals, and then great restlessness. He would not or could not answer questions. Croton oil was given, and acted freely. Late in the evening he answered a simple question sensibly. Temperature 101°.

October 25.—He passed a good night. Was quite sensible in the morning, and answered questions readily. He remembered falling off a cart and striking his head against a wall, but nothing further. He was under the impression that he was admitted on the 24th. He complained of slight pain in the forehead, and also in the shoulder, which was contused. His pulse was stronger. The temperature in the morning was 100·6°, in the evening 99·6°. He continued to improve, and left the hospital cured ten days afterwards.

Case 4.—*Compound Fracture of Orbital Arch and Punctured Wound into Orbit—Impaction of the Blade of a Knife—Recovery.*

J. S., aged twenty-three, a strong, healthy labourer, was admitted into the London Hospital on August 30, 1872, under Mr. Reeves, who had charge of Mr. Rivington's wards. He smelt a little of spirits, but was not actually intoxicated. There was a wound about an inch in length on the left side of the forehead, extending upwards and outwards from the centre of the orbital arch; and at the bottom a comminuted fracture of the arch could be felt. Two considerable fragments were removed by Mr. Cooke, the House-Surgeon, and the wound, which had been slightly enlarged, was stitched with wire. Ice was applied. The fragments comprised portions both of the frontal and orbital surfaces of the frontal bone, and comprised the superior margin of the orbit from the supra-orbital notch to the external angular process. The patient had been struck by another man a violent blow with the blade of a knife. The point of the knife had entered above the eyebrow, and caused the fracture. There was no reason to conclude that the blade had been left in the part. At 10 p.m. he was comfortable, but complained of pain in his eye. Pulse 100.

August 31.—2 a.m.: Sick twice; twitchings every ten minutes. Pulse 80. 7 a.m.: Very restless; quite conscious. Bowels relieved by an enema with benefit.

September 1.—Head felt full and ached. There was a great deal of extravasation round the wound, and swelling of the upper lid, causing complete closure of the left eye. Temperature 99·6°. He continued to progress favourably during the next few days, and the wound healed.

7th.—Patient had a rigor, and erysipelatous inflammation set in around the wound. He was sent to the outer ward. Temperature 103°.

The erysipelas subsided on the 19th, the temperature falling to 99°. From the 7th to the 19th it stood consecutively at 105°, 102·6°, 103·4°, 104°, 103·4°, 104°, 103·4°, 104·2°, 103·2°, 101·4°, 102·6°, and 100·6°.

25th.—Symptoms of irritation about the orbit; swelling and inflammation continued. Thinking there might be some bone to come away, Mr. Cooke cut down, and inserted his finger, but could find nothing loose. A sharp edge about half an inch in extent, with a smooth triangular surface a quarter of an inch in extent, were perceived. Mr. Cooke thought this was bare bone, but on enlarging the wound and dissecting away the tissues he found it was a knife impacted firmly. After some trouble, he extracted with a pair of bone-forceps the broken blade of a clasp-knife two inches and three-eighths in length. The knife had entered the frontal surface of the frontal bone about one-eighth of an inch above the orbital ridge, had taken a direction backwards and inwards, passed through the orbital arch and fractured it, and entered the orbit about one-eighth of an inch from the orbital arch, and finally passed into the frontal sinus.

The patient subsequently did uninterruptedly well. On October 18 he was discharged cured.

Case 5.—*Compound Fracture of the Skull—Depression of a Portion of the Left Frontal and Parietal Bones—Recovery.*

Ebenezer H., aged ten, admitted November 21, 1872. Was crossing the street, and was suddenly knocked down, he did not know how. His mother said that the shaft of a cart struck him. When admitted he had a scalp wound over the junction of the left parietal with the frontal bone, where the lateral joins the superior aspect of the skull. On passing the finger into the wound, a portion of bone about an inch and a half long by an inch wide could be felt depressed to the extent of about an inch. There were slight symptoms of concussion and of irritation. His arms twitched and were convulsed, the muscles of his face twitched, and his teeth were ground together. The convulsive seizure lasted five or ten minutes, subsided, and never recurred. He was drowsy, and did not care about being disturbed, and resented any interference. His pupils, rather contracted, acted on the stimulus of light. Temperature 99°; pulse 100; respirations 28. On the second day his temperature was 101·5°, and on the third day 102·2°. Subsequently it varied irregularly, but had a downward tendency. He vomited on the second and third days, and gradually recovered his faculties. On the twelfth day his temperature was 98·8°; pulse 79; respirations 29. Free suppuration followed at the seat of fracture; the bone became denuded of periosteum, then granulation sprang up and covered it in entirely. He had no bad symptoms for four weeks, when he seemed to catch cold, and had pain with discharge from his ear, lost his appetite, and was a little feverish, and obliged to remain in bed. The attack passed off in a few days.

Case 6.—*Lacerated Scalp—Effusion of Blood over Surface of Brain—Death.*

R. S., aged fifty-nine, was admitted January 15, 1873. He had been drinking heavily, and had fallen downstairs, but it was not known whether he was in a fit or not. He had lacerated his scalp down to the periosteum on the right side over the occipital bone, the wound running nearly vertically for two inches. He was brought in at 11 p.m., supported by two men; he did not walk, but he seemed able to move both his arms and legs—the legs most freely. The pupils were contracted. He did not respond to questions, although he said "Yes" once. He was semi-conscious, and when put into bed so restless that he had to be fastened down with a straight-waistcoat to prevent him from falling out of bed. He soon sank into an apoplectic state, with hemiplegia on the right side. The facial nerve did not appear affected on either side. Reflex action was perfect on the left side of the face, but was abolished on the right side. Both pupils were equally contracted. When an attempt was made to examine the eyes he rolled them upwards under the upper eyelid. When lifted and left go, his right arm and leg dropped helplessly. Tickling the sole of the right foot produced movement, the leg being drawn up. The left arm and leg were in a state of constant motion. The breathing was laboured, but not actually stertorous. There was a puffing of the cheeks, due apparently to paralysis of the buccinators. There was incontinence of urine and fæces. On the following day he remained much in the same condition, except that he partially regained the power of moving his right arm and leg. He seemed at one time a little more conscious, and when asked by the nurse if his name was "William," said "Yes." He swallowed with difficulty. But he soon sank into a state of profound insensibility, and expired at 11.30 a.m. on Saturday, the 18th.

The temperature twenty hours after admission was 100°; 17th, morning 101·4°, evening 102·4°; 18th, 103·2. Pulse 96, intermittent; 17th, morning 120, evening 112; 18th, 130.

Respirations 32; 17th, 30. The thermometer was in the axilla when the patient died, and registered 103·2°.

At the post-mortem no fracture of the skull was found at any part. The skull was very thick, and the diploë converted into dense bone. On the surface of the right hemisphere, underneath the arachnoid, a considerable effusion of blood had taken place, extending over the three lobes equally, except at one spot on the under aspect of the anterior lobe; here there was a collection of clot and broken-down brain-substance occupying a hollow in the brain. There was only sanguineous serum in the ventricles. The question arose whether the effusion of blood was due merely to *contrecoup* or to the prior rupture of a small miliary aneurism.

Case 7.—Compound Fracture of Skull with Depression of a Large Portion of Left Parietal Bone—Trephining—Death.

James C., thirty-five, a porter on the Great Eastern Railway, was knocked down by the engine of an express train on January 9, 1871. When brought to the London Hospital at noon he was insensible, with cold extremities and dilated pupils. He had a convulsive attack. There was a small wound in the scalp above and in front of the left ear, and the finger introduced into the wound and passed upwards could detect the fracture easily. The line of fracture was extensive, sweeping in a semicircle downwards and forwards to the external angle of the left orbit, and backwards to the occipital bone. The upper edge projected from two to three lines, and a large portion of the parietal bone was wedged in under this projecting edge. There was some bleeding from the wound, and a little from the nose, but none from the ear.

For some hours he was very restless, tossing about in bed and talking incoherently. At 4 p.m. he recovered consciousness, recognised his wife, and answered questions intelligibly. He appeared to be very drowsy. He could grasp a hand held out to him with both of his hands, but less powerfully with the right hand than with the left. Sight and hearing were good. Both pupils were dilated, and both acted on being stimulated, the left less than the right. The protruded tongue inclined towards the left side, but he could put it out when told to do so to the right side and to the centre. He was seen by Mr. Hutchinson in consultation with Mr. Rivington, and it was considered advisable to use the trephine for the purpose, if possible, of elevating the depressed portion of bone, and affording a free exit to the blood which had in all probability been poured out between the bone and dura mater from a wounded branch of the meningeal artery. Mr. Rivington enlarged the wound and applied the trephine over the sound bone close to the fracture at the point of greatest depression. Sufficient bone having been removed with the trephine and Hey's saw, the elevator was introduced and the depressed fragment freed as far as possible. Arterial blood welled up when the bone was raised. The wound was sponged out with carbolic acid lotion, and a piece of lint dipped in the same laid over it. A day or two afterwards the wound was attacked with erysipelas, which spread to the patient's face and neck, and was accompanied by fever and delirium. There were no symptoms of compression; no paralysis in any part; arachnitis was suspected. The patient died on the 27th, eight days after the operation.

At the post-mortem a large semicircular portion of bone, including the lower part of the parietal and the upper part of the great wing of the sphenoid and squamous portion of the temporal, was found to be detached, except posteriorly. The dura mater was sound, but a flattened clot lay between it and the bone above the middle fossa. The veins of the scalp and the emissary veins were distended. Lymph was found on the visceral arachnoid and serum in the sub-arachnoid space. There was a fracture across the base of the skull, extending from one petrous bone to the other through the left foramen rotundum and the sella turcica.

Electrolysis in Aneurism of the Arch of the Aorta.—In the *Bulletin de Thérapeutique* for July 15, M. Dujardin-Beaumetz, of the St. Antoine Hospital, relates the first instance in which electro-puncture has been employed for the cure of aneurism of the aorta in France. Bringing his report down to July 10, he says that a certain amount of the blood in the tumour has become coagulated, but the layer of coagulum thus produced is of slight extent. He proposes repeating the applications at intervals of a month, under the somewhat sanguine expectation of producing the eventual complete coagulation of the tumour.

SATURDAY, SEPTEMBER 1, 1877.

PHYSIOLOGY AND MEDICINE.

It is not very often, perhaps unfortunately, that we have two such Addresses in Physiology to comment upon as that delivered by Dr. Allen Thomson as President of the British Association for the Advancement of Science, and that delivered by Dr. Gamgee as President of the Physiological Section at the British Medical Association. Both were valuable, but in a different way. Dr. Allen Thomson spoke on a subject familiar to him for a lifetime, so carefully thought out that we find ourselves unable to attempt anything like an abstract of it. Dr. Gamgee, on the other hand, presents us (as will be seen elsewhere) with a capital *résumé* of the main acquisitions to the domain of physiology during recent days.

Of Dr. Allen Thomson's address we need say but little. The key-note, as given in his own words, is as follows. His study of embryology has been both deep and wide. As the outcome of it he says—"It appears to me that no one could have engaged in the study of embryological development for any time without becoming convinced that the phenomena which have been ascertained as to the first origin and formation of textures and organs in any individual animal are of so uniform a character as to indicate forcibly a law of connexion and continuity between them; nor will his study of the phenomena of development in different animals have gone far before he is equally strongly convinced of the similarity of plan in the development of the larger groups, and, to some extent, of the whole. I consider it impossible, therefore, for anyone to be a faithful student of embryology, in the present state of science, without at the same time becoming an evolutionist. There may still be many difficulties, some inconsistencies, and much to learn, and there may remain beyond much which we shall never know; but I cannot conceive any doctrine professing to bring the phenomena of embryonic development within a general law which is not, like the theory of Darwin, consistent with their fundamental identity, their endless variability,

their subjugation to varying external influences and conditions, and with the possibility of the transmission of the vital conditions and properties, with all their variations, from individual to individual, and, in the long lapse of ages, from race to race. There can be little doubt remaining in the minds of any unprejudiced student of embryology that it is only by the employment of such an hypothesis as that of evolution that further investigation in these several departments will be promoted so as to bring us to a fuller comprehension of the most general law which regulates the adaptation of structure to function in the universe."

Turning next to the address delivered by Dr. Gamgee, we have to thank him for a very clear exposition of modern doctrines as to intestinal ferments, vision-purple, and muscular electricity; but our main object at the present moment is to draw attention to certain observations made by the speaker in the opening part of his address. This we do not now quote at full length, but the following extracts will suffice to indicate the line of thought pursued by the speaker:—

"At first looked upon chiefly as a helpmate of medicine, physiology now occupies the position of an independent science. Yet medicine should look with jealousy upon all attempts to sever the connexion which has so long existed. There is no abrupt line of separation between health and disease; a knowledge of diseased processes can only be arrived at through a comparison with the healthy standard; and the comparison can only be made by the employment of methods as strictly accurate as those which the physiologist employs. Exactly in proportion as physiology defines with precision the acts and processes of the healthy organism, will medicine be in a position to become an exact study: the more the physician employs the habits of mind and the methods of research of the physiologist, the greater will be the progress of that profession, whose future shall be infinitely more glorious than even its honourable past. Believing, as I do, that physiology is the one great basis of rational medicine, I argue that a very accurate study of it should be considered essential on the part of all those who desire to enter the profession of medicine—a far more accurate study, I mean, than has yet been deemed possible. I would urge this, because of the facts of physiology being absolutely necessary to medicine, even were it not true that the habits of mind acquired by the cultivation of this science, at once experimental and observational, are the very habits of mind which should be cultivated by him whose life is to be spent in the observation of disease and in the performance of the complex experiments, if I may use the expression, which the most careful physician must needs be always performing."

We do not need to insist upon a more thorough knowledge of physiology on the part of our profession—that is, we take it, nowadays superfluous. There are, however, one or two points which are well worthy of attention. Let us put it thus—Why does physiology require so much pushing before students? Why do they not take to it as naturally and as eagerly as they for the most part do to anatomy? It seems to us that the vice hardly rests with the student. Were physiological teachers a little less learned, and something more practical, we fancy physiology would be better studied. Were teachers less fond of cramming men with dry facts, as geese are crammed with food; were the great broad facts and laws of physiology laid before them and enforced by examples, students would listen better than they do now. And this brings us to another point. In the study of physiology there is too much listening and too little seeing. No doubt there has been a great improvement in this direction, but we fear the pendulum has swung too far to the one side. A few years ago, a physiological lecturer would enter his class-room and read lectures, composed one knows not at what time; no explanation of difficult points, no illustration by experiment or otherwise. Nowadays physiological apparatus is somewhat more than preposterous. Students certainly see nowadays, but they see apparatus. Here again we must take care to keep ourselves from being misunderstood. Our belief is that exact investigations can only be carried on exactly—that is, by the help of exact machines. But the mind of the student just grasping the first principles of physiological science cannot always get rid of the machines; to him there is too often a *deus* in it. Therefore we hold that teaching machinery should be as simple as possible. Let the student carry away in his mind the fact, not the machine. Yet another sore point. The physiological teacher has to encounter still greater difficulties. According to our English system the newly entered student has to be instructed in physiology. Before he knows a bone, a muscle, a ligament, or a nerve, the unfortunate physiologist has to teach the student as well as he can what the structure and uses of these are; nay, more, he has too often to teach chemistry and physics besides. All this is absurd; but the crowning absurdity seems to us to be what follows a rejection at the College of Surgeons. If a student is rejected there he is relegated to the dissecting-room for three months, or six months, as the case may be. The candidate may have passed a satisfactory examination on anatomy; he may have been, as we have known over and over again, ignorant of physiology,—yet he, if rejected, is sent back to the dissecting-room. Until the examinations in anatomy and physiology are completely separated we can have little hope for the sound teaching of physiology. To put the two subjects on the same footing would be a great thing.

There are other and allied matters on which we desire to have a word, but meanwhile we fear that our readers may become wearied of what used to be called in Scotch sermons "the application" to Dr. Allen Thomson's and Dr. Gamgee's excellent addresses.

MECHANICAL GYNÆCOLOGY.

The subject of the remarks which follow has been suggested to us by some passages in the address with which Dr. Priestley opened the Section of Obstetric Medicine at the recent Manchester meeting. In the general tenor of Dr. Priestley's remarks we are at one with him. The only fault which we can find is that his denunciation is somewhat vague and general. He indicates an evil, and says it should be avoided; but he does not point out in what direction the better road is to be found.

He says, "There seems to have grown . . . . a proclivity to trust . . . . more than is desirable to instruments. These mechanical aids are often employed as a mere matter of routine . . . . in the vague hope that they may assist to find out something." "These remarks apply . . . . especially to the uterine sound." "There are many uterine affections in which it affords no information whatever, and many in which it is positively injurious." The truth of this is quite plain. All that the sound can do is to measure the length and indicate the direction of the uterine cavity—and this not always. In most cases the size and position of the uterus can be ascertained with greater accuracy by bi-manual examination; and these points known, the sound is not wanted. Its value in correcting flexions we shall refer to by implication further on.

We cannot entirely go with the first sentences, because "that vague hope that they may assist in *finding out* something" is just the one thing that can warrant the routine use of instruments. When any part of the body is diseased, the skilful investigator goes to that part, and uses every means in his power to detect changes in it; and it is only by their *routine* use that safe conclusions can be reached from new methods of observation. In making his diagnosis the obste-

trician may and ought to bring every sense and every resource of art into play (so far as is consistent with the welfare of the patient), so that he may get as accurate a conception as possible of the condition of the organs he is going to treat. But, diagnosis attained, there routine ought to end. Considered as applying to treatment, we thoroughly agree with Dr. Priestley's sentences. But we shall go further than he does, for we shall try and show the reason of the fault.

The speaker further on observes, "At one time ovarian pathology was in the ascendant; at another time, inflammation of the os and cervix uteri was regarded as the chief ailment from which women suffered; and lately these have given place to the theory that mechanical displacements of the uterus are the root of all evil. . . . Thus the world is afflicted suddenly with what seems an epidemic of flexions and versions of the womb, and a large amount of time and ingenuity are expended in the invention of pessaries, which might be more profitably employed in other directions." Here we will cease quoting Dr. Priestley; but we will take leave to supplement his words with some remarks made by Dr. West to the Obstetrical Society some months ago. The one describes the disease, the other the remedy. "Sydenham truly said that it was the duty of those who practised medicine to find out indications for treatment, rather than special remedies for this or that condition. The great point to aim at with regard to flexions of the uterus is to distinguish the different classes of these displacements, and lay down rules when treatment should *not* be adopted, because unnecessary or not beneficial."

Mr. Herbert Spencer somewhere remarks on the tendency of the average mind, in the presence of any emergency, immediately to *do* something, whereas the person of trained judgment suspends action until he sees how to interfere with advantage. Obstetricians at present seem to offer a curious illustration of this. Many of them appear not to have got beyond this natural impulse, not apparently able to see that *knowing* ought to precede *doing*, and that in the treatment of diseases in which we do not yet know how to do good, the next best thing is to know how to keep from doing harm. In the special diseases of women we see a great amount of industry and ingenuity expended in contriving things to cure diseases, of the natural history of which we know next to nothing. Let us take the particular instance Dr. Priestley refers to. We know that many women suffer from displacements of the uterus. It is proved that such conditions may exist without giving rise to any discomfort whatever. It is equally a fact that they often coexist with symptoms. Also that there are many cases in which the wearing of an instrument (which may to a greater or less extent alter the shape or position of the uterus) is followed by relief of symptoms. It is unfortunately just as undeniable, that in many of them the instrument does no whit of good, and often even harm. So much is recognised by all, and the explanation of the phenomena which the mechanical gynæcologist offers is, that the instrument fails to do good because it is not a suitable one; the displacement must be corrected, and if none of the existing instruments will answer, then a new one is wanted.

Let us for the present accept his position. The case may then be stated thus: that there are some cases which a simple and easily adjusted instrument will quickly cure; and others which, with our present means, it is either very difficult or impossible to amend. It seems to us that Dr. West's advice is here most pertinent. Before inventing new (and sometimes dangerous) instruments to combat these latter, the aim should be to distinguish between the two classes of cases; to find criteria which will enable the physician to tell his patient, either that she can be quickly cured, or the opposite. And even more than this, we want to know what will be the result if they are let alone. Seeing that it is certain that a uterus may be flexed and yet cause no symptoms, one would think that such a flexion might occur in a woman already out of health, without aggravating or altering her complaints. In such a case the mischief of putting in a pessary is evident.

This kind of investigation, although apparently, perhaps, more difficult, is really easier than an inquiry into diseases as revealed by the action of pessaries, because the sources of fallacy are fewer.

The pathology of disease is, in fact, the simplest problem that we have to solve. An exhaustive diagnosis is more difficult than pathology, and rational treatment than diagnosis, for each of the latter includes the former, plus its own peculiar difficulties. The treatment of diseases of the uterus, as of those of other organs, only becomes scientific when all the facts of the case are taken into consideration, when we know what will be the result of letting the case alone, and what will be the result of our remedies.

We do not maintain that nothing is to be learnt about disease from the effect of treatment; but it is at best a circuitous path. It is beginning at the wrong end. We must know the natural history of morbid conditions before we can arrive at *rational* treatment. But gynæcology at present (with a few exceptions), seems pursued wholly in this empirical fashion. From the apparent success of treatment, a theory is deduced about the disease, a mode of research which has led to the unsatisfactory state of things described by Dr. Priestley.

To invent a pessary does not need an intellect much higher than that of the artisan who makes it. To put in a pessary whenever the uterus is bent, is hardly more scientific than the practice of a bone-setter. An operation, even, can be dexterously performed by a person without much scientific knowledge. It will be a much greater and better thing to distinguish the conditions which need interference from those which do not, and of those which do, to show the consequences of neglect. Whoever does this, will do a work than which there are few things more needed.

THE WEEK.

TOPICS OF THE DAY.

A SINGULAR case is reported from Glasgow. Mr. James Stevenson (House-Surgeon), Sarah McKay (Matron), Mary Campbell and Sarah Ann Welch (nurses), all connected with the Glasgow Maternity Hospital, were last week apprehended on a charge of being culpably concerned in the death of an illegitimate infant which was born in the institution in April last. The first two prisoners were also charged with unnatural treatment of the mother. It is said that the child, though a healthy one, refused to take the breast, and the officials, though beseeched to do so, declined to supply it with milk. In consequence of starvation it died two days after birth. Several hours afterwards the mother "found the body of the child lying in a room cut up and ready for dissection."(?) Upon finding this the mother created a disturbance, and it is alleged that notwithstanding her weak state she was thrust into the street. All the prisoners have been committed for trial on the serious charge.

Professor Henry Draper, of New York, reports that he has discovered bright lines in the solar spectrum corresponding with the lines in the spectrum of oxygen. That there are no dark lines in the solar spectrum which correspond with those in the spectrum of this element has long been known, and there are none that correspond with those of any of the non-metallic elements, such as sulphur, phosphorus, iodine, chlorine, carbon, etc. The nebular hypothesis would lead to the belief that an element which is calculated to compose eight-ninths of the water and one-third of the crust of the earth could not be absent from the sun. Dr. Draper observes that in photographing the violet end of the solar spectrum he

finds interspaces between dark lines, and bright streaks corresponding with lines in the oxygen spectrum. The fact of the existence of bright lines as well as dark in the solar spectrum has long been recognised, but the coincidence of any of these with the lines of terrestrial spectra has not been hitherto observed. Professor Draper has made the existence of the bright lines in the violet end of the spectrum most conspicuous by taking photographs with suitable exposures. On comparing these photographs with the spectra of tubes containing oxygen, the coincidence of a large group of bright lines was at once recognised. The accuracy of the adjustment of the two spectra to one another is proved by the bright lines of iron in the spectrum corresponding with the dark iron lines in the solar spectrum.

About this time last year we commented on the unsanitary and immoral conditions of the people employed in hop-picking, and it is satisfactory to hear that the efforts of some of the largest hop-growers in Kent and Surrey to provide better accommodation for this class bid fair this year to be rewarded with success. The total want of sanitary arrangements, and the consequent disease and immorality, have assumed such glaring proportions that an Association has been formed, under the auspices of the clergy and principal residents of the two counties, having for its objects the strict supervision of the social and sanitary conditions of the hop-pickers, and the providing them, as far as possible, accommodation in the houses of the resident villagers. For some months past the Association and the large growers have been engaged in preparing accommodation for the hands on their arrival; honorary agents are appointed to meet trains carrying the pickers, prepared with gratuitous information relative to lodgings, places where labour is most urgently needed, etc. In many instances large barns, attached to the homesteads, have been partitioned off for families by means of rick-cloths.

According to returns furnished by the engineers of the Metropolitan Board of Works, the average daily quantity of sewage pumped into the River Thames during the week ended 18th ult. was 268,839 cubic metres at Crossness, and 369,863 cubic metres at Barking, equivalent to about as many tons in weight.

A profound sensation has been caused in the town of Macclesfield in consequence of a statement made by Mr. Allwood, surgeon, at an inquest upon the body of a child whose death occurred through starvation. He asserted that scores and scores of children died annually in Macclesfield through being purposely and habitually neglected. Medical men in the neighbourhood had plenty of moral, but no legal proof of child-murder, and they had to pass cases in which they knew the parents were as guilty as if they had cut their children's throats. The Coroner said his experience showed him that there was much indifference to life and much immorality among women of the lower class in Macclesfield. The Town Council have now taken the matter up, and have appointed a special committee to confer with the Coroner and medical men. The inquest under notice stands adjourned, but evidence has already been given as to the high rate of infanticide mortality in the borough.

The disastrous record of the number of lives annually sacrificed on the railways of the United Kingdom has just been published. From this return we gather that during the year 1876 the total number of persons reported to the Board of Trade as having been killed on all the railways during the year was 1245, and the number of injured 4724. Of these, 139 persons killed and 1883 persons injured were passengers. Of the remainder, 673 killed and 2600 injured were officers or servants of the railway companies or contractors; and 433 killed and 241 injured were trespassers or suicides, or others who had met with accidents at level crossings, or from miscellaneous causes. Of the passengers, according to the returns made to the Board of Trade, 38 were killed and 1297 were injured from causes beyond their own control. The report adds that the time has now come when the railway companies should agree upon a system of continuous brakes to be fitted on all lines, these brakes being admitted as one of the best methods for preventing accidents, and for mitigating their serious consequences.

An interesting experiment is being made by the Stafford Town Council in order to obtain a good water-supply for the town. They intend to bore to a depth of 600 feet by means of the diamond rock-boring process, and they hope to penetrate the water-bearing rocks of the new red sandstone formation, which exists widely in Staffordshire, and in many places lies at an elevated level. A depth of 300 feet has already been obtained, but as the process is necessarily slow, only a few feet being accomplished each day, a considerable length of time must elapse before the water-bearing rocks are entered. The opinion of scientific men fully corroborates the belief that an abundant supply of pure water may be obtained.

A hospital for the reception of English subjects settled in France was inaugurated in Paris at the end of last week by Sir Richard and Lady Wallace, who have largely endowed it. Sir Richard Wallace, in the course of a short speech, remarked that while this foundation was destined for English people alone, it was not to be forgotten that in London there is a vast hospital for the French poor supported principally by English charity.

It will be remembered that in the last annual report on the health of the Royal Navy, Dr. Messer, of H.M.S. *Pearl*, contributed an interesting paper on poisoned arrows, illustrated by the cases of Commodore Goodenough and the men who were wounded with him. A letter on this subject has recently been addressed by Professor Halford to the *Melbourne Argus*, which is as follows:—"A few years ago, the date I cannot recollect, I wrote to you on the subject of poisoned arrows, stating that I could not get any evidence of the poisonous nature of the matter with which the South Sea Islanders smeared their arrows. My experiments were made on dogs and pigeons, with arrows given me by Mr. Butters. Since that date Commodore Goodenough lost his life from wounds inflicted with, we suppose, similar arrows; but Dr. Messer, after experimenting with the supposed poison, came to the same opinion as I had myself been driven to. Dr. Messer had communicated his opinion to the authorities at home, with the result of surprising a great many people. Before leaving the colonies Dr. Messer wrote to me, enclosing some of the poison he had procured subsequently to the death of the lamented Commodore, requesting me to try its effects on the lower animals. I have done so, and am again driven to the same opinion—viz., that the tetanus following these wounds is not due to the matter with which the arrows are smeared, as I have failed to get any bad symptoms after freely wounding two dogs and one rabbit, and inserting two different samples of the poison at intervals of three weeks. It is two months since the animals were first wounded; no tetanus resulted, and they are now quite well. Now, as tetanus is produced both in man and dogs by similar vegetable poisons, it is not likely there can be much error in the opinion arrived at by Dr. Messer and myself—viz., that the stuff with which these arrows are smeared is not in any way poisonous. Should we be believed, it may lessen in some way the terror which has hitherto seized on everyone wounded by the arrows of the South Sea Islanders, and possibly avert, in many cases, fatal results."

Public opinion seems to be adverse to the purchase of the Thirlmere Lake for the purpose of providing a new source of water-supply for the town of Manchester, and it is expected

that the Bill to be presented to Parliament for carrying out this object will be vigorously opposed. The principal point of objection appears to be the erection of a huge wall across the lower end of the lake, which will have the effect of making the area covered with water 700 acres, instead of, as at present, 335, and will do much towards spoiling the picturesqueness of the neighbourhood.

ATROPHY OF TESTES FOLLOWING MUMPS.

M. Lereboullet recently brought forward at the Société Médicale des Hôpitaux a "Contribution to the Study of Atrophy of the Testes and Hypertrophy of the Mammary Gland in consequence of certain kinds of Orchitis." His remarks were founded on a case, of which the following is a *résumé*:—A young man, aged twenty-two, of robust health, well made, and possessed of all the characters, physical as well as physiological, of virility, was attacked with mumps. The disease seemed mild; at the commencement there were no febrile action and no complications. At the end of four days, although the parotid swelling had not disappeared, a double orchitis came on, so that within two days these glands were swollen to triple their normal size. The pain, however, was not great; *the epididymis was normal.* The disease evolved rather rapidly. When admitted into the Val-de-Grâce, the patient still presented peri-parotid swelling, and yet the atrophy of the testicle was well advanced. In about three weeks these glands were no larger than a haricôt bean. At the same time that the testes were undergoing this atrophy, and the sexual power and desire were disappearing, the mammary glands, which up to that time had been absolutely normal as for a young man of this age, began slowly but progressively to develope. But now, although there are no other external signs of femininism, yet one is distinctly struck by the development of the breasts: to the touch they are lobulated and hypertrophied, and do not at all feel like mere fat; they are increasing in size daily; the nipple undergoes erection after any excitation which is prolonged. There is an absence of beard, although the pubic hair continues. The penis has a normal development, but there is an absolute loss of the genetic sense. This case goes to show that an orchitis has supervened before the complete disappearance of the parotid troubles, and that it complicates a disease apparently mild in its type. This is not by any means an exceptional case or an exceptional complication. Many similar cases are recorded, especially in France. Some authors, and among them M. Juloux, believe that the atrophy, though it comes on slowly, nevertheless comes surely; and M. Laurens reported, out of thirty-two cases, sixteen of atrophy of the testis, and nine times impotence. M. Lereboullet, however, cannot accept these conclusions: he believes rather that the testicles may become modified, both as to volume and consistence, without there being any real progressive or persistent atrophy of these organs. He thinks that army surgeons, seeing the frequency of epidemics of this disease (mumps), would meet with more cases among old soldiers than they actually do, if the atrophy occurred at all frequently and persistently; and hence he concludes that the atrophy is only partial, and that it does not remain permanent. Atrophy of the testicles also occurs after traumatic orchitis as the result of excessive masturbation, and, though very rarely indeed, after gonorrhœal orchitis or syphilitic orchitis. But M. Reclus, in his thesis, "Du Tubercule du Testicule" (Delahaye, Paris, 1876), has shown that there are varieties of atrophy. Thus, in syphilitic orchitis, the testis atrophies very slowly; it is very hard, and often hypertrophied, in consequence of gummous deposits. Under the microscope it is seen that the lesion commences in the reticular tissue which surrounds the seminiferous tubercles; these then atrophy as the result of pressure, but very slowly. In the orchitis which follows mumps and masturbation the atrophy goes on with great rapidity, and the epididymis often remains intact. Under the microscope we find that the inter-canalicular tissue is but little altered, while the tubercles, which are alone affected, present a notable hypertrophy of their internal coat, with atrophy of their epithelial lining, and disappearance of their lumen. Thus, then, we have to do with a parenchymatous as opposed to an interstitial sclerosis. We reserve for another occasion a consideration of the mammary development which accompanies the disease.

THE MEDICAL DEFENCE ASSOCIATION.

The Council of this Association have just issued its first report. They give a brief summary of the origin of the Society. It was founded in May, 1875, with the object of checking the spread of unqualified practice, "which, through the apathy of the medical corporations and the profession generally, had increased to an unprecedented extent, and become a very serious public evil." The movement met with considerable support, chiefly, we believe, of general practitioners, whose interests it certainly was to suppress a practice which, quite irrespective of its illegal bearings and of its obvious evils, materially interfered with their own rights and privileges. From the cases published in which legal proceedings had been taken by the Society, it seems that they have chiefly busied themselves with so-called "quacks," or with offenders who have *openly* ventured to practise as "medical men." In many cases penalties have been obtained; in some cases—and this we see with regret—a compromise has been entered into, the Society undertaking not to prosecute on the "offender" undertaking to cease from practising. This is obviously weak, for nothing is so deterrent as being held up to public obloquy and having the name and circumstances published. There is, too, another point which the Association must take up—that is, "prescribing chemists." They are at the root, as we think, of the entire evil. Either they have the right to prescribe, or they have not. If they have not the right, they must be punished if they attempt to exercise it. The report tells us that the chemists and druggists have a defence association of their own, and that this Association has come forward to support a chemist who is appealing in the Court of Exchequer against an adverse verdict, by which £20 was recovered as a penalty for "counter prescribing." We congratulate the Association on this determination; it will become a *cause célèbre* in the annals of medicine, and will decide, probably, once and for all, the moot question as to whether chemists may or may not prescribe. We only hope that medical practitioners, whom this case most nearly concerns, will not allow the prosecution to miscarry for want of ample funds. It ought to be well defended, and put into the hands of first-rate counsel. We agree with the report in lamenting the practice of qualified medical men supporting and protecting unqualified practitioners and chemists who prescribe and visit. Such conduct is unworthy of their profession. The Society might call public attention to such disgraceful conduct, even though they possess not the means of putting a stop to it. Above all, the Society must not cease to work, and work hard, because the penalties do not come into their own hands. They will reap material advantages indirectly, if not directly, and every successful prosecution will add to the importance and influence of the Association, and to the facilities with which prosecutions may be taken up and successfully carried out.

THE ACTION OF SALICIN ON THE HEALTHY BODY.

In calling attention to the observations of Senator on the influence of salicin in febrile diseases (*Medical Times and Gazette*, August 4, 1877, p. 120) we omitted to refer to some interesting experiments by Professor Ringer and Mr. J. S. Bury, of University College Hospital, on the influence of

salicin on the healthy body, with special reference to its effect on the temperature (*Journal of Anatomy and Physiology*, July, 1877, p. 589). Their experiments were made on healthy boys, and the temperature was taken hourly from 9 a.m. to 12 p.m. The dose usually given was gr. xxx. in ʒj. water, for, to produce any symptoms characteristic of the drug, such a dose is absolutely necessary. Toleration of the drug is soon established, so that at last large doses fail to produce any marked symptoms, except slight fever, which delays and lessens the normal daily evening fall of temperature—an effect probably due to the development of slight gastric catarrh. As far as any depressing action on the temperature in health was concerned, it was found that even very large doses of salicin only seemed *to lessen the diurnal range of the temperature* on the day following their administration, while they very slightly increased the maximum temperature on that day. Speaking generally, the action of salicin on the healthy temperature (in male children) is practically *nil*. The most characteristic symptoms presented by a patient under the influence of full medicinal doses of salicin are a dusky flush uniformly suffusing the whole face on slight excitement, and a dull, heavy expression of the countenance. Other symptoms which are less constant are deafness, noises in the ears, frontal headache, trembling of the hands, and quickened breathing. Very large doses render the headache so severe that the patient buries his head in the pillow; they also cause very marked muscular weakness and tremor, and great irritability of the muscles, so that they contract strongly even with slight stimuli. Tingling may be complained of in the extremities and elsewhere, and the voice may become thick and husky. There is exaggerated breathing, though the patient has no sense of pulmonary oppression. Large doses often repeated raise the pulse to 140 per minute, and render it very weak. Delirium was not noticed during these experiments. Salicin renders the sweat neutral or alkaline even in rheumatic patients with acid urine.

UNQUALIFIED CHARLATANISM.

However happy may be the issue of the flirtations of the homœopaths with the scientific and orthodox section of the profession, there seems no reason to believe that medical treatment is approaching in any way to uniformity:

> "Our little systems have their day,
> They have their day and cease to be."

But if the homœopathists, as their uninvited advances seem to indicate, believe that their little system has had its day, the recent trial at South Molton, in Devonshire, shows that other forms of charlatanism have good reason to complain of repressive legislation. A man named Harper, who is known by the name of "The White Witch," but who calls himself a herbalist, was called in to see a patient. He went to the house of the woman, felt her pulse, and said he did not know whether he could do her any good, as he was only a humble instrument in the hands of God. He gave her four or five iron rods in succession, with which she tapped a piece of iron held by her in the other hand, while lying in bed. At the end of the rods were the names of different planets, such as Jupiter and Mercury. He also asked the age of the woman, and the hour she was born, saying he wanted to find out under what planet she was born. He gave her some bitters to take, but she died a few days afterwards. The man was unqualified, so in more than one sense are a good many homœopaths. As a treatment the iron rods and many homœopathic remedies are about on a par. The Bench sentenced the defendant to a month's imprisonment. Notice of appeal was given, and he was admitted to bail. The homœopathic requisitionists "hold that it is competent for any qualified medical man to adopt any theory or practice which he believes to be best for his patients"; but the fact of a man being "qualified," instead of making ridiculous theory and ridiculous practice acceptable to other qualified men, only justifies the assumption that there is a still graver element than absurdity in the case, and suggests the reflection that charlatanism does not cease to be reprehensible when it is associated with corporation seals and Latin diplomas, but on the other hand becomes disreputable in proportion to the respectability of the degrees which it dishonours. From this point of view it might be more advisable to look with favour upon the "subtle craft" of the White Witch of Barnstaple, than to listen to the social advances of the homœopaths; but as both parties seem to be in an advanced stage of senile decay, the dignity of the profession may be best consulted by allowing the White Witch to retire into the workhouse, and permitting the homœopathists to bury their dead "system" in the limbo of antiquated errors.

THE SANITARY STAFF OF DUBLIN.

At a special meeting of the Municipal Council of Dublin, held on Monday, August 27, the Town Clerk read the following report of the committee of the whole house appointed by order of the Council of the 13th inst., *in re* the dismissal of sanitary police, and appointment of other suitable and fit persons instead thereof:—

"Your committee, in obedience to your order of the 13th inst., whereby the following notice of motion by Councillor Murphy was submitted for consideration and report, viz.—'That the services of the sanitary police be discontinued from and after the 3rd September, 1877, being the next quarter-day; that notice hereof be given to Colonel Lake, or his successor; and that the Public Health Committee be authorised to advertise for, appoint, and employ other suitable and fit persons instead thereof at salaries of £1 per week for eight sanitary inspectors and 25s. per week each for the two superintendents; and that clothing as like as possible to the police uniform and of an approved pattern be provided for this staff; and that none be employed but *superannuated police-sergeants or constables discharged from the force with a pension and good character*'—beg leave to report that they met on Wednesday, the 15th August inst., and after careful consideration of the change proposed to be effected in the sanitary staff by Councillor Murphy, they, instead thereof, submit the following for consideration and approval by the Council, viz.—'That in order to reduce *the present needless expenditure* of the Public Health Committee, but at the same time maintaining complete efficiency, the present staff be arranged as follows:—*Metropolitan Police employed on Sanitary Duty*.—Present staff—2 inspectors at £160, £320; 4 sergeants at £94 9s. 4d., £377 17s. 4d.; 4 acting ditto at £89 5s. 4d., £357 1s. 4d.; 4 constables at £80 3s. 4d., £320 13s. 4d.; 1 constable at £86 0s. 8d., £86 0s. 8d. Total present cost, £1461 12s. 8d. Proposed staff—1 inspector at £160, £160; 3 sergeants at £94 9s. 4d., £238 8s.; 4 acting ditto at £89 5s. 4d., £357 1s. 4d.; 2 constables at £80 3s. 4d., £160 6s. 8d.,—£960 16s. Amount of reduction, £500 16s. 8d. The above amounts include clothing.' All which we submit as our report, this 15th day of August, 1877.—John Barrington, Chairman."

If there is one thing certain about the sanitary administration of Dublin, it is the necessity which at present exists for increasing the inspectorial staff of the Health Committee of the Corporation. The proposal, therefore, to reduce "the present needless expenditure" of the most important corporate committee by substituting for the active members of the metropolitan police-force, now employed as sanitary officers, "superannuated police-sergeants" and pensioned-off constables, seems rather out of place. To the credit of the Corporation of Dublin be it recorded that on reconsideration it was almost unanimously resolved—"That, considering the importance of a perfect system of sanitary inspection, it is inexpedient to make any change in the number of the present staff." It is worthy of note that in the debate on the question more than one speaker alluded to the vigilant eye kept on the Public Health Committee by the Dublin Sanitary Association. The allusion does not seem to have been thrown away on the "City Fathers."

INDIAN MEDICAL SERVICE.

The following is a list of the candidates for her Majesty's Indian Medical Service, who were successful at the competitive examination at London in February last, and who have undergone a course of instruction at the Army Medical School, together with the total number of marks obtained at the examinations at London and at Netley. The first-named gentleman gained the Martin Memorial Medal :—

	Marks.		Marks.

THE HEALTH OF BIRMINGHAM.

In issuing his fourth annual report on the health of the borough of Birmingham, for the year 1876, Dr. Alfred Hill, the Medical Officer of Health for that district, shows that the birth-rate for the period has been 42·53 per 1000 of the population, which is higher than recorded in any previous year. It is 4 per 1000 higher than the average of the last ten years, and higher than that of any of the large English towns, the ratio in London being only 36·5 per 1000. Dr. Hill remarks that the statement is very often made that the death-rate of a community is high because the birth-rate is high; this, he observes, has been refuted by several writers, notably by Mr. N. A. Humphreys, of the Registrar-General's office, and it certainly is not supported by a comparison of the respective birth- and death-rates in the borough of Birmingham during the last four years. During that period the highest birth-rate has coincided with the lowest death-rate, and the lowest birth-rate with nearly the highest death-rate, so that it is clear a high birth-rate taken by itself is not the general cause of a high death-rate. The infant mortality of the district has decreased from 196 to 160 per 1000 births registered; this is reported to be partly due to the considerably smaller fatality of infantile diarrhœa. It is also gratifying to find that there has been a diminution of mortality from zymotic diseases. During the year under notice Dr. Hill has given particular attention to the subject of defects in house-construction, and he appends to his report some very useful sketches, showing the best methods of arranging waste-pipes, etc., so as to carry off all obnoxious gases to the outside of the house, instead of allowing them to poison the atmosphere of the rooms. This latter subject is one of so much importance that it may, with great advantage to the public, enlist the attention of medical officers of health.

TURKISH HOSPITAL AT SCUTARI.

A correspondent of the *Daily Telegraph*, writing from Turkey, states that two days before going to the front Baker Pasha and several of the English officers on his staff visited the hospital at Scutari, accompanied by Mr. Pratt, of the Red Cross Society. There were 1184 patients under treatment, most of them badly wounded, and some suffering from ophthalmia. They were all wonderfully fine men in physique, and from the absence of alcohol, or any sort of intoxicating drinks, seemed to suffer comparatively little. The lives they lead keep their blood in such a healthy state that their wounds generally heal in an extraordinarily short time. Amputations cannot be performed without the permission or wish of the patient. Their objection is based on the idea of "going maimed before Mahomet"; and this prevails to such an extent that, as a rule, death is preferred. Sometimes, however, the love of life asserts its power, in which cases the operations are borne cheerfully and manfully. The rooms were clean and sweet, the beds possibly too near, unavoidably so on account of the crowded state. Beautiful gardens for the use of convalescents surround the hospital, which must not be confounded with the one used by the English during the Crimean War, and which has now reverted to the purpose for which it was originally built—viz., a Turkish barracks.

HOW MEDICAL APPOINTMENTS ARE MADE IN IRELAND.

Recently the post of Medical Officer to the North Dublin Union Workhouse became vacant by the resignation of Dr. John Rutherford Kirkpatrick, a gentleman who had for several years filled this responsible appointment with credit to himself, and advantage to the sick poor in the institution. As there is a salary of £150 per annum attached to the office, a very large number of candidates entered the field. Some of these gentlemen possessed the highest qualifications, both personal and professional. A closely contested election on August 22 resulted in the appointment of Dr. Robert Kenny by a majority of one over the candidate who secured the next highest number of the guardians' votes. Now, against Dr. Kenny we have not one word to say, but we confess we were surprised, nay, almost startled, when we read the following passage in an editorial comment on the election, in the columns of the *Freeman's Journal*, the leading Liberal and Roman Catholic daily newspaper in Dublin :—"On the whole, although the absence of some Liberals and defection of others is to be noted and regretted, the Liberals as a body made a good fight and carried their man against difficulties which their adversaries calculated to be insurmountable." Is it, then, possible that in Ireland the *medical* qualifications of candidates for medical appointments are so completely lost sight of, and that men are appointed as medical officers only according as they are Conservatives or Liberals, Protestants or Roman Catholics?

LONDON WATER.

When are we to get at the bottom of the water question? Are we to adopt Sir William Fergusson's motto, and take plenty of water, no matter whence it comes, provided we have plenty of it? Are we to listen to the most interested class—civil engineers,—and go in for some gigantic scheme in order to bring water from the lakes or from Wales—or, let us say at once, the ice regions of the North Pole? At the meeting of the British Association at Plymouth we had a new scheme aired, the absurdities of which are so paramount that the authors practically contradict themselves in different papers read before that would-be-learned body. Suffice it to say that the scheme entails the relaying of all the London water-pipes, not, as one might suppose, for the purpose of rendering them stronger or better adapted to a high pressure; no, the purpose is to lay them down in duplicate—high pressure and low pressure, good water and bad water. But there will be a great additional advantage: there will practically be a new water company—another of Sinbad's friends, whom we would fain get rid of. The subject is worthy of fuller discussion, but the inevitable autumn tourist has begun to make his appearance in the *Times*. We shall soon have the sea-serpent and the gigantic gooseberry.

NITRITE OF AMYL IN CHLOROFORM—DEATH.

A correspondent, *àpropos* of the two deaths under anæsthetics which we recently recorded, thinks that nitrite of amyl ought always to be tried in cases where death is threatened from chloroform, and suggests that a small bottle of it should be kept ready at hand on all occasions. We fully endorse the suggestion, believing that it may occasionally prove useful.

Sims' method of suspending the patient by his legs might also be borne in mind and tried. But—and on this we would insist—nothing will prevent deaths but a careful administration in each and every case. Those who are giving the anæsthetic should do nothing else, and they ought always to bear in mind that they are administering a drug which is dangerous to human life, and ought to act accordingly.

THE TREATMENT OF DISEASE WITH COMPRESSED AND RAREFIED AIR.

Compressed air has been used for some time in France and Germany to a limited extent in the treatment of various diseases of the lungs, and also as a general roboriser of the system; but in consequence of the expensive apparatus required for its administration, it has not had much vogue except in large establishments in which a number of patients are collected together under the care of a medical man who superintends the "cure." Under the old system, of which we are at present speaking, the patients undergoing the "cure," as the Germans call it, are placed in a strong air-tight chamber, somewhat resembling a diving-bell, in which the air is kept at a pressure of from half to one, or at the utmost two, atmospheres, and in which they remain a definite time. Thus, at Reichenhall, in Bavaria, the cure consists of sittings of two hours each, taken once a day for a month. Those who have undergone a course of treatment with compressed air in the above fashion describe the sensation as by no means pleasant, especially owing to the pressure on the tympana, which necessitates constant sipping of water in order to equalise the tension within and without the middle ear by opening the Eustachian tube in the act of swallowing. Furthermore, the idea of being shut up without the possibility of escape for even two hours is not agreeable; and we know of a case in which, though a lady fainted in the air-chamber, her companion was unable to obtain any assistance, the attendant outside, in answer to her knocks, refusing to open the door until the regulation period had expired.

Since 1870 the idea of enclosing people, so to speak, in a bath of compressed air has been abandoned by a number of physicians in Germany, and it has been proposed instead simply to make the patient inspire the compressed air from a reservoir by means of a tube and closely-fitting mouthpiece. In addition, the treatment of disease by air at a different pressure from that of the atmosphere has been extended by making use of *rarefied* air as well as of compressed air. A number of apparatus have been proposed for supplying compressed and rarefied air, the best of which appears to be that of Dr. Waldenburg.(a) This consists of an external cylinder of metal closed below and open above, and containing water up to a certain level, and of a second cylinder open below and closed above, which fits into the first one, and is suspended in it by cords passing over pulleys and to which weights are attached externally just as in an ordinary gasometer. Supposing now that the inner cylinder be filled with atmospheric air and hermetically closed by having its lower edge immersed in the water in the outer cylinder, we can either obtain compressed air by placing weights on it so as to make it sink deeper in the water, or rarefied air by increasing the weights suspended from the pulleys so as to raise it higher in the water and increase the space occupied by the air. In order to diminish the expense as well as to increase the portability of this kind of apparatus, Dr. Philip Biedert, of Worms, has suggested an air reservoir with collapsible walls, like those in fact of a bellows or accordion, which allow a diminution in the size of the receptacle without a corresponding diminution in its diameter, and therefore in the pressure that it maintains. As we are here bent rather on giving a comprehensive general account of what is at present known about the treatment with compressed and rarefied air, we shall not enter further into the minutiæ of the apparatus employed, but having indicated their principle, must refer those of our readers who desire more detailed information to Lecture No. 104, in Volkmann's *Sammlung Klinischer Vorträge*, (b) to which we are mainly indebted for the materials of this article, and which contains references to all the recent literature of the subject.

Before speaking of the application of compressed and rarefied air to the treatment of disease, we may say a few words on the physiological properties of these agents. In the first place, it will be seen at once that there is a difference between the old method of enclosing a person in a chamber containing compressed air, and the new system, by which he simply inspires the air by the mouth from a reservoir containing it. In the former, the air influences the whole surface of the body, and its action on the interior of the thorax is modified by its action on the outside and on other parts of the body; in the latter, the direct action of the air is limited to the interior of the thorax, and the system at large is only secondarily affected.

Leaving the old system out of further consideration, and limiting our attention exclusively to the new one, it may be stated that the general result of the inhalation of compressed air consists in the improvement of the nutrition, of the hæmopoietic function, and of the external appearance, owing to the increased amount of oxygen which is carried to the lungs at each respiration. Not only, however, is the amount of oxygen which the lungs respire augmented by the compression of the air, but also by the increase of *vital capacity* which the inhalation produces, and which Dr. Biedert has found to be as much as from 500 to 700 or even 1000 cubic centimetres, and this increase is not limited merely to the time during which the inhalation lasts, but continues long afterwards. Speaking generally, we may say that by the inhalation of compressed air the lung gets more air brought to it than it ordinarily does, and that, on the other hand, by the inhalation of rarefied air, more air is withdrawn from it than ordinarily occurs, and this statement is founded on the careful experiments of Waldenburg and others. Waldenburg has also shown that compressed and rarefied air exert an influence which extends beyond the lungs to the circulation of blood between the right ventricle and the left auricle of the heart, so that this lesser circulation can be rendered emptier if compressed air, and fuller if rarefied air, be inhaled. According to Biedert, in addition to their bio-chemical action on the lungs and the general system, both compressed and rarefied air exert a directly stimulating effect upon the lungs, owing partly to the friction of the air as it rushes vigorously into and out of them, and partly to the repeated alterations of pressure and the amount of distention of their blood-vessels. This latter property is one that requires to be remembered in considering the cases to which the method may be applied, and most care is needed is using rarefied air, which is found to be the most strongly irritating. It is probable that the freer expectoration which follows the use of the pneumatic apparatus is due to this stimulating or irritating property of the inspired air. In consequence of this property the inhalation of compressed and rarefied air is inapplicable *to all acute inflammatory processes in the lungs.*

The diseases in which this method of treatment, which we shall now pass on to consider, have been found most efficacious, are phthisis and a phthisical disposition, chronic bronchitis, emphysema, asthma, and compression of the lungs by pleuritic adhesions. It has been recommended by Waldenburg in stenosis of the larger air-passages, and also in certain diseases of the heart. In phthisis it is possible, by means of compressed air, to increase the capacity of a narrow thorax, and to strengthen the weak respiratory muscles by means of the exertion used in inspiring rarefied air. It is also probable that the compressed air may help to relieve the congestion of inflamed parts of the lung, and that the rarefied air, by increasing the depth, and perhaps the number of inspirations, may improve the general nutrition of the lung by rendering the circulation in it more active. According to Dr. Biedert, those cases of phthisis in which the irritating property of the inspired air makes itself most felt, especially those in which there is much fever, are the least suited to the pneumatic treatment; cases also in which there are large areas of consolidation are unsuitable to it. Moderate hæmoptysis is no contra-indication to the use of compressed air. As far as we can judge, however, from Dr. Biedert's statements, the pneumatic method appears rather to *alleviate* the symptoms in phthisis than to exert a definitely curative action on it, and it seems more probable that it will be of value in strengthening the chest muscles, and opening out the chest in persons with a phthisical predisposition, than in the actual disease itself.

In either case the method employed is the same. The sitting begins by the patient inspiring compressed air alone, and then, when the irritation and cough which it has set up diminishes,

(a) *Berl. Klin. Wochenschrift*, 1873, Nos. 39 and 40.
(b) "Die pneumatische Methode und der transportable pneumatische Apparat," von Philipp Biedert, Assistentarzt in Worms am Rhein.

he inspires rarefied air, and the sitting is ended by a few inspirations of compressed air. The compression of the air varies between $\frac{1}{92}$ and $\frac{1}{45}$ atmosphere, and the rarefaction from $\frac{1}{324}$ to $\frac{1}{68}$ atmosphere, and the number of inspirations at each sitting ranges from 20 to 60. The sittings take place once, or at the utmost twice a day, and in the commencement of the treatment the medical man must be always present, to superintend the use of the apparatus. Later on this duty may be handed over to an assistant, or to the patient himself, provided he be intelligent; the physician only exercising a general supervision from time to time. In the use of compressed air, it has been found advisable not to exceed a pressure of 1 atmosphere; and the patient should be directed, as soon as he has overcome the initial irritation, to inspire slowly and as deeply as possible, without using force. On the other hand, when he breathes rarefied air, he must inspire vigorously.

In *bronchitis* this treatment renders expectoration more easy, stimulates the lung, and improves the circulation in it; and since the compressed air penetrates further into the lungs than any other local application, it is probable that it reaches diseased parts which would be inaccessible to any other direct treatment. The ordinary pneumatic treatment of bronchial catarrh consists in inspiration of compressed air at the same pressure as in phthisis. The use of rarefied air is only indicated if we wish to stimulate the lung more vigorously, or to promote expectoration; and it must be followed, if there is much catarrh, by a few inspirations of slightly compressed air in order to remove the temporary congestion of the lung, which Waldenburg has shown to be produced by a rarefied air. In all cases excessive irritability of the lungs, or any aggravation of existing mischief, is an indication for reducing the pressure, or temporarily stopping the pneumatic treatment. In *emphysema*, the treatment begins with short sittings, in which from ten to twenty inspirations of compressed air ($\frac{1}{90}$ to $\frac{1}{68}$ atmosphere) are taken and repeated after an interval of ten minutes. On the second or third day the really curative treatment of the disease, as Dr. Biedert calls it, commences. Instead of breathing in compressed or rarefied air, the patient is made to *expire* into an atmosphere of rarefied air, the number of expirations ranging from thirty to fifty once or twice a day, and depending on the sensibility of the patient's lungs to the irritation of the air. The theory of action of this method is, that the rarefaction within the chest causes a diminution in the size of the thorax, and also of the lungs, owing to increased pressure on their outer surface; that the same pressure elevates the abnormally depressed diaphragm; and that the blood is sucked, as it were, into the tissues of the lungs so as to counteract the anæmia due to the emphysema.

In the so-called "bronchial asthma" the indications for the pneumatic treatment are the same as those in bronchial catarrh. During the actual asthmatic attacks, inhalation of compressed air appears to be quite useless. In two cases of compression of the lung by pleuritic adhesions, Dr. Biedert has succeeded in raising the vital capacity in one from 2600 to 3500 cubic centimetres, and in the other from 2200 to 2600 cubic centimetres. The patients inspired compressed air at pressures up to $\frac{1}{34}$ atmosphere, from 30 to 50 inspirations being taken at each sitting. The value of the pneumatic method appears to be as marked in some forms of heart disease as in any of the diseases we enumerated above. According to Waldenburg, affections of the mitral valve are those which are most benefited by it; and Dr. Biedert refers to a striking instance of disappearance of dropsy, and general improvement, under the influence of compressed air, in a case of mitral stenosis and incompetence. Rosenstein also, in his article on Valvular Diseases in the sixth volume of "Ziemssen's Cyclopædia," is equally favourable to this treatment.

The contra-indications to the use of *compressed* air are degeneration of bloodvessels and an apoplectic tendency; and to that of *rarefied* air, especially in the form of inspiration, pulmonary hæmorrhages. The whole method is unsuited to active inflammations in the lungs as well as to advanced bronchial dilatation.

In concluding this article, which does not pretend to do more than give our readers an outline of what is meant by the modern "pneumatic method," we may say that the method itself appears to us to be at present a tentative one, and that we need a much wider trial of its efficacy, and a longer experience of its merits and demerits before it can be allowed to take its place among recognised systems of treatment. Theoretically there is much to be said in favour of it, but we doubt very much whether it can permanently overcome the anatomical changes which give rise to emphysema, or oppose more than a temporary resistance to a contracting pleura. In any case, however, we ought to know something about it, and to experiment with it in this country as they are doing in Germany.

FROM ABROAD.

Alimentation of Young Infants.

Incited by a discussion upon this subject which occurred recently at the Academy of Medicine, M. Labbée has entered, in some recent numbers of the *Journal de Thérapeutique*, upon an elaborate investigation of all the documents and facts relating to it, and in the number for August 10 he sums up the conclusions at which he has arrived:—

1. Every year 10 per cent. of the 18 per cent. of infants who annually die during the first year of life in France, in all probability do so owing to defective alimentary hygiene. So fearful a mortality may be considerably reduced, if not quite prevented, the remedy exclusively residing in a proper mode of rearing. 2. Suckling is the best and most certain mode of alimentation, that which gives the infant the best chance of surviving at the end of the first year, and that which insures it the best constitution. Figures amply prove this; for while the mortality of infants fed artificially is comprised between 22 and 94 per cent., that of sucklings is comprised between 11·18 and 22 per cent. With regard to the constitution, it is known that scrofula is especially prevalent in the departments where most children are brought up by hand; and it is probable that ulterior investigations will show that athrepsia (diseases of innutrition), the scourge of early life, which attacks with such intensity ill-nourished infants, leaves behind it irreparable disorders, even when it is cured. 3. Maternal suckling is, beyond all contradiction, better both for mother and child than hired nursing. This statement as regards the child amounts to almost a commonplace, so generally is it admitted; but many mothers are unaware how beneficial suckling may prove to themselves, procuring for them not only the satisfaction of fulfilled duty, but also the incomparable advantage of a better and more complete re-establishment. 4. As far as regards the child, the maternal milk and that supplied by a wet-nurse at home may be placed on the same footing. A nurse not residing in the family is in general of but very slight use. As long as the infant has good milk in sufficient abundance whenever it desires, it is of little consequence, for, although woman's milk is better for it than any other, the maternal milk is not indispensable. This is, however, looking at the question in its scientific, not in its moral aspect. 5. In the choice of a nurse, the question of diathesis being put aside, we should be especially guided by the condition of her own infant. Neither the chemical analysis nor the microscopical examination of the milk can furnish data that are equivalent to inspection of the infant. 6. For the control of the value of suckling there is a method the results of which are absolutely certain, namely, the periodical weighing of the infant. It is to this alone we can have recourse to ascertain whether the nurse is a good one, and whether the infant attains its regular growth. For this purpose M. Labbée furnishes all the figures requisite for the verification of the development of the infant day by day. 7. The infant should be kept exclusively at the breast during the first six months, and milk should constitute the basis of its nutriment until the period of weaning. 8. There is no fixed epoch for weaning, although there are more or less favourable moments for doing so which will be best appreciated by a medical practitioner. As a general rule, it should not be thought of before a twelvemonth, and when the suckling can be prolonged until the eighteenth month the results obtained are better. The practice of Trousseau, which consisted in weaning the infant in the period of time comprised between the evolution of the two groups of teeth, should be adhered to. 9. When the mother has not sufficient milk she may supplement it by cows' milk, this mixture furnishing good results. This plan succeeds especially well in the country, but is still advantageous even in towns. 10. Suckling by means of an animal, as a goat for example, is but rarely practicable, but the infants in general thrive. 11. Many mothers cannot suckle from not having any milk, while others soon lose theirs, so that artificial alimentation becomes frequently a necessity. This procedure succeeds better in the

country than in towns, and exacts more care and intelligence than suckling; but, well carried out, it furnishes almost as good results as those procured from the breast. But in large cities it can scarcely be relied upon for bringing up infants in satisfactory condition. 12. In artificial alimentation, milk should constitute the exclusive food during the first six months, and that of the cow is preferable to goat's milk, which is too rich in casein and butter. Suckling by the bottle must be modelled, as far as possible, upon natural suckling,—that is, the quantities of milk given should be equivalent to those sucked. 13. A mixed regimen, whether the infant be brought up at the breast or by the bottle, should not be commenced until the end of the sixth month. From six months to a year, farinaceous and feculent diet may be employed; from the first year to the period of weaning, fatty bodies, eggs, and highly azotised aliments, such as meat, may be resorted to. 14. The various farinaceous foods for infants, announced as possessed of great nutritive power, are not possessed of the properties of good milk. They may, however, be also employed for the purpose of variety of food, which has its advantages. 15. Artificial milks are never of the same value as breast-milk, and should never be substituted for it. 16. When an infant is ill-nourished, and when its alimentary ration is insufficient, whatever may be the origin of such insufficiency, that assemblage of accidents arises which Parrot has designated by the term *athrepsie;* and if this affection is sometimes cured, its ulterior consequences are still to be dreaded—infants that have escaped its first onset still remaining feeble and miserable. Its only remedy is a well-devised alimentary hygiene.

REVIEWS.

Traité des Maladies de la Prostate. Par le Dr. Henri Picard, Professeur libre de Pathologie des Voies Urinaires à l'École Pratique. Paris: Baillière et Fils. 1877.

Treatise on Diseases of the Prostate. By Dr. Henri Picard, Professor, etc.

Dr. Picard commences his book upon diseases of the prostate with an excellent description of the anatomy and relations of the gland; and he points out the importance of a knowledge of the arrangement of the various fasciæ of the part, for the purposes of surgical diagnosis. The minute structure and also the average size of the prostate are carefully described, especial reference being made to the work of M. Ch. Robin.

He then discusses the physiology and pathology of the gland in relation to the organs of generation and to the urinary apparatus, and alludes to the influence of prostatic disease upon the bladder and kidneys, and sometimes even upon the heart. A section is devoted to the consideration of deformities and absence of the prostate, which are rare conditions; and this is followed by a chapter on contusions, wounds, and false passages. The first two injuries are not common, with the exception of those wounds which are made for the extraction of foreign bodies from the urethra or bladder. The last—false passages—are sufficiently frequent, and we think the author might with advantage have said somewhat more upon their management.

The most important part of the work, and in our opinion by far the most valuable, is that which deals with the subject of inflammation of the prostate and its consequences and treatment. The most common cause of prostatic inflammation is an urethritis, though it may sometimes have its origin in disease of the bladder. It is seldom a primary affection, but may be induced by forcible catheterism, lithotrity, or the application of other irritants. Exposure to cold, alcohol, drinking, and venereal excesses are frequently the immediate cause of a prostatitis when there is a pre-existing urethritis. The affection is one chiefly of middle life. The author gives a clear account of the symptoms and diagnosis of both the acute and chronic form. In the acute stage there is usually considerable fever, much pain in the perineum increased by micturition or defæcation, tenesmus, and often retention of urine. If suppuration occurs, as it often does, there will probably be rigors and throbbing pain. A digital examination of the rectum, which is very painful, reveals a swelling of the prostate and perhaps fluctuation. The passage of a catheter gives the same indications. Abscess may burst either into the urethra, the rectum, the perineum, or the ischio-rectal fossa; more rarely into the bladder. Abscess of the prostate may, moreover, have a pyæmic origin. In the chronic form the symptoms are less marked, and much resemble those of stone. The author devotes a good deal of attention to the diagnosis between chronic prostatis and spermatorrhœa, and shows that in the first the discharge never consists of the secretion of the prostate alone, but is a compound fluid consisting of the secretions of the various glands of the urethra mixed with that of the prostate, and sometimes containing also seminal fluid.

He points out that in spermatorrhœa, which he considers to depend usually upon lesions of the nervous centres, there are sometimes found in the seminal fluid crystals of phosphate of lime, which are never seen in health. The treatment of inflammation of the prostate is fully considered, and especial attention directed to the use of belladonna, both in suppositories and as an ointment, and also to the local application of astringent solutions. After a short section on peri-prostatic abscess, there is a chapter upon the various ulcerative deseases of the prostate. These are divided into—1, inflammatory ulcerations, and 2, diathetic ulcerations, including herpetic, arthritic, scrofulous, tuberculous, and cancerous. This chapter contains a short description of the endoscope, which, however, the author admits is not often available for diagnostic purposes, on account of its difficulty of management. The varieties of prostatic calculi are next described, and the author alludes to the share they have in producing enlargement of the gland.

Increase in the size of the prostate is the subject of an elaborate chapter, in which the pathology of the affection is discussed, and the different forms of enlargement are considered. The author remarks that the great number of medical and surgical remedies that have been employed in the treatment of prostatic enlargement, shows that the condition is not very amenable to any of them. Naturally, therefore, the chief point for consideration is the best method of emptying the bladder in these cases. The last chapter is upon atrophy of the prostate, a condition rarely met with.

The book shows a fair acquaintance with the literature of the subject, although the author does not seem so familiar with the latest suggestions with regard to the treatment of enlarged prostate, as with the rest of his subject. The volume is well printed, and is announced in the preface to be the first of three by Dr. Picard, upon the diseases of the urinary organs.

Epitome of Skin Diseases, with Formulæ. By Tilbury Fox, M.D., and T. C. Fox, B.A., M.B. Cantab. Second Edition. London: Renshaw. 1877.

The first edition of this little pocket companion is exhausted, and another has been issued. This is sufficient testimony to the value of the work. A few alterations and additions have been made. The subjects are arranged alphabetically, and a selection of formulæ is appended at the end of the book. We do not doubt that it will continue in high favour.

A New Original Discoverer of Etherisation.—The dispute concerning the claims of Wells, Morton, and Jackson, as the discoverers of etherisation, has been long and hotly contested in the United States. But now, acoording to an article in the *Virginian Medical Monthly*, by Dr. Marion Sims, a Dr. Long, of Athens, Georgia, is the real Simon Pure. The discovery of Dr. Long by Dr. Sims himself seems to have been quite accidental, a medical man who had recently come to consult him at New York having almost casually remarked that he had been present when Dr. Long removed a tumour under the action of ether in 1842, and performed other operations in 1843 and 1844. The patient who was operated upon in 1842, made an affidavit as to the fact in 1849. As Morton commenced etherisation in September, 1846, he was thus antedated by four years. However, Dr. Long seems to have attached very little importance to his procedure, and took no pains to make it public, and of course all knowledge of it would have died out had not more energetic persons re-discovered and utilised the properties of ether. The matter seems of little importance, and, at all events, requires more authentication. "It is proposed," says the *New York Medical Record*, "to compromise the difficulty by making Congress vote to each of the families of Long, Wells, Morton, and Jackson, $100,000! As there is not much likelihood that Congress will be in any hurry to take up the discussion, there may be still time and opportunity for a few more discoverers to put in their claims."

GENERAL CORRESPONDENCE.

"EXPERIMENTS ON HAY FEVER."

LETTER FROM DR. C. H. BLACKLEY.

[To the Editor of the Medical Times and Gazette.]

SIR,—In your issue for August 18 I find a short notice of some fragmentary experiments on the cause of hay-fever, tried by Dr. Patton, of Mississippi, U.S., at the suggestion of Professor Binz.

As there appears to be a considerable amount of misunderstanding with regard to the real nature of the disease in question, and as my name has been brought prominently forward in the article (Virchow's *Archives*, lxix. S. 410) which has given occasion to your remarks, I should be glad if you would permit me to make some observations on the experiments which are there cited to prove that pollen is not the cause of hay-fever. In order to give your readers a clear idea of the facts upon which Dr. Patton bases his objection to the pollen theory, I will give a condensed account of the experiments tried by him.

On June 10 last year, Dr. Patton inhaled a strong dose of the mixed pollens of *Festuca pratensis* and *Dactylis glomerosa*. Uneasiness and obstruction of the nostril operated upon were soon produced. After an hour and a half, however, every symptom had vanished. On the 13th and 14th the experiment was repeated. The result was the same as before. On June 15 a smaller quantity of pollen was placed in the left eye. Lively itching was brought on, with a moderate injection of the vessels, and a tolerably strong secretion of tears. After an hour no trace of these appearances was left. On June 20 a strong dose of the pollen of *Secale cereale* was blown up the nostril by means of an elastic tube. The irritation and obstruction were greater than before. A single attack of sneezing took place, but after two or three hours all had passed off. On June 22 the experiment was repeated in the same way. The result was less marked. The application of a small quantity of secale pollen to the conjunctiva on the 20th had the same effect as on the 15th. Rubbing in the pollen of grasses to scarified spots on the extremities . . . . had for result only very transitory irritation.

In concluding the account of his experiments, Dr. Patton says:—"As we see, I gave myself every chance of taking hay-fever, but the accredited cause—pollen—left me *in statu quo* either because it is not the cause of hay-fever or because it did not find present in me the still unknown predisposing causes under the influence of which it becomes a genuine irritant."

After reading the above account over, one is puzzled to decide whether to admire most the simplicity that permits these experiments to be put forward as a proof that hay-fever is not caused by pollen, or the logic that leads to the conclusion that, although it produces genuine irritation, it is not a "genuine irritant," because the effect soon passes off after the pollen ceases to be applied. On the same principle, if a purgative is administered and produces its specific effects it cannot be a genuine purgative if the disturbance passes off after the drug ceases to be given.

The truth is, Dr. Patton does not seem to me to understand the true nature of hay-fever. The symptoms he produced were, with one exception, exactly those of the early stages of the disease, and the only thing necessary to complete the picture was the continued application of pollen for a more lengthened period. The transitory character of the symptoms is just that that distinguished the malady, especially in its catarrhal form. Pollen has no zymotic properties, and no single circumstance in the history of hay-fever is brought out more prominently in my work than the fact that if a sufferer can get away from the contact with pollen he will begin rapidly to recover. The shorter the period of exposure has been the more rapid the recovery, and *vice versâ*.

But although I differ from Dr. Patton in the conclusions he draws from his experiments, I must express my sense of obligation to him for the testimony he brings in support of my views, and I can only hope that other observers who are susceptible to the action of pollen will test the validity of my opinions on the causes of hay-fever in the same manner. *Experientia docet.* I am, &c., CHAS. H. BLACKLEY.

Stretford-road, Manchester, August 21.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, August 23:—

Bothamley, Richard Broughton, Dorrington, Spalding.
Gimblette, George Hart Desmond, Southsea.
Le Fevre, George, Melbourne, Australia.
Plumbe, Samuel Thomson, Maidenhead.
Seth, Owen, 7, Powis-square, W.
Woods, John Francis, 61, Bunhill-row, E.C.

The following gentlemen also on the same day passed their Primary Professional Examination:—

Havens, Edward John, London Hospital.
Higgs, Alfred, London Hospital.
Lucas, Charles, Middlesex Hospital.
Mellor, Thomas, Manchester Hospital.
Roper, George Arthur, St. Thomas's Hospital.

BIRTHS.

CARTER.—On August 26, at Lynton House, Anerley, Surrey, the wife of J. Roe Carter, L.K.Q.C P. Ire., late Colonial Surgeon (St. Lucia, W.I.), of a daughter.

COOKE.—On August 16, at 16, Woburn-place, the wife of Thomas Cooke, F.R.C.S., of a daughter.

FLETCHER.—On August 23, at 149, Camden-road, N.W., the wife of J. Corbet Fletcher, M.D., of a son.

GOOD.—On August 21, at Ivy Cottage, Lower Sydenham, the wife of Surgeon-Major J. Good, L.R.C.S. Edin., of a daughter.

GULLAND.—On August 24, at St. Mark's House, St. Helier's, Jersey, the wife of Surgeon-Major Gulland, M.D., of a son.

TURLE.—On August 26, at Woodside Grange, North Finchley, the wife of James Turle, M.D., of a son.

WORTHINGTON.—On August 25, at Garston, near Liverpool, the wife of J. V. Worthington, L.R.C.P. Edin., of a son.

MARRIAGES.

ARMSTRONG—SMYTHE.—On August 23, at Booterstown Church, George Reid Armstrong, eldest son of Geo. C. Armstrong, M.D., of Blackrock, county Dublin, to Kathleen Mary, daughter of G. Sackville Smythe, Esq., of same place.

AXFORD—STEPHENS.—On August 23, at the Moravian Church, Bristol, William Herbert Axford, eldest son of the late William Axford, of Maddox-street, London, to Emily, second daughter of Henry Oxley Stephens, M.D., of Bristol.

BUCK—WALKER.—On August 27, at the parish church, Birstall, W. Elgar Buck, M.A., M.D., of Leicester, to Marian, elder daughter of W. H. Walker, of Birstall Holt, Leicester.

DOUGLAS—WRANKMORE.—On August 23, at St. John's Church, Croydon, Ernest Thornton Douglas, son of William Douglas, M.R.C.S. Eng., of Banbury, to Evelyn Hestern, only daughter of the late Richard Wrankmore, Esq., R.N.R.

GORDON—LEE.—On August 23, at St. Leonard's Church, Bilston, John Gordon, M.D., of New Cross, London, to Edith Emily, eldest daughter of the Rev. Charles Lee, M.A., Vicar of Bilston.

GWYNNE—DYER.—On August 28, at the parish church, Wimbledon, Aubrey Percival, second son of D. W. G. Gwynne, M.D., to Catherine, third daughter of the late S. Dyer, Esq., of Cromhall, Gloucestershire.

HART—MCENTEE.—On August 16, at St. Mary's, Moseley, Philip Neville Hart, M.B., M.R.C.S., of Erith, Kent, son of the Rev. Richard Hart, late Vicar of Old Catton, Norfolk, to Eliza Jane, eldest daughter of W. C. McEntee, Esq., of Altadore, Moseley, Worcestershire.

IRVING—GILLARD.—On August 29, at St. Mark's, Kennington, John Henry Irving, of Belvidere, Kent, younger son of the late Edward George Irving, M.D., R.N., to Sarah Evelyn, eldest daughter of Richard Gillard, M.R.C.S., of 60, Clapham-road, S.W.

KEEGAN—STERN.—On August 16, at the Church of St. Othmar, Vienna, Denis Francis Keegan, M.D., of the Bengal Medical Establishment, to Francisca M. Stern, fourth daughter of the late Herr Herman Stern, of Vienna.

MOORE—POPE.—On August 23, at West Malling, William, fourth surviving son of the Rev. Edward Moore, Rector of Broughton Malherbe, Kent, to Alice Montagu, eldest daughter of Peter Montagu Pope, M.D., of West Malling.

NORTH—BUTTS.—On August 28, at the parish church, Broadwater, Sussex, Walter Meyrick North, B.A., of Brasenose College, Oxford, barrister-at-law, to Earle Ada, elder daughter of Harry Grosvenor Butts, M.D., of Demerara, West Indies.

PEARLESS—RAIKES.—On June 18, at Christ Church, South Yarra, Australia, Walter Relf Pearless, M.R.C.S. Eng., of East Grinstead, Sussex, to Marianne Sessel, eldest daughter of H. Campbell Raikes, late Bengal Civil Service, of Weston-super-Mare, Somersetshire.

DEATHS.

BURKITT, WILLIAM ROBERT, L.R.C.S.I., Surgeon-Major late 52nd Light Infantry, at Marine Villa, Wicklow, on August 23, aged 42.

CURGENVEN, HILDA, daughter of Wm. Grafton Curgenven, M.D., of 41, Friar-gate, Derby, at Derby Villa, Bexley, Kent, on August 26, aged 3 months.

DAVIES, LOUISA JANE, the wife of W. Bowen Davies, L.R.C.P.L., of Brynarlais, Llandrindod Wells, at Eden-grove, Holloway, on August 23, aged 32.

DURRAN, DAVID, M.D., at Fulham, on August 16, in his 67th year.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made and the day of election (as far as known) are stated in succession.

ALCESTER UNION.—Medical Officer and Public Vaccinator of the Inkberrow District. Applications, stating age and qualifications, accompanied by testimonials as to character and ability, to J. Langston Jones, Clerk, on or before September 3.

BEAFORD GENERAL INFIRMARY.—Resident Surgeon. Applications, with testimonials, to the Chairman of the Weekly Committee, on or before September 27.

BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN.—Resident Medical Officer. Candidates must be unmarried, and registered members of the medical profession. Applications, with certificate of registration, accompanied by references, to be sent to the Medical Committee, Children's Hospital, Shelthouse-lane, Birmingham, not later than September 7.

CHORLTON UNION.—Assistant to the Workhouse Medical Officer. Applicants must be fully qualified and registered. Applications, accompanied by copies of recent testimonials and statement of qualifications, to Wm. N. Edgill, Clerk to the Guardians, Union Offices, Grosvenor-square, Manchester, not later than September 4, endorsed "Assistant to Medical Officer."

HOLBEACH UNION, LINCOLNSHIRE.—Medical Officers for the Lutton and Tydd Districts, and Public Vaccinator for the Lutton District. Applications, stating qualification, accompanied by testimonials and certificate of registration under the Medical Acts, to Richard P. Mossep, Clerk, on or before September 5.

NANTWICH UNION.—Medical Officer. Applications, with testimonials of qualification, to C. E. Speakman, Clerk, on or before September 12.

NORTH-EASTERN HOSPITAL FOR CHILDREN, HACKNEY-ROAD, E.—Physician. Candidates must be either F. or M.R.C.P. Lond. Applications, with qualifications and testimonials, to Alfred Nixon, Secretary, 27, Clement's-lane, E.C., on or before September 11.

ROYAL FREE HOSPITAL, GRAY'S INN-ROAD.—Assistant-Physician and Assistant-Surgeon. The Assistant-Physician must be a Member of the College of Physicians of London, and the Assistant-Surgeon a Fellow of the Royal College of Surgeons of England. Testimonials to James S. Blyth, Secretary, before September 1.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1871.

RESIGNATIONS.

Carmarthen Union.—The Carmarthen District is vacant; area 17,885; population 12,904; salary £80 per annum.

Walsingham Union.—Mr. F. E. Taylor has resigned the Wells District; area 13,318; population 4950; salary £68 10s. per annum.

Weymouth Union.—Mr. H. H. J. Sterling has resigned the Owermoigne District; area 3271; population 441; salary £16 per annum.

Wigton Union.—Mr. W. A. Tennent has resigned the Allonby District; area 12,800; population 2334; salary £13 per annum.

APPOINTMENTS.

Brentford Union.—Albert B. Day, M.R.C.S. Eng., L.S.A., to the Workhouse.

Hailsham Union.—Alfred H. Hackney, M.R.C.S. Eng., L.S.A., to the Third A District.

Kington Union.—Wm. Hanson, L.R.C.S. Edin., L.R.C.P. Edin., to the Kinsham District.

Leicester Union.—Claude Douglas, M.R.C.S. Eng., L.R.C.P. Lond., to the First District.

Leominster Union.—John Elliot, M.R.C.S. Eng., L.S.A., to the Bodenham District.

Lexden and Winstree Union.—Francis Trimmer, M.R.C.S., L.S.A., to the Ninth District.

Royston Union.—James G. Anderson, L.R.C.S. Edin., M.R.C.S. Eng., to the Fifth District.

Sleaford Union.—John C. Eaton, M.R.C.S. Eng., L.S.A., to the Wilsford District.

BERLIN UNIVERSITY.—Prof. Helmholtz has been elected Rector Magnificus for the ensuing year, and Prof. Du Bois Reymond Dean of the Medical Faculty.

DR. CONNEAU.—In the notice of the late Dr. Conneau inserted in our last number, it should have been stated that the 1,200,000 fr. donation from the Emperor's Civil List, entrusted to him for distribution, was an annual sum.

ABSENCE OF SMALL-POX IN BERLIN.—As for the last two years, no case of small-pox has been brought into the small-pox station attached to the Royal Charité Hospital, it has for the present been closed, provision having been made for immediately reopening it should the necessity arise.—*Deutsche Med. Woch.*, August 11.

AT an inquest held at Wednesbury on Saturday last, on the body of a child named Emma Harris, it appeared that the deceased, when taken ill, was conveyed to a herbalist, who prescribed for her. After taking the medicine she became worse, and soon afterwards died. The Coroner intimated that the herbalist would probably be prosecuted, and that the parents were liable to be indicted for manslaughter. The verdict returned was "Death from natural causes," and the mother was censured for not obtaining proper medical advice. The terrors of the law should be brought down upon this prescribing herbalist.

HEALTH OF THE PUNJAUB.—There was only one death registered under the head of cholera; it occurred in the town of Majitha, district Amritsar. From small-pox 377 deaths were registered, against 333 in the previous week. The disease continues to prevail with great severity in the districts of Gurgaon, Bannu, and Dera Ismail Khan; seventy-nine, sixty-five, and forty-one deaths respectively were registered in them. The districts of Karnál, Montgomery, and Mooltan also are suffering severely from it. The deaths registered under the head of fevers were 4651, against 4583 in the previous week.

MENTAL THERAPEUTICS.—In a paper read at the Neurological Association, Dr. Beard made the following psychological suggestions:—1. The ill-success of patients treating themselves, and of physicians treating their own families, is partly due to the want of awe and the emotion of wonder to co-operate with them. 2. The old custom of keeping patients ignorant of the contents of prescriptions, by writing them in Latin, had psychology on its side. Possibly, we may be going too far the other way. 3. It is entirely possible that hydrophobia and tetanus may be brought on, with all their distinctive symptoms, and that death may result, through the emotions of fear and expectation alone. 4. Patients whose will and intellect are feeble have a bad prognosis, for with them the subjective symptoms are trifling; and, *vice versâ*. 5. Physicians of great scientific attainment and real worth may fail when an ignorant and obscure charlatan succeeds, because with the latter wonder and awe are excited, and these are more powerful therapeutically than simple respect. 6. In experimenting in hospitals with new medicines, patients must be deceived, or else the results are complicated by mental influence.—*New York Medical Record*, July 21.

TREATMENT OF PARALYSIS OF THE FACIAL NERVE.—Dr. Mascarel strongly recommends the following procedure in cases of rheumatic facial paralysis *à frigore*, independent of intra-cranial complications. A platinum-needle is introduced to the depth of one or one and a half centimetres in the direction of the stylo-mastoidean foramen towards the exit of the facial nerve from the cranium, and a similar needle is carried horizontally into the superior fibres of the orbicularis of the eyelids of the paralysed side. Each needle being brought into contact with the poles of even a feeble pile, intermittent currents are kept up for a period varying from twelve to twenty minutes. Violent and almost convulsive contractions are determined in the orbicularis, and sometimes even after the first sitting the eyelids are brought into contact. Next day the same operation is repeated, the needle being now passed into the lower fibres of the orbit. On the third, fourth, fifth, and sixth days the needle is successivcly plunged into the muscles of the face which prove most refractory—the other needle on all the occasions being directed towards the stylo-mastoidean foramen. After the seventh or eighth day Dr. Mascarel has always found the paralysis disappear in a dozen cases that have come under his care.—*Bulletin de Thérap.*, July 30.

MEDICATION BY MEANS OF THE UNDERCLOTHING.—Under the title "Dermic Medication," Dr. Hachenberg, of Round Mount, Texas, gives an account of a method of treatment concerning the utility of which he had published as far back as 1852. The medicine is used in the form of a solution into which the woollen underclothes of the patient are dipped, being well dried and aired before they are worn. The perspiration dissolves the medicine, which is thus kept continually applied to the skin, producing in many instances the same effect as when employed in the ordinary modes. This method is of particular service in the weak, especially in diseases of the skin. The whole range of soluble medical salts can indeed be used in this manner. "For example, I have treated obstinate constipation with a saturated solution of sulphate of magnesia by the woollen shirt; a chronic intermittent fever with a weak acidulated solution of quinine; neuralgia and hysteria with several of the sedative and antispasmodic salts; skin diseases by alum, borax, chloride and sulphate of potash, etc.; and constitutional depression and paralysis by strychnine. I have used solutions of nauseants by the shirt in affections of the lungs, and the mucous tissue in particular, with the desired effect. Many of the excessive hæmorrhagic and morbid exosmotic operations of the body can, in a great measure, be controlled by the alum shirt, as colliquative sweats and diarrhœas, and even effusions into the cellular tissue not caused by some serious organic disease."—*New York Medical Record*, July 7.

SATURDAY HOSPITAL FUND.—Considerable discussion took place at the meeting of delegates, on Saturday last, of the Saturday Hospital Fund, on the subject of what allowance should be made to provident dispensaries. It was decided that the dispensaries shall receive allowances *pro ratâ* for those who are attended at them free only, striking out the number of patients who partially pay for advice and medicine.

THE POLITICAL MOVEMENT IN FRANCE AND THE PROFESSION.—The French Government is carrying its high-handed procedures with respect to the approaching elections into all quarters. The *Gazette Médicale de Bordeaux* appeals to the profession respecting the deprivation of their posts which two respectable *confrères* have undergone. M. Vernhes was medical officer to one of the railways, and M. Drouin surgeon to a prison. The one had committed the heinous crime of voting for the Liberal deputy on a former occasion, and therefore cannot be trusted in the present emergency; and the other had ventured to offer himself as a candidate for the municipal council in opposition to the nominee of the préfet. The *Gazette* has called upon (hitherto in vain) the French Medical Association to protest against this arbitrary procedure, and expresses its somewhat sanguine belief that no members of the profession will be found willing to offer themselves to fill the vacant posts.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Corrigendum.—Dr. Dupuy writes to us that an error occurs in his article in course of publication. It is to be found on page 86, line 57. Instead of *right* angular gyrus centre, read *left*.

Swinford.—The Association Scientifique de France met this year at Havre. The meeting commenced on the 23rd inst. M. Broca, Professor to the Faculté de Médecine, and director of the School of Anthropology in Paris, is the President, and M. Kuhlmann, the chemical manufacturer of Lille, the Vice-President.

Merritt.—The number of Indians of all descriptions at present inhabiting the United States is estimated at 300,000. Two centuries ago they numbered upwards of 2,000,000. Every tribe, with the exception of the Sioux or Dacotahs, is rapidly decreasing, owing to contagious diseases, intemperance, and wars, both among themselves and with the whites. They are placed under the management of the Indian Bureau—a branch of the interior department of the United States Government, and are governed by agents and superintendents specially appointed for that purpose, the districts in which they live being divided into fourteen superintendencies.

Victor.—The Arabian school of medicine, while the Saracens were masters of Spain, was well acquainted with several metallic remedies. The researches, however, of the chemists, or rather alchymists, first brought to light the value of metals in the hands of the physician. They made thus an important addition to the number of medicines, and effected a change in the healing art, which is felt to the present time.

A Metropolitan Teacher.—The annual registration of students pursuing their professional studies in this metropolis and in the provinces has *not* been suspended, but will take place as usual in October. Write to Mr. Stone.

The Manchester Meeting.—We are informed that a larger number than usual of the members of the Council of the College of Surgeons attended that meeting, read papers, and took part in the discussion; and, for the first time, amongst the latter was the President, Mr. J. Birkett, who readily responded to the request so courteously made to him by Mr. E. Lund, the President of the Surgical Section, to give them the benefit of his great experience.

Mr. Mitchell.—The name of David Griffith Jones was removed from the Register immediately after his conviction, and is not likely to be restored.

B., Westminster.—Dr. Prichard, perhaps, of all others merits the title of founder of modern anthropology. See his "Natural History of Man."

Buckley.—The general census of 1846 shows that Antwerp contained 88,487 inhabitants. In 1851 the population was 95,501, and in 1873 126,663, or, including the suburbs now situated within the fortifications, above 180,000.

Zoologist.—The invention, or rather growth, of the modern aquarium cannot, in the absence of precise data, be accurately traced. The aquarium, as we find it at Brighton, has, like many other things now in daily use, been elaborated from small beginnings. It is known that, more than two centuries ago, marine animals were, for the purposes of study and observation, removed from the sea and kept in confinement; and there is extant a drawing of the date of 1742, which represents the form of an aquarium containing zoophytes.

Denis.—Dominique Anel was celebrated for his successful treatment of aneurism and fistula lachrymalis, and was the inventor of the probe and syringe still known by his name. He wrote several medical works, published at Amsterdam in 1707, Turin 1713, and Paris 1822. He died about 1730.

Artoza.—According to history, Asclepiades died, at an advanced age, from the effects of a fall.

C. C. N.—Dr. William Balfour Baikie was the surgeon and naturalist to the Niger Expedition of 1854. The death of the senior officer occurring at Fernando Po, Dr. Baikie succeeded to the command. He died on his way home, at Sierra Leone, in November, 1863, aged thirty-nine years. An appropriate monument has been erected to his memory within the nave of the ancient cathedral of St. Magnus.

Quintus.—During the past summer session of the University of Leipzig the number of medical students was 366.

Ultima.—It was Sir Thomas Watson's remark. He said—"You will hear persons disputing about the term contagion; but such disputes can only arise from the want of a distinct definition of the sense in which it is employed. I understand a disorder to be contagious when it is in any way communicable from person to person."

Partan.—Anaxilaus, of Larissa, a physician and Pythagorean philosopher, was banished from Rome by Augustus, B.C. 28, on the charge of practising the magic art. This accusation appears to have originated in his superior skill in natural philosophy, by which he produced effects that the ignorant attributed to magic.

Vidus.—We believe the first mention of the capacity of those born deaf to receive instruction is in the writings of Rodolphus Agricola (born A.D. 1442), of Gröningen. He does not state who was the parent of the art, but he mentions in his posthumous work, "De Inventione Dialecticæ," that he had himself witnessed a person deaf from infancy, and consequently dumb, who had learned to understand writing, and, as if possessed of speech, was able to note down his whole thoughts. The truth of this relation was doubted by Louis Vives, of Valentia, who wrote in the beginning of the sixteenth century; but it appears there is as good reason to put trust in Agricola's account, as to join in Vives' disbelief.

Meteorologist.—It was in 1788, Mr. Wilson, of Glasgow, published a paper on hoar-frost in the *Transactions of the Royal Society of Edinburgh.*

H. L., Manchester.—The Government Inspector of the Provincial Medical Schools is Mr. John Birkett, the President of the Royal College of Surgeons. He succeeded Dr. Ogle.

Decimus.—Mr. John Bell was the first surgeon who successfully applied, in Scotland, the science of anatomy to practical surgery. In 1790, whilst yet a very young man, he built a theatre in Surgeon's-square, Edinburgh, where he delivered lectures on surgery and anatomy, carried on dissections, and laid the foundation of a museum. As there was then scarcely any private teaching, or means of cultivating anatomy by private dissections, the establishment of a school naturally excited great hostility against Mr. Bell; every attempt at private teaching being considered, in those days, an encroachment on the privileges of the professors and the rights of the University.

Dr. Williams.—The following is the account of the extraordinary person to whom you allude. He practised at the Cape of Good Hope for some time:—Dr. James Barry was Staff-Surgeon to the Garrison and the Governor's medical adviser. Lord Charles Somerset described him as the most skilful of physicians and the most wayward of men. He had been in professional attendance on the Governor, who was somewhat fanciful about his health; but the Æsculapius, taking umbrage at something said or done, had left his patient to prescribe for himself. The Earl of Albemarle says he had heard so much of this capricious yet privileged gentleman, that he had a great curiosity to see him, and soon after sat next him at dinner at one of the regimental messes. In the learned pundit he beheld a beardless lad, with an unmistakably Scotch type of countenance—reddish hair and high cheek-bones. There was a certain effeminacy in his manner which he seemed to be always striving to overcome. His style of conversation was greatly superior to that usually heard at a mess-table in those days of non-competitive examination. A mystery attached to Barry's whole professional career, which extended over more than half a century. While at the Cape he fought a duel, and was considered to be of a most quarrelsome disposition. He was frequently guilty of flagrant breaches of discipline, and on more than one occasion was sent home under arrest, but somehow or other his offences were always condoned at head-quarters. In Hart's Annual Army List for 1865 the name of James Barry, M.D., stands at the head of the list of Inspectors-General of Hospitals. In July of the same year the *Times* one day announced the death of Dr. Barry; and the next day it was officially reported to the Horse Guards that the doctor was a woman! It is singular that neither the landlady of her lodging, nor the black servant who had lived with her for years, had the slightest suspicion of her sex. The late Mrs. Ward, daughter of Colonel Tidy, stated that she believed the doctor to have been the legitimate granddaughter of a Scotch earl, and that the *soi-disant* "James Barry" adopted the medical profession from attachment to an army surgeon who had not been many years dead.

Mr. Kingsbridge.—In some parts of Devonshire the woodnuts are called "nits," hence the old saying—"The more nits, the more pits"; implying that with an unusual quantity of nuts the mortality that season will be large. During the recent most enjoyable excursion of some members of the British Medical Association to the English Lakes arranged by Messrs. Cook, a large quantity of nuts was pointed out by the tourists, and the above explanation given by a well-known member of our profession.

Histologist.—The late Professor Quekett was the third conservator of the Hunterian Museum. He died at Pangbourne, Berkshire, on August 20, 1861, in the 46th year of his age, leaving a widow (since deceased) and four sons. Messrs. Clift, Owen, and Quekett were Fellows of the Royal Society, as is the present conservator—Professor Flowers.

"The cry is, Still they come."—The names of 400 candidates for the preliminary examination in Arts, etc., for the diplomas of Fellow and Member of the Royal College of Surgeons have been entered at that institution for the examination which will take place at Burlington House in the ensuing month.

A Member and Dr. R.—No place has yet been decided on for the next annual meeting of the Association. A wish was generally expressed at Manchester that it should be in Ireland. Cork and Belfast were mentioned.

Spes.—The old Hôtel Dieu, Paris, on the other side of the square Notre Dame, will be demolished, and the site devoted to a public garden. The first hospital erected there is assigned to the year 656. The founder was Landry, Bishop of Paris. The chapel of the new hospital, and dome of the basement fittings, will not be completed for another twelve months.

COMMUNICATIONS have been received from—

Mr. Charles A. Fox, Stoke Newington; Mr. Haynes Walton, London; Mr. John Chatto, London; Dr. Sparks, Exmouth, Devon; Dr. J. W. Moore, Dublin; Dr. Russell, Birmingham; Dr. Robert Lawson, Sutton; Secretary of the Hospital Saturday Fund, London; Mr. Becher, Ramsgate; Dr. Dupuy, New York; Dr. J. M. Dolan, Halifax; Mr. T. M. Stone, London.

BOOKS AND PAMPHLETS RECEIVED—

John B. Roberts, M.D., Excision of the Lower End of the Rectum in Cases of Cancer—Dr. Emil Fleischer, A System of Volumetric Analysis—W. K. Parker, F.R.S., and G.T. Bettany, M.A., B.Sc., The Morphology of the Skull.

PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Berliner Klinische Wochenschrift—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Gazette Hebdomadaire—Le Progrès Médical—Bulletin de l'Académie de Médecine—Pharmaceutical Journal—Wiener Medizinische Wochenschrift—Medical Examiner—The Louisville Medical News—Boston Medical and Surgical Journal—Nature—Philadelphia Medical Times—Iron—Home Chronicler—La Province Médicale—Cincinnati Clinic—Gazeta Medica da Bahia—Tatler—Whitehall Review—New York Medical Journal—American Practitioner—Hardwicke's Science Gossip—Archives of Dermatology.

APPOINTMENTS FOR THE WEEK.

September 1. *Saturday (this day).*

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 1½ p.m.

3. *Monday.*

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

4. *Tuesday.*

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

5. *Wednesday.*

Operations at University College, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 1½ p.m.

6. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing-cross, 2 p.m.; St. Thomas's (ophthalmic operations), 4 p.m.

7. *Friday.*

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m.; Guy's, 1½ p.m.

VITAL STATISTICS OF LONDON.

Week ending Saturday, August 25, 1877.

BIRTHS.

Births of Boys, 1190; Girls, 1133; Total, 2323.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	29·650 in.
Mean temperature	62·0°
Highest point of thermometer	83·3°
Lowest point of thermometer	40·5°
Mean dew-point temperature	52·0°
General direction of wind	S.W.
Whole amount of rain in the week	1·67 in.

BIRTHS and DEATHS Registered and METEOROLOGY during the Week ending Saturday, August 25, 1877, in the following large Towns:—

Boroughs, etc. (Municipal boundaries for all except London.)	Estimated Population to middle of the year 1877.*	Persons to an Acre. (1877.)	Births Registered during the week ending Aug. 25.	Deaths Registered during the week ending Aug. 25.	Temperature of Air (Fahr.) Highest during the Week.	Temperature of Air (Fahr.) Lowest during the Week.	Temperature of Air (Fahr.) At the Royal Observatory, Greenwich, the mean reading of the barometer last week was 29·65 in. The highest reading was 30·03 in. on Friday morning, and the lowest 29·35 in. at the end of the week.

* The figures for the English and Scottish towns are the number enumerated in April, 1871, raised to the middle of 1877 by the addition of six years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the number enumerated in April, 1871.

THE STUDENTS' NUMBER

OF THE

MEDICAL TIMES AND GAZETTE

FOR

1877-78.

IN the present number of the *Medical Times and Gazette*, which is specially intended for the guidance of junior Students of Medicine and those about to become students, we have, to a great extent, overlooked the claims of the senior students for instruction and guidance. The reason is simple. As soon as a student enters a school he becomes, or ought to become, part and parcel of it. His teachers will be always glad to help him with advice as to what is best to be done; and as this advice must be founded on a special knowledge, such advice is sure to be better than what we can give, addressed to all. We therefore begin with the period of preparatory education, passing thence to the selection of a school for the first year's studies, thence on to the second year and its appropriate studies, culminating in the first professional examination. With the third year's studies comes the second and in some instances final examination; in the case of certain examining bodies, this comes at the end of the fourth year. In our remarks we shall have in mind for the most part the English Examinations, but those of Scotland and Ireland shall have due attention.

I.—PRELIMINARY EDUCATION.

By the Regulations of the General Medical Council, no person can be registered as a medical student unless he shall have previously passed a preliminary examination in the subjects of general education as hereinafter provided. For the present, testimonials of proficiency granted by educational bodies, according to the subjoined list, are accepted; the Council reserving the right to add to or take from the list. (A degree in Arts of any university of the United Kingdom, or of the colonies, or of such other universities as may be specially recognised from time to time by the Medical Council, is considered a sufficient testimonial of proficiency.)

LIST OF EXAMINING BODIES WHOSE EXAMINATIONS FULFIL THE CONDITIONS OF THE MEDICAL COUNCIL AS REGARDS PRELIMINARY EDUCATION.

I.—*Universities of the United Kingdom.*

Oxford.—Examination for a degree in Arts; Responsions; Moderations; Local Examinations (Senior), certificate to include Latin and Mathematics; Local Examinations (Junior), certificate to include Latin and Mathematics, and also one of the following optional subjects:—Greek, French, German, Natural Philosophy, including mechanics, hydrostatics, and pneumatics.

Cambridge.—Examination for a degree in Arts; Previous Examination; Local Examinations (Senior), certificate to include Latin and Mathematics; Local Examinations (Junior), certificate to include Latin and Mathematics, and also one of the following optional subjects:—Greek, French, German, Natural Philosophy, including the elements of statics and hydrostatics.

Durham.—Examination for a Degree in Arts; Examination for students in their second and first years; Registration Examination for medical students; Local Examinations (Senior), certificate to include Latin and Mathematics; Local Examinations (junior), certificate to include Latin and Mathematics, and also one of the following optional subjects:—Greek, French, German, Natural Philosophy, including mechanics, hydrostatics, and pneumatics.

Oxford and Cambridge Schools' Examination Board.(a)—Certificate to include—Arithmetic (including vulgar and decimal fractions), Algebra (including simple equations), Geometry (first two books of Euclid), Latin (including translation and grammar), and one of the following optional subjects:—Greek, French, German, mechanical division of Natural Philosophy.

London.—Examination for a Degree in Arts or Science; Matriculation Examination.

Aberdeen, Edinburgh, Glasgow, St. Andrews.—Examination for a degree in Arts; Preliminary Examination for Graduation in Medicine or Surgery.

Edinburgh.—Examination of (Senior) Candidates for Honorary Certificates under the Local Examinations of the University of Edinburgh.

Glasgow.—Senior Certificate of Local Examination Board of the University of Glasgow; certificate to include English Literature, Arithmetic, Algebra, Geometry, Latin, and also one of the following optional subjects:—Greek, French, German, Natural Philosophy.

St. Andrews.—Honours Certificates granted under Local Examinations; certificate to include English Literature, Arithmetic, Algebra, Geometry, Latin, and also one of the following optional subjects:—Greek, French, German, Natural Philosophy.

Dublin.—Examination for a degree in Arts; Public Entrance Examination.

Queen's University (Ireland).—Examination for a degree in Arts; Entrance Examination; Examination for the Diploma of Licentiate in Arts; Previous Examination for B.A. degree.

II.—*Other Bodies named in Schedule (A) to the Medical Act.*

Royal College of Surgeons of England.—Examination conducted under the superintendence of the College of Surgeons, by the Board of Examiners of the Royal College of Preceptors.

The Society of Apothecaries in London.—Examination in Arts.

Royal College of Physicians, Edinburgh, Royal College of Surgeons, Edinburgh.—Preliminary Examination in General Education, conducted by a Board appointed by these two Colleges combined.

Faculty of Physicians and Surgeons of Glasgow.—Preliminary Examination in General Education.

Royal College of Surgeons in Ireland.—Preliminary Examination; certificate to include Mathematics.

Apothecaries' Hall of Ireland.—Preliminary Examination in General Education.

III.—*Examining Bodies in the United Kingdom not included in Schedule (A) to the Medical Act.*

Royal College of Preceptors.—Examination for a First Class Certificate.

The Examiners for Commissions and Appointments in her Majesty's Service, Military, Naval, and Civil.—Certificate to include all the subjects required by the General Medical Council.

IV.—*Indian, Colonial, and Foreign Universities and Colleges.*

Universities of Calcutta, Madras, and Bombay.—Entrance Examination; certificate to include Latin.

M'Gill College, Moutreal.—Matriculation Examination.

University of Toronto; Trinity College, Toronto; Queen's College, Kingston; Victoria College, Upper Canada.—Matriculation Examination.

King's College, Nova Scotia.—Matriculation Examination; Responsions.

Medical College, Halifax, Nova Scotia.—Matriculation Examination.

University of Fredericton, New Brunswick.—Matriculation Examination.

University of Melbourne.—Matriculation Examination; certificate to include all the subjects required by the General Medical Council.

University of Sydney.—Matriculation Examination.

University of the Cape of Good Hope.—Matriculation Examination.

University of Adelaide.—Matriculation Examination.

Codrington College, Barbadoes.—1. English Certificate for Students of two years' standing, specifying the subjects of Examination. 2. Latin Certificate, or "Testamur."

Tasmanian Council of Education.—Examination for the Degree of Associate of Arts; certificate to include Latin and Mathematics.

Christ's College, Canterbury, New Zealand.—Voluntary Examinations; certificate to include all the subjects required by the General Medical Council.

South Australia, South Australian Institute, Adelaide.—Preliminary General Examination—First Class Certificate.

It is recommended that the Licensing Boards do not accept the certificate of proficiency in General (Preliminary) Education from any of the bodies, the names of which are contained in the list annually circulated, unless such certificate

(a) The *English* is provided for by the following resolution of the Executive Committee, passed October 27, 1876:—"That, as every candidate for the certificate of the Oxford and Cambridge Schools' Examination Board is required to answer questions in such a manner as to satisfy the examiners that he has an adequate knowledge of English Grammar and Orthography, this shall be held as conforming to the requirements of the Medical Council in reference to English Language."

testify that the student to whom it has been granted has been examined in the following subjects:—

1. English language—including Grammar and Composition.(b)
2. Arithmetic, including vulgar and decimal fractions; Algebra, including simple equations.
3. Geometry—First two books of Euclid, or the subjects thereof.
4. Latin, including translation and grammar.
5. And in one of the following optional subjects:—Greek, French, German, Elementary Mechanics of Solids and Fluids, meaning thereby Mechanics, Hydrostatics, Pneumatics, and Hydraulics.

The authorities of the University of Oxford simply say that each candidate for their degree must have graduated in Arts—that is, attained at least to the rank of B.A. The University of London insists on all men who want to enrol themselves as candidates for their degrees, save those who have passed at certain colonial establishments, passing the somewhat stiff matriculation examination of the University. Though almost all the other examining bodies have preliminary examinations of their own, nevertheless the certificate of having passed one of them is in almost every case accepted as evidence of a due knowledge of the subjects of preliminary education, so that practically a student may pass when and where he chooses. Nevertheless, the great majority of students select the body whose final qualification they seek; hence it comes that in England the great bulk of students select the preliminary examination of the Royal College of Surgeons or of the Apothecaries' Society. The former is conducted by the College of Preceptors, the latter by selected examiners. As the Preliminary Examination of the Royal College of Surgeons of England is that most largely frequented, and is a very fair sample of the several requirements from gentlemen desiring to enter the profession, we give their programme, which is as follows:—

For the year 1878, and until further notice, the following are the subjects of examination:

PART I.—COMPULSORY SUBJECTS.

1. Writing from dictation.
2. English Grammar.
3. Writing a short English Composition, such as a description of a place, an account of some useful or natural product, or the like.
4. Arithmetic. No candidate will be passed who does not show a competent knowledge of the first four rules, simple and compound, of vulgar fractions and of decimals.
5. Questions on the Geography of Europe, and particularly of the British Isles.
6. Questions on the outlines of English History; that is, the succession of the sovereigns, and the leading events of each reign.
7. Mathematics. Euclid, Books I. and II., or the subjects thereof. Algebra, to simple equations inclusive
8. Translation of a passage from the second book of "Cæsar's Commentaries—De Bello Gallico."

PART II.—OPTIONAL SUBJECTS.

Papers will also be set on the following six subjects; and each candidate will be required to offer himself for examination on one subject at least, at his option; but no candidate will be allowed to offer himself for examination on more than four subjects:—

1. Translation of a passage from the first book of the Anabasis of Xenophon.
2. Translation of a passage from X. B. Saintine's "Picciola."
3. Translation of a passage from Schiller's "Wilhelm Tell."

(Besides these translations into English, the candidate will be required to answer questions on the grammar of each subject, whether compulsory or optional.)

4. Mechanics. The questions will be chiefly of an elementary character.
5. Chemistry. The questions will be on the elementary facts of Chemistry.
6. Botany and Zoology. The questions will be on the classification of plants and animals.

(The quality of the handwriting and the spelling will be taken into account.)

N.B.—Each candidate (who has not at a previous examination paid the amount) is required to pay a fee of £2 on the morning of the first day of the examination prior to his admission thereto. Examinations are held in March and September. Particulars respecting the examination will be duly advertised in the journals. Candidates are required to apply for the prescribed form of application a month before the date of the examination, and to send the same to the College not less than three weeks before its commencement.

(b) The General Medical Council will not consider any examination in English sufficient that does not fully test the ability of the candidate—(1) To write a few sentences in correct English on a given theme, attention being paid to spelling and punctuation as well as to composition; (2) to write a portion of an English author to dictation; (3) to explain the grammatical construction of one or two sentences; (4) to point out the grammatical errors in a sentence ungrammatically composed, and to explain their nature; and (5) to give the derivation and definition of a few English words in common use. Provided always, that an examination may be accepted as satisfactory that secures, on the part of the candidate passing it, a sufficient grammatical knowledge of English.

Note.—A candidate, in order to qualify for the Membership, is required to pass at one and the same examination, in all the subjects of Part I. and in one subject in Part II., and failure in any one of those subjects necessitates re-examination in all. A candidate, in order to qualify for the Fellowship, is required, in addition to the subjects included in Part I., to pass in not less than four, at his option, of the subjects in Part II.

SYLLABUS OF SUBJECTS FOR EXAMINATION, 1878.

1. *The English Language.*—The leading features of its history; its structure and grammar; English composition.

[N.B.—The examiners direct the attention of candidates and of their teachers to the large proportion of failures in the English examination. They recommend the study of one of the following grammars:—Angus's, Adams's, William Smith's, Mason's, and, in additiou, Trench's "English Past and Present."]

2. *The Latin Language.*—January Examination: Cæsar, De Bello Gallico, Book V. April Examination: Cicero, De Amicitiâ. September Examination: Horace, Odes, Book III. Re-translation of easy sentences. Grammatical questions will be introduced into the Latin paper, and each candidate will be expected to give satisfactory answers to these.

3. *Mathematics.*—The ordinary rules of Arithmetic; Vulgar and Decimal Fractions; Addition, Subtraction, Multiplication, and Division of Algebraical Quantities; Simple Equations; the First Two Books of Euclid.

4. (*a.*) *Greek:* Xenophon, Anabasis, Books I. and II.; grammatical questions. (*b.*) *French:* Molière, L'Avare; translation from English into French; grammatical questions. (*c.*) *German:* Fouqué, Undine; translation from English into German; grammatical questions. (*d.*) *Natural Philosophy:* Mechanics; Hydrostatics and Pneumatics.

[N.B.—The books recommended for study in this subject are Smith's "Statics," and Smith's "Hydrostatics," or Newth's "Natural Philosophy."]

Certificates in Arts granted by any of the bodies whose certificate is recognised by the Medical Council will be accepted from candidates who present themselves at the professional examination at the Hall, as equivalent to their having passed the above examination.

The following is an outline of the subjects for the Matriculation Examination of the University of London:—

Candidates are examined in the following subjects:

Mathematics.—Arithmetic: The ordinary rules of arithmetic; Vulgar and Decimal Fractions; Extraction of the Square Root. Algebra: Addition, Subtraction, Multiplication, and Division of Algebraical Quantities; Proportion; Arithmetical and Geometrical Progression; Simple Equations. Geometry: The First Four Books of Euclid, or the subjects thereof.

Natural Philosophy.(c)—Mechanics: Composition and Resolution of Statical Forces; Simple Machines (Mechanical Powers)—Ratio of the Power to the weight in each; Centre of Gravity; General Laws of Motion, with the chief experiments by which they may be illustrated; Law of the Motion of Falling Bodies. Hydrostatics, Hydraulics, and Pneumatics; Pressure of Liquids and Gases, its equal diffusion and variation with the depth; Specific Gravity, and modes of determining it; the Barometer, the Syphon, the Common Pump and Forcing Pump, and the Air Pump. Optics; Laws of Reflection and Refraction; formation of Images by Simple Lenses. Heat: its Sources; Expansion; Thermometers—relations between different Scales in common use; difference between Temperature and Quantity of Heat; Specific and Latent Heat—Calometers; Liquefaction; Ebullition; Evaporation; Conduction; Convection; Radiation.

Chemistry.—Chemistry of the Non-metallic Elements, including their compounds as enumerated below, their chief physical and chemical characters, their preparation, and their characteristic tests. Oxygen, Hydrogen, Carbon, Nitrogen; Chlorine, Bromine, Iodine, Fluorine; Sulphur, Phosphorus, Silicon. Combining Proportions by weight and by volume; General Nature of Acids, Bases, and Salts; Symbols and Nomenclature. The Atmosphere - its constitution; effects of Animal and Vegetable Life upon its composition. Combustion; structure and properties of Flame; nature and composition of ordinary fuel. Water: Chemical peculiarities of Natural Waters, such as rain-water, river-water, spring-water; sea-water. Carbonic Acid; Carbonic Oxide; Oxides and Acids of Nitrogen; Ammonia; Olefiant Gas; Marsh Gas; Sulphurous and Sulphuric Acids, Sulphuretted Hydrogen. Hydrochloric Acid, Phosphoric Acid, and Phosphuretted Hydrogen; Silica.

Classics.—The Greek and Latin Languages.(d) The Latin subjects are—for January, 1878—*Livy:* Book II. For June, 1878—*Ovid:* Epistolæ ex Ponto, Book II. The Greek subjects for 1878 are—for January, 1878—*Homer:* Iliad, Book X. For June, 1878—*Xenophon:* Hellenics, Book II. The papers in Greek and Latin shall contain passages to be translated into English, with questions in grammar, and with questions in History and Geography arising out of the subjects of the books selected. Short and easy passages shall also be set for translation from other books not so selected. A separate paper shall be set containing questions in Latin Grammar, with simple and easy sentences of English to be translated into Latin. Special stress is laid on accuracy in the answers to the questions in Greek and Latin Grammar.

The English Language.—Orthography, Writing from Dictation, the Grammatical structure of the Language.

Outlines of English History and Modern Geography.—History of England to the end of the seventeenth century, with questions in modern geography.

The French or the German Language, at the option of the candidate.

The papers in French and German shall contain passages for translation into English, and questions in grammar, limited (except when German is taken as an alternative for Greek) to the Accidence.

Candidates shall not be approved by the Examiners unless they have shown a competent knowledge in each of the following subjects, according to the details specified under the several heads:—1, Latin; 2, any two of the following languages:—Greek, French, and German; 3, the English Language, English History, and Modern Geography; 4, Mathematics; 5, Natural Philosophy; 6, Chemistry.

(c) The questions in Natural Philosophy will be of a strictly elementary character.

(d) Candidates may substitute German for Greek.

ADVICE TO YOUNG CANDIDATES.

Thus far we have dealt with the mere rules and regulations of the various bodies, but it behovos us also to give the young candidates some advice on the subject. There can be no doubt of the exceeding great value of these examinations. Nothing has done so much good in raising the general status of medical men in the upholding of the dignity of our profession as the institution and general enforcement of these. It becomes everyone who desires to enter our profession, and to fight his way to its highest posts of honour, to do all he ean to maintain this status or to raise it to even a higher pitch.

To those who can by any possibility afford it, we should say, Take a degree in Arts before entering upon the study of Medicine. The training acquired at a University is simply invaluable, and the possession of a degree in Arts gives a man a start which ean be obtained in no other way. It at once gives him the ehances of thoso higher appointments so eagerly sought for, and gives him a stamp through life which is always acknowledged and respected.

Should the taking of a degree be impracticable, we should recommend as the next best qualification the Matriculation Examination of the University of London. This, too, is of great value, and is acknowledged by students among themselves, to say nothing of the outer world, as the mark of superior educational acquirements. It is notorious, too, that the medical graduates of this University, who eonstitute its real glory, number among their ranks the greater part of the most distinguished men of the day. Moreover, the possession of such a professional qualification as is given by the University of London is looked upon as the stamp and seal of superior professional acquirements. For all these and other reasons which could be adduced, we would strongly urge intending students of Medicine to pass their preliminary examination here; for, should they do so, they have the option at any future time of going on to take their degree in the University; but, according to the rules of the University, no part of medical education counts prior to the passing of their Matriculation Examination. For this reason, therefore, a student must pass this examination at the very beginning of his medical career. He eannot turn back in the middle of his studies; his ehance is gone.

By the note above it will be seen how little difference there is, as regards preliminary education, between the requirements demanded by the Royal College of Surgeons of those who look forward to the qualification of Membership, and those who aspire to the Fellowship. As the Fellowship of this body is looked upon as giving the same stamp to a surgeon as the M.D. of London does to a physician, we would earnestly urge all who ean attain to it to take up the additional preliminary subjects required for this qualification. For should they at any future time desire to become Fellows of tho College by examination, they will, in all probability, find that it is hard indeed to begin again the studies requisite for the passing of this preliminary examination.

APPRENTICESHIP.

In former days the mode of access to the profession was by apprenticeship to some regular praetitioner, and this was till recently the rule at Apothecaries' Hall, but practically it has been almost completely departed from. Then the plan was for the young apprentice to enter his master's dispensary or surgery, where he would learn to compound medicines, make a pill, and spread a plaster; by-and-by coming in due course to see and prescribe for patients of various ranks, and suffering from various maladies. With a good master, no course of instruction could be better, and with it men were apt to make better practical practitioners than now, especially as regards the prescribing of medicines and their eompounding. But with a careless master the system only tended to perpetuate routine practice, and to produce careless, ignorant, and self-conceited practitioners. Undoubtedly the plan rendered students, when they eame to the hospital—which they did towards the elose of their apprenticeship—much more at homo and much more able to appreciate what they saw and heard around them. The system is not yet wholly forgotten, and, with the proviso above mentioned, we heartily commend it. In a modified form it may still be usefully intercalated into the modern system of medical education. The number of years prescribed for this education is four, whilst most hospital courses are so arranged as to be got over in three, leaving a year unoccupied by class work. This year may be spent with advantage, either before entering the medical school, or after having finished the course. Of the latter we shall speak hereafter, but the young student may spend it well, before joining a hospital, in working in the laboratory of a general practitioner, learning something of Chemistry and Pharmacy, and thus preparing himself to enter the school with advantage. This gives him a decided pull over those who como straight to the hospital from a public school. Moreover, this is to be said: it is a good thing for a young man to feel his own weight, his responsibilities and duties, before entering a medical school. The change is so sudden and so violent, from the strict discipline of a school, to the almost unrestricted liberty of the medical student, that sometimes young lads lose their heads for awhile; but the almost uniform good behaviour of the medical students of the present day has a decidedly beneficial effect upon the newly entered candidates for medical qualification.

At all events, we would strongly urge on all intending students to acquire, before entering a medical school, some knowledge of Chemistry and Physics, and, if possible, an acquaintance with Human Osteology, commonly known as "the bones."

REGISTRATION.

As soon as the student has passed his preliminary examination, he ought to register his certificate at the office of the General Medical Council, 315, Oxford-street, W., or at that of one of the Branch Registrars, which will save him all further trouble as regards preliminary education. This is necessary, if the student desires to spend the first year with a general practitioner or at a country hospital, so as to make the time thus spent count. But when the student comes to enter a medical school, he must register the actual commencement of his hospital studies. In London the plan is this: On entering a school the student receives certain class-tickets or other certificate of having joined the school; with these in his hands he goes to the College of Surgeons, and is there registered as a Student of the College. This is necessary for admission to the examinations of the College as far as metropolitan students are concerned. Tho same kind of thing is done at Apothecaries' Hall; but it is now common for the return required by the General Medical Council to be sent in by the school authorities. *All registration must be made within fifteen days of the beginning of the session or other mode of study, or the year will be lost.*

II.—PRELIMINARY SCIENTIFIC EDUCATION.

Speaking of general education, we have incidentally referred to the importance of certain scientific acquirements. These, though not absolutely essential to some knowledge of Medicine, are so important as to bo held in the first rank of subsidiary subjects. Thus, by the rules of the College of Surgeons, a student may be examined on the following subjects, but the examination is not compulsory: these are—Mechanics, Chemistry, Botany, and Zoology. Of these, the first three are of most importance to the student, and every effort ought to

be made to acquire a knowledge of them sufficient at least to pass this examination. The University of London, however, has instituted an examination known as the Preliminary Scientific, dealing with these and allied subjects. This examination is a very powerful test of a man's acquirements, and many break down under it. We strongly counsel all to pass it, if possible, before entering on their purely medical studies. It is sad to see the loss of time implied by a man being forced to devote his attention to purely scientific subjects when he ought to be attending to others which belong to later periods of his career, and which he will havo to work up under like unfavourable auspices. The following are the regulations relating to this examination in the University of London :—

PRELIMINARY SCIENTIFIC (M.B.) EXAMINATION.

The Preliminary Scientific Examination shall take place once in each year, and shall commence on the third Monday in July.

[Candidates for the degree of M.B. are strongly recommended by the Senate to pass the Preliminary Scientific Examination before commencing their regular medical studies; and to devote a preliminary year to preparation for it according to the following programme:—Winter Session: Experimental Physics; Chemistry (especially Inorganic); Zoology. Summer Session: Practical Chemistry (Inorganic); Botauy.]

Candidates shall be examined in the following subjects:—

INORGANIC CHEMISTRY.

Differences betweeu mechanical mixture, solution, and chemical combination; outlines of crystallography; formation of crystals; dimorphism; isomorphism; conditions on which the melting-point and the boiling-point of a substance depend; difference between elementary and compound substances; laws of chemical combination; equivalent weights of the elements; multiple proportions; the atomic theory; atomic value (quantivalence); molecules; molecular weights; relation between the density of a gas and its molecular weight; abnormal densities; Avogadro's hypothesis; combination of gases by volume; compound radicals; atomic and molecular combination. Meaning of chemical symbols, formulæ, and equations; calculation of quautities by weight and by volume; chemical changes, and the conditions under which they occur; combination; decomposition; double decomposition; nature of acids, bases, and salts; capacity of saturation of acids and bases; nomenclature. Relation between atomic weight and specific heat; Faraday's electrolytic law; principles of spectrum analysis; diffusion of gases. Hydrogen, chlorine, bromine, iodine, fluorine; the combination of the last four elements with hydrogen. Oxygen; ozone; water and peroxide of hydrogen; the oxides and oxyacids of chlorine; chlorates and hypochlorites. Sulphur; sulphuretted hydrogen; the oxides of sulphur; sulphuric acid and the sulphates; sulphurous acid and the sulphites; chlorosulphuric acid. Nitrogen; the atmosphere and its relations to animal and vegetable life; ammonia; ammonium and its salts; the oxides of nitrogen; nitric acid and nitrates; nitrous acid and nitrites. Phosphorus; phosphoretted hydrogen; the oxides of phosphorus; phosphoric acid and the phosphates; chloride and oxychloride of phosphorus. Arsenic and its oxides; arseniuretted hydrogen; arsenious acid and its salts; arsenic acid and its salts; the sulphides of arsenic; detection of arsenic. Antimony, its oxides and sulphides; antimoniuretted hydrogen; chlorides of antimony; compounds of autimonic oxide; detection of antimony. Boron; boracic acid and the borates. Carbon; carbonic oxide and carbonic acid; the carbonates; carbon oxysulphide; sulphocarbonic acid; marsh-gas; ethylene; combustion; structure of flame; coal-gas; Davy lamp; principles of illumination. Silicon; Siliciuretted hydrogen; silicon chloride; silicon chloroform; silica and the silicates. Potassium; sodium; silver. Calcium; strontium; barium. Aluminium. Magnesium; zinc; cadmium. Lead. Manganese; iron; cobalt; nickel; chromium. Bismuth; copper; mercury; gold; tin. Platinum. The chief compounds of these metals with the more important acid radicals; the detection of these metals and their compounds, in powder or in solution.

EXPERIMENTAL PHYSICS.

[Candidates will be expected to show a general acquaintance with the methods and apparatus by which the leading principles of Physics as enumerated below can be illustrated and applied.]

Units of measurement. The laws of motion considered experimentally. The chief forces of nature. The general properties of solids, liquids, and gases. The nature, intensity, and transmission of fluid pressure in general. The pressure of liquids in equilibrium under the action of gravity. The equilibrium of solids floating or entirely immersed in gravitating fluids. The specific gravities of substances, with the ordinary modes of determining them. Measurement of the pressure of the atmosphere and of the elastic force of gases. Diffusion of liquids and gases. Definition of work and energy: conservation and transmutation of energy.

Acoustics.—Production and mode of propagation of sound; intensity, pitch and quality. Velocity of sound in air. Influence of temperature and density. Velocity of sound in other media. Laws of reflection and Refraction. Nature of musical sounds. Longitudinal vibrations of rods and of columns of air. Transverse vibrations of strings; variation in their rate of vibration by changes in their tension, length, thickness, and substance.

Heat.—Definitions of heat and temperature. Construction of instruments for the measurement of temperature. Expansiou of solids, liquids, and gases under heat. Change of state; tension of vapours; latent heat. Radiant heat; its reflection, refraction, and absorption. Conduction; definition of thermal conductivity. Convection. Specific heat; mechanical equivalent of heat.

Magnetism.—Properties of magnets; induction—magnetic relations of iron and steel. Terrestrial magnetism.

Electricity.—Two electrical states, and their mutual relations. Conduction and insulation. Induction. Electric attraction aud repulsion. Distribution and accumulation of electricity on conductors. Electric discharge. Voltaic electricity; the various batteries. Electro-motive force. Strength of currents, resistance; Ohm's law. Heating and chemical effects of electric currents; action between currents and magnets; electro-magnetism, Induced currents; magneto-electricity. Thermo-electricity.

Optics.—Laws of propagation of light; measurement of velocity of light; photometry. Laws of reflection and refraction of light. Reflection at plane and at spherical surfaces. Refraction at plane and at spherical surfaces. Refraction through lenses, ineluding the formation of images. Chromatic dispersion.

BOTANY AND VEGETABLE PHYSIOLOGY.(a)

Structure, functions, and life-history of simple unicellular plants, such as *Protococcus* and *Saccharomyces* (yeast), as types of vegetable life. Structure, functions, and life-history of *Penicillium*, *Mucor*, or some other simple fungus. Structure, functions, and life-history of *Chara* or *Nitella*. Morphology, histology, and history of the reproduction of a fern. Morphology and histology of a flowering plant; structure of a flower; homologies of leaves and floral organs; histology of ordinary vegetable tissues, such as epidermis, parenchyma, fibro-vascular tissue, and their arrangement in the stem and leaves. General principles of vegetable nutrition; food of plants; action of green parts of plants; nature and flow of sap. Growth of a flowering plant; formation of wood and bark; nature of cambium. Reproduction of a flowering plant; structure of ovule; methods of fertilisation; development of ovule into seed; distinctive characters of gymnosperms. Distinctive characters of the principal British natural orders, viz.,—*Dicotyledons*, Ranunculaceæ, Cruciferæ, Caryophylleæ, Leguminosæ, Rosaceæ, Umbelliferæ, Compositæ, Scrophulariaceæ, Labiatæ, Amentaceæ; *Monocotyledons*, Orchideæ, Liliaceæ, Cyperaceæ, Gramineæ; *Acotyledons*, Filices, Musci, Lichens, Algæ, Fungi. (Description in technical language of specimens of flowering plants to be provided by the examiners.) Derivation and meaning of the following terms, and demonstration of their application on specimens (provided by the examiners):—Thalamifloral, calycifloral, corollifloral; hypogynous, perigynous, epigynous; monandrous, diandrous, etc.; individual, variety, species, genus, order, class, kingdom.

ZOOLOGY.

General structure and life-history of the following animals, as types of some of the principal divisions of the animal kingdom:—Amœba, paramœcium, hydra, tænia, leech, mussel, snail, centipede, insect, lobster, frog. Comparative structure of the digestive apparatus (including the teeth) in the dog, sheep, pig, and rabbit. Comparative structure and actions of the circulating and respiratory organs in the animals enumerated in the first sentence of this paragraph, and also in each of the vertebrated classes. Essential structure of secretory organs; principal varieties in the structure of the liver and kidney. General plan of the nervous system in mollusca, arthrozoa, and vertebrata. Proportionate development of the spinal cord and of the several encephalic centres in the ascending series of vertebrata. Respective functions of those centres. Modes of reflex action. Outlines of the comparative history of embryonic development in frog, bird, and mammal.

III.—PROFESSIONAL EDUCATION.

THE COURSES NECESSARY FOR QUALIFICATION.

THE object of medical education may be said, though inaccurately, to be twofold. The final end is, of course, to enable a man to practise his profession with advantage to himself and safety to the public. But the only criterion or test of this capability available to the public is the *testamur*, certificate, or diploma of some responsible body, which is accepted and registered by the General Medical Council. These bodies are somewhat numerous, and their requirements very diversified; consequently, the young student must take care, provided he wants a given diploma, to make his course of instruction correspond with that required by the body whence he desires his qualification. Moreover, it often happens that after a time a man may, for certain reasons, desire the diploma of another body besides that he originally contemplated; and for this reason alone, were it for no other, a wide curriculum is most desirable. In strict logic, therefore, these rules should be here given, and we shall try to indicato them as briefly and clearly as possible.

(A.) REGULATIONS OF BODIES GRANTING THE DEGREE OF DOCTOR OF MEDICINE.

1. UNIVERSITY OF OXFORD.

DEGREES IN MEDICINE.

EVERY student in Medicine is required to have passed all the examinations for the degree of B.A., and to reckon the time of his medical study from the final examination for Arts.

1. Candidates for the degree of B.M. are required to pass two examinations, each of which is held yearly in full Michaelmas Term, usually at the end of November, due notice being given, in the usual manner, by the Regius Professor of Medicine.

The subjects of the first examination are Human Anatomy and Physiology, Comparative Anatomy and Physiology to a

(a) Candidates for this and other botanical examinations are expected to bring with them a pocket-lens or simple microscope of two powers, and also a sharp penknife.

certain extent, and those parts of Mechanical Philosophy, Botany, and Chemistry which illustrate Medicine. The subjects of the second examination are the Theory and Practice of Medicine (including Diseases of Women and Children), the Materia Medica, Therapeutics, Pathology, the Principles of Surgery and Midwifery, Medical Jurisprudence, and General Hygiene. Every candidate at this second examination is to be examined in two of the ancient authors, Hippocrates, Aretæus, Galen, and Celsus; or in one of those four, and in some more modern author approved by the Regius Professor, as Morgagni, Sydenham, or Boerhaave.

Before a candidate is admitted to the first of these two examinations, he must have spent two years in professional studies after having passed the examinations required for the degree of B.A., unless he was placed in the first or second class in the School of Natural Science, in which case, if he received from the public examiners a special certificate of his attainments in Mechanical Philosophy, Chemistry, or Botany, he may be admitted to this examination at once, and need not then be examined again in any science specified in such certificate.

Before a candidate is admitted to the second examination, he must have completed sixteen terms from the date of the same *testamur*, and two years from the date of his *testamur* in the first medical examination, and must deliver to the Regius Professor satisfactory certificates of his attendance at some first-class hospital.

No one from another University can be incorporated as a graduate in Medicine without passing these two examinations, as well as having previously passed all examinations for the B.A. degree at his own University.

2. A Bachelor of Medicine wishing to proceed to the degree of Doctor is required to read publicly within the precincts of the Schools, in the presence of the Regius Professor, a dissertation composed by himself on some medical subject approved by the Professor, and to deliver to him a copy of it.

2. UNIVERSITY OF CAMBRIDGE.

REGULATIONS FOR DEGREES IN MEDICINE AND SURGERY.

Degree of Bachelor of Medicine.—Before a student can become a Bachelor of Medicine he must have resided nine terms (three academical years) in the University, and have graduated in Arts, or have passed the Previous Examination.

Five years of medical study are required, unless the student has graduated with honours as Bachelor of Arts, in which case four years of medical study are deemed sufficient.

There are three examinations for M.B.

The first examination is in—1. Chemistry and other branches of Physics; 2. Botany. Before presenting himself for it the student must have attended lectures on Chemistry, including manipulations, and on Botany.

The second examination is in—1. Elements of Comparative Anatomy; 2. Human Anatomy and Physiology; 3. Pharmacy. The student must have completed two years of medical study; and must also produce certificates of attendance on lectures on the Elements of Comparative Anatomy, Human Anatomy and Physiology, and Pharmacy; and of one year's hospital practice, and of one season's dissections.

The third examination is in—1. Pathology and Practice of Physic; 2. Clinical Medicine; 3. Medical Jurisprudence; 4. Principles of Surgery; and 5. Midwifery. The candidate must have completed the course of medical study, and must produce certificates of attendance on one course of lectures on each of the following subjects:—Pathological Anatomy, Principles and Practice of Physic, Clinical Medicine, Clinical Surgery, Medical Jurisprudence, and Midwifery. With attendance on ten cases of Midwifery; and of having attended the medical practice of a hospital during three years, and the surgical practice during one year; and of having been clinical clerk for six months at a recognised hospital, or of having had special charge of hospital, dispensary, or union patients under a qualified medical practitioner.

After the third examination an Act has to be kept, which consists in reading an original thesis, followed by a *vivâ voce* examination on the subject of the thesis, as well as on other subjects of the Faculty.

The Degree of Doctor of Medicine may be taken three years after M.B. An Act has to be kept, with *vivâ voce* examinations, and an essay has to be written extempore. A Master of Arts of four years' standing can proceed direct to M.D. provided he produces the same certificates and passes the same examinations as for M.B.

Degree of Master in Surgery.—The candidate must have passed all the examinations for the degree of M.B., and must produce certificates of having attended a second course of lectures on Human Anatomy, one course of lectures on the Principles and Practice of Surgery, one year's clinical surgical lectures, a second season of dissections, three years' surgical practice of a recognised hospital, and of having been House-Surgeon or Dresser for six months. The subjects of the examination are—1. Surgical Anatomy; 2. Pathology and the Principles and Practice of Surgery; 3. Clinical Surgery.

The examinations are partly in writing and partly *vivâ voce* in the dissecting-room and in the hospital. They take place in the Michaelmas and Easter Terms.

3. UNIVERSITY OF LONDON.

This University grants degrees both in Medicine and Surgery, and certificates in subjects relating to Public Health. Those available for young students are the Bachelorships of Medicine and Surgery.

Every candidate for the degree of Bachelor of Medicine shall be required—

1. To have passed the matriculation examination in this University (unless he has taken a degree in Arts in one of the Universities of Sydney, Melbourne, Calcutta, or Madras, and Latin was one of the subjects in which he passed).

2. To have passed the preliminary scientific examination, which is in Experimental Physics, Inorganic Chemistry, Practical Chemistry, Botany and Vegetable Physiology, and Zoology.—See page 250. (Candidates for the degree of M.B. are strongly recommended by the Senate to pass the preliminary scientific examination before commencing their regular medical studies.)

3. To have been engaged in his professional studies during four years subsequently to matriculation or graduation in Arts, at one or more of the medical institutions or schools recognised by this University; one year, at least, of the four to have been spent in one or more of the recognised institutions or schools in the United Kingdom.

4. To pass two examinations in Medicine.

FIRST M.B. EXAMINATION.

No candidate shall be admitted to the first M.B. examination unless he have passed the preliminary scientific examination at least one year previously,(a) and have produced certificates to the following effect:—

1. Of having completed his nineteenth year.

2. Of having, subsequently to having passed the matriculation examination, or taken a degree in Arts in one of the before-named universities, been a student during two years at one or more of the medical institutions or schools recognised by this University; and of having attended a course of lectures on each of three of the subjects in the following list:—DESCRIPTIVE AND SURGICAL ANATOMY, GENERAL ANATOMY AND PHYSIOLOGY, COMPARATIVE ANATOMY, PATHOLOGICAL ANATOMY, MATERIA MEDICA AND PHARMACY, GENERAL PATHOLOGY, GENERAL THERAPEUTICS, FORENSIC MEDICINE, HYGIENE, OBSTETRIC MEDICINE AND DISEASES PECULIAR TO WOMEN AND INFANTS, SURGERY, MEDICINE.

3. Of having, subsequently to having passed the matriculation examination or taken a degree in Arts, dissected during two winter sessions.

4. Of having, subsequently to having passed the matriculation examination or taken a degree in Arts, attended a course of Practical Chemistry, comprehending practical exercises in conducting the more important processes of general and pharmaceutical Chemistry; in applying tests for discovering the adulteration of articles of the Materia Medica, and the presence and nature of poisons; and in the examination of mineral waters, animal secretions, urinary deposits, calculi, etc.

5. Of having attended to Practical Pharmacy, and of having acquired a practical knowledge of the preparation of medicines.

The fee for this examination shall be five pounds.

Candidates shall be examined in the following subjects:—ANATOMY, PHYSIOLOGY, MATERIA MEDICA AND PHARMACEUTICAL CHEMISTRY, ORGANIC CHEMISTRY.

(a) Candidates who matriculated previously to January, 1861, will not be required to pass the preliminary scientific examination in any other subjects than Chemistry and Botany; and they will be allowed to pass the preliminary scientific examination and the first M.B. examination in the same year, if they so prefer.

Law of substitution; compound radicals; homologous series; principles of ultimate analysis. The chemical history of the cyanogen group; cyanogen; hydrocyanic acid; cyanic acid and urea; sulphocyanic acid; uric acid. Amylaceous and saccharine substances; fermentation; alcohol, wine, beer, bread, etc. Homologues of alcohol; ethers, simple and mixed; oxidation of alcohol; aldehyd and acetic acid and their homologues. Glycol and oxalic acid and their homologues. Glycerine; fatty and oily bodies; saponification. Principal vegetable acids. Ammonia and its derivatives; ammonium and ammoniacal salts. The chief natural organic bases. The chief constituents of the vegetable organism; cellulose; vegetable fibrin; albumin, casein, glutin, etc. The chief constituents of the animal organism; animal fibrin, albumin, casein, gelatin; blood, milk, bile, urine, etc. Decay, putrefaction; destructive distillation. The chemical principles of the processes of nutrition and respiration in plants and animals.

SECOND M.B. EXAMINATION.

No candidate shall be admitted to the second M.B. examination within two academical years of the time of his passing the first examination, nor unless he have produced certificates to the following effect:—

1. Of having passed the first M.B. examination.

2. Of having, subsequently to having passed the first M.B. examination, attended a course of lectures on each of two of the subjects comprehended in the foregoing list, and for which the candidate had not presented certificates at the first M.B. examination.

3. Of having conducted at least twenty labours. (Certificates on this subject will be received from any legally qualified practitioner in medicine.)

4. Of having attended the surgical practice of a recognised hospital or hospitals during two years, with clinical instruction on and lectures on Clinical Surgery.

5. Of having attended the medical practice of a recognised hospital or hospitals during two years, with clinical instruction on and lectures on Clinical Medicine. N.B.—The student's attendance on the surgical and on the medical hospital practice may commence at any date after his passing the preliminary scientific examination, and may be comprised either within the same year or within different years; provided that in every case his attendance on surgical and medical hospital practice be continued for at least eighteen months subsequently to his passing the first M.B. examination. Attendance during three months in the wards of a lunatic asylum recognised by the University, with clinical instruction, may be substituted for a like period of attendance on medical hospital practice.

6. Of having, subsequently to the completion of his attendance on surgical and medical hospital practice, attended to Practical Medicine, Surgery, or Obstetric Medicine, with special charge of patients, in a hospital, infirmary, dispensary, or union, during six months.

7. Of having acquired proficiency in vaccination. (Certificates on this subject will be received only from the authorised vaccinators appointed by the Privy Council.)

The candidate shall also produce a certificate of moral character from a teacher in the last school or institution at which he has studied, as far as the teacher's opportunity of knowledge has extended.

The fee for this examination shall be £5.

Candidates shall be examined in the following subjects:—General Pathology, General Therapeutics and Hygiene; Surgery, Medicine, Obstetric Medicine, Forensic Medicine.

The examinations shall include questions in Surgical and Medical Anatomy, Pathological Anatomy, and Pathological Chemistry.

BACHELOR OF SURGERY.

No candidate shall be admitted to the examination for the degree of Bachelor of Surgery unless he have produced certificates to the following effect:—

1. Of having passed the second examination for the degree of Bachelor of Medicine in this University.

2. Of having attended a course of instruction in Operative Surgery, and of having operated on the dead subject.

Candidates are examined on Surgical Anatomy and surgical operations, by printed papers; examination, and report on cases, of surgical patients; performance of surgical operations upon the dead subject; application of surgical apparatus; *vivâ voce* interrogation.

MASTER IN SURGERY.

The examination for the degree of Master in Surgery shall take place once in each year, and shall commence on the fourth Monday in November.

No candidate shall be admitted to this examination unless he have produced certificates to the following effect:—

1. Of having taken the degree of Bachelor of Surgery(b) in this University.

2. Of having attended, subsequently to having taken the degree of Bachelor of Surgery in this University—*a*. To Clinical or Practical Surgery during two years in a hospital or medical institution recognised by this University. *b*. Or to Clinical or Practical Surgery during one year in a hospital or medical institution recognised by this University; and of having been engaged during three years in the practice of his profession. *c*. Or of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Surgery in this University. (One year of attendance on Clinical or Practical Surgery, or two years of practice, will be dispensed with in the case of those candidates who at the B.S. examination have been placed in the first division.)

3. Of moral character, signed by two persons of respectability.

These certificates shall be transmitted to the Registrar at least *fourteen days* before the examination begins.

DOCTOR OF MEDICINE.

The examination for the degree of Doctor of Medicine shall take place once in each year, and shall commence on the fourth Monday in November.

No candidate shall be admitted to this examination unless he have produced certificates to the following effect:—

1. Of having passed the second examination for the degree of Bachelor of Medicine in this University.

2. Of having attended, subsequently to having taken the degree of Bachelor of Medicine in this University—*a*. To Clinical or Practical Medicine during two years in a hospital or medical institution recognised by this University. *b*. Or to Clinical or Practical Medicine during one year in a hospital or medical institution recognised by this University; and of having been engaged during three years in the practice of his profession. *c*. Or of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Medicine in this University. (One year of attendance on Clinical or Practical Medicine, or two years of practice, will be dispensed with in the case of those candidates who at the second M.B. examination have been placed in the first division.)

3. Of moral character, signed by two persons of respectability.

These certificates shall be transmitted to the Registrar at least *fourteen days* before the examination begins.

EXAMINATION IN SUBJECTS RELATING TO PUBLIC HEALTH.

A special examination shall be held once in every year in subjects relating to Public Health, and shall commence on the second Monday in December.

No candidate shall be admitted to this examination unless he shall have passed the second examination for the degree of Bachelor of Medicine in this University at least one year previously; nor unless he shall have given notice of his intention to the Registrar at least two calendar months before the commencement of the examination.

Candidates shall be examined in the following subjects:—Chemistry and Microscopy, in relation to the examination of air, water, and food; Meteorology and Geology, as far as they bear on the duties of Health Officers, viz.:—General knowledge of meteorological conditions; reading and correction of instruments. General knowledge of soils; their conformation and chemical composition.

Vital Statistics, in reference to the methods employed for determining the health of a community; birth-rate; death-rate; disease-rate; duration and expectancy of life. Present amount of mortality, and its causes, in different communities.

Hygiene.—General principles of Hygiene. Special topics: Soil, construction of dwellings, conservancy of cities, unhealthy trades; supply of food to cities and examination of food; disposal of sewage, water-supply.

Medicine, in reference to the origin, spread, and method of prevention of diseases generally, but especially those of the epidemic class.

Sanitary Engineering, as far as regards the arrangements

(b) Candidates who have obtained the degree of Bachelor of Medicine previously to 1866 will be admitted to the examination for the degree of Master in Surgery without having taken the degree of Bachelor in Surgery; and in the case of such candidates, the attendance on surgical practice required by Regulation 2 may commence from the date of the M.B. degree.

connected with water-supply, sewerage, and ventilation. A knowledge of the reading of plans, sections, scales, etc.

Sanitary Law, as far as it relates to the duties of Officer of Health. A knowledge of the powers given under the various Sanitary Acts, as defined in the instructions issued by the Local Government Board, and of the methods of procedure in special cases.

The examination, which shall be both written and practical, shall extend over four days.

Candidates shall not be approved by the examiners unless they have shown a competent knowledge in all the principal subjects of the examination.

4. UNIVERSITY OF DURHAM.

For Registration.—Candidates for registration as students in Medicine must have passed the Medical Registration examination appointed by the University, or such other examination as the Warden and Senate may deem equivalent thereto.

Any Arts examination recognised by the General Medical Council is accepted by the University.

For Licences and Degrees in Medicine and Surgery.—Two licences and three medical degrees are conferred by the University of Durham, viz., licences in Medicine and Surgery, and the degrees of Bachelor of Medicine, Master in Surgery, and Doctor of Medicine.

Regulations for the Licence in Medicine.—1. The candidate must produce certificates of registration as a student in Medicine, of good moral conduct, of having attained the age of twenty-one years, and such certificates of attendance on lectures and hospital practice as the Warden and Senate shall require.

2. The candidate must have been engaged in medical and surgical study for four years after registration as a student in Medicine. One of the four years must be spent at the University of Durham College of Medicine, Newcastle-on-Tyne; the other three may be spent either at Newcastle-on-Tyne, or at one or more of the schools recognised by the licensing bodies named in Schedule (A) of the Medical Act, 1858.

There are two professional examinations—the first is held at the end of the second winter session; the final at the end of the fourth year of medical study.

Regulations for the Licence in Surgery.—The regulations are the same as those for the licence in Medicine, except that the final examination is directed more particularly to Surgery, and may or may not be passed at the same time as the final examination for the licence in Medicine.

Regulations for the Degree of Bachelor of Medicine.—1. The candidate must produce certificates of registration as a student in Medicine, of good moral conduct, of having attained the age of twenty-one years, and such certificates of attendance on lectures and hospital practice as the Warden and Senate shall require.

2. The candidate must have obtained a degree in Arts of the University of Durham, or must have passed the Arts examination for graduation in Medicine of the University, or must produce one or other of the following certificates:—(*a.*) A certificate of graduation in Arts at any of the following Universities, viz.:—Oxford, Cambridge, Durham, London, Queen's University (in Ireland), Edinburgh, Glasgow, St. Andrews, Aberdeen, Calcutta, Madras, Bombay, McGill College (Montreal), and Queen's College (Kingston). (*b.*) A certificate of having passed the preliminary or extra-professional examination for graduation in Medicine of any of the following Universities, viz.:—London, Edinburgh, Glasgow, St. Andrews, Aberdeen, Queen's University (Ireland); the Arts examination, qualifying for the Membership of the Royal College of Physicians of London; the Arts examination, qualifying for the Fellowship of the Royal College of Surgeons of England.

3. The candidate must have been engaged in medical and surgical study for four years after registration as a student in Medicine. One of the four years must be spent at the University of Durham College of Medicine, Newcastle-on-Tyne; the other three may be spent either at Newcastle-on-Tyne, or at one or more of the schools recognised by the licensing bodies named in Schedule (A) of the Medical Act, 1858.

There are two professional examinations. The first is held at the end of the second winter session, the final at the end of the fourth year of medical study. The subjects are the same as for the licence in Medicine, but the examinations are more stringent.

Regulations for the Degree of Master in Surgery.—The regulations are the same as for the degree of Bachelor of Medicine, except that the final examination is directed more particularly to Surgery.

Regulations for the Degree of Doctor of Medicine.—1. The candidate must have obtained the degree of Bachelor of Medicine, must be of the age of twenty-four years, and must have been engaged, subsequently to his having received the degree of Bachelor of Medicine, for at least two years in attendance on a hospital, or in the Military or Naval Services, or in medical and surgical practice. 2. The candidate must write an essay, based on original research or observation, on some medical subject, selected by himself, and approved of by the Professor of Medicine, and must pass an examination thereon, including the collateral medical sciences involved in the subject of the essay.

EXAMINATIONS.

Registration Examinations.—Registration examinations will be held at Durham, commencing September 18, 1877, and April 16 and September 17, 1878. Application must be made, at least one month before the day of examination, to Arthur Beanlands, Esq., Durham, to whom candidates must, at the same time, send the examination fee of £1, and certificates of age and character, and specify the optional subject in which they wish to be examined. The following are the subjects for the registration examinations:—Necessary Subjects—The history contained in the Acts of the Apostles; English Grammar and Composition; Arithmetic, including Vulgar and Decimal Fractions; Algebra, including Simple Equations; Euclid, Books I. and II.; Latin Grammar, with—*in September*, 1877 and 1878, Virgil, Æneid, Lib. I. and II.; *in April*, 1878, Cæsar, De Bello Gallico, Lib. I. and II. In addition to the above, all candidates are required to satisfy the examiners in one (at least) of the following optional subjects:—Greek Grammar, with Xenophon's Memorabilia, Books I. and II.; French Grammar, with Voltaire's Charles XII.; German Grammar, with Goethe's "Dichtung und Wahrheit," Book I.; elementary questions in Mechanics, Hydrostatics, and Pneumatics. In addition to the foregoing examinations the Warden has authority, in case of urgency, to appoint an extraordinary registration examination at any time. The fee for such examination is £2.

Professional Examinations.—The first professional examination for licences and degrees in Medicine and Surgery is held at the end of the second winter session. The following are the subjects of the examination:—Anatomy, Physiology, Chemistry, Botany. The next examination will be held in April, 1878. The final professional examination for licences and degrees in Medicine and Surgery is held at the end of the fourth year of medical study. The following are the subjects of the examination:—Materia Medica, Therapeutics, Medical Jurisprudence, Pathological Anatomy, Midwifery, Diseases of Women and Children, Medicine, and Surgery. The next examination will commence on June 10, 1878.

Examination for the Degree of Doctor of Medicine.—The candidate must write an essay, based on original research or observation, on some medical subject, selected by himself, and approved of by the Professor of Medicine, and must pass an examination thereon, including the collateral medical sciences involved in the subject of the essay. The examinations for licences and degrees in Medicine and Surgery are conducted in Newcastle—1. By printed papers of questions. 2. Practically in Anatomy, Physiology, Chemistry, Materia Medica, Pathology, Surgery, Medicine, Midwifery, and Medical Jurisprudence. 3. *Vivâ voce* on all the subjects.

Every candidate wishing to present himself for any of the above examinations must give at least fourteen days' notice to the Registrar of the College, and must, at the same time, send the fee (£1) and the necessary certificates.

Examination for the Degree of Doctor of Medicine, for Medical Practitioners of Fifteen Years' Standing, without Residence.—The Warden and Senate of the University of Durham, with the view of affording to practitioners of fifteen years' standing an opportunity of obtaining the degree of Doctor of Medicine, have instituted a special examination, under the following regulations:—

1. That the candidate shall be registered by the General Council of Medical Education and Registration of the United Kingdom.

2. That the candidate shall have been in the active practice of his profession for fifteen years.

3. That the candidate shall not be under forty years of age.

4. That the candidate shall produce a certificate of moral character from three registered members of the medical profession.

5. That if the candidate shall not have passed, previous to his professional examination (in virtue of which he has been placed on the Register), an examination in Arts, he shall be required to pass an examination in Classics and Mathematics. The subjects for this examination shall be as follows:—*a*. An English essay. (A short essay on some subject to be specified as the time of the examination.) *b*. Arithmetic. *c*. Euclid—Books I. and II. *d*. Latin—Translation from Virgil, Æneid, Lib. I. and II., together with grammatical questions. *e*. One of the following subjects:—(i.) Greek—Translation from Xenophon's Memorabilia, Books I. and II., with grammatical questions. (ii.) French—Translation from Voltaire's "Charles XII.," with grammatical questions. (iii.) German—Translation from Goethe's "Dichtung und Wahrheit," Book I., with grammatical questions. (iv.) Elements of Mechanics, Pneumatics, and Hydrostatics. (v.) Some treatise on Moral, Political, or Metaphysical Philosophy.

6. That if the candidate shall have passed, previous to his professional examination (in virtue of which he has been placed on the Register), a preliminary examination, he shall be required to translate into English a passage from some Latin author—such as Virgil, Cæsar, or Celsus,—and shall have an opportunity of showing proficiency in Greek, Moral Philosophy, or some modern language.

7. That the candidate shall be required to pass an examination in the following subjects:—*a*. Principles and Practice of Medicine, including Psychological Medicine and Hygiene. *b*. Principles and Practice of Surgery. *c*. Midwifery, and Diseases peculiar to Women and Children. *d*. Pathology, medical and surgical. *e*. Anatomy, medical and surgical. *f*. Medical Jurisprudence and Toxicology. *g*. Therapeutics.

8. That the fee shall be £52 10s., to be forwarded to the Registrar of the University of Durham College of Medicine, Newcastle-on-Tyne, when the candidate enters his name for the examination.

9. That if the candidate shall fail to satisfy the examiners, the sum of £21 shall be retained; but that if he shall again offer himself for the examination the sum of £42 only shall then be required.

An examination, in accordance with the above regulations, will be held on June 10, 11, 12, and 13, 1878.

The Arts examination will be held at the University, Durham, on June 10. The professional examination at the University of Durham College of Medicine, Newcastle-on-Tyne, on June 11, 12, and 13.

The following is the programme of the professional examination:—

First Day, *June* 11.—Morning, four hours (nine to one o'clock).—Paper of Questions: Medicine, 3 questions; Insanity, 1; Hygiene, 1; Pathology (medical), 1; Anatomy (medical), 1; Therapeutics, 1. Afternoon, three hours (two to five o'clock): Clinical examination of cases of disease (medical).

Second Day.—Morning, four hours (nine to one o'clock).—Paper of Questions: Surgery, 2 questions; Midwifery, 2; Pathology (surgical), 1; Anatomy (surgical), 1; Medical Jurisprudence, 1; Toxicology, 1. Afternoon, three hours (two to five o'clock): Clinical examination of cases of surgical disease and injury.

Third Day.—*Vivâ voce* interrogation, two hours.

Gentlemen intending to offer themselves as candidates are requested to forward their names to Dr. Luke Armstrong, Registrar of the University of Durham College of Medicine, Newcastle-on-Tyne, on or before May 1, 1878, together with the fee and the before-mentioned certificates.

5. UNIVERSITY OF ST. ANDREWS.

ORDINARY DEGREES.

The degrees in Medicine granted by the University of St. Andrews are those of Bachelor of Medicine (M.B.), Master in Surgery (C.M.), and Doctor of Medicine (M.D.).

The preliminary examination and professional curriculum and examinations for these degrees are generally the same as those of the Universities of Edinburgh, Aberdeen, and Glasgow. The following regulations, however, for candidates for the degrees of Bachelor of Medicine and Master in Surgery present some difference:—

No one shall be received as a candidate for the degree of Bachelor of Medicine or Master in Surgery unless two years at least of his four years of medical and surgical study shall have been in one or more of the following universities and colleges, viz.:—The University of St. Andrews; the University of Glasgow; the University of Aberdeen; the University of Edinburgh; the University of Oxford; the University of Cambridge; Trinity College, Dublin; Queen's College, Belfast; Queen's College, Cork; and Queen's College, Galway.

The remaining years of medical and surgical study may be either in one or more of the universities and colleges above specified, or in the hospital schools of London, or in the School of the College of Surgeons in Dublin, or under such private teachers of medicine as may from time to time receive recognition from the University Court.

Attendance on the lectures of any private teacher in Edinburgh, Glasgow, or Aberdeen shall not be reckoned for graduation in St. Andrews if the fee for such lectures be of less amount than is charged for the like course of lectures in the University of Edinburgh, of Glasgow, or of Aberdeen, according as the teacher lectures in Edinburgh, Glasgow, or Aberbeen.

Fees for Graduation.—For the degree of Bachelor of Medicine £5 5s. in respect of each of the three divisions of the examination on professional subjects; and if the candidate desires to be admitted to the degree of Bachelor of Medicine only, he shall not, on admission thereto, be required to pay any further fee in addition to the £15 15s. so paid by him; but if he desires to be admitted to the degree of Master in Surgery also, he shall, on being admitted to such degree pay a further fee of £5 5s.; and every candidate for the degree of Doctor of Medicine, who has previously obtained the degree of Bachelor of Medicine, shall pay, in addition to the fees paid by him as a candidate for the degree of Bachelor of Medicine, a fee of £5 5s., exclusive of any stamp duty which may for the time be exigible.

SPECIAL DEGREES.

The degree of Doctor of Medicine may be conferred by the University of St. Andrews on any registered medical practitioner above the age of forty years, whose professional position and experience are such as, in the estimation of the University, entitle him to that degree, and who shall, on examination, satisfy the medical examiners of the sufficiency of his professional knowledge; provided always, that degrees shall not be conferred under this section to a greater number than ten in any one year.

Regulations as to Special Degrees.—As regards registered medical practitioners above the age of forty years, the examinations are held in the United College of St. Salvator and St. Leonard, annually, in April. The graduation fee is £52 10s. Candidates must lodge with the Dean of the Medical Faculty the following certificates, along with application for admission to examination:—1. A certificate of age, being a baptismal certificate, or an affidavit of age. 2. Holograph certificates from at least three medical men of acknowledged reputation in the profession, or in the medical schools, recommending the candidate to the Senatus for the degree of M.D., and testifying to his professional position and skill. As only ten can graduate in each year, candidates are selected whose service and certificates seem, to the Medical Faculty, to present the highest professional claims; but where these seem equal, preference is given to priority of application and to age. 3. Candidates, when notified for examination, will remit a portion of the graduation fee—viz., £10 10s. This sum shall be forfeited should the candidate fail to appear, or to graduate, at the time appointed. 4. A satisfactory examination, written and *vivâ voce*, must be passed in the following departments:—(1) Materia Medica and General Therapeutics, (2) Medical Jurisprudence, (3) Practice of Medicine and Pathology, (4) Surgery, (5) Midwifery and Diseases of Women and Children.

6. UNIVERSITY OF EDINBURGH.

This University grants degrees in Medicine, Surgery, and Science (including Health).

No one is admitted to the degree of Bachelor of Medicine or Master in Surgery who has not been engaged in medical and surgical study for four years—the medical session of each year,

or *annus medicus*, being constituted by at least two courses of not less than one hundred lectures each, or by one such course, and two courses of not less than fifty lectures each; with the exception of the Clinical Courses, in which lectures are to be given at least twice a week during the prescribed periods.

Every candidate for the degrees of M.B. and C.M. must give sufficient evidence by certificates—

1. That he has studied each of the following departments of medical science—viz., Anatomy, Chemistry, Materia Medica, Institutes of Medicine or Physiology, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Children (two courses of Midwifery of three months each being reckoned equivalent to a six months' course, provided different departments of Obstetric Medicine be taught in each of the courses), General Pathology (or, in schools where there is no such course, a three months' course of lectures on Morbid Anatomy, together with a supplemental course of Practice of Medicine or Clinical Medicine), during courses including not less than one hundred lectures; Practical Anatomy, a course of the same duration as those of not less than one hundred lectures above described; Practical Chemistry, three months; Practical Midwifery, three months at a midwifery hospital, or a certificate of attendance on six cases from a registered medical practitioner; Clinical Medicine, Clinical Surgery, courses of the same duration as those of not less than one hundred lectures above prescribed, or two courses of three months' lectures being given at least twice a week; Medical Jurisprudence, Botany, Natural History (including Zoology), during courses including not less than fifty lectures.

2. That he has attended for at least two years the medical and surgical practice of a general hospital which accommodates not fewer than eighty patients, and possesses a distinct staff of physicians and surgeons.

3. That he has been engaged, for at least six months, by apprenticeship or otherwise, in compounding and dispensing drugs at the laboratory of a hospital, dispensary, member of a surgical college or faculty, licentiate of the London or Dublin Society of Apothecaries, or a member of the Pharmaceutical Society of Great Britain.

4. That he has attended for at least six months, by apprenticeship or otherwise, the out-practice of a hospital, or the practice of a dispensary, physician, surgeon, or member of the London or Dublin Society of Apothecaries.

The studies of candidates for the degrees of Bachelor of Medicine and Master in Surgery are subject to the following regulations:—

1. One of the four years of medical and surgical study required must be in the University of Edinburgh.

2. Another of such four years of medical and surgical study must be either in the University of Edinburgh, or in some other university entitled to give the degree of Doctor of Medicine.

3. Attendance during at least six winter months on the medical or surgical practice of a general hospital which accommodates at least eighty patients, and, during the same period, on a course of Practical Anatomy, may be reckoned as one of such four years, and to that extent shall be held equivalent to one year's attendance on courses of lectures as above prescribed.

4. One year's attendance on the lectures of teachers of Medicine in the hospital schools of London, or in the school of the College of Surgeons in Dublin, or of such teachers of Medicine in Edinburgh or elsewhere as shall from time to time be recognised by the University Court, may be reckoned as one of such four years, and to that extent shall be held as attendance on courses of lectures as above prescribed.

5. Candidates may, to the extent of four of the departments of medical study required, attend in such year or years of their medical and surgical studies, as may be most convenient to them, the lectures of the extra-academical teachers of Medicine specified in the foregoing Sub-section 4.

6. All candidates not students of the University availing themselves of the permission to attend the lectures of extra-academical teachers in Edinburgh must, at the commencement of each year of such attendance, enrol their names in a book to be kept by the University for that purpose, paying a fee of the same amount as the matriculation fee paid by students of the University, and having, in respect of such payment, a right to the use of the library of the University.

Every candidate must deliver, before March 31 of the year in which he proposes to graduate, to the Dean of the Faculty of Medicine—

1. A declaration, in his own handwriting, that he has completed his twenty-first year (or that he will have done so on or before the day of graduation), and that he will not be, on the day of graduation, under articles of apprenticeship to any surgeon or other master.

2. A statement of his studies, as well in Literature and Philosophy as in Medicine, accompanied with proper certificates.

Each candidate is examined, both in writing and *vivâ voce*—first, on Chemistry, Botany, and Natural History; secondly, on Anatomy, Institutes of Medicine, Materia Medica (including Practical Pharmacy), and Pathology; thirdly, on Surgery, Practice of Medicine, Midwifery, and Medical Jurisprudence; fourthly, clinically on Medicine and on Surgery in a Hospital. The examinations on Anatomy, Chemistry, Institutes of Medicine, Botany, Natural History, Materia Medica, and Pathology are conducted, as far as possible, by demonstrations of objects placed before the candidates.

The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degree of Bachelor of Medicine, and is of the age of twenty-four years, and produces a certificate of having been engaged, subsequently to his having received the degree of Bachelor of Medicine, for at least two years in attendance on a hospital, or in the Military or Naval Medical Services, or in medical and surgical practice: provided always that the degree of Doctor of Medicine shall not be conferred on any person, unless he be a graduate of Arts in one of the universities of England, Scotland, or Ireland, or of such other universities as are above specified, or unless he shall, before or at the time of his obtaining the degree of Bachelor of Medicine, or thereafter, have passed a satisfactory examination in Greek, and in Logic or Moral Philosophy, and in one at least of the following subjects—namely, French, German, higher Mathematics, and Natural Philosophy; and provided also that the candidate for the degree of Doctor of Medicine shall submit to the Medical Faculty a thesis, certified by him to have been composed by himself, and which shall be approved by the Faculty, on any branch of knowledge comprised in the professional examinations for the degree of Bachelor of Medicine, which he may have made a subject of study after having received that degree. The candidate must lodge his thesis with the Dean on or before April 30 of the year in which he proposes to graduate. No thesis will be approved by the Medical Faculty which does not contain either the results of original observations in Practical Medicine, Surgery, Midwifery, or some of the sciences embraced in the curriculum for the Bachelor's degree; or else a full digest and critical exposition of the opinions and researches of others on the subject selected by the candidate, accompanied by precise references to the publications quoted, so that due verification may be facilitated.

Candidates, settled for a period of years in foreign parts, who have complied with all the regulations for the degree of M.D. (under the new statutes), but who cannot appear personally to receive the degree, may, on satisfying the Senatus to that effect, by production of sufficient official testimonials, have the degree conferred on them in absence.

NOTICES TO CANDIDATES FOR GRADUATION IN MEDICINE.

1. An *annus medicus* is constituted by at least two winter courses of one hundred lectures each, or by one such course, and two summer courses of fifty lectures each, all being duly certified.

2. Four *anni medici* are required for graduates in Medicine. Two at least of these years must be passed at a university which grants degrees in Medicine, one of the two being at Edinburgh.

3. One or two of the *anni medici* may be taken at qualified extra-academical schools, in the manner stated in the succeeding paragraph:

4. In University College, in King's College, in the hospital schools of London, in the extra-academical School of Edinburgh, in the School of the College of Surgeons of Dublin, and in certain medical schools where at least two lecturers have been qualified by the University Court, a candidate may make *two anni medici*—one of which must be constituted by hospital attendance and Practical Anatomy, and the other by at least two courses of one hundred lectures, or one such course, and two courses of fifty lectures. The classes at these schools only qualify to the extent of four, and one of the four must be Practical Anatomy.

5. In provincial schools where there are no lecturers qualified by the University Court, a candidate can make *one annus medicus only*, and this is constituted by attendance on a qualified hospital, along with a course of Practical Anatomy.

The Fees are—For the degree of M.B., three Examinations, £5 5s. each, £15 15s.; for the degree of C.M., £5 5s. additional; for the degree of M.D., £5 5s. additional to that for M.B., exclusive of £10 Government stamp.

The fees for C.M. and M.D. are required to be paid on or before July 15.

Note.—Total fees and stamp for graduating as M.D. only, by regulations, for students commencing before February, 1861, £25.

N.B.—The above fees include all charges for the diplomas.

RIGHTS OF THE MEDICAL GRADUATES OF SCOTLAND ACCORDING TO THE MEDICAL ACT.

Before the passing of the Medical Act of 1858, the degree of Doctor of Medicine granted by the universities of Scotland (as the possessor underwent a complete education and examination in all departments of Physic and Surgery), qualified the graduate to practise every branch of the medical profession throughout Scotland. One principal purpose of the Medical Act was to extend local rights of practice over the whole of her Majesty's dominions. But according to the hitherto accepted reading of a dubious clause in the Act, no one can practise both Medicine and Surgery without possessing two distinct diplomas—one for Medicine, and another for Surgery. The universities were thus compelled, in justice to their graduates, to give them the additional title of Master in Surgery, not as implying any additional study or examination, but as declaring more distinctly their qualifications, and to permit registration as regularly qualified practitioners in the whole field of their professional education. The Secretary for War some time ago issued an order that candidates for admission into the Medical Service of the Army should obtain their qualifications in Physic and Surgery from two different sources; the effect of which would have been to prevent any one university from qualifying for this purpose. The Scottish Universities' Commissioners, recognising the serious evils of such a system, followed up a remonstrance which had been

offered on the part of the University of Edinburgh, and obtained the rescinding of all restrictions in the source of qualification. Consequently, any single university in Scotland can now qualify candidates for the military service as well as for any other public medical service in the country.

The Medical Faculty have resolved that the written and oral examinations on Chemistry, Botany, and Natural History, in October, 1877, and April, 1878, shall be restricted in the following manner:—

1. *Chemistry.*—Classification of elements; general laws of chemical combination and action, as illustrated in the simpler compounds of the more commonly occurring elements; symbolic notation. Preparation and properties of the non-metallic elements and their chief compounds; manufacture of sulphuric, nitric, and hydrochloric acids and ammonia. Classification and general properties of acids, bases, and salts. Manufacture and properties of soda, potash, nitre, gunpowder, lime, mortars, cements, earthenware, porcelain, and glass. Metallurgical operations in general; preparation of iron, zinc, copper, lead, tin, mercury, and silver, from their ores; alloys; preparation, properties, and composition of cast-iron, wrought-iron, and steel; principal salts of potassium, sodium, ammonium, barium, strontium, calcium, magnesium, zinc, aluminium, chromium, manganese, iron, cobalt, nickel, copper, lead, silver, gold, mercury, platinum, tin, bismuth, antimony, arsenic. Classification of organic compounds; alcohol, ethers, acetic acid, tartaric acid, citric acid, wood, sugars, starch, coal-gas, coal-tar, oils and fats, saponification. Simple qualitative analysis. [*The Examination in analysis is conducted practically.*]

2. *Botany.*—The structure and functions of plants, vegetable organography and physiology, the principles of classification, classes, sub-classes, and sections of the natural system. (See Balfour's "Class-book," or his "Manual of Botany.") Botanical characters to be demonstrated on conspicuous specimens of the following natural orders:—Ranunculaceæ, Papaveraceæ, Cruciferæ, Caryophyllaceæ, Malvaceæ, Leguminosæ, Rosaceæ, Onagraceæ, Umbelliferæ, Dipsacaceæ, Compositæ, Campanulaceæ (including Lobeliaceæ), Boraginaceæ, Labiatæ, Scrophulariaceæ, Primulaceæ, Euphorbiaceæ, Salicaceæ, Corylaceæ, Coniferæ, Cycadaceæ, Orchidaceæ, Amaryllidaceæ, Liliaceæ, Palmæ, Cyperaceæ, Gramineæ, Filices, Musci. The student will be examined practically on the microscopical structure of plants, and he will be required to describe the organs of fresh plants put into his hands.

3. *Zoology and Comparative Anatomy.*—The general characters of the animal kingdom, and the general structure and organisation of animals; principles of zoological classification; general plan of structure, and physiology of the types: Protozoa, Porifera, Cœlenterata, Echinodermata, Vermes, Articulata, Mollusca, and Vertebrata. The special distinctive characters of the following groups, with a knowledge of familiar examples of each, and the conditions and circumstances under which they occur (candidates will be required to refer any specimens shown to them by the examiner for this purpose to their respective groups):—Rhizopoda, Infusoria; Porifera silicea, calcarea; Zoantharia, Alcyonaria, Hydrozoa, Echinidea, Asteridea, Crinoidea; Platyelmia, Nematelmia, Annelida; Crustacea, Arachnida, Myriapoda, Insecta; Lamellibranchiata, Gastropoda, Cephalopoda; Pisces, Amphibia, Reptilia, Aves, Mammalia.

7. UNIVERSITY OF GLASGOW.—FACULTY OF MEDICINE.

Three medical degrees are conferred by this University, viz.:—Bachelor of Medicine (M.B.), Master in Surgery (C.M.), and Doctor of Medicine (M.D.); all of which are recognised by the Medical Act as qualifying for practice throughout the British dominions.

The degree of Bachelor of Medicine may be obtained by candidates of the age of twenty-one years who have complied with the regulations as to education and examination. The degree of Master in Surgery is only conferred upon those who at the same time obtain the Bachelorship of Medicine; and the degree of Doctor of Medicine may be conferred on candidates of not less than twenty-four years of age who have obtained the Bachelorship two or more years previously, and have fulfilled certain conditions to be afterwards mentioned.

The medical curriculum is as nearly as possible the same as that in the University of Edinburgh.

The following is the order of the course of study recommended to students:—

First Winter Session: Anatomy, elementary or descriptive and practical; Chemistry.

First Summer Session: Botany, Practical Chemistry, Anatomy.

There may be advantages in beginning study in a summer session preceding the first winter, in which case instruction should be sought in Botany, elementary Anatomy, or elementary Chemistry.

Second Winter Session: Advanced Anatomy and Practical Anatomy, Physiology, Surgery; hospital attendance, surgical wards and clinical lectures.

First Professional Examination in April or October.

Second Summer Session: Zoology, Practical Anatomy, or Practical Chemistry, Practical Pharmacy; hospital attendance, surgical wards and clinical lectures.

Third Winter Session: Surgery, second course; Materia Medica; Practice of Physic; hospital attendance, medical wards and clinical lectures; Pathology.

Second Professional Examination in April or October.

Third Summer Session: Hospital attendance, medical wards and clinical lectures; Surgical Anatomy, Operative Surgery, Forensic Medicine.

Fourth Winter Session: Practice of Physic, second course; Forensic Medicine (for students proposing to graduate in 1878), Midwifery; hospital attendance, medical or surgical wards and clinical lectures; Midwifery practice.

Final Examination in July.

PROFESSIONAL EXAMINATIONS.

The professional examinations are conducted in writing, orally and practically, in three divisions, as follows:—

First Division: On Chemistry, Elementary Anatomy, Botany.

Second Division: On Advanced Anatomy, Physiology, Zoology with Comparative Anatomy.

Third or Final Division: On Materia Medica, General Pathology, Surgery, Practice of Medicine, Midwifery, Forensic Medicine, Clinical Surgery, Clinical Medicine.

DEGREE OF DOCTOR OF MEDICINE.

The degree of Doctor of Medicine may be conferred on any candidate of not less than twenty-four years of age, who has obtained the Bachelorship two or more years previously, provided he possesses a degree in Arts, or has, in addition to the Preliminary Examination in General Education required for the Bachelorship, also passed before obtaining the Bachelorship, or within three years thereafter, an examination in Greek, and Logic or Moral Philosophy, together with any one of the other optional subjects belonging to the Examination in General Education. He must also produce evidence of having been engaged in professional study or avocations for two years after having obtained the Bachelorship, and must lodge an inaugural dissertation composed by himself on a medical, surgical, or allied subject. Theses for the degree of M.D. to be lodged with the Registrar on or before March 20, June 20, or October 20. As the granting or withholding of the degree depends chiefly on the character of the dissertation, candidates are advised to bestow both time and care on its preparation.

The fees for degrees are the same as in Edinburgh.

The Examinations in General Education take place twice yearly—viz., in October and March. The examinations for session 1877-78 will be held on Wednesday, Thursday, and Friday, October 10, 11, and 12, 1877, and Thursday, Friday, and Saturday, March 28, 29, and 30, 1878. Those who intend to present themselves for either of these examinations are required to send in their names to the Assistant Clerk of Senate on or before September 28 or March 20. A fee of 10s. must be paid on entering their names by those who are not matriculated students—which fee will be returned on matriculation within the year.

The Professional Examinations are held at the following periods—viz.: The first in October (October 16, 1877) and April (April 5, 1878); the second in October (October 17, 1877) and April (April 6, 1878); the third in July (July 22, 1878).

8. UNIVERSITY OF ABERDEEN.

The following are the degrees in Medicine granted by this University—namely, Bachelor of Medicine (M.B.), Master in Surgery (C.M.), and Doctor of Medicine (M.D.).

The preliminary examination and professional curriculum, and examination for the degrees of B.M., C.M., and M.D., being in conformity with the Ordinances of the Scotch Universities Commissioners, are nearly the same as those of the Universities of Edinburgh, Glasgow, and St. Andrews.

The studies of candidates for the degrees of Bachelor of Medicine and Master in Surgery are subject to these regulations:—

One at least of the four years of medical and surgical study must be in the University of Aberdeen.

Another of such four years must be either in this University or in some other University entitled to give the degree of Doctor of Medicine.

FEES FOR GRADUATION.

1. Each candidate for the degree of M.B. shall pay a fee of £5 5s. in respect of each of the three professional examinations.

2. If the candidate desires to be admitted to the degree of Bachelor of Medicine only, he shall not, on admission thereto, be required to pay any further fee in addition to the £15 15s.

so paid by him; but if he desires to be admitted to the degree of Master in Surgery also, he shall, on being admitted to such degree, pay a further fee of £5 5s.

3. And every candidate for the degree of Doctor of Medicine shall pay, in addition to the fees paid by him for the degree of Bachelor of Medicine, a fee of £5 5s., exclusive of any stamp duty which may for the time be exigible.

EXEMPTION FROM THE FOREGOING REGULATIONS.

Students who shall have begun their medical studies before the first Tuesday of November, 1861, are entitled to appear for examination for the degree of M.D. after four years' study, one of which must have been at the University of Aberdeen.

9. UNIVERSITY OF DUBLIN.

DEGREES AND LICENCES IN MEDICINE AND SURGERY.

The degrees and licences in Medicine and Surgery granted by the University are—1. Bachelor in Medicine. 2. Doctor in Medicine. 3. Master in Surgery. 4. Bachelor in Surgery. 5. Master in Midwifery.

1. *Bachelor in Medicine.*—A candidate for the degree of Bachelor in Medicine must be a graduate in Arts, and may obtain the degree of Bachelor in Medicine at the same commencement as that at which he receives his degree of B A., or at any subsequent commencement, provided the requisite medical education shall have been completed. The medical education of a Bachelor in Medicine is of four years' duration, and comprises attendance on the following course of lectures, viz.:—Courses of five months' duration (November to April)—Anatomy, Practical Anatomy (with Dissections), Surgery, Chemistry, Practice of Medicine, Midwifery. Courses of three months' duration (April to July)—Botany, Practical Chemistry, Medical Jurisprudence, Materia Medica and Pharmacy, Institutes of Medicine.

Hospital Attendance.—1. Nine months' attendance on the clinical lectures of Sir Patrick Dun's Hospital. 2. Nine months' additional attendance on the clinical lectures of any hospital recognised by the Board. 3. Instruction in practical Midwifery, including not less than six deliveries. 4. Certificate of personal attendance on fever cases, stating name and date of each case.

Any of the above-named six or three months' courses may be attended at any medical school in Dublin recognised by the Provost and Senior Fellows (and three of them, at the discretion of the candidate, may be attended in the University of Edinburgh), provided the candidate has kept an *annus medicus* in the School of Physic.

The schools recognised are—1. The School of the Royal College of Surgeons in Ireland. 2. The Carmichael School. 3. The School of Dr. Steevens' Hospital. 4. The School of the Catholic University.

An *annus medicus*, or a year's attendance in the School of Physic, may be kept in three ways:—1. By attending at least two, or not more than three, of the foregoing courses which are of six months' duration. 2. By attending one course of six months' and two of three months' duration. 3. By nine months' attendance on Sir Patrick Dun's Hospital and clinical lectures; together with one course of six months', or, in lieu thereof, two courses of three months' duration.

The fee for nine months' attendance at Sir Patrick Dun's Hospital is £12 12s. The fee for each course of lectures is £3 3s. The fee for the *Liceat ad Examinandum* is £5. The fee for the degree of M.B. is £11.

2. *Doctor in Medicine.*—A Doctor in Medicine must be M.B. of at least three years' standing, or have been qualified to take the degree of M.B. for three years, and must perform exercises for the degree before the Regius Professor of Physic, in accordance with the rules and statutes of the University. Total amount of fees for this degree, £13.

3. *Master in Surgery.*—A Master in Surgery must be a Bachelor in Surgery of three years' standing, or have been qualified to take the degree of Bachelor in Surgery for three years; and must read a thesis publicly before the Regius Professor of Surgery, or undergo an examination before the Regius Professor, according to Regulations to be approved by the Provost and Senior Fellows. Fee for the Degree of Master in Surgery, £11.

Hospital attendance for three sessions, each of nine consecutive months' duration, in any recognised hospital, together with attendance on the clinical lectures on Medicine and Surgery there delivered, are required. Any of the above-named courses may be attended at any of the medical schools of Dublin recognised by the Board, provided the candidate has kept an *annus medicus* in the School of Physic. The following hospitals are recognised by the Board:—1, Sir Patrick Dun's School of Physic Hospital; 2, Meath Hospital; 3, Richmond, Whitworth, and Hardwicke Hospitals; 4, Dr. Steevens' Hospital; 5, Jervis-street Infirmary; 6, City of Dublin Hospital; 7, Mercer's Hospital; 8, St. Vincent's Hospital; 9, Adelaide Hospital; 10, Mater Misericordiæ Hospital. Of the courses of lectures which are of five months' duration, not more than three can be attended during any one session. Candidates will also be required to perform surgical operations on the dead subject. Candidates for the degree of Master in Surgery, who have already passed the examination for the degree of Bachelor of Medicine, will be examined in Anatomy and Surgery only. Fee for the *Liceat ad Examinandum*, £5. Fee for the degree of M.Ch., £11.

4. *Bachelor in Surgery.*—A Bachelor in Surgery must be a Bachelor in Arts, and have spent four years in the study of Surgery and Anatomy. He must also have passed the M.B. examination, before presenting himself at the B.Ch. examination, having previously completed the prescribed curriculum of study. The curriculum comprises the following, in addition to the complete course for the degree of Bachelor in Medicine:—Theoretical and Operative Surgery, one course; Dissections, two courses; Ophthalmic Surgery, one course. Candidates are required to perform surgical operations on the dead subject, and will also be examined in Bandaging and Minor Surgery, and in Surgical Pathology. Candidates for the degree of Bachelor in Surgery, who have already passed the examination for the degree of Bachelor in Medicine, will be examined in Anatomy and Surgery only. Fee for the *Liceat ad Examinandum*, £5. Fee for the degree of Bachelor in Surgery, £5.

5. *Master in Obstetric Science.*—A Master in Obstetric Science must have passed the M.B. and B.Ch. examinations, and produce certificates of having completed the following curriculum:—1. One winter course in Midwifery. 2. Six months' practice in a recognised lying-in hospital or maternity. 3. A summer course in Obstetric Medicine and Surgery. 4. Two months' practice in the Cow-pock Institution. Existing Graduates in Medicine, of the standing of M.D., are entitled to present themselves for examination, without complying with Regulations 3 and 4. Fee for the degree of Master in Obstetric Science, £5.

UNIVERSITY LICENCES.

Candidates for the licences in Medicine, Surgery, or Midwifery must be matriculated in Medicine, and must have completed four years in medical studies. Candidates for the licences in Medicine, Surgery, or Midwifery must pass the following examination in Arts, unless they be students in the Senior Freshman or some higher class:—Homer's Iliad, Books I., II. (omitting catalogue of ships), III.; Lucian's Dialogues (Walker's edition); Xenophon's Anabasis, Books I., II., III.; Virgil, Æneid, Books I., II., III.; Sallust; Horace, Satires; Latin Prose Composition; English Prose Composition; English History; Modern Geography; Arithmetic; Algebra to the end of Simple Equations; Euclid, Books I., II., III. Students who have passed the foregoing examination will be required to pay the admission fee of £15.

1. *Licentiate in Medicine.*—The medical course and examination necessary for the licence in Medicine are the same as for the degree of M.B., with the exception that any general hospital approved by the Board of Trinity College may be substituted for Sir Patrick Dun's. Candidates who are already Licentiates in Surgery of the Royal College of Surgeons in Ireland, or Members of the College of Surgeons of England, on passing the foregoing Arts examination, will be admitted to examination for the licence in Medicine. Fee for the *Liceat ad Examinandum*, £5. Fee for the licence in Medicine, £5.

2. *Licentiate in Surgery.*—The surgical course and examination necessary for the licence in Surgery are the same as for the degree of Bachelor in Surgery. Fee for the *Liceat ad Examinandum*, £5. Fee for the licence in Surgery, £5.

3. *Licence in Obstetric Science.*—The course and examination for the licence in Obstetric Science are the same as for the degree in Obstetric Science. Fee for the licence in Obstetric Science, £5.

Total Expenses of obtaining the Degrees of Bachelor in Medicine and Bachelor in Surgery.—I. Lectures: 1. Anatomy (one

course), £3 3s. 2. Practical Anatomy (three courses), £9 9s. 3. Dissections (three courses), £15 15s. 4. Surgery (two courses), £4 4s. 5. Practice of Medicine, £3 3s. 6. Chemistry (two courses), £4 4s. 7. Materia Medica and Pharmacy, £3 3s. 8. Midwifery, £3 3s. 9. Botany. 10. Medical Jurisprudence, £3 3s. 11. Institutes of Medicine, £3 3s. Matriculation fee, 5s. II. Hospitals: Sir P. Dun's (first year), £9 9s.; ditto (second year), £9 9s.; ditto (third year), £9 9s.; Practical Midwifery, £3 3s. Ophthalmic Surgery, £2 2s. III. Degrees: 1. *Licent ad Examinandum in Medicinâ*, £5. 2. *Licent ad Examinandum in Chirurgiâ*, £5. 3. M.B. degree, £11. 4. M.Ch. degree, £11. Total Expenses: 1. Lectures, £52 15s. 2. Hospitals, £33 12s. 3. Degrees, £32. Total, £118 7s.

N.B.—As no degrees in Medicine or Surgery are conferred except upon graduates in Arts, the expense of the degree of Bachelor in Arts, amounting altogether to £83 4s., should be added to the foregoing, making the total £281 11s.

---

10. QUEEN'S UNIVERSITY IN IRELAND.

This University confers the degrees of M.D. and M.Ch. Students who wish to obtain the degree of M.D. or of M.Ch. in the Queen's University must be matriculated students of one of the Queen's Colleges at Belfast, Cork, or Galway, and must pursue the courses of study prescribed by the Senate of the University.

Each candidate for the degree of Doctor in Medicine or Master in Surgery is required—1. To have passed in one of the Colleges of the Queen's University the entrance examination in Arts, and to have been admitted a matriculated student of the University. 2. To have attended in one of the Queen's Colleges lectures on one modern continental language for six months, and lectures on Natural Philosophy for six months. 3. To have also attended, in some one of the Queen's Colleges, at least two of the courses of lectures marked below with an asterisk. For the remainder of the courses, authenticated certificates will be received from the professors or lecturers in universities, colleges, or schools recognised by the Senate of the Queen's University in Ireland. 4. To pass the University examinations—the first and second University examinations, and the degree examination. The curriculum extends over at least four years, and is divided into periods of at least two years each. Candidates are recommended to pass the matriculation examination prior to entering on the second period. It is recommended that the first period shall comprise attendance on the following courses of medical lectures: —*Chemistry; *Botany, with Herborisations for practical study, and Zoology; *Anatomy and Physiology; *Practical Anatomy; *Materia Medica and Pharmacy. And that the second period shall comprise attendance on the following courses of medical lectures:—Anatomy and Physiology (second course), Practical Anatomy (second course), *Theory and Practice of Surgery, *Midwifery, *Theory and Practice of Medicine, *Medical Jurisprudence. In addition to the above courses of lectures, candidates shall have attended, during either the first or second period, a course of lectures on a modern continental language (in one of the colleges of the University), and Experimental Physics (in one of the colleges of the University). Also, during the first period—Practical Chemistry, (in a recognised laboratory), and medico-chirurgical hospital (recognised by the Senate) containing at least sixty beds, together with the clinical lectures therein delivered, at least two each week—a winter session of six months. And during the second period—Practical Midwifery, at a recognised midwifery hospital, with the clinical lectures therein delivered, for a period of three months in a hospital containing not less than thirty beds, or six months in a hospital containing not less than fifteen beds; medico-chirurgical hospital (recognised by the Senate) containing at least sixty beds, together with the clinical lectures therein delivered, eighteen months, including either three winter sessions of six months each, or two winter sessions of six months each, and two summer sessions of three months each. Medical examinations are held in June, and in September and October. The June examinations are pass examinations. Both honour and pass examinations are held in September. Each candidate for examination in June must forward to the Secretary, on or before June 1, notice of his intention to offer himself as a candidate, along with his certificates, and each candidate for examination in September must forward similar notice, along with his certificates, before September 1.

(B.) BODIES GIVING LICENCES OR OTHER FORMS OF QUALIFICATION NOT BEING DEGREES IN MEDICINE.

1. THE ROYAL COLLEGE OF PHYSICIANS, LONDON.

In the Royal College of Physicians there are three grades—Fellows, Members, and Licentiates. Of these the first is purely honorary, and so in a certain sense is the second. The third is that taken by the student on leaving his studies, and is valuable as being at once a qualification to practise Medicine, Surgery, and Midwifery, and is recognised by the Poor-law Board as a qualification in Surgery as well as in Medicine.

The College will, under its charter, grant licences to practise Physic, including therein the practice of Medicine, Surgery, and Midwifery (which licences are not to extend to make the Licentiates Members of the Corporation), to persons who shall conform to the following by-laws:—

Every candidate for the College licence (except when otherwise provided by the by-laws) is required to produce satisfactory evidence to the following effect:—

1. Of having attained the age of twenty-one years.
2. Of moral character.
3. Of having passed, before the commencement of professional study, an examination in the subjects of general education recognised by the College.
4. Of having been registered as a medical student in the manner prescribed by the General Medical Council. ["After October, 1870, every candidate (not exempted from registration) is required to have been registered at least four years previously."]
5. Of having been engaged in professional studies during four years, of which at least three winter sessions and two summer sessions shall have been passed at a recognised medical school or schools, and one winter session and two summer sessions in one or other of the following ways:—*a*. Attending the practice of a hospital or other institution recognised by the College for that purpose. *b*. Receiving instruction as the pupil of a legally qualified practitioner holding any public appointment which affords opportunities, satisfactory to the examiners, of imparting a practical knowledge of Medicine, Surgery, or Midwifery. *c*. Attending lectures on any of the required subjects of professional study at a recognised place of instruction. Professional studies commenced *before* the candidate shall have passed an examination in the subjects of general education will not be recognised by the College.
6. Of having attended, during three winter sessions and two summer sessions, the medical and surgical practice at a recognised hospital or hospitals, of having discharged the duties of clinical clerk at a recognised hospital for a period of not less than three months; of having performed the duties of dresser at a recognised hospital for a period of not less than three months; and of having been engaged during six months in the clinical study of Diseases peculiar to Women.
7. Of having studied the following subjects:—Anatomy (with dissections) during two winter sessions; Physiology during two winter sessions; Chemistry during six months; Practical Chemistry during three months; Materia Medica during three months; Practical Pharmacy during three months (by Practical Pharmacy is meant instruction in the laboratory of a registered medical practitioner, or of a member of the Pharmaceutical Society of Great Britain, or of a public hospital or dispensary recognised by the College); Botany during three months (this course of lectures may be attended prior to the commencement of professional studies; and any candidate producing satisfactory evidence that Botany formed one of the subjects of his preliminary examination will be exempt from attendance on this course); Morbid Anatomy during six months (this includes attendance and instruction in the post-mortem-room during the period of clinical study); Principles and Practice of Medicine during two winter sessions (it is required that the Principles of Public Health should be comprised in this course of lectures, or in the course of lectures on Forensic Medicine: the attendance on these lectures must not commence earlier than the second winter session at a recognised medical school); Principles and Practice of Surgery during two winter sessions (the attendance on these lectures must not commence earlier than the second winter session at a recognised medical school); Clinical Medicine during two winter sessions and two summer sessions (the attendance on these lectures must not commence until after the first winter session at a recognised medical school); Clinical Surgery during two winter sessions and two summer sessions (the attendance on these lectures must not commence until after the first winter session at a recognised medical school: by Clinical Medicine and Clinical Surgery are meant special study and instruction at the bedside, with lectures on cases); Midwifery and the Diseases peculiar to Women during three months (certificates must also be produced of attendance on not less than twenty labours, and of instruction and proficiency in vaccination); Forensic Medicine during three months.
8. Of having passed the professional examinations.

Any candidate who shall produce satisfactory evidence of having passed an examination on Anatomy and Physiology, conducted by any of the bodies named in Schedule (A) to the Medical Act, and recognised by the College as requiring a course of study and an examination satisfactory to the College, shall be exempt from re-examination on the subjects of the primary examination. Any candidate who shall have obtained a degree in Medicine at a university recognised by the College, after a course of study and an examination satisfactory to the College, shall be exempt from re-examination on the subjects of the primary examination. Any candidate who shall have obtained a degree in Surgery at a university

in the United Kingdom, after a course of study and an examination satisfactory to the College, shall be exempt from re-examination on Surgical Anatomy and on the Principles and Practice of Surgery. Any candidate who shall have passed the examination on Surgery conducted by the Royal College of Surgeons of England, or the Royal College of Surgeons of Edinburgh, or the Royal College of Surgeons in Ireland, after a course of study and an examination satisfactory to the College, shall be exempt from re-examination on Surgical Anatomy and on the Principles and Practice of Surgery. Any candidate being a "registered medical practitioner," whose qualification or qualifications shall have been obtained before January 1, 1861, having been with the consent of the College admitted a candidate for the licence, will be examined on the Principles and Practice of Medicine, Surgery, and Midwifery; but he will be exempted from such other parts of the professional examinations as his qualifications may seem to the examiners to render in his case unnecessary.

Licentiates of this College shall not compound or dispense medicines except for patients under their own care.

BY-LAWS AND REGULATIONS RELATING TO THE EXAMINATION FOR THE LICENCE.

Every candidate for the College licence, before he is admitted to examination, will be required to sign a declaration, stating that he has not been rejected within three months by any of the examining boards included in Schedule (A) to the Medical Act.

Any candidate who shall be rejected at the first examination will not be readmitted to examination until after the lapse of three months, and will be required to produce a certificate of the performance of dissections, or other professional study satisfactory to the examiners, during that time.

Any candidate who shall be rejected at the second or pass examination will not be readmitted to examination until after the lapse of six months, and will be required to produce a certificate of attendance on the practice of a recognised hospital, and also of attendance on clinical lectures, or other professional study satisfactory to the examiners, during that time.

The fee for the College licence is £15 15s., of which £5 5s. are to be paid on admission to the first examination, which fee will not be returned to any candidate rejected at this examination, but will be allowed in the fee for the licence, and he will be admitted to one subsequent first examiuation without the payment of an additional fee.

Any candidate who shall be rejected at the second or pass examination will have the fee paid on admission to this examination returned to him, less £3 3s.

---

2. THE ROYAL COLLEGE OF SURGEONS, ENGLAND.

By far the most important qualification in this country is that of the Royal College of Surgeons of England, inasmuch as almost all English and many Scottish and Irish students become candidates for the Membership of that body. The College consists of two grades—Fellows and Members. The Fellowship is partly honorary, being obtained by the election of Members of a certain standing, but is now only obtainable by examination. The Membership is the qualification sought by students leaving their hospitals, hence the importance of the following regulations:—

I. Professional studies prior to the date at which the candidate shall have passed an examination in general knowledge are not recognised.

II. The following will be considered as the commencement of professional education:—

1. Attendance on the practice of a hospital or other public institution recognised by this College for that purpose.
2. Instruction as the pupil of a legally qualified surgeon holding the appointment of surgeon to a hospital, general dispensary, or union workhouse, or where such opportunities of practical instruction are afforded as shall be satisfactory to the Council.
3. Attendance on lectures on Anatomy, Physiology, or Chemistry, by lecturers recognised by this College.

The commencement of professional study, otherwise than by attendance on lectures in recognised medical schools, or by attendance on the practice of recognised hospitals, will not be admitted until a certificate thereof shall be furnished to the Secretary for registration at the College by the practitioner whose pupil the candidate shall have become, or by the medical superintendent of the hospital or other institution to the practice of which he shall have entered, and will, consequently, date only from the reception of such certificate by the Secretary; the certificate to be accompanied by proof of having passed the necessary preliminary examination in general knowledge.

III. Candidates will be required to produce the following certificates, viz.:—

1. Of being twenty-one years of age.
2. Of having been engaged, subsequently to the date of passing the preliminary examination, during four years, or during a period extending over not less than four winter and four summer sessions, in the acquirement of professional knowledge.
3. Of having attended lectures on Anatomy during two winter sessions.
4. Of having performed Dissections during not less than two winter sessions.
5. Of having attended lectures on General Anatomy and Physiology during one winter session.
6. Of having attended a practical course of General Anatomy and Physiology during another winter or a summer session, consisting of not less than thirty meetings of the class.

Note A.—By the practical course referred to in Clause 6, it is meant that the learners themselves shall, individually, be engaged in the necessary experiments, manipulations, etc.; but it is not hereby intended that the learners shall perform vivisections.

7. Of having attended lectures on Surgery during one winter session.
8. Of having attended a course of Practical Surgery during a period occupying not less than six months prior or subsequent to the course required by the preceding Clause 7.

Note B.—The course of Practical Surgery referred to in Clause 8 is intended to embrace instruction in which each pupil shall be exercised in practical details, such as in the application of anatomical facts to surgery, on the living person, or on the dead body. The methods of proceeding and the manipulations necessary in order to detect the effects of diseases and accidents, on the living person, or on the dead body. The performance, where practicable, of the operations of surgery on the dead body. The use of surgical apparatus. The examination of diseased structures, as illustrated in the contents of a museum of morbid anatomy, and otherwise.

9. Of having attended one course of lectures on each of the following subjects, viz.:—Chemistry, Materia Medica, Medicine, Forensic Medicine, Midwifery (with practical instruction, and a certificate of having personally conducted not less than ten labours); Pathological Anatomy during not less than three months.

Note C.—The course of lectures on Chemistry included in Clause 9 will not be required in the case of a candidate who shall have passed a satisfactory examination in this subject in his preliminary examination.

10. Of having studied Practical Pharmacy during three months.
11. Of having attended a three months' course of Practical Chemistry (with manipulations), in its application to medical study.
12. Of instruction and proficiency in the practice of Vaccination.

Note D.—In the case of candidates who commenced their professional education on or after October 1, 1868, the certificate of instruction in Vaccination will only be received from recognised vaccine stations, or from recognised vaccine departments in medical schools or hospitals, or other public institutions, where the appointed teacher of vaccination is not liable to frequent change, and where ample means for study are provided by not less than such a number of cases (eight or ten on an average weekly) as may be found, after due inquiry, to be sufficient for this purpose at each place.

Note E.—The certificates of attendance on the several courses of lectures must include evidence that the student has attended the practical instructions and examinations of his teacher in each course.

13. Of having attended, at a recognised hospital or hospitals, the practice of Surgery during three winter(a) and two summer(b) sessions.
14. Of having been individually engaged, at least twice in each week, in the observation and examination of patients at a recognised hospital or hospitals, under the direction of a recognised teacher during not less than three months.

Note F.—It is intended that the candidate should receive the instruction required by Clause 14 at an early period of his attendance at the hospital.

15. Of having, subsequently to the first winter session of attendance on surgical hospital practice, attended, at a recognised hospital or hospitals, clinical lectures on Surgery during two winter and two summer sessions.
16. Of having been a dresser at a recognised hospital, or of having, subsequently to the completion of one year's professional education, taken charge of patients under the superintendence of a surgeon during not less than six months, at a hospital, general dispensary, or parochial or union infirmary recognised for this purpose, or in such other similar manner as, in the opinion of the Council, shall afford sufficient opportunity for the acquirement of Practical Surgery.
17. Of having attended, during the whole period of attendance on surgical hospital practice (see Clause 13), demonstrations in the post-mortem rooms of a recognised hospital.
18. Of having attended, at a recognised hospital or hospitals, the practice of Medicine, and clinical lectures on Medicine, during one winter and one summer session.

Notice.—Clauses 6, 8, 11, 14, and 17, and Notes A, B, C, E, and F, together with the courses of lectures on Forensic Medicine and Pathological Anatomy mentioned in Clause 9, are applicable to candidates who commenced their professional education on or after October 1, 1870.

N.B.—Blank forms of the required certificates may be obtained on application to the Secretary, and all necessary certificates will be retained at the College.

SECTION II.

I. Certificates will not be received on more than one branch of science from one and the same lecturer; but Anatomy and Dissections will be considered as one branch of science.

II. Certificates will not be recognised from any hospital in the United Kingdom unless the surgeons thereto be members of one of the legally constituted Colleges of Surgeons in the

(a) The winter session comprises a period of six months, and, in England, commences on October 1, and terminates on March 31.
(b) The summer session comprises a period of three months, and, in England, commences on May 1, and terminate on July 31.

United Kingdom; nor from any school of Anatomy and Physiology or Midwifery, unless the teachers in such school be members of some legally constituted College of Physicians or Surgeons in the United Kingdom; nor from any school of Surgery, unless the teachers in such school be members of one of the legally constituted Colleges of Surgeons in the United Kingdom.

III. No metropolitan hospital will be recognised by this College which contains less than 150, and no provincial or colonial hospital which contains less than 100 patients.

IV. The recognition of colonial hospitals and schools is governed by the same regulations, with respect to number of patients and to courses of lectures, as apply to the recognition of provincial hospitals and schools in England.

V. Certificates of attendance upon the practice of a recognised provincial or colonial hospital, unconnected with, or not in convenient proximity to, a recognised medical school, will not be received for more than one winter and one summer session of the hospital attendance required by the regulations of this College; and in such cases clinical lectures will not be necessary, but a certificate of having acted as dresser for a period of at least six months will be required.

VI.—Certificates will not be received from candidates who have studied in London, unless they shall have registered at the College their cards of admission to attendance on lectures and hospital practice within fifteen days from the commencement of the session; nor from candidates who have studied in the provincial schools in England, unless their names shall be duly returned from their respective schools.

N.B.—At their first registration in October, candidates will be required to produce a certificate of having passed one or other of the preliminary examinations in general knowledge recognised by this College.

VII. Those candidates who shall have pursued the whole of their studies in Scotland or Ireland will be admitted to examination upon the production of the several certificates required respectively by the College of Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, and the College of Surgeons in Ireland, from candidates for their diploma, together with a certificate of instruction and proficiency in the practice of vaccination, and satisfactory evidence of having been occupied, subsequently to the date of passing the preliminary examination, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge; and in the case of candidates who shall have pursued the whole of their studies at recognised foreign or colonial universities, upon the production of the several certificates required for their degree by the authorities of such universities, together with a certificate of instruction and proficiency in the practice of vaccination, and satisfactory evidence of having been occupied, subsequently to the date of passing the preliminary examination, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge.

VIII. Members or licentiates of any legally constituted College of Surgeons in the United Kingdom, and graduates in Surgery of any University recognised for this purpose by this College, will be admitted to examination on producing their diploma, licence, or degree, together with proof of being twenty-one years of age, a certificate of instruction and proficiency in the practice of vaccination, and satisfactory evidence of having been occupied, subsequently to the date of passing the preliminary examination, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge.

IX. Graduates in Medicine of any legally constituted College or University recognised for this purpose by this College will be admitted to examination on adducing, together with their diploma or degree, proof of being twenty-one years of age, a certificate of instruction and proficiency in the practice of vaccination, and satisfactory evidence of having been occupied, subsequently to the date of passing the preliminary examination, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge.

The following are regulations as to the examination for the qualification of Membership:—

The examination is divided into two parts.

1. The first, or primary examination, on Anatomy and Physiology, is partly written and partly demonstrative on the recently dissected subject, and on prepared parts of the human body.

2. The second, or pass examination, on Surgical Anatomy and the Principles and Practice of Surgery and Medicine,(c) is partly written, partly oral, and partly on the practical use of surgical apparatus, and the practical examination of patients.

3. The primary examinations are held in the months of January, April, May, July, and November, and the pass examinations generally in the ensuing week respectively.

4. Candidates will not be admitted to the primary examination until after the termination of the second winter session of their attendance at a recognised school or schools; nor to the pass, or surgical examination, until after the termination of the fourth year of their professional education.

5. The fee of £5 5s., paid prior to the primary examination, and allowed on the whole fee of £22(d) payable for the diploma, is retained; and after any two consecutive failures at the primary examination, the candidate is required to pay an *additional* fee of £5 5s prior to being again admitted to that examination, which *additional* fee is also retained.

6. Five guineas, part of the sum of £16 15s., the balance of the whole fee due for the diploma, and paid prior to the pass examination, is retained; and after any two consecutive failures at the pass examination, the candidate is required to pay an *additional* fee of £5 5s. prior to being again admitted to the said pass examination, which *additional* fee is also retained.

7. A candidate having entered his name for either the primary or pass examination, who shall fail to attend the meeting of the Court for which he shall have received a card, will not be allowed to present himself for examination within a period of three months from the date at which he shall have so failed to attend.

8. A candidate referred on the primary examination is required, prior to his admission to re-examination, to produce a certificate of the performance of dissections during not less than three months subsequently to the date of his reference.

9. A candidate referred on the pass examination is required, prior to his admission to re-examination, to produce a certificatate of at least six months' further attendance on the surgical practice of a recognised hospital, together with lectures on Clinical Surgery, subsequently to the date of his reference.

CERTIFICATE OF QUALIFICATION IN MIDWIFERY.

This College also, after due examination, grants a special certificate of qualification in Midwifery. This, however, though of great value to the possessor, cannot be registered, and is only granted to men otherwise qualified.

1. Persons who were Fellows or Members of the College prior to the first day of January, 1853, will be admitted to examination for the certificate of qualification in Midwifery upon producing their diploma.

2. Persons having become Members of the College subsequently to the first day of January, 1853, will be admitted to examination on producing their diploma, together with a certificate or certificates of having attended twenty labours.

3. Members or Licentiates of any legally constituted College of Surgeons in the United Kingdom, and graduates in Surgery of any University recognised for this purpose by this College, will also be admitted to examination on producing, together with their diploma, licence, or degree, proof of being twenty-one years of age; of having been occupied at least four entire years in the acquirement of professional knowledge; of having attended one course of lectures on Midwifery; and of having attended not less than twenty labours.

4. Graduates in Medicine of any legally constituted college or university recognised for this purpose by this College, will also be admitted to examination on producing, together with their diploma or degree, proof of being twenty-one years of age; of having been occupied at least four entire years in the acquirement of professional knowledge; of having completed at recognised schools the anatomical and surgical education required of candidates for the diploma of Member of the College; of having attended one course of lectures on Midwifery; and of having attended not less than twenty labours.

5. Persons having commeneed their professional education, either by attendance on hospital practice or on lectures on Anatomy, prior to the first day of January, 1853, will be admitted to examination on producing the several certificates of professional education required for admission to examination for the diploma of Member of this College at the period when such persons shall respectively have, in such manner, commenced their professional education.

6. Persons having commenced their professional education, either by attendance on hospital practice or on lectures on Anatomy, after the 31st day of December, 1852, will be admitted to examination on producing certificates of being twenty-one years of age; of having been engaged during at least four entire years in the acquirement of professional knowledge; of having completed at recognised schools the professional education required of candidates for the diploma of Member of this College; of having attended one course of lectures on Midwifery and the Diseases of Women and Children; and of having personally conducted thirty labours.

Note.—All candidates who commenced their professional education on or after October 1, 1866, will, in addition to the certificates enumerated in the foregoing clauses, be required to produce a certificate of having, prior to such commencement, passed a preliminary examination in general knowledge recognised by this College.

N.B.—The fee for the certificate is as follows, viz.:—1. Persons who were Fellows or Members of this College prior to January 1, 1853, £2 2s. 2. Persons admitted Fellows or Members of this College subsequently to

(c) Candidates can claim exemption from examination in Medicine under the following conditions, viz.:—(1.) The production by the candidate of a degree, diploma, or licence in Medicine entitling him to register under the Medical Act of 1858; or a degree, diploma, or licence in Medicine in a colonial or foreign university approved by the Council of the College. (2) A declaration by the candidate, prior to his admission to the final examination for Membership or Fellowship, that it is his intention to obtain either of the medical qualifications mentioned in the foregoing paragraph, in which case the diploma of the College will not be issued to him until he shall produce either the said medical qualification or proof of having passed the several examinations entitling him to receive the same.

(d) This sum of £22 is exclusive of the fee of £2 paid for the preliminary examination.

January 1, 1853, £3 3s. 3, 4. Persons producing any other diploma or certificate or degree which may be considered by the Council to afford satisfactory proof of sufficient surgical and medical education, £3 3s. 5, 6. All other persons, £10 10s.

3. SOCIETY OF APOTHECARIES (ENGLAND).

Every candidate for a certificate of qualification to practise as an apothecary will be required to produce testimonials—1. Of having passed a preliminary examination in Arts, as a test of general education. (This examination must be passed before the commencement of professional studies, which is defined by the Medical Council to be "the time of commencing studies at a medical school.") 2. Of having attained the full age of twenty-one years, of which satisfactory evidence will be required. 3. Of good moral conduct. 4. A certificate of three months' Practical Pharmacy from some recognised hospital or dispensary, or from a qualified medical practitioner. 5. Of having pursued a course of medical study in conformity with the regulations of the Court.

Course of Study.—Every candidate must attend the following lectures and medical practice during not less than three winter and two summer sessions (each winter session to consist of not less than six months, and to commence not sooner than the 1st nor later than the 15th of October; and each summer session to extend from May 1 to July 31):—

First Year.—Winter Session: Chemistry; Anatomy and Physiology; Dissections. Summer Session: Botany; Materia Medica and Therapeutics; Practical Chemistry.

Second Year.—Winter Session: Anatomy and Physiology, including dissections and demonstrations; Principles and Practice of Medicine; Clinical Medical Practice. Summer Session: Midwifery and Diseases of Women and Children, and Vaccination; (a) Forensic Medicine and Toxicology; Clinical Medical Practice.

Third Year.—Winter Session: Principles and Practice of Medicine; Clinical Medical Lectures; Morbid Anatomy; Clinical Medical Practice.

All medical students presenting themselves for the second examination shall produce evidence of having served the office of clinical clerk at a recognised hospital during the period of six weeks at least; and also shall produce evidence that they have been examined at the class examinations instituted by the various lecturers and professors of their respective medical schools and colleges.

In consequence of the registration of students being now conducted by the General Medical Council, students are informed that in future the registration at the Apothecaries' Hall will be discontinued. Students, however, will be expected to bring proof of the above registration on presenting themselves for examination.

Professional Examinations.—The Court of Examiners meet in the Hall every Wednesday and Thursday, where all candidates are required to attend at 4.30 p.m. each day. Every person intending to offer himself for examination must give notice in writing seven days previous to the day of examination, and must at the same time deposit all the required testimonials and the fee at the office of the Beadle, where attendance is given every day, except Sunday, from ten to four o'clock; Saturdays, ten to two.

The examination of candidates is divided into two parts, and is conducted partly in writing and partly *vivâ voce*.

The written and clinical examinations will take place on Wednesdays, and the *vivâ voce* examination on Thursdays.

The first examination, which may be passed after the second winter session, embraces the following subjects:—The British Pharmacopœia; Latin of Physicians' Prescriptions; Anatomy and Physiology; General and Practical Chemistry; Botany; and Materia Medica.

Second or pass examination, at the termination of the medical studies:—Principles and Practice of Medicine; Pathology; Therapeutics; Midwifery, including the Diseases of Women and Children; Forensic Medicine and Toxicology.

1. All graduates in Medicine of British universities will be admitted to a clinical and practical examination in the Practice of Medicine and Midwifery only.

2. Licentiates of the Royal College of Physicians, London; of the Royal College of Physicians, Edinburgh; of the Royal Colleges of Physicians and Surgeons, Edinburgh; of the King and Queen's College of Physicians, Ireland; of the Faculty of Physicians and Surgeons, Glasgow; and of the Apothecaries' Hall of Dublin, will be admitted to a clinical and practical examination in the Practice of Medicine, Midwifery, Forensic Medicine, and Toxicology.

3. Any candidate who has passed his first examination for the licence of the Royal College of Physicians, London; the licence of the King and Queen's College of Physicians, Ireland; the joint licence of the Royal College of Physicians and Surgeons, Edinburgh, or for the single licence of the College of Physicians, Edinburgh; the licence of the Faculty of Physicians and Surgeons, Glasgow; the first professional examination for the degree of M.B., or Master in Surgery, in the Universities of Oxford, Cambridge, Durham, or London; or the second part of the professional examination for the degree of M.B., or Master in Surgery, in the Universities of Edinburgh, Aberdeen, St. Andrews, and Glasgow; or the first examination for the medical or surgical degrees in the Irish universities; or the first examination for the licence of the Apothecaries' Company, Dublin, will be admitted to a single examination in Anatomy and Materia Medica (to those candidates who have not undergone an examination in those subjects), Practice of Medicine, Pathology, Therapeutics, Midwifery, Forensic Medicine, and Toxicology, part of which examination will be conducted in writing.

4. Members of the Royal College of Surgeons, England; Licentiates of the Royal College of Surgeons, Edinburgh; and Licentiates of the Royal College of Surgeons, Ireland; and all candidates who have passed the first Anatomical Examination of the Royal College of Surgeons, London; the Royal College of Surgeons, Edinburgh; the Royal College of Surgeons, Ireland, are exempt from *writing* on Anatomy and Physiology *only* in their first examination.

All qualified candidates, unless registered, will be required to produce their diploma.

5. Candidates who were apprenticed before August 1, 1858, and those students who commenced their hospital attendance on or before October 1, 1860, will be admitted to a *vivâ voce* examination on the following subjects:—In translating physicians' prescriptions; in such parts of Chemistry and Materia Medica as bear upon the Practice of Medicine, and on Toxicology; in Forensic Medicine, Visceral Anatomy, the Practice of Medicine, including Diseases of Women and Children; and in Midwifery.

The examination of candidates for certificates of qualification to act as Assistant in compounding and dispensing medicines will be as follows:—In translating physicians' prescriptions; in the British Pharmacopœia; in Pharmacy, Pharmaceutical Chemistry, Materia Medica, and Medical Botany.

No rejected candidate for the licence can be re-examined until the expiration of six months from his former examination. A candidate rejected on his first professional examination can be admitted to re-examination until after the expiration of three months. No rejected candidate as an Assistant can be re-examined until the expiration of three months.

Fees.—For a certificate of qualification to practise, £6 6s., half of which is retained in case of rejection, to be accounted for at a subsequent examination. For the first examination, £3 3s.; for an Assistant's certificate, £2 2s.; both of which sums are retained in case of rejection, and accounted for subsequently.

Students' Prizes.—The Society of Apothecaries annually offer two prizes for efficiency in the knowledge of Botany, and also two prizes for proficiency in the knowledge of Materia Medica and Pharmaceutical Chemistry. The prizes consist of a gold medal awarded to the candidate who distinguishes himself the most in the examination; and of a silver medal and a book to the candidate who does so in the next degree.

The examination in Botany will be held at the Hall of the Society on the third Thursday in June, at 10 a.m., and will be conducted by printed papers and *vivâ voce* questions.

The examinations in Materia Medica and Pharmaceutical Chemistry will be held at the Hall of the Socciety on the third Wednesday in August, at 10 a.m., and will be conducted by printed papers and *vivâ voce* questions.

The Society's Botanic Garden at Chelsea is open daily (except Sunday), from ten to five. Cards of admission may be had at the Beadle's Office, Apothecaries' Hall, Blackfriars, E.C.

Examination in Arts.—An examination in Arts will take place at the Hall, three times a year—viz., on the last Friday

(a) In compliance with a request from the General Medical Council of Education, the Court of Examiners of the Society of Apothecaries of London require that in future all pupils applying for their certificate of qualification to practise shall be instructed and furnished with certificates of proficiency in vaccination by gentlemen holding appointments in conformity with the regulations of the Local Government Board, Whitehall.

and Saturday in the months of January, April, and September. The fee for the examination is one guinea; and this must be paid at least *one week* before the day of examination. If a candidate fail to pass the examination, the fee will not be returned to him, but he will be admissible to either, or to both, of the two next following examinations without payment of an additional fee, upon giving at least one week's notice.

To prevent the necessity of candidates who are desirous of entering to the Preliminary Examination in Arts of attending personally to sign their names, and also for the purpose of identification, the following notice must be written by the candidate, in the presence of a magistrate, clergyman, or a registered medical practitioner, and sent to Mr. Sargeant, at the Apothecaries' Hall, with the fee, at least *one week* before the day of such examination:—

(*This Form of Notice to be copied and written in full by the Candidate.*)

I, _____,
residing at _____,
intend to present myself for the Preliminary Examination in Arts at the Apothecaries' Hall, London, on the _____,
and that I intend to take _____ as my optional subject.

Signature _____

The above has been written and signed in my presence by the above-named candidate, with whom I am personally acquainted.

Date _____

Certificates in Arts granted by any of the bodies whose certificate is recognised by the Medical Council, will be accepted from candidates who present themselves at the professional examination at the Hall, as equivalent to their having passed the above examination.

In Scotland, besides the Universities, there are three licensing bodies, viz.:—

4. ROYAL COLLEGE OF PHYSICIANS, EDINBURGH;
5. ROYAL COLLEGE OF SURGEONS, EDINBURGH;
6. FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

The first alone can give a qualification in Medicine; the two latter can give only a surgical qualification. Each of the surgical bodies has, however, most sensibly joined with the College of Physicians, so that a candidate can, by a single set of examinations, acquire a qualification both in Medicine and Surgery. For this reason, and as the greater must include the less, we shall only give the rules applying to these conjoint examinations. These are so nearly identical, that one set of regulations will suffice.

The Royal College of Physicians and the Royal College of Surgeons, Edinburgh, and the Royal College of Physicians of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, while they continue to give their diplomas separately under separate regulations, have made arrangements by which, after one series of examinations, the student may obtain two separate licences—one in Medicine, and one in Surgery.

The general principle of this joint examination is, that it is conducted by a board in which each body is represented, the object being to give to students facilities for obtaining from two separate bodies, and at less expense, a double qualification in Medicine and in Surgery. Students passing these examinations successfully will be enabled to register two qualifications under the Medical Act—viz., Licentiate of the Royal College of Physicians and Licentiate of the Royal College of Surgeons, Edinburgh; and Licentiate of the Royal College of Physicians of Edinburgh and Licentiate of the Faculty of Physicians and Surgeons of Glasgow.

Candidates for these qualifications commencing professional study on or after October 1, 1866, must have been engaged in professional study during four years, and in actual attendance at a university or recognised school of medicine during not less than four winter sessions or three winter sessions and two summer sessions, and must have completed the following curriculum:—

1. Anatomy, two courses of lectures in distinct sessions, six months each.
2. Practical Anatomy, twelve months.
3. Chemistry, one course of lectures, six months.
4. Practical or Analytical Chemistry, one course of lectures, three months.
5. Physiology, not less than fifty lectures.
6. Practice of Medicine, one course of lectures, six months.
7. Clinical Medicine, extending to six months.
8. Another course of Practice of Medicine, or of Clinical Medicine, at the option of the candidate.
9. Principles and Practice of Surgery, one course of lectures, six months.
10. Clinical Surgery extending to six months.
11. Another course of Surgery, or of Clinical Surgery, at the option of the candidate.
12. Materia Medica, one course of lectures, three months.
13. Midwifery, one course of lectures, three months.
14. Practical Midwifery, attendance on at least six cases of labour.
15. Medical Jurisprudence, one course of lectures, three months.
16. Pathological Anatomy, instruction in the post-mortem rooms of a recognised hospital, three months.
17. Practical Pharmacy, instruction, three months.
18. General Hospital, attendance on the practice of a public general hospital, containing on an average not less than eighty patients, twenty-four months.
19. Proficiency in Vaccination, certified by a public vaccinator or a registered practitioner.

[Attendance for six months on the practice of a public dispensary, or certificate of having been engaged for six months as visiting assistant to a registered practitioner.—Edinburgh.]

Students are strongly recommended to avail themselves of any opportunities they may possess of studying Ophthalmic and Mental Diseases, Natural History, Comparative Anatomy, and Practical Physiology, in addition to what is required in the curriculum.

The examinations are conducted partly in writing and partly orally. Recent dissections, anatomical specimens, chemical tests, articles of the materia medica, the microscope, surgical and obstetrical apparatus, and pathological specimens, are employed at the discretion of the examiners. Candidates at the second examination are subjected in the hospital to a practical clinical examination in Medicine and Surgery.

Candidates for the double qualification who have passed the examination in Anatomy, Physiology, and Chemistry of one or other of the licensing bodies enumerated in Schedule (A) of the Medical Act, on complying with the regulations in other respects, are admissible to the second professional examination. No candidate is exempted from examination in any of the subjects of the second examination.

A candidate, on showing a sufficient reason, may be admitted to examination on a day specially arranged, on paying an extra fee of £5 (£7 7s., Glasgow), which will not be returned in the event of his being remitted to his studies.

---

7. KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

This body consists of Fellows and Licentiates. The regulations relating to the latter are as follows:—Candidates must produce—1. Evidence of having been engaged in the study of Medicine for four years. 2. A certificate of having passed the preliminary examination of one of the recognised licensing corporations before the termination of the second year of medical study. 3. Certificates of having studied at a school or schools recognised by the College, the following subjects, viz.:—Practical Anatomy; Anatomy and Physiology, or Institutes of Medicine; Botany; Chemistry; Practical Chemistry; Materia Medica; Practice of Medicine and Pathology; Surgery; Midwifery; Medical Jurisprudence. 4. Certificates of having attended a medico-chirurgical hospital in which regular courses of clinical lectures are delivered, together with clinical instruction, for twenty-seven months; or such hospital for eighteen months with nine months' attendance on a medical hospital, and similar courses of clinical lectures and instructions. 5. A certificate of having attended Practical Midwifery for six months at a recognised lying-in hospital, or evidence satisfactory to the College in each individual case of having attended Practical Midwifery. 6. Certificates of character from two registered physicians or surgeons.

A candidate who has already obtained a medical or surgical qualification recognised by the College is only required to

produce his diploma or certificate of registration, a certificate of Practical Midwifery, and testimonials as to character.

EXAMINATION FOR THE LICENCE IN MEDICINE.

The examination consists of two parts. The subjects of the first part, or previous examination, are—Anatomy, Physiology, Botany, Chemistry. The subjects of the second part, or final examination, are—Materia Medica, Practice of Medicine, Medical Jurisprudence, Midwifery.

All candidates for the second or final examination (with the exception below specified) (a) are examined in the Practice of Medicine at the bedside in one of the hospitals of Dublin, and afterwards in the College by means of printed questions and orally in the four subjects of examination.

Candidates qualified as follows are required to undergo the *second part* of the professional examination *only*, viz.:—1. Graduates in Medicine of a university in the United Kingdom, or of any foreign university approved by the College. 2. Fellows, Members, or Licentiates of the Royal College of Physicians of London or Edinburgh, who have been admitted upon examination. 3. Graduates or Licentiates in Surgery. 4. Candidates who, having completed the curriculum above mentioned, have passed the previous examination of any of the licensing corporations in the United Kingdom.

DIPLOMA IN MIDWIFERY.

Candidates already qualified in Medicine or Surgery may apply for permission to be examined for the diploma in Midwifery. The certificates required to be lodged are the same as those required from *qualified* candidates for the licence to practise Medicine.

Fees.—Fee for the licence in Medicine, £15 15s. Fee for licence in Medicine and diploma in Midwifery (for which latter there is a separate examination), if taken out within an interval of a month, £16. Fee for the diploma in Midwifery, £3 3s.

The election for Fellowship takes place twice a year, viz., on the first Friday in April and on St. Luke's Day (October 18). Candidates must be proposed and seconded three months previously.

RULES AND REGULATIONS RESPECTING FEMALE CANDIDATES FOR EXAMINATION FOR A LICENCE TO PRACTISE AS MIDWIVES AND NURSE-TENDERS.

Qualifications.—Age not less than twenty-one years; certificates of character.

Preliminary Examination.—Reading, writing, and arithmetic.

Course of Instruction.—Six months' attendance on systematic lectures on Midwifery, and not less than six months' attendance on bedside instruction in a lying-in hospital or maternity recognised by the College.

Subjects for the Examinations.—Midwifery (not including operations) and Nurse-tending.

Examination fee, £1 1s.

---

8. THE ROYAL COLLEGE OF SURGEONS, IRELAND.

This body grants two qualifications—that of Fellow, and Letters Testimonial equivalent to a Licentiateship. The regulations relating to the latter are as follows:—

Candidates for the Letters Testimonial of the College may present themselves either at a Special or at a Stated Examination, as follows:—

SPECIAL EXAMINATIONS.

Every registered pupil shall be admitted, upon payment of a special fee of £5 5s., to a Special Examination for Letters Testimonial, if he shall have laid before the Council the following documents:—

a. A receipt showing that he has lodged, in addition to his registration and special fees, a sum of £21 in the Bank of Ireland, to the credit of the President, and for the use of the College.

b. A certificate that he has passed a preliminary examination, conducted by a board recognised by the General Medical Council, into the curriculum of which the Greek language enters as a compulsory subject.

c. A certificate showing that he has been engaged in the study of his profession for not less than four years.

d. Certificates of attendance during three years on a hospital recognised by the Council, where clinical instruction is given.

e. Certificates of attendance on three courses of lectures on Anatomy and Physiology; three courses of lectures on the Theory and Practice of Surgery; and of the performance of three courses of Dissections, accompanied by demonstrations; also certificates of attendance on two courses of lectures on Chemistry, or one course of lectures on General and one on Practical Chemistry; one course of lectures on Materia Medica; one course of lectures on the Practice of Medicine; one course of lectures on Midwifery; one course of lectures on Medical Jurisprudence; and one course of lectures on Botany.

N.B.—The subjects for examination, and the mode of carrying these out, for a Special Examination, will be the same as those hereinafter laid down for the Stated Examinations, and any rejected candidate will only be entitled to receive back £15 15s. of the fees lodged by him.

STATED EXAMINATIONS.

1st. Stated Examinations shall be held in the months of April, July, and November, commencing on dates of which due notice shall be given beforehand by the Council of the College, and to which *candidates cannot be admitted unless they be registered pupils*, and at which they shall be divided into two classes—Junior and Senior.

2nd. The Junior Class shall produce certificates of having passed a preliminary examination conducted by a board recognised by the General Medical Council, into the curriculum of which the Greek language enters as a compulsory subject; and of having attended three courses of lectures on Anatomy and Physiology; three courses of lectures on Practical Anatomy, with dissections; two courses of lectures on Chemistry; one course of lectures on Materia Medica; one course of lectures on Botany; and one course of lectures on Forensic Medicine.

3rd. This class shall be examined in Anatomy, Histology, Physiology, Materia Medica, and Chemistry.

4th. The fee for this examination shall be £5 5s., in addition to the registration fee of £5 5s.—not to be returned in case of rejection, but to be allowed the candidate in case he presents himself a second time for examination.

5th. The Senior Class shall produce certificates of having attended three courses of lectures on the Theory and Practice of Surgery, one course of lectures on the Practice of Medicine, and one course of lectures on Midwifery; also certificates of attendance on a recognised hospital for three winter and three summer sessions.

6th. This class shall be examined in Surgery, Operative Surgery and Surgical Appliances, Practice of Medicine, Medical Jurisprudence, and Prescriptions.

7th. The fee for the Senior Class Examination shall be £15 15s., returnable to the candidate in case of rejection.

8th. Both of these examinations shall be conducted partly by written and partly by oral questions.

9th. In addition to the foregoing fees, a fee of £1 1s. is to be paid to the Registrar on handing each licentiate his diploma.

10th. Every candidate rejected at any of the Stated Examinations, on applying for re-examination, shall be required to pay to the College, in addition to the regular fees, the sum of £2 2s. to reimburse the College the necessary expense of his re-examination.

This body also grants a diploma in Midwifery, for which the following are the regulations:—

Qualifications of Candidates for the Diploma in Midwifery.—Any Fellow or Licentiate of the College shall be admitted to an examination for the diploma in Midwifery upon laying before the Council the following documents:—*a.* A certificate showing that he has attended one course of lectures on Midwifery and Diseases of Women and Children, delivered by a professor or lecturer in some School of Medicine or Surgery recognised by the Council. *b.* A certificate showing that he has attended, during a period of six months, the practice of a lying-in hospital recognised by the Council; or the practice of a dispensary for lying-in women and children recognised by the Council and devoted to this branch of Surgery alone. *c.* A certificate showing that he has conducted thirty labour cases, at least.

Fees to be paid by Candidates for the Diploma in Midwifery.—The candidate pays £1 6s. for the Midwifery diploma, provided he takes it out within one month from the date of his letters testimonial; after that date the fee will be £2 2s.

---

9. THE APOTHECARIES' HALL OF IRELAND.

This body grants a licence to practise, on the following conditions:—

1. Of having passed an examination in Arts previously to entering on professional study.

2. Of being at least twenty-one years of age, and of good moral character.

3. Of pupilage to a qualified apothecary, or of having been otherwise engaged in practical pharmacy for a period of

(a) Candidates who are physicians or surgeons of five years' standing are exempted from the clinical and written portions of the final examination.

twelve months subsequent to having passed the examination in Arts.

4. Of having spent four years in professional study.

5. Of having attended the following courses, viz.:—Chemistry, during one winter session; Anatomy and Physiology, during two winter sessions; Demonstrations and Dissections, during two winter sessions; Botany and Natural History, during one summer session; Practical Chemistry (in a recognised laboratory), during three months; Materia Medica, during three months; Principles and Practice of Medicine and Therapeutics, during one winter session; Midwifery and Diseases of Women and Children, during six months; Practical Midwifery at a recognised hospital (attendance upon twenty cases); Surgery, during one winter session; Forensic Medicine, during one summer session; instruction in the practice of Vaccination.

6. Of having attended, at a recognised hospital or hospitals, the practice of Medicine and clinical lectures on Medicine, during two winter and two summer sessions; also the practice of Surgery and clinical lectures on Surgery, during one winter and one summer session.

7. Of practical study, with care of patients, as apprentice, pupil, assistant, clinical clerk, or dresser, in hospital, dispensary, or with a registered practitioner.

8. Of having performed the operation of vaccination successfully under a recognised vaccinator.

The examination for the licence to practise is divided into two parts:—The first part comprehends Chemistry, Botany, Anatomy, Physiology, Materia Medica, and Pharmacy; the second—Medicine, Surgery, Pathology, Therapeutics, Midwifery, Forensic Medicine, and Hygiene.

The professional examinations will be held quarterly, and will commence on the first and second Mondays in the months of January, April, July, and October.

THE HIGHER QUALIFICATIONS.

Besides the ordinary qualifications available to students who have just finished their curriculum, there are certain higher grades attainable after a certain period. Thus, at the Universities the student first graduates M.B., and after certain years, with or without a special examination, proceeds to the degree of M.D. At the Royal College of Physicians, in the same manner, with or without the Licentiateship, one may proceed to take the Membership of the College; but this is rarely done save by those who desire to practise what is called "pure" Medicine. It is by the rules of most institutions a necessary qualification for one desiring the post of Physician. The reason of this limitation is that the by-laws of the College impose such restrictions on its Members that it is hardly possible for them to practise as general practitioners. Again at the College of Surgeons, those who have obtained the qualification of M.R.C.S.E. may, after certain special study, to which we need not here further refer, present themselves for examination for the Fellowship. This stands in the same relationship to the surgical branch of our profession as does the Membership of the Royal College of Physicians to the purely medical; but, inasmuch as the restrictions are less onerous, it is also possessed by many general practitioners. These, however, are not Student-qualifications, and consequently the rules and regulations relating to them are here omitted.

THE SELECTION OF A SCHOOL.

ENTRANCE SCHOLARSHIPS.

The pupil or his friends having determined in their own minds the body whose qualification is to be sought, and the consequent curriculum to be followed, the next thing is to seek the means of following out this curriculum, and of obtaining the knowledge necessary for the acquisition of the diploma. This is commonly a simple enough matter, for if a student desires to obtain the degree of M.B. Edinburgh, he naturally enters himself as a student in the University. In London it is otherwise. Here we would advise all who desire an ordinary qualification in Medicine and Surgery to look forward to those offered by the Royal Colleges of Physicians and Surgeons. The licence of the Apothecaries' Society is in many ways useful, but it does not possess the same high character as that given by the Royal College of Physicians. The curricula of the English schools are specially adapted to the regulations of these bodies, and hence there is no difficulty in obtaining what the student wants. The difficulty to be solved is, where to get it of the best quality. In other words, the student or his friends have to select one of the eleven metropolitan or of the provincial schools in which to pursue his studies. This, in many instances, is settled simply as a matter of convenience; the youth's residence, or that of some of his friends, may make them select the nearest school, be it great or small. But when neither this nor any other reason is operative, the selection of a school often becomes a somewhat difficult matter. Above all, there is the old difficulty of a large school or a small. The largest schools are St. Bartholomew's, Guy's, and University College; the first two having at the same time the largest hospitals, with the exception, perhaps, of St. Thomas's, in London; but, on the other hand, University College Hospital is one of the smallest. This very effectually deals with the idea that the success of a school exactly corresponds to the size of the hospital with which it is associated. The truth is, that the size of the hospital does not matter greatly. It is quite impossible for any one student to attend upon the whole practice of even a small hospital with advantage. A physician or surgeon finds that the number of beds he can use with advantage to himself and others is very limited; and still more is this the case with the student. Again, as regards class-work, there can be no doubt that with a large body of young men enthusiasm is highly contagious; but so, too, is indifference; and as regards tutorial work there can be no question of the superiority of a small class over a large one. The place to select—for all the recognised hospitals are large enough—is where the teachers are active and enthusiastic, and have got their way to make in the world, whose success must in great measure depend on the success of their school. University College is a good example of what may be done in this way, for the teachers there have by such means raised their numbers to a height which is hardly manageable in so small a hospital.

The following is a list of Entrance Scholarships given at the various London hospitals:—

St. Bartholomew's Hospital.—Two open Scholarships in Science, £100 for one year. Subjects: Physics, Chemistry, Botany, and Zoology. Also £50 for newly entered students in October. Preliminary education.

Charing-cross Hospital.—Two Entrance Scholarships, £30 and £20. Subjects—Compulsory: English, Latin, French or German, Mathematics; Optional (one only may be selected): Chemistry, Mechanics, German or French. The subjects and authors will be the same as those chosen for the London matriculation of the preceding June.

Guy's Hospital.—Two of £100—one in preliminary education, the other in science.

King's College.—Four Warneford Scholarships of £25—two for three years, two for two; Divinity, Classics, Mathematics, History (English), Chemistry, Botany, and Natural Philosophy.

London Hospital.—Two Entrance Science Scholarships, £60 and £40. Two Buxton Scholarships, £30 and £20. Preliminary education.

St. Mary's Hospital.—One Entrance Scholarship, £120; one Exhibition, £20. Natural Science.

St. Thomas's Hospital. — Two (£60 and £40) Entrance Science Scholarships. Subjects the same as for the Preliminary Scientific Examination of the University of London.

Middlesex Hospital.—Two Entrance Scholarships, £25 and £20, tenable for two years.

University College.—Three Entrance Scholarships, £30, £20, and £10, tenable for two years. Preliminary education.

Westminster Hospital.—Four Entrance Scholarships—two of £50 for two years, and two of £10 for one year. Latin, Mathematics, French or German, and Physics and Chemistry.

LONDON HOSPITALS AND MEDICAL SCHOOLS.

ST. BARTHOLOMEW'S HOSPITAL.

MEDICAL AND SURGICAL STAFF.

Consulting Physicians.

Sir G. Burrows, Bart., D.C.L., F.R.S., Dr. Farre, Dr. Harris, Dr. Martin.

Consulting Surgeon—Sir J. Paget, Bart., D.C.L., F.R.S.

Physicians.
Dr. Black.
Dr. Andrew.
Dr. Southey.
Dr. Church.

Assistant-Physicians.
Dr. Gee.
Dr. Duckworth.
Dr. Hensley.
Dr. Brunton, F.R.S.

Physician-Accoucheur.
Dr. Greenhalgh.

Assistant Physician-Accoucheur.
Dr. Godson.

Surgeons.
Mr. Holden.
Mr. Savory, F.R.S.
Mr. Callender, F.R.S.
Mr. Thomas Smith.

Assistant-Surgeons.
Mr. Willett.
Mr Langton.
Mr. Morraut Baker.
Mr. Marsh.

Ophthalmic Surgeons.
Mr. Power.
Mr. Vernon.

Casualty Physicians—Dr. Wickham Legg, Dr. Bridges, Dr. Champneys.
Dental Surgeon—Mr. Coleman.
Administrator of Chloroform—Mr. Mills.
Medical Registrar—Dr. Champneys.
Surgical Registrars—Mr. Butlin, Mr. Macready.

LECTURES.

Botany—Rev. George Henslow.
Chemistry and Practical Chemistry—Dr. Russell.
Clinical Medicine—Dr. Black, Dr. Andrew, Dr. Southey, and Dr. Church.
Clinical Surgery—Mr. Holden, Mr. Savory, Mr. Callender, Mr. Thos. Smith.
Comparative Anatomy—Dr. Moore.
Dental Anatomy and Surgery—Mr. Coleman.
Descriptive and Surgical Anatomy—Mr. T. Smith and Mr. Langton.
Forensic Medicine and Hygiene—Dr. Southey.
General Anatomy and Physiology—Mr. Morrant Baker.
Histology—Dr. Klein.
Materia Medica—Dr. Brunton.
Medicine — Dr. Black and Dr. Andrew.
Mental Diseases—Dr. Claye Shaw.
Midwifery and the Diseases of Women and Children—Dr. Greenhalgh.
Ophthalmic Medicine and Surgery—Mr. Power.
Pathological Anatomy—Dr. Gee.
Surgery—Mr. Savory and Mr. Callender.

DEMONSTRATIONS.

Diseases of the Ear—Mr. Langton.
Diseases of the Eye—Mr. Vernon.
Diseases of the Skin—Mr. Baker.
Mechanical and Natural Philosophy—Mr. Graham.
Morbid Anatomy—Dr. W. Legg.
Orthopædic Surgery—Mr Willett.
Practical Anatomy and Operative Surgery—Mr. Cumberbatch, and Mr. Walsham.
Practical Physiology—Dr. Shuter.
Practical Surgery—Mr. Marsh.

Medical Tutor—Dr. Moore.

This Hospital comprises a service of 710 beds, of which 676 are in the Hospital in Smithfield, and 34 are for convalescent patients at Lauderdale House, Highgate.

SCHOLARSHIPS AND PRIZES.

The following scholarships and prizes are awarded:—Open Scholarships in Science, founded 1873; subjects of examination—Physics, Chemistry, Botany, and Zoology. These scholarships, of the value of £100 each, tenable for one year, will be competed for on September 26 and following days. Preliminary Scientific Exhibition, founded 1873; subjects of examination—Physics, Chemistry, Botany, and Zoology. This Exhibition, of the value of £50, is awarded in October. Lawrence Scholarship and Gold Medal, of the value of £80, founded in 1873 by the family of the late Sir W. Lawrence. Brackenbury Scholarship in Medicine, and Brackenbury Scholarship in Surgery, founded in 1873 by the will of the late Miss Hannah Brackenbury, who left £2000 for this purpose. Senior Scholarship of the value of £50—Anatomy, Physiology, and Chemistry. Junior Scholarships of the value of £50, £30, and £20 are awarded after an examination in the subjects of study of the first year at the end of the summer and winter sessions. The Jeaffreson Exhibition, of the value of £20, and tenable for two years, is awarded at the commencement of each winter session to the student who passes the best examination in the subjects of preliminary education. The Wix Prize is awarded for the best essay on the following subject—"The Life and Works of Dr. Heberden." Hichens Prize: subject of examination—Bishop Butler's Analogy. Bentley Prize, for the best report of surgical cases occurring in the wards of the Hospital during the previous year. It is expected that the reports will comprise the histories, progress, treatment, and results of not less than twelve cases, with observations thereupon. Foster Prize: subject of examination—Practical Anatomy; senior. Treasurer's Prize: subject of examination—Practical Anatomy; junior. The Kirkes Gold Medal: subject of examination—Clinical Medicine.

FEES.

Whole fee for attendance on lectures and hospital practice £110 5s., payable by instalments, or a single payment of £105. Payment in either of these ways entitles to a perpetual ticket.

A College for resident students exists in connexion with the Hospital; Resident Warden, Dr. Norman Moore, from whom students will obtain information respecting rooms in the College, or will be advised regarding residence out of the Hospital.

All communications to be addressed to the Warden of the College, St. Bartholomew's Hospital.

CHARING-CROSS HOSPITAL.

MEDICAL AND SURGICAL STAFF.

Consulting Surgeon—Mr. H. Hancock, F.R.C.S.

Physicians.
Dr. A. J. Pollock.
Dr. A. Silver.
Dr. T. H. Green.

Assistant-Physicians.
Dr. J. Mitchell Bruce.
Dr. J. Pearson Irvine.
Dr. T. Barlow.
Dr. David B. Lees.

Physician Accoucheur.
Dr. J. Watt Black.

Physician for Skin Diseases.
Mr. A. Sangster.

Medical Registrar.
Dr. W. B. Houghton.

Surgeons.
Mr. E. Canton.
Mr. F. Hird.
Mr. R. Barwell.

Assistant-Surgeons.
Mr. E. Bellamy.
Mr. J. Astley Bloxam.
Mr. R. J. Godlee.

Dental Surgeon.
Mr. John Fairbank.

Chloroformists.
Mr. Woodhouse Braine.
Mr. G. H. Bailey.

Surgical Registrar.
Mr. James Cantlie.

LECTURERS AND TEACHERS.

Anatomy—Mr. Edward Bellamy.
Bandaging, etc.—Mr. R. J. Godlee.
Botany—Rev. J. C. Saunders.
Chemistry & Practical Chemistry—Mr. C. W. Heaton; Demonstrator, Mr. T. Bolass.
Clinical Medicine—Dr. Alexander Silver.
Clinical Surgery—Mr. H. Hancock.
Comparative Anatomy—Dr. J. F. Blake.
Demonstrations and Dissections—Mr. James Cantlie.
Dental Surgery — Mr. John Fairbank.
Diseases of Children—Dr. T. Barlow.
Forensic Medicine—Dr. J. Pearson Irvine.
Materia Medica and Therapeutics—Dr. J. Mitchell Bruce.
Mental Diseases — Dr. L. Forbes Winslow.
Morbid Histology—Mr. Jas. Cantlie.
Operative Surgery — Mr. Edward Bellamy.
Pathology and Morbid Anatomy—Dr. T. Henry Green.
Physiology, Theoretical and Practical—Dr. Alexander Silver and Dr. Mitchell Bruce.
Practical Chemistry—Mr. C. W. Heaton; Demonstrator—Mr. A. H. Hooker.
Principles and Practice of Medicine—Dr. A. J. Pollock.
Principles and Practice of Midwifery and Diseases of Women—Dr. J. Watt Black.
Principles and Practice of Surgery—Mr. Edwin Canton.
Public Health — Dr. J. Pearson Irvine, Mr. W. Heaton, and Mr. W. Eassie.
Skin Diseases—Mr. A. Sangster.
Surgical Pathology—Mr. J. Astley Bloxam.

SCHOLARSHIPS, MEDALS, AND PRIZES.

Two Entrance Scholarships, of the value of £30 and £20 respectively, tenable for one year, will be awarded annually in October, after a competitive examination in the following subjects:—Compulsory: English, Latin, French or German, Mathematics. Optional (only one of which may be selected): Chemistry, Mechanics, German or French. The subjects (as regards extent and the authors selected) will be the same as those chosen for the Matriculation Examination of the University of London in the June immediately preceding. Candidates must give notice of their intention to compete on or before Saturday, September 22, 1877. The successful candidates will be required to enter for their medical education at Charing-cross Hospital.

The Llewellyn Scholarship of £25 is open to all matriculated students who have just completed their second academical year. The examination is held at the end of the second summer session, and includes the following subjects:—Descriptive and Surgical Anatomy, Physiology, Materia Medica, Medicine, Surgery, Midwifery.

The Golding Scholarship of £15 is open to all matriculated students who have just completed their first academical year. The examination is held at the end of the first summer session, and includes the following subjects:—Descriptive Anatomy, Physiology, Materia Medica, and Chemistry.

The Pereira Prize of £5 is open to all matriculated students who shall have completed their third academical year. It is awarded to the author of the best Clinical Reports of Cases in the Hospital during the preceding year, Medical and Surgical Cases being selected in alternate years.

Each candidate must produce a certificate of good conduct from the Dean of the Medical School, at the time of giving in his name as a competitor; and the names of the candidates for Scholarships are to be delivered to the Librarian one week before the first day of the examination.

The Governors' Clinical Gold Medal.—The competition for this medal is open to matriculated students who shall have completed, at the end of the current session, their attendance on the Medical and Surgical Practice of the Hospital. Candidates are examined on the subjects of Clinical Lectures delivered during the session, and on Medical and Surgical Cases in the wards of the Hospital.

Silver Medals.—Silver Medals are awarded in all the classes.

Bronze Medals.—Where two sessions' attendance on a course are required, a Bronze Medal is awarded in the junior class, in addition to the Silver one in the senior class.

Certificates of Honour are awarded to both senior and junior students who, not being the most proficient, have yet attained a marked degree of excellence.

ST. GEORGE'S HOSPITAL.

MEDICAL AND SURGICAL STAFF.

Consulting Physicians—Dr. Wilson, Dr. Pitman, Dr. Ogle.
Consulting Surgeons—Mr. Cæsar Hawkins, F.R.S., Mr. Tatum, Mr. Prescott Hewett, F.R.S.

Physicians.
Dr. Barclay.
Dr. Wadham.
Dr. Dickinson.
Dr. Whipham.

Assistant-Physicians.
Dr. Cavafy.
Dr. Watney.

Surgeons.
Mr. Pollock.
Mr. Henry Lee.
Mr. Holmes.
Mr. Rouse.

Assistant-Surgeons.
Mr. Pick.
Mr. Haward.

Obstetric Physician—Dr. Barnes.
Ophthalmic Surgeon—Mr. Brudenell Carter.
Aural Surgeon—Mr. Dalby. *Dental Surgeon*—Mr. Edgelow.

LECTURERS.—WINTER SESSION.

Chemistry and Physics—Dr. Noad.
Clinical Lectures on Diseases of Women—Dr. Barnes.
Clinical Medicine—Drs. Dickinson and Whipham.
Clinical Surgery—Messrs. Pollock and H. Lee.
Descriptive and Surgical Anatomy—Mr. Pick.
Histology—Dr. Herbert Watney.
Morbid Anatomy—Dr. Ewart.
Ophthalmic Surgery—Mr. Brudenell Carter.
Pathology—Dr. Dickinson.
Physiological Chemistry—Dr Ralfe.
Physiology and General Anatomy—Dr. Cavafy.
Principles and Practice of Physic—Dr. Barclay.
Principles and Practice of Surgery—Mr. Holmes and Mr. Rouse.

SUMMER SESSION.

Aural Surgery—Mr. Dalby.
Botany—Dr. Whipham.
Clinical Demonstrations of Diseases of the Skin—Dr. Wadham.
Clinical Medicine—Dr. Wadham.
Clinical Surgery—Mr. Holmes.
Comparative Anatomy—Dr. Brailey.
Dental Surgery—Mr. Edgelow.
Materia Medica—Dr. Dickinson.
Medical Jurisprudence—Dr. Wadham.
Midwifery and Diseases of Women and Children—Dr. Barnes.
Practical Chemistry—Dr. Noad.
Practical Surgery—Mr. Haward.
Psychological Medicine—Dr. Blandford.

EXHIBITIONS AND PRIZES.

"The William Brown Exhibition," of £100 per annum, tenable for two years, to be competed for by perpetual pupils who have recently obtained their diploma. "The William Brown Exhibition," of £40 per annum, tenable for three years, to be competed for by students during their fourth year of study. The Brackenbury Prizes of £35 each in Medicine and Surgery, awarded annually after a competitive examination. The Treasurer's Clinical Prize of £10 10s., the gift of A. Shaw Stewart, Esq., to be competed for annually. Sir Charles Clarke's Prize for good conduct: The interest of £200 Consols, to be awarded annually to the student of the Hospital "who, by reason of his general good conduct during the preceding year, should be considered the most deserving." The Thompson Medal: A silver medal to be awarded annually for the best clinical report of medical and surgical cases observed in the Hospital during the preceding twelve months. Sir Benjamin Brodie's Clinical Prize in Surgery will be awarded to the pupil of the Hospital who shall have delivered to the Surgeons the best report of not more than twelve surgical cases which have occurred in the Hospital during the preceding twelve months. Dr. Acland's Clinical Prize in Medicine will be awarded to the pupil of the Hospital who shall produce the best report of not more than twelve medical cases which have occurred in the Hospital during the preceding twelve months. The Henry Charles Johnson Memorial Prize in Anatomy will be awarded to that pupil who shall, in the judgment of the Medical School Committee, exhibit the greatest proficiency in Practical Anatomy. General Proficiency Prizes: To pupils in their first year, £10 10s.; to pupils in their second year, £10 10s.; to pupils in their third year, £10 10s.

FEES.

Perpetual pupils pay at the time of entry a compounding fee of £105.

Gentlemen are admitted to the hospital practice and lectures required for the licensing bodies on payment of the following fees—viz., £42 for the first year of study, £42 for the second year of study, and £10 10s. for each succeeding year. Pupils may also enter to the hospital practice and lectures separately.

For further particulars apply to Dr. Barclay, Treasurer, or Dr. Wadham, Dean of the School.

GUY'S HOSPITAL.

MEDICAL AND SURGICAL STAFF.

Consulting Physicians—Sir William Gull, Bart., Dr. G. Owen Rees.
Consulting Obstetric Physician—Dr. Henry Oldham.
Consulting Surgeons—Mr. J. Hilton, Mr. E. Cock, Mr. Birkett.

Physicians.
Dr. S. O. Habershon.
Dr. S. Wilks.
Dr. F. W. Pavy.
Dr. W. Moxon.

Assistant-Physicians.
Dr. C. Hilton Fagge.
Dr. P. H. Pye-Smith.
Dr. Frederick Taylor.
Dr. J. F. Goodhart.

Obstetric Physician.
Dr. J. Braxton Hicks.

Assistant Obstetric Physician.
Dr. A. L. Galabin.

Medical Registrar.
Dr. Mahomed.

Curator of the Museum.
Dr. Fagge.

Surgeons.
Mr. J. Cooper Forster.
Mr. Thomas Bryant.
Mr. Arthur Durham.
Mr. H. G. Howse.

Assistant-Surgeons.
Mr. N. Davies-Colley.
Mr. R. Clement Lucas.

Mr. W. H. A. Jacobson.

Ophthalmic Surgeons.
Mr. C. Bader.
Mr. C. Higgens, *Asst.*

Dental Surgeons.
Mr. S. J. A. Salter.
Mr. H. Moon, *Asst.*

Aural Surgeon.
Mr. W. Laidlaw Purves.

Surgical Registrar.
Mr. Frederic Durham.

Dean—Dr. F. Taylor.

WINTER COURSES.—LECTURES.

Anatomy, Descriptive and Surgical—Mr. Howse and Mr. Davies-Colley.
Chemistry — Dr. Debus and Dr. Stevenson.
Clinical Medicine—Dr. Habershon, Dr. Wilks, Dr. Pavy, and Dr. Moxon.
Clinical Surgery—Mr. Forster, Mr. Bryant, Mr. Durham, and Mr. Howse.
Clinical Lectures on Midwifery and Diseases of Women—Dr. Braxton Hicks.
Experimental Physics—Prof. A. W. Reinold.
Medicine—Dr. Wilks and Dr. Pavy.
Physiology and General Anatomy—Dr. Pye-Smith.
Surgery — Mr. Bryant and Mr. Arthur Durham.

DEMONSTRATIONS.

Cutaneous Diseases — Dr. Pye-Smith.
Morbid Anatomy—Dr. Fagge and Dr. Goodhart.
Practical Surgery—Mr. Lucas.
Practical Anatomy—Mr. W. H. A. Jacobson, Mr. R. E. Carrington, and Mr. C. J. Symonds.
Practical Physiology—Mr. Golding-Bird.

SUMMER COURSES.—LECTURES.

Botany—Mr. Bettany.
Clinical Medicine—Dr. Fagge, Dr. Pye-Smith, Dr. F. Taylor, and Dr. Goodhart.
Clinical Surgery—Mr. Davies-Colley, Mr. Clement Lucas, Mr. Golding-Bird, and Mr. Jacobson.
Clinical Lectures on Diseases of Women—Dr. A. L. Galabin.
Comparative Anatomy and Zoology—Mr. Jacobson.
Dental Surgery—Mr. Moon.
Hygiene—Dr. F. Taylor.
Materia Medica and Therapeutics—Dr. Moxon.
Medical Jurisprudence—Dr. Alfred S. Taylor.
Mental Diseases—Dr. Savage.
Midwifery and Diseases of Women—Dr. Braxton Hicks.
Ophthalmic Surgery—Mr. Bader.
Pathology—Dr. Fagge.

DEMONSTRATIONS.

Morbid Histology—Mr. Howse.
Practical Chemistry—Dr. Debus.
Operative Surgery—Mr. Lucas.

This Hospital contains 695 beds.

Open Scholarships.—An open Scholarship of the value of £105 in Classics, Mathematics, Modern Languages. An open Scholarship of the value of £105 in Science.

PRIZES.

For First Year's Students.—At the end of the summer session, in Anatomy, Physiology, Chemistry, Materia Medica, Botany, and Comparative Anatomy: Prizes, £50, £25, and £10 10s. (presented by one of the Governors). *For Second Year's Students.*—In the winter session, the Michael Harris Prize of £10 in Anatomy. Summer session, examination in Anatomy and Physiology: The Joseph Hoare Prizes of £25 and £10; the Sands-Cox Scholarship of £15 per annum, tenable for three years—subjects, Physiology and Elementary Physics. *For Third Year's Students.*—Summer session, examination in Medicine, Surgery, Midwifery, and Medical Jurisprudence: Prizes £35 and £20. *For Senior Students.*—The

Treasurer's Gold Medal for Clinical Medicine; the Treasurer's Gold Medal for Clinical Surgery; the Gurney Hoare Prize of £25 for Clinical Medicine and Surgery.

FEES.

The fees for hospital practice and lectures are as follows:—The payment of £105 in one sum on entrance, or in two moieties at the commencement of the first winter and of the following summer session, entitles a student to a perpetual ticket.

Payment may be made by instalments at the commencement of each sessional year, as follows:—First year, £40; second year, £40; third year, £30 (on payment of this instalment the student is entitled to a perpetual ticket). Materials used in practical courses are charged extra.

For further information apply to the Dean, Dr. F. Taylor.

KING'S COLLEGE HOSPITAL.

MEDICAL AND SURGICAL STAFF.

Consulting Physicians—Sir Thos. Watson, Bart., M.D., Dr. George Budd, Dr. Arthur Farre, Dr. W. A. Guy, Dr. W. O. Priestley, Dr. A. B. Garrod.

Physicians.
Dr. George Johnson.
Dr. Lionel S. Beale.
Dr. Alfred B. Duffin.
Dr. William Playfair.
Dr. J. Burney Yeo.

Assistant-Physicians.
Dr. David Ferrier.
Dr. E. B. Baxter.
Dr. John Curnow.
Dr. T. C. Hayes.

Surgeons.
Mr. John Wood.
Mr. Joseph Lister.
Mr. Henry Smith.
Mr. H. Royes Bell.

Assistant-Surgeons.
Mr. William Rose.
Mr. Gerald Yeo.

Dental Surgeon.
Mr. S. Hamilton Cartwright.

Ophthalmic Surgeon—Mr. J. Soelberg Wells.
Aural Surgeon—Dr. Urban Pritchard.
Vaccinator—Mr. R. W. Dunn.
Pathological Registrar—Mr. A. B. Barrow.
Chloroformist—Mr. Charles Moss.
Registrars—Dr. Hebb and Mr. E. Ground.

LECTURES.

Anatomy, Descriptive and Surgical—Dr. John Curnow.
Botany—Mr. Robert Bentley.
Chemistry and Practical Chemistry—Mr. C. L. Bloxam; Mr. W. N. Hartley, Demonstrator; Mr. J. M. Thomson, Assist.-Demonstrator.
Clinical Medicine—Dr. George Johnson.
Clinical Surgery—Mr. John Wood, Mr. Joseph Lister.
Comparative Anatomy—Mr. A. H. Garrod.
Dental Surgery—Mr. S. Hamilton Cartwright.
Forensic Medicine—Dr. D. Ferrier.
Hygiene—Dr. W. A. Guy.
Materia Medica and Therapeutics—Dr. E. B. Baxter.
Principles and Practice of Medicine—Dr. L. S. Beale.
Obstetric Medicine, and the Diseases of Women and Children—Dr. W. Playfair.
Ophthalmology—Dr. J. Soelberg Wells.
Pathological Anatomy—Dr. A. B. Duffin.
Physiology and Practical Physiology—Dr. Gerald F. Yeo.
Psychological Medicine—Dr. Edgar Sheppard.
Principles and Practice of Surgery—Mr. Henry Smith.

Dean of the Faculty—Professor Bentley.
Sub-Dean and Medical Tutor—Mr. F. R. Cross.

University of London Preliminary Scientific Examination.—Special courses of lectures and demonstrations are given during the winter and summer sessions to meet the requirements of the University of London for this examination.

SCHOLARSHIPS AND PRIZES.

Warneford Scholarships: "For the encouragement of the previous education of medical students," two scholarships of £25 per annum for three years, two of £25 per annum for two years, and "For the encouragement of resident medical students," one scholarship of £25 per annum for two years. Medical Scholarships: The following are given every year to matriculated students of this department:—1. One of £40 for two years, open to students of the third and fourth years; 2. One of £30 for one year, open to students of the second year; 3. One of £20 for one year, open to students of the first year. Daniell Scholarship: £20, tenable for two years; is open to every student of the College who has worked in the laboratory for at least six months. Sambrooke Registrarships: Two of £50 every year. Science Exhibition: One annually of £100, for proficiency in Physics, Chemistry, Botany, and Zoology. Leathes Prizes: Bible and Prayer-book annually to two matriculated medical students. Warneford Prizes: £40 is expended annually in the purchase of medals and books as prizes to two matriculated medical students. Class Prizes are awarded annually of the value of £3 in each subject of study. Two Medical Clinical Prizes, one of £3 for the winter session, and the other of £2 for the summer session, and two Surgical Clinical Prizes of the same value, are given annually for attendance at the Hospital. Todd Medical Clinical Prize: This prize was founded in memory of the late Dr. Todd, and is awarded annually. It consists of a bronze medal and books to the value of £4 4s. Tanner Prize: Of the value of £10 in each year, for proficiency in the study of Obstetric Medicine.

FEES.

The fees, amounting to £105, may be paid either in one sum of £100 on matriculation, or in three amounts at the commencement of each winter session. Students are, however recommended to add to the above the fee for attendance on the medical tutor's class for one year—viz., £3 3s.; or in the case of those preparing for the Preliminary Scientific Examination of the University of London, £5 5s.

For further information apply to Professor Bentley, Dean of the Medical Faculty.

LONDON HOSPITAL.

MEDICAL AND SURGICAL STAFF.

Consulting Physician—Dr. Herbert Davies.
Consulting Surgeons—Mr. Luke and Mr. Curling.

Physicians.
Dr. Andrew Clark.
Dr. Ramskill.
Dr. Langdon Down.
Dr. Hughlings-Jackson.
Dr. Sutton.
Dr. Fenwick.

Assistant-Physicians.

Dr. A. E. Sansom.
Dr. J. Barlow.

Surgeons.
Mr. Hutchinson.
Mr. Maunder.
Mr. Couper.
Mr. Rivington,
Mr. Jas Adams.
Mr. Waren Tay.
Mr. McCarthy.

Assistant-Surgeon.
Mr. Reeves.

Obstetric Physician—Dr. Palfrey.
Surgeon-Dentist—Mr. A. W. Barrett.
Surgeons to the Ophthalmic Department—Mr. James Adams and Mr. Waren Tay.
Surgeon to the Aural Department—Mr. A. Gardiner Brown.
Physician to the Skin Department—Dr. S. Mackenzie.

LECTURES.

Anatomy and Pathology of the Teeth—Mr. A. W. Barrett.
Botany—Mr. John Gilbert Baker.
Chemistry—Dr. C. Meymott Tidy.
Comparative Anatomy—Dr. E. B. Aveling.
Descriptive and Surgical Anatomy—Mr. Walter Rivington.
Diseases of the Throat and Use of the Laryngoscope—Dr. Morrell Mackenzie.
Forensic Medicine—1. Toxicology, Mr. J. E. D. Rodgers; 2. Medical Jurisprudence and Public Health, Dr. C. Meymott Tidy.
Materia Medica and General Therapeutics—Dr. M. Prosser James.
Medicine—Dr. Sutton and Dr. S. Fenwick.
Midwifery and Diseases of Women—Dr. James Palfrey.
Pathology and Demonstrations of Morbid Anatomy—Dr. H. G. Sutton.
Practical Anatomy—Dr. Wilson.
Practical Chemistry—Dr. C. Meymott Tidy.
Practical Histology, and Use of the Microscope—Mr. J. McCarthy.
Physiology and General Anatomy—Mr. J. McCarthy.
Ophthalmic Surgery—Mr. J. Couper.
Special Operative Surgery—Mr. C. F. Maunder.
Surgery—Mr. John Couper.

Secretary to the College Board—Mr. R. Kershaw.

SCHOLARSHIPS AND PRIZES.

Nine scholarships will be offered for competition during the ensuing winter and summer sessions.

Two Entrance Scholarships in Natural Science, of the value of £60 and £40 respectively, will be offered for competition at the end of September. The subjects will be the same as those for the Preliminary Scientific (M.B.) Examinations at the University of London. (See the University Calendar for details.)

The two Buxton Scholarships will be awarded in October to the students who distinguish themselves most in the subjects appointed by the General Council of Medical Education and Registration as the subjects of the preliminary examinations. 1. A scholarship, value £30, to the student placed first in the examination. 2. A scholarship, value £20, to the student placed second in the examination. 3. A scholarship, value £20, will be awarded to the first-year student who shall pass in April, 1878, the best examination in Human Anatomy. 4. A scholarship, value £25, will be awarded to the first-year or second-year student who shall pass at the end of the winter session the best examination in Anatomy, Physiology, and Chemistry. 5. A hospital scholarship, value £20, for proficiency and zeal in Clinical Medicine. 6. A hospital scholarship, value £20, for proficiency and zeal in Clinical Surgery. 7. A hospital scholarship, value £20, for proficiency and zeal in Obstetrics (awarded at the end of June, 1878). A prize of £5 is also awarded to the student who has attended most midwifery cases for the Hospital during the previous twelve months. The Duckworth-Nelson Prize, value £10, will be awarded by competition biennially, and will be open to all students who have not completed their education. The subjects of examination will be Practical Medicine and Surgery. Money prizes, to the value of £60 per annum, are awarded by the House Committee to the most meritorious of the dressers in the out-patient rooms.

The Hospital contains 800 beds, and the number of in-patients last year amounted to nearly 7000.

Owing to the great size of the Hospital, the appointments are necessarily numerous and most valuable. They are all free to full students without additional fee.

The resident appointments consist of five House-Physiciancies, four House-Surgeoncies, and one Accoucheur, each being tenable for six months. There are also two Resident Dressers and two Maternity Assistants, the holders of which appointments are required to have passed the primary examination at the College of Surgeons.

Attached to the Pathological Department of the London Hospital is a laboratory, under the supervision of Dr. Sutton, which contains a large number of microscopic sections, carefully indexed and recorded. This important addition is entirely due to the liberality of the Hospital authorities, and was made a part of the "Grocers' Wing" lately erected.

FEES.

Perpetual fee for attendance on all the lectures with two years' Practical Anatomy, and for attendance on medical and surgical practice, qualifying for examination at most of the medical and surgical boards, £94 10s. if paid in one sum, or £105 in three instalments of £42, £36 15s., and £26 5s., at the commencement of the first, second, and third years respectively; composition fee for gentlemen entering at or before the beginning of their second winter session, their first year having been spent elsewhere, £73 10s.; perpetual fee for lectures alone, £52 10s.; perpetual fee for hospital practice alone, £52 10s. Extra fees: Practical Chemistry (for apparatus, etc.), £2 2s.; subscription to the library (compulsory), £1 1s. The composition fee is payable in two instalments of £42 and £31 10s.

Students in Arts of Universities where residence is required, who may have attended lectures in Anatomy, Physiology, Chemistry, Botany, or Comparative Anatomy, and have obtained signatures for such attendance, fulfilling the requirements of the Examining Boards, may become pupils of the London Hospital, eligible for all hospital prizes and appointments, on payment of the fee of £52 10s. for practice (perpetual) at the Hospital.

Communications addressed to the Secretary, at the London Hospital Medical College, Turner-street, Mile-end, London, E., will receive immediate attention.

ST. MARY'S HOSPITAL.

MEDICAL OFFICERS.

Consulting Medical Officers—Sir James Alderson, M.D., F.R.S., Dr. Chambers, Mr. Lane, Mr. White Cooper.

Physicians.	*Surgeons.*
Dr. Handfield Jones.	Mr. Spencer Smith.
Dr. Sieveking.	Mr. Haynes Walton.
Dr. Broadbent.	Mr. James R. Lane.
Assistant-Physicians.	*Assistant-Surgeons.*
Dr. Cheadle.	Mr. Norton.
Dr. Lawson.	Mr. Edmund Owen.
Dr. Shepherd.	Mr. Herbert W. Page.

Physician-Accoucheur—Dr. Alfred Meadows.
Assistant Physician-Accoucheur—Dr. Wiltshire.
Physicians in charge of the Department for Diseases of the Skin—Dr. Cheadle, Dr. Farquharson.
Surgeon in charge of the Ophthalmic Department—Mr. Haynes Walton.
Surgeon in charge of the Department for Diseases of the Throat—Mr. Norton.
Aural Surgeon—Mr. G. Field.
Surgeon-Dentist—Mr. Howard Hayward.
Instructor in Vaccination—Mr. W. A. Sumner.

LECTURES.—WINTER SESSION.

Anatomy—Mr. Norton.
Clinical Medicine—Dr. Handfield Jones, Dr. Sieveking, and Dr. Broadbent.
Clinical Surgery—Mr Spencer Smith, Mr. Haynes Walton, and Mr. J. R. Lane.
Chemistry and Natural Philosophy—Dr. C. R. A. Wright.
Dental Surgery—Mr. Howard Hayward.
Dissections—Mr. J. G. Garbutt, Demonstrator; Mr. C. D. Adam, Assistant Demonstrator.
Experimental Physiology—Dr. Shepherd.
Medicine—Dr. Chambers and Dr. Broadbent.
Pathology—Dr. Cheadle.
Physiology—Dr. Lawson.
Surgery—Mr. James R. Lane and Mr. Edmund Owen.
Practical Surgery—Mr. Herbert W. Page.

SUMMER SESSION.

Aural Surgery—Mr. G. Field.
Botany—Mr. Helmsley.
Comparative Anatomy—Mr. St. George Mivart.
Diseases of the Skin—Dr. Cheadle.
Medical Jurisprudence—Dr. Randall.
Materia Medica—Dr. Farquharson.
Midwifery—Dr. Meadows and Dr. Wiltshire.
Ophthalmic Surgery—Mr. Haynes Walton.
Practical Chemistry—Dr. C. R. A. Wright.

The Hospital contains 170 beds—68 medical, and 102 surgical. There are special departments for the Diseases of Women and Children, and for Diseases of the Eye, the Ear, the Skin, and the Throat.

SCHOLARSHIPS, PRIZES, ETC.

Three Scholarships in Natural Science, each of a total value of £120, tenable for three years, and an Exhibition in Natural Science, for one year, value £20. One of the Scholarships and the exhibition are awarded by open competitive examination at the commencement of the winter session. For the year 1877 an extra scholarship will be awarded in Natural Science of a total value of £100. A Scholarship in Anatomy, of the annual value of £20 (the holder of which is styled Assistant-Demonstrator, and assists in the teaching of Practical Anatomy), is offered for competition amongst those students who have completed their second winter session; and a Scholarship in Pathology, of the value of £40 (the holder of which is styled Assistant-Curator), for those students who have completed their third winter session. Examinations for prizes are held at the termination of each session in the various classes for students of the first, second, and third year. Two Prosectors are appointed annually, who each receive a certificate and £5 for their services in the dissecting-room.

FEES.

The entrance fee for general students may be paid in instalments by arrangement with the Dean of the School. Students who have kept the two years' course at the University of Cambridge are admitted as perpetual pupils on payment of £57 15s., and those who have kept a portion of the course elsewhere at a proportionate reduction. A fee of £1 1s. is required to be paid to the library and reading-room. Instruction in vaccination can be obtained; fee £1 1s.

Further information may be obtained from Dr. Shepherd, Dean of the School; or from the Registrar, at the Hospital.

MIDDLESEX HOSPITAL.

MEDICAL AND SURGICAL STAFF.

Consulting Physicians—Dr. Francis Hawkins, Dr. A. P. Stewart, Dr. Goodfellow.
Consulting Surgeon—Mr. Shaw.
Consulting Dental Surgeon—Mr. Tomes, F.R.S.

Physicians.	*Surgeons.*
Dr. Henry Thompson.	Mr. Nunn.
Dr. Greenhow, F.R.S.	Mr. Hulke, F.R.S.
Dr. Cayley.	Mr. Lawson.
Assistant-Physicians.	
Dr. Robert King.	*Assistant-Surgeons.*
Dr. G. H. Evans.	Mr. Morris.
Dr. Sidney Coupland.	Mr. Andrew Clark.

Obstetric Physician—Dr. Hall Davis.
Assistant Obstetric Physician—Dr. Arthur Edis.
Ophthalmic Surgeon—Mr. Critchett.
Dental Surgeon—Mr. Turner.
Curator of Museum and Pathologist—Dr. Sidney Coupland.
Registrars—Dr. D. W. Finlay and Dr. R. W. Lyell.
Resident Medical Officer—Mr. Lucas.
Chloroformist—Mr. G. Everitt Norton.

LECTURES.—WINTER SESSION.

Chemistry—Mr. Wm. Foster.
Clinical Lectures on Medicine and Surgery—The Physicians and Surgeons.
Clinical Lectures on Diseases of Women and Children—Dr. J. Hall Davis.
Descriptive and Surgical Anatomy—Mr. Morris.
Pathological Anatomy—Dr. Coupland.
Physiology and General Anatomy—Mr. B. Thompson Lowne.
Practical Demonstrations on Diseases of the Eye—Mr. Critchett.
Practical Surgery—Mr. Lawson, Mr. Morris.
Principles and Practice of Medicine—Dr. Cayley.
Principles and Practice of Surgery—Mr. Hulke.

SUMMER SESSION.

Botany—Mr. Hensman.
Clinical Lectures on Medicine and Surgery—The Physicians and Surgeons.
Clinical Lectures on Diseases of the Eye—Mr. Critchett.
Comparative Anatomy and Zoology—Mr. Hensman.
Materia Medica and Therapeutics—Dr. Thorowgood.
Medical Jurisprudence—Dr. R. King.
Midwifery and Diseases of Women and Children—Dr. J. Hall Davis.
Practical Demonstrations on Diseases of the Skin—Dr. G. H. Evans.
Practical Demonstrations on Diseases of Women and Children—Dr. Arthur Edis.
Practical Demonstrations on Diseases of the Larynx and Ear—Mr. Andrew Clark.
Practical Physiology and Histology—Mr. B. Thompson Lowne.
Practical Chemistry—Mr. Wm. Foster.
Psychological Medicine—Dr. Henry Rayner.
Public Health—Dr. G. H. Evans.

This Hospital contains 305 beds, of which 185 are for surgical and 120 for medical cases. There is a special department for Cancer cases, affording accommodation for thirty-three in-patients, whose period of residence in the Hospital is unlimited. Wards are also appropriated for the reception of cases of Uterine Disease and of Syphilis, and beds are set apart for patients from Diseases of the Eye. There are special out-patient departments for Diseases of the Skin, the Throat, the Eye and Ear.

PRIZES AND SCHOLARSHIPS.

Two Entrance Scholarships of the annual value of £25 and £20, tenable for two years, are afforded for competition at the commencement of the winter session.

Two Broderip Scholarships of tho annual value of £30 and £20, tenable for two years, and a clinical prize of £10 10s., are annually awarded to thoso students who pass the most satisfactory examination at the bedside, and in the post-mortem room.

The Murray Scholarship is open to all general students, and will next be awarded in 1880. Examinations in Medicine, Surgery, and Midwifery.

The Governors' Prize of £21 is awarded annually to the student who shall have most distinguished himself during his three years' curriculum.

FEES.

The fee for attendance on the hospital practice and lectures required by the Colleges of Physicians and Surgeons and the Society of Apothecaries is £90 if paid in advance, or £35 on entrance, £35 at the beginning of the second winter session, £20 at the beginning of the third winter session, and £10 for every additional year's attendance.

Dental students who intend to become Licentiates in Dental Surgery of the Royal College of Surgeons are admitted to attend the requisite courses of lectures and hospital practice on payment of a fee of £42, either in one payment or by instalments of £26 5s. on entrance, and £15 15s. at the beginning of the second winter session.

ST. THOMAS'S HOSPITAL.

Resident Assistant-Surgeon.
Mr. H. H. Clutton

Demonstrator of Morbid Anatomy—Dr. Greenfield.

Analytical Chemist of the Hospital—Dr. Albert J. Bernays.

Curator to the Museum—Mr. C. Stewart.

Apothecary—Mr. Plowman.

Medical Registrar—Mr. Norris.

Surgical Registrar—Mr. C. H. Newby.

LECTURES.—WINTER SESSION.

Chemistry—Dr. Albert J. Bernays.
Demonstrations—The Anatomical Lecturers, Dr. R. W. Reid, and Anatomical Assistants.
Descriptive Anatomy—Mr. Francis Mason and Mr. W. W. Wagstaffe.
General Pathology—Dr. Payne.
Physics and Natural Philosophy—Dr. Stone.
Physiology and General Anatomy—Dr. John Harley.
Demonstrations in Physiology—Dr. T. C. Charles.
Morbid Anatomy and Practical Pathology—Dr. Greenfield.
Practical and Manipulative Surgery—Mr. Croft and Mr. MacKellar.
Special Anatomical and Microscopical Demonstrations—Mr. Rainey.
Surgery—Mr. Sydney Jones and Mr. Mac Cormac.
Theory and Practice of Medicine—Dr. Bristowe and Dr. Ord.

SUMMER SESSION.

Botany—Mr. A. W. Bennett.
Comparative Anatomy—Mr. C. Stewart.
Forensic Medicine—Dr. Payne and Dr. Cory
Materia Medica—Dr. Stone.
Mental Diseases—Dr. William Rhys Williams.
Midwifery—Dr. Gervis.
Ophthalmic Surgery—Mr. Liebreich
Practical and Manipulative Surgery—Mr. Croft and Mr. MacKellar.
Practical Chemistry—Dr. Albert J. Bernays.
Practical Physiology—Dr. Charles.
State Medicine—Dr. A. Carpenter.

PRIZES AND APPOINTMENTS.

Entrance Scholarships of £60 and £40, awarded after an examination in Physics, Chemistry, Botany, and Zoology.

First Year's Prizes.—Winter: The Wm. Tite Scholarship of £30; College Prizes—£20 and £10. Summer Prizes: £15, £10, and £5.

Second Year's Prizes.—Winter: The Musgrove Scholarship of £42, tenable for two years; College Prizes—£20 and £10. Summer Prizes: £15, £10, and £5. The Dresserships and the Clinical and Obstetrical Clerkships are open to students who have passed the primary examinations at the Royal College of Surgeons.

Third Year's Prizes.—Winter: £20, £15, and £10. The Cheselden Medal, awarded after a special examination in Surgical Anatomy and Surgery. The Mead Medal, awarded after a special examination in Practical Medicine and Hygiene. The Solly Medal, with a prize of at least £10 10s. for a collection of surgical reports. The Treasurer's Gold Medal, for general proficiency during the entire course of study. The Grainger Testimonial Prize, of the value of £20, will be awarded biennially to the third or fourth year's students for a physiological essay, to be illustrated by preparations.

FEES.

Gentlemen are informed that the admission fees to practice and to all the lectures may be paid in one of three ways, entitling to unlimited attendance—1st, £100, paid on entrance, entitle a student to unlimited attendance; 2nd, £105 in two moieties, one on entrance and one at beginning of next session; 3rd, by three instalments, of £42 the first year, £42 the second, and £31 10s. the third. Special entries may be made to any course of lectures, or to the hospital practice.

There are special departments for Diseases of the Eye, Diseases of Women and Children, Vaccination, Diseases of the skin, Diseases of the Teeth, and Mental Diseases.

Visits to wards now take place at 2 p.m.

For further information, apply to Dr. Gillespie, Secretary, St. Thomas's Hospital, London, S.E.

UNIVERSITY COLLEGE HOSPITAL.

MEDICAL AND SURGICAL STAFF.

Consulting-Physician.
Dr. Walter H. Walshe.

Physicians.
Sir William Jenner, Bart.
Dr. Reynolds.
Dr. Wilson Fox.
Dr. Sydney Ringer.
Dr. H. Charlton Bastian.

Obstetric Physician.
Dr. Graily Hewitt.

Physician to the Skin Infirmary.
Dr. W. Tilbury Fox.

Assistant Physicians.
Dr. F. T. Roberts.
Dr. W. R. Gowers.
Dr. G. V. Poore.

Assistant Obstetric Physician.
Dr. John Williams.

Consulting-Surgeons.
Mr. Richard Quain.
Mr. J. Eric Erichsen.
Sir Henry Thompson, Bart.

Surgeons.
Mr. Marshall.
Mr. Berkeley Hill.
Mr. Christopher Heath.

Assistant-Surgeons.
Mr. Marcus Beck.
Mr. A. Barker.
Mr. R. J. Godlee (temporary).

Ophthalmic Surgeons.
Mr. Wharton Jones.
Mr. J. F. Streatfeild.

Dental Surgeon.
Mr. G. A. Ibbetson.

Assistant Professors of Clinical Medicine—Dr. F. T. Roberts and Dr. W. R. Gowers.

Assistant-Teachers of Clinical Surgery—Mr. Marcus Beck and Mr. A. Barker.

Assistant-Medical Officer in the Skin Department—Dr. H. R. Crocker.

Surgical Registrar—Mr. A. J. Pepper.

Resident Medical Officer—Mr. W. L. S. Jameson.

LECTURES.—WINTER SESSION.

Chemistry—Dr. Williamson.
Clinical Medicine—Sir W. Jenner, Dr. Reynolds, Dr. W. Fox, Dr. S. S. Ringer, Dr. Roberts, Dr. Gowers.
Clinical Midwifery—Dr. G. Hewitt.
Clinical Surgery—Mr. Erichsen, Mr. Marshall, Sir H. Thompson, Mr. C. Heath, Mr. W. Jones, Mr. Streatfeild.
Histology and Practical Physiology—Dr. B. Sanderson, Mr. Schäfer.
Descriptive Anatomy—Mr. Thane; Demonstrations—Mr. G. D. Thane, Mr. Rickman J. Godlee, Mr. Walter Ottley, Mr. R. S. Miller, Mr. W. Banks, Mr. C. J. Bond, Mr. P. E. Shearman.
Medicine—Dr. J. R. Reynolds.
Physiology and General Anatomy—Dr. B. Sanderson.
Skin Diseases—Dr. T. Fox.
Surgery—Mr. Marshall

SUMMER SESSION.

Botany—Mr. Oliver.
Comparative Anatomy—Mr. E. R.—Lankester.
Dental Surgery—Mr. Ibbetson.
Forensic Medicine—Dr. Maudsley.
Hygiene—Dr. Corfield.
Materia Medica—Dr. Ringer.
Mental Diseases—Dr. Sankey.
Midwifery—Dr. Graily Hewitt.
Morbid Anatomy and Pathology—Dr. H. C. Bastian.
Natural Philosophy—Prof. G. C. Foster.
Ophthalmic Surgery—Mr. W. Jones.
Practical Chemistry—Dr. Williamson.
Practical and Operative Surgery—Mr. B. Hill, Mr. M. Beck, Mr. E. A. Barker.
Practical Pharmacy—Mr. Gerrard.
Skin Diseases—Dr. T. Fox.

SCHOLARSHIPS AND EXHIBITIONS.

The Atkinson-Morley Surgical Scholarship, of £45 per annum, tenable for three years, is awarded every year for proficiency in the theory and practice of Surgery. The Sharpey Physiological Scholarship, of about £70 a year, for proficiency in Biological Science. The Filiter Prize of £30, for proficiency in Pathological Anatomy. Dr. Fellowes' Clinical Medals, one gold and one silver, each winter and summer session, and certificates of honour, for reports and observations on the Medical cases of the Hospital. The Liston Gold Medal, and certificates of honour, for reports and obser-

vations on the Surgical cases in the Hospital. The Alexandra Bruce Gold Medal, for Pathology and Surgery. The Cluff Memorial Prize, awarded every other year for proficiency in Anatomy, Physiology, and Chemistry. Gold and silver medals, as well as certificates of honour, are awarded as class prizes. The Jews' Commemoration Scholarship of £15 a year, tenable for two years, for general proficiency in the Faculty of Arts or of Science, for students of one year's standing, and the Clothworkers' Exhibition for Chemistry and Physics, of £50 a year, tenable for two years, may be held by students who, after obtaining it, enter the Medical Faculty.

ENTRANCE EXHIBITIONS.

Three Entrance Exhibitions, of the respective value of £30, £20, and £10 per annum, tenable for two years, are awarded upon examination to gentlemen who are about to commence their first winter's attendance in a medical school.

FEES.

For the lectures and hospital practice for the licences of the Royal College of Physicians, Society of Apothecaries, and M.R.C.S., first year, £47 16s.; second, £39 8s.; third, £14 7s.; fourth year, £4 4s.; perpetual, £105 15s.; for the hospital practice alone, £27.

Further information and detailed prospectuses may be obtained at the Office of the College.

WESTMINSTER HOSPITAL.

HOSPITAL STAFF.

Consulting Physicians and Surgeons—Dr. Kingston, Dr. Radcliffe, Dr. Basham, Mr. Lynn, Mr. Brooke, Mr. Barnard Holt, Mr. Holthouse.

Physicians.	*Surgeons.*
Dr. Fincham.	Mr. Cowell.
Dr. Sturges.	Mr. Richard Davy.
Dr. Allchin.	Mr. Macnamara.
Assistant-Physicians.	*Assistant-Surgeons.*
Dr. Horatio Donkin.	Mr. T. Cooke.
Dr. De Havilland Hall.	Mr. T. Boud.
Dr. Hughes Bennett.	Mr. Keene.

Obstetric Physician—Dr. Potter.

Assistant Obstetric Physician—Dr. Grigg.

Surgeon in charge of the Ophthalmic Department—Mr. Cowell.

Surgeon in charge of the Skin Department—Mr. Bond.

Surgeon in charge of the Aural Department—Mr. Keene.

Dental Surgeon—Mr. Walker.

Medical Registrar.	*Surgical Registrar.*
Mr. Murrell.	Mr. Robertson.

LECTURERS.

Anatomy—Mr. A. Pearce Gould.
Aural Surgery—Mr. Keene.
Botany—Mr. Worsley-Benison.
Chemistry Dr. Dupré.
Clinical Medicine—Dr. Basham, Dr. Radcliffe, Dr. Fincham, Dr. Sturges, Dr. Allchin.
Clinical Surgery—Mr. Holt, Mr. Holthouse, Mr. Cowell, Mr. Davy, Mr. Macnamara.
Comparative Anatomy—Dr. Carter Blake.
Dental Surgery—Mr. Walker.
Diseases of the Skin—Mr. Bond.
Forensic Medicine and Hygiene—Mr. Bond, Dr. Dupré.
Materia Medica and Therapeutics—Dr. Phillips.
Medicine — Dr. Fincham, Dr. Sturges.
Metallurgy—Dr. Dupré.
Midwifery and Diseases of Women—Dr. Potter.
Natural Philosophy—Mr. Brooke.
Ophthalmic Surgery—Mr. Cowell.
Pathology and Morbid Anatomy—Dr. Allchin.
Physiology—Dr. Maclure.
Practical Chemistry—Dr. Dupré.
Practical Surgery—Mr. Cowell, Mr. Richard Davy.
Practical Physiology and Histology—Dr Allchin.
Psychological Medicine—Dr. Sutherland.
Surgery—Mr. Cowell, Mr. Davy.

Dean of the School—Mr. Cowell. *Sub-Dean and Tutor*—Dr. Allchin.

Tutor—Dr. De Havilland Hall.

DEMONSTRATORS.

Anatomy—Mr. Walter Ottley, M.B.

Morbid Anatomy—Mr. Murrell, Mr. Robertson.
Minor Surgery and Bandaging—*Vacant.*

In addition to the practice of the Hospital, which contains 201 beds, and has just been enlarged and improved, the general students of this school are admitted to the practice of the Royal Westminster Ophthalmic Hospital, and to that of the National Hospital for Epilepsy and Paralysis.

PRIZES.

There are four Entrance Scholarships: the Fence and Houldsworth, value £50 a year each, tenable for two years; and two others, £10 a year each, tenable for two years; an Exhibition in Anatomy, Physiology, and Chemistry for first year's men, a Scholarship of £21 in Anatomy and Physiology for second year's men, the Frederic Bird Prize and Medal, value £15, the Chadwick Prize of the value of £21 for general proficiency, and two Clinical Prizes of the value of £5 5s. each. Prizes and certificates of honour are also awarded to the most meritorious students.

FEES.

The entry fee to lectures and hospital practice required by the College of Physicians and Surgeons and the Society of Apothecaries may be paid in one sum of £84, which is perpetual; in two payments of £45 each, at the commencement of the first two years, also perpetual; or in five payments, amounting to £94 10s., at the commencement of the first five sessions. The fees for Dental Students are £38 17s. in one sum, or £27 10s. and £14 10s. respectively at the commencement of each academic year.

Full particulars as to the preliminary scientific and tutorial classes, the courses of lectures and mode of instruction, will be found in the published Calendar, and any further information may be obtained by personal application to Mr. Cowell, the Dean of the School, or to Dr. Allchin, the Sub-Dean.

PROVINCIAL MEDICAL SCHOOLS.

OXFORD.

There is no complete and perfect School of Medicine in connexion with the University of Oxford, but classes or lectures may be attended.

Professors, etc., at the University Museum.—Regius and Clinical Professor of Medicine—H. W. Acland, M.D., F.R.S. Savilian Professor of Astronomy—Rev. C. Pritchard, M.A., F.R.S. Savilian Professor of Geometry—H. J. S. Smith, M.A., F.R.S. (Keeper of the University Museum). Experimental Physics—R. B. Clifton, M.A., F.R.S. Natural Philosophy: Demonstrators—W. N. Stocker, M.A., Brasenose, Rev. B. Price, M.A., F.R.S. Geology—J. Prestwich, M.A., F.R.S. Mineralogy—N. Story Maskelyne, M.A., F.R.S. Chemistry—W. Odling, M.A., F.R.S; Assistant—W. W. Fisher, M.A. Linacre Professor of Physiology—G. Rolleston, M.D., F.R.S.; Demonstrator—C. Robertson; Assistants—W. H. Jackson, B.A., George Coates, B.A. Zoology—J. O. Westwood, M.A., F.L.S.; Demonstrator at Sanitary Laboratory—W. F. Donkin, M.A. Radcliffe Librarian—H. W. Acland, M.D., F.R.S. Sub-Librarian—John Haines. Lee's Readers (Christchurch): Chemistry—A. G. V. Harcourt, M.A., F.R.S.; Physics—R. E. Baynes, M.A.; Anatomy—J. Barclay Thompson, M.A. Botanic Garden: Professor—M. A. Lawson, M.A.

Students may also be admitted to the practice of the Radcliffe Infirmary.

CAMBRIDGE.

The winter session will commence on October 11. The following is a list of the classes and lectures in the Cambridge University School of Medicine:—

WINTER COURSES.

Anatomy—Professor Humphry and the Demonstrator (Mr. Crighton).
Anatomy and Physiology—Professor Humphry.
Chemistry—Professor Liveing.
Dissections — Professor Humphry and the Demonstrator.
Materia Medica—Professor Latham.
Medicine—Professor Paget.
Physics—Professor Maxwell.
Practical Chemistry — Professor Liveing and Mr. Hicks.
Practical Physiology—Dr. Michael Foster.
Zoology and Comparative Anatomy—Professor Newton.

SUMMER COURSES.

Botany—Professor Babington.
Chemistry and Practical Chemistry—Professor Liveing and Mr. Hicks.
Comparative Anatomy, Dissections—Mr. Bridge.
Human and Comparative Osteology—Professor Humphry.
Human Osteology—Professor Humphry and the Demonstrator.
Pathology—Dr. Bradbury.
Practical Physiology—Dr. Michael Foster.
Practical Histology—The Demonstrator.

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

This Hospital contains 120 beds.

MEDICAL AND SURGICAL STAFF.

Physicians.	*Surgeons.*
Dr. Paget.	Mr. Lestourgeon.
Dr. Latham.	Dr. Humphry.
Dr. Bradbury.	Mr. Carver.

Fees for attendance upon the practice (medical and surgical), £15 15s. for an unlimited period; £10 10s. for one year; £8 8s. for six months.

THE QUEEN'S COLLEGE, BIRMINGHAM.

WINTER SESSION.

Chemistry—Professor A. C. Bruce.
Demonstrations on Practical Anatomy—Mr. Bennett May and Mr. G. H. Evans.
Descriptive and Surgical Anatomy—Professors Thomas and Jolly.
Medicine—Professor Foster.
Pathology—Professor Sawyer.
Physiology — Professors Norris, Bartleet, and Rickards.
Surgery — Professors Pemberton and Furneaux Jordan.

SUMMER SESSION.

Botany—Professor Hind.
Comparative Anatomy—Professor Savage.
Dental Surgery—Professor Howkins.
Diseases of Women and Children—Professors Berry and R. C. Jordan.
Materia Medica—Professor Mackey.
Forensic Medicine and Toxicology—Professors J. St. S. Wilders and Bruce.
Midwifery—Professors Clay and Bassett.
Ophthalmic Surgery—Professor Solomon.
Practical Chemistry—Professor Bruce.
Operative Surgery—Professors Pemberton and Jordan.

SCHOLARSHIPS AND PRIZES.

The Warden's Prize, of the value of £3 3s., is offered by the Rev. W. H. Poulton to the most proficient student of the first year. The Percy Prize, books of the value of £5 5s., are offered by Dr. Percy, Professor of Metallurgy in the Government School of Mines, to the student attending lectures in German who may pass the best examination in two German works. There must be not less than three competitors. The Ingleby Scholarships.—Two Ingleby Scholarships, founded in memory of the late Dr. Ingleby, formerly Professor of Midwifery in this School, will be awarded annually, after examination in Obstetric Medicine and Surgery and Diseases of Women and Children. These scholarships are open to students who have completed the first two years of their curriculum in this College. Class Prizes.—Medals and certificates of honour are awarded annually in each class after examination.

THE GENERAL AND QUEEN'S HOSPITALS, BIRMINGHAM.

GENERAL HOSPITAL STAFF.

Consulting Surgeon—Mr. D. W. Crompton.

Physicians.
Dr. Bell Fletcher.
Dr. Russell.
Dr. Wade.
Dr. Foster.
Dr. Rickards.

Surgeons.
Mr. Alfred Baker.
Mr. Oliver Pemberton.
Mr. T. H. Bartleet.
Mr. W. P. Goodall.
Mr. Robert Jolly.

Resident Physician and Medical Tutor.
Dr. P. Bindley.

Resident Surgeon and Surgical Tutor.
Mr. Alex. F. Hawkins.

Registrar and Pathologist—Dr. Robert Saundby.

QUEEN'S HOSPITAL STAFF.

Physicians.
Dr. Heslop.
Dr. Sawyer.
Dr. Mackey.
Dr. Carter.

Surgeons.
Mr. West.
Mr. Gamgee.
Mr. Furneaux Jordan.
Mr. J. St. S. Wilders.

House-Physicians.
Mr. Hugh Thomas.
Mr. I. Spofforth.

House-Surgeons.
Mr. Wilkins.
Mr. Cordley Bradford.

Obstetric Surgeon—Mr. John Clay.
Ophthalmic Surgeon—Mr. Priestly Smith.
Pathologist—Mr. Thomas.
Dental Surgeon—Mr. Charles Sims.

CLINICAL PRIZES.

The following prizes will be given annually:—Senior Medical Prizes, for third or fourth year students: First Prize: £5 5s.; Second Prize, £3 3s. Senior Surgical Prizes: First Prize, £5 5s.; Second Prize, £3 3s. Junior Medical Prizes, for second year students: First Prize, £3 3s.; Second Prize, £2 2s. Junior Surgical Prizes: First Prize, £3 3s.; Second Prize, £2 2s. Midwifery Prize, £4 4s.

The examination for all the above-mentioned appointments and prizes will be conducted by the Clinical Board, and will be open for competition to all students registered by the Clinical Board.

BRISTOL SCHOOL OF MEDICINE.

COURSES OF LECTURES.—WINTER SESSION.

Chemistry—Mr. Thomas Coomber.
Descriptive and Surgical Anatomy—Mr. Nelson C. Dobson, and Dr. Henry Waldo.
Medicine—Dr. William H. Spencer.
Physiology—Mr. George F. Atchley and Dr. R. Shingleton Smith.
Principles of Surgery and Practical Surgery—Mr. Robert W. Coe and Mr. Robert W. Tibbits.

SUMMER SESSION.

Botany—Mr. Adolph Leipner.
Comparative Anatomy—Mr. George F. Atchley.
Materia Medica and Therapeutics—Dr. George F. Burder.
Medical Jurisprudence—Mr. Wm. P. Keall.
Midwifery and Diseases of Women—Dr. Joseph G. Swayne.
Pathological Anatomy—Dr. Wm. H. Spencer.
Practical Chemistry—Mr. Thomas Coomber.
Practical Physiology—Mr. Geo. F. Atchley and Dr. R. Shingleton Smith.

BRISTOL ROYAL INFIRMARY.

MEDICAL AND SURGICAL STAFF.

Honorary and Consulting Physicians—Dr. William Budd, Dr. Frederick Brittan, and Dr. Alexander Fairbrother.

Honorary and Consulting Surgeons—Mr. John Harrison, Mr. Thomas Green, and Mr. Augustin Prichard.

Physicians.
Dr. Edward L. Fox.
Dr. William H. Spencer.
Dr. R. Shingleton Smith.
Dr. Henry Waldo.

Surgeons.
Mr. Crosby Leonard.
Mr. Robert W. Tibbits.
Mr. Charles Steele.
Mr. Edmund C. Board.
Mr. Christopher H. Dowson.

Assistant-Physician.
Dr. John E. Shaw.

Assistant-Surgeon.
Mr. Arthur W. Prichard.

House-Surgeon—Mr. Henry M. Chute.
Assistant House-Surgeon—Dr. J. Greig Smith.

This Infirmary was founded in the year 1735, and is one of the largest provincial hospitals in England. It contains 250 beds.

PRIZES.

Suple's Medical Prize, consisting of a gold medal of the value of £5 5s., and about £7 7s. in money, is given annually to the successful candidate in an examination held by the Physicians. The examination comprises reports of cases in the medical wards, and the preparation of morbid specimens illustrative of disease, accompanied, if possible, by microscopic and chemical illustrations, besides written replies to questions in Medicine.

Suple's Surgical Prize corresponds in value and character to the medical one described above. In this case the examination is conducted by the Surgeons, and comprises surgical subjects only.

Clark's Prize.—The interest of £500, bequeathed by the late Henry Clark, Esq., Consulting Surgeon to the Infirmary, will be given annually to the prizeman of his third year at the examination held at the Medical School, provided he has attended his hospital practice at the Bristol Royal Infirmary, and can produce certificates of good moral character.

Pathological Prize.—The Pathological Clerk at the expiration of his term of office will receive a prize of the value of £3 3s. if his duties have been performed to the satisfaction of the Faculty.

FEES.

An entrance fee of £5 5s. to the Infirmary, and subscription of £1 1s. per annum to the Library. Surgeon's pupil, £12 12s. for one year; £21 for two years (at one payment); £26 5s. for three years (at one payment). Dresser (extra fee), £12 12s. for one year; £21 for two years (at one payment); £26 5s. for three years (at one payment). Physician's pupil—For six months, £8; for one year, £15; for eighteen months, £20; perpetual, £25.

The fee for apprenticeship to the House-Surgeon is £315, which includes five years' residence in the Infirmary and all attendance of hospital practice required by the various examining bodies, excepting dressers' fees. House Pupils may also enter for a shorter period, at the rate of £52 10s. per annum to the Infirmary, with a fee of £52 10s. to the House-Surgeon.

BRISTOL GENERAL HOSPITAL.

MEDICAL AND SURGICAL STAFF.

Honorary and Consulting Physician—Dr. Henry E. Fripp.

Honorary and Consulting Surgeons—Mr. Robert W. Coe, Mr. W. Michell Clarke, Dr. Henry Marshall.

Honorary and Consulting Physician-Accoucheur—Dr. Joseph G. Swayne.

Physicians.
Dr. George F. Burder.
Dr. E. Markham Skerritt.
Dr. Joseph B. Siddall.

Surgeons.
Mr. F. Poole Lansdown.
Mr. George F. Atchley.
Mr. Nelson C. Dobson.
Mr. William P. Keall.

Physician-Accoucheur.
Dr. A. E. Aust Lawrence.

House-Surgeon.
Mr. William H. Harsant.

Physician's Assistant.
Mr. William J. Seaward.

Assistant House-Surgeon.
Mr. Arthur F. Parker.

Dentist—Mr. Thomas C. Parson.

SCHOLARSHIPS AND PRIZES.

Lady Haberfield's Prize.—This prize, founded by the late Lady Haberfield, and consisting of the interest of £1000, is awarded annually to the student who exhibits the greatest proficiency.

Sanders Scholarship.—A Scholarship, founded by the late John Nash Sanders, Esq., and consisting of the interest of £500, is awarded annually after examinations in Medicine and Surgery. Two of these scholarships will be available in the ensuing session.

Martyn Memorial Scholarship.—This Scholarship of £20 per annum has been founded by public subscription, in memory of the late Dr. Samuel Martyn, Physician to the Hospital, and will be awarded annually after competitive examinations.

Clarke Scholarship.—A Surgical Scholarship of £15, founded by H. M. Clarke, Esq., of London, is awarded annually to the

most diligent student attending the surgical practice of the Hospital.

FEES.

Medical or Surgical Practice, £6 for six months; £10 for one year; £20 perpetual. Extra fee for Clinical Clerk or Dresser, £5 5s. for six months. Extra fee for Obstetric Clerk, £3 3s. for three months. Library fee, £1 1s. per annum. Resident pupils (including board, lodging, and washing), £100 for the first year, £60 for each subsequent year; or for five years, with apprenticeship to the Hospital, £260.

UNIVERSITY OF DURHAM.—COLLEGE OF MEDICINE, NEWCASTLE-ON-TYNE.

LECTURERS.—WINTER SESSION.

Anatomy—Dr. Armstrong, Mr. Russell.
Chemistry—Professor Marreco.
Medicine—Dr. Philipson.
Mental Diseases—Mr. Wickham.
Physiology—Dr. Hume and Dr. Barron.
Public Health—Mr. H. E. Armstrong.
Surgery—Dr. Heath and Dr. Arnison.

SUMMER SESSION.

Botany—Vacant.
Diseases of Women and Children—Dr. Gibson.
Materia Medica—Mr. McBean.
Medical Jurisprudence—Dr. Page.
Midwifery—Dr. Nesham.
Operative Surgery—Dr. Heath.
Pathological Anatomy—Dr. Gibb and Dr. Bramwell.
Practical Chemistry—Prof Marreco.
Practical Physiology—Dr. MacDiarmid.
Pharmacy—Mr. Proctor.
Therapeutics—Dr. Drummond.

Hospital practice can be attended at the Newcastle Infirmary, which contains 230 beds.

FEES.

Composition fee for all the lectures payable on entering to the first winter session, £52 10s. Perpetual ticket for Pharmacy curriculum, £12 12s. Separate courses of lectures, each £4 4s. The composition fee entitles the holder to attend the lectures on Botany, Chemistry, Materia Medica, and Pharmacy, and to use the Museum of Materia Medica in the Library of the College.

Twelve months' hospital practice, £7 7s.; six months', £5 5s.; three months', £4 4s.; perpetual fee, £17 17s.; or, if paid by instalments, first year £7 7s., second year £6 6s., third year £5 5s. These fees also are payable in advance.

The winter session will open on October 1, 1877.

SCHOLARSHIPS AND MEDALS.

Four Scholarships of £25 a year each, tenable each for four years. Dickinson Memorial Scholarship, £15, tenable for one year, for general proficiency. Tulloch Scholarship, £20, tenable for one year, for Anatomy, Physiology, and Chemistry. Charlton Memorial Scholarship, £35, tenable for one year, for Medicine. Four Resident Dressers, who also act as Physicians' Clinical Clerks, are chosen every six months from the Senior Students. Fee for six months' board and residence £10 10s. Two Assistants in the Pathological Department are chosen every six months.

At the end of each session a Silver Medal and Certificate of Honour will be awarded in each of the required Classes.

R. H. B. Wickham, F.R.C.S. Ed., Medical Superintendent of the Cox Lodge Lunatic Asylum, will deliver a course of lectures on Psychological Medicine, illustrated by cases in the Asylum, to students in their third and fourth years, during the latter half of the winter session.

Further particulars may be obtained of Dr. Luke Armstrong, Registrar, or Dr. Page, Secretary.

NEWCASTLE-UPON-TYNE INFIRMARY.

This Infirmary contains 230 beds. There are special wards for the treatment of Children, Ophthalmic, and Syphilitic Diseases.

MEDICAL AND SURGICAL STAFF.

Physicians.
Dr. Embleton.
Dr. Philopson.
Dr. B. Bramwell.
Dr. Gibson.

Surgeons.
Dr. Heath.
Mr. Russell.
Dr. Arnison.
Dr. Armstrong.

Assistant-Surgeons.
Dr. Hume.
Dr. Page.

Pathologist.
Dr. Bramwell.

Senior House-Surgeon.
Mr. Williamson.

Junior House-Surgeon.
Mr. J. D. Dixon.

FEES.

Fees for hospital practice and clinical lectures:—Twelve months, £7 7s.; six months, £5 5s.; three months, £4 4s. Perpetual fee, £17 17s.; or if paid by instalments—first year £7 7s, second year £6 6s., third year £5 5s.

LIVERPOOL SCHOOL OF MEDICINE.

LECTURERS.

Anatomy—Mr. W. Mitchell Banks.
Botany—Dr. W. Carter.
Chemistry and Toxicology—Dr. J. C. Brown.
Comparative Anatomy—Dr. E. H. Dickinson.
Dental Mechanics—Mr. R. E. Stewart.
Dental Surgery—Mr. J. Snape.
Forensic Medicine—Dr. Ewing Whittle.
Diseases of Children—Dr. R. Gee.
Materia Medica—Dr. J. B. Nevins.
Medicine—Dr. A. T. H. Waters.
Obstetric Medicine and Gynæcology—Mr. A. B. Steele.
Ophthalmic Medicine—Mr. T. Shadford Walker.
Pathological Anatomy—Dr. A. Davidson.
Physiology—Dr. Richard Caton.
Surgery—Mr. Rushton Parker.

DEMONSTRATORS.

Histology and Practical Physiology—Mr. H. Ashby.
Practical Anatomy—(Not filled up for next year.)

ROYAL INFIRMARY.

Consulting Physicians—Dr. Vose, Dr. Turnbull.
Consulting Surgeons—Mr. Long, Mr. Stubbs, Mr. Hakes.

Physicians.
Dr. Waters.
Dr. Glynn.
Dr. Davidson.

Surgeons.
Mr. Bickersteth.
Mr. Harrison.
Mr. Banks.

Resident Medical Officer—Mr. Paul.
Assistant-Surgeon—(Vacant.)
Pathologist—Mr. Parker.
Dental Surgeon—Mr. Snape.
Surgeons to the Lock Hospital—Mr. McCheane, Mr. F. W. Lowndes.

The Infirmary contains nearly 300 beds. There are special wards for the treatment of Uterine and other Diseases of Women.

The Lock Hospital, adjoining the Infirmary, contains sixty beds.

SCHOLARSHIPS AND PRIZES.

Roger Lyon Jones Scholarship.—By the will of the late R. L. Jones, Esq., of Liverpool, the sum of £2000 has been left to the School for the purpose of founding a scholarship, to be named after the donor. This sum will yield about £85 annually, which will be divided, after competitive examination, between two gentlemen, students of Medicine at the School.

Torr Medal.—A gold medal for Anatomy and Physiology, presented by Mr. John Torr, M.P., is awarded to the first student in the second year subjects.

Bligh Medal.—This gold medal, which is presented annually by Dr. John Bligh, Liverpool (also for the encouragement of the study of Anatomy and Physiology), is awarded to the first student in the first year subjects.

FEES.

Composition Fee.—A payment of £47 5s. on entrance or in two equal instalments (one-half on entrance, and the remainder within twelve months), entitles the student to attendance on all the lectures and demonstrations (exclusive of Practical Chemistry) required for the Membership of the Royal College of Surgeons, the Licence of the College of Physicians and the Apothecaries' Society.

Library.—All medical students on registering are required to pay an annual fee of 10s. 6d. to the library and reading-room, or a perpetual fee of £1 1s.

The perpetual Hospital fee (£33 12s.) and the School composition fee for lectures required by the licensing bodies (£47 5s.) amount together to £80 17s. In addition to this must be reckoned Practical Chemistry (£3 3s.), Library fee (£1 1s.), Ophthalmology (£1 1s.), Vaccination fee (£1 1s.), Dissecting-room expenses (roughly estimated at £3 3s.), and a summer course of Practical Anatomy, which, though not absolutely essential, is generally taken (£2 2s.), in all amounting to £11 11s. The total expenses of the education necessary to procure a medical and surgical qualification thus amount to somewhat over £90.

LIVERPOOL ROYAL SOUTHERN HOSPITAL.

Physicians.
Dr. Cameron. | Dr. Carter.

Surgeons.
Dr. Nottingham. | Mr. Hamilton.
Dr. Wollaston.

Senior House-Surgeon—Mr. Owen Gwatkin.

Junior House-Surgeons.
Mr. Wearing. | Mr. Roughton.

Two hundred beds.

Clinical Lectures given by the Physicians and Surgeons during the winter and summer sessions. Clinical Clerkships and Dresserships open to all students. A special ward for Accidents and Diseases of Children. Rooms for a limited number of resident students.

FEES FOR HOSPITAL PRACTICE AND CLINICAL LECTURES.

Perpetual, £26 5s.; one year, £10 10s.; six months, £7 7s.; three months, £4 4s.

The practice of the Hospital is recognised by all the examining bodies.

LIVERPOOL NORTHERN HOSPITAL.

The winter session will commence on Monday, October 1.

MEDICAL AND SURGICAL STAFF.

Physicians.

Dr. Dickinson. | Dr. Caton.

Surgeons.

The Hospital contains 144 beds.

FEES FOR HOSPITAL PRACTICE AND CLINICAL LECTURES.

Perpetual, £26 5s.; one year, £10 10s.; six months, £7 7s.; three months, £4 4s. Students can enter to the medical or surgical practice separately on payment of half the above fees. The Hospital receives one resident pupil, fee £63 per annum. Attendance on the practice of this Hospital qualifies for all the examining boards.

For further particulars apply to the Houre-Surgeon, Mr. Craigmile.

LEEDS SCHOOL OF MEDICINE.

CLASSES AND LECTURES.

Chemistry (at the Yorkshire College of Science) — Professor T. E. Thorpe.
Clinical Medicine — Dr. J. D. Heaton, Dr. T. Clifford Allbutt, and Dr. John Edwin Eddison.
Clinical Surgery — Mr. C. G. Wheelhouse, Mr. T. P. Teale, Mr. T. R. Jessop, and Mr. Edward Atkinson.
Demonstrations of Anatomy — Mr. E. Robinson, Mr. A. F. McGill, and Mr. Robson.
Descriptive Anatomy — Dr. Robert T. Land, Mr. John A. Nunneley, and Mr. Edmund Robinson.
Forensic Medicine — Mr. Thomas Scattergood.
Physiology — Mr. C. J. Wright and Mr. John Horsfall.
Materia Medica — Dr. Thomas Churton.
Medicine — Dr. John D. Heaton, Dr. T. Clifford Allbutt, and Dr. John Edwin Eddison.
Mental Diseases — Dr. Herbert Major.
Midwifery — Mr. W. N. Price, and Dr. James Braithwaite.
Pathology — Mr. A. F. McGill.
Practical Chemistry (at the Yorkshire College of Science) — Professor T. E. Thorpe.
Practical Physiology — Mr. James Walker.
Surgery (including the Practical Course) — Mr. T. R. Jessop, and Mr. Edward Atkinson.

LEEDS GENERAL INFIRMARY.

MEDICAL AND SURGICAL STAFF.

Consulting Physician—Dr. Charles Chadwick.

Consulting Surgeon—Mr. Samuel Hey.

Physicians.	*Surgeons.*
Dr. John Deakin Heaton.	Mr. C. G. Wheelhouse.
Dr. T. Clifford Allbutt.	Mr. T. Pridgin Teale.
Dr. John Edwin Eddison.	Mr. T. R. Jessop.
	Mr. Edward Atkinson.

Surgeons to the Eye and Ear Department.

Mr. John A. Nunneley, Dr. Robert T. Land, Mr. R. P. Oglesby.

SCHOLARSHIPS AND PRIZES.

The Hardwick Scholarship in Clinical Medicine.—Candidates for this prize must be in attendance on the lectures of the Leeds School of Medicine, and must have completed their first year's course there. They must be in registered attendance upon the medical practice of the Hospital, and have served the office of Clinical Clerk, or be holding that office at the time of competition. The prize is given annually for the best set of reports of medical cases in the Hospital during the winter session, subject to such regulations as may be laid down at the commencement of the session. Its value is £10 in money. Should the funds admit, a second prize may be given.

The Surgeons' Clinical Prizes.—Three prizes of the value of £8, £5, and £3 in money will be given annually by the Surgeons of the Hospital, subject to conditions similar to those relating to the Hardwick Prize.

The Thorp Scholarship in Forensic Medicine.—This is a prize of £10 (founded by a former member of Council), awarded at the close of each summer session, subject to such regulations as may be made from time to time, of which due notice will be given. A second prize of £5.

FEES.

The composition fee for attendance upon all the required courses of school lectures is £46 4s., to be paid on entrance; or £24 3s. on entrance, and £24 3s. in twelve months. The fees for the Comparative Anatomy course and for a second course of Practical Chemistry are not included in the composition fee. The entrance fee to the library and reading-room, £1 1s., is paid by all students on joining the School. Instruction in vaccination, as required by the College of Surgeons and by the Poor-law Board, is given by one of the Public Vaccinators—fee £1 1s.; students must attend during a period of six weeks. The fees for attending the medical practice or the surgical practice alone are as follows:—One winter session, £7 7s.; one summer session, £6 6s.; twelve months, £12 12s.; eighteen months, £15 15s.; three years, £21.

The fee of £21 for surgical practice is payable at the commencement of the first winter session, and that for medical practice at the commencement of the second winter session.

OWENS COLLEGE (MANCHESTER ROYAL) SCHOOL OF MEDICINE.(a)

PROFESSORS AND LECTURERS.—WINTER SESSION.

Chemistry—Dr. Henry E. Roscoe.
Clinical Medicine — Dr. William Roberts.
Comparative Anatomy—Mr. W. C. Williamson.
Descriptive and Practical Anatomy —Dr. Morrison Watson.
General Pathology and Morbid Anatomy—Dr. Henry Simpson, Dr. Julius Dreschfeld.
Hospital Instruction — The Physicians and Surgeons to the Royal Infirmary.
Organic Chemistry—Mr. C. Schorlemmer.
Physiology and Histology — Dr. Arthur Gamgee.
Principles and Practice of Medicine —Dr. J. E. Morgan.
Surgery—Mr. Edward Lund.
Practical Surgery — Mr. S. M. Bradley.

SUMMER SESSION.

Botany—Mr. W. C. Williamson.
Materia Medica and Therapeutics — Mr. Alexander Somers, Mr. Daniel John Leech.
Medical Jurisprudence and Public Health—Dr. Arthur Ransome.
Midwifery and Diseases of Women and Children.—Dr. J. Thorburn.
Obstetrics—Dr. John Thorburn.
Ophthalmology—Mr. T. Windsor.
Practical Chemistry—Mr. Henry E. Roscoe.
Practical Morbid Histology — Dr. J. Dreschfeld.
Practical Physiology and Histology —Dr. Arthur Gamgee.

Medical Tutor—Mr. J. Beswick Perrin.

Demonstrator in Anatomy—Mr. A. H. Young, M.B.

Demonstrator in Physiology—Mr. J. Priestley.

Registrar—Mr. J. Holme Nicholson.

Dean of the Medical School—Professor Gamgee, M.D., F.R.S.

EXHIBITIONS, PRIZES, ETC.

A *Turner Scholarship* of £25 for third year's students, a Scholarship of £15 for second year's students, and one of £10 for first year's students. Prizes will also be given for general proficiency.

Platt Physiological Scholarships.—Two Scholarships of £50 each, tenable for two years, one of which is offered annually, are open to the competition of all students of the College who shall have studied Physiology in the College laboratory during one entire session, and whose age on January 1 preceding the examination shall not be under eighteen nor over twenty-five years. The next examination will be held on the 8th and 9th of October, 1877. The Scholarship will be awarded for the best original investigation in Physiology prosecuted in the College laboratory, and on the results of a written examination in Physiology and such subjects connected therewith as shall be prescribed. The Scholarship will not be awarded on the ground of comparative merit only. The candidate elected to the Scholarship will be required to attend during one year of his tenure the practical class in the physiological laboratory of the College, and during the other year the same or some other physiological laboratory in England or on the Continent approved of by the Council and the Senate of the College. If no original investigation shall have been carried on worthy of the Scholarship, the Council may, if they think fit, award one or more exhibitions to the candidate or candidates who shall have been most distinguished in the examination.

Dunville Surgical Prize, value £20.—The Prize will consist of books or surgical instruments at the option of the winner. Candidates must have studied in the Medical Department and the Manchester Royal Infirmary during the winter session of 1875-6, the summer session of 1876, and the winter session of 1876-7, and have attended four courses of lectures, including one, at least, on Surgery. The examination will be conducted by means of written answers to questions on the Principles and Practice of Surgery, including Surgical Anatomy, and, at the option of the examiners, will also include the examination of patients and operations on the dead subject, together with reports of three surgical cases which have occurred in the wards of the Manchester Royal Infirmary during the preceding six months—the reports to comprise the history, progress, treatment, and results (with observations thereon) of these

(a) No return made this year.

cases. The examination will take place soon after the end of the winter session of 1877-78. Notice of intention to compete must be sent to the Registrar in writing on or before March 26, 1878.

Gilchrist Scholarships.—Three of £50 each, tenable for three years, one of which is annually awarded to the candidate who shall stand highest at the Matriculation Examination of the University in London in June, provided that he pass in the honours division, and, failing such, two of £25 each will be given to the two candidates who stand highest in the first division. Further particulars will be found in the "Calendar" and in the prospectus of scholarships, exhibitions, and prizes.

FEES.

A composition fee, which may be paid in one sum of £48, or in two sums of £25 each at the commencement of the first and second years of studentship, admits to the whole of the lectures required to qualify, and to attendance on the class of Practical Anatomy during two winter sessions. Should a student desire to continue his study of Practical Anatomy beyond two sessions, he can do so on payment of extra fees at the rate of £2 2s. for a three months' or £3 3s. for a six months' course.

Extra fees of £1 1s. will be charged for attendance on the Demonstrations in Botany and in Comparative Anatomy; and of £2 2s. for each of the courses of Morbid Histology, Operative Surgery, and the Medical Tutor's Class.

A charge of £1 1s. is also made for the chemicals used in the class of Practical Chemistry.

MANCHESTER ROYAL INFIRMARY.

MEDICAL AND SURGICAL STAFF.

Consulting Physicians—Dr. R. F. Ainsworth, Dr. Frank Renaud, Dr. T. H. Watts.

Physicians.	*Surgeons.*
Dr. M. A. Eason Wilkinson.	Mr. F. A. Heath.
Dr. Henry Browne.	Mr. Edward Lund.
Dr. William Roberts.	Mr. George Bowring.
Dr. Henry Simpson.	Mr. S. M. Bradley.
Dr. John E. Morgan.	
Obstetric Physician.	*Ophthalmic Surgeon.*
Dr. John Thorburn.	Mr. Thomas Windsor.
Assistant-Physicians.	*Assistant-Surgeons.*
Dr. Daniel J. Leech.	Mr. W. Whitehead.
Dr. Julius Dreschfeld.	Mr. J. Hardie.

Dental Surgeon—Mr. G. W. Smith.

Resident Medical Officer—Dr. George Reed.

Medical Supt. of the Royal Lunatic Hospital at Cheadle—Mr. G. W. Mould.

Pathological Registrar—Mr. Thomas Jones.

Registrar—Dr. D. Ross.

Secretary—Mr. B. Brown.

CLINICAL PRIZES.

One Medical and one Surgical Clinical Prize is offered annually for the best reports and commentaries on six medical and on six surgical cases respectively. The cases must be selected from those treated in the Infirmary within the preceding twelve months.

The reports shall be signed with a motto, and transmitted (together with a sealed envelope containing the name and address of the student and the motto chosen by him) to the Chairman of the Medical Committee not later than September 1.

The two Prizes shall be open respectively to the medical and surgical pupils for the current year; they shall be each of the value of £6 6s., and shall consist of books or instruments, at the option of the successful candidates.

STUDENTS' FEES.

Medical Practice.—Three months, £6 6s.; six months, £9 9s.; twelve months, £12 12s.; full period required by the examining boards, £18 18s.

Surgical Practice.—Three months, £9 9s.; six months, £12 12s.; twelve months, £18 18s.; full period required by the examining boards, £31 10s.

Composition Fee.—The fees for the full period required by the examining boards of both medical and surgical practice may be paid by a composition fee of £42 on entrance, or by two instalments of £22 each at an interval of twelve months.

In addition to the practice of the Infirmary, the Monsall Fever Hospital and the Barnes Convalescent Home will also be open, under certain regulations, to students for the purposes of instruction.

SHEFFIELD SCHOOL OF MEDICINE.

LECTURES.—WINTER SESSION.

Anatomy, Descriptive and Surgical—Mr. Skinner, Mr. E. Skinner.
Chemistry—Mr. Allen.
Clinical Surgery—The Surgeon of the Infirmary and Public Hospital and Dispensary.
Clinical Medicine—The Physicians of the Infirmary and Public Hospital and Dispensary.
Dental Mechanics—Mr. G. Mosely.
Physiology—Dr. O'Keefe, Dr. Dyson.
Demonstrations of Anatomy—Dr. E. Thomas, Mr. O. Barber, Mr. S. Snell.
Principles and Practice of Medicine—Dr. Bartolomé, Dr. Banham, Dr. W. R. Thomas.
Principles and Practice of Surgery—Mr. W. F. Favell, Mr. A. Jackson.
Lecturer on Diseases of the Eye—Mr. Snell.

SUMMER SESSION.

Botany—Mr. Birks.
Demonstrations of Pathology and Microscopy—The House-Surgeon (at the Infirmary).
Demonstrations of Operative Surgery—Mr. Favell.
Demonstrations of Practical Histology and Physiology—Dr. Gwynne.
Dental Surgery—Dr. Merryweather.
Materia Medica and Therapeutics—Dr. Young.
Medical Jurisprudence and Toxicology—Mr. Baker, Mr. Harrison.
Midwifery and Diseases of Women—Dr. Hime.
Practical Chemistry—Mr. Allen.
Practical Surgery—The House-Surgeon (at the Infirmary).
Public Medicine—Dr. Drew.

SHEFFIELD GENERAL INFIRMARY.

MEDICAL AND SURGICAL STAFF.

Physicians.	*Surgeons.*
Dr. Bartolomé.	Mr. Barber.
Dr. Law.	Mr. Favell.
Dr. Banham.	Mr. Jackson.

Ophthalmic Surgeon—Mr. Snell.

House-Surgeon—Mr. Laver.

The Infirmary contains 180 beds for in-patients.

FEES.

The fees for perpetual attendance at the Infirmary are £15 15s. for medical, £21 for surgical practice. For twelve months' practice: Medical, £10 10s.; surgical, £6 6s. Six months': Medical, £6 6s.; surgical, £4 4s.

PUBLIC HOSPITAL and DISPENSARY.

Physicians.	*Surgeons.*
Dr. H. J. Branson.	Dr. Keeling.
Dr. Dyson.	Mr. Thorpe.
Dr. W. R. Thomas.	Mr. Pye-Smith.

House-Surgeon.—Mr. Shera.

This Hospital contains 100 beds. The fees are the same as those of the Infirmary. Recognised by the Royal College of Surgeons.

SHEFFIELD HOSPITAL FOR DISEASES OF WOMEN.

MEDICAL OFFICERS.

Dr. Jackson, Dr. Keeling, Dr. Hime, Mr. Woolhouse.

FEES.

Anatomy and Physiology, first course, £6 6s.; second course, £4 4s. Practice of Medicine, first course, £4 4s.; second course, £2 2s. Practice of Surgery, first course, £4 4s.; second course, £2 2s. Chemistry, first course, £4 4s. Midwifery and Diseases of Women, first course, £3 3s. Materia Medica, first course, £3 3s. Medical Jurisprudence, first course, £3 3s. Botany, first course, £3 3s. Practical Chemistry, first course, £3 3s. Practical Physiology, £3 3s. Practical Surgery, £3 3s. These fees include demonstrations.

Perpetual fee for attendance on all the lectures required by the Royal College of Surgeons and the Apothecaries' Hall, £42.

All further information may be obtained on application to the Hon. Secretary, Arthur Jackson, St. James's-row, Sheffield.

SCHOOLS AND HOSPITALS IN SCOTLAND.

UNIVERSITY OF EDINBURGH.—FACULTY OF MEDICINE.

SESSION 1877-78.

Principal—Sir Alexander Grant, Bart., LL.D.

WINTER SESSION.

THE session will be opened on Tuesday, October 30, 1877, at two o'clock, when an address will be delivered by the Principal.

Anatomy—Prof. Turner.
Anatomical Demonstrations—Prof. Turner.
Botany—Prof. Balfour.
Chemistry—Prof. Crum Brown.
Clinical Medicine—Profs. Maclagan, Sanders, and Grainger Stewart. (Prof. Simpson on Diseases of Women.)
Clinical Surgery—Vacant.
General Pathology—Prof. Sanders.
Institutes of Medicine or Physiology—Prof. Rutherford.
Materia Medica—Prof. T. R. Fraser.
Midwifery and Diseases of Women and Children—Prof. Simpson.
Natural History—Prof. Sir C. Wyville Thomson.
Practice of Physic—Prof. Grainger Stewart.
Surgery—Prof. Spence.

WINTER AND SUMMER SESSION.

Anatomical Demonstrations—Prof. Turner.
Bandaging and Surgical Appliances—Prof. Spence.
Operative Surgery—Prof. Spence.
Obstetrical and Gynæcological Operations—Prof. Simpson.
Practical Physiology, including Histology, Chemical Physiology, and Experimental Physiology—Prof. Rutherford.
Practical Anatomy—Prof. Turner.
Practical Chemistry—Prof. Crum Brown.

SUMMER SESSION.

Practical Instruction in Mental Diseases at an Asylum — Prof. Grainger Stewart.
Practical Natural History — Prof. Sir C. Wyville Thomson.
Practical Morbid Anatomy and Pathology—Prof. Sanders.
Practical Botany—Prof. Balfour.
Vegetable Histology—Prof. Balfour.
Tutorial Class of Clinical Medicine in the Wards of the Royal Infirmary by the Clinical Tutor, Mr. Jas. Murdoch Brown.

During the summer session lectures will be given on the following subjects:—

Anatomical Demonstrations—Prof. Turner.
Botany—Prof. Balfour.
Chemistry—Prof. Crum Brown.
Clinical Medicine—Profs. Maclagan, Sanders, Grainger Stewart, and Simpson (Diseases of Women).
Clinical Surgery—Prof. Lister.
Medical Psychology and Mental Diseases—Prof. Grainger Stewart.
Medical Jurisprudence—Prof. Maclagan.
Natural History — Prof. Sir C. Wyville Thomson.
Obstetrical and Gynæcological Operations—Prof. Simpson.

Information relative to matriculation and the curricula of study for degrees, examinations, etc., will be found in the University Calendar, and may be obtained on application to the Secretary at the College.

A list of fees is given in the next column.

During the summer session the following means are afforded for practical instruction:—

The *Dissecting Rooms* are open daily, under the Superintendence of the Professor, assisted by D. J. Cunningham, M.D., J. Symington, M.B., and G. A. Gibson, D.Sc. and M.B.

The *Royal Edinburgh Asylum* is open to members of the class of Medical Psychology exclusively for practical instruction in Mental Diseases by Professor Grainger Stewart and the Physician-Superintendent, Dr. Clouston.

Chemical Laboratories.—The laboratory for instruction in Analytical Chemistry and for chemical investigation, under the superintendence of the Professor, assisted by R. M. Morrison, B.Sc., and G. C. Robinson, is open from ten to four. The Laboratory for Instruction in Practical Chemistry, under the superintendence of the Professor, assisted by A. P. Aitken, M.A., D.Sc.

The *Physiological Laboratory* is open daily for physiological investigation, under the superintendence of the Professor, assisted by William Stirling, M.D., C.M., Sc.D.

The *Physical Laboratory* is open daily from ten to three, under the superintendence of Professor Tait.

The *Medical Jurisprudence Laboratory* is also open daily from ten to three, under the superintendence of the Professor, assisted by J. O. Affleck, M.D.

The practice of Obstetrical and Gynæcological Operations is carried out in the Obstetrical Museum, under the superintendence of the Professor, assisted by David B. Hart, M.B.

The *Natural History Laboratory* is open daily, under the superintendence of the Professor, Sir C. Wyville Thomson, assisted by Isaac Bayley Balfour, Sc.D.

The *Natural History Museum* in the Museum of Science and Art, Chambers-street, is accessible to the students attending the Natural History Class.

The *Royal Botanic Garden*, *Herbarium*, and *Museum* are open daily.

MEDICAL FELLOWSHIPS, SCHOLARSHIPS, BURSARIES, AND PRIZES.

Fellowships.—The Falconer Memorial Fellowship, value £100, tenable for two years. It is for the encouragement of the study of Palæontology and Geology, and is open to graduates in Science or Medicine of the University of not more than three years' standing.

The Syme Surgical Fellowship, value about £100, tenable for two years, open to competition among Bachelors of Medicine of not more than three years' standing, who shall present the best thesis on a surgical subject, giving evidence of original research.

Scholarships.—The Sibbald Scholarship, value about £40, tenable for four years.

Bursaries.—The Abercromby Bursary of £20, tenable for four years, is open to students who have been brought up in Heriot's Hospital during their medical curriculum. The Sibbald Bursaries are open to the sons of duly registered medical men practising, or who may have practised in Scotland, and to the sons of parents who are, or who may have been, householders in Edinburgh. They are of the value of £30 each, tenable for four years, and available for the Faculty either of Arts, Law, Medicine, or Divinity. Four Grierson Bursaries of £20 a year. One Tyndall-Bruce Bursary of £25, tenable for one year, to be competed for by students who have reached the end of their third winter session—subjects of examination to be Materia Medica and Pathology. Competitors for the above bursaries must have studied the subjects of examination at the University of Edinburgh; and these are not to be held along with any other bursary or fellowship.

PRIZES.

The Ettles Medical Prize is awarded annually to the graduate in Medicine whom the Medical Faculty may consider the most distinguished of the year. Value about £40.

The Hope Chemistry Prize, open to all students of the University of not more than twenty-five years of age, who have worked for eight months, or for two summer sessions, in the Chemical Laboratory of the University. Value £100.

A Hope Scholarship, value £30; particulars as to which may be obtained on application to the Professor of Chemistry.

The Neil Arnott Prize, of about £40, is awarded to the candidate who shall pass with the greatest distinction the ordinary examination in Natural Philosophy for the degree of M.A. Candidates must have been medical students of this University during either a summer or a winter session, and the successful candidate must continue a medical student of this University during the winter session. No student can appear for examination after the completion of his third *annus medicus;* no candidate shall be allowed to offer himself more than once.

The Ellis Prize for the best essay "On the Respiration of Plants as distinguished from their Nutrition," is open to students or graduates of five years' standing. Value, proceeds of the sum of £500 accumulated for three years.

The Goodsir Memorial Prize of £60 is awarded triennially for the best essay containing results of original investigations in Anatomy or in Experimental Physiology.

The Medical Faculty Prizes.—Gold medals are given on the day of graduation to Doctors of Medicine whose theses are deemed worthy of that honour.

LECTURESHIP.

The Swiney Lectureship on Geology, value £144, tenable for five years, is open to Doctors of Medicine of the University of Edinburgh. It is in the patronage of the trustees of the British Museum.

MINIMUM COST OF ATTENDING THE MEDICAL CLASSES, WITH THE ORDER OF STUDY.

Whilst there is no authorised order of study, the usual course is given below—Preliminary Examination in Arts to be taken in the month of March or October, before entering medical classes. By order of the General Medical Council, all medical students require to be registered as such within fifteen days after the commencement of the session. Students are recommended to commence their medical studies by attending the summer session.

First Summer Session.—Preliminary examination fee, 10s.; matriculation fee, 10s.; Botany (garden fee, 5s.), £4 4s.; Natural History, £4 4s.; total, £9 8s.

First Winter Session.—Matriculation (for whole year), £1; Anatomy, £4 4s.; Practical Anatomy, £3 3s.; Chemistry, £4 4s.; hospital, £5 5s. (perpetual ticket, £10); total, £17 16s.

Second Summer Session.—Botany or Natural History, if not attended previously; Practical Chemistry, £3 3s.; examination in Botany, Natural History, and Chemistry, in October following,(a) £5 5s.; total, £8 8s.

Second Winter Session.—Matriculation, £1; Institutes of Medicine, £4 4s.; Surgery, £4 4s.; hospital, £5 5s.; examination in Botany, Natural History, and Chemistry, in April, if not previously passed; total, £14 13s.

Third Summer Session.—Practical Pharmacy, £2 2s.; dispensary, £2 2s.; hospital; total, £4 4s.

Third Winter Session.—Matriculation, £1; Materia Medica, £4 4s.; Pathology, £4 4s.; Clinical Surgery, £4 4s.; dispensary, £1 1s.; hospital; examination in Anatomy, Physiology, Materia Medica, Pathology, in April or July, £5 5s.; total, £19 18s.

Fourth Summer Session.—Medical Jurisprudence, £4 4s.; hospital and clinical lectures; total, £4 4s.

Fourth Winter Session.—Matriculation, £1; Practice of Medicine, £4 4s.; Midwifery, £4 4s.; Practical Midwifery, £1 4s.; Clinical Medicine, £4 4s.; Vaccination, £1 1s.; hospital; total, £15 17s.

Fifth Summer Session.—Hospital; final examination for M.B. and C.M., £10 10s.; total minimum expenses for M.B. and C.M., £104 18s.

Only one course of instruction on each subject is here stated, that being the minimum.

Fees for Degrees.—Examination in Botany, Chemistry, chemical testing, and Natural History, £5 5s.; examination in Antomy, Institutes of Medicine, Materia Medica, Pathology, £5 5s.; final examination in Surgery, Midwifery, Practice of Physic, Clinical Medicine, Clinical Surgery, Medical Jurisprudence, and prescriptions, during last summer session, £5 5s.; total fees for M.B. diploma, £15 15s. Additional fee for C.M. diploma, £5 5s.;

(a) For those who have certificates for two summer sessions and one winter session, and who have attended two courses during each of these three sessions.

additional fee for M.D. diploma, £5 5s.; Government stamp-duty (for M.D. only), £10.

Note.—Total fees and stamp for graduating as M.D. only, by regulations for students commencing before February, 1861, £25.

N.B.—The above fees include all charges for the diplomas.

ROYAL INFIRMARY, EDINBURGH.

In this Hospital a portion of the beds is set apart for clinical instruction by the Professors of the University of Edinburgh. Courses of Clinical Medicine and Surgery are also given by the ordinary Physicians and Surgeons. Special instruction is given in the Medical Department on Diseases of Women, Physical Diagnosis, etc., and in the Surgical Department on Diseases of the Eye. Separate wards are devoted to fever, venereal diseases, diseases of women, diseases of the eye; also to cases of incidental delirium or insanity. Post-mortem examinations are conducted in the Anatomical Theatre by the Pathologist, who also gives practical instruction in Pathological Anatomy and Histology.

MEDICAL DEPARTMENT.

Professors of Clinical Medicine—Dr. Maclagan, Dr. Sanders, Dr. Grainger Stewart.

Extra Physicians and Lecturers on the Diseases peculiar to Women—Dr. J. Matthews Duncan, Dr. Alex. R. Simpson.

Ordinary Physicians and Lecturers on Clinical Medicine—Dr. Rutherford Haldane, Dr. George W. Balfour, Dr. T. Grainger Stewart, Dr. Claud Muirhead.

Assistant-Physicians—Dr. John Wyllie, Dr. David J. Brakenridge.

SURGICAL DEPARTMENT.

Consulting Surgeons—Dr. Dunsmure, Dr. J. D. Gillespie.

Professor of Surgery—Mr. Spence.

Ordinary Acting Surgeons—Dr. P. H. Watson, Mr. Thos. Annandale (Lecturers on Clinical Surgery); Dr. Joseph Bell.

Professor of Clinical Surgery—Mr. Lister.

Ophthalmic Surgeons—Mr. Walker, Dr. D. A. Robertson.

Extra Surgeon for Treatment of Ovarian Diseases—Dr. Thomas Keith.

Assistant-Surgeons—Dr. John Duncan, Dr. John Chiene.

Dental Surgeon—Dr. John Smith.

Pathologist—Dr. John Wyllie.

HOSPITAL TICKETS.

Perpetual, in one payment, £10; annual, £5 5s.; half-yearly, £3 3s.; quarterly, £1 11s. 6d. Separate payments for two years entitle the student to a perpetual ticket.

THE SCHOOL OF MEDICINE, EDINBURGH.

On October 1 the Practical Anatomy Rooms and Chemical Laboratories will be opened. On October 30 the inaugural address will be delivered by Dr. John Duncan, at eleven o'clock. On October 31 the Lectures will be commenced.

WINTER SESSION.

Anatomy: Practical Anatomy, Lectures, Anatomical Demonstrations—Dr. P. D. Handyside.

Chemistry: Lectures, Practical Chemistry, Analytical Chemistry—Dr. Stevenson Macadam, Mr. J. Falconer King, and Mr. Ivison Macadam.

Materia Medica and Therapeutics—Dr. Francis W. Moinet.

Surgery—Dr. P. H. Watson, Mr Joseph Bell, Mr. Chiene, Dr. John Duncan.

Midwifery and Diseases of Women and Children — Dr. Matthews Duncan.

Institutes of Medicine or Physiology—Dr. Andrew Smart.

Clinical Medicine (Royal Infirmary)—Drs. Rutherford Haldane, Geo. W. Balfour, and Claud Muirhead. Dr. Matthews Duncan (for Diseases of Women).

Clinical Surgery (Royal Infirmary)—Dr. P. H. Watson & Mr. Annandale.

Medical Jurisprudence and Public Health—Dr. Littlejohn.

Practice of Physic—Dr. Rutherford Haldane and Dr. Claud Muirhead.

Natural History, Zoology, and Comparative Anatomy—Dr. Andrew Wilson.

General Pathology and Pathological Anatomy—Dr. John Wyllie.

Diseases of the Ear — Dr. Kirk Duncanson.

Vaccination (Royal Dispensary)—Dr. Husband.

Diseases of Children—Dr. R. Peel Ritchie.

SUMMER SESSION.

Anatomy: Practical Anatomy, Anatomical Demonstrations—Dr. P. D. Handyside.

Chemistry: Practical Chemistry, Analytical Chemistry—Dr. Stevenson Macadam, Mr. J. Falconer King, and Mr. Ivison Macadam.

Materia Medica and Therapeutics—Dr. Francis W. Moinet and Dr. William Craig.

Midwifery and Diseases of Women and Children—Dr. Keiller, Dr. Angus Macdonald, Dr. Underhill, and Dr. Halliday Croom.

Medical Jurisprudence and Public Health—Dr. Littlejohn.

Clinical Medicine (Royal Infirmary)—Drs. Rutherford Haldane, Geo. W. Balfour, and Claud Muirhead. Dr. Matthews Duncan (for Diseases of Women).

Clinical Surgery (Royal Infirmary)—Dr. P. H. Watson and Mr. Annandale.

Vaccination—Dr. Husband.

Natural History, Zoology, and Comparative Anatomy—Dr. Andrew Wilson.

Diseases of the Ear—Dr. Kirk Duncanson.

Diseases of the Skin—Dr. Allan Jamieson.

Diseases of the Eye—Dr. Argyll Robertson.

Medical Anatomy and Practical Medicine—Dr. Claud Muirhead.

Pathological Histology—Dr. John Wyllie.

Insanity—Dr. J. Batty Tuke.

Syphilology—Dr. Cadell.

Diseases of Children—Dr. R. Peel Ritchie.

Operative and Practical Surgery—Dr. P. H. Watson.

Surgical Appliances and Operative Surgery—Mr. Joseph Bell.

Surgical Anatomy and Operative Surgery—Mr. Chiene.

Practical Surgery—Dr. John Duncan.

The lectures qualify for the University of Edinburgh and the other Universities; the Royal Colleges of Physicians and Surgeons of Edinburgh, London, and Dublin, and the other medical and public Boards.

FEES.

For a first course of lectures, £3 5s.; for a second, £2 4s.; perpetual, £5 5s. To those who have already attended a first course in Edinburgh the perpetual fee is £2 4s. Practical Anatomy (six months' course), £3 3s. Anatomical Demonstrations, £2 2s.; with Practical Anatomy, £1 1s.; perpetual, £4 4s. Practical Chemistry, £3 3s.; Analytical Chemistry, £2 a month, £5 for three months, or £10 for six months. Vaccination, £1 1s. Syphilology, £1 1s. For summer courses of Clinical Surgery and Clinical Medicine, each £2 4s.; Practical Anatomy (including Anatomical Demonstrations), Medical Anatomy, Operative Surgery, Diseases of the Ear, Diseases of the Skin, Insanity, and Diseases of Children, each £2 2s.

The minimum cost of the education in this School of Medicine for the double qualification of Physician and Surgeon from the Royal College of Physicians and Surgeons, including the fees for the joint examination, is £90 4s., which is payable by yearly instalments during the period of study; whilst the minimum cost for the single qualification of either Physician or Surgeon, including the fee for examination, is £80.

UNIVERSITY OF GLASGOW.—FACULTY OF MEDICINE.

LECTURES AND CLASSES.—WINTER SESSION.

Anatomy, Junior; Anatomy, Senior; Practical Anatomy—Prof. A. Thomson and Demonstrators.

Chemistry, Chemical Laboratory—Prof. Ferguson.

Clinical Medicine—Prof. McCall Anderson.

Clinical Surgery — Prof. George Buchanan.

Forensic Medicine—Prof. P. A. Simpson.

Physiology—Prof. McKendrick.

Materia Medica—Prof. Cowan.

Midwifery—Prof. Leishman.

Practice of Physic—Prof. Gairdner.

Surgery—Prof Macleod.

Pathology—The Pathologists of the Infirmaries.

SUMMER SESSION.

Botany, Botanical Demonstrations—Prof. A. Dickson.

Clinical Medicine—Prof. McCall Anderson.

Clinical Surgery — Prof. George Buchanan.

Embryology, and Demonstrations on Anatomy, Elementary Anatomy, Practical Anatomy—Prof. A. Thomson and Demonstrators.

Practice of Medicine—Prof. Gairdner.

Lectures on the Eye—Dr. T. Reid.

Operative Surgery—Prof. Macleod.

Practical Chemistry. Chemical Laboratory—Prof. Ferguson.

Practical Pharmacy—Prof. Cowan.

Practical Physiology—Prof. McKendrick.

Zoology—Prof. Young.

CLASS FEES.

Fee for each course, £3 3s., except lectures on the Eye, for which the fee is £1 1s.

In addition to the University courses, the following Hospitals and Dispensaries afford ample means for practical instruction in the various departments of Medicine and Surgery:—

WESTERN INFIRMARY.

This Hospital contains beds for medical and surgical patients, with wards for skin diseases and for diseases of women.

MEDICAL AND SURGICAL STAFF.

Physicians.	*Surgeons.*
Prof. W. T. Gairdner.	Prof. George H. B. Macleod.
Prof. T. McCall Anderson.	Prof. George Buchanan.
Dr. James Finlayson.	Dr. Alexander Patterson.

Diseases of Women—Prof. W. Leishman.

Dispensary Physicians—Dr. Gavin P. Tennent, Dr. Joseph Coats, and Dr. Gemmell.

Dispensary Surgeons—Dr. James G. Lyon, Mr. D. N. Knox, Dr. Christie, and Dr. Renton.

Pathologist—Dr. Joseph Coats.

Medical Superintendent—Dr. Alexander.

Lady Superintendent—Miss E Clyde.

The hour of visit is 9 a.m.

FEES.

The fees for admission to the practice of this Infirmary are—First year, £10 10s.; second year, £10 10s.; afterwards free. The fees for clinical lectures are included in the foregoing.

GLASGOW ROYAL INFIRMARY SCHOOL OF MEDICINE.

The winter session commences on October 30, and the summer session on May 1. Lectures are delivered on the subjects necessary for qualifying, and extra courses are given on practical subjects now required by examining boards. During summer, lectures on Insanity will be given by Dr. A. Robertson, and the City Parochial Asylum under his charge is free to students of this School.

LECTURES AND DEMONSTRATIONS.

Anatomy—Mr. H. E. Clark.
Chemistry—Dr. John Clark.
Clinical Medicine — Physicians of the Hospital.
Materia Medica—Dr. John Dougall.
Clinical Surgery—Surgeons of the Hospital.
Medicine—Dr. A. Wood Smith.
Physiology—Mr. W. T. Fleming.
Surgery—Dr. H. C. Cameron.

The Royal Infirmary contains 570 beds. Of these 240 are for medical and 320 for surgical cases, with special wards for the treatment of venereal disease in males and diseases of women. Diseases of the ear and throat are specially treated at the outdoor department.

MEDICAL AND SURGICAL STAFF.

Physicians.
Dr. Perry.
Dr. Maclaren.
Dr. Wood Smith.
Dr. Charteris.

Physician for Diseases of Women.
Dr. Stirton.

Surgeons.
Dr. Cameron.
Dr. Morton.
Dr. Macewen.
Dr. E Watson.
Dr. Dunlop.

Dispensary Physicians.
Dr. Mather.
Dr. Lawrie.

Extra Dispensary Physicians.
Dr. J. W. Anderson.
Dr. Weir.
Dr. Dougall.

Dispensary Surgeons.
Mr. Clark.
Dr. Lothian.

Extra Dispensary Surgeons.
Dr. Whitson.
Mr. Fleming.
Dr. Foulis.

Vaccinator.
Dr. Tannahill.

Pathologist.
Dr. Foulis.

Diseases of the Throat.
Dr. Eben Watson.

APPOINTMENTS.

There are five Physicians' and five Surgeons' Assistants, who are boarded and lodged in the Hospital at the rate of £25 per annum, and who perform all the duties of House-Physicians and House-Surgeons. These appointments are held for twelve months—six in the medical, and six in the surgical wards—and are open to those students of the Infirmary who have passed all their examinations except the last, or who have a qualification in Medicine or Surgery.

Clinical Assistants, Dressers, and Dispensary Clerks are selected from the students without any additional fee; and from the large number of accident cases and cases of acute disease received into the wards, these appointments are numerous, and invaluable to the student. Attendance at the Dispensary for the treatment of out-patients, and admission to the Pathological Museum, are also free.

FEES.

For each course of lectures, first session, £2 2s ; second ditto, and perpetual, £1 1s.

The Anatomy Class fees are—first session, £4 4s. ; second ditto, £4 4s.; afterwards, £1 1s. per annum for Practical Anatomy.

HOSPITAL FEE.

The fee for unlimited attendance on the practice of the Infirmary and on the courses of clinical instruction and lectures does not exceed £21.

Further information may be obtained from Dr. Thomas, the Superintendent of the Hospital.

ANDERSON'S COLLEGE, GLASGOW.

LECTURES AND CLASSES.

Anatomy—Dr. Buchanan.
Chemistry—Mr. Dittmar.
Institutes of Medicine or Physiology—Dr. McVail.
Materia Medica—Dr. Mortou.
Medical Jurisprudence (in Summer)—Dr. Alex. Lindsay.
Midwifery (in Summer)—Dr. J. G. Wilson.
Ophthalmic Medicine and Surgery—Dr. Wolfe.
Practice of Medicine—Dr. Charteris.
Surgery—Dr. Dunlop.

FEES.

Fee for each class, £2 2s. ; second session, £1 1s. The fees for all lectures and hospital practice required for a diploma do not exceed £48.

Hospital practice and clinical lectures in the Royal Infirmary, containing 600 beds.

The lectures at Anderson's College qualify for the various licensing boards in the kingdom.

Students may also attend the Maternity Hospital (Physicians-Accoucheur—Drs. J. G. Wilson and Tannahill), Eye Infirmary, Ophthalmic Institution, Dispensary for Skin Diseases, etc.

A syllabus, with full information, may be obtained by applying to Dr. A. M. Buchanan, 149, St. George's-road, Glasgow, Dean of the Medical Faculty.

UNIVERSITY OF ABERDEEN.—FACULTY OF MEDICINE.

LECTURES.—WINTER SESSION.

Anatomy—Professor Struthers.
Chemistry—Professor Brazier.
Institutes of Medicine—(Vacant.)
Medical Logic and Medical Jurisprudence—Professor Ogston.
Midwifery and Diseases of Women and Children—Professor Stephenson.
Practical Anatomy and Demonstrations—Professor Struthers and Demonstrator.
Practice of Medicine—Professor Smith-Shand.
Surgery—Professor Pirrie.
Zoology with Comparative Anatomy—Professor Nicol.

SUMMER SESSION.

Botany—Professor Trail.
Materia Medica—Professor Harvey.
Practical Pharmacy—Professor Harvey and Assistant.
Practical Anatomy and Demonstrations—Professor Struthers and Demonstrator.
Practical Chemistry—Professor Brazier.
Zoology with Comparative Anatomy—Professor Nicol.

The Anatomical Course in summer includes instruction in Histology and in the use of the microscope; and instruction in Osteology for beginners.

FEES.

Matriculation fee (including all dues) for the winter and summer session, £1 ; for the summer session alone, 10s.

Pathological Anatomy, Dr. Rodger, £2 2s. Practical Ophthalmology (in summer), Dr. A. D. Davidson. Dental Surgery (in summer), Mr. Williamson.

The regulations relative to the registration of students of Medicine, and the granting of degrees in Medicine and Surgery, may be had of Professor Brazier, Secretary of the Faculty of Medicine.

Full information regarding the classes and degrees in the Faculties of Arts, Law, and Divinity, and in regard to Bursaries and Scholarships, will be found in the University Calendar, published by Messrs. Wyllie and Son, Union-street, Aberdeen, by post 2s. 2d.

ABERDEEN ROYAL INFIRMARY.

The Aberdeen Royal Infirmary contains about 300 beds.

MEDICAL AND SURGICAL STAFF.

Consulting Physician—Dr. A. Harvey.
Consulting Surgeon—Mr. David Fiddes.

Physicians.
Dr. J. W. F. Smith-Shand.
Dr. R. Beveridge.
Dr. Angus Fraser.

Surgeons.
Mr. W. Pirrie.
Mr. A. Ogston.
Mr. J. O. Will.
Mr. R. J. Garden.

Resident Assistant-Physician.
Mr. William Henry.

Resident Assistant-Surgeon.
Mr. Andrew Norrie.

Ophthalmic Surgeon—Dr. Alex. D. Davidson.
Dental Surgeon—Mr. Williamson.
Chloroformist—Dr. P. B. Smith.
Resident Superintendent and Apothecary—Dr. R. Rattray.
Pathologist and Curator of Museum—Dr. J. Rodger.
Treasurer and Secretary—Mr. W. Carnie.

UNIVERSITY OF ST. ANDREWS.

There is no proper Faculty of Medicine in this University, but it is possible for the student to make an *annus medicus* by attendance on certain of the courses—as Natural History, Professor Nicholson, M.D.; Chemistry, Professor Heddle, M.D.; and Anatomy and Medicine, Professor Pettigrew, M.D.

SCHOOLS AND HOSPITALS IN IRELAND.

UNIVERSITY OF DUBLIN.—SCHOOL OF PHYSIC.

THE School of Physic is under the conjoint superintendence of the University authorities and those of the King and Queen's College of Physicians.

LECTURES AND CLASSES.

Anatomy and Surgery—Dr. Benjamin G. M'Dowel.
Botany—Dr. E. Percival Wright.
Chemistry—Dr. G. Emerson Reynolds.
Comparative Anatomy and Zoology—Dr. Alexander Macalister.
Institutes of Medicine—Dr. J. M. Purser.
Materia Medica and Pharmacy—Dr. Aquilla Smith.
Medical Jurisprudence—Dr. Robert Travers.
Midwifery—Dr. Edward B. Sinclair.
Natural Philosophy—Rev. J. Leslie.
Operative Surgery—Dr. Richard G. Butcher.
Ophthalmic Surgery—Mr. Henry Wilson.
Physic—Dr. William Stokes.
Practice of Medicine—Dr. W. Moore.
Surgery—Dr. William Colles (Trin. Coll., Dr. Edward H. Bennett).
University Anatomist—Dr. Thomas E. Little.

Winter Session, 1877-78.—The winter session commences on October 1. Lectures will commence on November 1. The dissecting-room will be opened on October 1.

SCHOLARSHIPS AND EXHIBITIONS.

Medical Scholarships.—Two medical scholars are elected annually, by the Board of Trinity College, at an examination held at the end of June—subject to conditions stated in the College Calendar. Each scholarship is worth £20 per annum, and is tenable for two years.

Medical Exhibitions.—The Professors of the School of Physic give three exhibitions annually, amounting altogether in value to £40—subject to conditions prescribed by the Professors themselves.

SIR PATRICK DUN'S HOSPITAL.

MEDICAL AND SURGICAL STAFF.

Consulting Physician.—Dr. William Stokes.
Consulting Surgeon.—Dr. W. Colles.

Clinical Physicians.	*Clinical Surgeons.*
Dr. John Malet Purser.	Dr. Benjamin G. M'Dowel.
Dr. William Moore.	Dr. Thomas E. Little.
Dr. Aquilla Smith.	Dr. Edward H. Bennett.
Midwifery Physician.	*Lecturer in Operative Surgery.*
Dr. Edward B. Sinclair.	Dr. Richard G. Butcher.

FEES.

Clinical Lectures and Hospital Attendance.—The payment of £3 3s. to the Hospital entitles any student to attend the clinic of the Hospital for twelve months, and to attend the lectures delivered by Dr. R. G. Butcher, University Lecturer in Operative Surgery. Students who have taken out the degrees of Bachelor in Medicine and Master in Surgery in Trinity College are entitled to attend the Hospital as perpetual free pupils. In addition to the Hospital fee, the payment of a fee of £6 6s. is required for the privilege of attending the clinical lectures. Total fees for hospital and lectures for twelve months, £9 9s.

Practical Midwifery.—Students desirous of entering for twelve months' instruction in Practical Midwifery are required to pay a maternity fee of £3 3s. each. Students of Trinity College are not liable to any other payment for instruction in Practical Midwifery. Other students are required to pay £3 3s. each to the King's Professor for twelve months' practical instruction, in addition to the Hospital maternity fee. Students who have paid the Hospital maternity fee are entitled to attend the demonstrations in Obstetric Surgery given by the King's Professor. Total fees for College Students, £3 3s.; total fees for Externs, £6 6s.

PRIZES.

Clinical Medals.—The Governors of the Hospital award a Silver Clinical Medal in Medicine to the student who shall pass the best examination on the medical cases treated in the Hospital during the year; and a Silver Clinical Medal in Surgery to the student who shall pass the best examination on the surgical cases treated in the Hospital during the year.

QUEEN'S COLLEGE, BELFAST.

The lectures will commence on Tuesday, October 30.

Anatomy and Physiology—Dr. P. Redfern.	Natural Philosophy—Dr. Everett.
Chemistry—Dr. Thomas Andrews.	Practice of Medicine—Dr. James Cuming.
Materia Medica—Dr. J. S. Reid.	Practice of Surgery—Dr A. Gordon.
Medical Jurisprudence—Dr. J. F. Hodges.	Zoology and Botany—Dr. R. O. Cunningham.
Midwifery—Dr. R. F. Dill.	

The demonstrations in Anatomy are delivered by Dr. Anderson. The lectures in Midwifery and in Medical Jurisprudence, and the courses of Botany and Practical Chemistry, and a second course of Experimental Physics, will commence in May.

FEES.

Anatomy and Physiology—First course, £3; each subsequent course, £2. Anatomical Demonstrations and Practical Anatomy—each course, £3. Practical Chemistry, £3. Other medical lectures—first course, £2; each subsequent course, £1.

SCHOLARSHIPS.

Two Medical Scholarships are awarded to the students of each year of the medical course. The examinations commence on October 17.

BELFAST GENERAL HOSPITAL.

FEES.

Clinical Instruction—Perpetual fee, payable in one sum of £10 10s., or two instalments of £5 5s. each on entering for the first and second years. Hospital fee, 10s. 6d. each session.

BELFAST LYING-IN HOSPITAL.

Fee for the session, £3 3s.

QUEEN'S COLLEGE, GALWAY.—FACULTY OF MEDICINE.

LECTURERS.

Anatomy and Physiology, and Practical Anatomy—Dr. J. Cleland.	Medical Jurisprudence—Dr J.P.Pye.
Botany and Zoology—Dr. A. G. Melville.	Midwifery and Diseases of Women and Children—Dr. R. J. Kinkead.
Chemistry—Dr. T. H. Rowney.	Natural Philosophy—Dr. A. H. Curtis.
Logic and Mental Philosophy—Dr. T. W. Moffett.	Practice of Medicine — Dr. N. Colahan.
Materia Medica—Dr. J. P. Pye.	Practice of Surgery—Dr. J. V. Brown.

The County Galway Infirmary, Town, and Fever Hospitals are in the immediate vicinity of the Queen's College.

SCHOLARSHIPS AND EXHIBITIONS.

Eight scholarships of the value of £25 each, and exhibitions varying in value from £12 to £16, are appropriated to students pursuing the course for the degree of M.D.

FEES.

Anatomy and Physiology, £3 first session; afterwards £2. Practical Anatomy, £3; Practical Chemistry, £3; Operative Surgery, £3; other classes, £1 for each course extending over one term only, £2 for each course extending over more than one term, and £1 for each re-attendance on the same.

For further information, application may be made to Professor Curtis, M.A., LL.D., Registrar.

QUEEN'S COLLEGE, CORK.—FACULTY OF MEDICINE.

LECTURERS.

Anatomy and Physiology—Dr. J. J. Charles.	Practical Anatomy—The Professor, assisted by Demonstrators.
Chemistry and Practical Chemistry—Dr. Maxwell Simpson.	Practice of Medicine—Dr. D. C. O'Connor.
Materia Medica—Dr. M. O'Keefe.	Practice of Surgery—Dr. W. K. Tauner.
Midwifery—Dr. J. R. Harvey.	Zoology and Botany—Mr. Robert Harkness.
Natural Philosophy — Mr. John England.	

SCHOLARSHIPS.

Eight scholarships are awarded to students in Medicine, if qualified. Two junior scholarships of £25 each to students commencing their first, second, third, and fourth years. Clinical Medicine and Surgery at the North and South Infirmaries, and Clinical Midwifery at the Lying-in Hospital.

THE ADELAIDE HOSPITAL, PETER-STREET, DUBLIN.

MEDICAL AND SURGICAL STAFF.

Physicians.	*Surgeons.*
Dr. Henry H. Head.	Dr. Albert J. Walsh.
Dr. James Little.	Dr. John K. Barton.
	Mr. Benjamin Wills Richardson.
Obstetric Physician.	*Ophthalmic Surgeon.*
Dr. Richd. Purefoy.	Dr. Richard Rainsford.
Assistant-Physician.	*Assistant-Surgeon.*
Dr. Walter G. Smith.	Mr. Montgomery A. Ward.

Further particulars can be obtained from Mr. Richardson, 22, Ely-place, or any other member of the medical staff.

ST. VINCENT'S HOSPITAL, DUBLIN.

HOSPITAL STAFF.

Physicians.	*Surgeons.*
Dr. Francis J. B. Quinlan.	Dr. Edward D. Mapother.
Dr. Robert Cryan.	Mr. William H. O'Leary, M.P.

Gynæcologist—Dr J. A. Byrne.
Surgeon-Dentist—Mr. William J. Doherty.
Apothecary—Mr C. T. Boland.

FEES.

Winter and summer session, £12 12s.; separately, £8 8s. and £5 5s.

Further particulars may be learned on application to the Secretary, or at the Hospital during the hours of attendance.

DR. STEEVENS' HOSPITAL AND MEDICAL COLLEGE, DUBLIN.

MEDICAL AND SURGICAL STAFF.

Dr. T. W. Grimshaw.	Mr. E. Hamilton.
	Mr. R. M'Donnell.
Physician-Accoucheur.	*Resident Surgeon.*
Dr. James Isdell.	Dr. H. J. Tweedy.

Surgeon-Dentist—Mr. J. A Baker.
Surgeon-Oculist—Mr. Henry R. Swanzy.

LECTURERS.

Anatomy—Dr. Bookey, Dr. Warren, Mr. Fox, Mr. Johnston, and Dr. McVittie.
Anatomy and Physiology—Mr. E. Hamilton.
Surgery—Mr. W. Colles.
Chemistry—Mr. McHugh.
Botany—Vacant.
Materia Medica—Dr. T. W. Grimshaw.
Medical Jurisprudence—Dr. H. J. Tweedy.
Medicine—Dr. H. Freke.
Midwifery—Dr. James Isdell.
Curator of the Museum—Dr. Henry J. Tweedy.

FEES.

Hospital Practice, nine months, £12 12s.; ditto, six months, £8 8s. Practical Anatomy, £5 5s. Lectures, each course, £3 3s.

Further particulars may be learned from any of the Professors; from the Resident Surgeon at the Hospital; or from Dr. Edward Hamilton, Hon. Sec., 120, Stephen's-green West.

JERVIS-STREET HOSPITAL, DUBLIN.

MEDICAL AND SURGICAL STAFF.

Physicians.

Dr. Stephen M. MacSwiney. | Dr. William Martin.

Surgeons.

Mr. M. Harry Stapleton. | Mr. Austin Meldon.
Dr. J. Stannus Hughes. | Mr. James Edward Kelly.
Mr. J. K. Forrest. | Mr. M. J. Kilgarriff.
Dr. E. W. Collins.

This Hospital is most central in situation, and in the immediate vicinity of the Catholic University and Carmichael Medical Schools. From its proximity to the quays and principal factories it presents unrivalled opportunities to the students of seeing every form of surgical injury. An extensive Dispensary for out-door patients is attached to the Hospital, at which the students are allowed to perform minor operations, under the guidance of the Surgeon on duty, and are rendered familiar with the details of dispensary practice.

Instruction is given by the Physician and Surgeon on duty on alternate mornings, between nine and eleven o'clock, at the bedside, when the nature, progress, and treatment of each case are explained. Two clinical lectures are delivered each week on the most important cases under treatment, when pathological specimens are exhibited. Surgical instruments and appliances of all kinds are constantly made the subject of special instruction.

Surgical Operations are performed on Saturday mornings, at ten o'clock, except in cases of emergency, when due notice is given, if possible.

Practical Pharmacy is taught under the superintendence of the Apothecary.

Resident Pupils and Dressers are selected from among the most attentive of the advanced students, without payment of any additional fee. Two Interns are appointed each half-year, and are provided with apartments, etc., free of expense. Special Certificates are given to the Resident Pupils and Dressers who have performed their respective duties to the satisfaction of the Physicians and Surgeons.

Certificates of attendance are recognised by all the licensing bodies and examining boards in the United Kingdom.

CARMICHAEL SCHOOL OF MEDICINE, DUBLIN,

In immediate proximity to the Richmond, Whitworth, and Hardwicke Hospitals, North Brunswick-street, Dublin.

LECTURERS.

Anatomy—Dr. Christopher Gunn, Mr. Wm. M. A. Wright.
Botany—Mr. E. B. Blakeley.
Chemistry—Dr. C. R. C. Tichborne.
Institutes of Medicine & Pathology—Dr. S. Woodhouse.
Materia Medica—Dr. G. F. Duffey.
Midwifery—Mr. W. B. Jennings.
Medical Jurisprudence—Mr. H. A. Auchinleck.
Ophthalmic and Aural Surgery—Dr. C. E. Fitzgerald.
Physiology—Dr. R. J. Harvey.
Practice of Medicine—Dr. S. Gordon, Dr. J. W. Moore.
Surgery—Dr. A. H. Corley.

The School will open for Dissections on Monday, October 1, and the Lectures will begin on Thursday, November 1.

Prizes to the value of £64 on the foundation of the late Richard Carmichael, Esq., and the Mayne Scholarship, value £15, are awarded annually.

For further particulars apply to the Registrar, Dr. Harvey, at the School, or at 7, Upper Merrion-street, Dublin.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

MEDICAL AND SURGICAL STAFF.

Physicians.

Dr. Arthur Wynne Foot. | Dr. John William Moore.

Surgeons.

Mr. George H. Porter. | Mr. Rawdon Macnamara.
Mr. James H. Wharton. | Mr. R. Perrié White.
Mr. Philip Crampton Smyly. | Mr. Lambert H. Ormsby.

The ensuing winter session will commence on October 1, and the course of clinical lectures on the first Monday in November.

Clinical lectures, of which four will be delivered weekly, and instructions in Medicine and Surgery, will be given on alternate days.

The Physicians and Surgeons on duty will visit the Hospital at 9 a.m., so as to allow the members of the class to be in attendance at their respective Schools of Medicine at 11 a.m.

The Hospital, which contains 120 beds for the reception of medical and surgical cases, and to which an extensive dispensary (open daily), lending library, and physical laboratory are attached, is within a few minutes' walk of the University, the College of Surgeons, and the Ledwich School of Medicine.

An additional ward has been erected for the reception of children, in which the pupils will have an opportunity of studying that highly important subject—infantile disease.

Certificates of attendance at this Hospital are recognised by all the universities, colleges, and licensing bodies in the United Kingdom.

Prizes will be given at the termination of the winter course to the best answerers in their respective classes.

The office of Resident Pupil is open to pupils as well as apprentices.

Further information may be obtained on application to Lambert H. Ormsby, Esq., Hon. Sec., 12, Lower Fitzwilliam-street; or at the Hospital.

CATHOLIC UNIVERSITY SCHOOL OF MEDICINE, CECILIA-STREET, DUBLIN.

LECTURES AND CLASSES.

Anatomy and Physiology — Dr. Hayden and Dr. Cryan.
Anatomical Demonstrations — The Professors of Anatomy and Physiology.
Botany—Dr. Sigerson.
Chemistry—Dr. Campbell.
Dissections—Dr. Hayes, Dr. Nixon, Dr. Coppinger, Dr. Kilgarriff, and Mr. Carroll.
Medical Jurisprudence—Dr. MacSwiney.
Materia Medica—Dr. Quinlan.
Natural Physiology—The Rev. Dr. Molloy.
Pathology—Dr. Lyons.
Practical Chemistry—Dr. Campbell.
Theory and Practice of Medicine—Dr. Lyons.
Theory and Practice of Midwifery—Dr. Byrne
Theory and Practice of Surgery—Mr. Tyrrell.
Ophthalmology—Dr. Hayes.

PRIZES AND EXHIBITIONS.

At the termination of the winter session, public examinations will be held, when, in addition to prizes in each class, the University Gold Medal, value £7, will be awarded for the subjects mentioned in the School prospectuses.

At the termination of the summer session, the University Exhibition, value £20, will be awarded, in addition to the usual prizes in each class.

FEES.

For each course £3 3s., excepting Dissections and Practical Chemistry, which are £5 5s. A reduction of one-sixth is made to perpetual pupils paying the entire of their fees in advance, or in two instalments at the commencement of the first and second years of their course. Parents and guardians are recommended to forward all fees directly, by cheque or order, to the Registrar, Dr. Hayes, 29, Westland-row, or at the School.

Further particulars may be learned from any of the Professors; from the Medical Registrar, Dr. Hayes, 29, Westland-row; or on application at the School.

CITY OF DUBLIN HOSPITAL, UPPER BAGGOT-STREET.(a)

MATER MISERICORDIÆ HOSPITAL, ECCLES-STREET, DUBLIN.

MEDICAL AND SURGICAL STAFF.

Physicians.

Dr. John Hughes.
Dr. Thomas Hayden.
Dr. Christopher J. Nixon.

Assistant-Physician.

Dr. Christopher Gunn.

Surgeons.

Mr. Francis R. Cruise.
Mr. Henry J. Tyrrell.
Mr Patrick J. Hayes.

Assistant-Surgeon.

Mr. Charles Coppinger.

This Hospital contains 210 beds, including fifty beds for fever and other contagious diseases.

Certificates of attendance upon this Hospital are recognised by all the licensing bodies in the United Kingdom.

PRIZES.

Two clinical prizes (the "Leonard Prizes") of £15 each, one medical and one surgical, will be given at the end of the

(a) No return made for the last two years.

winter session, in accordance with the directions contained in the will of the late Mark Leonard, Esq., for the best report of not less than twenty cases for each prize; the cases reported to be those occurring in the Hospital during the winter session.

Fee for nine months, £12 12s.; six winter months, £8 8s.; three summer months, £5 5s.

Further particulars may be learned by application to Dr. Nixon, Secretary to the Medical Board, 32, Upper Merrion-street, or to any of the other medical officers.

MERCERS' HOSPITAL, WILLIAM-STREET, DUBLIN.

STAFF.

Physicians—Dr. T. P. Mason and Dr. George F. Duffey.
Surgeons—Mr. E. Ledwich, Mr. E. S. O'Grady, and Mr. B. F. M'Dowell.

This Hospital, one of the first founded in Dublin, is situated in a central position, and is in close proximity to the Schools of the Royal College of Surgeons' Catholic University and the Ledwich.

ROYAL COLLEGE OF SURGEONS IN IRELAND. SCHOOL OF SURGERY.

LECTURES.—WINTER SESSION.

Anatomy and Physiology — Dr. Mapother.
Descriptive Anatomy—Dr. Bevan and Mr. Thornley Stoker.
Midwifery—Dr. Roe.
Surgery—Mr. J. Stannus Hughes and Mr. Stokes.
Practice of Medicine—Dr. James Little.
Chemistry—Dr. Cameron.

SUMMER SESSION.

Materia Medica—Mr. Macnamara.
Medical Jurisprudence—Dr. Davy.
Botany—Dr. Minchin.
Practical Chemistry—Dr. Cameron.
Midwifery—Dr. Roe.
Hygiene—Dr. Cameron.
Ophthalmic and Aural Surgery—Mr. Swanzy.

A public course of lectures on Comparative Anatomy will be delivered by the Professor of Anatomy and Physiology, at the commencement of the session, and additional lectures on the same subject will be delivered during the winter.

The dissections are under the direction of the Professor of Anatomy, assisted by the demonstrators—Dr. Stoney, Dr. Ormsby, Dr. Wheeler, Dr. Wm. Stoker, Dr. Peele, Dr. Franks, Dr. Legge Roe, and Mr. Knott,—who will daily attend to give instruction and to assist the students.

The fee for each course of lectures is £3 3s., excepting Descriptive Anatomy, which is £8 8s., Practical Chemistry, which is £5 5s., and Ophthalmic and Aural Surgery and Hygiene, which are free.

A composition fee of £56 17s. 6d. is taken as payment in full for all lectures and dissections required for the diploma in Surgery.

A Junior Exhibition of £15, a Senior Exhibition of £25, and Honorary Certificates will be awarded at the end of each winter session.

LEDWICH SCHOOL OF ANATOMY, MEDICINE, AND SURGERY, PETER-STREET, DUBLIN.

COURSES OF LECTURES.

Anatomy, Physiology & Pathology, etc.—Mr. E. Ledwich, Mr. T. P. Mason, and, Mr. J. E. Kelly.
Botany—Dr. McNab.
Forensic Medicine and Hygiene—Dr. R. Travers.
Surgical and Descriptive Anatomy, Demonstrations, and Dissections—Mr. Mason, Mr. Ledwich, Mr. Glanville, Mr. Robinson, and Mr. Porter.
Materia Medica and Therapeutics—Dr. M'Dowel.
Midwifery and Diseases of Women and Children—Dr. S. A. Mason.
Theory of Chemistry, Practical Chemistry, & Natural Philosophy—Dr. Griffiths.
Theory and Practice of Medicine—Dr. Foot.
Theory and Practice of Surgery—Mr. Wharton and Mr. Barton.

The fee for each of the above courses will be £3 3s.

A course of operations to be performed by the students, under the superintendence of the lecturers (subjects, etc., included), £5 5s.

Further information may be obtained from any of the lecturers, or from Mr. Edward Ledwich, Secretary, 7, Harcourt-street, Dublin.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

MEDICAL AND SURGICAL STAFF.

Consulting Physician.—Sir D. J. Corrigan, Bart.

Physicians.
Dr. J. T. Banks.
Dr. B. G. M'Dowel.
Dr. S. Gordon.
Dr. R. D. Lyons.

Surgeons.
Mr. William Stokes.
Mr. William Thomson.
Mr. W. Thornley Stoker.
Mr. A. Corley.

Assistant Physician—Dr. Reuben J. Harvey.
Ophthalmic Surgeon—Dr. Charles E. Fitzgerald.
Resident Surgeon—Mr. R. J. Martyn.

Clinical instruction will commence on October 1. These Hospitals contain 312 beds—110 for surgical cases, 82 for medical cases, and 120 for fever and other epidemic diseases. Premiums will be awarded in Clinical Medicine and Surgery. The Richmond Institution for the Insane, containing over 1000 patients, adjoins these Hospitals.

FEES.

For the winter and summer session (nine months), £12 12s.; for the six winter months, £8 8s.; for the three summer months, £5 5s. Resident clinical clerks, £21 for the winter session, £15 5s. for the summer session, including certificate of attendance.

Application to be made to Dr. Gordon, 13, Hume-street, or to Mr. Stokes, 5, Merrion-square North, Dublin.

EDUCATIONAL VACCINATING STATIONS.

In order to provide for the granting of those special certificates of proficiency in vaccination which are required to be part of the medical qualification for entering into contracts for the performance of Public Vaccination, or for acting as deputy to a contractor, the following arrangements are made:—

1. The Vaccinating Stations enumerated in the subjoined list are opened under certain specified conditions, for the purposes of teaching and examination.

2. The Public Vaccinators officiating at the stations are authorised to give the required certificates of proficiency in vaccination to persons whom they have sufficiently instructed therein; and

3. The Public Vaccinators whose names in the subjoined list are printed in italic letters are also authorised to give such certificates, after satisfactory examination, to persons whom they have not themselves instructed:—

London.—Principal Station, Surrey Chapel, Blackfriars-road: *Mr. James Furness Marson*, who attends on Tuesday and Thursday, at 1 p.m. North-west Stations—Marylebone General Dispensary, 77, Welbeck-street: Mr. William A. Sumner, on Tuesday, at 2 p.m.; Hall of the Working Men's Christian Association, Omega-place, Alpha-road: Mr. Wm. A. Sumner, on Wednesday, at 10 a.m. West Station—9, St. George's-road, Pimlico, S.W.: Mr. Edward Lowe Webb, on Thursday, at 10 a.m. East Station—Eastern Dispensary, Leman-street: Mr. Charles T. Blaekman, on Wednesday, at 11 a.m. North Station — Tottenham-court Chapel, Tottenham-court-road: Mr. William Edwin Grindley Pearse, on Monday and Wednesday, at 1 p.m. South-west Station—2, Regent-place, Horseferry-road: Mr. Wm. Edwin Grindley Pearse, on Tuesday, at 2 p.m. Strand Station—14, Russell-street, Covent-garden: Mr. Robert William Dunn, on Thursday, at 11 a.m.

Birmingham.—St. John's Wesleyan Chapel, Inge-street, Hurst-street, on Monday; the Assembly Rooms, 103, Constitution-hill, opposite Bond-street, on Tuesday; St. Mark's School-rooms, St. Mark's-street, on Wednesday; and "The British Workman" Reading Rooms, Sherborne-street, near Grosvenor-street, on Thursday: *Dr. Edmund Robinson*, at 11 o'clock on the days before mentioned.

Bristol.—The Public Vaccination Station, Peter-street: *Dr. Henry A. P. Robertson*, on Wednesday, at 10 a.m.

Exeter.—Odd Fellows' Hall, Bamfyld-street: *Mr. Charles H. Roper*, on Thursday, at 3 p.m.

Leeds.—Heed-street: *Mr. Frederick Holmes*, on Tuesday, at 2.30 p.m.

Liverpool.—4, Oldham-street: *Mr. Arthur Browne Steele*, on Thursday, at 2 p.m.

Manchester.—72, Rochdale-road: *Mr. Ellis Southern Guest*, on Monday, at 2 p.m.

Newcastle-on-Tyne.—The Central Vaccination Station, 21, Nun-street: *Mr. John Hawthorn*, on Wednesday, at 3 p.m.

Sheffield.—The Public Vaccination Station, Townhead-street: *Mr. William Skinner*, on Tuesday, at 3 p.m.

Edinburgh.—The Royal Dispensary: *Dr. William Husband*, on Wednesday and Saturday, at 12. The New Town Dispensary: Dr. James O. Affleck, on Tuesday and Friday, at 12.

Glasgow.—The Hall of the Faculty of Physicians and Surgeons: *Dr. Hugh Thomson*, on Monday, at 12. The Royal Infirmary: Dr. Robert Dunlop Tannahill, on Monday and Thursday, at 12.

THE STUDENT BEGINNING TO WORK.

TO ENTERING STUDENTS.

THERE should be present to the mind of each gentleman who commences his studies with the coming Session the rapid advances which the medical profession has made within the last few years. For these advances—in the power of alleviating human suffering and in social position—teach the all-important lesson that the watchwords have been hard work, a firm integrity, and a strict honour, and that without these no one entering the profession can hope to succeed.

Within even a few years the conditions under which men commence their studies have changed. Prelimiuary examinations have been instituted, the old system of "apprenticeship" is practically gone, and new methods of teaching and new methods of examination have been introduced. Minor changes spring up year by year, and these, almost equally with the greater, teach us that the student in the midst of so many vicissitudes has need of particular, as well as of general advice. We can only dwell on a few particular points, and the general advice which we shall give will be of little value unless we can persuade each of our readers to copy the example of their predecessors, who have done much to increase the honour of the profession, and to emulate their doings. It is all-important that a young student should remember that—at first, at any rate, consciously or unconsciously—he will tread in the wake of examples. Happily, in the medical profession he can have uo difficulty in finding lights worthy of pursuing. Not only does the roll of medical celebrities yield examples, but there are those practisiug in the most remote places whose conduct and skill are fitted to teach everyone who cares to consider the highest lessons. There are hundreds of medical practitioners who will tell us that they learnt in the days of their pupilage, from their first teacher in some far-away country district, that success in the profession could not be attained without hard work and integrity, and that their sense of duty was first instilled into them by a country doctor.

But the great majority of those whom we especially address come to their medical school "fresh from school or college," and are iu almost complete ignorance of the new life and studies so soon to be theirs. Various feelings work within them, which we cannot even enumerate, much less analyse: one thanks fate that he is no longer to be under school-boy rule; another is lost in the enthusiasm which has been excited by dreams of months or perhaps years; a third burns with hope of winning renown, and sees fields of future fame before him; while but few remember that they will have difficulties to surmount, temptatious to overcome, aud disappointments to endure,—otherwise, however humble their expectations, they cannot succeed in the race that is for them to run. It would be unfortunate were there not difficulties, for, if properly encountered, they will strengthen the mind of the young student, and bring to the front his best intellectual powers. He should, therefore, above all things remember that he has difficulties before him, and that on the way in which he meets them and takes advantage of them depends his whole making. This should be one of his constant thoughts, and should pervade and temper the other and many various emotions which must always arise in the minds of young men starting on a new life. In the "pupilage days," students came to their school with some knowledge of what we have written,—they had experienced a taste of the difficulties as well as of the joys of the profession; but now most euter on their studies complete novices, unless perchance a relative in the professiou has initiated them into some of its secrets, and in oft-told tales in the surgery or the library taught them something of the pleasures and troubles of a medical student's career. Those entering the profession may find satisfaction—as we do—in the fact that many come year by year into our students' ranks who have had such opportunities, for it shows better than all arguments that there is in the study and in the practice of medicine a source of pleasure, often, in point of fact, greatest where pecuniary success is least. These gentlemen do not miss the loss of pupilage, for to all intents and purposes they have had its advantages. Of the advantages and disadvantages of apprenticeship we here say nothing; but we do not hesitate to say that the former were considerable, and it is our duty to ask those who have neither directly nor indirectly experienced them to acquire for themselves such advantages as far as is possible during the years of studentship. The passing of preliminary examinations, the introduction of which has done so much good, and will do still more, cannot yield these advantages. For "pupilage" did not mean, except in times very far back, the dispensing of mixtures for five years—a downright waste of valuable time,—but instruction in the minor branches of general practice, and an introduction into the "ways of people"—a study of human nature, of its strength and its weaknesses—and the groundwork of a knowledge of life which is so essential for the successful treatment of the sick. A student may have passed the best of preliminary examinations; he may have gone beyond these, and have graduated in some one of our universities; yet, while we welcome him all the more on that account, we ask him never to forget that though the training through which he has passed will be of exceeding value to him, the apprentice of former years had advantages which he has not had, and such as no amount of classics, no amount of mathematics—in fact, no amount of book knowledge—can of themselves yield. It seems to us all-important that every student should, from the very outset of his career, be firmly convinced that, for his own good and the good of his patients, he must cultivate a familiarity with human nature as well as with human ills. The student will learn this iu the out-patients' room of his hospital better than in the hospital wards; and no one, unless he has attained this valuable species of experience, which the "apprentice" acquired before entering his medical school, should deem himself fit to practise the profession of medicine.

But no matter what his previous circumstances, the first-year's man has a fixed line of study drawn out for him. As far as within him lies he should follow the programme given to him; nor should he be depressed by the vastness of the programme, nor by the novelty of his surroundings. He has teachers whose method of teaching is strange; the subjects are new, or almost so, and the terms used are vague and unmeaning in his ears, and not a little tantalising. He has become one of a company gathered from all poiuts of the compass, and which by its very variety discourages him. Everything is strange; friends are far away, and the first-year's man is for awhile in an unknown world. It is during this time that much good or much ill may be done him; and, as often happens, if he cannot secure other advice, he should take that which his teachers are always ready to give him, and set at once to work with those subjects which are best for him. There are, unfortunately, in every school of medicine a few men who seize on the new comers and attempt to dissuade them of the usefulness of this or that course of study recommended by the school authorities. Against these mischievous advisers let each new student be on his guard; he will not fail in a little while to find fellow-students who will initiate him into a more sensible view of things. His way is plain: those who have gained their position as teachers by hard work have determined certain methods of study as best suited for the medical student; do the opinions of the grumbling and disappointed deserve consideration in face of the deliberate determination of those best qualified to judge?

Every man who contemplates entering a school of medicine in the coming session should fairly make up his mind to be

diligent in his attendance on lectures above all things. His diligence in this respect will save him time and labour—and, what is more, keep him level with the work of each session. Every lecture missed means something lost. It is frequently the case that students become backsliders as regards lectures because some particular teacher does not impress them favourably; and, no doubt, it is irksome enough to listen day by day to one whose style we cannot appreciate. But remissness in one class leads to neglect of others; and the student who is careless of one soon becomes notorious by his neglect of all, and he thus brings about, even though he pass his "examinations," a source of regret which will exist throughout his whole life. The weakest-minded of students laughs at his teachers; the earnest worker strengthens his powers day by day by attention to them, and finds in all—in varying degree, of course—a constant well of information. "Once a student, always a student," must be treasured words among those who are to practise medicine; and the greatest amongst us are great because they act up to them.

We earnestly recommend each student also to take notes of his lectures, and to study them in the quiet of his own room. Thus will he master what his teacher has said. It is no loss of time to transcribe the notes, for frequent repetition is an absolute gain to one entering on a new course of study. The student should compare his notes with his text-book, and "things" omitted in the one or the other become more prominent and more fixed in the mind when thus observed, because of the omission. We would remind each individual that the science and practice of medicine are making such rapid strides that text-books can scarcely bear pace with them, and that from lectures alone can he acquire what is most recent in each branch of study.

From the very outset of his student-life the medical student should remember that he must acquire a fair all-round knowledge of his profession. It is the fact that of late years certain men have commenced their studies rather with the intention of attaining a particular excellence in some one special department than a general knowledge of medicine, and have persuaded themselves that their powers were of a particular and special kind. Such men, under the influence of this delusion, have studied only subjects which they deemed as bearing on their especial case. Against this suicidal and ridiculous practice let students and the advisers of students set themselves. A man is not fit to be a physician, surgeon, or obstetrician unless he has mastered by careful study all the main principles of medicine, and has acquainted himself with its general practice. A specialist is an ephemeral and mushroom growth unless he has mastered the groundwork of medicine; and the student must not devote himself to any particular line of study. He must keep predilections in abeyance until the ordinary years of studentship have passed. There is, unfortunately, too much need of warning in these respects. The medical wards, for example, are neglected for the surgical; and first-year's men, who are better away from both, are too apt to imitate some of their seniors, who persuade themselves that they are acquiring a sound knowledge of their profession by regular attendance in the operating-theatre. One man likes chemistry, another anatomy, another physiology, and, favouring his choice, thinks the others can wait. But nothing can "wait" for the medical student, and in every branch of study laid down he must steadily work. He can make no greater mistake than to fancy at the outset of his career that his line is this, that, or the other. A thousand circumstances crop up to defeat him, and, remembering this, he should labour to fit himself for all-round practice, no matter what may be his ultimate lot. Specialists have failed because clever general practitioners have detected their ignorance on points outside their speciality; and we are afraid that even the "apothecaries" of fifty years ago would have confounded many of those who see in the ills of their patients nothing but their own especial diseases.

In hospital work students often find enticements which lead them away from their legitimate work; but, speaking generally, the hospital is no place for a student until he has passed his anatomical and chemical examinations. Nevertheless, even the first-year's man may find profit there during hours which he cannot otherwise turn to account. The student's days are but few, and from the first bedside teaching may be turned to practical account. In the out-patients' room the young student will never be objectionable, and in it he has opportunities of good work which in after years he will fully appreciate; and he will find numerous examples of senior students who to the very last apply themselves with increasing advantage to out-patient practice. He knows that he sees "life" there; that his future life will in great part be similar to the out-patient prescriber. It is in the out-patient room that the student can best appreciate the difficulties under which the most able labour in their treatment of disease and in its diagnosis. We most earnestly recommend the student to remember throughout the whole of his career at his school that what seems mere routine in the examination and treatment of out-patients is not routine, and that "rapidity" of examination means in most cases thorough training and the power of arriving at diagnosis with ease as a result of a wide experience.

The relationship which will exist between each new student and his seniors is of the utmost importance. His seniors include all about his school from the second-year's man to the most ancient on the medical staff. We look back, and most certainly the retrospect persuades us that the student who, while not sacrificing his independence as one sent forth to make for himself a line, and to use his own individual methods of thought and reasoning under proper guidance, never forgets that he is a student, and that to his teachers, good and bad, a certain respect is owing, in the end accomplishes the most. Fortunately, however, there is little need for us to say much on this point, for there is nothing more gratifying, and nothing more encouraging to all connected with the medical profession, than the marked consideration which the medical students of this country pay to their various teachers; and it may be added, equal encouragement is to be found in the kindly treatment which teachers manifest towards students. It is the student's business to make himself acquainted with his various teachers; it is the teacher's business to make himself a friend of the student: and when each one attempts to bring about a freedom of intercourse, and at the same time remembers what is owing to, and what is due from, their respective positions, the happiest results must issue. The gentlemen who begin their studies with the coming session will find themselves differently affected by their different teachers; but in the conflict of these natural feelings, let them above all things be persuaded that those to whom their training has been entrusted will labour to their utmost to pilot them safely to the haven they seek.

The teachers of a medical school do much to make it famous, but their labours are scarcely rewarded unless they are abetted by steadiness in work on the part of their students, and an earnest desire to benefit by the teaching. The strong current of gentlemanly feeling which runs full and free amongst the new students of the present day cannot fail to impress on their minds that the reward which their teachers most value is evidence of improvement in the student's knowledge, and an appreciation of their attempts to improve him. Every first-year's man should remember that the opportunities of familiar intercourse with the staff of his school depend almost entirely on his own efforts, and we have no hesitation in saying that he who sets before him the duty we have attempted to impress, and works up to it, will quickly

attract the notice of all, and become in his relationship with his teachers quite as much a friend as a pupil. Arrogance can never accomplish this, no matter how far backed by brain-power; but perseverance and a sense of responsibility, with gratitude for all done, can not only accomplish it, but is the surest way to professional success. The line of conduct which each new man ought to follow is, indeed, best defined by an appeal to his highest and best emotions. Far distant friends are watching, perhaps anxiously, his progress—so too, it may be, are friends who have made sacrifices to set him on the road to an honourable career, and possibly to fame. Scarcely one of the gentlemen who are to enrol their names in the coming session can say that no such sacrifices have been made. The student should treasure the recollection of these, and encourage emotions of gratitude within him—for nothing is more calculated to ennoble the mind of a young man than the remembrance of sacrifices made for him, and a continual appreciation of these sacrifices. We expect, indeed, from all candidates for admission into our profession the attributes of gentlemen. They must come with an earnest desire to support and advance the honour of the profession, and be anxious to increase its power of doing good to human kind. We decline altogether to discuss the monetary question as it concerns the medical man, simply because we are of opinion that higher motives than those which money can yield influence the majority of students. And even when pecuniary success comes, the medical man will not be satisfied, and will not be appreciated by his medical brethren, unless he has laboured for those things which yield moral and intellectual profit and satisfaction. Men labouring in remote country districts (and many of those whom we address may with happiness thus labour) have achieved such results, and pecuniary success has had no share in them. Let the student from the very moment of his decision to embrace the medical profession impress on his mind that, whether his lot be in town or country, at home or abroad, duty claims, and success depends upon, hard work in his student-career and the steady observance of those rules which all gentlemen obey, though the rules be unwritten. There is indeed an unwritten law in the medical profession, an acquaintance with which the best of students will quickly acquire. And they must acquire it, if honour be their aim, by a patient industry and a constant regard of the opinions of the best of those with whom they are thrown in contact. All we have written, we hope, indicates this:—That new men ought to understand the grave responsibilities they are undertaking. We shall think ourselves fortunate if we can persuade all to regard these responsibilities, and to keep them. A first-year's man who is conscious of these things can scarcely go wrong. He cannot fail to remember that he owes a duty to himself, to his medical school, to distant friends, and to suffering humanity; and, remembering these things, he will not long have a soul which cannot rise above pounds, shillings, and pence considerations. With money he may be enriched in after-life, and deservedly enriched; but whether enriched or not, he in his after-life will never have reason to regret that duty from the onset of his career was uppermost in his mind. The profession of medicine gives happiness not by riches alone, and often apart from them. In itself it commands the exercise of the highest emotions. Each first-year's man has a duty before him, and unless he labour to perform that duty his reward should be small. Each one should remember that posterity will praise him not for acquired wealth, but for the power he exercised in alleviating pain and curing disease, and that his own generation will value him by the light of the work he does, and not by the wealth he gains,—and this, no matter whether his lot casts him in the greatest of our cities or in the most remote of country districts.

THE STUDENT'S FIRST WINTER SESSION.

Let us suppose, then, that the young student comes to his medical studies with a good sound English education, and some little knowledge of Physics and Chemistry; his attention during the first winter will be mainly devoted to Chemistry, Anatomy, and Physiology. In Chemistry, he will find an enormous advantage in the little knowledge he brings with him; and it would greatly assist teachers of Chemistry in fulfilling their duty to be able to address gentlemen whose knowledge extended to the most important facts relating to Inorganic Chemistry, for then the time of the medical student could be directed mainly to Organic Chemistry, the part which is to be of most use to him in after-life: whereas, as matters now stand, he rarely reaches those studies, and still more rarely masters them. We would very strongly, therefore, endeavour to impress on the minds of those about to become students of Medicine the importance of acquiring some knowledge of Chemistry, and still more of Botany, before entering a medical school. In most public schools nowadays both of these subjects are taught, and every effort ought to be made to encourage the practice. Be that, however, as it may, let the student work hard to master the science of Chemistry during this his first year, for each succeeding session brings its own work with it.

Turning next to Anatomy, the first thing to which a student directs his attention is the "bones," and these should be mastered as soon as possible. This is, as a rule, not very difficult; he will have plenty of aid from his fellow-students. A thorough knowledge of the bones is invaluable, and carries with it much knowledge of the soft parts. Each groove, ridge, foramen, and channel has its own story, and the knowledge of how each is occupied must be constantly exercised in after-life. The next step should be a thorough study of the joints and ligaments; but this varies a good deal in different schools. In some—and perhaps this is the best plan—after the joints and ligaments, the student is sent at once to the study of muscles, as to origin, insertion, course, shape, composition, and mode of action. And these three subjects may be said to be the foundation of all surgical knowledge. In other schools, however, the student is at once turned into the dissecting-room to study all parts—muscles, nerves, vessels, fasciæ—as they are laid bare. This plan, too, has its excellencies; but on the whole, it is better, if there is material for the purpose, to acquire a knowledge of the bones, ligaments, and muscles before attempting the more difficult concrete Anatomy. But whatever plan be adopted, let the knowledge acquired be real—a knowledge not of the memory, but of the understanding; for at the basis of Surgery, and of much of Medicine also, lies a sound knowledge of Anatomy. This leads us to point out another thing the student should do early—that is, to acquire some knowledge of the relative positions of the different viscera, and their external indications. This is best acquired in the post-mortem-room, which from the first the student should frequent. What of dissecting? The student should take to it as early as may be possible. He should endeavour, it is true, to master everything laid bare, but if he only acquire a manual dexterity, that at least is something.

And now as regards Physiology. Here we are almost reduced to despair. The absurd existing regulations compel a man to enter on the study of the very highest branches of Chemistry, in the shape of Physiological Chemistry, on the same day on which he begins to study its rudiments; to study the minute structure of a part or organ with whose shape or outward appearance he is altogether unacquainted. We can only tell him to do his best, and to learn as much as he can by means of his eyes; he must trust more to his ears another session.

Finally, as regards Hospital Practice, the sooner the young

student begins to study what is, after all, to be the great business of his life, the better; but it should be begun with reason. Students should not be let loose like an undisciplined crowd of star-gazers; there should be rule in everything. In some hospitals the preposterous system of introducing the raw student into the medical wards did at one time prevail, and Sir Astley Cooper used to congratulate his class on having left the study of Medicine for the higher walk of Surgery. The sooner the young man understands that time spent in the medical wards at this period of his career is wasted, the better for him. Let him instead go at once to the surgical out-patient room; here he can *see* something. He can learn what an ulcer is, and how to dress it; what to do for a bad wound or bruise; that in many cases it is necessary to use a knife. He will see how different kinds of bandages are put on, and the different dodges, if one may say so, necessary to bandage different parts properly. In short, it is here that the student can best spend his time, thence proceeding in due course to the surgery of the wards. On the other hand, we would anxiously warn the young student against the physician's out-patient department. Here he will do no good, and he may be much harmed by it. He sees a gentleman busy prescribing for a crowd of patients, and he sees them rapidly disposed of; but he does not see the years of study and hard work which have enabled the physician to make in a few minutes a trenchant diagnosis. Vast numbers of these patients suffer from the same kind of illness: they are subject to the same influences—close, ill-smelling houses in foul alleys; a want of light and air; improper or badly cooked food, partaken of at improper times; and, above all, the only solace they have for so much squalor and discomfort —that which ever tends to perpetuate this—too much beer and gin. But we are diverging from our subject. Let, however, the young student avoid such studies until he is better qualified to appreciate them, and let him stick to those things he can see for himself in the surgical section.

In due time comes the First Summer Session. This is commonly devoted to the study of Botany, Materia Medica, and Practical Chemistry. About these we have a word to say, especially as regards the first. Botany and its uselessness is a favourite subject of declamation with some; but with these we can in nowise agree. Like other studies, it might well be excluded from the medical curriculum, but it certainly ought not to be excluded from the scheme of medical education. Botany is far best and easiest learnt at school; of all branches of natural science it is that which requires fewest appliances. Its material is everywhere; and, rightly taught and rightly learned, it is a source of unfailing delight. Hunting for plants is quite as exciting as hunting anything else. Let Botany be taught and studied, then, but let it be out of the curriculum; or, if in it—as needs must be sometimes —let the student acquire the principles here, and apply them for himself in the fields and lanes. Materia Medica, too, has come in for much abuse; but was it so when men went through an apprenticeship? Then they imbibed Materia Medica, as it were, insensibly; by constant handling they knew the colour, smell, taste, relative weight, and a hundred other things concerning drugs. But that system has passed away, and something must take its place if men are to live by their profession. Therapeutics, again, which some men would substitute, should be taught at a later period of the student's course of study. Fortunately, we are all agreed on the necessity for practical Chemistry, but that should really take the shape of the analysis of vegetable and animal solids and fluids, not of simple solutions.

SECOND WINTER SESSION AND FIRST EXAMINATION.

With the Second Winter comes the near approach of the First Professional Examination. At the Royal College of Surgeons, whither nearly all students flock, the subjects are Anatomy and Physiology, not separately, but conjointly. This arrangement is unfortunate, for it leads the student to the study of Anatomy at the expense of Physiology, the idea having got abroad that it is the more important subject of the two. As a consequence, we believe we are right in saying that the majority of those plucked are so in Physiology. We mention this because it is in this winter that a competent knowledge of Physiology is to be acquired, and the student should pay at least as much attention to it as to Anatomy. But there is another thing the student should also look after—that is, the art of passing an examination. It is not enough that a student should have a full knowledge of his subjects: that knowledge should be methodised, and so formulated as to be at hand when wanted. There is nothing does this so well as class examinations, which are now held almost everywhere; but the student should also accustom himself to note-taking and to writing answers to questions, such as those set at the College, and regularly published in our columns. This will give him that ease and accuracy of expression so essential for passing a good written examination. There should be no "shots" at answering questions, no beating about the bush; with an examiner everything should be straightforward, simple, and unmistakable. Finally—a little thing—when sitting down to an examination, read over your paper carefully, and see what question you can best answer; write down that answer first on one piece of paper; take the next one that suits you, and do likewise; and so on, gradually attacking the more difficult, until you finish. In this way you are left with plenty of time on your hands, whereas, did you hesitate and bungle over the first difficulty, you might be unable to finish the writing out of the answers to those questions with which you were best acquainted.

By the time the student has passed his First Examination he should be out of leading-strings, and able, with the advice of his teachers, to employ his time to good advantage. He has passed beyond the class we have meanwhile specially in view.

DEGREES IN SCIENCE IN THE DEPARTMENT OF PUBLIC HEALTH.

UNIVERSITY OF EDINBURGH.

In consequence of the great demand which now exists for Medical Officers of Health, and the importance to the public of some means of ascertaining that members of the medical profession have specially studied the subject of Public Health, Science Degrees in the Department of Public Health have been instituted by the University of Edinburgh under the following conditions:—

1. Candidates for graduation in Science in the Department of Public Health must be graduates in Medicine of a British University, or of such foreign or colonial Universities as may be specially recognised by the University Court.

2. Candidates who have not passed an *annus medicus* in the University of Edinburgh must, before presenting themselves for examination, have attended as matriculated students in the University at least two courses of instruction, scientific or professional, bearing on the subjects of the examinations.

3. There are two examinations for the degree of Bachelor of Science in the Department of Public Health. Candidates who have passed the first examination may proceed to the second, immediately or at any subsequent Medical or Science examination.

4. Candidates must produce evidence that, either during their medical studies or subsequently, they have attended a course of lectures in which instruction was given on Public Health, and that they have studied Analytical Chemistry practically for three months with a recognised teacher.

5. The examinations are written, oral, and practical, and are conducted by University examiners selected by the University Court.

6. The subjects of the examinations for the degree of

Bachelor of Science in the Department of Public Health are as follows:—

FIRST EXAMINATION.

1. *Chemistry.*—Analysis of air, detection of gaseous emanations and other impurities in the atmosphere; analysis of waters for domestic use, and determination of the nature and amount of their mineral and organic constituents; detection, chemical and microscopical, of adulterations in articles of food and drink, and in drugs: practical examination, including at least two analytical researches.

2. *Physics.*—Hydraulics and hydrostatics, in reference to water-supply, drainage, and sewerage; pneumatics, in reference to warming and ventilation; meteorology, and methods of making meteorological observations; mensuration in reference to the plans and sections of public and private buildings, mines, waterworks, and sewers.

3. *Sanitary Law.*—Knowledge of the leading sanitary Acts of Parliament.

4. *Vital Statistics.*—Knowledge of statistical methods and data in reference to population, births, marriages, and deaths.

Examination.—First day: Chemistry and Physics. Second day: Sanitary Law and Vital Statistics.

An oral examination and an examination in practical chemistry in the laboratory will take place a few days after the written examination.

SECOND EXAMINATION.

1. *Medicine.*—Origin, nature, and propagation of epidemic and contagious diseases; prevention of contagion and infection; endemic diseases and the geographical distribution of disease; insalubrious trades; overcrowding; epizootics, including pathological changes.

2. *Practical Sanitation.*—Duties of a Health Officer in reference to water-supply; insalubrious dwellings and public buildings; removal and disposal of sewage and other refuse and impurities; cemeteries; nuisances from manufactories, etc.: bad or insufficient supplies of food; outbreaks of zymotic diseases; quarantine; disinfectants and deodorisers; construction of permanent and temporary hospitals.

The written examinations will take place on October 19 and 20, 1877, and April 1 and 2, 1878, at eleven o'clock each day. Candidates who intend to present themselves for examination in October are required to lodge with the Clerk of the University proof of their being eligible, and to pay the fee on or before October 1; and for the examination in April on or before March 1.

DOCTOR OF SCIENCE.

Bachelors of Science in the Department of Public Health may, after the lapse of one year, proceed to the degree of Doctor in the same department on producing evidence that they have been engaged in practical sanitation since they received the degree of Bachelor of Science, and on presenting a thesis on some subject embraced in the Department of Public Health. Every such thesis must be certified by the candidate to have been composed by himself, and must be approved of by the examiners.

Candidates for the degree of D.Sc. must lodge their theses with the Dean of the Medical Faculty on or before January 31 in the year in which they propose to graduate. No thesis will be approved which does not contain either the results of original observations on some subject embraced in the examination for B.Sc., or else a full digest and critical exposition of the opinions and researches of others on the subject selected by the candidate, accompanied by precise references to the publications quoted, so that due verification may be facilitated.

The fees for the degrees in Science in the Department of Public Health shall be—For the first B.Sc. in Public Health examination, £5 5s.; for the second B.Sc. in Public Health examination, £5 5s.; for the degree of D.Sc. in Public Health, £5 5s.

The following are recommended as books to be studied in preparation for the above examinations:—E. Parkes' "Practical Hygiene"; George Wilson's "Handbook of Hygiene"; Edwd. Smith's "Manual for Public Officers of Health" and "Handbook for Inspectors of Nuisances"; Michael, Corfield, and Wanklyn's "Manual of Public Health," edited by F. Hart; Baldwin Latham's "Sanitary Engineering"; Henry Law's "Rudiments of Civil Engineering"; George Monro's "The Public Health (Scotland) Act"; Alexander Buchan's "Introductory Text-book of Meteorology."

UNIVERSITY OF CAMBRIDGE.

EXAMINATION IN STATE MEDICINE.

An examination in so much of State Medicine as is comprised in the functions of Officers of Health will be held in Cambridge, beginning on the first Tuesday in October, 1877.

Any person whose name is on the Medical Register of the United Kingdom may present himself for this examination provided he is twenty-four years of age. The examination will be in two parts.

Part I. will comprise:—Physics and Chemistry. The principles of Chemistry, and methods of analysis with especial reference to analyses of air and water. Application of the microscope. The laws of heat, and the principles of pneumatics, hydrostatics, and hydraulics, with especial reference to ventilation, water-supply, drainage, construction of dwellings, and sanitary engineering in general.

Part II. will comprise:—Laws of the realm relating to public health. Sanitary statistics. Origin, propagation, pathology, and prevention of epidemic and infectious diseases. Effects of overcrowding, vitiated air, impure water, and bad or insufficient food. Unhealthy occupations, and the diseases to which they give rise. Water-supply and drainage in reference to health. Nuisances injurious to health. Distribution of diseases within the United Kingdom, and effects of soil, season, and climate.

Candidates may present themselves for either part separately, or for both together, at their option; but the result of the examination in the case of any candidate will not be published until he has passed to the satisfaction of the examiners in both parts. Every candidate will be required to pay a fee of £1 4s. before admission to each part of the examination. Every candidate who has passed both parts of the examination to the satisfaction of the examiners will receive a certificate testifying to his competent knowledge of what is required for the duties of an Officer of Health.

All applications for admission to this examination, or for information respecting it, should be addressed to Professor Liveing, Cambridge.

Candidates who desire to present themselves for examination in October next must send in their applications and transmit the fees on or before September 18.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

GENERAL REGULATIONS.

Candidates shall be already on the Medical Register, and be entered there as possessing a qualification in Medicine. Candidates shall not, in the meantime, be required to attend any special courses of instruction; but their attention is directed particularly to courses of lectures on State Medicine, and to the practice of Analytical Chemistry. Candidates shall be subjected to two examinations. Such examinations may be taken simultaneously, or with an interval not exceeding twelve months. The examinations shall be written, oral, and practical. The examinations shall be held in the Physicians' Hall, or elsewhere if found more convenient. Rejected candidates shall not be admitted for re-examination till after the expiry of six months. Fees will not be returned, except in the case mentioned in the paragraph relating to fees given below.

EXAMINATIONS.

I. The First Examination shall embrace—1. Physics: Especially pneumatics, hydrostatics, hydraulics, and engineering in relation to sanitary operations, including a knowledge of architectural and other plans, sections, etc. 2. Chemistry: Especially analysis of air, water, food, including the biology of putrefaction and allied processes. 3. Meteorology: Including climate, topographical and seasonal influences in relation to health and disease.

II. The Second Examination shall embrace—1. Epidemiology and Endemiology: Including the corresponding departments in the diseases of animals and plants; contagious diseases; diseases of periods of life, professions, trades, seasons, and climates. 2. Practical Hygiene: Duties of a health officer; food; water-supply; sewerage and drainage; construction of hospitals, public buildings, dwellings; manufactories; cemeteries; nuisances. 3. Sanitary Law and Vital Statistics.

Meetings for both examinations shall be held annually in April and October. The first examination shall be held on the second Tuesday of the month, and shall occupy two days;

the second examination on the immediately succeeding Thursday of the same week, and shall occupy two days. Candidates may enter for both examinations in the same week, or for one only. The examinations must be passed in their order, first and second. Candidates must appear for the second examination not later than twelve months after having passed the first. A candidate remitted at his second examination will be allowed to come up again after a further period of six months; but if he then fail to pass, he will be required again to undergo the first as well as the second examination before obtaining the certificate.

FEES.

No one shall be recognised as a candidate till he has paid the fee for the first examination. The fees for examinations must be paid at least a week before the day of examination. The whole charges by the College for the certificate amount to £10 10s. The fee for the first examination is £3 3s.; the fee for the second examination is £3 3s.; the fee payable before receiving the certificate is £4 4s. Candidates forfeit the fee for the examination which they have been unsuccessful in passing. If a candidate who has offered himself for both examinations fail to pass the first, he shall not be allowed to present himself for the second, and his fee for the second shall be returned to him.

DENTAL SURGERY.

REGULATIONS RELATING TO THE DIPLOMA IN DENTAL SURGERY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

EDUCATION.

CANDIDATES are required to produce the following certificates:—

1. Of being twenty-one years of age.
2. Of having been engaged during four years in the acquirement of professional knowledge.
3. Of having attended, at a school or schools recognised by this College, not less than one of each of the following courses of lectures, delivered by lecturers recognised by this College, namely:—Anatomy, Physiology, Surgery, Medicine, Chemistry, and Materia Medica.
4. Of having attended a second winter course of lectures on Anatomy, or a course of not less than twenty lectures on the Anatomy of the Head and Neck, delivered by lecturers recognised by this College.
5. Of having performed dissections at a recognised school during not less than nine months.
6. Of having completed a course of chemical manipulation, under the superintendence of a teacher or lecturer recognised by this College.
7. Of having attended, at a recognised hospital or hospitals in the United Kingdom, the practice of Surgery and clinical lectures on Surgery during two winter sessions.
8. Of having attended, at a recognised school, two courses of lectures upon each of the following subjects, viz.:—Dental Anatomy and Physiology (human and comparative), Dental Surgery, Dental Mechanics, and one course of lectures on Metallurgy, by lecturers recognised by this College.
9. Of having been engaged, during a period of not less than three years, in acquiring a practical familiarity with the details of Mechanical Dentistry, under the instruction of a competent practitioner.
10. Of having attended at a recognised dental hospital, or in the dental department of a recognised general hospital, the practice of Dental Surgery during the period of two years.

N.B.—The students of the London schools are required to register the above certificates at this College; and special returns will be required from the provincial schools.

[*Note.*—All candidates who shall commence their professional education on or after October 1, 1877, will, in addition to the certificates enumerated in the foregoing clauses, be required to produce a certificate of having, prior to such commencement, passed the preliminary examination in general knowledge for the diploma of Member of the College, or an examination recognised as equivalent to that examination.]

Candidates who were in practice as dentists, or who had commenced their education as dentists prior to September, 1859—the date of the Charter—and who are unable to produce the certificates required by the foregoing regulations, shall furnish the Board of Examiners with a certificate of moral and professional character, signed by two members of this College, together with answers to the following inquiries:—Name, age, and professional address. If in practice as a dentist, the date of the commencement thereof. Whether member or licentiate of any College of Physicians or Surgeons of the United Kingdom; and, if so, of what College. Whether graduate of any University in the United Kingdom; and, if so, of what University; and whether graduate in Arts or Medicine. The date or dates of any such diploma, licence, or degree. Whether member of any learned or scientific society; and, if so, of what. Whether his practice as a dentist is carried on in connexion with any other business; and, if so, with what business. Whether since September, 1859, he has employed advertisements or public notices of any kind in connexion with the practice of his profession. The particulars of professional education, medical or special. The Board of Examiners will determine whether the evidence of character and education produced by a candidate be such as to entitle him to examination.

N.B.—In the case of candidates in practice or educated in Scotland or Ireland, the certificate of moral and professional character may be signed by two Licentiates of the Royal College of Surgeons of Edinburgh, or of the Faculty of Physicians and Surgeons of Glasgow, or of the Royal College of Surgeons in Ireland, as the case may be.

EXAMINATION.

The examination is partly written and partly oral. The written examination comprises general Anatomy and Physiology, and general Pathology and Surgery, with especial reference to the practice of the dental profession. The oral practical examination comprises the several subjects included in the curriculum of professional education, and is conducted by the use of preparations, casts, drawings, etc. Members of the College, in the written examination, will only have to answer those questions set by the section of the Board consisting of persons skilled in Dental Surgery; and in the oral examination will be examined only by that section. A candidate whose qualifications shall be found insufficient will be referred back to his studies, and will not be admitted to re-examination within the period of six months, unless the Board shall otherwise determine. Examinations will be held in January and June. The fee for the diploma is £10 10s., over and above any stamp duty.

[*Note.*—A ticket of admission to the museum, to the library, and to the College lectures will be presented to each candidate on his obtaining the diploma.]

LONDON SCHOOL OF DENTAL SURGERY AND DENTAL HOSPITAL OF LONDON.

The winter session will commence on Monday, October 1.

HOSPITAL STAFF.

Dental Surgeons.	*Assistant Dental Surgeons.*
Mr. Fox.	Mr. Moon.
Mr. Medwin.	Mr. A. Gibbings.
Mr. Gregson.	Mr. D Hepburn.
Mr. Coleman.	Mr. R Woodhouse.
Mr. H. Harding.	Mr. Bartlett.
Mr. Hill.	Mr. S. J. Hutchinson.

House-Surgeon—Mr. Laurence Read.
Dean—Mr. T. F. K. Underwood.

COURSES OF LECTURES.

Dental Anatomy and Physiology—Mr. C. S. Tomes.	Mechanical Dentistry—Mr. J. S. Turner.
Dental Surgery and Pathology—Mr. S. H. Cartwright.	Metallurgy—Mr. G. H. Makins.

On every day during the lecture session the Surgeons of the day will, if practicable, give demonstrations, especially intended for the junior pupils, of the operations performed in Dental Surgery.

The Dean will attend at the Hospital from five to six o'clock in the afternoons, from September 24 till October 6 inclusive; and on Wednesday mornings from half-past nine to half-past ten o'clock.

THE NATIONAL DENTAL HOSPITAL AND COLLEGE.

HOSPITAL STAFF.

Dental Surgeons.	*Assistant Dental Surgeons.*
Mr. James Stocken.	Mr. F. Henri Weiss.
Mr. Oakley Coles.	Mr. W. Taylor Smith.
Mr. G. Williams.	Mr. Thomas Gaddes.
Mr. A. F. Canton.	Mr. L. Stevens.
Mr. H. T. K. Kempton.	
Mr. Harry Rose.	

LECTURERS.

Dental Anatomy and Physiology—Mr. Thomas Gaddes.
Dental Mechanics—Mr. G. Williams.
Dental Surgery and Pathology—Mr. Oakley Coles.
Dental Metallurgy—

SUPPLEMENTAL LECTURERS.

Dental Materia Medica—Mr. James Stocken.
Elements of Histology—Mr. Thomas Gaddes.
Demonstrator of Dental Mechanics—Mr Harry Rose.
Deformities of the Mouth—Mr. Oakley Coles.
Arts and Literature—Rev. H. R. Belcher, M.A.

Special arrangements for the education of dental students are made at Charing-cross and Middlesex Hospitals.

PHARMACEUTICAL CHEMISTRY.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN. SCHOOL OF PHARMACY.

THE session will commence on October 1, 1877, and extend to July 31, 1878.

Lectures on Chemistry and Pharmacy will be delivered by Professor Redwood on Monday, Tuesday, and Wednesday mornings at nine o'clock, commencing on Monday, October 1. The course consists of sixty lectures, comprising an exposition of the leading principles and doctrines of the science of Chemistry, and of those branches of allied physical science, the applications of which are involved in the highest qualifications required for the practice of Pharmacy. There will be two of these courses during the session—the course which commences in October and ends in February being repeated in the following five months. Each course will be complete in itself, and will include a description of all the most important chemical and Galenical preparations used in medicine, which will be fully illustrated with experiments, diagrams, and specimens.

Lectures on Botany and Materia Medica by Professor Bentley, on Thursday, Friday, and Saturday mornings at nine o'clock, commencing Friday, October 5. During the session two courses of lectures will be delivered, each consisting of sixty lectures. The first course, extending from October to the end of February, will comprise Botany and Materia Medica, with especial reference to Structural Botany, and the use of the microscope in distinguishing the various drugs; and the second course, which commences in March and extends to the end of July, will also comprise Botany and Materia Medica, with especial reference to Systematic and Practical Botany. Each course will be complete in itself, although each will have a definite object in view. The portion of the second course on Systematic and Practical Botany, consisting of twenty lectures, commences in May and ends in July. Separate entries may be made for this portion.

The Laboratories for the study of Practical Chemistry will be opened on Monday, October 1, at 10 a.m., under the direction of Professor Attfield. The Laboratories are fitted up with every convenience for the study of the principles of Chemistry by personal experiment. They are specially designed for the study of Pharmacy, but are also well adapted for the acquirement of a knowledge of Chemistry in its application to manufactures, analysis, and original research. There is no general class for simultaneous instruction, each student following an independent course of study always determined by his previous knowledge; pupils can therefore enter for any period at any date. A complete course of instruction, including the higher branches of Quantitative Analysis, occupies ten full months, and dates from the day of entry to that day twelvemonth. The Laboratories are open from ten o'clock in the morning until five in the afternoon daily, except on Saturdays, when they are closed at two o'clock. Vacation months, August and September.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC,

23, 24, and 25, Queen's-square, Bloomsbury.

The Hospital contains 90 beds, of which 15 (contained in the In Memoriam Wing) are allotted to patients able to contribute a portion of the bare cost of their maintenance whilst in the Hospital; the County Convalescent Branch, at Finchley, 25 beds. The Physicians attend every Monday, Tuesday, Wednesday, and Friday, at half-past two o'clock. In- and out-patients' electrical room and general practice at that hour.

Physicians—Drs. Ramskill, Radcliffe, Hughlings-Jackson, Buzzard.
Physician for Out-patients—Dr. Charlton Bastian.
Assistant-Physicians—Drs. Maclure, Gowers.
Surgeon—W. Adams, F.R.C.S.
Resident Medical Officer and Registrar—H. R. O. Sankey, M.R.C.S.

Medical practitioners and students will be admitted on showing their

SPECIAL INSTRUCTION.

SCHOOLS AND OTHER PLACES OF GENERAL AND SPECIAL INSTRUCTION.

BESIDES the regular Schools with their various departments, there are many other institutions—devoted, some of them, to special purposes—where students and practitioners may acquire a sound knowledge of various subjects which hardly enter into the ordinary curriculum. We have already indicated that in the plan of studies the student may avail himself of a year at the beginning or at the end for such purposes. If at the beginning, we could not do better than advise him to take a session at the Royal School of Mines, studying especially Chemistry and Natural History, the value of which we have already inculcated. If he takes the year at the end, then such special studies as Eye Diseases, Skin Diseases, Lunacy, Diseases of Women and Children, may well engage his attention. These may, as a rule, be studied in connexion with his school; or, if a wider field is desired, in some one or other of the following institutions:—

Preliminary.

ROYAL SCHOOL OF MINES.

Department of Science and Art.

During the twenty-seventh session, 1877-78, which will commence on October 1, the following courses of lectures and practical demonstrations will be given:—

Applied Mechanics—Mr. Goodeve.
Chemistry—Dr. E. Frankland.
Geology—Mr. John W. Judd.
Metallurgy—Dr. John Percy.
Mechanical Drawing—Rev J. Edgar.
Mineralogy and Mining—Mr. Warington W. Smyth.
Natural History—Professor T. H. Huxley.
Physics—Mr. Frederick Guthrie.

The lecture fees for students desirous of becoming Associates are £30 in one sum, on entrance, or two annual payments of £20, exclusive of the laboratories. Tickets to separate courses of lectures are issued at £3 and £4 each. Officers in the Queen's service, her Majesty's Consuls, Acting Mining Agents and Managers, may obtain tickets at reduced prices. Science teachers are also admitted to the lectures at reduced fees. For a prospectus and information apply to the Registrar, Royal School of Mines, Jermyn-street, London, S.W.

SOUTH LONDON SCHOOL OF CHEMISTRY AND PHARMACY,

325, Kennington-road, and Central Public Laboratory, Kennington-cross, S.E.

Director—Dr. Muter.

Daily lectures in Classics, Chemistry, Physics, Botany, Materia Medica, and Pharmacy. Laboratory open for Practical Chemistry from ten till five. Special instruction for Medical Officers of Health in Water, Air, Gas, and Food Analysis. For fees, etc., apply to W. Baxter, Secretary, Laboratory, Kennington-cross, S.E.

THE HARTLEY INSTITUTION, SOUTHAMPTON.

In the department of preliminary medical education, which is recognised by the Royal College of Surgeons and Physicians, students are prepared for the regular curriculum of the medical schools, one winter and two summer sessions thus passed counting towards the four years' professional study required of all candidates for a diploma. Students in this department also receive instruction in dressing, taking notes of cases, etc., at the Southampton Royal Infirmary. For further information address the Principal.

LONDON SCHOOL OF MEDICINE FOR WOMEN,

30, Henrietta-street, Brunswick-square, W.C.

LECTURERS.

Anatomy—Mr. Reeves, London Hospital.
Physiology—Mr. Schäfer, University College.
Chemistry—Mr. Heaton, F.C.S., Charing-cross Hospital.
Botany—Dr. P. H. Stokoe, Guy's Hospital.
Materia Medica—Dr. Sturges, Westminster Hospital, and Dr. H. Donkin, Westminster Hospital.
Practice of Medicine—Dr. King Chambers, St. Mary's Hospital, and Mrs. Garrett Anderson, M.D.
Midwifery and Diseases of Women—Dr. Ford Anderson and Dr. Elizabeth Blackwell.
Forensic Medicine—Dr. Dupré, F.C.S., Westminster Hospital.
Clinical Medicine—Dr. O'Connor, Royal Free Hospital, and Dr. Cockle, Royal Free Hospital.
Surgery—Mr. Cowell, Westminster Hospital.
Clinical Surgery—Mr. F. J. Gant, Royal Free Hospital, and Mr. W. Rose, Royal Free Hospital.
Ophthalmic Surgery—Mr. Critchett, Royal Ophthalmic Hospital, and Mr. James Adams, London Hospital.
Pathology—Dr. Bastian, F.R.S., University College, and Dr. Cheadle, St. Mary's Hospital.
Mental Pathology—Dr. Sankey, University College.
Comparative Anatomy—Dr. Muric, Middlesex Hospital.

Dean of the School—Mr. A. T. Norton, St. Mary's Hospital.

The Winter Session of 1877-78 will commence on October 1, and will comprise classes in Anatomy, Physiology, Chemistry, and Practical Anatomy, with Demonstrations. Clinical instruction will be given at the Royal Free Hospital, and will include lectures on Clinical Medicine, Clinical Surgery, and Hospital attendance. Dressers, Clinical Clerks,

and a Pathological Registrar will be selected from the students after competition.

Fees for non-clinical lectures £30, or £40 the first year, £30 the second, and £15 the third. Fees for clinical instruction and lectures for four years £45, or £20 the first year, £15 the second year, and £15 the third, the fourth being free. Apply for information to the Dean.

DOWNING COLLEGE, CAMBRIDGE.

Every alternate year an election to a Fellowship takes place, the holder of which must be engaged in the active pursuit of the studies of Law or Medicine. These Fellowships are of the annual value of £200, and are tenable for twelve years. They are not vacated by marriage, and the Fellows are not required to reside. Foundation Scholarships of £50 per annum (in some cases with rooms and commons) are offered annually for distinction in Natural Science, tenable until the B.A. degree, and in cases of special merit for three years longer. Minor Scholarships of £60 per annum tenable for two years, are offered each year for competition before entrance, and one or more of these is awarded for proficiency in Natural Science.

UNIVERSITY OF DURHAM COLLEGE OF PHYSICAL SCIENCE, NEWCASTLE-ON-TYNE.

The College has taken over the laboratories, lecture-room, etc., of the College of Medicine, and provides the full courses in Chemistry required by the licensing boards. A chair of Natural History in connexion with the College has been established, and the course qualifies for the F.R.C.S. Eng.

LONDON.

General Hospitals.

GREAT NORTHERN HOSPITAL,
Caledonian-road.

Physicians—Dr. Leared, Dr. Cholmeley, Dr. Crucknell, Dr. R. Bridges, Dr. Cook.
Obstetric Physician—Dr. Gustavus C. P. Murray.
Diseases of the Eye—Mr. B. T. Lowne.
Surgeons—Mr. Gay, Mr. W. Adams, Mr. T Carr Jackson, Mr. W. H. Cripps, W. Spencer Watson.
Aural Surgeon—Mr. A. E. Cumberbatch.
Dental Surgeon—Mr. C. J. Fox.
Chloroformist—Mr. G. Eastes. House-Surgeon—Mr. T. H. Gillam.
Junior Resident Medical Officer—Mr. W. L. Batson.
Dispenser—Mr. J. W. Burgess.
Registrar of Out-Patients—Mr. F. Adams.

SEAMEN'S HOSPITAL (late *Dreadnought*), GREENWICH, S.E.

Consulting Physicians—Drs. George Budd and Stephen H. Ward.
Visiting Physicians—Dr. Chas. H. Ralfe, Mr. Harry Leach, M.R.C.P.L.
Surgeon—Mr. W. Johnson Smith.
Visiting Surgeon—Mr. N. Davies-Colley.
House-Physician—Dr. H. H. Murphy
House-Surgeon—Mr. F. Shann, B.A. Cantab.
Secretary—Mr. Henry C. Burdett.

Special Hospitals.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON. (Number of beds, 245.)

Consulting Physicians—Dr C. J. B. Williams, Dr. W. H. Walshe, Dr. Richard P. Cotton, and Dr. Richard Quain.
Consulting Surgeon—Prof. John Marshall
Physicians—Dr. Jas. E Pollock, Dr. E. Symes Thompson, Dr. C. Theodore Williams, Dr. R. Douglas Powell, and Dr John Tatham.
Assistant-Physicians—Dr Reginald E. Thompson, Dr I. Burney Yeo, Dr. Fredk. T. Roberts, Dr. T. H. Green, and Dr. J. Mitchell Bruce.
Dental Surgeon—Mr. W. Penny Bartlett.
Resident Medical Officer—Dr. W. T. Law.

The clinical practice of this Hospital is open to students of Medicine and practitioners. Fee for three months, £3 3s.; six months, £5 5s.; perpetual, £10 10s.

A course of clinical instruction in Auscultation will be given by the medical officers.

Certificates of attendance on the medical practice of this Hospital are recognised by the University of London, the Apothecaries' Society, and by the Army, Navy, and Indian Boards.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park. Office—24, Finsbury-circus, E.C.

Consulting Physicians—Dr. T. B. Peacock, Dr. J. R. Bennett, and Dr. E. L. Birkett.
Consulting Surgeon—Mr. J. Hilton.
Physicians—Dr. S. H. Ward, Dr. J. Andrew, Dr. J. C. Thorowgood, Dr. A. B. Shepherd.
Assistant-Physicians—Dr. Eustace Smith, Dr. J. B. Berkart, Dr. G. H. Evans, and Dr. J. M. Fothergill.
Resident Medical Officer—Mr. Ernest O. Bark.

The Hospital affords accommodation for 164 in-patients. Information respecting medical instruction at the Hospital may be obtained on application to the Physicians.

THE HOSPITAL FOR SICK CHILDREN,
48 and 49, Great Ormond-street, W.C., and Cromwell House, Highgate.

Consulting Physician—Dr. West.
Physicians—Dr. Dickinson, Dr. Gee, and Dr. W. B. Cheadle.
Assistant-Physicians—Dr. R. J. Lee, Dr. O. Sturges, Dr. Thos. Barlow, Dr. D. S. Lees, Dr. Bridges.
Surgeon—Mr. Thomas Smith.
Assistant-Surgeons—Mr. Howard Marsh, Mr. J. W. Haward, and Mr. Edmund Owen.
Surgeon-Dentist—Mr. Alex. Cartwright.
Secretary—Samuel Whitford.

166 beds. In-patients, 1876, 1274. Out-patients attending, 9149. The practice of the Hospital, in both in- and out-patient departments, is open at nine every morning.

BELGRAVE HOSPITAL FOR CHILDREN,
1, Cumberland-street, and 72, Winchester-street, Eccleston square, S.W.
Twenty beds.
President—His Grace the Duke of Westminster.
HONORARY MEDICAL STAFF.
Physicians—Dr. Farquharson and Dr. Hope.
Surgeons—Mr. Thos. P. Pick and Mr. Stirling.
House-Surgeon—Mr. Drewitt.

New patients last year—in, 103; out, 1014. Pupils will be admitted to the practice of the Hospital upon producing a certificate of being duly registered as medical students, and on such other conditions as the Committee may from time to time direct.

EVELINA HOSPITAL FOR SICK CHILDREN,
Southwark-bridge-road.

Founded in 1869 by the Baron F. de Rothschild.—100 beds.
Consulting Physician—Dr. W. S. Playfair.
Consulting Surgeon—Mr. Prescott C. Hewett.
Physicians — Dr. E. Buchanan Baxter and Dr. Fredk. Taylor.
Physicians to Out-Patients — Dr. T. Crawford Hayes and Dr. Jas. Goodhart.
Surgeons—Mr. W. Morrant Baker and Mr. H. G. Howse.
Surgeon to Out-Patients—Mr. R. Clement Lucas.
House-Surgeon—Mr. W. E. Paley.
Secretary—Mr. Frank Livesay.

ST. LUKE'S HOSPITAL FOR LUNATICS,
Old-street, E.C.

Physicians—Dr. Henry Monro and Dr. William Wood.
Surgeon—Mr. Alfred Willett.
Resident Medical Superintendent—Dr. George Mickley.

There are two resident Clinical Assistants, whose appointments are tenable for six months. The Visiting Physicians are also allowed by the Committee to take pupils. Patients admitted gratuitously, or on payment according to their circumstances. For information address the Secretary, H. Crespin, Esq.

VICTORIA HOSPITAL FOR CHILDREN,
Gough House, Queen's-road, Chelsea, and Churchfields, Margate.

This Hospital contains seventy beds—viz., sixty at Gough House and ten at Margate,—and has a large Out-patient Department of over 400 weekly. The Physicians attend daily at 9 a.m., and on Mondays and Thursdays at noon. The Surgeons attend at 10 a.m., except on Wednesday and Saturday. The Surgeon-Dentist attends on Saturday at 9.30 a.m.

Physicians—Dr. Julian Evans and Dr. T. Ridge Jones.
Assistant-Physicians—Dr. Grigg, Dr. Pearson Irvine, Dr. W. H. Allchin, and Dr. Albert Venn.
Surgeon—Mr. George Cowell.
Assistant-Surgeons—Mr. Fisher and Mr. F. Churchill
Dental-Surgeon—Mr. Risdon.
House-Surgeon and Registrar—Mr. G. R. Trewman.
Secretary—Captain Blount, R.N.

EAST LONDON HOSPITAL FOR CHILDREN.
This institution contains thirty-six beds.

Physicians—Dr. Barnes, Dr. Andrew Clark, Dr. Eustace Smith, and Dr. Horatio B. Donkin.
Assistant-Physicians—Dr. Warner and Dr. Crocker.
Surgeons—Mr. B. Shillitoe, Mr. A. Cæsar, and Mr. H. A. Reeves.
Assistant-Surgeon—Mr. R. W. Parker.
House-Surgeons—Mr. Frederick H. Spooner and Mr. J. Cæsar.
Secretary—Ashton Warner.

LONDON FEVER HOSPITAL, ISLINGTON.
260 beds.

Consulting Surgeon—Mr. W. S. Savory, F.R.C.S.
Consulting Physicians — Dr. A. Tweedie and Dr. C. Murchison.
Physicians—Dr. Broadbent and Dr. Cayley.
Resident Medical Officer—Mr. Shirley F. Murphy.
Secretary—Mr. Charles Finn.

BRITISH LYING-IN HOSPITAL,
Endell-street, St. Giles's, W.C.

Consulting Physician—Dr. Priestley.
Consulting Surgeon—T. Spencer Wells, F.R.C.S.
Physicians—Dr. Heywood Smith, Dr. Arthur Edis, and Dr. Fancourt Barnes.
Matron—Miss Freeman.
Secretary—Mr. Vincent Yardley.

ROYAL LONDON OPHTHALMIC HOSPITAL,
Blomfield-street, Moorfields, E.C.—Founded 1804.—100 beds.

Consulting Physician—Dr. F. J. Farre.
Consulting Surgeons—Mr. J. Dixon, Mr. G. Critchett, and Mr. W. Bowman, F.R.S.
Surgeons—Messrs. Wordsworth, Streatfeild, J. W. Hulke, G. Lawson, J. Hutchinson, J. Couper, Waren Tay, James Adams, and Dr. J. Soelberg Wells.
House-Surgeons—Messrs. R. M. Gunn, and G. H. Burnham.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL,
King William-street, Charing-cross.

The Hospital contains thirteen wards with forty-two beds, and the patients (10,000 new cases annually) are seen daily at one, and operations performed at two. The following are the days of attendance of the Surgical Staff:—Monday and Friday, Mr. Power. Monday, Tuesday, and Friday, Mr. Rouse. Wednesday, Thursday, and Saturday, Mr. Cowell.

The practice of the Hospital is open to students. Fees—for six months £3 3s.; perpetual, £5 5s.

Secretary—Mr. Geo. C. Farrant.

HOSPITAL FOR DISEASES OF THE SKIN,
52, Stamford-street, Blackfriars.

Surgeons—Mr. Jonathan Hutchinson and Mr. Waren Tay. Assistant-Surgeons—Mr. Wyndham Cottle and Mr. Edward Nettleship.

THE BRITISH HOSPITAL FOR DISEASES OF THE SKIN,
West Branch, Great Marlborough-street, W.; East Branch, Finsbury-square, E.C.; and South Branch, Newington-butts, S.E.

Surgeons—Mr. Balmanno Squire and Mr. George Gaskoin.

ST. PETER'S HOSPITAL FOR STONE AND GENITO-URINARY DISEASES.
54, Berners-street, W.

The practice is free to hospital students.
Surgeons—Mr. Walter J. Coulson and Mr. W. F. Teevan.
Assistant-Surgeon—Mr. F. R. Heycock.

HOSPITAL FOR DISEASES OF THE THROAT,
Golden-square, W.

Consulting Physician—Dr. Billing, M.D.
Consulting Surgeon—Sir W. Fergusson, Bart.
Physicians—Dr. Morrell-Mackenzie, Dr. Semple, Dr. Prosser James, Dr. W. MacNeill Whistler.
Surgeon—Mr. Edward Woakes.
Emergency Surgeon—Mr. W. R. H. Stewart.

ROYAL INFIRMARY FOR CHILDREN AND WOMEN.
Waterloo-bridge-road.—Instituted 1816.

Consulting Physicians—Dr. Samuel Wilks and Dr. John Williams.
Consulting Surgeon—Mr. J. Cooper Forster.
Physicians—Dr. G. V. Poore, Dr. Wm. Park, Dr. George Roper, and Dr. W. S. Greenfield.
Surgeon—Mr. Edwin Canton.
Surgeon-Dentist—Mr. R. M. Drury.
Resident Medical Officer — Mr. Edmund Overman Day.
Secretary—Mr. William Champion

Advanced students in Medicine, and such practitioners as may desire it, are permitted to attend the practice of this Hospital gratis. If a certificate signifying such attendance be required, the sum of £5 5s. must be paid to the Physicians aud Surgeons in ordinary conjointly.

PROVINCIAL.

NORFOLK AND NORWICH HOSPITAL.
120 beds.

One year's attendance recognised by Examining Boards. Fees: for the Physicians' practice, £10 10s.; for the Surgeons' practice—one year, £20; two years, £30; perpetual, £40. Pupils resident and non-resident.
Physicians—Dr. Copeman, Dr. Eade, Dr. Bateman.
Honorary Consulting Surgeon—Mr. Nichols.
Surgeons—Mr. Firth, Mr. Cadge, Mr. Crosse.
Assistant-Surgeons—Mr. Williams, Dr. Beverley.
Resident Medical Officer—Mr. Charles Firth.

WEST RIDING LUNATIC ASYLUM, WAKEFIELD.

Dr. Herbert Major, the Medical Director of the West Riding Lunatic Asylum, lectures on Mental Diseases during the summer session. The systematic lectures are given at the School, and the clinical lectures at the Asylum, which now accommodates over 1400 patients. It is needless to point out how great and unusual an advantage is here presented to those inclined to make themselves conversant with the improvement made of late years in the treatment and management of the insane.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.
(A Clinical and Training Institution for Gentlemen intended for the Medical Profession.)

Medical Officers—Dr. Millington, Dr. Totherick, Mr. Vincent Jackson, Mr. J. O'B. Kough, Mr. C. A. Newnham.
House-Surgeon—Wm. Gillibrand, L.K.Q.C.P.I., M.R.C.S., L.S.A. Lond.
Surgeon's Assistant—George Herbert Rowe, Esq.
House-Physician—T. M. Pinnell, M.B., M.R.P.S.
Physician's Assistant and Pathologist—John S. Joule, Esq.

This Hospital contains 210 beds; large male and female accident wards; wards for cases of burn; general medical and surgical wards: a ward for diseases peculiar to women; a children's ward, and a detached fever wing; also a commodious semi-detached out-patient department. To the general wards a clinical-room is attached, in which the analysis and microscopic inspection of the urine are conducted, also ophthalmoscopic and laryngoscopic examinations. Instruction is given in Chemistry, in Natural Philosophy, and in the Anatomy of the Dry Bones, Ligaments, Viscera, and Topographical Anatomy. The course of Practical Surgery includes the use of surgical apparatus, the performance of surgical operations, and the demonstration of Morbid Surgical Anatomy. In the Hospital the pupils are required to attend daily in the casualty-room, in the out-patient department, and in the wards, the instruction afforded being of a practical nature, including bandaging, the application of splints, tooth-drawing, and every kind of elementary professional detail, likewise how to observe and examine patients. The art of dispensing, the preparation of drugs, and of pharmaceutical compounds, can also be learnt in the Hospital Dispensary and Laboratory. Operations are performed every Thursday at eleven o'clock, and practitioners are admitted. The practice of the Hospital is recognised by all the examining boards.

Fees for hospital practice—For one year, £10 10s.; perpetual, £21. Some members of the honorary staff receive resident pupils. For further particulars apply to Mr. Vincent Jackson (Honorary Secretary to the Medical Committee), 46, Darlington-street, Wolverhampton.

GLASGOW ROYAL ASYLUM, GARTNAVEL.

The Asylum contains nearly 600 patients, including all classes. Clinical instruction is given, and in summer Dr. Yellowlees, Physician-Superintendent, lectures on Mental Diseases at the University; fee, £2 2s.

ROYAL DISPENSARY, EDINBURGH.

Consulting Physician—Professor Sanders.
Consulting Surgeon—Professor Spence.
Consulting Physicians-Accoucheur—Dr. Keiller and Dr. J. Matthews Duncan.
Medical Officers—Dr. Linton, Dr. W. Husband, Dr. James Andrew, Dr. D. Wilson, Dr. R. P. Ritchie, Dr. F. W. Moinet, Dr. A. J. Sinclair, and Dr. W. Gordon.
Midwifery Department—Dr. Andrew and Dr. Moinet.
Vaccination—Dr. Husband.
Apothecary—Mr. R. Urquhart.
Secretary to Medical Officers—Dr. Andrew.

ROYAL HOSPITAL FOR SICK CHILDREN, MEADOWSIDE HOUSE, EDINBURGH.

Consulting Physicians—Professor Sir Robert Christison, Bart., Drs. Charles Wilson, Graham Weir, and Matthews Duncan.
Consulting Surgeon—Professor Spence.
Pathologist—Professor Sanders.
Ordinary Physicians—Drs. Ritchie, Linton, Dunsmure, and Angus Macdonald.
Extra Physicians—Drs. Andrew and Cumming.
Assistant-Physician—Dr. Cuthill.
Surgeon-Dentist—Dr. Smith.
Ophthalmic Surgeon—Dr. Argyll Robertson.
Resident Physician—Dr. J. M. Chapman.
Honorary Secretary—Mr. John Henry, 20, St. Andrew-square.
Hon. Treasurer—R. S. Wyld, 19, Inverleith-row.

Fees: To Hospital, three months, £1 1s.; to Dispensary Department, three months, £1 1s.

GLASGOW EYE INFIRMARY,
Berkeley-street, and 76, Charlotte-street.

Consulting Surgeon—Dr. George Buchanan.
Surgeons—Drs. Thomas Reid, Thos. S. Meighan.
Assistant-Surgeons—Drs. Henry E. Clark and J. Crawford Renton.
Resident Clerk—Mr. W. J. Shaw.
Secretary—George Black, 88, West Regent-street.

Hour of visit, 1 p.m. Sixty-four beds. Student's fee for six months, attendance, £2 2s.; or for one year's attendance, £3 3s. To those attending, or who have attended, the lectures on the Eye in Glasgow University, £1 1s. for six months; or £1 11s. 6d. for twelve months.

GLASGOW DISPENSARY FOR DISEASES OF THE EAR,
241, Buchanan-street.

A course of lectures and clinical instruction are given to the students attending the Dispensary during the months of May, June, and July. Average number of cases treated, 800 annually.
Surgeon and Lecturer—Dr. James Patterson Cassells.

ST. MARK'S OPHTHALMIC HOSPITAL AND DISPENSARY FOR DISEASES OF THE EYE AND EAR.

Attending Surgeons—Richard Rainsford, M.B., M.Ch., F.R.C.S.I., and John B. Story, M.B., B.Ch.

Instruction is given daily from ten to twelve o'clock, and operations performed on Wednesdays and Saturdays at eleven o'clock. Fee for three months' attendance, £3 3s.

Special courses on the Ophthalmoscope and the Anomalies of Refraction and Accommodation are held from time to time.

ROTUNDA HOSPITALS, DUBLIN.

Master—Dr. Lombe Atthill.
Assistant-Physicians—Dr. R. D. Purefoy and Dr. Wm. Smyly.
Pathologist—Dr. G. F. Duffey.

This institution consists of two distinct Hospitals—namely, the Lying-in Hospital, into which 1200 labour cases are on an average admitted annually, and the Auxiliary Hospital, set apart for the reception and treatment of patients suffering from the various forms of uterine and ovarian disease; about 500 patients are received into this Hospital during each year.

There is also a large Extern Maternity in connexion with the Hospital, and a Dispensary for Diseases Peculiar to Women, which is open daily.

Pupils are admitted to the practice of all these departments.

Accommodation is provided for a number of Extern Pupils.

Applications to be made to the Master or Assistant-Physicians, at the Hospitals, Rutland-square, Dublin.

THE INTRODUCTORIES.

THE following are the days and hours of the various Introductory Lectures, with the names of the respective lecturers:—

Hospital.	Date.	Lecturer.	Hour.
St. Bartholomew's	Mon. Oct. 1	None.	
Charing-cross	„	Mr. Astley Bloxam	4 p.m.
St. George's	„	Mr. Pick	4 p.m.
Guy's	„	None.	
King's College	„	Mr. Lister	4 p.m.
London	„	None.	
St. Mary's	„	Mr. H. Page	3.30 p.m.
Middlesex	„	Mr. A. Hensman	3 p.m.
St. Thomas's	„	Mr. Wagstaffe	4 p.m.
University College	„	Dr. John Williams	3 p.m.
Westminster	„	Dr. Grigg	3 pm.

THE PUBLIC SERVICES.

ARMY MEDICAL DEPARTMENT, WHITEHALL-YARD.

SCHEDULE OF QUALIFICATIONS

Necessary for Candidates desirous of obtaining Commissions in the Army Medical Department, with extracts from the Regulations prescribed by the Royal Warrant of April 28, 1876 (*Clause* 58, *Army Circulars*, 1876), *by which the Pay, Promotion, and Retirement of Medical Officers are regulated and determined.*

(I.)—1. Every candidate desirous of presenting himself to compete for a commission in the Army Medical Department must be twenty-one years of age and not over thirty-two years at the date of commencement of the competitive examination. He must produce an extract from the registrar of his birth, or, in default, a declaration, made before a magistrate by one of his parents or guardians, giving his exact age. He must also produce a recommendation from some person of standing in society—not a member of his own family—to the effect that he is of regular and steady habits, and likely in *every* respect to prove creditable to the Department if a commission be granted; and also a certificate of moral character from the parochial clergyman, if possible.

2. The candidate must sign a declaration upon honour that both his parents are of unmixed European blood, and that he labours under no mental or constitutional disease, nor has any hereditary tendency thereto, nor any imperfection or disability that can interfere with the efficient discharge of the duties of a Medical Officer in any climate; also that he does not hold, and has never held, any commission or appointment in the public services. His physical fitness will be determined by a Board of Medical Officers, who are required to certify that the candidate's vision is sufficiently good to enable him to perform any surgical operation without the aid of glasses. A moderate degree of myopia will not be considered a disqualification, provided it does not necessitate the use of glasses during the performance of operations, and that no organic disease of the eyes exists. The Board must also certify that he is free from organic or other disease, and from constitutional weakness, or tendency thereto, or other disability of any kind likely to unfit him for military service in any climate.

3. Certificates of age, registration of diplomas, etc., and of character, must accompany the declaration when signed and returned.

4. Candidates will be examined by the Examining Board in the following compulsory subjects, and the highest number of marks attainable will be distributed as follows:—*a*. Anatomy and Physiology, 1000 marks; *b*. Surgery, 1000; *c*. Medicine, including Therapeutics, the Diseases of Women and Children, 1000; *d*. Chemistry and Pharmacy, and a practical knowledge of drugs, 100 marks. N.B.—The examination in Medicine and Surgery will be in part practical, and will include operations on the dead body, the application of surgical apparatus, and the examination of medical and surgical patients at the bedside. The eligibility of each candidate for the Army Medical Service will be determined by the result of the examinations in these subjects only. Examinations will also be held in the following voluntary subjects, for which the maximum number of marks will be—French and German (150 each), 300 marks; Natural Sciences, 300 marks. The knowledge of modern languages being considered of great importance, all intending competitors are urged to qualify in French and German. The natural sciences will include Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany with special reference to Materia Medica. The number of marks gained in both the voluntary subjects will be added to the total number of marks obtained by those who shall have been found qualified for admission, and whose position on the list of successful competitors will thus be improved in proportion to their knowledge of modern languages and natural sciences.

5. After passing this examination, every candidate will be required to attend one entire course of practical instruction at the Army Medical School on—(1) Hygiene; (2) Clinical and Military Medicine; (3) Clinical and Military Surgery; (4) Pathology of Diseases and Injuries incident to Military Service.

The following extracts from the Royal Warrant of April 28, 1876 (Clause 58, Army Circulars, 1876), are republished for the information of candidates for commissions in the Army Medical Department:—

1. The ranks and rates of pay of the officers of the Army Medical Department shall be as follows:—Daily pay: Surgeon-General £2, after twenty-five years' service £2 5s., after thirty years' service £2 7s., after thirty-five years' service £2 10s.; Deputy Surgeon-General £1 10s., after twenty-five years' service £1 12s., after thirty years' service £1 15s., after thirty-five years' service £1 17s.; Surgeon-Major, on appointment £1, after five years' service as such £1 5s.; Surgeon, on appointment £250 a year, after ten years' service 17s. 6d. daily. Charge pay: The Principal Medical Officer of an army in the field consisting of 10,000 men and upwards, £1 daily; of 5000 men and upwards, 15s. daily; of less than 5000, 10s. daily. Or the Principal Medical Officer of a colony where the number of commissioned officers and enlisted men is 1500 and upwards, 5s. daily.

2. The pay of officers shall be issued monthly in arrear.

3. The relative rank of the officers of the Army Medical Department shall be as follows:—(1.) A Surgeon-General shall rank as Major-General, according to the date of his commission. (2.) A Deputy Surgeon-General shall rank as Colonel, according to the date of his commission. (3.) A Surgeon-Major shall rank as Major, according to the date of his commission: after twenty years' full-pay service as Surgeon and Surgeon-Major, he shall rank as Lieutenant-Colonel, but junior of the latter rank. (4.) A Surgeon shall rank as Lieutenant, according to the date of his commission; and, after six years' full-pay service, as Captain, according to the date of the completion of such service.

4. The relative rank of these officers shall regulate choice of quarters, rates of lodging-money, servants, fuel and light, or allowances in their stead, detention and prize-money, as well as allowances granted on account of wounds or injuries received in action, and pensions and allowances to widows and families.

5. Forage shall be granted to officers of the Army Medical Department for such number of horses as are necessarily kept by them for duty.

6. Admission to the Army Medical Department shall be by public competition.

7. Every candidate for appointment to the Army Medical Department shall possess two diplomas or licences, one to practise Medicine, and the other Surgery, in Great Britain or Ireland, and be registered under the Medical Act in force at the time of his appointment.

8. A successful candidate, who, having passed through a course of instruction at the Army Medical School at Netley, in Military Medicine, Surgery, Hygiene, and Pathology, shall have proved, after examination, that he possesses a competent knowledge of those subjects, shall receive a commission as Surgeon for a limited period of ten years' service on full pay. From the date of joining at Netley, and up to that of passing his final examination, a candidate shall receive 5s. a day.

9. On the completion of ten years' commissioned service, unless the Surgeon be specially selected for further employment in the Medical Department of our Army, or if he be unwilling to continue to serve therein, his services shall be dispensed with, and he shall be entitled to receive, in lieu of all pension or retirement, pension for wounds excepted, the sum of £1000.

10. A Surgeon of less than ten years' service, disqualified for duty by ill-health, certified by a Board of Medical Officers to have been contracted in and by the Service, may, at the discretion of our Secretary of State for War, be granted half-pay at a rate not exceeding 8s. a day if he have served five years or more, or 6s. a day if he have served less than five years, for a period not exceeding six months at one time.

11. At the expiration of that period of six months, if the Surgeon be able to resume his duties, he shall be entitled to complete his term of ten years' service. If he be unable to resume duty, as certified by a Board of Medical Officers, he shall be allowed, if he have not served five years, a further period of six months, without half-pay; at the expiration of which period, if still unable to resume duty, his services shall be dispensed with.

12. If the Surgeon have served five years on full pay, and be unable to resume duty as certified by a Board of Medical Officers, his services shall be dispensed with, and he shall be entitled to receive, in lieu of all further pension or pay, pension for wounds excepted, a gratuity at one of the following rates, viz.:—If he shall have completed nine years' full-pay

service, £800; eight years' full-pay service, £700; seven years' full-pay service, £600; six years' full-pay service, £500; five years' full-pay service, £400.

13. If a Surgeon be unable to complete his ten years' service from any cause other than wounds or ill-health, certified by a Board of Medical Officers to have been caused in and by the service, or reduction of establishment, he shall be allowed not more than six months' leave without pay, after which, if unable to resume duty, his services shall be at once dispensed with, and he shall have no further claim on the Department.

14. If the services of an officer be temporarily dispensed with in consequence of a reduction of establishment, he shall be granted the rates of half-pay fixed by Article 10 until there be an opportunity of re-employing him, or if he have served five years, he may retire from the service with a gratuity according to the rates specified in Article 12.

15. Every year it shall be competent for our Commander-in-Chief, on the recommendation of the Director-General of the Army Medical Department, to select, with the approval of our Secretary of State, a number of Surgeons not exceeding six, who shall be retained in the service, and shall be promoted after twelve years' service on full pay to the rank of Surgeon-Major.

16. All promotion from the rank of Surgeon-Major to that of Deputy Surgeon-General, and from the rank of Deputy Surgeon-General to that of Surgeon-General, shall be given for ability and merit upon the selection or our Commander-in-Chief, with the approval of our Secretary of State; and the grounds of such selection shall be stated to us in writing, and recorded in the Department. In all such cases the amount of foreign service shall be expressly stated.

17. A Medical Officer retiring after full-pay service of twenty-five years and upwards, may, if recommended for the same by the head of his department, receive a step of honorary rank, but without any consequent increase of half-pay.

18. Good-service pensions shall be awarded to the most meritorious officers of the Army Medical Department, under such regulations as shall be from time to time determined by us, with the advice of our Secretary of State.

19. Six of the most meritorious officers of the Army Medical Department shall be named our Honorary Physicians, and six our Honorary Surgeons.

20. Medical Officers shall have a right to retire on half-pay after twenty years' service. Medical Officers of the rank of Surgeon-Major or Surgeon shall be placed on the retired list at the age of fifty-five, and all Surgeons-General and Deputy Surgeons-General at the age of sixty years.

21. Our Secretary of State may, when he shall deem it fit, employ Medical Officers on the half-pay list in special situations, at such rates of pay, in addition to half-pay, as he shall from time to time determine; but such officers shall vacate their appointments on attaining the age of sixty-five years.

22. A Medical Officer who, having voluntarily resigned his commission, has subsequently been permitted to re-enter the Department, shall not, except under very special circumstances to be approved by our Secretary of State, be allowed to reckon his former service.

SERVICE ON THE WEST COAST OF AFRICA.

23. Service of Medical Officers upon the West Coast of Africa shall be voluntary.

24. Each year or portion of a year shall be allowed to reckon double towards retirement or towards the gratuities fixed by Articles 9 and 12, but not towards increased pay, provided that the officer shall serve at least twelve months on the West Coast of Africa.

25. For each year's service on the Coast, a Medical Officer shall be entitled to a year's leave at home, and for every additional period beyond a year he shall have an equivalent extension of leave.

26. Officers who may volunteer for service on the West Coast of Africa shall receive double pay while actually serving on the Coast.

NON-EFFECTIVE PAY.

27. A Medical Officer of more than ten years' service placed on half-pay by reduction of establishment, or on the report of a Medical Board in consequence of wounds or ill-health caused in and by the discharge of his duties, or on account of age (under Article 20), shall be entitled to half-pay in accordance with the following scale:—Daily pay: Surgeon-General, after thirty years' service, £1 17s. 6d.; after twenty-five years' service, £1 13s. 6d.; after twenty years' service, £1 10s. Deputy Surgeon-General, after thirty years' service, £1 5s. 6d.; after twenty-five years' service, £1 2s. 6d.; after twenty years' service, £1 1s. Surgeon-Major, after twenty-five years' service, £1; after twenty years' service, 16s. 6d.; after fifteen years' service, 13s. 6d.; after twelve years' service, 11s. Surgeon, after ten years' service, 10s.

28. The rate of half-pay awarded to officers retiring for their own convenience, after twenty years' service on full pay, under Article 20, shall not exceed one-half of their full pay at the time of retirement.

29. Every Medical Officer who shall retire after a service upon full pay of twenty-five years, shall be granted a rate of half-pay equal to seven-tenths of the daily pay he may have been in receipt of when thus retiring on half-pay, provided he shall have served three years in his rank, or shall have served abroad for ten years in all ranks, or for five years with an army in the field. An officer of twenty-five years' full-pay service, whose service falls within neither of these conditions, shall be entitled to only seven-tenths of the daily pay he was in receipt of prior to his last promotion.

30. A Medical Officer of twenty years' full-pay service, placed temporarily on half-pay on account of ill-health, may, however, be allowed to retire on permanent half-pay, at the rates fixed by Article 27, if after one year on half-pay he shall be reported by a Medical Board to be permanently unfit for further service.

31. In all matters not specially provided for in our present Warrant, the officers of the Medical Department of our Army shall be subject to the general regulations for the departments of our Army.

N.B.—The rates of pay, including allowances, while serving in India, will range from 317 rupees (£31 14s.) to 433 rupees (£43 6s.) per month, according to length of service.

DECLARATION.

Recommended by _____, I _____ _____ years of age on _____ last (*vide* accompanying Certificate), a Candidate for a commission in the Medical Department of the Army, do hereby engage for general service, under the conditions detailed in the Schedule of Qualifications, and attest my readiness to proceed on duty abroad whenever required to do so.

I declare upon my honour—(1st) That both my parents are of unmixed European blood; (2nd) that I am not at present suffering from, nor have I any tendency to, any form of disease or mental and bodily infirmity, nor have I any hereditary tendency or predisposition to mental or constitutional disease, or labour under any imperfection or disability that can or is likely to interfere with the efficient discharge of the duties of a Medical Officer in any climate; (3rd) that I will fully reveal to the Medical Board, when physically examined, all circumstances within my knowledge that concern my past and present health; (4th) that I do not now hold, nor have I ever held, any commission or appointment in the public services (if the contrary, specify here).

N.B.—A mis-statement by a candidate will invalidate any subsequent appointment, and cause forfeiture of all privileges for services rendered.

I forward the Certificate of Registration under the Medical Act, showing that I possess the following Degrees, Diplomas, and other Qualifications in Medicine and Surgery, which I will produce when called up for examination, viz.:—

Medicine _____

Surgery _____

I also possess a degree in Arts } _____
(or, if others, state particulars) }

I wish to be examined in the voluntary subjects, viz.:—

French, _____. German, _____. Natural Sciences, _____

Date, _____. Signature, _____

Address, _____

[When this Declaration is returned, it must be accompanied by an extract from the Register of Birth (not of Baptism), or in default a Declaration made by one of the parents or guardians before a magistrate, giving the exact age, also the Certificate of Registration under Medical Act, etc., and by a recommendation from some person of standing in society, not a member of the candidate's family, to the effect that he is of regular and steady habits, and likely in every respect to prove creditable to the Department, if an appointment be granted, as well as a Certificate of moral character from the parochial clergyman, if possible. Any omission of the particulars set forth will render this application void.]

ARMY MEDICAL SCHOOL.

President of the Senate.—Sir William M. Muir, K.C.B., M.D., Director-General of the Army Medical Department.

Members of the Senate.—Surgeon-General Sir Joseph Fayrer, M.D., K.C.B., C.S.I., Physician to the Council of India; Sir Alexander Armstrong, M.D., K.C.B., F.R.S.; The Principal Medical Officer, Royal Victoria Hospital (*ex officio*); and the Professors of the Army Medical School.

Professors.—Surgeon-General T. Longmore, C.B., half-pay, Professor of Military Surgery; Inspectors-General W. C. Maclean, M.D., C.B., Professor of Military Medicine; William Aitken, half-pay, M.D., F.R.S., Professor of Pathology: Surgeon-Major F. S. B. F. De Chaumont, M.D., Professor of Military Hygiene: Deputy Inspector-General J. W. Macdonald, M.D., F.R.S., R.N., Professor of Naval Hygiene.

Assistant-Professors.—Surgeons-Major J. H. Porter, W. M. Webb, F. H. Welch, F.R.C.S.; Surgeon J. L. Notter, M.D.; and Surgeon-Major J. P. H. Boileau, M.D.

Candidates for commissions in the Army and Navy and in the Queen's Indian Service proceed to Netley after passing the examination in London. At Netley they attend the medical and surgical practice of the Royal Victoria Hospital, and learn the system and arrangements of naval and military hospitals. During four months they attend the lectures given by the Professors and Assistant-Professors, and go through a course of practical instruction in the hygienic laboratory and microscopical room.

INDIAN MEDICAL SERVICE.

The regulations relating to the Indian Medical Service may be said to be identical with the Queen's. The rules as to service are now, however, different.

The candidate for the Indian Medical Service may be either married or unmarried, and must not exceed twenty-eight years of age. After passing the final examination, pay is granted at the rate of 10s. a day. Indian pay and allowances only come into force after landing in India.

NAVAL MEDICAL DEPARTMENT, ADMIRALTY.

QUALIFICATIONS AND REGULATIONS FOR THE EXAMINATION OF CANDIDATES FOR COMMISSIONS IN THE MEDICAL SERVICE OF THE ROYAL NAVY.

The Lords Commissioners of the Admiralty are pleased to direct that the following regulations, relative to the examination of candidates for the appointment of Surgeon in the Royal Navy, shall in future be adopted:—

1. Every candidate desirous of presenting himself for admission to the Naval Medical Service must be not under twenty-one nor over twenty-eight years of age. He must produce a certificate from the District Registrar, in which the date of birth is stated; or, if this cannot be obtained, an affidavit from one of the parents or other near relative, who can attest the date of birth, will be accepted. He must also produce a certificate of moral character, signed by a clergyman or a magistrate to whom he has been for some years personally known, or by the president or senior professor of the college at which he was educated.

2. He must be free from organic disease, and will be required to make a declaration that he labours under no mental or constitutional disease or weakness, nor any other imperfection or disability that can interfere with the most efficient discharge of the duties of a Medical Officer in any climate. His physical fitness will be determined by a Board of Medical Officers, who are to certify that his vision comes up to the required standard, which will be ascertained by the use of Snellen's test-types. He must also attest his readiness to engage for general service, and to proceed on foreign service when required to do so.

3. He must be registered under the Medical Act in force at the time of his appointment as licensed to practise Medicine and Surgery in Great Britain or Ireland.

4. Certificates of registration, character, and age must accompany the schedule when filled up and returned.

5. Candidates will be examined by the Examining Board in the following subjects:—Anatomy and Physiology; Surgery; Medicine, including Therapeutics and the Diseases of Women and Children; Chemistry and Pharmacy, and a practical knowledge of drugs. (The examination in Medicine and Surgery will be in part practical, and will include operations on the dead body, the application of surgical apparatus, and the examination of medical and surgical patients at the bedside.) The eligibility of each candidate for the Naval Medical Service will be determined by the result of the examinations in these subjects only. Candidates who desire it will be examined in Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany with special reference to Materia Medica, also in French and German; and the number of marks gained in these subjects will be added to the total number of marks obtained in the obligatory part of the examination by candidates who shall have been found qualified for admission, and whose position on the list of successful competitors will thus be improved in proportion to their knowledge of these branches of science.

6. After passing this examination, every candidate will be required to attend one entire course of practical instruction in the Medical School at Netley on—(1) Hygiene, (2) Clinical and Naval and Military Medicine, (3) Clinical and Naval and Military Surgery, (4) Pathology of Diseases and Injuries incident to Naval and Military Service.

7. At its conclusion the candidate will be required to pass an examination on the subjects taught in the school. If he give satisfactory evidence of being qualified for the practical duties of a Naval Medical Officer, he will be eligible for a commission as Surgeon.

8. During the period of his residence at the Netley Medical School each candidate will receive an allowance of 5s. per diem with quarters, or 7s. per diem without quarters, to cover all costs of maintenance; and he will be required to provide himself with uniform (viz., the Regulation undress uniform of a Surgeon, but without the sword).

9. All candidates will be required while at Netley to conform to such rules of discipline as the Senate may from time to time enact.

10. After completing three years' full-pay service, Surgeons will be allowed to be examined for the rank of Staff Surgeon; but no Surgeon can be promoted to the rank of Staff Surgeon until he shall have served five years, two of which must have been in a ship actually employed at sea.

RANK, PAY, AND POSITION OF NAVAL MEDICAL OFFICERS.

1. Promotion to the rank of Fleet Surgeon is open to officers for distinguished or special service, although twenty years on full pay may not have been completed; such Fleet Surgeons will have 16s. a day half-pay.

2. Fleet Surgeons rank with Commanders, according to date of commission.

3. The whole time served on full pay as a Surgeon to be allowed to Staff Surgeons to qualify for the rank of Fleet Surgeon, provided the examination for Staff Surgeon is passed before the officer completes ten years' service, otherwise only ten years served as Surgeon will be allowed to count.

4. Fleet Surgeons are appointed to the flag-ships of commanders-in-chief on foreign stations, with an allowance of 5s. a day in addition to their established pay.

5. The hospital allowances for Naval Medical Officers at home and abroad, in lieu of provisions, for themselves and servants, and for fuel and light, are as follows:—Inspectors General of Hospitals, £85 at home, £130 abroad; Deputy Inspectors-General, £65 at home, £112 abroad; Fleet-Surgeons and Staff-Surgeons, £53 at home, £112 abroad; Surgeons, £39 at home, £108 abroad. In cases where Medical Officers draw provisions or fuel from public stores, they will be charged for the same at cost price.

6. The travelling allowances, extra pay, lodging money, and compensation for losses are fixed for Naval Medical Officers according to their relative rank in the service.

7. Medical Officers have cabins according to their relative rank in the service.

8. The full and half-pay of Naval Medical Officers is in accordance with the following scale:—

Full-pay: Surgeon—Under five years' service (except during the session at Netley) [see Regulations], 11s.; under eight years' service, 12s. 6d.; under eleven years' service, 14s.; under fourteen years' service, provided he passed his examination for Staff Surgeon while under ten years' service, 15s. 6d.; above fourteen years' service, ditto, 17s. Staff Surgeon—On promotion, or under fourteen years' service, 18s.; ditto, or under seventeen years' service, £1; and for each additional year of service 1s. a day more until the maximum is reached—namely, £1 2s. Fleet Surgeon—On promotion, or under twenty years' service, £1 3s.; ditto, or above twenty years' service, £1. 4s.; and for each additional year of service 1s. a day more until the maximum is reached—namely, £1 10s. Deputy Inspector-General of Hospitals and Fleets—On promotion, or under twenty-two years' service, £1 11s.; ditto, or above twenty-two years'

service, £1 12s.; and for each additional year of service 1s. a day more until the maximum is reached—namely, £1 18s. Inspector-General of Hospitals and Fleets—On promotion, or under twenty-five years' service, £2 5s.; ditto, or above twenty-five years' service, £2 6s.; and for each additional year of service 1s. a day more until the maximum is reached—namely, £2 10s. Half-pay: Surgeon—Under five years' service, 6s.; under eight years' service, 8s.; under eleven years' service, 10s.; above eleven years' service, provided he passed his examination for Staff Surgeon while under ten years' service, 17s. Staff Surgeon—On promotion, or under fourteen years' service, 11s.; ditto, or under seventeen years' service, 13s.; ditto, or above seventeen years' service, 14s. Fleet Surgeon—On promotion, or under twenty years' service, 16s.; ditto, or above twenty years' service, 16s. 6d.; and for each additional year of service 6d. a day more until the maximum is reached—namely, 18s. 6d. Deputy Inspector-General of Hospitals and Fleets—On promotion, or under twenty-two years' service, £1 1s.; ditto, or above twenty-two years' service, £1 2s.; and for each additional year of service 1s. a day more until the maximum is reached—namely £1 7s. Inspector-General of Hospitals and Fleets—On promotion, or under twenty-five years' service, £1 11s.; ditto, or above twenty-five years' service, £1 12s.; and for each additional year of service 1s. a day more until the maximum is reached—namely, £1 18s.

9. Retirement is provided for according to age and service, under special regulations.

DECLARATION.

Recommended by_____, I _____, _____ years of age in _____ last (*vide* accompanying Certificate), a candidate for appointment as a Medical Officer in the Royal Navy, do hereby engage for general service, and attest my readiness to proceed on duty abroad whenever required to do so.

I declare that I labour under no mental or constitutional disease or weakness, nor any other imperfection or disability which can interfere with the most efficient discharge of the duties of a Medical Officer in any climate.

Signature, _____

Date, _____

Place of residence, _____

SCHEDULE OF QUALIFICATIONS.

I have in my possession the following Degrees, Diplomas, and other Qualifications in Medicine, Surgery, and in Arts:—

I wish to be examined in the following voluntary subjects, viz.:—

Signature, _____

CIRCULAR No. 12, C.W.

Admiralty, March 6, 1875.

(*Medical Officers of the Navy.*)

My Lords Commissioners of the Admiralty having had under their consideration the position of the Medical Officers of the Navy, are pleased, under the authority of her Majesty's Order in Council of February 4, 1875, to establish the following regulations:—

1. Surgeons on entry to have the same relative rank as Paymasters, Chief Engineers, and Naval Instructors—namely, to rank with Lieutenants under eight years' seniority, and to wear uniform corresponding to such relative rank.

2. Staff Surgeons to be denominated "Fleet Surgeons," and Staff Surgeons second-class simply "Staff Surgeons"; the distinction in rank between these two grades to be denoted by a small difference in the uniform of the Staff Surgeon, who instead of three stripes of gold lace round the sleeve of the coat, which the Fleet Surgeon will wear, will wear two stripes of gold lace, with a stripe of narrow gold braid between them.

3. Inspectors-General to be compulsorily retired at the age of sixty; to be allowed £2 per day, provided they shall have completed the period of service now required to entitle them to the maximum half-pay of their rank; should they not have completed such period of service, they will be retired at the rate of half, or retired pay, specified in the Order in Council of February 22, 1870.

4. Deputy Inspectors-General to be compulsorily retired at sixty; if in the first six of their rank, to be allowed 33s., others 30s. per diem, provided that they shall have completed the period of service now required to entitle them to the maximum half-pay of their rank; should they not have completed such period of service, they will be retired at the rate of half, or retired pay, specified in the Order of Council of February 22, 1870.

5. Fleet Surgeons and Staff Surgeons to be placed on the same scale of retirement as chaplains and naval instructors, secretaries and paymasters; that is, the maximum to be £450 per year instead of £400.

6. Fleet Surgeons to have the option of retiring after twenty years' full-pay service in all ranks at 15s. per day, and after twenty-five years' full-pay service 21s., subject in each case to their Lordships' approval; but of those now on the list, not more than ten to retire under this clause in each year (the Officers having the option according to seniority) unless their Lordships should approve (with the consent of the Treasury) of a larger number so retiring. Applications from Officers wishing to retire under this clause should be lodged at the Admiralty before November 30 in each year, in order that they may be dealt with, according to seniority, before the end of the year.

7. All Medical Officers hereafter entered to have the option of so retiring, subject to the approval of their Lordships in each case. By command of their Lordships,

ROBERT HALL.

To all Commanders-in-Chief, Captains, Commanders, and Commanding Officers of Her Majesty's Ships and Vessels.

SATURDAY, SEPTEMBER 8, 1877.

THE WEEK.

TOPICS OF THE DAY.

THE amount of recklessness exhibited by the uneducated classes in times of epidemic disease is so great, that the most unimpeachable testimony scarcely suffices to carry conviction. The following is a case in point. Dr. Collier, Medical Officer of Health to the Fulham District Board of Works, at the meeting of that Board held last week, reported that during the past month twenty-four cases of small-pox had occurred in the district. Fourteen of the cases were reported from one street, viz., Rectory-place Walham-green, where the outbreak had been so serious that a public-house there had to be entirely closed, and many other houses also, scarcely a house being free from it. He attributed the spread of the disease in this instance to the fact that he was not informed of its first outbreak until a fortnight after it had occurred. He went there immediately, and found a woman, who had been the first person attacked, just recovering, and sitting in her own room amongst a number of neighbours, who had called to congratulate her on her convalescence. The woman was then in a

most dangerous condition for spreading the disease, and the consequence was that tho infection was conveyed to the houses of her visitors, aud shortly afterwards four deaths occurred. Several members commented on the medical officer's report, and one stated that he knew of a woman just recovering from the complaint who was going about selling milk; whilst another member mentioned the case of a woman going into a public-house, with her veil down to conceal the pustules of the disease, which were just appearing. Dr. Collier further reported that he had collected a large amount of hearsay evidence, but he could not get eye-witnesses to come forward. His report was ultimately referred to a committee.

The Committee of the British Association for investigating the circulation of underground water in the new red and permian rocks has been reappointed, and the inquiry extended to the oolites. Mr. De Rance, F.G.S., the Honorary Secretary, read an elaborate report of the work done by the Committee during the last year, and it is evident the Association considers the inquiry one of growing importance. Mr. M. Reade, F.G.S., presented a report upon the wells of South-west Lancashire, in which he analysed the information he had collected during the last three years, and demonstrated, by calculation of the water collected from certain wells and bore-holes, that the yield of a well is dependent upon striking certain fissures or channels which ramify through the sandstone, forming ducts, conveying underground water to the pumping-stations. These ducts, which may be vertical fissures or may bo channels along the planes of bedding, like arteries, convey water from large areas of sandstone that have absorbed the rainfall from surface percolation. He also showed that the wells are nearly all affected by local percolation, and insisted on the necessity in most cases of excluding the water from the strata immediately surrounding the well, as it is liable to all sorts of organic contamination, by water-tight cylinders. Mr. Reade's report was accompanied by sections showing the water lines of the various wells, which will be published with the report, and bid fair to be of considerable practical utility.

In consequence of the Local Board of St. Columb, Cornwall, refusing to provide an efficient system of sewerage in accordance with the requirements of the Local Government Board, notice has been given by the Government Department that they intend to hold an inquiry, with a view of dissolving the Local Board. Sir Joseph Bazalgette, C.E., who has prepared plans for the drainage of the easteru portion of Bournemouth, including an important district recently added, has submitted his scheme to the Improvement Commissioners. By this it is intended that all the drainage of the western and central portion shall be diverted from its present outfall, and taken to Boscombe, a distance of about 2000 yards to the eastward, and there discharged into the sea, after receiving the drainago of the eastern district. The inhabitants of Boscombe strongly object to this scheme, and Mr. Thornhill Harrison, one of the Local Government Board Inspectors, after holding an inquiry, reported in favour of two outfalls, and took other exceptions to Sir Joseph's plau. The Improvement Commissioners are divided in opinion ou the subject, but the majority have passed a resolution in favour of one outfall only. Sir Joseph has gone iu detail through Mr. Harrison's report, and expresses his conviction that the scheme propounded by him will be found to work best for the interests of the town aud neighbourhood. He has promised to embody his views in a report to be presented to the Commissioners for their consideration.

At the Wandsworth aud Clapham Union, last week, a letter was read from the Brookwood Asylum, stating that no more patients can at present be admitted on the female side of the institution. It was stated that other asylums in the district were similarly crowded.

The Earl of Dudley has arranged, at his own expense, to convey water to about 500 cottages at Lower Gornal, where fever broke out some sime since, and pure water is almost entirely absent. This will be effected through negotiations with a local water company, who hitherto had declined to extend their mains to the place.

A very singular caso of mistaken identity of a body is reported from Grantchester, near Cambridge. It appears that one evening last week an inquest was held upon a body supposed to be that of a man named James Dazely, who was found drowned in the water at Grautchester. At the inquiry before the county coroner, however, two witnesses identified the body as that of John Adams, of Chesterton, and the jury returned a verdict accordingly. Upon a police officer making inquiries at Chesterton, he found Dazely in the union there, and Adams alive and with his wife. The document for the interment of the body as John Adams had actually been made out. The body as yet has not been identified.

Dr. Battistini has been named Physician to his Holiness the Pope of Rome, in place of Dr. Pelagallo, who has been summarily dismissed from his post by the Pope himself, his name having been struck out of the list of members of the Pontifical household. The dismissal of Dr. Pelagallo is said to be due to palaco intrigues and to reports conveyed to his Holiness that, neglecting the observance of that secrecy which the Vatican requires, he has given particulars to the outside world regarding the unsatisfactory condition of the Pope's health. Dr. Battistiui has already entered upon his duties.

The death is announced of Sir Francis Hicks, Treasurer of St. Thomas's Hospital. Sir Francis, who was greatly respected, and who has always shown the greatest attention and assiduity in discharging the duties of his office, was formerly a West Indian merchaut. He was appointed Treasurer of St. Thomas's Hospital on the retirement of Mr. Baggallay, in 1865, at the time when the Hospital was iu a transition state, and immediately after the Charity Commission investigation. Owing to the illness of Sir John Musgrove, President of the Hospital, the work of reconstructing the Hospital buildings devolved upon Sir Francis. In 1871, on the occasion of the opening of the new Hospital on the Albert-embankment, by her Majesty the Queen, Sir Francis was knighted. For the past few months he had suffered from illness, and since the middle of last month had been staying at the Cliftonville Hotel, Margate, where he died somewhat suddenly on Saturday last.

Recently, at the Cannock (Staffordshire) Police-court, a grocer, named Ridding, was fined £16 9s. for selling drugs not of the substance demanded by the purchaser. The defendant was selling "castor oil pills," manufactured by a firm in Wolverhampton, which, upon analysis, were found to contain uo castor oil, but calomel, aloes, colocynth, etc. Dr. Day, F.R.C.S., who was summoned to give evidence, said these pills, if taken in ignorance by certain persons, would act deleteriously. The defence set up by the defendant was that castor oil was only a name given to tho pills, which were harmless aperieuts; but, very properly, this plea was not admitted in extenuation.

A MEDICAL CLUB FOR AGRICULTURAL LABOURERS.

Some time ago there was established at Eye, in Suffolk, a Medical Club, which met with so much favour that within a year and a half it enlisted 4000 members, almost without solicitation. As the working-men of that district seemed to appreciate the advantages held out to them by this institution, which rendered them independent both of gratuitous advice and the parish doctor, it has been decided to found a similar Club, whose operations shall extend to the whole of the county

of Suffolk. The benefits are to be restricted to persons whose earnings do not exceed 20s. a week, or maid-servants whose wages do not exceed £8 a year, and this restriction secures the advantages of the Club mainly for agricultural labourers, as most mechanics earn considerably higher wages. The payment for a man or woman is 5s. a year; for a man and his wife, 9s.; and for each child, 1s., with a *maximum* payment of 5s. for children, no matter how large the family. A member of any benefit club may claim an abatement of 4s. from these rates. Women in their confinements are to be attended for 10s.; the remaining fees payable to a medical man being supplemented by the honorary fund. One of the rules allows any member a choice of doctors, living within a specified distance, who have agreed to work with the Club; and it is stated that most of the principal doctors in the county have consented to accept the scale of fees embodied in the rules. The Club is to be managed by stewards chosen in each parish, who will communicate, through a secretary appointed in every union district, with the central organisation at Ipswich. The rules and rates of membership have been so framed that the Club will be self-supporting except as to cost of management, surgical provision for accidents, and extra payments for confinements. These expenses it is intended to cover by means of subscriptions from honorary members and others. The scheme is well worthy of support, as it may, properly worked, do much to establish a feeling of independence amongst the class of agricultural labourers, and do away with the existing notion that the parish doctor and the union infirmary are the legitimate sources of relief in all cases of sickness.

SURGEON-IN-ORDINARY TO THE QUEEN IN SCOTLAND.

All those who love a good man and esteem a first-rate surgeon will be gratified to learn that Professor George Macleod, of Glasgow, has been appointed Surgeon-in-Ordinary to the Queen in Scotland, necessarily vacated by the migration of Mr. Lister to London. It is quite right that Glasgow should have her fair share of honours.

MEDICAL NEWS.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, August 30:—

Edwardes, William Whitfield, Llansantffraid, Oswestry.
Claughton, Charles Knox, Birkenhead.
Steventon, Walter Thomas, Snaith, Yorkshire.

The following gentlemen also on the same day passed their Primary Professional Examination:—

Bridges, Ashley Colston, St. Mary's Hospital.
Webster, Ridley Manning, Middlesex Hospital.
Wright, Herbert Elliston, Guy's Hospital.

NAVAL, MILITARY, &c., APPOINTMENTS.

War Office.—Medical Department.—Surgeon-Major Daniel John Doherty retires upon half-pay. The following gentlemen to be Surgeons under the Royal Warrant of April 28, 1876:—Jarlath Joseph Mullen, M.D.; Francis Henry Swinton Murphy, M.D.; William Thomas Johnstone, M.D; Frederick de Caux; Abraham Walker Brown; Robert Doveton Hodson; Caleb K. Powell, M.D.; Hugh Cunningham Kirkpatrick, M.D.; John Armstrong; William Wallace Kenny, M.B.; Philip Mackay Ellis; Patrick Joseph O'Sullivan, M.D.; Edward Michael Angelo Hogan; Andrew Irwin; Thomas Kearney; William McCarthy; James Fitzgerald Brodie.

Bombay Medical Establishment.—Surgeon Henry Cook, M.D., Surgeon Isidore Bernadotte Lyon, and Surgeon Andrew Barry, M.D., to be Surgeons-Major.

Scots Guards.—Surgeon Ernest Wyndham Cottle resigns his commission.

BIRTHS.

Crombie.—On August 28, at 140, Finborough-road, South Kensington, the wife of John M. Crombie, M.A., M.D., of a daughter.

Fyffe.—On August 27, at Netley House, Victoria-square, Clifton, the wife of W. Johnstone Fyffe, M.D., of a son.

MARRIAGES.

Brown—Steele.—On August 28, at St. Mary's, Scarborough, William Brown, L.R.C.P. Edin., etc., of Carlisle, to Clara, daughter of the late John Steele, of Carlisle.

Elkington—Derrington.—On August 29, at Chetwynd Church, Ernest Alfred Elkington, M.B., of Newport, Shropshire, son of George Elkington, of Edgbaston, to Maria Eliza, daughter of the late Thos. Derrington, of Chetwynd Villa, Newport.

Hardy—Otley.—On August 22, at the parish church, Otley, Yorks, William G. Hardy, M.B., of 1, Sturt-villas, Bournemouth, to Annie, second daughter of the late John Dacre Otley.

Mack—Scott.—On August 30, at Pitcairn-green House, Perthshire, N.B., J. Steele Mack, L.R.C.S. Edin., of Colmonell, Ayrshire, N.B., to Emma Jane Anne, only daughter of Mr. Thomas Scott.

Mallam—Dodd.—On August 28, at St. Luke's, Uxbridge-road, W., William Prior Mallam, L.R.C.P. Lond., M.R.C.S. Eng., of 6, Boscombe-terrace, Shepherd's-bush, to Jessie Helen, elder daughter of John Packman Dodd, of 6, Wilton-villas, and formerly of Throwley Parsonage, Kent.

Paget—Salomons.—On August 29, in London, George Edmund Paget, M.A. Cambridge, eldest son of Professor Paget, M.D., of Cambridge, to Stella Rosalind Jeanette, youngest daughter of the late Philip Salomons, Esq., of Brighton.

Robathan—Wilkie.—On September 3, at St. Mary's Islington, George Beckett Robathan, M.R.C.S., of Brighton, to Frances Elizabeth Muirhead, widow of the late Joseph Wilkie, J.P., of Melbourne.

Shapter—Bayly.—On September 3, at St. Sedwell's Church, Exeter, Lewis Shapter, M.D., of The Barnfield, Exeter, to Charlotte, youngest daughter of Captain E. Bayly, of Friar's Lodge, Exeter.

DEATHS.

Carr, Jabez, M.R.C.S., L.S.A., at Effingham House, Leamington, on September 1, in the 67th year of his age.

Dukes, Arthur E., youngest son of E. Dukes, M.R.C.S., of 52, Marquess-road, Canonbury, on September 4.

Geddes, James Loraine, late Surgeon-General Madras Army, at Coonoor, Madras Presidency, on August 6, aged 78.

Scott, William, M.D., Surgeon-Major, late Madras Army, at 27, India-street, Edinburgh, on August 28, aged 60.

Yorke, Christopher Francis, M.D., at Granard, Co. Longford, on August 27, aged 42.—R.I.P.

York, George Billing, M.D., at Great Bowden House, Market Harborough, on September 1, aged 44.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made and the day of election (as far as known) are stated in succession.

Beaford General Infirmary.—Resident Surgeon. Applications, with testimonials, to the Chairman of the Weekly Committee, on or before September 27.

Nantwich Union.—Medical Officer. Applications, with testimonials of qualification, to C. E. Speakman, Clerk, on or before September 12.

North-Eastern Hospital for Children, Hackney-road, E.—Physician. Candidates must be either F. or M.R.C.P. Lond. Applications, with qualifications and testimonials, to Alfred Nixon, Secretary, 27, Clement's-lane, E.C., on or before September 11.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

A Pupil.—You are too late for the Arts Examination for the fellowship of the College. The advertisement appeared some weeks ago in the *Medical Times and Gazette*. Write to the Hall on the subject.

A Member of the B.M.A.—The excursion to the lakes took place immediately after the annual meeting at Manchester, when, as usual, Mr. Cook, who organised it, gave the greatest satisfaction to the members who accompanied him. We have not heard where the next meeting will take place; Belfast and Cork have been named.

Bibliopole.—As stated last week, the library of the College of Surgeons will be closed during September.

L. E. C.—"Words are things, and a small drop of ink
Falling, like dew, upon a thought, produces
That which makes thousands, perhaps millions, think."
Byron.

C.B.S.—Kew Gardens were first opened to the public in 1847, at the recommendation of Sir William Hooker.

Sic.—Anatomy of the human body was renounced for many ages, and was not revived till the sixteenth century. The dissection of a human body was held sacrilege till the reign of Francis I.; and there is a consultation extant which the Emperor, Charles V., caused the professors of theology at Salamanca to hold, in order to inquire whether a human body might be dissected for the knowledge of its structure with a safe conscience. Vesal, a Flemish physician, who died in 1564, was the first who reinstated anatomy.

Inventor.—Addison says—"There is not a more painful act of the mind than that of invention. Yet in dreams it works with that care and activity that we are not sensible when the faculty is employed."

Sanitas.—One of the first legislative enactments of modern times on the subject of sewers was an Act of 9th Henry III., about 1225, which was followed by others; and the whole of the legislation then prevailing was carefully reviewed and condensed by Sir Thomas More in the "Bill of Sewers," which became law in 25th Henry VIII., or in 1531.

BOOKS AND PAMPHLETS RECEIVED—

Cassell's History of India, part 21—John Millar, L.R.C.P. Edin., Hints on Insanity and Signing Insanity—William W. Keen, M.D., On the Surgical Complications and Sequels of the Continued Fevers—Herbert Fry, The Royal Guide to the London Charities for 1877-78—W. T. Lusk, M.D., Morphia in Childbirth—Emilie Bovell, M.D., De quelques Accidents de l'Epilepsie de l'Hystéro-Epilepsie.

PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Berliner Klinische Wochenschrift—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Gazette Hebdomadaire—Le Progrès Médical—Bulletin de l'Académie de Médecine—Pharmaceutical Journal—Wiener Medizinische Wochenschrift—Medical Examiner—The Louisville Medical News—Boston Medical and Surgical Journal—Nature—Philadelphia Medical Times—Iron—Home Chronicler—La Province Médicale—Cincinnati Clinic—Obstetrical Journal of Great Britain and Ireland—National Anti-Compulsory Vaccination Reporter—Leisure Hour—Sunday at Home—Veterinarian—Archives Générales de Médecine—Monthly Microscopical Journal—Edinburgh Medical Journal—New York Druggists' Advertiser.

TO CORRESPONDENTS.

We beg to return our best thanks to the Registrars and Secretaries of the various Universities, Colleges, and Schools for their prompt replies to our Circular, and for the trouble they have taken in supplying the latest Regulations of the Institutions with which they are connected.

As this number is almost entirely devoted to matter mainly concerning Students, many most important communications and contributions unavoidably stand over.

We have here given everything of importance for the entering Student to know; for any further details he should apply for a prospectus to the authorities of the School he may select.

APPOINTMENTS FOR THE WEEK.

September 8. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 1½ p.m.

10. *Monday.*

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

11. *Tuesday.*

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

12. *Wednesday.*

Operations at University College, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 1½ p.m.

13. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing-cross, 2 p.m.; St. Thomas's (ophthalmic operations), 4 p.m.

14. *Friday.*

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1½ p.m.; Guy's, 1½ p.m.

At the Royal Observatory, Greenwich, the mean reading of the barometer last week was 29·72 in. The lowest reading was 29·35 in. at the beginning of the week, and the highest 29·94 in. on Saturday morning.

* The figures for the English and Scottish towns are the numbers enumerated in April, 1871, raised to the middle of 1877 by the addition of six years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the number enumerated in April, 1871.

ORIGINAL LECTURES.

THE HUNTERIAN LECTURES FOR 1877.

ON DEFECTS OF VISION WHICH ARE REMEDIABLE BY OPTICAL APPLIANCES.

DELIVERED AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

By ROBERT BRUDENELL CARTER, F.R.C.S.,
Late Professor of Surgery and Pathology to the College; and Ophthalmic Surgeon to St. George's Hospital.

LECTURE VI.—ASTHENOPIA.

MR. PRESIDENT,—In a large proportion of cases of ametropia, and in some in which no ametropia is discoverable, we find that the employment of the eyes is limited by conditions of time. After a period of use, longer or shorter according to circumstances, either the vision becomes indistinct, or pain is experienced in the eyes themselves, in the orbital regions, or even generally about the head. In many instances the symptoms of distress commence with indistinctness, which, if the visual effort be continued, leads on to pain. In many there will be found some form of obstinate conjunctival trouble. In a few the headache is the precursor of sickness, vertigo, palpitation, and other symptoms, which may collectively occasion the belief that the patient is suffering from some obscure cerebral or cardiac affection. The foregoing conditions are conveniently included under the general term of asthenopia, or weak sight, depending, as they all do, upon some cause which renders sustained visual effort impossible. The word is only a convenient way of saying that the patient cannot use the eyes for long together; and it requires to be supplemented, in every case, by some other descriptive of the precise nature and apparent cause of the affection.

In some cases asthenopia is associated with manifest defect of vision; in others the vision is little, if at all, below the normal standard.

For many years, asthenopia, although well known to ophthalmic surgeons, was regarded as incurable. The ordinary prescription for it was to abandon all endeavours to use the eyes in near vision; and, as a means of carrying out this recommendation, patients were often further advised to become farmers or emigrants.

When Donders discovered the existence and the nature of hypermetropia, he saw at the same time that many cases of asthenopia were dependent on the strain thrown upon the accommodation of hypermetropic eyes, and that such cases could be effectually relieved by the use of convex spectacles. He was even disposed, for a time, to look upon all cases of pronounced asthenopia as being of this kind. The increased attention which was soon given to the subject was not long, however, in producing evidence that many asthenopic patients were not hypermetropic, but myopic; and it was assumed by Von Graefe that in these the cause of the distress was in the strain thrown upon the interni in maintaining the convergence of the visual axes to some given distance. He described this as muscular asthenopia, and the hypermetropic form as accommodative asthenopia; and to these two categories nearly all cases of asthenopia were for some time referred. Later experience has shown that emmetropic eyes sometimes suffer from asthenopia, and that the causes of the affection may be exceedingly obscure; but still the two forms first mentioned, the accommodative and the muscular, may be taken to include the large majority of the cases which present themselves in ordinary practice. In the former, inability to maintain the accommodation effort; in the latter, inability to maintain the convergence effort, is the immediate cause of the failure of sight.

I think it must be conceded that the liability to asthenopia in any community, whatever the immediate causes of the affection in each case, bears a great relation to the general nervo-muscular excitability of the people. In England we are sufficiently familiar with asthenopic patients, and their ailments form an appreciable proportion of the claims upon the attention of ophthalmic surgeons. There can be little doubt, however, that in the United States asthenopia is much more prevalent than on this side of the Atlantic. At the International Ophthalmic Congress, held at New York in 1876, two of the ophthalmic surgeons of that city read papers on asthenopia—one of them founded upon an analysis of 1079 cases, and the other upon an analysis of 1060 cases; all, as I understood, observed in private practice. I much doubt whether any two practitioners in any other capital in the world could have cited similar numbers; and I feel sure that the conditions of life in America must be largely contributory to the state of things which they disclose.

I have already said that asthenopia is often associated with conjunctival troubles; and that this should be the case is not surprising. Asthenopia has one universal character; which is that some one or more of the muscles of the eye are unduly fatigued or strained by exercise of the visual function; and such fatigue or strain tends naturally to the production of active congestion while it continues, and of passive congestion when the effort is temporarily laid aside. Extending to the conjunctival surface, this congestion relieves itself by oversecretion of mucus; and leads, after a time, to hypertrophy of the papillæ and to consequent roughness of the lids. These troubles react upon and increase the irritability of the eye; and sometimes occasion nutritive changes of a still more serious kind. The chief peculiarity of asthenopic conjunctival affections is their obstinate and recurrent character; and, when any form of conjunctival disorder either resists treatment, or shows a marked tendency to relapse after improvement, as soon as the eyes are taken into regular use, asthenopia should be suspected and sought for. In many cases the patient will attribute the symptoms of asthenopia to the conjunctivitis, and careful examination will be required in order to determine their actual nature.

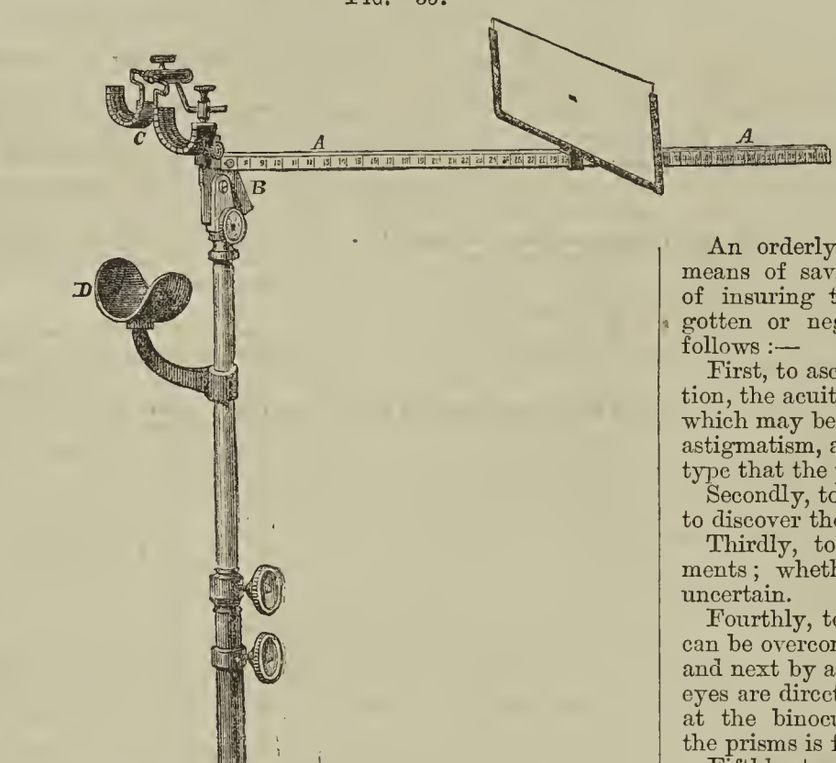
During many years the ophthalmoscope served to surround cases of asthenopia with all manner of unreal or imaginary dangers. The congestion already mentioned is not limited to the ocular surface, but may extend also to the deeper parts of the organ, notably to the optic disc and its immediate surroundings. In this region it may even give rise to some slight effusion into the fibre layer of the retina. Congestion of the optic disc and retina, when first made known by the ophthalmoscope, and when coupled with incapacity for continued use of the eyes, were eagerly accepted as signs of threatened, or impending, or actual retinitis; and, when coupled with symptoms of head distress as part of the asthenopia, were accepted as signs of impending or actual mischief in the brain. It is wearisome to think of the amount of nonsense which has been talked and written on the basis of these two errors; which have also been answerable for a vast deal of misdirected and even mischievous treatment. The idea of retinitis, or the idea of brain disease, led directly to the prescription of "rest" for the eyes; a prescription which, in 1874, I ventured to describe as being utterly wrong in principle, and as leading invariably to unfortunate results in practice. Setting aside manifest inflammation, such as iritis or irido-choroiditis, we may lay it down as a rule, almost if not quite without exception, that pain as a result of visual effort is symptomatic of some purely muscular trouble, that congestion associated with the pain is due to disturbed or excessive muscular action, and that the remedy is always to be sought in careful analysis of the muscular elements of the visual act, in the relief of any strain which this analysis may disclose, and in the regular and systematic employment of the eyes under improved conditions. To rest asthenopic eyes may be to relieve them from pain while the rest continues; but the relief is dearly bought at the cost of rendering the disused muscles even less fit for exertion than they were before. The brain troubles which occasion loss of sight—*e.g.*, intra-cranial tumours—may be associated with headache, but only with headache which is independent of visual effort; and retinal affections, such as neuro-retinitis leading to nerve atrophy, and the like, are even characteristically painless. The attention of the patient is usually first called to them by the discovery that his sight is fading away without pain. I have come to regard pain, other than glaucomatous or inflammatory pain, as a symptom which alone is almost sufficient to justify a favourable prognosis in any case of imperfect or conditioned vision.

In the great majority of cases of ametropia, and especially in hypermetropia and astigmatism, some pain will form part of the complaint made by the patient. Generally speaking, however, the pain will be relieved by the correction of the obvious defect, and no more trouble will be experienced. Such cases are primarily classified as ametropia, and their asthenopia is obviously a mere complication or result. There are others, however, in which asthenopia is present in great severity, and in which the cause is either not obvious, or the relief of some obvious defect fails to cure the asthenopia. These cases may be looked upon as typical examples of asthenopia, and their treatment requires much care and

circumspection. It can only be conducted upon the basis of a complete knowledge of the state of every single element in the performance of the visual function; and this knowledge can only be attained by a thorough, systematic, and orderly examination.

In order to facilitate this examination, I designed, and Mr. Hawksley constructed for me in 1875, an optometer intended to hold certain combinations of lenses and prisms, and to carry an object of vision at convenient distances. In America, last year, I found that the same idea had occurred to Dr. Risley, of Philadelphia, whose instrument, in many points of detail, was more complete.than mine; and I was therefore glad to take it into use. It can now be obtained from Mr. Hawksley, and is shown in Fig. 35.

Fig. 35.



The instrument consists of an upright pedestal, supported by a heavy foot, and containing a rod which is made to slide up and down, and is capable of being fixed at any desired height by a binding screw. At the top of this rod there is a quadrilateral brass bar, A A, fifty centimetres long, and graduated both in centimetres and in English inches. By means of a quadrant and screw, B, the bar can be fixed either in a horizontal position or with an inclination downwards, and, when not in use, it folds down out of the way. Along the bar there slides a slight metal carrier, to receive cards or other contrivances for test objects; and at the proximal end of the bar there are two semicircular clips, C, capable of being approximated or separated, and each one grooved to receive three lenses. On the sliding rod there is a chin rest, D, which may be turned aside when not wanted; and, when the object-carrier is removed, the bar is also made to carry a quadrant intended to be used as a perimeter. For testing vision, the apparatus being first set at a comfortable height, and the bar at a convenient angle, the clips are so adjusted that their centres may be as far apart as the pupils of the eyes. A suitable test object—a word, line, dot, star, or whatever may be necessary—is placed in the carrier, and any required lenses or prisms in the clips, which, having three grooves, admit of all sorts of combinations. When the bar is lowered, the same clips will serve to hold lenses, or prisms, or both, for the purpose of testing the vision with distant objects. The apparatus can in no sense be described as essential to a complete examination of the visual functions; but it has the merit of rendering such an examination more easy, and of saving much time in its accomplishment.

An orderly and systematic method of proceeding is also a means of saving time; and it has the additional advantage of insuring that no part of the examination shall be forgotten or neglected. My own course of proceeding is as follows:—

First, to ascertain, for each eye singly, the apparent refraction, the acuity of vision, the manifest degree of any ametropia which may be discovered, the presence or absence of evident astigmatism, and the distance of the near-point for the smallest type that the patient can read near at hand.

Secondly, to find whether there is binocular vision, and, if so, to discover the distance of the binocular near-point.

Thirdly, to observe the characters of the ocular movements; whether they are regular and steady or jerky and uncertain.

Fourthly, to ascertain what are the strongest prisms which can be overcome, first by abduction, with their bases inwards, and next by adduction, with their bases outwards, while the eyes are directed to a word printed in small type, and placed at the binocular near-point. The evidence of overcoming the prisms is furnished by the maintenance of single vision.

Fifthly, to ascertain what is the nearest point to which the visual axes can be directed, accommodation being reinforced by convex lenses.

Sixthly, to test the powers of abduction and of adduction once more; the eyes being directed to an object, preferably a steady candle-flame, placed at a distance of from eight to twenty feet.

Seventhly, to prescribe a solution of neutral sulphate of atropia, of the strength of four grains of the salt to the ounce of distilled water, a drop of which is to be applied to one or both eyes at bedtime, and twice, with an interval of two hours, on the following morning. Two hours after the last application, the refraction should be again very carefully examined, with especial reference to small degrees of either ordinary ametropia or of astigmatism.

By following this routine, and by noting down the results as we proceed, we obtain a precise account of the state of the refraction, the accommodation, and the convergence; and we ascertain whether the normal relations of these functions are disturbed. In a general way, the first part of the examination, up to the use of atropia, may be easily accomplished at a single interview; but it is better to see the patient a second time than to run any risk of being misled by careless answers when the eyes are tired. Whether the atropia should be applied to one or to both eyes, should generally depend upon the engagements of the patient. As a rule, I prefer to apply it to both at once; but, where there is any business which requires attention, it is best to let the first eye recover its power of accommodation before the other is taken in hand. The results of the examination may be most quickly and conveniently recorded by filling up blank spaces in a printed form; and this method is also the best way of obtaining materials for tabulation when a sufficient number of cases has been observed.

When all the facts bearing upon the question have been investigated and set down in order, they will at once suggest the most probable reply to the inquiry whether the asthenopia must be attributed primarily to strain of accommodation, or primarily to strain of convergence.

Strain of accommodation may be produced by any of the following conditions:—

1. Deficient power of the ciliary muscle, either as a matter of formation, or as a result of enfeebling illness.
2. Impaired elasticity of the lens, as in presbyopia.
3. Excessive demand, as in hypermetropia.
4. Constant variation of demand, as in astigmatism.
5. Unequal demand in the two eyes, as in anisometropia or antimetropia.

The cases which belong to the first three classes have the common characteristic that the need for the exercise of accommodation is greater than the power of exercising it; and they differ chiefly in respect of the side from which the inequality arises. In some, as in presbyopia, the difficulty is on the side of the lens; in others, as in weakness, it is on the side of the muscle; in others, as in high degrees of hypermetropia, the demand is in excess of the normal activity of the function. In all these varieties we may lay down the general rule to which I have already referred—namely, that if the demand for accommodation, whether it be normal or abnormal, is in excess of half the power of the function in the particular case, the demand will not be continuously satisfied without pain and distress; and hence that the strain of the accommodation, in all such cases, may be accepted as a probable explanation of the asthenopia, and should be relieved by spectacles as a first step in treatment. If the spectacles prescribed for this purpose are not successful, they will at least clear the ground for further investigation. It is obvious that some patients will be able to exert habitually something more than half their accommodation, while others will only be able to exert habitually something less than half; but in this, as in all analogous cases, no rule can be laid down which will be more than an approximation to the truth, or which will not require modification in practice in order to adapt it to individual necessities. Still, if the working distance of the patient does not demand the exercise of half, or nearly half, his accommodation, and if neither of the conditions mentioned under the two last headings is present, the first hypothesis about the asthenopia would be to seek its cause in some undue strain of the convergence.

The following cases may be cited as typical illustrations of their respective kinds; it being supposed that each patient requires to apply the eyes continuously to an object of vision at a distance of fifteen inches from them.

A. Emmetropic; age twenty-one. In consequence of paresis of the ciliary muscle, produced by diphtheria, has only four dioptrics of accommodation. Half this range, or two dioptrics, would bring the near-point to twenty inches; and, to bring it to fifteen inches, 2·66 dioptrics are required—an amount about equal to two-thirds of the total range.

B. Emmetropic; age forty-three. Accommodation normally reduced to four dioptrics by presbyopia. Excess of demand the same as in the preceding case.

C. Hypermetropia of two and a half dioptrics; age twenty-one. Accommodation of nine dioptrics. Of the 4·5 dioptrics of accommodation which can be continuously exercised, 2·5 are consumed by the hypermetropia, leaving only 2 dioptrics available for near objects, and hence the same conditions as in the former cases.

In estimating the strength of the convex glasses which should be prescribed for these three patients, it must be borne in mind that, under favourable hygienic conditions, the accommodation of patient *A* will probably be restored to the normal standard in a few weeks or months; and hence it is not desirable to give him more help than is absolutely necessary. Convex glasses of too high a power, which completely relaxed his accommodation, would deprive his ciliary muscle of wholesome exercise. He should therefore receive lenses of 0·75 only, and should be encouraged to use his eyes in a reasonable degree. Patient *B*, on the other hand, is at a period of life when his accommodation will decline rapidly; and he may at once receive lenses of a dioptric and a half. The accommodation of patient *C* will, at his age, change but slowly; and his hypermetropia may be corrected completely, either at once or by two gradations of glasses, on the plan described in the fourth lecture. When it is fully corrected he will need no farther assistance until he arrives at the age of commencing presbyopia. When that times comes he will need an addition to his spectacles equal to the power which an emmetropic person would require at the same period of life.

In cases of the fourth class, although there is often great strain of the accommodation, the degree of this strain can no longer be measured by the total range of the faculty. In astigmatism the strain arises from the constant variation of the demand, which has to provide in quick succession, and with unchanged convergence, for clear vision of those boundaries of figures which correspond with the chief meridians of corneal curvature. Supposing these meridians to be vertical and horizontal, the patient, in every act of seeing, accommodates first for the vertical and then for the horizontal boundaries of the object, or *vice versâ*. The effort is even greater than that which would be necessary if the object—a printed page, for example—were moved quickly to and fro before the eye, because in such movement the convergence would be altered together with the accommodation. The effect of the constantly varying accommodation will depend, in some degree, upon the amount of the variation—that is, upon the grade of the astigmatism; but, even in low grades, it is often beyond the powers of the normal function. When different forms of astigmatism are compared, my experience is that the hypermetropic forms occasion more distress than the myopic, the compound more than the simple, and the mixed forms most of all; but the difference between the susceptibilities of different persons is too great to allow any general rule of this kind to be laid down. Donders originally expressed the opinion that astigmatism of less than a dioptric was scarcely disturbing to vision; but such a degree is certainly highly disturbing in some cases; and in every instance of obscure asthenopia any discoverable astigmatism, however small, should be corrected, more especially if it should be of the mixed variety. The correction of even half a dioptric has been followed by excellent results in certain instances.

In the fifth class, comprising anisometropia and antimetropia, the accommodation strain is often felt when the range of the faculty, for each eye singly, is normal, and it then appears to depend upon the inequality of demand in the two. The nerve stimulus which produces accommodation is believed to be transmitted from the centre in an equal degree to each eye, and no inequality of accommodation is thought to be possible, except from peripheral failure in one of them. Supposing the eyes, although unlike in their refraction, to be in all essential respects healthy, and to be directed to the same object of vision, it is assumed that only one of them will receive a perfectly sharp image, or will be perfectly accommodated for the object; the other being incorrectly accommodated, and therefore receiving an image which is less sharp, but which may still be sufficient to maintain binocular vision. It would seem, at first sight, as if such an arrangement must lead to the constant employment of the eye which is most easily adjusted, and to a practical neglect of the dim image received by the other, such as obtains in ordinary squint. If this were so, there would be no apparent cause for asthenopia, unless the accommodation of the eye most used was itself unduly strained. But, as a matter of fact, we find asthenopia in a large proportion of such cases; and it may possibly be brought about by the relations which exist between the two eyes. There is much reason to believe that, in ordinary binocular seeing, although both eyes are concerned, they are not, at any given moment, both concerned equally; but that one of them is active, and the other more or less passive or complementary, the two exchanging their functions in this respect from time to time, and each becoming, so to speak, anode and cathode by turns. Assuming this relationship between them to exist, so that each eye takes up the more active seeing alternately with its fellow, we shall have a demand for a correspouding variation of accommodation whenever the change of function takes place; and I am disposed to think that this is the true explanation of the occasional asthenopia of unequal eyes. Let it be supposed that the right eye has a myopia of one dioptric, and the left a hypermetropia of the same degree. There would then be an increase or a relaxation of accommodation equal to two dioptrics, whenever the transference of the more active seeing occurred; and the familiar experiment of looking at a star with one eye only, until it disappears from view, leads to the supposition that such a transference must occur every few minutes. If this be so, the alternate tension and relaxation of the accommodation, for the same degree of convergence, may very well become a source of visual strain.

It would appear, at first sight, that the correction of anisometropia or of antimetropia would be simple, and would require only the application, to each eye, of the lens necessary for its own defect. Sometimes this plan will answer well, but sometimes it is impracticable. Every lens, placed before an eye, alters the size of the retinal image; and hence, when two unlike lenses are employed, the effect is to give the two eyes images of unequal magnitudes, which cannot always be fused into one. We shall find some persons who fuse the unequal into one. We shall find some persons who fuse the unequal images readily, and others who cannot fuse them at all. My

mpression is, that the cases in which fusion is resisted are usually those in which binocular vision was previously sacrificed to the defect; and that in these we seldom meet with asthenopia as a consequence of it. The only possible rule of practice is to test the power of fusion with unequal glasses, and, if it exists, to let such glasses be worn continuously. When fusion cannot be accomplished, the requirements of the better eye of the two must chiefly be taken into account, and the patient should be encouraged to use it singly. At the same time, the worse eye must not be neglected; but, being furnished with a lens suitable to its wants, it should be used at regular intervals, in order to keep its retina duly exercised and receptive. By reading with it systematically, even for a few minutes at a time, three or four times a day, its vision may often be improved; and I have sometimes seen the increased attention thus paid to its impressions result in the restoration of binocular vision, so that each eye could eventually be separately corrected, and yet the two be employed in unison.

(To be continued.)

CASES OF INHERITED SYPHILIS.

NOTES FROM A CLINICAL LECTURE AT ST. MARY'S HOSPITAL.

By Mr. HAYNES WALTON,
Surgeon to the Hospital.

How the Infection is received.—Markings on Infant.—Clinical Examination of Three Cases.—Proof of their Syphilitic Nature.—How the Symptoms appear.—Treatment.

Gentlemen,—The eye is an organ of special sense, in which the morbid influences of syphilis, as an inherited effect, are frequently and strongly developed. The three cases of this ocular juvenile constitutional poisoning, now in the hospital, shall supply us with stock material for this day's clinical remarks.

In the first place, I should tell you how the bad inheritance is derived, whence and under what conditions it is received. It comes from the one or the other parent. A father or a mother, with a primary sore, or with constitutional syphilis, may beget a child and transmit syphilis to it. After impregnation from a healthy male, the woman may receive syphilis by inoculation from another man who has a primary sore, and give it to the fœtus in her womb. A father may beget a syphilitic child without inoculating the mother directly, although she may be secondarily syphilised by absorbing the diseased secretions from the diseased fœtus. A fœtus and its membranes may show the strongest marks of syphilitic implication.

In all the cases before us, an ophthalmitis, *i.e.* inflammation of all the tunics of the eyeball, has prevailed. In Case 1, the girl aged sixteen, the ocular subjective symptoms on admission were—loss of useful vision of the right eye, so that fingers could not be counted a foot off; impaired vision, loss of acuteness, in the other eye. The objective symptoms were alike in both eyes, but much more marked in the left, viz., redness of the sclerotica, especially in the ciliary region, partial adhesion of the pupil, haziness of vitreous body. In the left the retinal vessels were not visible, and in the right but faintly so. According to the girl's account she never had good sight, had had several inflammatory attacks in the eyes, and an unusually severe one had induced her to seek aid at St. Mary's Hospital.

In Case 2, also a girl, aged fourteen, the subjective symptoms were—loss of sight in the right eye, and only enough sight in the left to enable her to find her way about in the ward. The objective symptoms were hyperæmia of both scleroticæ; interstitial opacity of the right cornea to a degree that hid the pupil and nearly all the iris, and general interstitial opacity of the left, but yet thin enough to enable one to see that the iris was discoloured, and the pupillary margin much adherent. The history told me that the eyes had been bad so long as the patient could remember; that the degree of the symptoms had fluctuated; and only in the later years had the sight been so seriously affected.

In Case 3, a male, seemingly aged about eighteen, the subjective symptoms were so nearly like those of Case 2 that they need not be described; and the objective symptoms were alike, but more severe. No history could be got, as the poor fellow is deaf, which deafness is acquired, and of syphilitic origin.

Now as to the evidence of these eye affections being syphilitic. Case 1 was a first child; Case 3 was the child that lived, the first-born having been a miscarriage.

It is usual in constitutional syphilis that the first or the earlier children become diseased, and it is very common for an infected fœtus to be prematurely expelled: There were, too, in both marks of sores about the mouth and anus. But all the patients had the notched and undeveloped teeth—Hutchinson teeth—so characteristic of inherited syphilis.

The usual typical commencing symptoms of inherited syphilis in infants and children are these:—The infant is attacked or is born with copper-coloured eruptions, snuffles, aphthæ of the mouth, and mucous tubercles about the genitals or anus. The eyelashes are exfoliated, and the nails may be unhealthy. When the second teeth appear, the undeveloped peg-like or notched condition of the front and lateral incisors is seldom absent.

The time of appearance of inherited syphilis in the eye is frequent in infancy, and if not then, certainly in childhood.

There is no essential difference between the symptoms of inherited syphilitic ophthalmitis and secondary syphilitic ophthalmitis in the adult, except in the former being less acute and severe. The surface of the eyeball, the sclerotica, and the conjunctiva, are seldom very red. The as yet undeveloped eyeball may account for this.

Treatment.—The principles for this are the same as those which I recommend to you and practise for the same disease in the adult, adapted only to the early age of the patient. Mercury is the chief remedy. In infancy and early childhood we must resort to inunction, and rub the drug into the soles of the feet, the axillæ, the groins, or the calves, from a scruple to a scruple and a half of the ung. hydr. being used daily. This ageney should be employed and continued, as a rule, according to the effect on the disease. The general health and feeding of infants and young children demand the most careful attention. For the former a wet-nurse during the ordinary suckling period supplies the best of all food. When such a nurse cannot be got, milk diet—that is, cows' milk with a proper dilution and sweetening according to the age of the child—should be solely given for nine months. Our patients, from their ages, were treated by the internal administration of mercury. You know that my plan is to give the chalk and mercury with the extract of hyoscyamus, in the proportion of one, one and a half, or two grains of the former, to two, three, or four of the latter, two or three times a day, taking care to avoid purgation, depression, or salivation, by lessening the frequency of the taking, or altering the proportion of the pill. But we must not make an abstraction of the disease syphilis, consider mercury to be the antidote, and ignore other curative measures. Tonics and stimuli are often needed along with it.

(Mr. Walton now proceeded to point out the effect of the treatment on the patients. Case 1 could read large type with one eye, and any type with the other eye. Case 2 could read ordinary type with the left eye, and the interstitial opacity of her other eye was much less. Case 3 had made progress so far that the hyperæmia of the scleroticæ was lost, and the opacities of the corneæ were little less, but not enough reduced to improve vision materially. He pointed out that little could be expected in the way of improvement in corneæ which had been so much damaged. The deafness had not lessened.)

Prize Questions of the Reale Istituto Lombardo di Scienze e Lettere in Milano.—From among these we quote the following:—1. *Premio Straordinario di Fondazione Cagnola*, 1879—"The nature of miasmata and contagia." A prize of 1500 lire (£60), and a gold medal of the value of 500 lire. 2. *Premio Straordinario Castigliani*, 1878—"Demonstrate whether humanised vaccination or animal vaccination constitutes the most preferable prophylaxis for variola." A prize of 700 lire. 3. *Premio di Fondazione Fossati*, 1878—"The functions of the anterior lobes of the human brain, with particular reference to modern opinions on the origin and seat of language." A prize of 2000 lire. 4. The same for 1879—"The history of the progress of anatomy and physiology of the brain during the present century, with especial reference to the doctrine of Gall." A prize of 3000 lire. 5. The same for 1880—"The illustration of some macroscopical or microscopical facts of the human encephalon." A prize of 2000 lire. The essays, written in the Italian, French, or Latin language, must be delivered, postage-free, at the Institute by February 28 of the respective years for the first two prizes, and by April 1 for the last three. Additional information may be obtained of the secretaries of the Institute, Milan.

was greatly checked, bowels became confined (and a purgative is at best a poor substitute for a healthy evacuation), and therefore the kidneys became the sole scavengers; these not being able to get rid of more than a certain quantity, nitrogeu accumulated, and scurvy was the result.

It is well known that when our dogs, and especially our pet dogs, get old and lazy, they frequently get mangy; and, if their gums be examined, they are found to be injected and scorbutic—this I have observed on numerous occasions. These animals are fed almost exclusively on lean meat, the fat being thought unwholesome, and more is given than is necessary for their sustentation; they care little for exercise, and spend most of their time in sleeping on the hearth-rug or in their baskets, so that little nitrogen is required by the system. Dogs are frequently confined in their bowels, so that the work of elimination must be wholly performed by the kidneys; these are frequently impaired in old age,(f) and accumulation of nitrogenous matter must result. Their teeth, too, aro worn out, and thus the food is ill-masticated; this throws extra work on the already decaying organs, and hastens their dissolution. It may be asserted, in opposition to this, that mange in dogs is the same as scabies in man; this may be the ease occasionally, but not in the majority of cases, as any one who will take the trouble to observe closely may prove for himself. That scurvy will make the hair fall off is certain, from frequency of baldness in scorbutic people, and the return of the growth of hair when the disease is checked. I have observed that veterinary surgeons almost invariably prescribe a farinaceous diet for dogs suffering from mange; this is prescribed empirically. Old lions and tigers when killed are frequently found to be "mangy," and their teeth worn to stumps; and this "mange" I believe to be scorbutic, and to be caused in the same way as in old dogs.

I have frequently cured the mange of old dogs, and the accompanying soreness of the gums, by the administration of olive oil, and have administered eod-liver oil to scorbutic sailors with the best results.

We know that every Arctic expedition has suffered from scurvy, and it seems that during intense eold men are more subject to the disease. From its having broken out in the *Tegathoff*, of the Austrian Arctic Expedition, when lime-juice was regularly served out, Lieutenant Payer was led to believe that this much-vaunted antiscorbutic loses its power in a low temperature; but it seems to me far more probable that lime-juice is an insufficient antidote. During extreme cold, elimination by the skin is checked, or altogether suspended; men are usually more costive in cold than in warm weather: these two outlets being elosed, a glut ensues aud scurvy is the result.

Before going further it may be well to say a few words about lime-juice, and see how far or how little we cau trust to it as an antiscorbutic. Its use was introduced into the Navy at the instigation of the Society of Friends, who demonstrated its efficacy to the satisfaction of the powers that were; but on what evidence I have been unable to discover. Siuce that time every writer on the subject of scurvy has recommended the use of lime-juice, but invariably this has been done empirically; and none should know better than the medical profession how likely empiricism is to err. It is generally asserted, and with truth, that since the use of lime-juice in the Royal Navy, scurvy has ceased to appear, and the immunity enjoyed is attributed to its use. How is it, I ask, that the same results are not obtained in the Merchant Navy? The fact is, we must look further than lime-juice for the cause of the effects produced. At about the same time as lime-juice was brought into use in the Navy, other important changes were introduced into the dietary scale of the men. Up to this period half a gill of rum was supplied thrice daily, *i.e.*, at breakfast, dinner, and supper, and at this time, for the morning and eveuing grog, eocoa and tea were substituted, and a gill instead of half a gill of rum was giveu at diuner.(g) Shortly after this period iron water-tanks were substituted for wooden casks, and as these preserve the water in a sweeter and more wholesome coudition, the health of the meu is better sustained, and they are thus rendered less liable to the disease. To these several facts rather than to the use of lime-juice alone should be attributed the reduction of the number of scorbutic eases. It seems to me that the only way in which lime-juice can act as an antiscorbutic, is iu its diuretic action aiding, to a eertain degree eliminatiou of the superfluous nitrogen.

That scurvy may occur on a fresh meat diet is certain it may be asked if salt meat is more liable to produce disease than fresh. This is a difficult question to solve v out further knowledge than we have on the subject, indeed without a long course of exhaustive experiments; I think that it may possibly be the case, for habitual m eaters(h) eat no salt with their food, whilst those who, on eontrary, live entirely on vegetable food, eonsume large q tities of it. This would seem that instinct or experience proved its necessity in the one case, and its inutility in other. The Guachos, who live entirely on meat, eat l quantities of fat;(i) probably they have discovered, many others, that a fair admixture of carbon is necessary food.

The facts that I have mentioned eoncerning the disea and I might bring forward many others of the same ki seem to justify us in the belief that scurvy arises fro accumulation of a superabundance of nitrogen in the sys and that lime-juice, however useful as an adjunct, is n eertain preventive. It is therefore necessary to see wha may do in this direction.

It should be madc imperative on shipowners to serve butter and potatoes to their erews; the latter are easily ried, both *au naturel* or in a preserved form. The we amount of sugar should be increased, for even with g economy the present allowance seldom lasts through the v It would be advisable to substitute cocoa for coffee at br fast; but with butter, potatoes, and extra sugar this is absolutely necessary. The amount of meat given—a p and a quarter of beef or a pound and a half of pork daily absurdly large, so that it would be well to think of the po of shipowners; and in consideration of the additions that I advised in thc present dietary scale, I would also propose the amount of beef and pork be reduced to three-quarters pound of either daily.

The apostrophe of an old Cornish captain—"Kip 'is empty an kip 'e 'ard at wurrk, an 'e warnt 'ave scurvy" not without truth, but it is scarcely necessary to lay m stress on the benefits of a good evacuation daily, or the use of laxatives, for sailors are fond of a good "clear o and from my knowledge of shipmasters, they are not the to serve out purgatives in too gentle a manner.(k)

In the event of another Arctic voyage, I would recomm that our sailors should take pattern by the Esquimaux eat a larger portion of fat than they have been in the hab doing hitherto.

For the eure of scurvy a proper *régime* of diet shoul insisted on. The cruciferæ are in great repute, and doub they are somewhat beneficial, though to what extent hard to say, as they have never been tried alone; the be derived from the use of acid fruits is probably much exa rated, but as they are always grateful to the sufferer, the to be recommended. Dr. Niemeyer(l) states that "the he effect of a fresh vegetable diet upon scurvy is much positively ascertained than is the dependence on the wa such nourishment." This author also states that the val beer has a great reputation as an antiscorbutic. I have n seen it prescribed, but on theoretical grounds would be inc to uphold it. Dr. Aitken(m) speaks highly of the us rabbits' blood that was administered to two scorbutic cases this is merely bearing out my views that a properly m diet is needed, the blood of the rabbit containing much o earbon that was required by the patients. Of medicine the early stage of the disease, when the patient is costive should begin with an oleaginous purge, and follow it up some of the neutral salts, such as sulphate of soda or po eombined with liq. ammon. acet.

For the diarrhœa which usually supervenes on the cos ness, I have usually prescribed five grains of the subni of bismuth, with ten drops of castor oil in mucilage peppermint water, with the best results. If there is

(f) I have made several post-mortem examinations on old dogs, and frequently found the kidneys granular. I have so often found only one kidney at these examinations as to lead me to suppose that this is not an infrequent abnormality in dogs.

(g) This has since been reduced to half a gill.

(h) See accounts of the Guachos, in "The Voyage of the *Beagl* Mr. Darwin.

(i) *Ibid.*

(k) I knew one shipmaster whose favourite purge was an ou salts and a wineglassful of castor oil, with a little essence of peppe and water; and another who had a stock pill of gamboge, croto and podophyllin.

(l) "Text Book of Practical Medicine."

(m) "Science and Practice of Medicine."

(n) I have quoted from memory, as I have not a copy of Dr. Ai excellent work at hand.

hæmorrhage from the bowels, turpentine will be found most effectual, and in all cases of debility cod-liver oil acts like a charm. For the local treatment of the mouth it seems to me superfluous to lay down any form of treatment, for as the disease gets well the soreness disappears, but local treatment alone is of no avail.

REMARKS ON

THE PRESENT AND THE LAST EPIDEMIC OF SMALL-POX IN LONDON.

By CHAS. A. FOX, Surgeon.

It may be within the remembrance of your readers that, at the commencement of the severe visitation of small-pox in 1871-72, I endeavoured to point out the laws which regulate the fatality of this exanthem in the metropolis, and ventured to predict that a continuation and even increase of the epidemic was to be expected. This unfortunately, as we know, proved to be the case; and thus afforded one among many examples of the utility of statistical research.

The epidemic referred to far exceeded all previous ones that have occurred since the Returns of the Registrar-General have been issued. Its mortality reached the unique proportions of 2 *per cent.* of the population in London, and of 0·1 in the country at large. These were the ratios of death to population (not, as so often erroneously understood by "mortality," the number of deaths) for the year 1871.

It may be as well to mention here that the calculations employed in this paper have been corrected for deaths from causes not specified, for reducing the quarter to a uniform length, and for taking the population at the middle of the quarter. The population, too, has been assumed to have increased, since the Census of 1871, in the same ratio as in the previous decade, and the unequal length of years has been allowed for.

The figures of the great epidemic of 1870-72 have a considerable interest to the statistician and the medical inquirer. On a chart exhibiting its course per week for London, and including each of the five districts, we see that the highest number of weekly deaths was 288. This number was attained at the beginning of May, 1871, when it had lasted just six months. The epidemic had pretty regularly risen to this point from October, 1870, when the deaths first exceeded the weekly average of thirty years,—a point from which I propose to consider the disease as *epidemic*, in the absence of any better definition of the word. At the end of June the number of deaths suddenly declined, until, in the cold months of October and November, they came down to about sixty. The second maximum, the existence of which in the case of small-pox I mentioned in the papers referred to, soon occurred—the deaths reaching, in December, 1871, 106. Thenceforward the disease gradually declined in fatality or prevalence until early in August, when the deaths again came within the average count, and we may regard the epidemic as having ceased. Its duration had been ninety-three weeks—more than seven quarters of a year. It had thus been unusual both in severity and in duration.

The quarterly mortality for small-pox in the metropolis I shall show to be ninety-one to every million of the population. This, of course, has reference to a long series of years. But an idea may be gained of the severity of the late visitation, from the fact that, *whilst it lasted*, the average quarterly mortality was 435 to the million.

It might have been hoped that the force of the disease would be somewhat spent; and such seems to have been the case. The period since our last review, as it witnesses the highest, furnishes the lowest, mortality for small-pox within recent years; as it gives us the instance of longest duration of the disease, so it supplies one of the longest intervals of comparative exemption. The *quarterly* mortalities were as many as seven times (in this quiescent period) less than was ever the case during the thirty years previous: and these eleven amongst them included *all* the quarters of 1874. In the first quarter of 1876 the mortality was not more than 2 per million.

As hinted at the outset of these observations, the *yearly* death-rates, both for London and for England and Wales, exceeded in the midst of the epidemic any occurring in the previous generation, being 2434 to the million for the former, and 1006 for the latter—which surpasses even the high mortality (917) of the year 1838. On the other hand, although during the period by which the epidemic was followed the annual mortality for the country is greater than that for the metropolis, there is in both a marked diminution. The three *continuous* years (1873, 1874, and 1875) were each freer from variola than any in the series—perhaps than any in former times,—sixteen only having died to the million in London in 1874. On an average of these years the ratio of deaths was not more than twenty-four in the metropolis, and seventy-seven for England and Wales; whereas (as will be shown) the death-rates, taken for a long series of years, are respectively 350 and 245.

We are in a position now to verify or correct what were previously stated as the laws of small-pox mortality, since we have a longer series of years from whence to deduce them. The yearly averages for London and the country could at that time only be drawn from the facts of twenty-two years common to both; now we may review thirty years of which we have the requisite data, and these give us as the yearly mortality for London 350 per million, and 245 as that for England and Wales. Or we may take thirty-seven years for the metropolis, when we obtain an average for it of 301, which is still more valuable, though not comparable with the country at large.

On this large basis of thirty-seven years I have also set down the average mortalities for each quarter of the year, which are 104, 102, 74, and 87 to the million respectively. These figures exceed, in each case, those I gave in former papers. They also exceed those which are given by the ten years (1850-60), and by the following decade (1860-70). The difference between the highest and lowest of the seasonal numbers above given is thirty, which is nearly one-third of the average of the four, and indicates a higher range for the disease than appeared on a consideration of the facts of thirty years only. The difference was shown to be nineteen in the previous calculation, eleven less than above stated. The average here referred to is ninety-one, which is thus the quarterly mortality for small-pox on an average of thirty-seven years, and a proportion more reliable than that arrived at when I previously wrote.

The maximum quarter is still found to be the first or winter, and the minimum the third or summer quarter. The first and second quarters, however, as estimated by the present long range of observation, exceed the mortality noticed in my former papers far more than the third or fourth. And it may be justly queried, in view of this fact, whether the unusual severity of the disease in the early part of the year 1871, to which this alteration is mainly due, may not be owing to the remarkably cold character of the winter of 1870-71.

The various mortalities per quarter above noticed may be stated in other terms by the following figures, which give the average number dying per *week* of small-pox in each of the quarters. They are:—Ten for the first, eleven for the second, six for the third, and seven for the fourth quarters.

In a former paper I pointed out the law of recurrence for small-pox epidemics, and endeavoured to show that, as nearly as could be ascertained, they observed an interval of about fifteen quarters.

I would now make a very few remarks upon the visitation of the disease from which we have been recently suffering in the metropolis. This was separated from the last, which we have been considering, by a period of nearly seventeen quarters. For it may be said to have commenced in the middle of October of last year, on the principle assumed in the early part of these remarks.

The returns hitherto obtainable show it to have lasted forty-four weeks (more than three quarters), since on the principle above expressed it must still be considered as epidemical. It pursued in its earlier part an irregular course, and was most virulent at the beginning of the year (116 deaths). It has three times exhibited more than 100 deaths in the week. The mortality it reached in the first quarter of this year was as high as that of the latter part of 1871, being 337 deaths per million of the population. That of the second and last quarter, however, is less than the ratio given by the spring quarter of 1872, when the great visitation was declining, being, in fact, 233 to the million.

What I have here sought to point out will show that the epidemic of 1876 was to be anticipated, and consequently that it cannot be taken as throwing any discredit upon vaccination.

Stoke Newington, N.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

BIRMINGHAM GENERAL HOSPITAL.

A CASE OF UNILATERAL CHOREA WITH ORGANIC CEREBRAL HEMIANÆSTHESIA AND CROSSED AMBLYOPIA—ALBUMINURIA.

(Under the care of Dr. RUSSELL.)

The observations of Charcot, Türck, Landolt, and others, have attached peculiar interest to three elements in the following case—viz., the hemianæsthesia; the impaired vision, in so far as relates to its affecting the entire field in a single eye; and the hemichorea. The source of the interest attaching to these elements is derived from their existing in connexion with each other, and from an important question thence arising respecting the special seat of the lesion to which this group of disordered function is to be referred.

The hemianæsthesia conformed to the type furnished by the *hémianesthésie des hystériques* as described by Charcot, but which has also been found to exist, under very special circumstances, in connexion with coarse disease of the brain (hæmorrhage or softening), and is then distinguished by the same eminent observer by the appellation of *hémianesthésie cérébrale organique*, an appellation designed to separate this form of hemianæsthesia from all other forms not recognising for origin a cerebral lesion properly so-called (*Le Progrès Médical*, August 14, 21, 28, 1875). In the form of anæsthesia in question, at least in the best marked cases, all modes of sensibility are involved, and in the mucous membranes and in the muscles not less than in the outer integument; the external mucous membrane being more or less insensible to contact, and the muscles to contractions excited by faradism; moreover, the special senses are alike involved on the same side. In the insensible part, too, some restriction to the freedom of circulation in the smaller vessels appears to exist, as evidenced by the little tendency to bleed after punctures. As regards the visual affection, it is peculiar in this respect, that it affects the entire of one eye, the eye of the side affected by the insensibility (*l'amblyopie croisée*), and is thus distinguished from ordinary homologous hemiopia. This form of amblyopia completes the sensitive defect in the form of hemianæsthesia under consideration; in it, as exemplified by my patient, not only is acuity of vision in the affected eye seriously diminished, but the visual field is markedly contracted. A third characteristic has also been described by M. Galezowski, viz., abnormal limitation in the perception of colours—a peculiarity which could not be tested in the subject of the following case.

As is generally known, an interesting discussion has been raised by Charcot, Veyssière, Türck, and others, in connexion with this form of hemianæsthesia, and particularly with its relation to the monocular form of impaired vision (*Le Progrès Médical*, 1875; and Charcot's "Leçons," première série, dixième leçon). This discussion relates to the situation in the brain of the centre for sensory impressions, the part wherein intellectual recognition of sensory impressions is effected; to adopt the language of Dr. Hughlings-Jackson, the part of the hemisphere where the sensori element in the sensori-motor operations of the convolutions predominates over the motor element. The problem, however, is a complex one, as it depends not only on anatomical data as to the seat of lesion in the cases under review—which data are at present very scanty—but also upon other anatomical data concerning the decussation or non-decussation of the nervous fibres in the optic commissure, which themselves depend for their elucidation mainly on the interpretation given to the phenomena presented by such cases as the present one. With respect to the former of these subjects, the well-known observations of Türck, of Vienna, have ascertained that the seat of the lesion in four cases has lain in the superior and external part of the thalamus, in the third part of the lenticular nucleus, and in the posterior part of the internal capsule; and, eliminating the two first-mentioned lesions, as being common to other cases also, Charcot lays stress on the lesion affecting the posterior region of the internal capsule as the essential element, so far as present observation allows of an opinion being formed upon the subject; he regards these fibres, with Meynert, as being centrifugal, serving to transmit sensiti impressions to the posterior region of the hemisphere.

The interpretation of the ocular symptoms, in so far relates to their affecting the entire of one field, and not pr senting the form of hemiopia, depends on the conclusi formed as to the course of the fibres in the chiasma. Accep ing the theory of a semi-decussation, M. Charcot lays dow the thesis that homologous hemiopia implies the direct indirect implication of one optic tract; indirect implicati covering the details of many cases in which the optic thalam is involved, by inferring injury or pressure inflicted on t portion of the tract most nearly related to that ganglio But, with respect to the monocular affection, the *amblyop eroisée* of the cases now under consideration, the suggesti is made that those fibres which do not decussate in the co missure do effect a decussation in a farther part of their cour deeper in the brain, thereby conforming with the type pr sented not only by the decussating fibres of the commissur but by the other cerebral, and indeed also by the spinal nerv The part where this decussation takes place is supposed M. Landolt to lie beyond the corpora geniculata in the posteri part of the thalamus, not far from the corpora quadrigemi (*Le Progrès Médical*, 1875, p. 769).

On this supposition, a lesion of that particular part of t hemisphere may be supposed to produce the crossed amblyop affecting the entire field of the opposite side; and thus t combination presented by *hemianesthésie cérébrale organiq* may be accounted for. It may, however, be added that ho satisfactory soever may be this mode of explaining the ph nomena so far as anatomical details are concerned, a difficul would seem to be opposed by the theory of cerebral represe tation as ordinarily understood, since, so far as the represent tion of any one organ is subservient to its proper function, should suppose it would be the homologous halves of each e which would converge to the perceptive centre, so that t unilateral suppression of conscious sensation as regards t other nerves would have its analogue, so far as vision is co cerned, in the associated segments of the two eyes, rather th in the dissociated halves of the single eye.

Passing to the third element in my case, the hemichore MM. Charcot and Landolt (*Progrès Médical*, 1875) have describ some cases under the title of *hémichorée post-hémiplegique*, which, after the occurrence of an attack of hemipleg peculiar movements have been developed in the affected limb without, however, extending to the muscles of the face. The movements are stated to bear considerable resemblance the rhythmical movement occurring in insular sclerosis, b approximating also to the type of chorea in a certain degr of instability of the affected limbs, when the patient is n performing any voluntary movement. In severe cases t movements may constitute a permanent agitation, in no w differing from the movements of ordinary chorea. Now, this condition, as existing in adults, M. Charcot has fou the form of hemianæsthesia in all its particulars describ above. And thus, from the analogy of clinical details, su ported by the results of post-mortem examination in thr cases, he believes the lesion peculiar to the cases to be o affecting the posterior part of the foot of the corona radiat though he is unable to account for the choreic movemen otherwise than hypothetically.

M. Charcot has also met with the same combination motor derangement in cases of partial atrophy of the brain young children; but here, contrary to what happens in adul sensation may be unaffected.

The case which has suggested these remarks, although pr senting characteristically the form of hemianæsthesia a crossed amblyopia, with choreic movement superadded, y does not accord with the description just given, as regards t character of the movements, which had no resemblance to the of insular sclerosis, and were, indeed, slight in degree, a altogether subordinate to the motor incoördination of chore which constituted the prominent symptom. The face, too, w affected equally with the limbs; and the paresis was prese in only a minor degree, and did not precede the other symptom But M. Charcot goes on to comment on cases of hemichor accompanied or not by hemianæsthesia, and not necessari followed by hemiplegia, to which my case bears a clos resemblance. The disease probably results in these cas from the development of certain neoplasms in the substance the hemisphere, and he regards it as probable that the seat the new formation is the same with that of the lesions me tioned in a former part of this paper. He gives a case of

woman subject for five years to indefinite epileptic crises, and for the same period to permanent choreiform "*tremblement*" in the right upper extremity, augmented by voluntary movement. During the last year hemianæsthesia was superadded, but special sensation has since been nearly regained, and also common sensation, excepting in the choreic arm.

By way of bringing the clinical details nearer to my own case, I may refer to a remark by Trousseau ("Lectures," Syd. Soc., I., p. 402), who, in observing that more or less anæsthesia usually accompanies chorea, and is always greatest on the side most convulsed, refers to a patient affected with chorea who presented also a very marked degree of anæsthesia, and who also stated that she could not see very well with her right eye, adding that the weakness of vision had set in since her first attack of chorea a year previously, and had since undergone no amendment. "This impairment of vision," adds M. Trousseau, "which is probably due to paralysis of the retina, has been pointed out by several authors. Dr. G. Sée records an instance of it which fell under his own observation, but he justly adds that the accident is excessively rare."

Case.—E. F., aged twenty-seven, single, a barmaid. She presents no feature of importance in her previous history, save a liability to headaches and much overwork; nor in the history of her family, with the exception that a brother had "St. Vitus's dance." Eight days before admission she fell down the cellar-steps, but was not seriously hurt nor much frightened; but on the morning of the next day but one she found herself unable to hold her fork at breakfast on account of choreic movement in her right hand. She was sent out for a walk, but soon afterwards her right leg became affected, and she had difficulty in getting home. She continued to get worse. Soon after the accident she lost the sight of her right eye for ten minutes. The same eye has always been liable "to run water," but I can obtain no evidence of any ocular defect.

When admitted she had characteristic unilateral chorea on the right side, with decided paresis of the right upper extremity; she was quite unable to direct her fingers to pick up a pin, and when placed erect could not direct her right leg to make a single forward step; on the contrary, the limb moved in so irregular a manner as nearly to throw her down. When undisturbed she lay nearly without movement, excepting that her forehead was frequently corrugated on *both sides*, and that *both sides* of the mouth were often in movement, illustrating very forcibly the community of movement, in the bilaterally acting muscles, seen in hemichorea. From the same circumstance—the implication of the muscles of both sides in the trunk—it was almost impossible for her to rear herself up in bed, although the limbs on the left side were quite unaffected.(a) She had too a curious trick of constantly screwing up the lids of her right eye, doubtless from discomfort occasioned by the visual defect. When aroused, choreic movement was developed in the upper extremity. She swallowed well, but speech was decidedly affected; she began each sentence very deliberately, but ended it in rapid speech, articulation becoming at the same time thick and hardly intelligible.

There was very decided anæsthesia on the right side: a pin could be thrust deeply into the arm without exciting any but slight sensation; and no blood issued from the puncture. The loss of sensation was less complete in the leg. It was also decided in the region of the fifth nerve, and still more so in the other regions of the scalp on the right side. She, however, discriminated correctly between heat and cold, though the sensation was less distinct than on the other side. Electro-sensibility was similarly low; electro-contractility was normal. The mucous membranes of the right cheek, nostril, and eyeball had very low sensibility to contact. Smell, tested by assafœtida and peppermint, was nearly, if not quite, abolished on the right side, and the vapour of ammonia was felt less sensibly than by the opposite nostril; taste to salt and quinine was much less acute on the right side of the tongue; and hearing, both ordinary and perosseal, tested by the turning-fork, was very dull. Mr. Priestley Smith assisted me in testing vision; as regards acuity the difference between the two was that between $1\frac{1}{2}$ or 2 and $3\frac{1}{4}$ Snellen. There was a very decided peripheral contraction of the field of vision, chiefly laterally on the right side, and an equal contraction in the field for discriminating colours, but her being confined to bed precluded the making of any more exact observation on these points. The fundus oculi was quite normal. She manifested a very marked degree of inertia in doing what she was desired to do for the purposes of examination, and soon became wearied. I have only one record of the comparative temperature of the two sides, the report of a second examination having been mislaid: in that one record there was only a fractional difference. There was no ovarian tenderness; menstruation has been suspended for six months. She has never had a hysterical fit, but during her residence in the hospital the nurse reported on one occasion an attack of excitement with involuntary micturition, inability to speak, and occasional rigidity of limbs; she recovered from the attack very rapidly. At admission there was a large amount of albumen in the urine; there was no œdema. Once or twice it was believed that a faint mitral bruit was audible.

She improved steadily whilst under my notice. The albumen lessened to a trace, and then disappeared. At first some variation in the degree of anæsthesia, both absolutely and relatively, took place. The choreic symptoms had disappeared at the last report I had of her, but the field of vision had not extended, and the special senses on the right side were all very imperfect. Common sensation was nearly restored.

(a) A rather interesting undesigned confirmation of the truth of Dr. Broadbent's theory as exemplified in unilateral chorea is afforded in an article on Chorea by M. Jules Simon, in the *Nouveau Dictionnaire de Médecine et de Chirurgie Pratiques*. The author observes that in hemichorea "the nervous disorders are rarely limited in an exact manner. In these cases, apparently limited, it is easy to observe that the muscles of the face and of the head frequently share in the disorders of the limbs, and that the malady tends to disseminate itself on a larger number of muscles."

ITALIAN HEALTH-RESORTS.

No. II.—San Remo.

San Remo is a place that has wonderfully improved in many ways since its discovery as a health-resort. In 1868, when the writer first visited it, the town itself was much in the same state as it had probably been for the last fifty or a hundred years, although signs of impending change were visible. To the east and west of the town, on the outskirts, two hotels had been recently built, and contained a fair number of English visitors; and there were half

a dozen available villas. One or two shops for English groceries, and a small reading-room, represented the chief provision for the comfort of visitors; and an English church was nearly completed. Since that time progress has been continuous. The municipal authorities have energetically striven to develope the resources of the town and neighbourhood, and the inhabitants have seconded their efforts in a most enlightened manner. Great transformations have been effected in the town, and the main street has been re-paved, levelled, and extended westward, so as to be scarcely recognisable. The external appearance of the multitude of new shops, which now are capable of supplying nearly every want, is far superior to that of the Mentone shops, and even rivals those of Cannes. Instead of two, there are now nine first-class hotels, and a tenth is rapidly being finished, to open in the coming season; while there are from sixty to seventy villas of various sizes, as well as several *pensions*, at the disposal of families or persons disliking hotel life.

San Remo lies about sixteen miles to the east of Mentone, and eleven from Ventimiglia, in 43° 47′ 56″ north latitude, at the foot of an amphitheatre of hills, the highest of which, to the NN.E., the Monte Bignone, has an altitude of very nearly 4000 feet. The hills have a comparatively gentle slope from below upwards, and are clothed with vegetation more or less completely to the summit, the olive being replaced in the higher regions by the pine. San Remo itself is built at the southern end of a ridge which runs almost due north and south. Beginning by a wide base along the seashore at almost equal distances from the promontories on the east and west, the Capo Verde and Capo Nero, which bound the amphitheatre of hills on the south, it gradually contracts as it ascends the hill in a triangular form, the apex of the figure being a church with dome and cupola—the Sanctuary—upon the hill, and the base the harbour and the coast on either side. The houses which form the triangle are densely massed together, and with their various tints of ochre, brown, pink, grey, etc., present a most picturesque appearance when viewed from the shore; and the stranger who climbs up the steep brick-paved streets, or lanes, under arched passages and flying buttresses innumerable, will find many objects of interest in his ascent to repay the toil. The winter visitor finds it difficult to realise the need of such deep shade as he encounters in the old town of San Remo, but there can be no doubt that the summer comfort of the inhabitants is greatly due to their contrivances for excluding the sun.

At the foot of the hill on which the old town is built, a long street, which is the continuation of the Corniche carriage-road, bends round from north-east to west, so as to divide San Remo proper into a northern and a southern district. The former, which is the larger, contains the poorer part of the town, the principal churches, the market-place, the chief shops, and the theatre; while the latter is occupied by a number of detached houses, villas, and gardens, some of the old palatial residences of the Italian nobility; the new boulevard, which runs from the railway station to the sea; and the harbour, with its marine stores, its trees, its fort and mole—the latter curving round through south to west, so as to form a fair protection to the shallow anchoring-ground. The main street, which thus divides San Remo, contains a number of the principal shops, the *cafés*, the post-office, and one or two hotels. The other shops are in one or two streets which run at right angles to it, and in some of the lower streets of the old town to the north. On either side of the old town a valley runs inland, that to the east being the most defined; but on both sides these valleys slope up to the lower hills of the general amphitheatre, and come to an end completely under the shelter of the higher ranges. The entrance to the western valley is to a considerable extent filled in by houses. The low hills which form its western side bend round and form a gentle slope, which runs parallel to, and at a short distance from, the se and is studded with villas embowered in foliage of vario kinds—the olive, however, predominating.

In this part of San Remo the improvement since 1868 is wo derful. The railway station now stands near the shore co nected with the harbour, and with the main road to the latt by a broad boulevard; and in order to conceal the railway itsel which was closely shut in between the sea and the carriag road just to the west of the station, the carriage-road has bee considerably raised, and carefully banked with masonry. C the sea side a broad and excellent pavement has also been la down, separated by palm, eucalyptus, and other trees from t dusty carriage-road, and it has been carried on westward as f as the new public garden, almost opposite the Hôtel Bellevu On this side of the town are some of the best hotels, the Roya Bellevue, Londres, and West-end. The latter, which is to t extreme west, was formerly Lady Kay-Shuttleworth's Vil Ponente. None of them are far enough from the sea to b free from the noise of the waves; and with the exception the last they are fully exposed to the sea-breeze and the S. wind. Built at a short distance up the slope to the north the main road, they have a good sea-view, and they all ha gardens of greater or less extent. Beyond the outskirts the town to the west, the road follows the shore and win gradually round to the eastern side of the promontory of Ca Nero. Before it turns it is intersected by one or two sma valleys or ravines. On the eastern side of San Remo, betwe the old town and the base of the Capo Verde, with its voti church of the Madonna della Guardia, there is a broad space land between the sea and the Corniche road, which is nearly fla On the north side, too, the near hills come down with a muc gentler slope than on the west, so that houses in this part ha the double advantage for an invalid of being some way fro the sea, and of not being perched up so high as to require climb to get to them. On either side of the main road in th part (eastern suburb) there are a number of detached vill and hotels with their gardens. Among the latter may be men tioned the Hôtels de Nice, d'Angleterre, and Victoria, the latt of late years frequented by Germans. A new and fine hote the Mediterranée, will be open next season. Many of th villas in this quarter are of very convenient size. At Mento there has been too great a tendency to build enormous villa which can only be let at exorbitant rents; but their proprieto have suffered in consequence, as only very wealthy people ca afford to take them, and they often remain unoccupied. A San Remo things have as yet been better managed, and the appears to be an increasing demand for small houses.

The road to the east of San Remo is more sheltered than tha on the west, and is planted with plane trees. The pavemen on this side are also excellent, and are being further extende Beyond the outskirts of the town the road runs through oli groves nearly due east at a distance from the sea for about mile, and then turns southwards to skirt the base of the pr montory of the Capo Verde, close to the railway and the se On both sides of San Remo, but especially on the easter there are plenty of pleasant walks in the olive woods to th north, and that without the fatigue of steep ascents; an there are also sheltered spots in which the invalid can wal with safety when the east or south-east wind is blowing Numerous excursions, which it does not enter into the scope this letter to describe, can be made to the village of La Coll to the north-west, to San Romolo (how Romulus would hav smiled at his brother Remus if he had known he was to b made a saint!), Taggia, Ruffini's birthplace, etc.

The cost of living at San Remo is much the same as Mentone and Cannes. Since 1868 prices have risen, as they hav everywhere else. At an hotel the *pension* ranges from ten o eleven to fifteen francs a day per head, according to the positio of the rooms, and wine, fuel, and lights are all extras. Furnishe

villas are let for the season at from 2000 to 10,000 francs and upwards, according to size. In the town, furnished single rooms may be taken for 40 to 100 francs per month, or a suite for 200 to 600 francs, but attendance and board are both extras, and in many cases the meals must be taken at a restaurant, a proceeding quite unsuited to the class of invalids who frequent the town. San Remo has enjoyed a good water-supply since 1828. The market is an excellent one, vegetables, butter, game, and meat being imported from Piedmont and other parts of Italy, while fish is caught at San Remo itself and at Bordighera. There is certainly no deficiency of creature comforts. There are plenty of carriages, and for the healthy who require "*distractions*" in the evening a new theatre has been erected, at which an excellent opera company performed during the past winter.

The climate of San Remo is one of the mildest on the Riviera, and, according to some authorities, while closely resembling that of Mentone, it enjoys an even more equable temperature than the latter. According to the reports published by the Italian Minister of Agriculture, Industry, and Commerce, the mean temperatures from 1866 to 1874 for the four seasons were—winter, 49°; spring, 58°; summer, 73°; autumn, 62° Fahr.

The mean temperatures of the winter months for the years 1865 to 72, inclusive, were as follows:—October, 62°; November, 54·5°; December, 56°; January, 49°; February, 52·5°; March, 54°; April, 59°. According to the late Dr. Dührssen, at Mentone (*Deutsche Med. Wochenschrift*, No. 6, 1876, s. 67), owing to the nearness of its protecting mountains, and to the greater height which they attain in the immediate neighbourhood of the town, the temperature in certain sheltered parts of Mentone is higher on *sunny* days in winter, and still more so in spring, than at San Remo; while, on the other hand, there are spots at the entrance to the Turin and Cabrol Valleys which the wind can reach, which have a colder climate than the best parts of San Remo.

On the whole, however, "The climatic differences between these two winter stations are so trifling that they need scarcely be considered in choosing one of them as a winter residence." With this view, which is also held by other good observers, we are in the main inclined to agree. San Remo is, if anything, more evenly sheltered on the north than Mentone, at any rate, than the west bay, and the prevalence of northerly currents is chiefly indicated by a general depression of temperature, the air being calm. In January, 1869, the temperature was so low for several days that the lemons seriously suffered, and the small streams in the neighbourhood, as we can personally testify, were frozen up. On January 23 the thermometer fell to 26° in the night, and on January 24 there was ice an inch thick in the shade.

The winds from the east and south-east are those which are chiefly felt at San Remo, the former especially being sometimes very rough and unpleasant. In December, 1868, we noted four days of easterly and three of south-easterly wind, and in January, 1869, eight days of easterly and four of north-easterly wind. The latter wind, or Tramontana, blows occasionally in winter with icy coldness, and (although some authorities endeavour to disguise the fact) the Mistral is by no means unknown, as, indeed, the conformation of the hills to the north-west would lead one *à priori* to expect. We ourselves have notes of it on three occasions in January, 1869. According to Dührssen (*loc. cit.*), the Mistral blows with a force which is rare at Mentone; and Schulze states (Die Klimatischen Curorte der Riviera, etc.," 1875) that in February and March, 1875, there were twenty-one days on which it blew with greater or less intensity. The south and south-west winds are often accompanied with rain. The average annual number of rainy days, according to Dr. Onetti ("Le Climat de San Remo," 1876), is from 40 to 50, distributed as follows:—Autumn, 15 to 20; winter, 12 to 15; spring, 10 to 12; summer, 5 to 6. From October to April there are on the average 35 days on which rain falls, while at Mentone, according to Bréa, there are 51. If, however, less rain falls at San Remo than at Mentone, the nature of the soil is such as to retain the moisture longer at the former than the latter. Marly clay is the predominating soil at San Remo near the shore on both sides of the town, while the sand rock on which Mentone stands allows the rain-water to percolate it rapidly. On this point Dr. Dührssen expressed himself (*loc. cit.*) as follows:—"It seems to me improbable that San Remo is, geologically considered, drier than Mentone; for in my numerous walks among the hills at the former place I frequently met with places in which the subsoil consisted of an impervious clay, whereas at Mentone it is generally readily percolable by water, and hence dries up much more quickly after storms than was the case at San Remo." The higher ranges of hills are limestone, and sandstone of various degrees of fineness is also not uncommon. In the tertiary deposits which are met with here and there is found a yellow clay of considerable value to the potter.

The absence of mist and snow is common to nearly the whole of the Riviera, and we need only note that the statement is true of San Remo. The snow, which falls on rare occasions, rapidly melts. The general character of the climate may be judged of by the statement that of 212 days from October 1 to April 30, 83 are on the average clear, 87 partially clouded, and 42 overcast (35 of these being rainy); though, according to Bréa, in the same period at Mentone there are 117 clear days, 28 partially clouded, 16 overcast, and 51 days overcast with rain.

Dr. Onetti gives a favourable report of the sanitary condition of the adult population of San Remo.(a) He states that the average death-rate is 1 in 50, or 20 per 1000, and that not only is phthisis rare among the inhabitants, but that it never assumes the acute form, and usually runs a very protracted course. The infant mortality is large, chiefly from diarrhœa in the hot weather. San Remo has a population of 12,000 people, and in the ten years (from 1864 to 1874) in the four parishes of Saint Siro, Les Anges, Saint Joseph, and Saint Donat de Verezzo, there were 2354 deaths, of which 1030 were in children under seven years, and 219 in people over eighty. Dr. Onetti regards the climate of San Remo as tonic and stimulating, and especially adapted for cases of phthisis of a torpid character, for anæmic and scrofulous cases, for affections of the lungs and heart generally, and for acute and chronic rheumatism. Our personal experience is unfavourable to San Remo as a place for rheumatic subjects, as we suffered from that complaint more or less the whole time we were there. Others, on the contrary, have had their rheumatism improved by a sojourn there. The chief drawbacks to San Remo are the clay soil, and the prevalence of easterly and south-easterly winds. Putting these aside, the indications for it are similar to those for all parts of the Riviera, where warmth in winter, sunlight, and pure air are the objects sought for. The rapid rise into public favour which San Remo has enjoyed, and the energy with which the authorities have exerted themselves to supply the needs of their foreign visitors, are strong arguments in favour of its still further development and success.

(a) It may interest some members of the profession to know that close to the Sanctuary on the hill immediately behind San Remo there is a Leper Hospital of fifty beds, and liberally endowed. We visited it in 1868, when there were about thirty cases of true leprosy in various stages in the wards, among others a young man who had never been further away from San Remo than to Toulon, and whose grandmother, mother, and maternal aunt (mother's sister) had all had the disease, though his father's side was free. This year we were unfortunate enough to call at the Hospital at a time when it was closed to visitors, but the porter informed us that the number of patients was gradually diminishing, and that they never had more than fourteen or eighteen in it now, though cases were admitted even from Nice and the French territory. The largest contingent is furnished by the villages among the mountains.

THE AIR OF CITIES.

Some time ago, Dr. Russell, the Medical Officer of Health for the city of Glasgow, resolved to make a series of investigations into the chemical constitution of the atmospheric air of that city, and received from the Health Committee a small grant for the prosecution of his project. The carrying out of such an undertaking has involved the lapse of considerable time and the exercise of tedious observation; but the results, though in themselves by no means insignificant, are of value principally on account of the indications they afford for the useful prosecution of similar inquiries.

Mr. E. M. Dixon, B.Sc., in co-operation with Dr. Russell, has submitted to the Health Committee of the Magistrates and Council of Glasgow a draft report, showing in a tabulated form the facts which they have collected during the course of their investigations; and he promises to publish a detailed account of the mechanical and chemical processes whereby these results have been obtained. In the meantime, Mr. Dixon thinks it sufficient to say that at each of the selected stations "the air was drawn by aspiration, and continuously for two or three days, in several distinct currents through as many distinct solutions, each of which was adapted to withdraw a special substance from the current of air which passed through it; that the amount of air which passed in each current was measured by a special gas-meter through which that current subsequently passed; and that the amount of the substance which was specially absorbed from each of the air-currents was finally determined by a method sufficiently delicate for the estimation of quantities which would be called traces."

The instrument employed was suggested by a French chemist, and consists of a glass tube with a bulbous end minutely perforated. Glass beads in the solution retard and break up the currents of air, and each current of air is passed through three of these perforated and bead-mounted bulbs. The process is seen to be effectual in retaining atmospheric impurities in solution, by the fact that the third solution invariably remains pure.

The Glasgow investigators made their observations at seven stations so selected as to render probable the detection of various forms of atmospheric impurities. Thus, one was situated under the Broomielaw-bridge, another in the crowded district of the Cowcaddens, another in the more salubrious atmosphere of the New Western Infirmary, and others at points correspondingly diverse. Their tables show the results obtained with regard to (1) carbonic acid, (2) sulphur in combination, (3) chlorine, free and combined, (4) nitrogen in the form of ammonia, and (5) nitrogen in the form of "albuminoid ammonia"; and they are accompanied by a map of Glasgow, showing the position of the selected stations, their topographical relation to density of population, and to the situation of large works from which volumes of smoke and noxious vapours proceed. This arrangement is one of great importance, as is shown by the fact that at one station, situated near a very large factory of that kind, the average amount of chlorine collected during stated periods was at the rate of 0·63, as compared with 0·09 down to 0·05 at other stations; while the amount of sulphur at the same station was at the rate of 0·42 as compared with 0·36 downwards—expressed in milligramme units of the substances in every 100 cubic feet of air.

The tables which deal directly with the presence of qualifying atmospheric ingredients are supplemented by others relating to wind, temperature, and rainfall; and the importance of the last is specially mentioned, and in all future observations will be more rigidly acted upon, both locally and at a distance.

With regard to the observations as far as they have yet been made, two things deserve comment. The first is, that as yet all the air has been collected in the open streets; and when the atmosphere of confined courts, alleys, and slums comes to be analysed, results more startling than pleasant may be anticipated. Again, at the time the report was published no comparative researches had been made regarding the co-existent conditions of the atmospheric air in country districts; but a station is now in operation at Eaglesham, about twelve miles south from Glasgow—a locality which is reported to be so remote from manufacturing and even agricultural industry that air and rain collected there may safely be taken as a sufficiently normal standard for comparison.

The conclusions arrived at by Mr. Dixon and Dr. Russell are:—1. That the general character of the air prevailing in any part of the city can only be ascertained by means of observations carried on continuously for some time under the varying circumstances of weather. 2. That the effect of a fresh breeze of wind in the way of purifying the air of the city is very marked. 3. That the circumstances connected with the fall of rain appear to merit careful examination.

The Glasgow magistrates deserve great credit, not only for respecting the advice of Dr. Russell with regard to these experiments, but for their general devotion to sanitary measures; and their example might well be imitated by other civic rulers. The steady prosecution of air analysis by Mr. Dixon and Dr. Russell is certain to lead to striking results and to supply valuable sanitary suggestions.

THORACENTESIS.

We propose briefly to review some of the points raised at the discussion on thoracentesis at the recent meeting of the British Medical Association. It cannot be denied that from some of the wisest and most experienced physicians present there was a general coincidence of opinion expressed that paracentesis of the chest had in many cases been too lightly and too hastily undertaken. We do not by any means undervalue such "general impressions"—vague though they be—as to the gravity of a therapeutic method, especially coming from the lips of men like Jenner, Fox, and Gairdner. But, in a paper specially devoted to the criticism of thoracentesis, we expected something more instructive than mere statistics of mortality, which practically are all that Dr. Fox has given us.

The outcome of Dr. Fox's paper was that cases of pleurisy without operative interference, taken in the aggregate, fare better than those in which paracentesis is performed. If it be permitted to us to criticise the work of so accomplished a physician, we should say that Dr. Fox would have contributed much more to the elucidation of the question at issue by an analysis of his own cases, setting forth in what ways paracentesis had seemed to prove hurtful, rather than by the elaborate digest of other men's statistics.

In no disease more markedly than in pleurisy is it necessary, in comparing the results of operative interference, to have full details not only as to the assumed co-existence of tubercle, but as to the actual condition of the patient when the operation was done, as to how it was done, and, above all, as to whether precautions were taken to insure complete evacuation. The first of Dr. Fox's tables, giving the mortality of all cases of pleurisy treated without operation in different hospitals, appears to us almost valueless. To compare this table, giving numbers which range from 1·6 per cent. to 23 per cent., with Table III., showing results after paracentesis, in which the numbers range from 8 to 52 per cent., appears to us unfair for the following reasons:—In Table I. there is every reason to believe that many of the cases were mild *ab initio*, whilst in the practice of English physicians, at all events, cases treated by paracentesis may be set down as presumably severe from one cause or other. Again, it is well known that in hospital practice many cases of pleurisy are discharged either with still some fluid in the pleura, or with damaged lung. These cases are lost sight of—their subsequent life-history is

not traced. They may reappear as chronic pneumonia, as tuberculosis, or as cirrhosis of lung; but the point is that they do not swell the mortality-list of *untreated pleurisy*. Now, with cases of pleurisy treated by paracentesis, let it be noted that after an operation has been performed the case is kept under more protracted observation. The curiosity of the physician is roused to trace the case to its end, and the result of treatment is more carefully recorded. Whatever the accompanying conditions, whatever the diathesis of the patient—whether the operation is performed *in extremis* or not,—if fatal from any cause, the case goes to swell the dire column of mortality after paracentesis. We decline to compare the results of interference and non-interference in cases of pleurisy unless we have the subsequent histories of both sets of patients side by side up to the post-mortem conditions found; for in that way only can we really compare any given set of similar cases.

We cannot admit that we have received anything of practical value from these statistics, except that in tapping for serous pleurisy there is a danger of purulent transformation. This is a valid objection, with the *caveat* that, in children especially, in a vast number of cases, purulent transformation occurs without tapping. But we presume that in the practice of most English medical men it is not usual to tap for serous effusion except in cases of considerable dyspnœa or of retarded absorption. In the first of these conditions Dr. Fox admits that paracentesis is justifiable, in spite of the danger of purulent transformation. With regard to the second of these conditions, we beg to draw attention to an empirical fact stated in the discussion—viz., that the removal of an exceedingly small quantity of serum had been in some cases followed by the starting of absorption. In aspiration for serous pleurisy, far more than for empyema, it has appeared to us important to prevent the admission of air, and, as Dr. Silver pointed out, to look well to our instruments being antiseptic.

With respect to empyema, Dr. Fox observes that "a spontaneous external perforation is a much less dangerous and fatal event than an artificial opening."

We had supposed that the most favourable mode of spontaneous evacuation was through the lung. But setting this question aside, let us ask, What is the outcome of Dr. Fox's conclusions with regard to the treatment of empyema? When in a given case the existence of purulent effusion has been established, is the practitioner to fold his arms, and in calm "expectancy" await the spontaneous opening of the empyema? Dr. Fox at the outset admits that operation is not to be withheld "if there is grave dyspnœa, threatened failure of cardiac action, hectic, or signs of purulent infection." In other words, wait till your patient is *in extremis*, then perform the operation, and let the case swell the statistics showing the extremely fatal results of paracentesis.

We venture to believe that in this as in other cases of internal suppuration, when once we have established the existence of pus we place the patient in the greatest safety then possible to him by removing the pus, and preventing its re-accumulation.

Dr. Allbutt's paper was a more hopeful, and, as we believe, a more practical discussion of the question of thoracentesis. It was of importance as setting forth the preference in the treatment of empyema, which now obtains in many quarters, for free incision under antiseptic precautions as compared with aspiration.

It is important to note that whilst Dr. Lee on theoretical grounds proposed the use of what might be styled "continuous aspiration," with a view to promote the expansion of the lung on the affected side; Dr. Gairdner, on the other hand, laid stress on the use of the minimum amount of force in withdrawing fluid from the pleura, with a view to avoid rupture of the lung.

One of the most important points raised with respect to prognosis was that mentioned by the President—viz., the age of the patient.

It is quite certain that the results of repeated aspiration, and indeed of thoracentesis generally, in children are much better than in adults. The reason of this is doubtless that hinted at by Sir William Jenner—viz., that the chest-walls in advanced life become rigid and cannot retract. In children, on the other hand, so great is the mobility of the thoracic walls that when the fluid has been removed the side of the chest contracts, adhesion between the two pleural surfaces occurs, and then re-expansion of the lung with restoration of the chest to its normal shape ensues.

Very little was said about washing out the pleural cavity. One reason for this appeared to us to be the evidence of preference for *double openings* by the majority of those who recommended free drainage. There can, we think, be no doubt that this method in a vast proportion of cases dispenses with the necessity for syringing out the chest, with its attendant risks.

The last word has not yet been spoken on thoracentesis. To quote the judicious sentence of Dr. Allbutt—"No method can make a vast internal abscess of the chest anything but a terrible malady." Seeing, however, some of the brilliant results which have been obtained, and not ignoring the failures (of which we desire a more complete account), we confidently look forward to the perfection of operative methods which shall give incomparably better results than the expectant and antiphlogistic treatment of our forefathers.

THE WEEK.

TOPICS OF THE DAY.

Considering its importance as one of the great centres of education, it is satisfactory to learn that, at a recent meeting of the Town and University Improvement Commissioners of Cambridge, the chairman was enabled to draw attention to the satisfactory state of the health of the borough. According to the death-rate of several towns with a population equal to, or exceeding, the population of Cambridge, compiled from a return made in May last at the second annual conference on the "Health and Sewage of Towns," published by the Society of Arts, it would be seen that Cambridge was one of those exhibiting the lowest death-rate. It was considered desirable that this important information should be made known to the public, together with the fact that the Improvement Board would not, on this account, relax their exertions. Dr. Anningson, upon being reappointed to the post of Medical Officer of Health, said he was sorry that the Board, from circumstances over which it had no control, had not been able to do more for the public health; at the same time he must observe that the Commissioners had taken a deep interest in the welfare of the town, and had always shown an anxiety to carry out any undertaking of importance which tended to improve the health of the borough.

At a meeting of the Portsmouth Town Council, held last week, the Mayor read a letter intimating that the British Medical Association would accept an invitation from the Mayor and Corporation and the local members of the Association to visit Portsmouth in August, 1878. The matter was ordered to be referred to a committee, as the visit would cost the town £400.

An alarming statement of the great increase of drunkenness in Yorkshire was recently made public at the annual Brewster Sessions for the Staincross Division of the West Riding Constabulary. Mr. Superintendent Sykes called the attention of the magistrates to the distressing fact that during the past year 1040 persons had been proceeded against for drunkenness, whereas in the previous year the number was only 884. He further reported that drunkenness amongst the wives of work-

ing-men had seriously increased during the past two years, owing to the facilities afforded for purchasing intoxicating liquors under the guise of "groceries." It was stated that the Bench disallowed every possible application by grocers for licences to sell wines and spirits.

At the usual monthly meeting of the East Moulsey Local Board, held last week, it was stated that in a case of suicide, Mr. William Carter, the Coroner for East Surrey, had delayed the holding of an inquest for six days, the body becoming during that long interval in a state highly dangerous to the health of those living in the same cottage with it. A representation had been made to the Home Secretary on the subject, to whom also Mr. Carter had written the following letter of explanation:—"Sir,—I much regret the Home Secretary should be troubled with the complaint of the Rev. Mr. Reynolds. The delay complained of was quite unavoidable on my part, in consequence of the number of cases I had fixed before receiving the official information of this death—nine in number; some at St. Thomas's Hospital, the authorities and relations of the persons wishing the cases disposed of in consequence of the extreme heat. Some were cases of drowning; the persons, having been in the water many days (eight to ten), were in a terrible state of decomposition. I had upwards of twenty cases last week, and others I had to forward to my colleague, that there should not be any unnecessary delay. Some of mine were far apart. I did all I possibly could to take them. My last case last night was six o'clock; so that I did not get home till just before nine, having first gone a distance of twenty-two miles out. Hoping this will be satisfactory, I am, Sir, yours obediently, Wm. Carter." After considerable discussion, the Board resolved to instruct their clerk to write to Mr. Carter, informing him that his letter to the Home Secretary had been sent to them, and that they did not consider his excuse at all satisfactory. This decision of the East Moulsey Board is scarcely fair to Mr. Carter when the abnormal pressure upon his time is dispassionately considered.

The Stafford House Committee for affording relief to the wounded Turks report that urgent appeals have been received from their commissioner, Mr. Barrington Kennett, for further assistance for the constantly increasing number of wounded requiring treatment, owing to the continued desperate fighting in Bulgaria. They have, in consequence, resolved to despatch at once five more surgeons and ten dressers to the seat of the war, making up the staff of surgeons maintained by the Committee to twenty-one, with ten dressers; at the same time it must not be forgotten that the Committee assist with stores the ten surgeons sent out by Lord Blantyre and others.

In accordance with his promise, Sir Joseph Bazalgette, C.E., has presented his full report on the drainage of Bournemouth to the Improvement Commissioners of that town. The objections to his scheme, which had been stated to the Local Government Board by Mr. Thornhill Harrison, one of their inspectors, is carefully dealt with, and Sir Joseph still expresses his decided opinion that there should be but one outfall for the drainage, namely, at Boscombe, the eastern suburb of Bournemouth. At present the outfall is at a short distance beyond the head of the pier, which is a principal place of attraction for visitors, including bathers from the beach, and yachtsmen whose vessels lie alongside the pier. The drainage of Bournemouth, according to the report, would never be satisfactory unless the whole of it were taken to Boscombe, and there discharged. In the course of a discussion which followed the reading of the report, it was stated that Sir Joseph Bazalgette estimated the cost of carrying out his scheme at £44,000, including £14,000 for an esplanade along the beach.

A short time ago, Dr. Littlejohn, Medical Officer of Health for Edinburgh, received information of a serious outbreak of typhoid fever at Coltbridge and other districts in the west end of the city, which it was believed had been caused by means of milk sold at a dairy in which a person was suffering from the fever. The district in which the outbreak first occurred is beyond the municipal boundaries, but Dr. Littlejohn lost no time in moving in the matter, the patient being removed to the infirmary. At the same time he communicated with the sanitary inspector for the district, with a view to steps being taken to have the surroundings of the dairy in question improved. The retailers of milk in Edinburgh who received their supplies from this dairy have been advised to discontinue their orders for the present, and this recommendation has been acted on. At present over twenty families in the district are suffering from the fever, several of the cases having terminated fatally. Dr. Littlejohn is carefully watching the progress of the epidemic, and taking all the necessary precautions to prevent its spread.

The attention of the Metropolitan Board of Works should surely be called to the following case. At an inquest held last week before Dr. Thomas, at Marylebone, on the body of a child two years and a half old, who died at 21, Nightingale-street, Lisson-grove, apparently from natural causes, Dr. Rugg, of 1, Grove-road, called attention to the disgraceful condition of the houses in the street. The deceased child which he was called to see, weighed, he said, only fourteen pounds, whereas it ought to have weighed at least thirty pounds. He did not wonder at children wasting and dying in such wretched rooms and dwellings as were to be found in Nightingale-street. The condition of the houses generally was very bad; the sanitary inspectors seemed to be afraid of going into these back streets. A juror said that these places would not be rooted out until there was a house-to-house sanitary inspection set on foot.

At the last meeting of the Lewisham Board of Works, the analyst reported that a large quantity of treacle, which had become accidentally poisoned with arsenic, had found its way into the market, and was being extensively sold. Two families had, it was stated, already been poisoned with the noxious compound, and the analyst advised the Board to have samples taken from every seller in the neighbourhood. The clerk told the Board that this would necessitate the purchase of at least a hundred samples; it was therefore resolved to take two samples from each parish for the purpose of immediate analysis. If the danger is likely to be so wide-spread, more effectual measures ought to be resorted to without delay.

It is stated that the Lord Mayor has declined to allow himself to be nominated for the vacant post of Treasurer to St. Thomas's Hospital, his official and other engagements not allowing him the time requisite for the discharge of the onerous duties appertaining to such a responsible post.

THE INDICATIONS FOR DRAINAGE OF THE KNEE-JOINT.

Dr. J. Scriba, Assistant in the Surgical Clinic at Freiburg (Baden), recommends drainage of the knee-joint, instead of excision, in the following cases:—1. In acute serous inflammation, in the rare event of there being abnormal pain of sufficient severity to affect the patient's general health. 2. In acute purulent inflammation of the joint, as soon as there is distinct fluctuation; in the rare cases of osteomyelitis involving one or both epiphyses; in the purulent inflammation which may complicate pyæmia, pneumonia, acute infectious diseases, and phlegmonous erysipelas of the lower extremities. 3. In chronic serous inflammation of the joint. 4. In fungous inflammation—(*a*) where the fluid secretion in the joint exceeds the fungous granulation in amount, and where the cartilage is still intact; (*b*) where there is excess of fungous granulation, but where caries is still absent. The presence of caries is a contra-indication for drainage, and an indication for excision. Scriba lays down the following maxim in opposition to those British surgeons who counsel very early excision:—"The earlier a chronic fungous inflam-

mation of the joint comes under treatment, the better hope is there of giving the patient a useful, movable knee-joint by means of drainage." It should be stated that Scriba only speaks of drainage applied to a joint *which is opened at the moment the tube is inserted*, and not to one in which there is a previous wound, either surgical or accidental, of some standing. The operation, as performed by Scriba, is briefly as follows:—An incision, two to three centimetres long, is made on either side of the patella down to the joint, and a thick drainage-tube inserted. If the bursa under the extensor muscles communicates with the joint, as is the rule, no further incision is needed. In the rare case in which it is isolated, an incision is made down through the quadriceps femoris, and a short tube inserted. The operation must be carried out *with the strictest antiseptic precautions*. Before the drainage-tube is introduced the joint is swabbed with a soft sponge; in acute cases using a 5 per cent. solution of carbolic acid; in chronic cases, or where there is fetidity, a 12 per cent. solution of zinc chloride. The tube is then put in, and the joint washed out through it with carbolic acid (2½ to 5 per cent.) until the solution returns quite clear. During the injection the joint must be gently kneaded with the hand. In acute inflammation the tube must be removed as soon as possible. The greater part may be taken out after the third or fourth dressing if the wound is perfectly sweet, and the remainder on the tenth to fourteenth day. If the secretion does not quickly diminish, the joint must be washed out again with carbolic acid, and the drainage somewhat prolonged; but the whole tube must never be left in after the tenth to twelfth day, for fear of irritating the cartilage on which it lies. In chronic cases, or where fungosity is present, the tube must be allowed to lie across the cavity of the joint for twenty to thirty days, in order to stimulate the lining membrane.

THE PLAGUE.

At a recent meeting of the Paris Academy of Sciences an important communication on the subject of the plague was read by Dr. Tholozan, of Teheran, the well-known physician of the Shah of Persia. After a lull of about six months, he states, this disease reappeared at Bagdad in February of this year. Its ascending and genuinely epidemic progress dates only from the month of March, and at the end of April the deaths were about fifty per day. The epidemic of this year has been shorter than that of 1876; the mortality has been much less, and its spread beyond the capital has been almost *nil*. For four successive years plague has shown itself as an epidemic in Mesopotamia in April and May, so that its existence as an endemo-epidemic in that country is now an established fact. The malady has resisted all attempts of local quarantine and disinfection. The fruitless application of these prophylactic measures does not prove their uselessness; it only shows that public hygiene leaves much to be desired in the East. But, on the other hand, it must be admitted that the plague, like cholera, diphtheria, and typhoid fever, may assume at certain seasons, and in certain circumstances, an epidemic development, the real causes of which science is at present unable to determine, and the progress of which cannot be arrested. Dr. Tholozan further communicated some fresh facts bearing on this subject. In the village of Sharoud, twenty-five leagues from the south-east corner of the Caspian Sea, in a climate cold in winter and temperate in summer, a most extraordinary disease broke out in December, 1876. Inflammatory swellings occurred in the groin, the armpits, and lastly in the ear; they were accompanied by intense fever, headache, and mental derangement. Death followed on the second or fourth day. The malady lasted about a month, and disappeared at the end of the following January. It is to be remarked that no one in the locality had made the pilgrimage to Mesopotamia for more than two years. Another epidemic of a similar kind was observed at Resht, the capital of the province of Guilan, at the beginning of the month of March. Resht is situated in the midst of a marshy forest, some leagues from the Caspian Sea. It is surrounded by streams and large mulberry plantations. All investigations have been useless at Resht, as at Sharoud, to discover any relation whatever between this plague, which Dr. Tholozan believes to be of Persian origin, and that of Mesopotamia, which is evidently of Turkish origin. The first cases of plague occurred at Resht at a time when the disease was scarcely developed at Bagdad; moreover, neither pilgrims nor caravans from Mesopotamia had arrived at Resht. Dr. Tholozan believes, therefore, that it must be admitted that there were in Persia, in the beginning of 1877, two centres of origin of bubonic plague—the one almost insignificant, and confined to one spot; the other extending over a town of 20,000 inhabitants, and threatening to invade the whole of Guilan, and perhaps other parts of the kingdom.

THE RECENT MEDICAL APPOINTMENT BY THE NORTH DUBLIN UNION BOARD OF GUARDIANS.

In the *Medical Times and Gazette* for September 1 we commented on the recent election of a medical officer to the North Dublin Union Workhouse. Dr. William Stoker, who was defeated by a majority of one vote in the final round of voting, has since petitioned the Local Government Board for Ireland to declare him legally elected, or, at all events, to order a new election, on the grounds (1) that in the first and second pollings he had a majority of the votes of the guardians present, and (2) that one of the guardians who voted for Dr. Kenny was not qualified to do so, he being a bankrupt at the time. To this appeal the Local Government Board have replied that they have been in communication with the guardians on the subject, and have ascertained through their inspector, Mr. O'Brien, the precise manner in which the voting was conducted at the election. The Board are of opinion that the final poll, when each guardian simply recorded one vote, is the only one that can be recognised as determining the question, and Dr. Kenny on that poll appears to have obtained a majority of one vote. As regards the second objection, the Local Government Board have been advised by counsel that the fact of bankruptcy may or may not be a disqualification, according to the precise circumstances of the case. In any event, the 30th section of the Irish Poor Relief Act (1 and 2 Vic., cap. 56) provides that no defect in the qualification, election, or appointment of any person acting as a guardian at the board of guardians shall vitiate or make void any proceedings of such board in which he may have taken part. Under these circumstances the Local Government Board see no reason for setting aside Dr. Kenny's election. The Local Government Board also wrote to the Board of Guardians approving of Dr. Kenny's appointment.

CEREBRAL THERMOMETRY.

M. Broca communicated to the Association Française pour l'Avancement des Sciences, which was sitting at Le Havre towards the end of last month, an interesting paper on the above subject. We are indebted to our contemporary *Le Progrès Médical*, No. 36, for the following details. M. Broca believes that thermometry will become a valuable aid in the diagnosis of brain disease. He uses very delicate thermometers, and, after applying them to corresponding positions on the two sides, covers with wool the part of the bulb which is not in contact with the skull, in order to guard against any thermic influence which the surrounding air might exercise. M. Broca has usually employed six thermometers, which were placed in sets of three pairs on corresponding parts of the skull. The anterior pair were placed directly behind the orbital apophyses, the middle pair above the ear, and the posterior pair in the occipital region. His first care was, of

course, to obtain the average temperature, and to this end he tested the temperature of his *internes* and dressers at the hospital. He found that the maximum temperature of the brain was 34·85° C., and the minimum 32·80° C., the *mean* temperature therefore being 33·82° C. But, further, he found that the thermometers on the *left* side invariably marked a *higher* temperature than those on the *right* side. Thus, on the right side the mean temperature was 33·90°, while on the left side it was a little over 34°. This difference was found to average about one-tenth of a degree; *but this difference is only found when and so long as the brain is at rest.* When the brain is active the equilibrium tends to establish itself, and the temperature figures correspond. M. Broca argues that the left hemisphere is more freely supplied with blood than the right, and that the latter, less prepared and less apt, when brain-work has to be done, requires a larger supply of blood than the left, and hence the temperature on the two sides becomes equalised. Further, M. Broca has found that not only on the two sides of the brain is there a difference, but that this extends to different lobes of the same side; thus he has shown that the temperature of the occipital lobe was only 32·92° C., that of the temporal lobe was 33·72° C., and of the frontal lobe 35·28° C., which is accounted for by the greater functional activity of the latter. Then when the brain is actually working there is a rise of temperature; thus, after reading aloud for ten minutes a rise of about *one half of a degree* can be shown. The clinical bearings of these observations are not less important. M. Broca considers that the thermometer supplies an additional and an important sign of cerebral embolism; he can even diagnose the part of the brain which is deprived of its blood. As the result of his observations, it appears that at the level of an embolism there is a decrease in the temperature. The subject is necessarily in its infancy at present, but with the aid and example of such an authority on matters craniological as M. Broca, we shall hope shortly to be in a position to publish more extensive details.

ROYAL COLLEGE OF SURGEONS.

During the past week, 378 candidates for the diplomas of Fellowship and Membership of this institution have been undergoing their preliminary or Arts examinations by the College of Preceptors at Burlington House. Of this number 112 were for the Fellowship, and 266 for the Membership of the College. The library and museum, which, with the College generally, are now undergoing cleaning, repairing, and painting, will be re-opened on Monday, October 1, when the annual registration of gentlemen pursuing their studies at the metropolitan hospitals will be commenced. The primary and pass examinations for the diplomas of Fellowship and Membership will take place in November.

THE HEALTH OF THE HOLBORN DISTRICT.

Dr. Septimus Gibbon, the Medical Officer of Health for the Holborn District, has recently published his annual report for the year 1876. Dr. Gibbon wishes to acknowledge the courtesy and public spirit of the medical practitioners and registrars of the district, through the kindness of whom most of the cases and deaths arising from epidemic and preventable diseases are brought to notice, though the Registrar-General refuses to supply the registered particulars of deaths. The births of the district show an increase of 4·8 per cent. on the previous year, but a decrease of 35 in the whole on the average number for the previous ten years; and the birth-rate is only 28·2 per 1000, as compared with 36·5 for the whole metropolis. This apparent lowness is attributable, Dr. Gibbon thinks, to the fact that many births among the Irish and Italians of the district escape registration, more especially as, during the recent epidemic of small-pox, evidence was afforded him of six children not having been registered. There was a marked decrease in the death-rate for the year under notice; the lowest number of deaths being furnished by the west portion, and the highest by the east portion of the district. The deaths from violence had decreased, and Dr. Gibbon expresses a hope that, now the playgrounds of the Board schools are to be opened and made available for all the children of the surrounding neighbourhoods, the number of children whose lives are annually sacrificed in the streets will be still further decreased. Torrens' Act has been applied in the past year to seven places, and the list of sanitary improvements carried out shows that even in Central London at the present time there are places where the elementary want of a supply of domestic water to houses has to be ordered under the authority of Act of Parliament. Dr. Gibbon records in this report the fact that a mortuary has at length been provided for the district, to which dead bodies are now removed, in most cases, from rooms inhabited by the living.

THE EPIDERMIS OF THE GENITO-CRURAL FOLD AND ITS VICINITY AS A BREEDING-PLACE FOR THE OXYURIS VERMICULARIS.

Under the above title, Dr. Michelson, of Königsberg (*Berl. Klin. Wochenschrift*, No. 33, 1877), describes the case of a healthy boy of thirteen, who was brought to him with eczema of the scrotum and the neighbouring parts of the thighs, and in which he found numerous eggs of the *Oxyuris vermicularis* embedded in the affected epidermis. The perineal region, and the back and lower part of the scrotum were free. The itching was so severe as to prevent sleep. The question was, from whence had come the female oxyurids which had laid the eggs? On inquiry, the boy stated that he had suffered from rectal worms as long as he could remember; but as the oxyuris requires a skin covered with some glutinous material for it to travel on, and quickly dies on a dry epidermis, it was unlikely that the worms had crawled directly to the affected part along the perineum. It seemed most probable that they were carried on some fæcal matter which adhered to the boy's shirt, the front border of which he had a trick of tucking back between his legs. An attempt was made by means of warm compresses to see whether the ova could be brought to maturity in this position, as Leuckart asserts that the embryocs require the action of gastric juice in order to set them free. The experiment failed. The eczema was cured in a few days by warm baths, and a powder of one part salicylic acid and five parts starch.

NATIONAL MEDICAL CONGRESS.

The fifth of these meetings is being held at Geneva from September 9 to 15. Among the subjects of interest under discussion are—"An International Pharmacopœia," introduced by Dr. Gille, of Brussels; "Artificial Bloodlessness," by Professor Esmarch; "The Effect of Wounds on Pregnancy," by Professor Verneuil; "The Artificial Nourishment of Very Young Children," by Dr. Zweifel; "The Effect of Alcoholism on Mental Diseases," by Dr. Magnan; "The Localisation of Functions in the Brain," by Dr. Broadbent; "The Etiology and Prophylaxis of Myopia," by Dr. Haltenhoff," etc. There is also an exhibition of new medical and scientific instruments. Professor Prévost is the General Secretary.

DECREASE OF ZYMOTIC DISEASE IN SOUTHWARK.

The annual report of Dr. Bianchi, Medical Officer of Health for Southwark, is principally noticeable from the fact that it records a large diminution of deaths from the class of zymotic diseases. But Dr. Bianchi thinks a great deal more might still be done in this direction if medical officers received more assistance from the public. As the law now stands, a case of infectious disease is only brought to the knowledge of the medical officer of health circuitously, or perhaps not at all, and he therefore follows in the steps of a large number of the profession to whom the health of the public is entrusted all over

the kingdom, in suggesting that legislation should compel the householder in whose residence an infectious case occurs, to make known the same to the medical officer of health for the district as soon as he receives notice of the same from the medical attendant in charge of the case. An ample and extended experience shows that Parliament is not easily moved to inaugurate sanitary reforms, but repeated representation on this subject must eventually bear fruit; and in this hope we persistently continue to record the opinions of medical officers of health from different parts of the country, all bearing on the necessity for legislation to strengthen their hands in this matter.

THE DUBLIN ARTISANS' DWELLINGS COMPANY.

The half-yearly meeting of this Company was held at the offices, Nassau-street, Dublin, on Monday, September 10. Sir Arthur E. Guinness, Bart., M.P., presided. The chairman, in moving the adoption of the report, said he believed far more in improving the condition of the working-classes by giving them suitable dwellings, than by the most stringent legislation. The Company had already built or contracted for 186 tenements at an average cost of £116 10s. each. They were building on three sites—in Buckingham-street, Echlin-street, and Dominick-street. The Board of Directors had for some time declined offers of other building sites because the Corporation, since the passing of the Artisans' Dwellings Act, had obtained a provisional order for the purchase of several sites in the city, and the directors looked forward to obtaining some of those sites from the Corporation. Those which they particularly desired to obtain were the Coombe, on which they contemplated building 195 tenements at a cost of £23,400, and Boyne-street, where they intended building 114 tenements at a cost of £12,980. The report was adopted, and a warm vote of thanks was passed to Sir Arthur Guinness. We understand that the tenements built by the Company are being constructed on the most modern and improved sanitary principles.

ST. BARTHOLOMEW'S HOSPITAL.

We are requested to draw attention to the fact that no fees are now required for House-Physiciancies or House-Surgeoncies at St. Bartholomew's Hospital. This appears to be not generally known; but in the Handbook to the Hospital and College it is stated that each of the four House-Physicians and four House-Surgeons is provided with rooms by the Hospital authorities, and receives a salary of £25; and that "no fees for these offices are now required."

Composition of Quack Medicines.—This is not a secret with regard to most of these, thousands of analyses by competent chemists having supplied revelations that would fill volumes. This is, however, of no avail, for neither the chemists nor governments are disposed to incur the expenses which would be required to make known the deceptions of these widely advertised compounds. Richter states that among 938 secret remedies analysed by him, he found (1) 22 per cent. contained substances of violent or poisonous action: and (2) 25 per cent. which, although less active, yet were possessed of medicinal power; while (3) 52 per cent. were of no importance, or quite inoffensive. The first category especially comprises violent and poisonous agents for the skin and hair; opiates for children, capable of inducing chronic cerebral disease or even death; "purifiers of the blood," composed of arsenic or mercury; and a whole legion of violent purgatives capable of doing in inappropriate cases an immense amount of mischief. The third category comprises preparations which have nothing in common with the noxious and poisonous effects produced by those of the first and second, but yet agree with them in being sold at from five to a hundred times their proper value, and thus constituting robberies. All these attacks on the public health and morals take place with the full cognizance of the public authorities.—*Lyon Méd.*, Sept. 2.

ON NERVE-STRETCHING AS A SURGICAL OPERATION.

There are few subjects in surgery of greater importance than the one now under consideration. Nerve-stretching is not new as a proceeding, but its application as a surgical operation only dates as recently as 1872. Dr. Paul Vogt,(a) Professor of Surgery in the University of Greifswald, has the merit of writing the first systematic book on the subject, and it is our intention to give a short summary of what it contains.

It is divided into five chapters. The first gives some physiological and anatomical researches on the effect of nerve-stretching under normal circumstances. The second treats of the effect of nerve-stretching under pathological conditions. Chapter III. collects all the cases which have hitherto been published, with the clinical results. Chapter IV. enters into the indications for the operation; while the last chapter summarises the topographical anatomy, and shows the points at which the chief nerves may best be exposed and got at.

I. Physiological and anatomical experiments on the action of nerve-stretching under *normal conditions*:—Though numberless experiments on the action of the most varied physical and chemical agents on the function of the nerves have been made, yet that of stretching has been almost left out of consideration; and this is the more strange because very various degrees of, and alterations in, the tension of nerves must occur during the constant changes of position which the body assumes within the normal limits. The first experiments were made by Harless and Haber (1858), but it was Valentin who, in 1864, published the first detailed researches on this subject. He arrived at the following conclusions:—

1. Stretching lengthens the primitive fasciculi, and decreases their calibre, and the nerve-sheaths press upon the medullary substance. Electric excitability is not much interfered with, provided the stretching be not too considerable.

2. If the stretching has not been carried too far, a nerve will quickly recover itself. The time required for recovery is in direct ratio to the weight applied, and the length of time during which it was applied. If the stretching has been carried to such a point that no further excitability can be produced, it may nevertheless recover perfectly after a sufficient period of rest.

3. The microscopic examination of nerves which have been stretched to their uttermost, fails, as a rule, to discover anything abnormal, except that the medullary substance seems in places to be separated from the nerve-sheath, just where rupture of the sheath seemed to be commencing.

4. The electro-motor qualities of the medullary substance become changed under the influence of powerful mechanical action. Tutschek's and Conrad's experiments have since confirmed Valentin's; and it may therefore be laid down that "the excitability of a nerve-trunk, and the reflex excitability in the parts supplied by it, are lowered by any prolonged stretching." The manner in which this change is brought about does not appear, but it is in one of three ways—the stretching either acts on the nerve as a conductor, or on the central organ, or on the terminal organ. As regards the first of these three ways: The median nerve of a male subject, 50 centimetres long, extending from the wrist to the axilla, is fixed at one end, while to the other a weight is attached; 3 kilogrammes suffice to increase its length by 2 centimetres, and an increase in length of 3 centimetres can only be obtained by the greatest amount of stretching that can be applied by the hand. After several weightings with 2 or 3 kilogrammes, the nerve retracted again to its normal length; and after repeated and long-continued trials, a permanent lengthening of 0·2 centimetres only was obtained. The elasticity decreases from the central towards the peripheral extremity. Again, if an amputation of the thigh of a dead body be made, so that everything is divided except the sciatic nerve, and if the leg, weighted with 30 kilogrammes, be allowed to hang supported only by the nerve, the distance between the upper and lower cut sufaces will increase to 10 centimetres. This, however, is not all to be put down to the elasticity of the nerve, but rather to the rupture of some of its attachments to the muscles of the leg. If the lower extremity of a dead body

(a) "Die Nerven-Dehnung, als Operation in der chirurgischen Praxis." Leipzig: Vogel. 1877. Pp. 80.

be forcibly flexed on the abdomen with the leg extended, it is impossible to produce any extension of the peroneal nerve, previously exposed, behind the head of the fibula; neither can any extension of the sciatic be produced under similar circumstances. If any great force be used, there is rupture rather than yielding of the nerve. The same applies to the upper extremity. The head being turned towards the left, the right arm extended and abducted, with the forearm and hand extended, it is impossible to produce any stretching in either the median nerve or in the brachial plexus. Hence we are to conclude "that the nerve is only elastic and stretchable within certain limits. The limits of the normal elasticity correspond with the physiological limits of the motions of the human body. Any attempts to stretch nerves beyond these limits are followed by rupture in their continuity." Thus, in replying to the first question, whether the mechanical action of nerve-stretching acts on the conducting power of a nerve, we are bound to conclude that as we cannot get beyond the physiological limit of nerve-elasticity without loss of continuity in the nerve, so we cannot alter the conducting power of a nerve within those limits.

Then, as regards the second point—the effects of nerve-stretching on the central organ,—the less elastic a nerve is, the more likely will stretching it be to act on its points of attachment. In order to test this, the sciatic nerve of a full-grown goat was laid bare between the tuber ischii and the trochanter, and then its attachment to the spinal cord was also laid bare. The nerve-trunk was then seized by the finger, and strong traction was made, but not the slightest participation of the stretching could be appreciated at its junction with the spinal cord—not even when a traction was made which finally resulted in rupture of the nerve-trunk. Other and similar experiments were made, and as the result it may be laid down "that in the simple laying bare and stretching of a spinal nerve the traction is not conveyed to the central organ."

We now come to the last proposition: the effect of nerve-stretching on the peripheral terminal organ. If a small opening, three centimetres square, be made on the flexor surface of the forearm just above the wrist, so as to expose the median nerve; and then, with the arm hanging down by the side, if the brachial plexus be laid bare, and traction exercised on the median nerve, the latter will be seen at the opening to undergo considerable displacement outwards. The same can be stated of both the radial and ulnar nerves on making suitable openings over each. Hence, then, the centripetal stretching of a nerve-stem is conveyed to its peripheral termination, and may thus act on the parts which it supplies.

It only now remains to point out in what this alteration consists. It may be summed up as follows:—The stretching of a nerve-trunk is followed chiefly by a displacement and loosening of its attachments within its surroundings, both in a central and peripheral direction, and by a simultaneous stretching and displacement of the bloodvessels running within the nerve-sheath. This latter effect, as seen in the injected nerves, is indicated by the tortuosity and marked dilatation of the vessels supplying the nerves, while an altered condition of the vessels within the nerve-trunk does not seem to take place. Further, these changes may be observed immediately after the operation, and also for some considerable time subsequently to it. The effect thus produced, then, may be called Neurolysis and Neurokinesis, instead of neurotony, which means simply nerve-stretching.

Thus, if the activity of a nerve, according to the experiments of Harless, depend on the pressure exercised by its sheath, it must necessarily follow that a change in the function will temporarily follow on the stretching and the displacement which has been shown to take place. And, further, if we are to suppose that the activity is also dependent on the nutrition of a nerve, then the conditions of nutrient arteries of the nerve will come into considerable play. A dilatation and tortuosity will be brought about by this stretching, which in its turn will lead to a slowing of the blood-current, a diminution in the blood-pressure and in the chemical changes which go on in the nerve-trunk. And with every alteration in the tissue metamorphosis, comes an alteration of function. Thus we get two factors, which are probably more important than the "concussion of nerve-substance and nerve-cells," which have hitherto been made so much of.

II. The author next proceeds to discuss the action of nerve-stretching under *pathological conditions*. In order to be able rightly to understand this action on diseased nerves we ought to be well acquainted with the appearances which nerves present under varying circumstances, and unfortunately we know very little about the subject. The author, though he has often made experiments, has never succeeded in artificially producing what is called neuralgia or tetanus in animals. At most a little local neuritis seems to have been caused, which subsided again, but which, after nerve-stretching, appeared to heal still more quickly than when left to itself. There is another field for observation on this subject, and as a more extended knowledge of neuropathy would be of material service, the study ought to be warmly taken up.

III. Record of published cases in which the operation has been performed, with date:—

a. Billroth (operation 1869, published in 1872): Laying bare the sciatic nerve, and examining it with the finger. Nothing abnormal was detected. The spasm of the leg, for which the operation had been undertaken, completely ceased within three months of the operation.

b. Von Nussbaum (operation 1872): (b) Laying bare and stretching the brachial plexus, on account of an intense neuralgia, of spasmodic contractions, and loss of sensation of the muscles of the arm. This operation was most completely successful.

c. Gärtner (1872): Laying bare and stretching the brachial plexus for a paralysis of thirty-four years' standing. The arm was greatly wasted, and the fingers contracted.

d. Patruban (1872): Laying bare and stretching of the sciatic nerve for sciatica. Great amelioration.

e. Vogt (1874): Laying bare and stretching of the ulnar nerve for paralysis, in consequence of adhesions with nerve. Cured.

f. Von Nussbaum (1875): Laying bare and stretching of the tibial and peroneal nerves in a case of reflex epilepsy. Complete cure.

g. Callender (1875): Laying bare and stretching of the median nerve in the stump of a forearm on account of neuralgia. Cured.

h. Von Nussbaum (1876): Laying bare and stretching the sciatic and crural nerves of both sides for central disease. Paralysis of lower extremities with clonic spasms, following on a fall eleven years ago. Spasm entirely cured.

i. Vogt (1876): Laying bare and stretching the brachial plexus in traumatic tetanus following extensive injury to the hand. Cured.

k. Kocher (1876): Laying bare and stretching of the tibial nerve for traumatic tetanus.

l. Petersen (1876): Laying bare and stretching of the tibial nerve for neuralgia.

m. Vogt (1876): Laying bare and stretching of the inferior dental for neuralgia. Cured.

Though the number of cases thus far is small, the results of the operation are striking. In these cases there was one symptom common to all—viz., the abnormally *increased excitability* of either the sensory or motor tracts,—and the result of the operation in each case was to lessen it. A closer inspection of the cases showed, first, changes in the neighbourhood of the nerves acting as a mechanical irritant, which were removable by the exposure of the nerve-trunks simply; and, secondly, changes in the nutrition of the nerves manifesting themselves as neuralgias, for which the nerve-stretching was especially indicated.

To the above list of published cases the Author now adds *three* of his own. *The operation was undertaken each time for tetanus, and in two of the three cases the patients recovered.*

IV. If any justification of the operation were necessary, the cases just quoted might be appealed to; and, further, the old maxim, "*Remedium anceps melius quam nullum*," would more than call for it. When it is compared, however, with the only other operative procedure which is open to the surgeon, it stands out in prominent and favourable contrast; for neurotomy or neurectomy, hitherto employed, brings about its mechanical interruption in nerve-conduction by means of *solution of continuity*. On this account, therefore, the operation has, for the most part, only been applied to *sensory* nerves; for division of a motor nerve would be followed by immediate paralysis of muscles or even limbs supplied by such nerve—a sequence by no means desirable. Further, the disease may be either central or peripheral, and division of the nerve under any circumstances could scarcely affect a central cause, and hence in many cases would even be contra-indicated.

(b) This is the first *published* case.

There are at present some definite indications for this operation, and the author lays them down somewhat as follows :—

A. *In Neuralgia.*—If it be generally true that secondary changes take place in a nerve-centre as the result of a peripheral irritation, which, in its turn, leads to an alteration in the vaso-motor district, and then to trophic changes in the nerve itself, we can easily understand why simple neurotomy is so seldom followed by good or permanent results. And after what has been said as to the supposed *modus operandi* of nerve-stretching, it will be conceded that the latter operation is the more likely to be of benefit, either in combination with neurotomy or alone.

1. Nerve-stretching in combination with neurotomy. When we have to deal with a neuralgia of peripheral origin affecting a purely *sensory* nerve, and one which has resisted all previous treatment, and which we cannot influence by electro-therapeutical means, a case in which no special local measures are indicated (removal of a scar, foreign body, or morbid growth), *then neurotomy of the affected nerve, in combination with simultaneous stretching, both centripetally and centrifugally, is indicated.* By means of this combination we dispose of the peripheral irritation, or at least we get an interruption of communication with the nervous centre, and also a diminution of the irritability in the course of the entire nerve-trunk, since the action of nerve-stretching goes much further in this direction than simple division of a nerve; and also from the circulatory changes there results an alteration in the nutrition—altered though it already is—of the nerve. Thus there is a combination of effects, which must almost necessarily produce a favourable influence on the disease, provided always that the *secondary changes in the nerve-centre* are not altogether beyond the possibilities of resolution. This operation, of course, is only admissible for sensory nerves.

2. Nerve-stretching alone will be indicated under analogous conditions for *mixed* nerves. If we are called to treat a neuralgic affection, we should, of course, remove all local irritations by local measures (such as removing or detaching scars in the neighbourhood of nerves), and at the same time by "stretching" seek to paralyse the result of the previous irritation. We might even, under certain circumstances, proceed to stretch the nerve-trunk without adopting the above-mentioned preliminary measures, when all medicinal and electro-therapeutical measures had previously failed. In the latter case we should seek to get at the nerve at the nearest possible point to its centre; and by vigorous stretching endeavour to influence the local condition also.

3. Neurotomy alone is indicated in neuralgic affections of *a very localised nature*, where a *subcutaneous* division of the affected nerve-twig would suffice, and where the laying bare of the nerve-trunk would scarcely be justifiable. In this group may be placed neuralgias of single sensory twigs in the case of extensive, and hence not easily extirpated, scars, tumours, and the like.

B. *In Epilepsy.*—The cases of epilepsy to which this plan of treatment is adapted are those which we call *reflex epilepsy*, depending on some appreciable or fairly obvious injury of a peripheral nerve distribution. There is on record a large number of cases where the removal of scars, neurotomy, etc., have led to a perfect cure. Cases 1 and 6 (before given) are also examples of the favourable effect of stretching under analogous circumstances. The following would seem to be an exceedingly suitable case for the operation :—A man had a small tumour removed from the cheek. The wound only closed slowly. Shortly afterwards, after any great exertion or excitement, he began to experience a feeling of heat about the scar, and occasionally a twitching and spasm in the muscles of the neck. These symptoms became aggravated after a time, and now he is the subject of well-marked epileptic attacks. On examining the local conditions more thoroughly, a scar, about the size of a florin, is found in front of and beneath the angle of the right jaw. It is not painful or tender, and nothing abnormal is found in the surrounding parts. But there is one point, which is painful, from which the twitchings seem to start. Topographically it corresponds exactly to the point of exit of the nervus cutaneus colli superior et medius of the cervical plexus. The author believes that he has here found the source of the peripheral irritation, and has advised stretching of the nerve-trunk where the twig arises. The case is to be recorded later on. In all cases, however, the indication must be exact and precise if we would be successful.

C. *Traumatic Tetanus.*—Contrary to the advice given in the two previous classes of cases, we must in this disease *proceed to operation at once*, and *not wait* until all therapeutic and anæsthetic measures have been tried. If needs be, order these measures *in addition* to the nerve-stretching, but not *in its stead*. The surgical treatment may be both local and central. The cases, however, where any active local treatment can be of avail, are those in which no important changes in the central nervous system have shown themselves. The period during which local treatment *might* be of service is exceedingly short. In some patients the central manifestations come on simultaneously with the disease; and here, of course, local treatment would not be of any avail whatever. As compared with all previous operative interference, nerve-stretching accomplishes much more, is a harmless operation if it even do not succeed, and does not require a solution of continuity in the nerve.

The group of cases above given has been selected in order to give some definite indications for undertaking this operation. But it is obvious that a much larger group might have been given. In order to sum up, then, we may state that the prominent symptoms which call for this treatment are *exalted irritability*, and *disturbed function due to a disturbed blood circulation* at the peripheral termination of a nerve.

V. *Technology of the Operation.*—The actual accomplishment of such an operation appears very simple, and yet from a study of all the published details it is clear that final success depends very much on attention to small matters, which sometimes are apt to be forgotten. The operation may be divided into three stages :—1. Laying bare the nerve within its sheath. 2. Drawing forwards and stretching the nerve. 3. Reposition and application of dressings. The first act of the operation is a most important one. In the case of traumatic tetanus before reported, some important changes were found, not only in the nerve itself, but also in the surroundings of its sheath; in all such cases *it is recommended directly to free* the nerve-sheath on all sides as far as one can reach; stretching then accomplishes the rest. The second act of the operation may be performed either manually or instrumentally. For the drawing forward of the nerve one naturally uses a blunt hook, or an elevator, or for a small nerve an ordinary aneurism needle. The actual stretching is best accomplished by passing the forefinger, appropriately curved, beneath the nerve, and using it in conjunction with the thumb. By this means we secure as much force as is necessary, provided we place the limb in a suitable position. Were a hook used for the stretching, there would be a danger of locally injuring the nerve itself, which is not possible when the finger is used. In the case of small nerves it would be impossible to pass the finger beneath them, and hence a thin elastic band may be substituted. In this way an *elastic* traction can be exercised without the risk of bruising or otherwise injuring the nerve itself. The last part of the operation consists of the dressing. If the stretched nerve does not recede when the limb is placed back in its normal position, or if the part operated on is one (the face) in which these movements would be impossible, the operator must gently tuck in the nerve into its bed. A small bit of drainage-tube is to be placed at the bottom of the wound, which may then be appropriately closed by a few sutures. Lister's dressing and spray ought to be used in these cases, as rapid union and a small scar must be tried for.

It does not seem to us necessary to follow the author any further. All practical surgeons will be acquainted with the points at which the nerves can best be got at. It is obvious that in this operation, as in tying arteries, there is a *lieu d'election*, and that success will be in proportion to the skill with which the operation is performed and the after-treatment attended to.

Salicylic Acid in Pertussis.—Amidst the round of trials which salicylic acid is undergoing, may be mentioned its use in pertussis as recommended in the *Petersburg Med. Woch.*, Nos. 22 and 23. Inhalation of a 2 per cent. solution for five minutes every evening during the convulsive stage effects an immediate influence, a cure resulting, on the average, within two weeks.

Lady Doctors.—In addition to the names already entered in the Medical Register, the following ladies, having qualified, have recently been added to the number, viz. :—Louisa Catherine Fanny Atkins, of St. John's-wood; Sophia Jex-Blake, of Bernard-street; Eliza Louisa Walker Dunbar, of Clifton, Bristol; and Frances Elizabeth Hoggan, of Rutland-gate. Others, it is stated, are about to follow.

FROM ABROAD.

The Diarrhœa of Infants.

The number of the *Journal de Thérapeutique* for July 25 contains an instructive paper upon the diarrhœa of infants from the pen of M. Blache, who has a large practice in the diseases of children.

Diarrhœa, he observes, must not be considered in children merely as a symptom, constituting, as it often does, a disease in itself. From a practical point of view it may be considered as consisting of several stages; and if we do not interfere hygienically and medically in the first of these (simple diarrhœa or catarrhal flux), we soon find it passing into the second stage (inflammatory diarrhœa), and then to a more advanced degree (dysentery), to terminate in choleriform diarrhœa, which annually carries off so large a number of infants. It is the persistence of the disturbed condition of the secretions which determines the progressive intensity of the affection. It is remarkable, after even the most intense diarrhœa, how seldom any considerable intestinal lesions are found. It is during the period of dentition that diarrhœa most frequently appears, but it is of much less frequency in children at the breast than in those brought up artificially—the casein of cow's milk coagulating in large clots, while woman's milk produces only small flocculent coagula. We must be careful, under the idea that such a flux is favourable to the issue of the teeth, not to allow the diarrhœa of dentition to continue too long unchecked. After dentition, the most frequent cause is cold, and especially humid cold; and a very important mediate cause is allowing the infant to suckle at irregular intervals. For although it may be impossible to insist upon the rule of never suckling under two hours' interval, yet a frequent recourse to the breast on every trifling pretext, soon after suckling, even when it does not give rise to an immediate diarrhœa, fatigues the intestinal canal, and predisposes to enteritis. In older children diarrhœa is often induced by the irritation caused by improper aliment, or food being given too abundantly.

The stools may be simply aqueous or contain the remains of undigested food; while in children brought up by hand they are sometimes too compact, sometimes accompanied by masses of undigested milk, and at others by clear yellow liquids, issuing in a jet accompanied by flatulence. Sometimes inodorous, they are oftener fetid, the fetor sometimes preceding the diarrhœa. The stools, however, are oftenest found of a greenish colour resembling chopped spinach, this being due to the conversion of the brown colouring matter of the bile into biliverdin by acids, this transformation sometimes occurring only after the stools have been voided and mixed with the urine. Observation of these appearances is of importance, as they may indicate that the milk of the nurse does not agree with the child, from fault of regimen or other cause. In the advanced period of catarrhal diarrhœa the stools become mucous or glairy, and streaks of blood may indicate the approach of dysentery. It is chiefly in infants artificially brought up, or in those whose development is not satisfactory, that colourless, clayey stools are found to precede the diarrhœa. It is the bad character of the evacuations rather than their number which constitutes diarrhœa; but after awhile their number and abundance induce other symptoms. Thus, the reiterated passage of the stools induces a redness and burning sensation, which extends from the anus to the genitals, the inner part of the thighs, the legs, and sometimes even to the heels; and in profuse diarrhœa those rapid emaciations occur which are observed in their most marked form in infantile cholera. But without proceeding to this extreme, the arrest in the development of the infant is to be noted as one of the results of diarrhœa. This can only be verified by the aid of the scales. By these it is ascertained that the infant may cease to increase in weight, and even commence to lose, within twenty-four hours or less; but in simple intestinal catarrh, or that accompanying dentition, it will be by the end of three days that the infant ceases to increase in weight, and if the diarrhœa still persists, loses it more and more. It may be laid down as an axiom that, during the first year of life, every infant who does not increase in weight proportionally to his original weight has entered into that complex morbid condition designated by Parrot as "*athrepsié*." Although diarrhœa of a medium intensity is only exceptionally accompanied by fever and general phenomena, this is far from being the case with it when arrived at its third stage, bearing so much analogy to the dysentery of adults. In this are met with intense fever with dryness of the skin, and alternations of irritability and depression; and the disturbance of the nervous system is so considerable that convulsions may arise which resemble those observed at the commencement of meningitis. The urine in the diarrhœa of infants is very acid, and the diminution of the acidity, when not due to ammoniacal fermentation, is generally of good prognosis. Its quantity, especially in serous diarrhœa, is greatly diminished. Albumen is by no means of rare occurrence in the urine of sick children, but it has rarely the same consequence as in the adult. When serous diarrhœa has lasted some time a considerable quantity of albumen may be present; and its diminution, followed by its disappearance, is a good sign; while its gradual increase, or sudden manifestation, is a bad one.

In the treatment of diarrhœa the dietetic and hygienic question is of great importance. When during the first few days the infant can only take a very little milk at a time, it may be put to the breast every hour or hour and a half; while from the end of the second week it should only suckle every two hours. When, having acquired some strength, the infant is able to suck more abundantly, the state of its stools should be watched, for it often happens between the third and sixth week that diarrhœa appears consecutively to dyspepsia due to excess of alimentation. It commences with the regurgitations and hiccups which nurses regard with so much satisfaction, but which should be considered as signs of repletion precluding diarrhœa, and which may be prevented by due regulation of the nutriment. At the period of dentition supervision is especially demanded, for a predisposition to diarrhœa already exists; while at the period of weaning, when the child begins to eat, indigestion may give rise to intense diarrhœa. The diarrhœa is usually most difficult of arrest when it succeeds to premature weaning; and a return to the breast, when practicable, is the most certain of remedies. It is of great importance to continue the use of milk at the period of weaning; but still it is not rare to meet with children by whom the best cow's milk is not tolerated, and seems even to keep up diarrhœa. Before giving up milk in these cases, that of the goat or ass should be tried, as both of these have proved of great use at the end of obstinate diarrhœa. Sometimes, however, in these refractory cases, lacteal diet has to be entirely suspended. About the sixth month a small panada, made of bread which has been gently roasted for three quarters of an hour, may be given; and towards the eighth month broths may be commenced. As a good hygienic measure, acting as a preventive of intestinal disturbances, the child's abdomen should be encircled in a flannel bandage from the time of the fall of the funis to nearly the end of dentition. Not only does this preserve the child from the action of cold, to which it is so susceptible, but it serves to support the abdomen and repress the tendency to distension which is produced by the slightest intestinal disturbance.

As to medical treatment, whatever be the nature of the diarrhœa, its origin, intensity, and even its prolonged duration, the following procedure, modified in different cases, has always proved successful:—1. Diminution of nutriment, enemata repeated according to requirements, and cataplasms to the abdomen. 2. The administration during three, four, or five days in succession of a small teaspoonful of equal parts of castor oil and gum syrup, which are emulsified at the time they are given by simply shaking the phial. Three or four days usually suffice for modifying the nature of the stools and diminishing their number. If by the second day the diarrhœa has become moderated without disappearing, the medicine should be suspended for a day, to be resumed the day after. While the medium dose is a teaspoonful, this will have to be varied with the age; and as a general rule it may be stated that one gramme of the oil will suffice before the first six months, and that from two to three grammes will be required to the second year. The gum moderates and regulates the action of the oil, which, given alone, acts with too much violence. In some cases, in which the stools are especially fetid and glairy, a second dose may be given in the evening. When the diarrhœa is very abundant, occurring twelve or fifteen times in the twenty-four hours, the quantity of gum syrup should be doubled or tripled, and a small quantity of vinum opii added. The purgative so modified may then be given every two or three hours. The dose of the vinum opii is limited to from one to three drops (at most) in the twenty-four hours, and when there is a disposition to vomit, a little orange-flower water may be added. It is to this same opiated

form we should have recourse when there is relapse of the diarrhœa. But, useful as this mild form of purgation is, it is much aided by the other means. The diminution of food is in some cases not required in consequence of loss of appetite, and in these the action of the purgative is speedily followed by desire for food. Indeed, the child should not pass more than half an hour after the purgative without sucking, or an hour without taking light broth. The utility of cataplasms is too obvious to be insisted upon, and oily or aromatic embrocations are very useful as a mechanical means of diminishing the gases of the intestinal canal which are of such frequent occurrence in disturbance of the digestive passages in childhood. The utility of enemata is also indubitable, and the following rules should be observed for their administration:—A large enema of camomile tea is to be followed in twenty minutes by a very small starch enema; and these two are to be repeated in the same manner whenever a series of four or five stools has occurred within the space of eight or ten hours. When the diarrhœa is sufficiently considerable to necessitate two or three repetitions of this kind within the twenty-four hours, it will be better that they should consist either of decoction of bran or decoction of marsh mallow, returning only to the camomile enema when the diminution in the number of stools renders it unnecessary that the large enema should be followed by the small starch one. In mild diarrhœa the purgative mixture is not required, the use of the camomile enema for a day or two sufficing. When with the diarrhœa there are combined manifest signs of *embarras gastrique*, an ipecacuanha emetic should precede the treatment; and before resorting to the castor-oil mixture, minute doses of calomel should be administered, when ardent fever, conjoined to nervous manifestations, leads to the fear of the occurrence of convulsions. It cannot be too often repeated that convulsions often accompany diarrhœa when it results from too abundant or indigestible food.

REVIEWS.

The Spas of Aix-les-Bains and Marlioz, Savoy. By Francis Bertier, M.D. Paris. London: J. and A. Churchill. 1877. Pp. 159.

Dr. Bertier has done good service to the profession and the public alike in publishing this little book. It is an account of the waters of this favourite resort, noting their physiological action, modes of application, and their medical effects. The waters are sulphurous, hot, and exceedingly abundant; they are stimulant and alterative in their properties, and are indicated in rheumatism, rheumatic arthritis, gout, certain skin diseases, bronchial affections, and in various forms of paralysis. Dr. Bertier describes the mode in which these waters are administered, and points out the indications for this or that method. The book contains also much useful information for those who go to such places for the first time, and we heartily recommend it to all who may think of going to Aix. The climate is very fine, and the means of access are ample and easy. English visitors, too, will have the advantage of having in the person of Dr. Bertier a physician who speaks English fluently, and whose genial and kindly manners, not less than his skill as a physician, will add much to the pleasure and advantage of a few weeks' stay at this pretty little watering-place.

A Treatise on the Theory and Practice of Medicine. By John Syer Bristowe, M.D., F.R.C.P., Physician to St. Thomas's Hospital, etc. Pp. 1166. Smith, Elder, and Co. 1876.

We welcome Dr. Bristowe's book very heartily, for it shows evidence of long and steady work in pathology and practical medicine, and of wide reading bearing on the task the author has undertaken. We do not, however, like the "get up" of the book. It is too unwieldy—at least, we expect this will be the student's view,—but for this, of course, the publishers, and not the author, are to blame.

The first part of the work is devoted to general pathology, in which are included etiology and a general account of physiological processes in health and disease. This section of the book is well and carefully written, and especially those pages devoted to tumours. The remarks on the local and general spreading of morbid growths, on the part played by the lymphatics in these processes, and on the elective affinities of tumours, we commend to our readers' notice as being of both clinical and pathological value.

The second part of the volume treats of special pathology, and therefore of particular diseases. "Specific febrile" affections are first noticed, and with the author's introductory remarks on contagion we mostly agree. But we are by no means convinced that typhoid fever does not sometimes arise *de novo*; and there can be no doubt that it is met with after the opening of long-closed drains in districts where it has not been known previously to exist. Many country practitioners can bear witness to this, and in such cases there is at least a doubt as to the precise mode of origin of the fever. The author's remarks on the general management of epidemic disease (page 136) are eminently practical. His descriptions of the acute diseases are, on the whole, excellent, and we can commend, particularly to anti-vaccinators, the overwhelming evidence adduced in proof of the protective power of vaccination.

The sections which are devoted to pulmonary affections are remarkably clear, though we do not agree with the author in his account of some physical signs. There are, in a manner, small points but worth noticing in a work which is likely to, and we hope will, become one of our standard text-books. For instance, Dr. Bristowe applies the term "tympanitic" to the percussion-note of both emphysema and pneumothorax; but surely the notes in the two diseases are as different as they can well be. And we certainly prefer the old term "hyper-resonance" for "emphysema," and "tympanitic" for "pneumothorax"; for (as Dr. Bristowe himself says further on) the note in the latter often exactly resembles that got on percussion of the small intestines. Tympanitic note means a distinct loss of lung resonance, and so is got in cases of partial consolidation and compression, where, as the author points out, beginners are apt to think there is an increased lung resonance, and consequently no serious mischief. We are glad to find mention made of the occurrence of cracked-pot sound in healthy children. This important fact is passed by in most text-books, and no mention is made of it even in works devoted to lung diseases. At the same time, the value of this percussion-sound as a sign of cavities is not diminished, for it is not difficult to distinguish between the true and false "*bruit de pot fêlé*," if a little care be taken. We agree with Dr. Bristowe, also, that "fine crepitation" is not, as is generally asserted, limited to the end of inspiration; it may be heard both in inspiration and expiration. And we think the author might have gone further, and declared that it is very often audible in the stage of consolidation, as well as in the first stage of pneumonia.

As we have said, thoracic diseases are on the whole well and clearly written. But some of the articles do not quite satisfy us. For instance, in the description of acute bronchitis too little attention is given to the effects of age on this disease, nor (as occurs in many other text-books) does acute capillary bronchitis of young children receive that especial consideration which it deserves. So, again, in all text-books intended for students, care should be taken to warn them against confusing bronchitis and pneumonia in the aged, as is too often done. Dr. Bristowe recognises the important fact that in bronchitis the temperature may acquire a pneumonic degree, and run up as high as 104° Fahr.

The author evidently supports the tubercular theory of phthisis, and refrains from a discussion of the catarrhal view of this disease. His account of asthma is excellently written, and prominence is justly given to the observations of the late Hyde Salter, whose work Continental writers have often adopted without acknowledgment. It is too often forgotten of this disease that quite young children may suffer severely from it, and in consequence absurd errors in diagnosis and treatment are not infrequently made. Dr. Bristowe notices its occurrence in the quite young.

Though at the present time there is a conflict of opinion as to the manner in which morbid sounds are caused in the heart, we do not quarrel with Dr. Bristowe because he neglects to argue the whole question, and asserts dogmatically that murmurs are due to "molecular vibrations produced in the blood as it traverses one or other of the cardiac orifices." In a text-book such as this it would have been out of place to launch into a discussion of theories not likely to be settled for some time to come. We think with the author that it is better to use the term "diastolic" for those murmurs heard at the apex other than systolic, because thus may be avoided all the misunderstandings which have followed the employment of

the terms "presystolic" and "auricular-systolic," though these terms have much to recommend them.

We cordially assent to most of Dr. Bristowe's descriptions of the symptoms and physical signs of heart disease, and when we raise doubts in regard to them it is only in the hope that his attention will be directed more particularly to some points. For example, is it not common in mitral obstructive disease to have an increase in the arterial fuluess and tensiou? We believe it is common, and as the busy practitioner is compelled to rely so much on digital examination of tho pulse, all authors of practical works should be particularly guarded in everything they write upon it. The description of Graves's disease is exceptionally clear; and with regard to angina pectoris we agree with Dr. Bristowe that an essential feature in it is contraction of the systemic capillaries, and a consequent damming-up of the blood in the heart. We must call atteution to one statement, because of its practical importance. Dr. Bristowe says that embolism of the lungs is almost invariably due to thromboses in the veins. Is it not the case that in mitral disease, which, whatever its nature, leads to mechanical impediment in the right heart, thrombi are frequently found in the right auricular appendix, and that parts of these, becoming detached, are carried to form infarcts in the lungs?

The diseases of the lymphatics form a feature of great value in this book, and especially do we commend the author's succinct description of the symptoms and signs of mediastinal tumours. And of the remaining sections of the volume we have little to say except in praise. As might be expected, the chapters on affections of the abdomen are generally good; and when we reach the subject of brain diseases we cannot but concede to the author additional praise. Space will not permit us to enter into particulars, nor are these needed where everything is good. The descriptions have been worked up with care, and include the most recent observations, both physiological and clinical. The work of Charcot and of Duchenne has been laboriously introduced into the volume before us, nor have the observations of our own countrymen been neglected. We particularly commend the articles on sclerosis of the nervous centres and on locomotor ataxy.

We have said little as to the author's remarks on treatment. We believe that, on the whole, such remarks are among the most valuable in the book. As a general rule it is best that definite rules of treatment should be laid down in books intended to guide students, and that their attention should not be diverted by too many details. This rule Dr. Bristowe has observed; and sometimes, we think, almost too closely. In nearly all our modern text-books the scientific aspects of therapeutics are too much neglected, and the use of medicine is apt, in consequence, to degenerate more and more into an empirical routine. As an excellent illustration of the author's consideration of treatment we refer to that recommended in delirium tremens. On the whole this contains exactly what we should do in the majority of cases. Dr. Bristowe does not discard opium and the hypodermic use of morphia, and we agree with him that the latter is a most valuable remedy in this disease. We do not side with those who abstain from medicines because unaided nature will in time cure the disease. They adopt a line of argument much to be deprecated in diseases like delirium tremens, where such rapid changes occur for the better and also for the worse; aud those who are guided by it are likely to be worse practitioners than our forefathers, who ventured far iu the exhibition of powerful drugs. But as an instance for the need of more particular directions as to the use of some drugs—especially anodynes and narcotics—we refer to the author's recommendation of chloral in delirium tremens. While often advantageous, it is as often a dangerous remedy. We cannot but think that the student and beginner in practice should be cautioned as to its use in delirium tremens until he has seen several cases of this disease. It very often seems to paralyse the respiratory powers, and to favour the accumulation of secretions in the bronchi - an accident common enough in the completely alcoholised without the assistance of drugs, and one which very often is the direct cause of death.

It is, of course, impossible in text-books to discuss all the ins and outs of medical practice, and Dr. Bristowe cannot be found fault with because space would not allow him to lay down more particular indications for the use of drugs. Sometimes, however, he is too definite and dogmatic, and we would instance his method of treating obscure cases of obstruction of the bowels (the article on which is uncommonly well written). He says, in the first place, use purgatives; if these fail, fall back on opiates and belladonna; and, if these fail, resort again to purgatives. We cannot think this safe advice to students, though the line of treatment is often very properly adopted. Obstruction of the bowels, when obscure, is one of those diseases for which no special line of treatment can be laid down; and in discussing its treatment space should be given, even in text-books, for particulars. All the recent reports of cases of obstruction show that both medicine and surgery are achieving, and will achieve, triumphs in their combat with this disease; and they also show that our diagnostic knowledge is at present too small for us to arrive at a definite mode of treating it generally.

But, we repeat, the treatment of the various diseases is admirably summed up, and we pronounce Dr. Bristowe's book to be eminently practical iu this respect. A fair space is given to dietetics of disease, and we are glad that this important subject is receiving more and more attention in works on medicine. We have ventured to find fault with some parts of Dr. Bristowe's book, not by any means in a spirit of hostility, but rather to suggest for future editions. We give the author our hearty congratulations, and his book our best commendation; and wish it all success.

FOREIGN AND COLONIAL CORRESPONDENCE.

FRANCE.

Paris, September.

How to make the Best Use of the Paris Hospitals and Medical Schools: Free Admission of Foreign Medical Men and Students; Hospital Service; Private "Cliniques"; Scientific Laboratories; the Library of the School of Medicine; Excellence of the Clinical Teaching at the Hospitals, more particularly in "Specialties."

I propose in my present letter to give a few hints for the service of medical men who may be intending to pay a visit to Paris. From personal experience I know how much time may be lost at the outset of such a visit, from a want of knowledge of what to do and where to apply for information.

I may mention, in the first place, that Paris is a very generous city to foreign medical visitors; for any foreign medical man or student who can establish his identity has the recognised and official right, without any payment whatever, to attend all the lectures at the Faculty of Medicine, to use the library and museum, and to follow the practice of any physiciau and surgeon at any of the uumerous hospitals in the town; and this for as long a period as he likes.

In order to obtain au order of admission at the School of Medicine, all that need be done by a foreign visitor is to see the secretary, and to show his diploma if a doctor, or his certificate of registration if a student. Should he have come to Paris without these, he can apply at the British Embassy, where he will be able, without difficulty, to obtain a letter of recommendation from the British Ambassador. To obtain official admission to the hospitals he must apply in the same way at the chief office of Public Assistance in the Avenue Victoria, near the Hôtel-de-Ville. It is not absolutely essential to obtaiu an official order of admission, but I should advise anyone who is intending to make a prolonged visit to do so.

On a first visit to a hospital—even when a general card of admissiou has been obtained from the Assistance Publique—it is as well to see the director. He will give a special admission for that hospital, and the visitor will always afterwards be at liberty to walk straight into the service he wishes to attend. There are, however, one or two institutions where a little difficulty may be met with. One of these is the Salpêtrière. Except wheu a course of lectures is being delivered there, this hospital is not supposed to be set apart for teaching purposes, and a visitor will probably be stopped by the concierge. If he be intending to pay only one visit, the director will furnish him with a card for that day; but if he wish to study for some time at the institution, it will be better—I may say, indeed, necessary—that he should ask the chief of the service he wishes to attend, or the interne of that service, to speak to the director on his behalf, when he will be given a permanent card of admission. So much is admission to the Salpêtrière looked upon as a matter of favour, that any foreign visitor wanting to make much use of it should, if

possible, get a private introduction to Professor Charcot, or whatever other physician he may wish to work under.

In Paris all the visits of the physicians and surgeons to the hospitals are made, without exception, in the early morning, beginning generally at from half-past eight to nine, and rarely ending later than eleven or half-past. After that hour nothing more is done in the wards, and after twelve o'clock no one is admitted without a special order from the director. By noon, then, all chance of hospital work is over. To anyone making a long stay it becomes a question how to utilise the afternoons to the best advantage. There are several ways in which the time may be usefully employed. In the first place, there are *cliniques* for special diseases held by private doctors in the afternoons, at which poor patients are seen gratuitously, which any student may attend. It is especially in connexion with diseases of the eye that such *cliniques* exist. Dr. Galezowski holds a consultation of this kind at 26, Rue Dauphine, and Dr. Fano another at 14, Rue Séquier. Patients are seen every day at one o'clock, and, as large numbers attend, capital work can be done by anyone wishing to study diseases of the eye. There are several other *cliniques* of the same kind, not only for the eyes, but for other specialties.

All men coming to study at Paris should plan out for themselves some special work to be undertaken in one of the many scientific laboratories of the town. It is perfectly easy to obtain admission into most of these, nothing more being necessary than to call upon the chief of the laboratory, and to ask his permission, which is readily accorded. As a rule, a small payment is asked for the use of apparatus. I give a list of the principal laboratories. There are two laboratories under the nominal direction of M. Robin, the Professor of Histology: one of these is at the Ecole Pratique, and is devoted chiefly to the study of normal human histology; and the other is in an old house in the Boulevard St. Germain, opposite the School of Medicine. This is presided over by M. Pouchet, and is intended for the prosecution of the higher microscopical studies, especially in connexion with embryology. Embryology and teratology also form the chief object of study in the laboratory of M. Dareste, at the Ecole Pratique. Pathological anatomy is best studied in the laboratories of M. Charcot, at the Ecole Pratique, and M. Ranvier, at the Collége de France. There are two principal physiological laboratories—that of M. Claude Bernard, at the Collége de France, where biological chemistry forms the chief basis of study; and that of M. Marey, at the same institution, the mechanical problems of biology being especially studied there. Biological chemistry may also be studied in the laboratory of M. Schutzenberger, at the Collége de France.

Those who are intending to make investigations in comparative anatomy will find every facility for doing so in the laboratories of M. Milne-Edwardes at the Jardin des Plantes, and of M. Lacaze du Thiers at the Sorbonne, the former being especially set apart for the study of the vertebrata, and the latter for that of the invertebrata.

There are, in addition, laboratories at certain hospitals, notably at the Hôtel-Dieu and at the Charité. The laboratory at the old Hôtel-Dieu is at present dismantled, whilst that of the new building has not yet been fitted up for work, but in a few months the latter, which, it is said, will be a very fine one, will be in working order. To obtain admission into these, all that is necessary is to speak to the *chef de laboratoire* and to ask permission of the director to enter the hospital after twelve o'clock.

Anyone wishing to pursue a serious course of study will be able to pass many useful hours in the library of the School of Medicine. There are about 40,000 books in the library, including most of the principal English, German, and Italian standard medical works. Every facility is accorded to visitors, and with the material at command there need be no excuse for finding the time hang heavily.

I think it will be abundantly evident that whoever wishes to employ his time profitably in Paris can do so, notwithstanding that after eleven or half-past eleven in the morning hospital work is at an end. In reference to this hospital work, I think it very important that if the visitor intends to make a prolonged stay he should attach himself to some three or four services only, and confine himself to these for two or three months at a time, going twice a week or so to each, rather than run indiscriminately from one service to another, without stopping long enough in any of them to enable him either really to learn anything about the patients, or to gather the general tone of the teaching of the physician or surgeon under whose care they are. One not unfrequently hears complaints from English or American visitors that they have learnt very little in Paris. This must surely be their own fault, for the material and the teaching are alike excellent, and for the most part the complaint owes its origin to the habit of running about from one hospital to another, and from one service to another, without system and without any definite object in view.

Before closing my letter I should wish to say a few words about the teaching—not of the teaching involved in the ordinary curriculum at the School of Medicine, of which I know little, but of the clinical teaching at the hospitals. This is excellent, and in certain ways, I think, better than anything we have in London, and better in this way: that more use is made of the specialties. At every hospital where services are set apart for special objects, the chief of the service, in addition to the bedside teaching, which is for the most part extremely good, undertakes to give one or more courses of lectures in the year on some division of his specialty. The subject treated of is thoroughly exhausted, and as each year a fresh branch is taken up, we have at last a fine series of lectures, embracing in a full and exhaustive manner a large part of the specialty. The courses of lectures given by Professor Charcot at the Salpétrière on nervous diseases have now a world-wide reputation, and the book into which they have been collected forms the standard work on this class of diseases. M. Fournier has given many courses of lectures at St. Louis on syphilis in its various manifestations, at one time confining himself to the purely clinical and pathological aspects—as when he lectured on syphilitic nervous diseases, on syphilitic disease of the tongue, etc.,—at times treating rather of the social problems in connexion with the disease, as the influence of syphilis on marriage, the communication of the disease from a child to its nurse and *vice versâ*, etc. At the same hospital courses of lectures are given every session by MM. Besnier and Sallier on some branch of diseases of the skin. M. Magnan gives very instructive lectures at the Asylum of St. Anne on mental diseases. M. Magnan selects cases of allied or contrasted diseases, and examines them before his class, bringing into prominence the characteristics of each case. The student has thus the opportunity of seeing in a short time a number of cases illustrative of the chief forms of insanity, and, aided by the very able and scientific expositions of M. Magnan, he has excellent opportunities for acquiring a knowledge of this branch of medicine. I may mention, in addition, the lectures given by M. Parrot at the Hospice des Enfants Assistés, by MM. Archambault and Bouchut at the Enfants Malades, by M. Luys at the Salpétrière, and others. Most of these lectures acquire additional interest from the natural ease and fluency which is inherent in most of the French professors, in common with so many of their countrymen, and which, in some instances, amount to real oratory. Though evidently prepared with great care, the lectures are generally delivered extempore or with but slight reference to notes, and it is a pleasure to listen to the uninterrupted flow of well-turned sentences, in which, nevertheless, the matter is in no degree subordinate to the manner.

The Militia Surgeons of Last Century.—In the early days of the militia the pay of the surgeon was so small (being only 4s. a day), that no one could be found to take it unless an ensign's commission was added. We find mention of this arrangement made as late even as 1801.—*Athenæum*, Aug. 25.

Lithotomy by Means of the Thermo-Cautery.—M. Anger observed at the Society of Surgery that he had hitherto only employed the thermo-cautery in lithotomy for the preliminary stages of the operation; but on another case occurring he should not hesitate to practise the entire operation by this method. He has experimented upon the dead body in the following manner:—The catheter having been introduced, the tissues were divided by means of the thermo-cautery, until the groove of the catheter could be felt. A puncture was then made also by the thermo-cautery, and a three-branched *ecarteur* was carried along the groove into the bladder. The catheter was then removed, and the prostate divided through its whole extent between the branches of the *ecarteur*, so that the finger could easily penetrate into the bladder. On another body, M. Anger made two small lateral incisions, with an equally satisfactory result.—*Union Méd.*, Sept. 8.

GENERAL CORRESPONDENCE.

JUSTICE TO MANCHESTER WORTHIES.

[To the Editor of the Medical Times and Gazette.]

SIR,—Scanty justice has been done to more than one of the Manchester medical worthies by some of the speakers at the late meeting of the British Medical Association. For instance, Mr. Kinder Wood, who is very well known as having written "On a Fatal Affection of the Pudenda of Female Children" in an early volume of the *Royal Medical and Chirurgical Transactions*, is described as a "Mr. Ward" by Dr. Priestley three times over in your report of his opening address to the Obstetric Section. There is not a surgeon who may not be called upon to distinguish in a female child between the effects of criminal assault and idiopathic vulvitis, the result of debility and dirt; and for an early and emphatic paper on the diagnosis he has to thank Mr. Kinder Wood, not "Ward."

The other worthy for whose reputation I plead is Mr. Charles White, who was an example of the union which Dr. Barnes so much desires of great obstetrical skill with general surgery and medicine. White is spoken of with great respect by Sir William Fergusson for his achievements in surgery, especially with regard to excision of the hip-joint and reduction of dislocations; but it is his treatment of lying-in women which ought to insure him immortality. He repudiated the hot and sweating system then in vogue among midwives, and advocated the use of cold water and cold air, such as had been recommended by Sydenham a century before in the treatment of small-pox.

I am, &c., R. D.

August 30.

NEW INVENTIONS AND IMPROVEMENTS.

NEW ILLUMINATING LAMP FOR MEDICAL PURPOSES.

MESSRS. SALT AND SON, of Birmingham, have brought out a new illuminating lamp for medical purposes. An examination of the woodcut (scale one-third size) will show that it is neat and portable, and being nickel-plated is cleanly.

The flame burns with a steady light, its intensity being increased by means of a reflecting mirror, whilst the rays are concentrated by a bi-convex lens so that they may be directed on any given point. No shade is required, and the flame, being inclosed in a lantern, is not affected by currents of air. The wick is fed by a sponge saturated with petroleum.

TOUGHENED GLASS VAGINAL SPECULUM.

NOT the least useful adaptation of the new process for toughening glass is that of lining vaginal and other specula with this material. All are familiar with the "starring" of the plain old glass specula, and many have cause to lament the accident of breakage while in use. It is to obviate this that Messrs. Maw and Son, of Aldersgate-street, have made specula lined with toughened class. The sample sent us is excellent. We have subjected it without any consequent damage to several severe tests, such as would have inevitably been destructive to any ordinary glass speculum. We can confidently recommend it for more extended trial and use.

HOSPITAL SATURDAY FUND.—The amount received by the Hospital Saturday Fund up to last night was about £2500. This is exclusive of the sum collected in the streets on Hospital Saturday. The amount as at present known is about £300 in excess of the sum received at the corresponding date last year. M. Leopold de Rothschild, one of the Vice-Presidents, has sent a donation of £50.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, September 6:—

Bately, Robert Godfrey, Balaam-street, Plaistow, E.
Bottrell, James Francis Henry, 42, Bloomsbury-square, W.C.
Buckle, John, The Oaks, Catten, Norwich.
Hooker, Joseph Stenson, 46, Watling-street, E.C.
Leah, William, Birchfield, Birmingham.
Salter, John Reynolds, Taunton.
Trevan, Frederick Adolphus, Port Isaac, Cornwall.

The following gentlemen also on the same day passed their Primary Professional Examination:—

Griffiths, Ernest Edward, Middlesex Hospital.
Jeram, James William, St. Bartholomew's Hospital.
Pearce, John Puckey, Middlesex Hospital.
Ward, George Smith, King's College.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

GIBBONS, R. A., M.B., M.R.C.S.—Junior House-Surgeon to the Hospital for Sick Children, 49, Great Ormond-street, W.

NAVAL, MILITARY, &c., APPOINTMENTS.

ADMIRALTY.—Staff Surgeon James Crowder Eastcott has been promoted to the rank of Fleet Surgeon in her Majesty's Fleet, with seniority of August 30. The under-mentioned Surgeons have been promoted to the rank of Staff Surgeon in her Majesty's Fleet:—William Middleton Power and George Kell, with seniority of the 5th inst.; William Dudley Woodsworth and Fleetwood Buckle, M.D., with seniority of the 7th inst.; Edward William Doyle, James Hamilton Martin, William Henry Stewart, M.B., and Thomas Conry, with seniority of the 16th inst.

ST. JAMES'S PALACE.—The Queen has been pleased to appoint George Husband Baird Macleod, M.D., Regius Professor of Surgery, University of Glasgow, to be one of the Surgeons-in-Ordinary to her Majesty in Scotland, in the room of Professor Joseph Lister, resigned.

BIRTHS.

ADAM.—On September 6, at Caterham, the wife of James Adam, M.D., Medical Superintendent, Caterham Asylum, of a son.

HYDE.—On July 18, at Aller Park, near Ladysmith, Natal, the wife of G. Clarence Hyde, M.R.C.S. Eng., District Surgeon, J.P., of a son.

MARRIAGES.

DENNIS—PARSONS.—On September 5, at Eynsford, Kent, Augustine Dennis, M.R.C.S.E., of Great Berkhempstead, Herts, second son of A. V. Dennis, M.R.C.S.E., of Burnham, Westgate, Norfolk, to Susannah, elder daughter of Richard Parsons, of Eynsford, Kent.

DOVE—SUNDERLAND.—On September 5, at Ravensden, Beds, Harry Dove, M.R.C.S. Eng., of Stowmarket, only son of the late H. Dove, M.D., Norwich, to Mary Anne, third daughter of the late Rev. T. L. J. Sunderland, M.A., of Ravensden Grange, Beds.

HARRIS—BARNETT.—On September 6, at St. George's, Hanover-square, William Henry Harris, M.D., Surgeon-Major Army Medical Department, to Annie Mary, second daughter of John Barnett, of Halford.

JAMESON—BURKE.—On September 5, at St. Peter's Church, Dublin, Andrew Jameson, second son of the late Andrew Jameson, of Alloa, N.B., to Grace E. A. M., only daughter of W. Burke, F.K.&Q.C.P. Ire., Registrar-General for Ireland.

SEATON—SAUNDERS.—On September 4, at Chipping Norton, Oxon, Ernest William Attree, second son of Joseph Seaton, M.D., of Halliford House, Sunbury-on-Thames, to Fanny Emma, daughter of the late Robert Merry, Esq., of Hemel Hempstead, and widow of the late John Saunders, Esq., of Watford, Herts.

SWANWICK—DODDS.—On September 1, at St. John's Church, Low Fell, Gateshead-on-Tyne, Eustace Maclean Swanwick, M.R.C.S., L.R.C.P., of West Hartlepool, second son of Thomas Swanwick, Esq., of Manchester, to Edith, youngest daughter of M. S. Dodds, Esq., of Low Fell.

WATTS—BROWNE.—On September 12, at Rusholme-road Congregational Chapel, Manchester, James, only son of Sir James Watts, of Abney Hall, Manchester, to Anne Hadfield, second daughter of Henry Browne, M.D., of Manchester.

DEATHS.

BUCHANAN, ANDREW, M.D., at Dijon, on September 4, in his 70th year.

CLARKSON.—At Eden Lodge, Tunbridge Wells, the wife of W. H. Clarkson, M.R.C.S. Eng., on September 2.

DOWMAN, JOSEPH RYMER, M.R.C.S. Eng., at Hartland, near Bideford, North Devon, on August 4, aged 37.

FRASER, JOHN, youngest son of Surgeon-Major A. H. Fraser, L.F.P.S. Glasg., Principal Medical Officer, British Troops, Burmah, at Rangoon, on August 4, aged 9.

GULLAND, OLIVIA JESSIE, wife of Surgeon-Major Gulland, M.D., daughter of the late Charles Denroche, Esq., C.E., of Cardiff, at St. Mark's House, David-place, St. Helier's, Jersey, on September 2, aged 25.

HENTSCH, ELLEN, wife of J. P. Hentsch, M.R.C.S. Eng., at 32, Bruce-road, Bromley-by-Bow, on September 8, aged 34.

LAKIN, JAMES HENRY, M.D., of Sutton Coldfield, on September 2, aged 53.

MERYON, C. L., M.D.. F.R.C.P., at The Grove, Hammersmith, on September 11, aged 96.

RANDOLPH, JOHN, M.R.C.S. Eng., of 16, Bessborough-gardens, Vauxhall-bridge-road, S.W., on September 8.

SLACK, H. W., L.R.C.P. Edin., M.R.C.S. Eng., at 41, Rodney-street, Liverpool, on August 29.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made and the day of election (as far as known) are stated in succession.

BEAFORD GENERAL INFIRMARY.—Resident Surgeon. Applications, with testimonials, to the Chairman of the Weekly Committee, on or before September 27.

BRISTOL GENERAL HOSPITAL.—Physician's Assistant. Candidates must produce proof of a registered medical qualification, also satisfactory testimonials of ability and good moral conduct. Applications to the Secretary, at the Hospital, on or before September 21.

BRISTOL ROYAL INFIRMARY.—Assistant House-Surgeon. Candidates must be Fellows of the Royal College of Surgeons of London, Edinburgh, or Dublin, or Masters in Surgery of one of the universities of the United Kingdom, and also possess a registered medical qualification. Applications, with testimonials and certificates of registration, to the Secretary on or before September 18.

CITY OF LONDON LYING-IN HOSPITAL, CITY-ROAD.—Consulting Surgeon. Candidates must be Fellows of the Royal College of Surgeons of England. Applications, stating qualifications, etc., to the Secretary, on or before September 18.

NORTH DEVON INFIRMARY, BARNSTAPLE.—House-Surgeon. Candidates must be registered in Medicine and Surgery under the Medical Act, unmarried and free from the care of a family, and produce satisfactory testimonials as to moral character. Certificates and testimonials to the Secretary (under cover), addressed to the House Committee, on or before September 21.

WESTERN DISPENSARY, 40, QUEEN ANNE'S-GATE, WESTMINSTER, S.W.—Resident Medical Officer. Application by letter, stating age, qualifications, etc., and enclosing testimonials, to the Secretary, on or before September 17, and candidates must attend personally the election on Wednesday, September 19, at five o'clock.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1871.

RESIGNATIONS.

Alresford Union.—Mr. G. R. Lawrence has resigned the Second District; area 23,903; population 3538; salary £100 per annum.

St. Asaph Union.—Mr. J. H. Wolstenholme has resigned the Rhuddlau District; area 7478; population 7724; salary £78 per annum.

Aysgarth Union.—Mr. J. Thompson has resigned the Hawes District; area 30,233; population 2419; salary £40 per annum.

Bideford Union.—The Hartland District is vacant; area 18,451; population 2103; salary £40 per annum. The Clovelly District is vacant; area 2502; population 759; salary £13 per annum.

Castle Ward Union.—Mr. Robt. Torrance has resigned the Stamfordham District; area 28,338; population 2345; salary £20 per annum.

Dursley Union.—Mr. H. Collins has resigned the Third District; area 6410; population 2316; salary £80 per annum.

Sedgefield Union.—Mr. G. R. Sheraton has resigned the Sedgefield District; area 14,115; population 2811; salary £15 per annum. Also the Bishopton District; area 9677; population 868; salary £15 per annum.

Southmolton Union.—Dr. Sanders has resigned the Seventh District; area 4910; population 1642; salary £31 10s. per annum.

Thame Union.—Mr. Richard Lee has resigned the Thame District; area 11,955; population 4870; salary £100 per annum.

APPOINTMENTS.

Gateshead Union.—Arthur W. Attwater, L.R.C.P. Edin., M.R.C.S. Eng, L.S.A., to the Whickham District.

Isle of Wight Union.—Edward A. Waterworth, M.D., M.R.C.S., to the Workhouse.

Nuneaton Union.—Albert N. Cookson, M.R.C.S. Eng., L.S.A., to the Chilvers Coton District.

Wimborne and Cranborne Union.—Arthur F. Van, M.R.C.S. Eng., L.S.A., to the Fourth District.

Wisbech Union.—John W. Measures, M.R C.S. Eng., L.S.A., to the Tenth B District.

Woburn Union.—John A. Macdonald, F.R.C.S. Edin., M.D. Queen's Univ., Ire., to the Workhouse.

Faringdon Union.—Charles G. Parker, F.R.C.S. Eng., to the Shrivenham District.

Folehill Union.—Herbert C. P. Masser, M.R.C.S. Eng., L.S.A., to the Lowe and Stoke Districts.

Grantham Union.—John C. Eaton, M.R.C.S. Eng., L.S.A., to the Ancaster District.

St. Ives Union.—Joseph W. Ellis, M.R.C.S. Eng., L.S.A., to the Swavesey District.

Sunderland Union.—Harry Drinkwater, B.M. and M.C. Edin., M.R.C.S Eng., to the Bishopwearmouth West District.

Ware Union.—Harry May, L.R.C.P., L.S.A., M.R.C.S., to the Workhouse and the Third District.

THE next examination for the certificate in sanitary science of the University of Cambridge will begin on October 2. Application for admission to this examination, which is open to all whose names are on the Medical Register of the United Kingdom, should be made to Professor Liveing, Cambridge, on or before September 18.

NERVOUS ALBUMINURIA.—M. Teissier, of Lyons, read a paper at the recent meeting of the French Association for the Advancement of Science, in which he stated that albuminuria may not only be produced by renal lesion and a changed condition of the blood, but also through the influence of the encephalic or sympathetic nervous systems. Most authors reject any influence of this kind, further than it modifies the capillary circulation of the kidneys or the composition of the blood—everyone acknowledging, however, the existence of important nervous disturbances at the onset of albuminuria, but attributing them to renal congestion and to the loss of albumen. Numerous cases have led M. Teissier to form the opinion that these nervous phenomena play, not unfrequently, the part of cause rather than of effect, existing indeed long prior to the appearance of the albuminuria, of which he cites some examples in vertigo, hemiplegia, spinal disease, etc. Again, other cases occur in arthritic patients, in whom alternations are observed between albuminuria and glucosuria and phosphaturia, such alternation, which is much dependent on regimen and medication, continuing sometimes for years. From the facts he has observed he draws two practical conclusions—first, that in albuminuria of nervous origin we should especially rely on quinine, valerian, nux vomica, iron, and arsenic; and secondly, that in arthritic, diabetic, and irritable subjects we should avoid giving large doses of alkalies, for fear of giving rise to cerebral lesions.—*Gaz. Médicale*, Sept. 1.

NOTES, QUERIES, AND REPLIES.

"He that questioneth much shall learn much."—*Bacon.*

HUNTER AND JENNER.

In addition to the correspondence which has already appeared in the *Medical Times and Gazette* between these two distinguished men, we have the pleasure of adding another copy of a letter purchased last week at Messrs. Sotheby's, by Mr. Erasmus Wilson, for presentation to the library of the Royal College of Surgeons, which institution, our readers will no doubt be surprised to learn, does not possess a single letter of the founder of the Hunterian Museum. There were three letters to be sold by auction, which Professor Wilson wished to have secured, but by some misunderstanding only the following was purchased, viz.:—

Dear Jenner,—
I have received the Bustard safe as also the Bones. Your friend Mr. Hazeland has been very kind for which I have wrote (*sic*) to him and thankd him, but when you see him, or write to him, express the same to him, as an indirect thank is better than a thousand direct ones. Are Hedgehogs in great Plenty? I should like to have a few. You must pursue the Cuckoe this Summer.
I am imployd as much as a thousand Bees. I am building surveing &c. I wish this summer was well over. When I am fitted up I hope you will come and see me
Ever Yours,
April 22. JOHN HUNTER.

The orthography, punctuation, etc., are preserved; the handwriting is fairly good; it is endorsed in Jenner's writing, "J. Hunter." We understaud that some very interesting letters of Hunter and Jenner to and from each other will shortly be sold by Messrs. Sotheby and Co.

Dr. Denham.—As the members of the Midwifery Board all resigned their seats, there is consequently an end to the examinations for the "L.M." for the present; in fact, no additions to the Licentiates in Midwifery have been made during the past collegiate year.

Epidemiologist.—Yes; the International Sanitary Conference assembled in 1866, at Constantinople, to devise measures to insure Europe from future visitations of cholera. In 1874 Austria proposed that another conference should be held to reconsider the subject, the sittings of which commenced at Vienna on July 1 in that year.

Nero.—The lines are—

> ". . . With awakened eyes they took revenge
> For past credulity in casting shame
> On my real knowledge, and I hated them."
> *Browning's "Paracelsus."*

Danubian.—The mean temperature of the lower valley of the Danube is said to be 24° Fahr. during January, or 14° below that of Aberdeen, and 15° below that of Dublin. An exceptionally cold year was 1861, and then the thermometer often fell below zero, and on one occasion exceeded 34° of frost.

Tom M.—Anthony Petit, an eminent physician-accoucheur and anatomist, was a native of Orleans. He acquired great reputation as a practitioner, and in 1763 was appointed inspector of the military hospitals throughout France. In the following year he was made professor of anatomy and surgery at the Royal Garden, in which office he was attended by an extraordinary concourse of auditors. He finally retired from practice, and died near Orleans in 1794 at the age of ninety-two. He was a voluminous medical writer.

A Surgeon—R. V.—According to a Parliamentary paper recently issued, the proportion of the male population between the ages of fifteen and thirty-five serving in the militia, yeomanry, and volunteers of Great Britain, is about six in every hundred. Scotland stands highest, the rate in some counties being 16 per cent., while in some of the Welsh counties and in the Isle of Man the proportion is as low as 2 per cent.

THE BITER BIT.

At the Rugeley (Staffordshire) Petty Sessions, last week, a chemist was convicted for selling a small quantity of arsenic without having a witness. The arsenic was obtained by a policeman in plain clothes, against whom a summons has been taken out for having given false information to the defendant when the poison was purchased.

Howard.—The list of Fellows of the New York Academy of Medicine comprises the *élite* of the profession practising in the cities of New York and Brooklyn and their vicinity, and of some eminent practitioners in more distant towns.

Anti-Tobacco.—There is a French Anti-Tobacco Society (Société contre l'Abus du Tabac), and it offers prizes for papers on the following points:—1. A prize of 100 fr. to the schoolmaster who will write the best paper in view of warning youth against the dangers of prematurely indulging in the use of tobacco. 2. A prize of 200 fr. to the medical man who will relate the greatest number of interesting and unpublished observations on diseases arising from the use of tobacco. 3. A prize of 300 fr. to the author of the best paper relating to the influence of tobacco on studies, especially in universities, civil and military schools. The papers are to be directed, before the end of the year, to the office of L'Abeille Médicale, 3, Rue St. Benoît, Paris.

COMMUNICATIONS have been received from—

Mr. R. BRUDENELL CARTER, London; Dr. BARLOW, London; Dr. LAWSON, Banstead Downs, Sutton, Surrey; Dr. SPARKS, Crewkerne, Somerset; Mr. J. CHATTO, London; Dr. JAMES RUSSELL, Birmingham; Messrs. SALT and SON, Birmingham; Dr. J. PEARSON IRVINE, Carnforth; Mr. J. BATELY, Yarmouth; Dr. DRUITT, London; Mr. H. STYRAP, Isle of Man; THE REGISTRAR OF THE APOTHECARIES' HALL, London; Mr. T. M. STONE, London; Mr. GEORGE BROWN, London; Professor NEUMANN, Vienna; Dr. NORMAN MOORE, London; Mr. BOWES, London; Mr. D. H. GABB, Hastings; Messrs. CALVERT and Co., Manchester; Mr. USSHER, Burton-on-Trent; Dr. CARMICHAEL, Edinburgh; Mr. HENRY REECE, London; Mr. ED. WALFORD, Ramsgate; Dr. STURGE, Paris; Dr. J. W. MOORE, Dublin; Messrs. LEE and NIGHTINGALE, Liverpool; Mr. G. H. ROND, Wolverhampton; Mr. BURGESS, Leamington; Dr. BULKLEY, New York; Dr. ANNINGSON, Cambridge; Mr. GEORGE MEADOWS, Hastings; Dr. HEINEMANN, London.

BOOKS AND PAMPHLETS RECEIVED—

E. Kunemann, La Principauté de Monaco considérée comme une Station Sanitaire—Edward Dowden, LL.D., Shakespere—Robt. Campbell, M.D., The Relations existing between Eczema and Psoriasis—Robert Bentley, F.L.S., and Henry Trimen, M.B., F.L.S., Medicinal Plants, part 24—Arthur Trehern Norton, F.R.C.S., The Examiner in Anatomy—Mary Putnam Jacobi, M.D., The Question of Rest for Women during Menstruation—S. Weir Mitchell, M.D., Fat and Blood, and How to Make Them—A. S. Wilkins, M.A., Roman Antiquities.

PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Berliner Klinische Wochenschrift—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Gazette Hebdomadaire—Le Progrès Médical—Bulletin de l'Académie de Médecine—Pharmaceutical Journal—Wiener Medizinische Wochenschrift—Medical Examiner—The Louisville Medical News—Boston Medical and Surgical Journal—Nature—Philadelphia Medical Times—Iron—Cincinnati Clinic—Analyst—Guy's Hospital Gazette—Practitioner—Dublin Journal of Dental Science—Canada Medical and Surgical Journal—Trade Marks.

APPOINTMENTS FOR THE WEEK.

September 15. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 1½ p.m.

17. *Monday*.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

18. *Tuesday*.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

19. *Wednesday*.

Operations at University College, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex. 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 1½ p.m.

20. *Thursday*.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing-cross, 2 p.m.; St. Thomas's (ophthalmic operations), 4 p.m.

21. *Friday*.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m.; Guy's, 1½ p.m.

VITAL STATISTICS OF LONDON.

Week ending Saturday, September 8, 1877.

At the Royal Observatory, Greenwich, the mean reading of the barometer last week was 29·84 in. The lowest reading was 29·49 in. on Monday morning, and the highest 30·18 in. on Tuesday evening.

* The figures for the English and Scottish towns are the numbers enumerated in April, 1871, raised to the middle of 1877 by the addition of six years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the number enumerated in April, 1871.

ORIGINAL LECTURES.

CLINICAL LECTURES

ON A CASE OF

PROGRESSIVE PERNICIOUS ANÆMIA CURED BY ARSENIC.

By BYROM BRAMWELL, M.B.,

Physician and Pathologist to the Newcastle-on-Tyne Infirmary; Lecturer on Clinical Medicine and Pathology in the University of Durham College of Medicine at Newcastle-on-Tyne.

LECTURE I.

THE man whom I now introduce is well known to many of you, for while he was in the wards we had long and interesting discussions at his bedside. He was admitted under my care on November 26, 1875, suffering from "progressive pernicious anæmia," and was discharged on January 20, 1876.

The following is a summary of the very copious notes which are entered in the case-book:—J. D., aged thirty-eight, married, a chemical worker, was admitted on November 26, 1875, complaining of extreme shortness of breath and palpitation on exertion, swelling of the feet, hands, and face, and general debility.

He enjoyed excellent health until seven months ago, when his present illness commenced with a rigor after exposure to cold and wet. The shivering was followed by general weakness. His colour changed; his hair became grey. He several times vomited, and had frequent attacks of diarrhœa. Three months ago he was slightly jaundiced; two months ago his face swelled; two weeks ago his feet became œdematous. He lives at the top of a fairly healthy house, situated in the midst of smoke, but in a district where malarious fevers are unknown. He has had abundance of good and varied food. There has been no return of the shivering since the commencement of the attack. He thinks the "gas" was partly the cause of the complaint. His family are all healthy. He has not had syphilis, and has not been an excessive drinker.

On admission his condition was as follows:—He looked very much older than his years. The feet, legs, hands, and face were slightly swollen. The skin was soft and smooth, and of a faint yellow tinge; the hair was grey. There was a small fatty deposit at each internal canthus. The mucous membranes were profoundly anæmic. There was no loss of fat, but the muscles were soft and flabby. Muscular irritability was very marked. His weight was eleven stone one pound; his height five feet nine inches. The temperature was normal.

He was very short of breath on exertion, and suffered from violent palpitation. He often, too, felt giddy and faint on movement. Loud blowing murmurs were audible at all the cardiac orifices, a mitral murmur, systolic in time, and propagated upwards towards the axilla, being especially noticeable; indeed, so marked was it that our then Junior House-Surgeon, Dr. Mickle, diagnosed the case as one of cardiac dropsy from mitral insufficiency. The size of the heart was slightly increased. The pulmonary second sound was not accentuated. A loud venous hum was audible at both sides of the neck. The left external jugular vein was distended and prominent. The pulse was 76, somewhat full, jerking, and of very low tension. The tongue was clean and moist, but very pale. The appetite was good; there was no thirst. The liver-dulness was normal. The splenic dulness was slightly increased. The urine was normal in amount, very pale, neutral, specific gravity 1020; it contained no albumen and no bile.

He complained of headache and a singing noise in the left ear. The feet and hands were numb. This was especially the case after exposure to cold. Very marked reflex movements were produced in the lower extremities by tickling the soles of the feet. He complained of pain in the back, and slight tenderness on pressure over the lumbar spines. The application of the hot sponge test elicited nothing abnormal. Sight was dim in both eyes; the pupils were widely dilated, but very sensible to light; the fundus was markedly bloodless; the disc ill defined. There were no retinal hæmorrhages.

A drop of blood was obtained with difficulty in the usual manner by pricking the finger. It was of a dull red colour, and seemed to separate into two parts, looking as if minute drops of blood and oil had been brought together. On microscopical examination, it presented the following characters:—The red globules were diminished in numbers, and did not form rouleaux. They were markedly altered in shape, some of them being large and no longer bi-concave, others irregular, and with one or more tail-like projections; others appeared nucleated, the nucleus being of a pinkish-red colour. There were also numerous small red globules; indeed, these (the red globules) seemed to be of all sizes, from minute masses of protoplasm to the abnormally large oval corpuscles which I have described. The white corpuscles were not in excess.

He was ordered five grains of quinine and fifteen minims of the tincture of the muriate of iron three times a day. On December 3 a teaspoonful of phosphorised cod-liver oil was added (one-thirtieth of a grain of phosphorus).

On December 6 the eyes were again examined with the ophthalmoscope, and several large retinal hæmorrhages were seen in both eyes. These hæmorrhages were mostly situated in the course of the vessels; the stratum of blood was very thin. The pupils had been very widely dilated ever since his admission, the result of sulphate of atropia.

On December 15 it was noted that he had gradually been getting worse, and was then confined to bed. He had several times vomited, and had had a severe attack of diarrhœa. There had been an irregular attack of fever. Temperature 100·2° Fahr.; pulse 120. The dropsy was greater. The iron, quinine, and phosphorised cod-liver oil were discontinued, and two minims of liquor arsenicalis, thrice daily, were prescribed.

The after-progress of the case may be described as one of slow but uninterrupted improvement. The dose of the liquor arsenicalis was gradually increased to sixteen minims three times a day.

On January 20 he expressed a wish to go home, and was discharged. He attended as an out-patient, and continued to take the arsenic until the end of April, when he considered himself perfectly well. He tells me to-day that he has been at work since the end of March; that he has never lost a single day during the whole of that time; that he now feels as well as ever he did in his life. He is not in the least degree short of breath; all cardiac murmurs have disappeared; the blood is now natural. His hair is darker than it was, but you will see that it is still grey. His sight is not quite so good as it used to be.

This is the history of the case. I had no difficulty in recognising its nature, for I had previously met with several others of a similar character.

The first one was that of R., a sailor, aged eighteen, who was admitted to the Tyne Floating Hospital, under the care of my brother, Dr. J. W. Bramwell, at the end of 1874, as a supposed case of typhoid. He presented most of the symptoms which I have described in D.'s case, the most prominent being great anæmia and debility, with irregular attacks of vomiting, diarrhœa, and pyrexia. He was treated with quinine in large doses, iron, fresh vegetables, and other remedies, but made no improvement. After three months, my brother, being completely puzzled, sent him up to me.

He was admitted under my care on March 21, 1875. It so happened that at that time, in conjunction with our late Senior House-Surgeon (my friend Dr. Beatson), I was investigating the microscopical characters of the blood in disease, and I was then (as I am now) in the habit of examining the fundus with the ophthalmoscope in all important cases admitted into my wards. I was thus led to examine the blood and the retina in this case. The blood presented exactly the same characters as it did in the case of the patient D., and there were well-marked hæmorrhages on the retinæ.

This was a combination of symptoms which I had not come across before, and I was as completely puzzled as my brother had been.

On June 10 another case, presenting all the same appearances, was admitted, and the patient died a fortnight afterwards. The post-mortem revealed fatty degeneration of the heart, liver, and kidneys, a well-marked enlargement of the thyroid gland, and a peculiar mammillated appearance of the stomach about the pyloric orifice. There was nothing, however, to account for death, and I was still as much in the dark as ever.

About this time, Dr. Beatson, while on a visit to Edinburgh, mentioned these cases to Professor Grainger Stewart, who at once recognised their nature, and referred me to an article in the *Medical Times and Gazette*, November 21, 1874, and to a letter from Dr. Wilks which appeared in the *British Medical Journal* for November 28, 1874.

I thus found that the disease had been first described many years ago by the celebrated physician of Guy's Hospital, Dr. Addison, who by-the-bye, was born at the village of Long Benton, close to Newcastle. Dr. Addison gives the following description of the disease:—

"For a long period I have from time to time met with a very remarkable form of general anæmia, occurring without any discoverable cause whatever—cases in which there had been no previous loss of blood, no exhausting diarrhœa, no chlorosis, no purpura, no renal, splenic miasmata, glandular, strumous, or malignant disease. Accordingly, in speaking of this form of anæmia in a clinical lecture, I, perhaps with little propriety, applied to it the term *idiopathic*, to distinguish it from cases in which there existed more or less evidence of some of the usual causes or concomitants of the anæmic state. The disease presented in every instance the same general character, pursued a similar course, and, with scarcely a single exception, was followed after a variable period by the same fatal result. It occurs in both sexes, generally, but not exclusively, beyond the middle period of life, and, so far as I at present know, chiefly in persons of a somewhat large and bulky frame, and with a strongly marked tendency to the formation of fat. It makes its approach in so slow and insidious a manner, that the patient can hardly fix a date to his earliest feeling of that languor which is shortly to become so extreme. The countenance gets pale, the whites of the eyes pearly; the general frame flabby rather than wasted; the pulse perhaps large, but remarkably soft and compressible, and occasionally with a slight jerk, especially under the slightest excitement; there is an increasing indisposition to exertion, with an uncomfortable feeling of faintness or breathlessness on attempting it; the heart is readily made to palpitate; the whole surface of the body presents a blanched, smooth, and waxy appearance; the lips, gums, and tongue seem bloodless; the flabbiness of the solids increases, the appetite fails, extreme languor and faintness supervene, breathlessness and palpitation being produced by the most trifling exertion or motion; some slight œdema is probably perceived about the ankles; the debility becomes extreme, the patient can no longer rise from his bed; the mind occasionally wanders, he falls into a half-torpid state, and at length expires. Nevertheless, to the very last, and after a sickness of perhaps several months' duration, the bulkiness of the general frame and the obesity often present a most striking contrast to the failure and exhaustion observable in every other respect. On examining the bodies of such patients after death, I failed to discover any organic lesion that could properly or reasonably be assigned as an adequate cause of such serious consequences."

In the *Guy's Hospital Reports*, vol. iii., Dr. Wilks describes several cases of a similar nature, and points out that the chief pathological lesion is fatty degeneration of the heart. The disease was, however, lost sight of until it was re-discovered a few years ago by a Swiss physician, Dr. Biermer, of Zürich, who named it "progressive pernicious anæmia." Dr. Biermer has materially added to our knowledge of the affection; he was the first to discover the retinal hæmorrhages which I have described.

You see, therefore, that my observations with regard to this point were anticipated; and thus it is, gentlemen, that the old saying, "There is nothing new under the sun," is often verified in medicine. Do not, however, let that be any discouragement to you, for an immense deal yet remains to be done in almost every subject. It is only, however, by laborious work, by spending much time daily in the patient study of cases in the wards, as you know is my custom, and by following out these cases in the post-mortem theatre, that you can hope, as I hope, to gain a sound knowledge of disease, and to fit yourselves for making original observations. In medicine, as in everything else, discoveries are not the result of lucky chance; and I cannot enforce this truth better than by again telling you that this idiopathic or progressive pernicious anæmia was first discovered by that type of a physician, Dr. Addison.

The remarkable alteration in the microscopical characters of the blood which I have described to you, and which was present in all my cases, has also been independently observed by Professor Eichhorst of Jena. His observations were published in the *Centralblatt Med. Wiss.*, No. 26, 1876, and are thus translated in a note which appeared at the end of a clinical lecture by Professor H. Quincke of Bern, published in the *Medical Times and Gazette*, October 14, 1876:—"He asserts that a constant alteration of the red blood corpuscles can always be detected. While a part of the latter retain their normal size, and are only distinguished by their remarkable paleness and slight tendency to form rouleaux, the remainder immediately attract attention by their diminished size. Their diameter may scarcely be a quarter that of a healthy corpuscle, while their colour is of a deeper red than normal, and when seen in profile they are found to have more or less completely lost their biconcave outline. Their size may be even so much diminished that many of them resemble small red-tinted fat-drops. The alteration here described has not been detected in anæmic and cachectic conditions other than pernicious anæmia. The white corpuscles were present in all the cases observed (seven in number) in remarkably small proportion."

This description tallies remarkably with my own. The only point in which I differ from Professor Eichhorst is that in my cases some of the red globules were apparently nucleated,(a) and many of the small red globules were much smaller than a quarter that of a healthy corpuscle. I failed to observe that they, *i.e.*, the small red globules, were of a deeper red than normal. Those small red globules which were apparently nucleated certainly had this appearance. Those small globules which were not nucleated were of a very pale yellow colour; in fact, of the same colour as the large globules. In one case which was fatal, numerous small emerald-green molecules were seen. These were probably not of much consequence, for I have noted their presence, though never in the same number, in other diseases.

In the same clinical lecture, Professor Quincke describes the appearances of the blood in his own cases. He found the red blood corpuscles diminished in number and altered in shape and size; some of them smaller than normal, "and amongst them there were a number of tiny yellowish particles." "In several cases," he says, "those finely granular masses which are sometimes lustreless and sometimes shining, and which are common in the blood of cachectic individuals, were found in great abundance, either singly or in groups. In my eighth case they were so abundant that they rendered the serum of the blood cloudy."

The case which I have described to you presents all the typical features of the disease. It is important to note that the retinal hæmorrhages only appeared after the pupils had been for some days widely dilated. The same thing occurred in my first case. Other points of interest are—firstly, the appearance of old age which the patient presented, and the alteration in the colour of the hair; secondly, the intensity of the reflex movements (in another case this was so great as to induce an incomplete pseudo-paraplegia).

So much, then, for the symptomatology. Little is known as to the causation; probably, as Professor Quincke says, "we have not to deal with a single diseased condition, but pernicious anæmia, just like anæmia in general, is the product of extremely various morbid processes, and represents the very last stage of the anæmic process" (*Medical Times and Gazette*, October 14, 1876).

Pregnancy seems to be a predisposing cause, and this explains why the disease occurs more frequently in women than in men. Of the six cases I have met with, only one was a woman; but this is accounted for by the fact that a much greater number of men than women are admitted to the medical wards of this Infirmary.

In two of my cases there had been a recent attack of yellow fever. The man whom I have shown you to-day thinks "the gas" (chlorine and hydrochloric acid fumes) was partly the cause of his complaint. I am not disposed to give any weight to this belief, for all these men blame "the gas" for any illness which may affect them. In none of my cases could a malarious origin be made out. It is probable, however, that in some cases it is the cause of the disease.

Professor Quincke separates cases of the disease into two divisions. In the first he places all those cases in which there is defective formation of new corpuscles, the causes of which are chronic inanition, atrophy of the mucous membranes, and the disturbance of nutrition in the blood-forming organs. In the second he includes all those cases in which there is increased destruction of the elements of the blood. Examples of this class are, he says, perhaps those in which there is an increased amount of iron in the liver (*Medical Times and Gazette*, October 14, 1876, page 429).

In my next lecture I shall speak to you of the pathology, diagnosis, and treatment.

Note.—The subject of this lecture was shown to the members of the Northumberland and Durham Medical Society on December 9, 1875, and the condition of the blood described.

(a) The apparent nucleation was no doubt due to the separation of the hæmoglobin from the stroma, as described by Messrs. G. Mackern and Henry Davy in the *Lancet* for May 5, 1877.

HUNTERIAN LECTURES FOR 1877.

ON DEFECTS OF VISION WHICH ARE REMEDIABLE BY OPTICAL APPLIANCES.

DELIVERED AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

By ROBERT BRUDENELL CARTER, F.R.C.S.,
Late Professor of Surgery and Pathology to the College; and Ophthalmic Surgeon to St. George's Hospital.

LECTURE VI.—ASTHENOPIA.

(*Continued from page* 300.)

WHEN the original examination of the patient affords no reason to suspect strain of accommodation as a cause of the asthenopia, attention must next be directed to the convergence; and here we enter upon ground which is no longer secure. Von Graefe was the first to point out that, in a certain number of cases, asthenopia is dependent upon inability to main the necessary convergence, instead of upon inability to maintain the necessary accommodation; and he invented the phrase "insufficiency of the internal recti," to fulfil the double purpose of describing the condition and of conveying his hypothesis about its nature. He appears to have meant, by insufficiency, a state of weakness which bears no resemblance to paralysis or to paresis, and which is attended by no paralytic symptoms, but which renders the affected muscles unable to discharge continuously their most important natural function. In the majority of the cases, the internal recti, when tried by any test which would be applicable to other muscles, are found to be in full possession of their powers. The range of adduction of each eye, in correspondence with the abduction of its fellow, may be complete, and may cover a much greater extent of movement than any which can possibly be called for in convergence for binocular vision. The binocular near-point may be as close to the eyes as in the normal state, and the power of overcoming prisms by adduction may leave nothing to be desired; but, notwithstanding, when the maintenance of a given convergence is difficult or impossible, we are asked to believe that "muscular insufficiency" is the ordinary cause of the trouble. We are even told by some writers that this mysterious affection is one of "very common occurrence."

A man of commanding and fertile intellect, like Von Graefe, can hardly fail at times to suggest hypotheses which will not bear the test of examination, and I have little doubt that, if his life had been spared, he would long ago have repudiated this one. Many of his pupils, however—some, perhaps, from a laudable veneration for the memory of their master, others from a less laudable conviction that the chief use of a great philosopher is to save other people the labour of thinking,—have continued to repeat his words as if they were necessarily the exponents of verity; and hence the notion of insufficiency of the interni has taken deep root in the literature of ophthalmology. It has done so the more effectually, because Von Graefe devised two tests of insufficiency, according to which this condition may be found in almost every case of myopia in which it is looked for. His successors, when they have met with apparent muscular asthenopia, have applied Von Graefe's tests, and the results which he declared to be characteristic of insufficiency have been produced. The diagnosis has then been considered to be complete, and the real value of the tests themselves, until quite recently, has remained unquestioned.

Von Graefe's first test for insufficiency was to direct the patient to look steadily at some object in the median line, at a distance of six or eight inches from the eyes. A screen, or the hand of the surgeon, was then interposed in such a manner as to conceal the object from one eye. If the eye so excluded from vision retained its direction unchanged, the interni were supposed to be normal; but if the covered eye deviated outwards, the interni were supposed to be insufficient. In order to ascertain the degree of the insufficiency, another and more delicate test was next to be applied.

In this more delicate test, the object of vision is a small black dot, bisected by a vertical line. A card thus marked is fixed in the median line, at a distance of eight or ten inches from the eyes, and the patient is directed to look at it steadily. A prism of ten or twelve degrees, with its base either upwards or downwards, is then placed before one eye; and, as the power of the superior or inferior rectus to overcome double vision is very limited, this prism necessarily produces a vertical diplopia. The patient will therefore see two dots, one above the other. If the original convergence for the object is accurately maintained, the duplication of the vertical line will only cause it to appear elongated; and the two dots will be seen one above the other on the same line. If, on the contrary, the convergence is not maintained, the patient will see two lines with a dot upon each; and, as the diplopia is a consequence of relative divergence of the optic axes, the double images will be crossed, and the extent of the divergence will determine the distance between them. A second prism, with its base inwards, will produce approximation of the images; and the prism which brings them back to the same vertical line is assumed to be the measure of the insufficiency, as it certainly is of the relative divergence. In other words, the assumed test of "sufficiency" of the interni is that they shall be able to maintain an unchanged convergence when one eye is excluded from vision of a near object to which both were originally directed; and that they shall also maintain an unchanged convergence notwithstanding an artificially produced vertical diplopia. When the requirements of these tests are not fulfilled, the existence of "insufficiency" has been taken for granted; and it has also been thought that the best method of treatment for this insufficiency is by tenotomy of one or both of the external recti. It has been assumed, generally speaking, that the insufficiency is relative rather than absolute; that is, that in any given case the strength of the interni did not preponderate over that of the externi in a sufficient degree to allow of the maintenance of convergence, and that division of the externi, by weakening them, would redress the balance of power. In this assumption, another is manifestly involved, namely, that both the external and internal recti muscles live in a state of continual tension, and that the externi, even when not receiving any volitional impulse, present an impediment to the free performance of ocular adduction.

In dealing with this piling up of hypothesis upon hypothesis, this continued postulation of something to explain something else, the chief difficulty is to select among the many objections which oppose themselves to the acceptance of Von Graefe's doctrine. In my own case, this difficulty is enhanced by the consideration that I have never seen any non-squinting asthenopic patient who even seemed to require tenotomy of the externi; so that my knowledge of the operation is practically limited to cases in which it has been done with unfortunate effect by some one else. As far as I am aware, there is no other instance in which abductor muscles have even been supposed to present an impediment to the ordinary range of movement of unparalysed adductors; and there is no other instance in which it has been proposed to divide an abductor or an extensor muscle as a means of relieving the weakness of its assumed antagonist. The affection called "scrivener's palsy" may by a trifling stretch of imagination be described as an "insufficiency" of the flexors of the thumb and fingers; but I have never heard that division of the extensors has been suggested as a possible means of treatment. As soon as the ordinary range of movement of any set of muscles is exceeded, their antagonists come into play as inhibitory structures; but within the ordinary range the antagonists exert no such influence. Acrobats of the class called contortionists differ from untrained persons in the degree in which the opponency of antagonistic muscles has been overcome by stretching; but no such stretching is needed until the limits of customary movement are overpassed. An acrobat, who can allow his feet to separate until his perineum touches the ground, has overcome by exercise the natural rigidity of the adductor muscles of his thighs; and, in like manner, a person who could perform adduction of the eyes until the corneæ became invisible, would have overcome the natural rigidity of the externi. It is clear, however, from all analogy, that the natural rigidity of the externi does not come into play, as an inhibitory power, within the limits of the ordinary movements effected by the interni; that is, for example, within the limits of the customary adduction of either eye in looking to the right or to the left with both. The assumption that volitional visual convergence can be impeded by the preponderating strength of the externi is likewise opposed to all analogy; for there is no other instance in which the strength of a muscle interferes with the free use of its antagonist. We never hear of an athlete whose flexors are so strong that he cannot extend his limbs, or whose extensors are so strong that he cannot flex his limbs. Even the showman's little dog, whose tail was so tightly curled that he could not put his hind legs to the ground, would be a less strange phenomenon. Natural convergence, if impeded by the externi at all, can only be impeded by some condition analogous to spasm; and liability to spasm is characteristic of weak muscles rather than of strong ones.

My attention was first called to the relation between the convergence function and sustained vision by the writings of Dr. Scheffler; and, in the *Practitioner* for 1874, I published some papers on the hygiene of vision which indicated dissent from the generally accepted view. In consequence of these papers, Dr. Theobald, of Baltimore, was good enough to send me a copy of an essay of his own, which had appeared in the American *Monthly Journal of the Medical Sciences* for the preceding January, and in which he discussed the value of Von Graefe's tests, and showed, I think, conclusively, that they would not bear the interpretation which had been placed upon them. Still later, Dr. Krenchel and Dr. Hansen, both of Copenhagen, have written very lucidly upon the question of insufficiency; and I think it must now be conceded that Von Graefe's fabric of postulates has been overturned. The difficulties in the way of sustained convergence, whatever they may be, are certainly not due to "insufficiency of the interni," and cannot be rationally treated by tenotomy of the antagonists.

We have seen already that the purpose of ocular convergence is the fusion of the two retinal images into a single sensory impression; and hence that single vision with the two eyes, and not clear vision, is the proper stimulus to the performance of the convergence function. To afford clear vision is the office of the accommodation; and, since accommodation and convergence are normally exercised in corresponding degrees, a certain correlation, probably in part structural and in part acquired, usually exists between them. We have seen also that this correlation between accommodation and convergence is more or less elastic—that is, that the accommodation may be varied while the convergence remains the same, and that the convergence may be varied while the accommodation remains the same; the extent of this relative play between the two functions being different in different persons, so that the accommodation and the convergence are sometimes more and sometimes less closely united. The performance of fusion, however, requires exact convergence; and the smallest deviation of the visual lines is followed by the appearance of double images. In Von Graefe's first test, the exclusion of one eye from perception of the object prevents the possibility of fusion, and excludes the demand for fusion from operation; so that the test only shows what degree of convergence will continue to attach itself, in the case of the individual under examination, to the amount of accommodation which the seeing eye is at the moment exerting. If, as commonly happens, the patient is myopic, and the object is not very much within his far-point, he will require very little accommodation, and this little will only call for a correspondingly small amount of convergence; so that the visual lines will naturally diverge from the position in which the requirements of fusion had originally placed them, and will assume a position which is determined by the requirements of accommodation alone, without the aid of fusion. There is here no question of strength or weakness, of sufficiency or insufficiency, but there is simply a diminution of convergence consequent upon a diminution of the nerve stimulus by which the convergence effort is called forth. If the patient is not myopic, but if his accommodation and convergence faculties are only loosely united, having a large amount of relative play, precisely the same result will be produced. The withdrawal of the fusion stimulus will leave the interni at liberty to assume a position of smaller effort; and, like all other muscles, they will undergo relaxation when there is nothing to call them into action. It is only when the relation between accommodation and convergence is close and intimate, so that the two functions are inseparably united, that the test would establish "sufficiency." It is only in such a case that the withdrawal of fusion would leave the position of the visual axes still held unchanged by the accommodation; and this result would follow whether the interni were strong or weak. The test points to the intimacy of the relation between accommodation and convergence, and it points to nothing else.

The second of the two tests differs but little from the first. The immediate stimulus to convergence being the desire for single vision, this desire itself appears to arise from the confusion produced by double images of surrounding objects. Von Graefe's test-object, however, is of such a nature that double images produce no confusion, because it is quite as natural to see two dots upon a piece of card as to see one only; and hence the fusion stimulus to convergence is wanting. As in the former test, the degree of convergence which follows the removal of the desire for fusion is solely determined by the accommodation; and the test only shows the degree of convergence which the eyes assume, as the result of being accommodated for a given distance. In every case of myopia the tendency of the visual axes would be towards divergence, an in every case of hypermetropia the tendency would be toward convergence, as soon as the control exercised by the deman for fusion was withdrawn.

The ordinary clinical history of a case of so-called insuff ciency of the interni is that the patient is myopic, say to fi dioptrics, which would place the far-point at eight Englis inches. At this distance, or even a little within it, he is unab to read continuously, and the effort to do so is attended by variou distressing symptoms. In one case, which I have formerly pul lished, these symptoms were of such a kind as to lead to a di gnosis of obscure intracranial disease; and the patient, wh wanted nothing but a pair of spectacles, was sent to Austral and back in order to afford rest to his brain by a long voyag In such an instance, the effort to read means an effort to mainta convergence to eight inches in absolute repose of the accor modation. To an emmetrope this would be impossible, eve for a few minutes; as may be proved by any young emm tropic person who will put on convex spectacles of five dio trics, and will attempt to read in them. The strain and tensi of the eyes will soon become unbearable; and it may shown, by a simple experiment, that this strain is not due to t convergence effort *per se*, but solely to the fact that the co vergence effort is required during repose of the accommodatio If we combine with the convex lenses prisms with the bases inwards, of sufficient power to rest the convergen as well as the accommodation, reading immediately becom easy. If we then give the same person concave spectacl such that he is able to overcome them by accommodation, a bid him look at the horizon, the strain upon his eyes will so become unbearable. He will be exerting a good deal of accommodation to overcome the glasses, but he will be exerti no convergence, because the distance of the object of visi requires that, for the sake of fusion, he should keep his visu lines parallel. We may relieve the strain instantly by placi before the concave lenses prisms with their bases outward which will call for a convergence effort in addition to the acco modatiou effort; so that we create strain by causing either fun tion to be performed singly, and we relieve strain either placing both at rest or by calling both into play. This appl chiefly to emmetropic persons; for, in the myopic, habit a necessity cause the functions of accommodation and conv gence to be less strictly dependent upon each other; and t patient will be able, especially for the sake of fusion, to co verge to some extent without accommodating, although pr bably not to the full extent which the state of his refracti would require. If we give him concave lenses of three dio trics, according to the rule which I have already laid down speaking of myopia, they will remove his far-point to twel inches; and then, in order to read at twelve or fifteen inches, will have to exert both accommodation and convergence, a both, perhaps, in an approximately equal degree. If distr should continue, we have next to ascertain which of the t functions is working in excess as compared with the othe whether the accommodation or the convergence; and simplest method of investigation is to try whether diminishi or increasing the convergence will afford relief. We may this either by Risley's optometer, or by a spectacle-frame w double clips. We let the patient read with the lenses of th dioptrics, at the stated distance, until the eyes begin to fatigue; and then we add to the lenses prisms, say of f degrees, with their bases inwards, so as to diminish the conv gence. A very few minutes will show whether these pris so placed, facilitate reading; and, if they do, we know t the patient was previously exerting too much convergence the amount of his accommodation. If the prisms incre the difficulty instead of diminishing it, they should be tur so as to bring their bases outwards, when they will requir greater degree of convergence than was originally necessa If they give relief in this new position, we learn that with concave lenses alone the eyes were exercising too m accommodatiou for the degree of their convergence.

Under either of the foregoing conditions, it was once practice to use combinations of concave and prismatic glas but of late years, whenever the range of accommodation sufficient, I have adopted a more simple method. I assu convergence to fifteen inches to be an invariable requirem and modify the concave lenses in such a way that the dem for accommodation shall be such as can most easily be c bined with this invariable convergence. If the prism shows that the patient is exerting too much convergence the degree of his accommodation, I increase the demand accommodation by strengthening his concave lenses; and the prisms show that his convergence is too little for

accommodation, I diminish the accommodation to the level of the convergence requirement by weakening the concave lenses. Thus, if the patient in the case supposed were to read more easily with the addition to his lenses of prisms with their bases inwards—that is, with less convergence effort—I should redress the balance, not by diminishing the convergence effort, but by increasing the accommodation effort to keep pace with it: I should give him concaves of three dioptrics and a half, or of four dioptrics, or should even wholly neutralise his myopia; and the result would be, as a general rule, that the convergence effort to fifteen inches, which was irksome when combined with a less degree of accommodation effort, would become easy when the accommodation effort was increased. In like manner, if the patient was relieved by prisms with their bases outwards—that is, by increased convergence effort—I should say, "With this amount of accommodation he wants more convergence in order to bring the two functions into harmony." Hence, in order to maintain the convergence unchanged, he must be called upon for less accommodation, and his concave lenses must be reduced in strength. Lenses of two dioptrics and a half would render the accommodation almost passive for fifteen inches; and the patient might be perfectly well able to converge to fifteen inches with passive accommodation, although the effort of convergence to eight inches was more than he could continuously accomplish.

I assume, therefore, that insufficiency of the interni is a condition which has no real existence, that all unparalysed interni are strong enough to maintain convergence to fifteen inches, and that the difficulty sometimes experienced depends either upon an excessive convergence demand, as in a myopia which brings the far-point nearer than to fifteen inches, or upon a disruption of harmony between the accommodation effort and the convergence effort. In the former case, concave lenses which put back the reading distance to fifteen inches are all that will be required; and in the latter, taking the convergence distance as a fixed point, it is only necessary to vary the accommodation demand by lenses until the harmony between the two functions is restored. By this means we may in most cases relinquish the use of prismatic spectacles, and may cure our patients by glasses which are everywhere procurable.

Dr. Hansen has pointed out that, besides these cases of somewhat high degrees of myopia, we may have apparent insufficiency in other conditions. In emmetropia, in hypermetropia, and in minor degrees of myopia, we find a few persons who preserve the parallelism of their eyes in testing equilibrium for distance, but in whom an excluded eye (as by Von Graefe's first test) becomes divergent at reading distance. If the divergence is small, it means that the relative play of accommodation and convergence is large; so that, fusion being suspended, convergence cannot be maintained unchanged by accommodation alone. If the divergence is large, it means that the normal relation between accommodation and convergence does not exist; so that, although fusion produces convergence, accommodation without fusion cannot do so. In such cases the severance between accommodation and convergence is due to congenital or acquired central defect. He describes yet another form, in which there is the normal relation between accommodation and convergence, with absence of fusion. In these cases, which are also due to central defect, he describes as symptoms an exceedingly defective endurance alternating with diplopia, a small divergence at reading distance, and feeble adduction and abduction. Since I have been made acquainted with Dr. Hansen's views, I have been on the watch for examples of these two kinds of central defect, but I have not at present clearly identified either of them. Dr. Hansen's description of them is exceedingly graphic, and he speaks favourably of prismatic glasses as means of affording relief.

Putting aside these instances of central defect, which are few in number, and which certainly require a more careful examination than they have yet received, our plan of dealing with a case of asthenopia should be, in the first instance, to determine and to correct any obvious ametropia or astigmatism, even if only of small degree. If the symptoms are still unrelieved, we have next to consider whether accommodation and convergence stand in their normal relations to each other; and, if not, how these relations may be favourably modified. Wherever there is sufficient range of accommodation, the change should be made by altering the accommodation to meet an invariable convergence requirement—stronger convex or weaker concave lenses calling for less accommodation; stronger concave or weaker convex lenses for more. Sometimes, when the range of accommodation is very limited, this simple plan must be laid aside, and the convergence must be modified to suit the accommodation. Prisms with their bases inwards diminish convergence; prisms with their bases outwards increase it. When we employ prisms with their bases inwards to diminish convergence effort, there is always some liability to weaken the interni by diminished use; and in such cases it is generally prudent to use also prisms with their bases outwards, for a few minutes at a time and at regular periods, so as to strengthen the convergence muscles as if by gymnastic exercise. A convenient measure of the strength of the interni, by which they can be tested at any time, is furnished by their power to overcome the artificial diplopia produced by prisms with their bases outwards, when the eyes are directed to a moderately distant object.

In asthenopia of great severity or of long standing, even when we have corrected every discoverable ocular defect, and have brought the accommodation effort and the convergence effort into harmony, we shall sometimes find that the use of the eyes is as painful or difficult as before. For a time this will be so in most cases; and it is well to warn patients that their glasses call upon the eyes to work under new conditions, which, although better than those which they supersede, may yet be irksome so long as they are new. We must not, therefore, expect immediate relief as a rule; and it is best to insist upon diligent use of the prescribed glasses for at least a fortnight, before we attempt to form a definite opinion about their probable efficacy. After the lapse of that time, if the patient is still complaining, and if we are sure that we have placed the ocular mechanism under the most favourable attainable conditions, we have next to develope the powers of this mechanism by carefully regulated exercise. We often have to deal with the effects of that most pernicious of all recommendations, the recommendation to "rest the eyes"; and, consequently, with organs of which the whole nervo-muscular apparatus has been brought by disuse into a state at once of debility and of excitability. Such conditions can only be relieved by careful strengthening of the weakened muscles; and for this purpose the employment of the eyes must be so regulated as not to impede nutrition by occasioning fatigue. The indications for the fulfilment of the required conditions were first clearly laid down by Dr. Ezra Dyer, of Pittsburgh, whose rules for this purpose have proved so useful, and their value has been so thoroughly established by experience, that, in the United States, the process is commonly called "Dyerising." Dr. Dyer first corrects any hypermetropia or astigmatism, and generally prescribes such glasses as will place the eyes under the most favourable optical conditions. The remainder of his instructions I will give in his own words, which, on this side of the Atlantic, are not so well known as they deserve to be:—

"The exercise of the muscles is best accomplished by reading. The patient is directed to select a book of good type, but not too absorbing, and to read regularly with the prescribed glasses three times a day. He must determine by trial the number of minutes he can read without discomfort. He may find this to be thirty seconds, five minutes, ten minutes, or even more. He must, however, find the initial point. Starting at this point, he must read regularly, and always with the glasses. The first reading must not be until one half-hour after breakfast, the second at noon, the third finished before sundown. The periods of reading must be regularly increased from day to day. No other use of the eyes should be allowed. In cases where discomfort occurs in less than five minutes, the increase should not be more than one half-minute per day until ten minutes are reached. In other cases the patient may increase one minute each day until he can read thirty minutes three times a day without pain. If this can only be done with pain, the patient must be encouraged to persist, notwithstanding the pain; the surgeon, however, exercising his judgment in not pushing the treatment too rapidly. Should the pain continue from one period to the next, it is evidence that he has gone beyond the maximum of his ability, and that he should fall back to a period at which he can read without discomfort, should regard that as a new point of departure, and proceed as before. As said above, reading is the best exercise; but it frequently happens that the patient is very desirous to write or sew. This may be attempted when thirty minutes has been reached in the middle period. After the exercise has begun by reading ten minutes, sewing or writing may be tried for ten minutes, and the period finished by reading. From this point I permit an increase of two minutes a day, and a relative increase in the time of writing. This may be gradually introduced into the morning and evening period. I do not consider the treatment completed until an hour and a half is reached."

"I have found it of great assistance to explain the *rationale* of the treatment to the patient. These cases rarely occurring except in the educated classes, they readily understand their nature, and are anxious to assist the surgeon. I tell them that, in reading, pure muscular action is required as much as in lifting a weight; that, through want of use, debility, or some derangement of the system, they have lost the power to exert the reading muscle without fatigue; that they can strengthen this muscle and increase its power of endurance by regular, constant, and systematic exercises, as well as with any other muscle in the body. The course of treatment serves to distract the mind of the patient, and restores his confidence in his ability to use his eyes. He has become discouraged; he has had the horror of blindness carefully instilled by friends, and sometimes by well-meaning physicians, who, not feeling quite sure of their ground, err on the safe side, and prescribe entire rest. In these cases 'the safe side' is the wrong side. When the glasses are procured, and the patient is assured that there is no absolute disease of the eye as revealed by the ophthalmoscope, he commences his course of treatment with hope and zeal. The mere fact that he is told that he *must* use his eyes gives him, to a certain extent, the power to do so."

Dr. Dyer elsewhere lays great stress upon the importance of restraining impatience when improvement is beginning to be declared. The patient who finds that he can read for ten minutes without distress is very likely to go on for twenty minutes, or until pain warns him to stop; but to do this is to invite relapse. With an increase of only one minute a day, the duration of the treatment would be about three months: and it is better to submit quietly to this period of modified use, and of self-restraint, than to lose time at the beginning by fruitless endeavours to hasten a process which depends essentially upon the gradual improvement of muscular nutrition.

In many obstinate cases of asthenopia we shall find some derangement of the health, or some need for better regulation of the regimen and habits. Under such circumstances, the ophthalmic surgeon, if he should be so unfortunate as to be in the narrow sense a specialist, must call to his aid the advice of the general physician; and must not expect to render unnecessary, by the employment of spectacles, all the other resources of the healing art. When debility of the ciliary muscles and of the interni is a consequence of debility of a more general character, the condition of the eyes may, indeed, often be greatly improved by treatment specially directed to them; but complete functional restoration is hardly to be hoped for, except in conjunction with a correspouding degree of improvement in the state of the organism as a whole.

Effects of Working under Increased Atmospheric Pressure.—Dr. Lehwess read a paper at the St. Petersburg Medical Society, giving an account of these observed during the sinking of the *caissons* for a new bridge. The pressure varied between one and two atmospheres, and only exceptionally attained three atmospheres, the workmen passing two periods of six hours each daily in the *caissons*. From September, 1876, to March, 1877, there were employed 160 men in this manner; and of these there were treated in the outdoor dispensary 51 for so-called rheumatism, 40 for bronchial catarrh, 32 for so-called otitis, and 34 for various other affections. Into the hospital 38 were received for such causes as fever, febrile diarrhœa, injuries, etc. With respect to the so-called otitis, it is to be observed that the men frequently complained of pain in the ears on leaving or entering the *caisson*. The pains in the joints called "rheumatic" came on in from an hour and a half to two hours after leaving the *caisson*, and disappeared again on their return to it. They were usually only moderate, requiring about three days' treatment; but in some cases they were very severe. In one case, every joint of the body was affected—even the vertebral articulations. The workmen who had been only employed a short time were especially the subjects of these pains. No fever nor any trace of swelling being present, rheumatism is obviously a wrong name. Dr. Lehwess explains these pains by the occurrence of dilatation of the articular vessels after having been compressed in the *caissons*. Salicylic acid given in ten-grain doses every two hours proved very effectual. In three cases there were temporary symptoms of cerebral hyperæmia. Neither phthisis, heart disease, nor hæmorrhages of any kind were met with; and the use of alcohol did not give rise to any obvious mischief. When the men became well accustomed to the work the above-mentioned inconveniences ceased to be felt.—*Petersburg Med. Woch*, September 1.

ORIGINAL COMMUNICATIONS.

TWO CASES OF IDIOPATHIC TETANUS WITH CLINICAL REMARKS.

By C. HANDFIELD JONES, M.B. Cantab., F.R.S.,
Physician to St. Mary's Hospital.

Case 1.—*Non-traumatic Tetanus—Improvement under Physostigm —Death from Engorgement of Lungs.*

X. Y., female, aged thirteen, seen with Dr. Brisbane, January She was suffering from well-marked idiopathic tetanus, th first symptoms of which appeared about a month ago, con sisting in contraction of the neck and jaw muscles. Ther has been no wound or injury, but she has had wet feet. Fac is pale; shoulders raised; vertebral column arched backward The muscles of the neck and jaw are rigid, as well as those o thighs, but not those of calves or arms. At times she ha paroxysms in which the arms are contracted, as it seems clon cally, and the body is arched as in opisthotonos. In thes attacks she is apt to roll out of bed. She cannot open he mouth at present, but she manages to take a good deal o liquid food. Pulse 120, distinct; temperature 98°; it ha been taken three or four times before, but has never exceede 100°. Has been taking K. Br. and tinct. bellad. hitherto. It wa agreed to continue this, and to give besides ext. physostig matos liquid. gr. $\frac{1}{12}$ subcutan. more or less frequently. Thi treatment was markedly beneficial, lessened the spasms ver much, and great hopes were entertained that she would recover but the lungs became engorged and œdematous, and from thi she died.

Case 2.—*Non-traumatic Tetanus—High Rise of Temperatu from Warm Bath during Malady—No such Effect durin Convalescence—Use of Physostigma—Recovery.*

E. J. M., aged thirteen, admitted May 8, 1877. Says he ha always been fairly healthy, but has suffered from his teeth fo a long time, especially lately, during the last fifteen days. Hi mouth and tongue were then ulcerated, but do not appear t be so at present. His front teeth are large and crowded, an cause pain now. Twelve days ago he first complained of stif ness in the back, and two days later had a fit or attack o spasms, which has repeatedly occurred ever since. Pain i the back he affirms was the first symptom, not trismus. Hi body has often been arched. Has a peculiar expression o face, and grins now and then. Pressure on dorsal spine whe pain is felt causes an opisthotonic spasm. Neck is stiff. Mout cannot be opened. He cannot turn in bed. Chest moves ver little in breathing; an expiratory grunt is made every fe minutes. He can move his limbs, but the legs get stiff no and then. He is intelligent, and answers questions clearly Has never lost consciousness. Pulse 66, weak, soft; ten perature 99·2°; respirations 28. Face of a dull earthy tin Has taken nothing but cold tea. Bowels have been opened b enema, and a good deal of hard, lumpy fæces, free from smel have been brought away. Heart and lungs acting normally Potass. bromidi gr. xx., aq. ʒj., 4tis horis. S. diet.

May 9.—Pulse 74, distinct. Swallows fairly. Slept from to 10 p.m., but after that was calling out all night. Ha every half-hour, or oftener, paroxysms of opisthotonos; a present they occur every few minutes. Morph.-muriatis gr. atropia gr. $\frac{1}{60}$, glycerine ℥j., aq. ℥ix., subcut., bis die. A 8 p.m. a warm electric bath (at 98°) was given, the continuou current passing through the water. Attacks of spasm occurre frequently while he was in the bath. The temperature ro to 103·6° a quarter of an hour after the bath, and at midnig was 105·2°, pulse being 160. A cold pack was administere from 12.30 a.m. to 1.30 a.m. of the 10th, and at its close temp rature was 101·7°. A good deal of stimulant was given in th night—as much as eight ounces of brandy. Ordered ext. phy sostigmatos liquidi gr. $\frac{1}{15}$, aq. ℥x., to be given subcutaneous two or three times a day on 10th.

11th.—Pulse 104, distinct, soft; temperature 98·6°. H had three injections of physostigma, and five nutrient enemat Has been lying asleep most of the morning. A spasm occu every time an attempt is made to feed him.

12th.—Passed a very restless night; had a good many spasm but only two have occurred to day. Swallows better; ate egg. Pulse 78, distinct, rather weak.

14th.—Lies much quieter, and has had fewer spasms.

15th.—Says he is better, and seems so. Night was quiet; had no spasms. Moves his limbs naturally. Appetite for eg good.

16th.—Had severe spasms last evening—four in a short space of time; but after an injection of gr. $\frac{1}{2}$ of physostigma had a quiet night, and no more spasms. Has eaten nine eggs in last twenty-four hours.

19th.—Doing quite well; eats stewed eels.

21st.—Seems to be doing well, but his abdomen as he lies on his back is quite hard and boardy, and he can't open his mouth more than half an inch. No spasms. Has had only one injection daily last two days. Sleeps three hours at a time. Appetite voracious. Lies very quiet. Urine pale, watery, not albuminous, specific gravity 1014.

22nd.—The hard, board-like rigidity of the abdominal wall continues, and the back and neck also are rigid, but the arms and legs are mobile.

24th.—Abdominal muscles less rigid, and he can move his head from side to side freely. Ext. physostig. gr. $\frac{1}{10}$, aq. ℥ss., ter die.

31st.—Doing well; the belly does not feel so hard; he can sit up in bed, and open his mouth wider.

June 4.—Is quite unable to stand; when attempting to walk, supported on each side, his feet are pointed with the toes downwards and the heels drawn up. When, however, he is lying on his back he can exert considerable force in both the flexors and extensors of the legs.

11th.—Doing well. Capiat ol. morrhuæ ℥ij. bis die, loco physostigmat.

15th.—Is saucy and well, but looks pale; can walk now. He was put in a bath this evening, just such as he had on May 10; he struggled in it a good deal; was in fifteen minutes. Before bath his temperature was 99°; just after it was 100·4°, as soon as he got into bed. The temperature was taken twice subsequently, during the night about 1 a.m., and again later, but was never above 100·4.

He was quite well on 21st, and went out soon after.

Mr. H. Hayward examined his mouth while he was in the hospital, and found no other disease except considerable crowding of the teeth.

Temperature Table.

Date.	Morning.	Evening.
May 8 . . .	99·4°	98°

June 15.—Temperature just before bath, 99°
,, ,, after ,, 100·4

The opinion is held by some high authorities that severe tetanus is necessarily a febrile disorder, inasmuch as the chemical action occurring in the muscles during contraction is not, as in the normally acting organs, expended in the production of movement, and therefore appears as heat. Supposing the formula to hold good, that chemical action = heat developed + mechanical work performed, it is plain that if the latter be *nil*, the former must be increased. However, that mechanical work is not performed when free movement is prevented by opposing force (as of antagonist muscles) seems to be very questionable. Hermann, indeed, states (p. 266) that "during tetanus a muscle performs no external mechanical work, as no weight is lifted by it; the weight already lifted to a certain height being merely maintained at that height." Yet surely keeping a weight from falling after it has been raised by muscular power implies a continued exertion of that power. He proceeds to say—"As the chemical changes which go on in a muscle which is in a state of tetanus are greater in amount than in a muscle at rest, we must assume that a tetanised muscle actually does perform work, the muscle losing and immediately thereafter regaining the whole of its tension during the extremely short intervals between two successive stimulations; this sudden regain of tension must, whenever it occurs, lead to a development of heat."

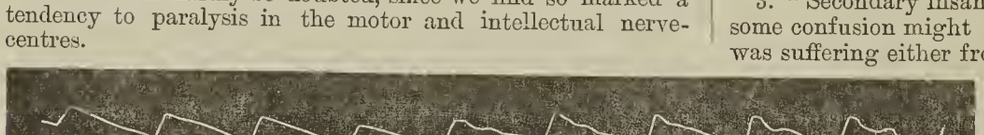
Admitting the above, I should imagine that a tetanised muscle would be in much the same situation as a muscle in ordinary contraction, *quâ* generation of heat. Heat is produced during ordinary contraction, and probably to a somewhat greater amount during tetanic, but not to the extent characteristic of severe pyrexia. Such temperatures may often occur in tetanus, but are no essential part of the process, and have their origin, not in the muscular contractions *per se*, but in paralysis of heat-regulating nerve-centres. Clinical observation seems to confirm this view. The lad E. J. M. had, even during the height of his malady, a temperature barely above the upper normal limit. Nearly the same may be said of Case 2, where the temperature had never exceeded 100°. In one case that recovered, recorded by Senator, the temperature varied from 98·6° to 110·7°; while in another, which proved fatal about the eleventh day, the temperature was almost the same during the tetanic period as during six days previous of wound fever. In a fatal case related by Nothnagel, the temperature was only 101·7°. Dr. E. Long Fox states (see *Medical Times and Gazette*, vol. i. 1870, page 601) that in tetanus the temperature may persist at or very little above the normal point until the fatal close of the disease approaches. This evidence is perhaps sufficient to show that tetanus is not essentially a pyrexial disorder, though it often becomes so.

The circumstance that all the contractions are attended with intense pain, with cramp, as Sir T. Watson writes, shows plainly that the muscular action is of an unnatural kind, for in no voluntary or reflex acts is any such sensation experienced. The sense of fatigue is a different matter, and so is the pain of myalgia, which is by no means confined to the periods of contraction.

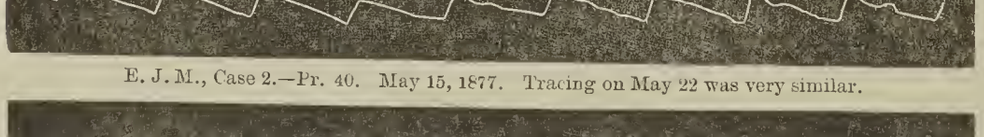
The occurrence of tetanus without any peripheral irritation or with only trifling, contrasted with its absence in states of severe neuralgia or other sensory irritation, indicates very strongly that the centric change is much more important than the peripheral. The visible part of this change consists in hyperæmic distension of the vessels of the cord, and effusion of their contents—of the liquid more than of the corpuscular. The relation of these vascular changes to the muscular spasms is not, I think, doubtful. Dr. Maudsley, noticing such lesions as the result of strychnia-poisoning, remarks very truly that the congestion is plainly a secondary result of the intense morbid activity of the directly poisoned nervous element. Its absence in some cases proves, I think, that this is so. The same view is quite applicable to tetanus and chorea. The hyperæmias and exudations in these maladies seem to me only illustrations of the general law that the activity of a tissue, and of the vessels which supply that tissue, is always in inverse ratio to each other. If the vessels—*i.e.*, their walls—are active they contract, and the tissue becomes anæmic and quiescent. If the tissue is active the vessels dilate and admit more blood, which ministers to the wants of the working tissue. If the activity of the tissue be excessive the hyperæmia becomes excessive too, and the small vessels give way. The rule seems to be that the capillaries follow the lead of the arteries, and lose their retentivity in proportion as the arteries lose their contractility. Hence the blood, either in its entirety or in its liquid part, is effused into the interstices or among the elements of the tissue. The relation of alternating activity between the tissue and the vessels is no doubt mediated by the vasal nerves and those supplying the tissue, which, as in the limbs, are often derived from the same trunk. When the nerve-force is, so to speak, absorbed by the tissue, this force in the case of muscles being converted into motor force, the arterial muscles are left in a *minus* state, and so relax.

The invisible part of the change cannot be described in detail, inasmuch as we have no opportunity of observing the cells during their period of action, and can by no means conclude that their post-mortem appearance truly represents their living. We have, however, good ground for believing that this change does not consist in a true increase of functional power in the cord, but rather in a loss of its faculty of remaining at rest. What I wrote four years ago with respect to paralysis agitans (see *British Medical Journal*, vol. i. 1873, page 248) is quite applicable to tetanus:—"In the construction of a motor nerve-centre it is requisite to create an apparatus which shall be always ready to evolve force, but which shall not do so spontaneously—not without the application of a stimulus of some kind or other, physical or mental. Now, the peculiarity of nerve-cells is that they possess these two qualities: they prepare material which, by undergoing oxidation or in some other way, generates force; and yet they can prevent this material from so acting, although blood is circulating all round it charged with oxygen. The cells of other organs, as of the kidney, the testes, and the liver, seem to be acting constantly; the only condition requisite for their action is that they should receive a due supply of blood. But the

motor nerve-cells may lie for hours ready to act energetically, and yet scarce act at all. Now, in states of spasm this property of the nerve-cell is lost or much impaired. It still generates force; it does so continuously, but not in obedience to appropriate stimuli. As long as blood is supplied, it works on blindly, draining away the nerve-force from other centres, till at last the heart is exhausted, and circulation ceases. If it should be thought that the action of the nerve-cells of the corpora striata and anterior spinal horns is regulated by those of the convolutions, which keep the former quiescent when this is desirable, yet the question recurs, How is the quiescence or regulation of these superior nerve-cells obtained? How is it that, while fully supplied with healthy blood, they can refrain or not from functioning? If we must refer this to a constant operation of the mind, how is it that the muscles are at rest during sleep and insensibility from narcosis or injury? Most of us, however, I suppose, hold that quiescence of the intellectual and volitional centres coincides with the same state of the motor centres, and *vice versâ:* so that more need not be said on this point. In states of cerebral excitement, mania, and delirium, this faculty of quiescence is lost in the cells of the convolutions, and in great measure in those of the motor centres too; and here also the pathological change is commonly induced by causes which depress and exhaust nervous energy." In their valuable paper on "The True Nature of Tetanus," Drs. Ringer and Murrell maintain the view that the tetanus produced by poisons depends essentially on loss of the resisting power of the cord, and not on excitation or stimulation of its cells. Strychnia no doubt produces an excessive discharge of nervous force in the cord, but this is not due to mere stimulation, for the normal reflex faculty is not rendered more vigorous and active, but is lost amid the general hyperactivity of the motor cells. The existence of the two faculties—the resisting or restrictive, and the motor—is well shown by the varying effects of agents, some of which act much more on one than on the other. Gelseminum produces considerable paralysis, with slight tetanus; box, strong tetanus, with slight paralysis; while strong blows on the back depress both functions very considerably. The affinity existing between tetanus and paralysis is well shown by the effects of box, which produces—(1) depression of the reflex faculty of the cord; (2) tetanus, the reflex paralysis still progressing; and (3) complete paralysis (see *Medical and Chirurgical Transactions*, 1877, p. 390). That this view is also very applicable to chorea can hardly be doubted, since we find so marked a tendency to paralysis in the motor and intellectual nerve-centres.



E. J. M., Case 2.—Pr. 40. May 15, 1877. Tracing on May 22 was very similar.



E. J. M., Case 2.—Pr. 90. June 15, 1877.

The remarkable elevation of temperature produced by the warm bath during the height of the malady deserves special notice. I know not how it can be accounted for otherwise than on the view that the warmth still further enfeebled the already weakened nerve-centres which regulate temperature, and allowed it to run up. The very same result ensues in fever when the patient is placed in a hot pack. And in both cases it is found that the rise produced by the same treatment during convalescence is very much less. The observation indicates very plainly that the condition of the cord in tetanus is one of enfeeblement, and also illustrates the effect of paresis of the cord on temperature.

The administration of physostigma was undoubtedly beneficial in Case 2. Whether it saved life is, perhaps, uncertain, but that it deprived the disease of its severity cannot be questioned. In Case 1 it also seems to have been decidedly useful. The drug must be reckoned a cardiac depressant, but it is probably a safer one to use than tobacco or aconite. All these agents need, for the most part, to be guarded by the simultaneous exhibition of stimuli, which were pretty freely used in Case 2.

The annexed tracings, which I believe are tolerably true, indicate that during the disease the arteries generally are in a state of contraction, which disappears during convalescence. Such certainly seems to be the case in some instances, as I have been informed of a case where the radial pulse was on several occasions imperceptible during the paroxysms, but became tolerably full and distinct during the administration of nitrite of amyl.

NOTE ON THE

PRUSSIAN SYSTEM OF CLASSIFYING MENTAL DISEASES.

By H. SUTHERLAND, M.D., M.R.C.P.

The number of the *Medical Times and Gazette* for April 7, 1877, contains an interesting paragraph on "Prussian Lunatics in 1875," in which the insane are classed under certain heads. These are—(1) melancholia; (2) mania; (3) secondary insanity; (4) insanity with paralysis: (5) insanity with epilepsy; (6) idiocy and cretinism; (7) imbecility; (8) delirium potatorum.

This classification of insanity adopted by the Berlin Statistical Bureau, appears to be based on the suggestion, contained in Dr. Bucknill's manual, that the subject must be approached from every standpoint. In this system at Berlin, the psychological symptoms and also the bodily causes of mental disorders are touched upon, thus meeting half-way the views of Esquirol and Skae, the deceased, and of Clouston and Crichton Browne, the living and energetic champions of these two principal systems of nomenclature.

Without pretending in any way to put forward a new classification of insanity, it appears desirable that the hints contained in this paragraph on Prussian lunatics should not be allowed to pass unnoticed, and that the classification here laid down may be advantageously compared with those systems suggested by the article itself.

1 and 2. As regards melancholia and mania, it need only be remarked that by adopting these terms the Prussian authorities agree so far with Esquirol and his subdivisions, although it must not be forgotten that the word "mania" is frequently made use of by Skae, apparently instead of the word "insanity," in his classification.

3. "Secondary insanity" appears to be a term about which some confusion might arise. It might imply that the patient was suffering either from a second attack, or from some form of insanity (as secondary dementia, *folie circulaire*), differing from the one with which he was previously afflicted.

4. The same remark will apply to insanity with paralysis. This term is very ambiguous. It might refer to general paralysis of the insane, or to paralysis dependent upon lesions of the brain, local contractions, etc., which are common to dementia, idiocy, and all forms of mental derangement.

5. Insanity with epilepsy is a most useful subdivision, but it is taken for granted that epileptic idiots and imbeciles are not included in this class.

6. Idiocy and cretinism would have been better separated. The ages at which these two disorders usually commence, the etiology and the prognosis, are different in both cases; and, above all, cretinism is, whereas idiocy is not, endemic.

7. Imbecility would have been better placed with idiocy. The lines of demarcation between these two forms are in some cases so very faint as to render it almost impossible to say whether the patient should be called an idiot or an imbecile.

8. Delirium potatorum. At the International Congress of Alienists, held in Paris in 1867, delirium tremens was placed outside the typical forms of mental disease (Blandford). Dr. Bucknill (*British Medical Journal*, March 3, 1877) has lately told us that the commonly accepted forms of insanity from drink are—mania *e potu*, chronic alcoholism, dipsomania, and delirium tremens. With regard to the last two, it may be said that it is very questionable if a man suffering from either of them could be at present legally detained as a lunatic in an asylum. It may therefore be concluded that this Prussian subdivision—delirium potatorum—is also somewhat obscure, as it leaves us in doubt as to whether or no a patient suffering

from it is really insane, or merely attacked by a love of drink or by delirium tremens.

Apart from these minor objections, the Prussian system of classification appears to be founded on sound and liberal principles. It acknowledges the mental symptoms (mania and melancholia), and also the somatic etiology of insanity (as insanity with epilepsy).

In the *Journal of Mental Science* for April, 1877, Dr. T. A. Chapman, in an exhaustive paper on the mortality of the insane, displays in a table the percentages of deaths among different classes of patients in the Hereford Asylum.

His sub-divisions are as follows:—1. Probably curable cases. 2. Congenital cases: (*a*) free from epilepsy, (*b*) with epilepsy. 3. Epileptics, non-congenital. 4. Organic brain disease: (*a*) general paralysis, (*b*) other forms. 5. Chronic insanity: (*a*) more or less excited (chronic mania), (*b*) quiet (dementia, monomania, etc.).

A committee of the Medico-Psychological Association, in 1869, put forth a table, as a specimen, in which cases might be arranged (Blandford). They enumerated four incurable forms of insanity—(1) General paralysis; (2) epileptic insanity; (3) senile insanity; (4) paralytic insanity. And to these four might almost have been added idiocy, in which form complete recoveries are, as is well known, very exceptional.

Finally, Griesinger enumerates two great sub-divisions of mental disease. The first includes curable forms—mania, monomania, and melancholia; the second incurable—chronic mania and dementia.

In these three classifications—Dr. Chapman's, that of the Medico-Psychological Association, and Griesinger's—we see that one great principle is kept in view. This is the division into curable and incurable forms.

But besides this principle being recognised by comparatively modern writers, we observe that the traditions of the past have not been altogether ignored. This is seen in the Nomenclature of the College of Physicians; there the classification of mental diseases proposed by Hippocrates is not disregarded.

Thus we have a past and a future influence to be considered with regard to the subject of nomenclature. It may be asked, What is the present influence which suggests the sub-divisions of insanity? The reply is, Asylum convenience. The attendants of asylums are every day unconsciously discussing the respective claims of Drs. Skae and Esquirol, when considering to which ward they shall request the superintendent to send a patient. Hence the terms epileptic, paralytic, etc., are acknowledged as being true sub-divisions even by the uneducated.

From the above remarks it may be concluded that we are gradually recognising the fact that a really practical classification of mental diseases must be founded on prognosis, whilst at the same time due consideration must be given both to the traditions of the ancients and also to the views of modern writers, founded on physiological research.

LARGE ABSCESS TREATED CHIEFLY BY THE ASPIRATOR—RECOVERY.

By JAS. D. GUNNING,
Surgeon, Army Medical Department.

B., aged fourteen, low caste, verydelicate, and wasted to a skeleton, presented himself on December 27, 1876, with a large fluctuating swelling in the left iliac region, and extending to the umbilicus. It was oval in shape, the long diameter being parallel to Poupart's ligament, about eight inches long and four inches broad. The margin was well defined. It was at once aspirated, and proved to be an abscess from which ten ounces of fairly healthy pus were evacuated, giving great relief. A compress was then applied.

December 30.—Great pain last night, having been comparatively free of it for two days. Aspirated, and withdrew nine and a half ounces healthy pus. Ordered two ounces of port wine and a pint of strong beef-tea daily.

January 2.—Nine and a half ounces to-day.

4th.—Four ounces to-day; pain in abscess last night, with slight fever. Temperature 101·6°. Had twenty grains of choral. General health, however, improving.

10th.—Up to this date has kept fairly well. Six ounces pus to-day. Ordered two grains quinine, ten minims tincture muriate of iron, and one ounce water three times a day. Walls of sac feel very thick and solid.

15th.—Six ounces to-day. Not so healthy-looking; complains of a good deal of pain. Treatment continued.

19th.—Five ounces, tinged with blood, but otherwise healthy.

25th.—Four ounces to-day.

30th.—Four ounces to-day. Anterior wall of sac thinning. The needle was accidentally tilted up, and caused an opening about an inch above the pubis.

February 1.—Abscess opened of itself at the place where the needle tilted.

3rd.—Two free openings were now made—one where the needle came through, and the other higher up. The sac was injected with carbolic acid and oil (1 to 10), and then stuffed with lint saturated with the same oil and acid.

From this time it began to close rapidly, and at the present date there is only a small superficial healthy granulating sore where the higher of the two openings was made. The lad has increased in weight, and looks plump and healthy, running about freely.

The abscess was situated entirely in the abdominal wall, and had no connexion with the spine. From December 27 to January 30 the aspirator was used nine times, and fifty-eight ounces of pus were withdrawn by it.

Had this abscess been opened in the ordinary way, I am convinced, owing to its size, the shock would have proved fatal. With the aspirator this was reduced to a minimum, and contraction of the sac proceeded so steadily, that when it was placed in the condition of a freely incised abscess, owing to the accident alluded to, no bad effects followed. Earlier this would not have been the case. I had hoped to have effected a cure entirely by the aspirator, injecting the sac when the boy's condition of health permitted, but was forestalled.

Fyzabad, India.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

ST. GEORGE'S HOSPITAL.

TWO CASES IN ILLUSTRATION OF THE EFFICACY OF CHRYSOPHANIC ACID IN THE TREATMENT OF PSORIASIS, AFTER FAILURE OF VARIOUS OTHER REMEDIES.

(Under the care of Dr. WHIPHAM.)

Case 1.—E. F. S., aged seven, was admitted into St. George's Hospital, under my care, on March 21, suffering from a copious eruption of psoriasis. His mother was a person of strumous habit. Of six brothers and sisters, one died in infancy; one, at ten months old, had an abscess on the cheek; the others are very healthy. The boy himself was brought up by hand. Had measles when three years old; no other disease. He was always pale and delicate, with a bad appetite, and subjec to vomiting after food; occasionally he suffered from headache. Has always lived well. He had never suffered from cough or glandular swellings; there is no history or appearance of hereditary syphilis. Has always been "nervous," and is less intelligent than his brothers and sisters. The present eruption of psoriasis began with one spot on the back in September, 1876; a month later it appeared on the legs. His general health has not been in any way affected.

On admission there were numerous patches of psoriasis, with thick masses of scales, and varying in size from that of a threepenny-piece to that of half-a-crown, upon the legs, arms, and trunk; one small one on the left upper eyelid. The patient is well nourished, but of markedly strumous appearance. General health good; no cough; tongue red, with prominent papillæ; bowels open. Ordered—Ol. morrhuæ 3 jss., syr. ferri iodid. 3ss., bis die. Picis Burgund., sapon. moll., sp. methyll., part æqual; to be rubbed into the affected skin. Pulv. rhei c. sod. gr. v. om. nocte.

March 27.—The scaliness has disappeared, and the subjacent thickening of the skin has diminished; while at the same time the redness of the patches has markedly subsided. The bowels have been confined for the last day or two, but are well open to-day; tongue as before.

29th.—The pitch ointment to be applied to the left leg, and to the right the ointment of nitrate of mercury.

31st.—The condition of the right leg is much improved,

whereas the patches on the left are very little altered. Ordered —Liq. potassæ ℥vj., haust. ciuchouæ ʒj., ter die. Pulv. rhei c. sod. ϑss. omni altern. nocte. The nitrate of mercury ointment to be used solely.

April 10.—Both legs are improved as regards scaliness, but there is no appearance of healthy skin iu the centres of the larger of the affected parts, although the smaller spots are gradually fading.

12th.—A drachm of cod-liver oil to be given with each dose of the medicine, and a soda bath every night.

Little or no improvement was observed up to April 28, when the following ointmcnt was ordered to be applied to the eruption:—Acid. chrysophanici ʒ ss., adip. ʒj.

On the eighth day after this application the eruption had almost disappeared; one or two minute spots only remained on the legs where the ointmeut had been too sparingly applied: these disappeared in the course of a few days. The patient suffered from incontinence of urine, and as the prepuce was very long, it was removed, and he remained in hospital under the supervision of the surgeon for a few weeks. The chrysophanic acid ointment was discontiuued on May 11, and he was kept under observation until June 29, up to which time no recurrence of the disease had takcn place. A few hours subsequently to the application of the ointment the unaffected skin became of a purple-red colour, which disappeared on pressure, while the sites of the patches of psoriasis, after the thickening had subsided, remained perfectly white. This dusky red colour speedily faded after the ointment was discontinued, and the skin gencrally, including that of the diseased parts, assumed a natural appearance.

Case 2.—In the spring of the year 1874, Selina W., aged fifteen, a domestic servaut, living in the country, came under my care as an out-patient iu the departmeut for diseases of the skiu at St. George's Hospital. She had then a copious eruption of psoriasis over the trunk, arms, and legs. The eruption had commenced two years previously, and, with partial remissions at different times, had been steadily on the increase, this increase being more especially marked in the spring.

She was a remarkably well-grown girl, and looked six or seven years older than her stated age; she was, moreover, in robust health, her only complaint being profuse and occasionally deferred catamenial periods. She, however, never exceeded six weeks.

Her family history was good, her parents lived in the country, and there was no account of syphilis either hereditary or acquired. The appearance of the eruption and the catamenia were contemporaneous, but, beyond the slight irregularity of the latter above mentioned, the girl was in perfect health.

The treatment consisted in careful attention to her diet; beer, which she had been in the habit of drinking in moderate quantity, was discontinued, and her food was to be of the plainest description. She was ordered—Liq. arsenical. ℥iij., dec. ciuchon. ʒjss., ter die. At first the treatment seemed to be productive of good results, more especially as regards the trunk, but eventually lost its effect as the autumn came on. No alteration was, however, made in the treatment until February 11 in the following year, when nitrate of mercury ointment was ordered to be rubbed into the affected parts.

On May 6, 1875, as the eruption was rapidly increasing, the treatment was altered with a view of increasing the action of the kidneys, and the following prescription was ordered:—Sp. æther. nitros. ʒj., tinct. scillæ ℥x., potass. acetat. ϑss., h. acet. ammon. ʒjss., t.d.s. Rep. unguent. hydrarg. nitrat.

This change produced speedy results, and on July 29 the note runs:—"Only one or two patches on the arms, but there is an increasing tendency to the formation of fresh spots, which, however, soon fade." It appeared that the disease was again on the increase.

On August 26 she was much better.

On October 21 the eruption had not improved, and it was deemed advisable to try a mixture containing tincture of rhubarb and bicarbonate of soda in infusion of cloves.

She continued stomachics, etc., with little or no benefit until January 20, 1876, when her treatment was again altered as follows:—Liq. hydrarg. et arseni. hydriodat. (Donovan's) ℥viij., inf. gent. co. ʒj., ter die; and upon this she again improved for a time, but in about six weeks the improvement ceased, and the eruption again began to spread. The medicine was continued for some months, until finally the gums showed decided evidence of mercurial poisoning, and all medicine was discontinued for a time. Before this the patient had ceased to attend the hospital, owing to a regulation of the Board limiting the period of attendance for out-patients.

At the beginning of March, 1877, I saw her again, and found that the psoriasis had recurred in all the original situations, and that she was as bad as when she first came under observation. I then ordered her to take three times a day a pill containing one-twentieth of a grain of phosphorus.

On April 1, I found that the psoriasis was rapidly disappearing. The improvement, however, was of very short duration; and on May 31, 1877, the eruption was rapidly extending on the limbs and trunks. I prescribed for her an ointment: Acid. chrysophanici gr. l., adipis præp. ʒj., to be rubbed well into the patches night and morning. At the end of a week I heard that the unaffected skin was "of the colour of a red Indiau," and that she had a running at the eyes and slight dimness of sight. I therefore directed the ointment to be applied every other night.

On June 21, exactly three weeks after the commencement of chrysophanic acid ointment, I saw my patient, and found that, with the exception of one or two scaly unthickened spots (each rather less than the size of a pea, on each wrist), she was quite free from all trace of the skin disease. Her skin at the time of this visit was of a dull purple colour, such as one sees when the face of a person with a florid complexion is sunburnt. Her health was excellent, and the catamenia were quite natural, both in time aud amount. She was directed to apply the ointment to the spots on the wrists once a day.

On July 22 I again saw her, and found all traces of the eruption gone, aud her skin natural. She had discontinued the ointment for some weeks.

Remarks.—Of the two cases, the second is a most striking example of the remarkable effects of chrysophanic acid in the cure of psoriasis. I have briefly alluded to it in the *St. George's Hospital Reports*, vol. viii., page 227, and the statement therein, that the disease had baffled all my attempts at cure, must uow be considerably modified. The "Notes from the Skin Clinique" were written many months before the publication of the volume, and at that time no remedy had produced any permauently good effects in my patients. In a footnote on page 227 of the *Reports*, mention is made of the fact that the psoriasis was disappearing under the use of phosphorus, which was commenced in March, 1877. By the end of May, however, the disease was nearly as bad as ever, and it was evident that the drug was of no use in relieving her ailment. After to many aud repeated failures (the majority of which have been mentioned in the necessarily curtailed notes of a case which had been under treatment for more than three years), it was not without a feeling of despair that I had recourse to chrysophanic acid; the result, however, and the rapidity with which that result was brought about, surprised me extremely—a surprise which is not lesseued by the recollection that the girl had suffered from the skin disease for five years and a quarter at the time when the acid was first employed, and that she was entirely free from psoriasis in twenty-one days. Possibly the psoriasis might have yielded to local applications of pitch, etc., but, as I have mentioned in the *Hospital Reports*, I had no opportunity of trying it, owing to the inveterate dislike of her mistress to the smell of such preparations. The case of the boy also illustrates the beneficial effect of the drug, though to a less degree. I have here placed the two cases together, because they *appear* to me to show that chrysophanic acid has some distinct action in certain forms of skin disease independently of the patieut's diathesis. The subjects of the above notes differed in almost every respect. The boy was pallid, of small stature, and very delicate in appearance; he was, in fact, as stated by Dr. Owen (Medical Registrar at St. George's, to whom I am indebted for the notes of the case), essentially a strumous child. Selina W., on the other hand, was a remarkably well-proportioned country girl with a florid complexion, who, with the exception of a trifling catamenial irregularity when she first came under notice, was in most robust health. In the case of the boy the eruption had disappeared eight days after the employment of the chrysophanic acid, aud so far this case contrasts favourably with that of the girl S. W. It must, however, be borne in mind that the scaliness of his disease had been greatly modified, if not entirely removed, by previous applications, while to hers no local treatment had been employed for a long time. In the case of S. W., certain irritating effects resulted from the use of the drug. Redness of the skin is a usual sequela of its local application, but this redness in the majority of cases seems to be limited to the neighbourhood of

the affected parts to which the acid has been applied. In the present instance the effects were more extensive; the face generally became swollen (it must be noted that the eruption did not involve the head or neck, and consequently the ointment was not used above the shoulders). Dimness of sight was also mentioned by the patient as one of the effects of the remedy, but on questioning her I was inclined to attribute this symptom rather to the "running at the eyes" than to any interference with the function of the eye itself, more especially as she recovered her natural powers of sight within a few hours of discontinuing the use of the acid. Failures will, doubtless, occur with this, as with all other remedies, which at first appear to be productive of such extraordinary results. At present our knowledge of the action of the drug is limited, and recorded cases are few in number. It is with a view of adding to these records that the above cases are published.

ST. PETER'S HOSPITAL.

STONE IN BLADDER—INTERNAL URETHROTOMY AND LITHOTRITY—RECOVERY.

(Under the care of Mr. TEEVAN.)

W. W., a saddler, sixty-one years old, was admitted into the hospital, on July 6, 1877, suffering from stone in the bladder. The patient was born at Ware, his father in Essex, and his mother in Shropshire. Last January he noticed that his water did not pass easily, and that he suffered pain at the end of the penis when he rode in an omnibus. Three months ago he began to experience a pain whenever he made water, and occasionally passed a little blood after riding. Never suffered from rheumatism, gout, gonorrhœa, or syphilis. On July 2 the patient sought Mr. Teevan's advice in the out-patients' room. After considerable difficulty, on account of the existence of a valvular fold situated two inches from the meatus externus, Mr. Teevan managed to introduce a sound having a short beak, and found a stone, apparently small.

State on Admission.—The patient, who was a healthy man, wanted to make water every quarter of an hour in the day, but not in the night, when he was rarely troubled. So long as he was quiet he suffered no pain. Urine contained some mucus.

July 11.—The patient having been put under the influence of ether by Mr. Knott, Mr. Teevan tried, without success, to pass different lithotrites; neither could he get any catheter, soft or metal, to pass the obstruction.

18th.—To-day Mr. Teevan divided the valvular fold from before backwards, the patient being under ether. At 8 p.m. Mr. Arthur Simon, the House-Surgeon, found the patient's temperature 99·2°, and pulse 90.

19th.—Patient suffers a good deal of smarting when urinating. Pulse 92; temperature 100°.

20th.—Pulse 80; temperature 99°.

21st.—A No. 26 olivary bougie was passed to-day, and again on the 23rd.

26th.—To-day at 3 p.m., the patient being under ether, Mr. Teevan passed a lithotrite scoop, found the stone (which was only half an inch in diameter), and crushed it. At 10 p.m., temperature 90°, pulse 88.

28th.—Passed some fragments to-day. Urine clear, but little pain. Temperature 98·4°; pulse 80.

30th.—Had a good deal of pain in the night from difficulty in passing urine. Temperature 99°; pulse 72.

August 1.—Has but little pain when he urinates. Pulse 84; temperature 99·2°.

2nd.—Pulse 76; temperature 98°. Lithotrity repeated to-day.

4th.—Several pieces of stone have come away. Is quite free from pain, and says he feels quite well.

6th.—Mr. Teevan sounded patient's bladder, and declared it free from stone.

7th.—To-day the man left the hospital quite well, free from pain, and able to hold his water for two hours. Urine pale, acid, specific gravity 1005. The stone was composed of lithic acid.

STONE IN BLADDER—LITHOTOMY—RECOVERY.

(Under the care of Mr. TEEVAN.)

Charles W., thirteen years old, was admitted into the hospital on April 9, 1877, suffering from stone in the bladder, detected the same day in the out-patients' room by Mr. Teevan.

History.—The patient was born in London, his mother at Honiton, his father at Monmouth. It appeared, from the report given by the boy's mother, that three years ago he began to suffer pain when he made water. Two years ago he commenced to wet his bed at nights, and for the past year his urine had dribbled away night and day.

Condition when Admitted.—The patient was plump, healthy-looking, and very cheerful. His water ran away from him night and day. If he rode in a cab or attempted to run he suffered pain.

On April 16, at 3 p.m., the patient was put under ether by Mr. Knott. Mr. Teevan then passed a rectangular staff, which he gave to Mr. Heycock to hold, and extracted, by the lateral operation, a phosphatic stone weighing two drachms. An hour after the operation the patient was chatting and laughing, and said he was quite comfortable.

17th.—Had a very good night. Holds his urine, and passes it freely through the wound. Expression good. Tongue clean and moist. At 9 a.m., temperature 100°, pulse 120 9 p.m., temperature 100°, pulse 100.

18th.—Some urine is passed through the penis. At 9 a.m., temperature 100·3°; 9 p.m., temperature 99·8°.

19th.—At 8 a.m., temperature 99°, pulse 105; 9 p.m., temperature 99·8°.

20th.—Going on well. Temperature 99·8°; pulse 114.

21st.—Wound contracting. Pulse 108; temperature 99·8°.

22nd.—All urine is passed by the wound. Temperature 99·8°; pulse 106.

23rd.—A little water comes by the penis.

26th.—Nearly all the urine passes by the penis.

28th.—All the water now comes through the penis.

May 1.—Patient left the hospital quite well, not suffering from incontinence. The wound was closed.

Mr. Teevan remarked that the first case presented a very unusual feature which he had not met with before, and which consisted in the presence of a valvular fold two inches down the urethra, which effectually barred the passage of the lithotrite. He had been able to pass a sound because its beak was only half the length of that of the lithotrite, and the sound moreover permitted of a degree of manipulation denied to a lithotrite. By dividing the obstruction from before backwards, no further difficulty was encountered. The second case formed the nineteenth boy on whom he had performed lithotomy without losing one. The lad was plump and healthy, and made a very rapid recovery.

Case of Imperforate Anus and Fistulous Opening into the Bladder.—Dr. Rowan relates the case, of which the following is an abridgment:—A male child was brought (April 11, 1876) for advice, three days after birth, having an imperforate anus, and the abdomen being very distended and tender. No depression or other sign of the position of the anus existed, and an incision was made at the centre of the fundament large enough to admit the index-finger as a guide. On cutting to a depth of about two inches and a half, a fluctuation in the line of the rectum could be felt. On opening this fluctuating mass a large quantity of meconium and gas escaped with immediate relief. Oiled lint was passed into the wound, and replaced every morning for about a week, after which a bougie was introduced every second or third day to keep the aperture open. Nothing was heard of the case from May until February 1, 1877, when the passage was found closed so that a probe could not be introduced. For two months nothing had passed by this aperture, the motions having come away during that time by the penis until the day before the child's arrival, when the foreskin had become so much closed that it could only pass water with great pain and difficulty. This was remedied by circumcision, and on February 6 an attempt was successfully made to restore the natural passage. The canal had closed about an inch from the orifice, which was now somewhat enlarged by incision, so as to get the finger in and divide some very tight adhesive bands. The rectum having been opened, was found to contain some very hard fæces. Since the second operation the finger was passed every day, and the canal seems now perfect—no fæces or flatus having been passed by the penis since two days after the operation. Dr. Rowan regrets that at the first operation he did not make the opening large enough into the rectum so as to be able to pass the finger into it, instead of trusting to a bougie. The case is extraordinary as showing that defæcation may be carried on through the bladder and penis during two months without causing inflammation or other serious effects.—*Australian Med. Jour.*, March.

SATURDAY, SEPTEMBER 22, 1877.

ITALIAN HEALTH-RESORTS.

No. III.—Alassio, Pegli, Cornigliano.

The following notes deal with some Italian watering-places which are in a much less advanced stage of development than Cannes, Mentone, or San Remo, and in some respects even than Bordighera. They ought not, however, to be passed over undescribed; not only because their climate differs in some respects from that of the places above named, but also because, at present, at any rate, they are less expensive to live at than these latter. Moreover, owing to the opening of the railway, which now runs along the whole coast from the French frontier at Ventimiglia, a few miles east of Mentone, to Spezia, south-east of Genoa, the facilities for travelling are far greater than under the old system of conveyance by *diligence* or *vetturino*. Hence the numbers of northern visitors, valetudinarian and others, to the Riviera in winter are vastly greater than they were a few years back, and bid fair to continue to increase. Under these circumstances we need not be surprised if the railway along the north shore of the Mediterranean proves as powerful a stimulus to the progress of certain towns as it so often is in our own country.

Alassio, a town about sixty-five miles from Genoa, and sixty from Ventimiglia, with from 5000 to 5500 inhabitants, is situated at the eastern extremity of a bay about two miles wide, and protected by a complete semicircle of hills from east through north to west-south-west. The hills are nearest to the sea just behind and to the east of the town, and recede towards the centre of the bay, so as to leave a plain of some extent thickly covered with olives between them and the sea. Their height is from 1000 to 1500 feet, the highest points possibly reaching 2000 feet. They are not barren at the summit like the Mentone mountains (which are, however, much higher), but are fertile nearly to the top, and covered with fine olive woods, beech-trees, and pines. Compared with the east bay at Mentone, Alassio is less shut in between the hills and the sea. The orange is cultivated largely, both at Alassio and at Laiguiglia—a small but picturesque town which lies under the hills on the western side of the bay. The lemon is said to flourish also, but it did not seem to us to be very abundant. The town itself consists of one long, narrow street, parallel to the shore, and only separated from it by the sandy beach. The street, though dark from the height of the houses on either side, is clean and well paved with stone. A high wall, anciently used for purposes of defence, has until lately surrounded the greater part of the town and the gardens at the back, but it is now being rapidly blasted away and removed. There are plenty of shops, including the indispensable druggist's. Good fish and vegetables are to be obtained, but at present poultry and meat are difficult to procure. The water-supply is good, and the quality of the water said to be, if anything, superior to that of the other towns of the Riviera.

Dr. Schneer, a German physician, who has practised for about five years among the inhabitants of the town and district, has, with great kindness, furnished us with the results of his observations on the climate. They are embodied in the following remarks; and we here take the opportunity of expressing our best thanks to him for his courtesy in responding to our request for information.

The inhabitants of Alassio as a rule enjoy excellent health, and this we can well believe, judging from the opportunity which their habit of sitting at their doors and working affords of seeing large numbers of them in passing through the streets. The mortality on the average of ten years from 1866-1876 was 25 per 1000. There is no fever, and epidemic diseases are rare; hereditary phthisis, however, occurs in certain families. Bronchial catarrh is not uncommon in winter, owing to the absence of proper warming apparatus, and to the use of tiled floors, and too thin clothing. Pneumonia is rare. In the hot weather diarrhœa is common. Acute rheumatism with consecutive heart-disease seldom occurs, and kidney diseases are also rare.

The following table gives the mean temperature for the different months, the mean differences between the temperature at 9 a.m. and 3 p.m. during the winter months, and the *maxima* and *minima* mean temperatures for each month. The thermometer had a north aspect in shade.

For greater accuracy we have preferred to retain the Centigrade scale which Dr. Schneer used.

	Mean day temperatures.	Difference between temperatures at 9 & 3 o'clock.	Maximum.	Minimum.
January	9·00°	2·40°	15·00°	—2·80°
February	11·20	2·45	20·00	—2·10
March	12·10	2·14	22·20	—1·30
April	14·90	1·92	23·10	—2·90
May	19·00	—	29·00	7·10
June	22·10	—	31·00	6·70
July	24·50	—	31·60	12·80
August	24·10	—	32·60	12·80
September	22·30	—	29·40	12·30
October	14·00	1·60	27·00	0·30
November	12·90	2·20	23·80	0·00
December	10·00	2·24	18·70	—2·00

The mean barometric pressure for the whole year is 761·67 millimetres. The mean pressure for each month is given below:—

January	764·10	May	761·80	September	761·30
February	766·20	June	761·00	October	761·00
March	759·00	July	760·75	November	761·20
April	762·00	August	760·20	December	761·40

The greatest oscillations in pressure occur in February and March. The mean relative humidity of the air is 65·2, 100 being taken as saturation point. The driest month is March; the wettest months are February and September.

Wind is little felt. The north wind is warded off by the hills, but the *tramontana* or north-east wind occasionally blows.

In summer the sea-breeze helps to keep the heat from becoming oppressive.

Dr. Schneer sums up his impressions of the climate of Alassio by saying that it is tonic and invigorating, moderately dry, and enjoying a comparatively warm and even temperature in winter. Fogs and mists are rare near the sea. Dew falls abundantly; snow very seldom, and it never lies.

It is probably owing to its salubrity that Alassio has been selected as the site of a large seminary or college for Italian boys, the fine new buildings of which are an ornament to the town.

At present the great want at Alassio is proper accommodation for visitors. However, the old Hôtel de Londres, to the east of the town near the sea, has lately been considerably enlarged and improved, and we understand that a second hotel is in process of construction. No doubt the number of villas, which at present is very limited, will be increased. Two well-built houses a short distance behind the Hôtel de Londres are practically unavailable for winter visitors, owing to the view of the sea being quite shut out by the adjacent houses. One or two English families have already settled at Alassio and built villas, and no doubt they will form a nucleus for more. The hope for Alassio depends very much on the wisdom displayed by the hotel and other proprietors. If they choose to keep the prices moderate, and to abstain from the rapacity which is so characteristic of similar individuals further west, they will attract and retain visitors and invalids. But if the prices are at once assimilated to those of the Grand Hôtel du Louvre at Marseilles or Paris, although nothing to correspond is offered in the way of comfort, Alassio will deservedly fail to develope. These remarks are prompted by the remembrance of an exorbitant bill which we were called on to pay at the Hôtel de Londres last December, and by complaints which have reached us from other and reliable quarters.

The cost of living at Alassio is as yet moderate, judging from the market prices. The inhabitants, it should be stated, are civil, cleanly, and respectable, and ready to do all that they can to oblige strangers.

The scenery in the neighbourhood is very picturesque, and there are pleasant walks, with well-paved causeways, by which the hills can be ascended without difficulty. The view over the plain and bay looking west towards Laiguiglia is by no means a common one, and the curious island of Gallinaria just outside the bay to the east cannot fail to attract attention. Moreover, the neighbouring town of Albenga, with its quaint brick towers, will repay many a visit.

Between Alassio and Genoa there are two other places which are more or less frequented by English visitors in winter and spring—Pegli and Cornigliano; the former about half an hour distant by rail from Genoa, and the latter still nearer. We shall say a few words about each.

Pegli is built on the sea-shore, with a southern aspect; it is a town of about 4000 inhabitants, whose chief employment is fishing and shipbuilding. The interest of the place for visitors concentrates itself chiefly on the beautiful gardens which are attached to the villas of several Italian noblemen behind the town, under the shelter of the northern hills, which are comparatively near, and range up to 700 or 800 feet. The garden of the Villa Pallavicini is justly celebrated, and probably is unique in its extent and in the admirable way in which every part of it is kept up. Here all kinds of delicate plants and tropical trees grow in the open air, and the number and variety of rare palms, aloes, and ferns in the shrubberies near the Palace speak volumes for the mildness of the climate. We noticed, however, that the banana, which grows uncovered between the Cap St. Martin at Mentone and Monte Carlo, here required protection in winter. The hills behind Pegli are covered with fir, which in the Pallavicini woods is mixed with laurel, cedar, and various southern trees, among others the camphor tree. The shelter which Pegli enjoys is a local one, and within a mile to the eastward there is a valley running from north to south, which allows the descent of the cold winds on the portion of coast opposite its entrance. On the east and west there is a fair amount of protection from the hills which skirt the bend of the coast, but the *tramontana*, or cold north-east wind, makes itself felt severely sometimes near the shore. Much more rain falls here, as far as we can learn, than at the health-resorts further west; but, owing to the slaty or schistous character of the soil, the latter probably soon dries. Pegli is already far better equipped for the wants of visitors than Alassio. There are three good hotels, and we were told that a fourth was to be opened shortly. For invalids only the Hôtel Gargini and Hôtel de la Méditerranée are to be recommended, as the Hôtel Michel, opposite the railway-station, though in other respects excellent, has no south rooms with a sea-view, nor any garden. The two former hotels face the sea, the Méditerranée being somewhat raised above the street. They both have good dining- and drawing-rooms, and comfortable bedrooms, and a garden at the back. The prices at Gargini's are a little the lower—7 fr. a day (*pension*) on the second, and 8 fr. on the first floor, but the rooms and the general style of the Méditerranée are better, and it is under Swiss management. The *pension* prices are 10 fr. a day on the first floor, 10 fr. 50c. on the ground and second floors, and 9 fr. 50c. on the third floor. One objection to living close to the sea at Pegli is the hammering of the shipbuilders, which begins about daylight; and a second is, that the near proximity of the native population in *deshabille* is unpleasant to some people. However, private rooms can be rented further from the sea—for instance, in the street at the back of the hotel gardens, not far from the railway cutting, and we believe also in one or two villas. Carriages can be hired near the railway-station. There is an English church and resident chaplain, and the proximity of Genoa renders the attainment of any extra comforts, such as may not be found in the hotels, a comparatively easy matter.

Pegli would certainly be a much more desirable place for the winter than it is at present if the extensive grounds belonging to some of the villas already mentioned were not practically closed to the general public. For instance, an order has to be obtained every time the garden and woods of the Villa Pallavicini are entered, and no one can go a step without a guide to prevent his doing mischief to the plants and summer-houses, etc. For this reason the resident at Pegli has his rambles much restricted, and access is denied to the places which are most sheltered and best adapted for invalids.

Cornigliano, about four miles from Genoa, a small fishing town of no internal pretensions, is mainly noticeable on account of the excellent hotel, the Villa Rachel, which has been opened there in the last three years. The town itself lies on the shore, and is fully exposed (as we can testify) to the north-east wind, but the hotel is more under the shelter of a ridge a few hundred feet high, and stands about a third of a mile from the sea. It is, however, inadequately sheltered from northerly winds, owing to the fact that a valley comes down from the north almost immediately behind it. Hence it cannot be so warm as Pegli, and we should fancy that it must be at least four or five degrees colder than Mentone. The same amount of rain probably falls at Cornigliano as at Pegli. On December 14, 1876, camellias were in flower in the open air. The Villa Rachel faces south-west, and consists of the hotel proper, which has three storeys of equal height, with rather deep windows, and mostly without outside shutters, and a wing in which some of the rooms have a south-easterly aspect. There is a sheltered garden planted with orange, eucalyptus, and other trees, and well provided with seats. Internally the fittings are very good. There are capital *salons* (two) and a billiard-room in the English style, and plenty of newspapers

are provided—a not unimportant point, for we have frequently noticed that hotel-keepers who are stingy in supplying their guests with papers, are stingy in other respects, and *vice versâ*. The bedrooms are comfortable and well-furnished, and the only drawback we noticed was the absence of fireplaces in some, which is accounted for by the house being warmed by a *calorifère*. The same remark applies to the sitting-rooms, and the deficiency should certainly be remedied. The closets have an abundant water-supply, and we heard no complaints of bad smells. The food is good, and the number of complimentary expressions in the visitors' book, in English, German, and Italian, as well as the favourable reports which we heard from English people in the hotel, all testify to the way in which things are managed. The *pension*, it should be added, is eight francs a day.

We have spoken at some length about the Villa Rachel because, though there are other warmer and more sheltered places available for mid-winter, it seems to be well adapted as a place at which invalids may rest, either in spring or autumn, on their way to or from the Riviera by way of Italy; and we can conceive that when the weather begins to get warm in the end of March or middle of April, a change to the cooler climate of Cornigliano might be of service.

The attention of Madame Rachel in cases of sickness we have heard very highly and gratefully spoken of, and it is only right that the medical profession should be aware of the existence of her establishment.

In concluding this notice of the less known health-resorts of the Western Riviera, it may be well to state that not only Pegli and Cornigliano, but also Alassio, are much frequented in summer, chiefly by Italians, as bathing-places. At Alassio especially there is as fine a sandy beach as could possibly be wished for, and at a later stage of the development of this latter sanatorium, for which a more or less prosperous future may safely be predicted, English invalids also, and others for whom sea-bathing is advisable, and who do not object to the moderate heat of the early summer months, may perhaps also utilise the facilities which are thus offered them.

THE EXCRETION OF INDICAN AND LIME IN DISEASE.

In an interesting communication to the *Centralblatt Med. Wiss.* (Nos. 20-22, 1877), Professor Senator, of Berlin, sums up the main results of a series of observations on the excretion of indican by the kidneys which he has made in more than a hundred cases of diseases of various kinds. He also adds some remarks on the excretion of lime in the urine in various diseased conditions. We may premise that these researches have a direct bearing on diagnosis, and are therefore of clinical as well as of scientific interest. "In general terms it may be stated," says Professor Senator, "that an abnormal excretion of indican occurs much more frequently in chronic than in acute diseases, and it is especially in consumptive states and wasting diseases that it is observed. Patients who can scarcely eat anything, and who either vomit part of their food or else digest it badly, frequently pass enormous quantities of indican in the urine, especially in comparison with healthy persons taking the same or even a larger amount of food. The greater the anæmia, the greater the excretion of indican generally becomes." Indican excretion is enormously increased in diffuse peritonitis, and to a less extent in subacute, and in certain cases of circumscribed peritonitis it is also considerable. In other febrile diseases (pneumonia, pleurisy, meningitis) the amount of indican in the urine is frequently very large when compared with the small amount of nourishment taken by the patients; and in typhoid fever there may even be an absolute increase, whether diarrhœa be present or not.

Among chronic diseases, *cancer of the stomach*, whether the neighbouring organs be involved or not, is attended by the largest excretion of indican, and this independently of the condition of the stools. Professor Senator examined twelve cases of this disease, and in all the amount of indican was enormous. In ulcer of the stomach the indican is also present in abnormal quantity relatively to the food ingested, especially if there have been recent hæmorrhages; the amount is, however, generally smaller than in cancer. Next to cancer of the stomach, the largest increase in the excretion of indican is caused by multiple *lymphomata* and *lympho-sarcomata*, especially when situated in the abdominal cavity. The urine of children with glandular swellings and the symptoms of the so-called *tabes mesenterica* is also often extraordinarily rich in indican, and it may be stated generally that in a number of children's diseases indican is present in large quantities. In advanced phthisis, especially where there is violent diarrhœa and amyloid degeneration of the liver, spleen, and kidneys, indican is generally much increased. Amyloid degeneration of the kidneys due to other causes, *e.g.* syphilis, causes *no* increase in the amount of indican in the urine; and the same is true of acute or chronic diffuse parenchymatous nephritis. On the other hand, in four cases of granular kidney, a large amount of indican was found to be excreted. In chlorosis, in the various forms of *leukæmia* and *pseudo-leukæmia*, and in progressive pernicious anæmia, there is a moderate increase in the indican excretion; but even when the amount of wasting and the loss of strength in pernicious anæmia exceed those in cancer of the stomach, as far as Professor Senator's observations go, the excretion never attains the same proportions as in the latter disease. The diagnostic value of this fact, if confirmed by other observers, is self-evident. Intestinal obstruction dependent on mechanical causes, or on intussusception, appears (in the absence of cancer or peritonitis) *not* to cause much excretion of indican. In some cases where there is an abnormal excretion of indican there is a simultaneous increase in the amount of lime in the urine. This is the case in phthisis, even where very little food is taken, and in spite of the presence of diarrhœa. It also occurs in children with multiple swellings of the glands and with rickets. In acute febrile diseases, however, such as pneumonia or typhoid fever, the excretion of lime and that of indican appear to diverge from one another, that of the former being diminished, and that of the latter increased. In pleurisy with effusion alone has Professor Senator several times observed that there was an increased excretion of lime, notwithstanding the presence of fever.

The method adopted in testing for indican in the above research was the following:—The urine is, if necessary, to be freed from albumen in the usual way, and ten to fifteen cubic centimetres are to be mixed with an equal quantity of fuming hydrochloric acid in a rather large test-glass. A concentrated solution of chloride of calcium is then to be added gradually, drop by drop, until the blue colour of indigo is fully developed, and the whole is then to be shaken up with chloroform. The latter takes up the freshly precipitated indigo, and sinks with it to the bottom of the glass, where the amount can be estimated with a little practice, in the same way as albumen is usually estimated, but far more accurately. This remark applies to *pale* urines (which, as a rule, are the richest in indican). Highly pigmented urines must be first decolourised by acetate of lead, avoiding an excess of the latter reagent before applying the indican tests.

POISON IN THE PERAMBULATOR.

During the last three years a kind of perambulator with a collapsible head of "American cloth" has been in great favour with the German public, both in Berlin and elsewhere. From the fact of a number of healthy children having suffered of late

from symptoms of lead-poisoning, attention became directed to the American cloth as the source of the lead, more especially as there was a unanimous agreement in the reports, from a number of widely separated places, that the cases of poisoning had been almost all observed since the beginning of the hot weather, and that there was a distinct connexion between their number and the intensity of the sun's rays. The German Health Office, from one of whose reports (No. 28) we derive our information, at once had a number of samples of the cloth (chiefly from factories at Leipsic, Zeitz, and Hamburg) analysed, and in all an extraordinary amount of lead was detected. In one specimen, bought in a Berlin shop, as much as 42·7 per cent. of metallic lead was found, or 4·27 grammes in ten grammes of the cloth. From a small piece of the latter, lighted and allowed to smoulder away like tinder, globules of metallic lead, reduced by the ignited carbon, could be seen to run out. Further examination showed that exposure of the cloth to direct sunlight for six hours rendered its coating friable, and made it scale off. "When we consider," says the report, "that many children pass the greater part of their first year in this carriage (which also serves as a cradle), and are exposed in it in summer to the destructive action of the sun and rain, and in winter to the heat of the stove; and when we remember the amount of friction which the cloth undergoes when the head is opened and shut, and the cloud of lead-dust which must be thus inhaled, not to mention the possibility of the children sucking or chewing the cloth itself, it is our urgent duty to warn the public against the use of perambulator hoods made of American cloth in the sanitary interest of the child-world." The British public may also benefit by this advice, and keep "American cloth" from their perambulators. Whether the said cloth is equally injurious when used for covering arm-chairs (which generally stand in winter near the fire) and other chairs, or for lining carriages, we cannot say. Those who employ American cloth for such purposes should, at any rate, be on their guard; and the knowledge of the fact that it may be a source of lead-poisoning may help medical men to detect a hitherto unsuspected cause of chronic disease.

THE WEEK.

TOPICS OF THE DAY.

SOME idea may be formed of the importance of sanitary supervision in the City of London by briefly examining the report recently presented to the Commissioners of Sewers by Dr. Sedgwick Saunders, the Medical Officer of Health. The report sets forth that during the recess 1579 houses had been inspected, of which 176 required sanitary improvements in various particulars; 288 of the sanitary orders of the Commission had been executed, and 80 were in hand. These included cases of smoke nuisance, overcrowding, cellar-dwellings, defective drainage, improper storage of live stock, tallow-melting, and deficient water-supply. Fifteen bodies had been received at the mortuary during the period, and kept in decent custody until the time of burial. The general health of the City during the recess had been satisfactory, and the deaths below the average of the last four years. The number of cases of small-pox have been steadily decreasing, and none have been reported for upwards of a fortnight. In the metropolis generally the same tendency existed, as was shown by the diminution in the number of deaths, the figures for the last seven weeks being 27, 22, 20, 23, 11, 20, and 8. In the City, 8 cases had been reported, all of which were promptly removed to hospital, with one exception. Edmunds-place continued to supply fresh cases of diseases of the zymotic class; in the last few weeks 9 cases of small-pox occurred there in succession, and on the 15th ult. a case of fever was removed thence to hospital which proved fatal on the following day. Having previously noticed the unhealthiness of this place, Dr. Saunders made special surveys of the different houses. The houses exteriorly have a modern appearance, and are fairly clean, but this is only facing; internally they are defective from great age in many particulars. In some of the houses the water-supply is insufficient, and in many the drains and back yards are out of repair and dilapidated. These, with other defects of a cognate nature, are being remedied, and in the meantime every conceivable precaution has been adopted to prevent the spread of contagious diseases, and continuous exertions are applied in ferreting out the cause. During the last seven weeks 139 deaths were registered, and 151 births.

The public announcement of the intended formation of a medical club at Eye, Suffolk, has, as we expected, brought prominently forward a statement of the main reason why such institutions have hitherto been found to be practically impossible. The Rev. Samuel Barnett, of St. Jude's, Whitechapel, in a letter addressed to the *Times*, says:—"Last year we drew up rules and a scale of fees, similar to those to be used in Suffolk, for the institution of a similar club. The doctors best known in the neighbourhood agreed to be on the staff, and a collector has been employed. Everyone has worked well, but as yet the scheme is not a success. The cause of failure is the facility with which the working-people can get attendance at the London Hospitals, and Free Dispensaries. It is hopeless to expect that they will put aside even a penny a week for medicine and a doctor's attendance, when they can obtain as much for the mere asking. As long, therefore, as hospitals give their relief so freely and indiscriminately, we must expect that the people will use this 'stepping-stone to pauperism,' and be deprived of that 'happiest of results, the healthy feeling of self-help and independence,' which belongs to those who do their duty in providing for the necessities of life." When the increased wages earned by the working-classes in the present day are taken into consideration, it is evident that the time has arrived for instituting inquiries into the means of those applying for relief at the great metropolitan hospitals, before admitting them as patients, except under urgent circumstances. If this can ever be fully carried out, there may be some prospect for the ultimate success of medical clubs; but, in the metropolis, not before.

Dr. Collier, the Medical Officer of Health to the Fulham District Board of Works, having recently reported that there had been an extensive outbreak of small-pox, and several deaths, at Rectory-place, Walham-green, in consequence of the first case not having been reported to him till a fortnight after it appeared, the Fulham District Board of Works, at their meeting held last week, resolved "to put themselves in communication with the Home Secretary with a view to the Government providing in the proposed new Public Health Bill a clause making it compulsory upon medical men to give notice to local authorities of the occurrence of cases of infections or contagious diseases." Mr. Brown, in seconding the resolution, observed that it hardly went far enough, as other persons besides medical men should be compelled to give the information. We quite agree with Mr. Brown; for obvious reasons the medical man is not the channel through which the information should be conveyed to the authorities. In many instances the services of a medical man are not obtained, although the relatives of the patient are perfectly aware that he is suffering from an infectious disease. The onus should be placed by the law upon the householder, and, as we remarked only last week, the weight of public opinion will eventually impress this important fact upon the members of the Government.

During the absence of her Royal Highness Princess Louise

from town, the milk from two cows belonging to her Royal Highness has, by her order, been given daily to the Victoria Hospital for Sick Children, of which institution the Princess is Patroness. This has proved a most acceptable gift, as necessarily in a children's hospital containing sixty beds the quantity of milk consumed is very great.

At a recent meeting of the Commissioners of Sewers, a long discussion took place as to the steps to be taken to destroy the large quantities of diseased meat seized by the City inspectors. It was stated that during last month fifty tons of meat were so seized. The Sanitary Committee recommended that tenders should be invited for the removal of the meat for destruction to a distance not less than four miles from the Guildhall. Mr. Game thought that this would not be the most effectual means of preventing the meat being improperly used either for human consumption or as food for animals. The Medical Officer of Health (Dr. Saunders) said he had been experimenting for some time, and had at last succeeded in producing a fluid which, while acting as a deodoriser, would turn the meat black, and cause it to taste so that no one would eat it. Three hundred gallons of the fluid could be produced for 17s., and any quantity of meat could be destroyed by it. The subject was eventually adjourned for further consideration. Meanwhile we will suggest a trial of scientific cremation.

It is difficult to imagine that anything short of official misunderstanding can have delayed a reply to the application put forward by the Corporation of Rochester to the War Department, for the grant of a suitable site on the outskirts of the city on which to erect a hospital for the reception of patients suffering from infectious diseases. The subject was discussed at a recent meeting of the Corporation, and gave rise to some strong animadversions on the part of several of the members. The Government holds all the land in Chatham and Rochester which is suitable as a site for such a hospital; but, although repeated applications have been made to the War Department by the Corporation to grant a suitable site, no attention has been paid to these representations. It was stated at the meeting that, in the event of the Government still remaining silent, the compulsory powers of the Corporation would be put in operation.

The Duke of Cleveland, who owns a racecourse in the centre of Wolverhampton, which the people want for a public park, offers fifty acres in the middle on lease, at a little over £300 a year for sixty-three years, with the option of purchase then at £400 per acre. The offer was read at a special meeting of the Town Council held last week. The terms were pronounced to be extremely liberal, and his Grace was warmly thanked. The offer is to be formally accepted forthwith.

The Hertford bench of magistrates have awarded the sum of ten shillings to a boy named Patmore for an act of bravery brought to notice by Superintendent Jarrett. On the previous Sunday a dog in a rabid state was observed at large in the streets at Hertford, and after it had bitten three persons, and upwards of twenty dogs, the boy Patmore caught it, and held it firmly until its brains were knocked out by a policeman. Which required the most courage—the action of the lad; or that of the magistrates in thinking ten shillings a fitting reward?

On Monday last the *Andaluza* (Captain Anderson), of Glasgow, arrived at Falmouth from the West Coast of Africa, with most of the crew sick from scurvy. The vessel left Rotterdam for the outward voyage on March 11. When at Oporto several of the men suffered from ague, and scurvy broke out as early as the beginning of July. One man died at sea on August 20. The captain put into Terceira for medical advice on September 4. Four of the crew are now very ill, and will be brought ashore to hospital.

THE ASTLEY COOPER PRIZE.

It will be remembered that we announced, a month ago, that this triennial prize of £300 had been awarded to Professor Albert Eulenburg, of Greifswald, and Privat-Docent Dr. Paul Guttmann, the author of an excellent work on Physical Diagnosis, for their essay on "The Physiology and Pathology of the Sympathetic Nervous System." The *Berliner Klin. Wochenschrift* naturally expresses its satisfaction at this intelligence; and it seems only too probable, looking at the present restrictions on English scientific work imposed by our Legislature, that the future prizes will also go to Germany. But we must further add that unhappily the award made on this occasion has excited not a little dissatisfaction at home—not, we hasten to add, because of any doubts as to the ability and entire good faith of the judges, or as to the merits of the selected essay, but because the prize has been adjudged to a joint composition—to an essay written by *two* authors. We must confess that it does appear to us that the award is on this ground a mistake. Unless we are much mistaken, the notice issued to intending competitors of the conditions of the competition states that "the prize will be awarded to the *author*" of the best essay or treatise, etc., and that each essay or treatise must be accompanied by a sealed envelope "containing the name and address of the *writer*"; and in the original conditions drawn up by the testator it is provided that the essay or treatise of "the successful *candidate*" shall be the property of Guy's Hospital. The italics are, of course, our own, used to mark that in none of these instances is the word italicised used in the plural number. We do not pretend to say what the legal right in the matter may be, but we greatly doubt whether English workers in science would ever have thought, much less hoped, that any two or more of them would be accepted as "a candidate"; and we are quite sure of this, namely, that if joint compositions are to be admitted into the competition,—and if an essay by two authors is permissible, one by half a dozen or any other number must be,—if treatises by joint authors are admissible, it ought to be clearly so stated in the conditions. As the matter stands, all the writers of single-handed essays on the recent occasion seem indisputably to have a grave grievance.

ABERDEEN UNIVERSITY COURT.

Owing to the Rev. Dr. Christie being appointed to the chair of Church History, a vacancy occurs in the University Court of Aberdeen. Since the death of Dr. Kilgour, the first elected Assessor of the General Council, there has been no medical representative in the governing body of the University. The present occasion seems a good opportunity for remedying this defect. The medical members of the University Council are greater in number than the clerical, whilst the medical school has undergone such development that the medical undergraduates are nearly ten times more numerous than the divinity students. It is manifestly to the best interests of the University that the most active and popular faculty should have an official representative of its own profession in the Court, instead of, as heretofore, a member of another faculty. The name of the ex-Dean of the Medical Faculty, Dr. Macrobin, the Emeritus Professor of Medicine, has been mentioned as likely to be brought forward. There is little doubt that Dr. Macrobin would be welcomed by the professorial body—his long associated colleagues—and the general body of medical members of the General Council. Dr. Macrobin was for five years the representative of the University in the General Medical Council, where his large experience and business habits were much valued. There is probably no one who, from long and intimate acquaintance with the affairs and interests of the University, could so fitly represent the medical faculty in the University Court as Dr. Macrobin. The election

is named for October 10, and, should there be no contest (no name but Dr. Macrobin's has hitherto been mentioned), will be completed on that day. Should, on a show of hands, a poll be demanded, the Registrar is required to send voting papers to all members of the General Council, who can thus make their influence felt without being put to any expense.

DR. CHARLES MAYO.

We greatly regret to have to announce the death of Dr. Charles Mayo, M.A. and M.D. Oxon., and Fellow of New College, of that University. He is reported to have died on board ship, somewhere near the Fiji Islands, where he went as soon as the Islands were ceded to England, in 1874. Dr. Mayo had seen much foreign war service, and had received several foreign orders and distinctions. He was also for some time Coroner for the University of Oxford. We hope to be able next week to give a fuller account of his active and useful life.

THE FLESH OF OXEN SUFFERING FROM PLEURO-PNEUMONIA.

The Public Health Committee of the Corporation of Dublin have addressed the following queries to every registered medical practitioner in Dublin, asking for replies and observations on them:—"1. Do you consider the flesh of oxen killed whilst suffering from contagious pleuro-pneumonia fit for food for man? 2. If you consider that such flesh may be used under certain circumstances, please state whether or not it is fit for food in the second stage of the disease, in which the lungs are usually much increased in size, partially hepatised, and sometimes more or less infiltrated with pus?" While we give the Public Health Committee credit for their laudable desire to gain information on an all-important hygienic question, we cannot but think that the mode of conducting the inquiry is far from satisfactory, and that the results will, unfortunately, have little or no scientific value. Would it not have been much better to have referred the question to a small committee of sanitary experts, or to the Irish Colleges of Physicians and Surgeons—corporations which have ever displayed an intelligent interest in the progress of sanitary science. As it is, we are at a loss to understand of what practical value a mere majority of "ayes" or "noes" will be on one side or the other of the question. If most of the replies are discarded as valueless, and tho (necessarily) few of real scientific merit are made public, then only will some practical results redound from the inquiry.

GLASGOW ROYAL LUNATIC ASYLUM.

We have received a copy of the sixty-third annual report of the Glasgow Royal Asylum for Lunatics at Gartnavel, for the year 1876. The indefatigable Physician-Superintendent, Dr. David Yellowlees, after recording the usual statistics, remarks that there is nothing new to report as regards treatment, but he gives the history of two or three prominent cases which have made good recoveries during the past year, and the means adopted for bringing about such satisfactory results. In compiling a table which is attached to this report, showing the causes of insanity in the patients admitted, Dr. Yellowlees remarks that the causation of insanity is a very complex question, and the cause assigned is often palpably absurd. Very frequently an early symptom or some coincident circumstance is fixed on by the friends, which has in reality nothing to do with the matter. The real cause is to be found in the unstable nervous system of the patient. This instability may be inherited or acquired, but its degree is the true measure of liability to insanity. This explains why some minds are upset by apparently trivial causes, while others remain calm and unshaken through a lifetime of affliction and sorrow. This nervous instability is ignored every day, and is rarely thought of in connexion with marriage, even by those who would recoil from entering a family afflicted with cancer or consumption. An objectless, luxurious life, with frivolous, restless excitement, late hours, and sensational reading, inevitably developes a nervous irritability, which is the first step towards instability, and of which headaches and neuralgia, hysterical fancies, and uncontrolled emotions are the significant indications. How to rectify and how to avert nervous instability are large questions, which, Dr. Yellowlees thinks, have never yet received a tithe of the attention they deserve.

THE CHAIR OF PHYSIOLOGY, ABERDEEN.

We are glad to learn that Dr. Stirling has been appointed by the Crown to the vacant chair of Physiology, or, as it is in Scotland called, of the Institutes of Medicine, in the University of Aberdeen. Dr. Stirling, who was acting as assistant to Dr. Rutherford in Edinburgh, had already made his mark both as an observer and a teacher in physiology; and when speaking of the vacant chair in Aberdeen some weeks ago, we observed that the Crown could not do better than confer it on Dr. Stirling. We congratulate all parties—the University, Dr. Stirling, and the Government—on the appointment.

DEATH UNDER THE BICHLORIDE OF METHYLENE.

We have heard with regret of another fatal case under anæsthesia at the Radcliffe Infirmary, Oxford. A young man was operated on for disease of the bones of the foot, and amputation was performed above the ankle-joint. Bichloride of methylene was administered on lint. Before the dressing of the stump was completed, it was observed that the patient was pulseless, and that respiration had ceased. Artificial respiration was attempted, but, unhappily, without success. A case of death during anæsthesia occurred at this Infirmary about five years ago.

INCREASE OF INSANITY.

The Controller of the Post-office Savings Banks notices, in his report on the year 1876, that the number of cases in which depositors were shown to be insane averaged only about twenty-nine in the first three quarters of the year, but suddenly rose in the last quarter to forty-eight, and that the increase was to a great extent maintained in the first quarter of 1877, there being thirty-nine cases in that period. He adds that the experience of the department, therefore, seems to justify the somewhat prevalent idea that there has lately been a rapid increase of insanity, particularly among the working-classes. It may be observed, however, that if the last quarter of the year 1876 had not shown a decided increase, the total for the year would have been less than in 1875. Still, it is worthy of remark that the number for the entire year 1876—namely, 136—was more by thirteen than the number in the preceding year, and that 1875 had shown precisely the same increase over 1874.

SUICIDE IN GERMANY.

The statistics of the second quarter of 1877 give the total number of deaths by suicide in 147 of the largest towns of the German Empire as 667, or 1·3 per cent. of the deaths from all causes. That this is a large number is shown by comparing it with the percentages of deaths from certain diseases. Thus small-pox only gave 0·02 per cent.; measles, 1·1; scarlet fever, 1·8; whooping-cough, 1·4; typhus, 0·1; dysentery, 0·1; typhoid fever, 1·4; and puerperal fever, 0·5. In Berlin a good many suicides are reported every week. Thus, taking cases at random, we find that in the week ending June 9 there were 2 suicides by drinking mineral acids, 1 by shooting, 1 by hanging, and 2 by drowning; in the week ending July 14 there were 2 by mineral acids, 1 by shooting, 1 by hanging, and 4 by drowning. Suicide by mineral acids seems

rather a favourite form of death, as are also hanging and drowning. The existence of so large an amount of misery and despair as must be prevalent in Germany to cause so many persons to put an end to their lives is not a very good sign of internal contentment and prosperity. It is not pleasant to be "ruled with a rod of iron," and perhaps the remorseless demands of an overwrought military system may have more suicidal victims to account for in the dismal list than the German Government would care to confess.

ROYAL COLLEGE OF SURGEONS.

THE following is the report from the Court and the Board of Examiners of the number of candidates who have presented themselves for the primary and pass examinations for the diploma of Member of the College during the collegiate year 1876-77, showing the number who have passed and have been rejected from each medical school during that period:—

Primary Examinations.

Medical School.	Totals.	Number passed.	Number rejected.
St. Bartholomew's	119	82·50	36·50
University College	100·50	69	31·50
Guy's	80	70	10
St. Thomas's	60	38·50	21·50
London	42·16	24·3	17·83
St. George's	40·6	26·3	14·3
King's College	33·50	24·50	9
St. Mary's	27·50	18·50	9
Middlesex	24	20	4
Charing-cross	20·6	15·3	5·3
Westminster	11	8	3
Manchester	35·50	23·50	12
Liverpool	30·50	25	5·50
Bristol	23	8	15
Birmingham	21	15	6
Leeds	20	15	5
Sheffield	7·50	3·50	4
Newcastle-on-Tyne	13	9	4
Cambridge	9·50	7·50	2
Dublin	20·50	7	13·50
Belfast	3	3	—
Cork	2	1	1
Galway	0·50	—	0·50
Edinburgh	25	18·50	6·50
Glasgow	4	2	2
Aberdeen	0·50	0·50	—
Montreal	3·50	2·50	1
Toronto	3	2·50	0·50
New York	1	—	1
Ohio, Cincinnati	1	1	—
Laval	0·50	0·50	—
Bombay	5·50	4·50	1
Calcutta	2	2	—
Madras	1	1	—
Berlin	1	1	—
Leipsic	0·50	0·50	—
Totals	792	546	246

Pass Examinations.

Guy's	83	68	15
St. Bartholomew's	72	63	9
University College	64·3	51·3	13
King's College	45·50	32·50	13
St. Thomas's	42·6	32·6	10
St. George's	27	24·50	2·50
London	26	19	7
St. Mary's	19·3	14·50	4·83
Middlesex	15·16	11·3	3·83
Charing-cross	7·83	6·50	1·3
Westminster	7·83	3·83	4
Manchester	25	18	7
Birmingham	24	19	5
Leeds	20·3	14·50	5·83
Liverpool	10·16	4·83	5·3
Bristol	9·50	4	5·50
Newcastle-on-Tyne	6·3	2·3	4
Cambridge	3·50	1·50	2
Sheffield	2	1	1
Dublin	9·50	5·50	4
Belfast	2	2	—
Galway	0·50	0·50	—
Cork	0·50	—	0·50
Edinburgh	23·16	13·3	9·83
Aberdeen	5·3	4·3	1
Glasgow	1	1	—
Bombay	2·50	1·50	1
Calcutta	2	1	1
Caraccas	1	1	—
Liége	1	1	—
Toronto	3	3	—
Montreal	3	2·50	0·50
New York	1·3	1·3	—
Ohio, Cincinnati	1	1	—
Totals	569	432	137

In the above lists candidates who are indicated by a fraction have received their education at more than one school of medicine. The report is signed by William Scovell Savory and John Birkett, as Chairmen respectively of the Board and Court of Examiners.

YELLOW FEVER IN JAMAICA.

AN occasional correspondent of the *Times* reports that there is at present, unhappily, not only a very general epidemic of fever in its more or less dangerous form in Kingston, Jamaica, but that several deaths have occurred from true yellow fever. Mr. Rushworth, C.M.G., D.C.L., who has been Lieutenant-Governor of Jamaica since the departure of Sir William Grey from the colony, and who has served in the tropics since 1855, has fallen a victim to yellow fever after a very short illness; and two members of his family died of it before this. His stepson, Mr. Crichton, an Oxford undergraduate, who had gone to Jamaica for the Long Vacation, was the first to die from the disease. Miss Rushworth followed him within twenty-four hours; and her father fell ill and died in the next week. Major-General Mann, who succeeded him as Lieutenant-Governor, had hardly taken the oaths of office before he also, and his wife and daughter, were attacked by the same malady; but they happily are reported to have all recovered. Various rumours as to the cause of the disease are afloat in the island: it is attributed to a clogged drain in the late Lieutenant-Governor's house, and it is said that Mr. Crichton was very much out of health when he landed; but though either of these conditions will predispose people to fever, neither will cause yellow fever. The illness in General Mann's family is said to have been caused by the presence in his house of some soiled linen left there by Mr. Crichton; but we do not know that it has ever been *proved* that yellow fever can be communicated in that manner. There will probably be an outcry now against Jamaica as an exceptionally unhealthy place; but for a place within the tropics it is far from being unhealthy, and it is said that the country districts of the island, with the exception of a few swampy places, may justly be regarded as indeed exceptionally healthy places of residence, even for white men, though the island is not to be recommended as a health-resort.

"THE SCIENCE OF TEMPERANCE."

A LECTURE on this subject was delivered by Dr. B. Ward Richardson, F.R.S., in the Ancient Concert Rooms, Dublin, on Thursday evening, the 13th inst. The chair was occupied by Dr. Samuel Gordon, President of the King and Queen's College of Physicians. The points made by the lecturer were briefly the following:—*First:* That the substance now called alcohol, and which had been so called for some three centuries, could not be considered as a food, as most people supposed—standing alone in the world as something which was to be taken as if it were a food. *Secondly:* That common alcohol was, therefore, not a special gift sent to them to be used as a food any more than the other chemical bodies coming under the head "Alcohol." *Thirdly:* That when, as physiologists and biologists, they looked on the construction of the animal kingdom, and considered how it was made up of certain fluids and solids, they were struck with the fact that there was no provision whatever made for the use of such an agent as alcohol. Nature had produced the organisation simply of one fluid, and that fluid was water. *Fourthly:* That ethylic alcohol acted on the bodies of men and animals in the same manner as other chemical substances. It did not act after the manner of a food at all, but produced effects which were phenomenal in their character. He found that a fatal dose meant a proportion of a drachm of fluid to the pound weight of the warm-blooded animals. In a man weighing 120 lbs., a dose of fifteen ounces would certainly be fatal unless scientific means averted death. The lecturer then graphically described the phenomenal effects of various doses of alcohol on the organism, and remarked, in conclusion, that if alcohol did anything that was of use in the animal organisation, it was in the first stage of this action, and to that point he would ask to direct attention at his next lecture. This was delivered on Thursday evening, the 20th inst., and was on "The Promotion of Temperance."

REGISTRATION OF MEDICAL STUDENTS.

THE Society of Apothecaries have given notice that as the registration of medical students is now conducted by the General Medical Council, students will not be required to attend for the same purpose at the Apothecaries' Hall. We regret that a similar notice has not been issued by the Royal College of Surgeons. "As soon as possible" after December 31 in each year, a list of all students registered is to be prepared and printed by the Registrar of the Medical Council, and copies of it are to be supplied to each of the bodies enumerated in Schedule (A) to the Medical Acts, and through the branch registrars to the medical schools and hospitals. We cannot see, therefore, why medical students should be required to waste time and labour in getting registered at the College; and we trust that the Council of the College will, after this year at any rate, follow the good example set by the Apothecaries' Hall. The preliminary Examination in Arts at the Hall will take place on the 28th and 29th inst.

AN EPIDEMIC OF LEAD-POISONING.—An event has just occurred at Paris which has filled a whole *quartier* of the town with alarm. This arose from large numbers of the customers of a baker at Batignolle becoming the subjects of lead-poisoning, owing to the oven having been heated with painted wood derived from the demolition of houses. One practitioner of the *quartier* had under his care no less than sixty patients suffering from lead-colic, while some thirty others were under treatment at Beaujon and other hospitals. A curious circumstance occurred regarding two *eonciergcs*, husband and wife—one of whom, only eating the crumb of the bread, owing to bad teeth, suffered no injury; while the other, who consumed all the crust, had violent colic.—*Révue Méd.*, August 27. [Lead was detected by Prof. Carnot in the bread sold by this baker.]

THE PROSPECTS OF A QUALIFIED PRACTITIONER.

WHEN writing a week or two ago for students, the thought struck us that it might not be amiss to say something on the professional prospects of one who has succeeded in qualifying himself, and is looking about him for some means of making a livelihood by his professional acquirements. For the time that was deferred, but we still think that a few words may not come amiss on the prospects of a qualified practitioner.

These, it must be confessed, are not brilliant. To a man who has no real love of his profession they might well be deterrent. The average medical income throughout the country has been roughly calculated at £400 a year. This, of course, includes the large incomes, and we may say fortunes, that are made by a few; consequently, in the majority of instances, the income is less than this. It may be laid down as a broad rule that men do not make money in our profession, and as an illustration of this fact we would refer our readers to a little apologue published in these columns some years ago. But the little apologue was fact.

Should a man make up his mind to encounter the risks of private practice, we should advise him, above all things, if he loves his own peace, to eschew "assistantships with a view to partnership." For the most part they are snares. How, then, is a man to start? That is most difficult to say. In any shape or form, it requires, as in all matters of business—grocers, butchers, and bakers will not concede the claims of a profession without cash,—money-capital. And this capital must be made somehow. It may be that a man has capital of his own, that he marries a rich wife, or that he has well-to-do and kind relations. Such a man starts fairly in the game of life if he is not foolish. But to make a capital, and to live at the same time—more especially with those hostages to fortune supposed to be necessary for a medical man's respectability—is hard indeed. Instances occur to us, as we write, where men have been tied down as partners or assistants under most galling conditions, in order to make their capital; and when they find themselves in a position to cast off their shackles—when their capital has been worked for, as did Jacob for Rachel,—they find themselves bound hand and foot. What, then, is to be done? We fear we must go back to Carlyle's advice to a young gentleman who had come to London for the purpose of becoming a leading star in the literary world. He asked Carlyle's advice; this was soon given in his own particular form of language, which we do not venture to attempt—"Why don't you become a carpenter or a stonemason, where your work will be real and tangible,—not the mere manufacture of words which have not even got sound in them?" It is not good for a poor man to enter a poor profession; and rich men as a rule don't. If they do, they, as a rule, leave it, or pursue it only in a *dilettante* fashion.

But suppose a man possessed of a moderate capital: how best to dispose of it? Neither is this a question easily answered, but we shall try to give the benefit of a tolerably wide experience of all sides of the question. We have over and over again been consulted by young men as to what is the best thing to do. It is never easy nor yet safe to answer such a question, for such an answer requires great and intimate knowledge of things and circumstances. We shall give three illustrations applying to three different conditions, and these will probably be more useful than abstract didactics.

A sudden death-vacancy occurred, and a gentleman, who was dissatisfied with his position as "assistant with a view to partnership," made inquiries. He had not a large capital at command, and the risk of failure would have been disastrous. He was leaving what he could make, in course of time, a good thing, for a risk. In this case, however, the *elientèle* belonged to a somewhat clannish community, who were prepared to help the widow and aid her in getting what she could for the practice. A knowledge of this fact enabled us to give the advice that the risk was worth running. The risk was run, and the practice is now better than it ever was. It was the special knowledge which aided us in giving the advice; without this it would have been worse than useless. A case comes up before us again: A sudden death-vacancy occurred; the practice was a *personal*, not a *local* one. An ill-advised young man eagerly snatched at the apparent chance, and lost

all he had, for the practice was broken up into a score of fragments.

Take another illustration. A gentleman whom we knew well determined in disgust to work his way unaided into practice, preferring to spend capital in living rather than in buying a risky practice. He selected, as he thought, a good suburban neighbourhood, apparently rapidly increasing. Things took a wrong turn; the neighbourhood did not increase, save with those who preferred a moonlight "flitting" to the more usual way of paying debts. Thus, at the end of seven years, and after the expenditure of about £700 over and above professional earnings, he was still in a position of difficulty, finding it hard to make both ends meet. This, too, it must be remarked, with an exceedingly plain and moderate style of living.

Still another plan of starting. A gentleman was in search of a partnership—many are in search of partners, and one was soon found. In this he invested all the money he could command, including some belonging to his mother and sister, who were anxious to have a home with him. In a very short time he found that the practice was not enough for one; that the booked debts had been in some cases imaginary, and in others impossible. The partner, who a few years before had been the soul of honour, had been driven by circumstances to such extremities that he had not hesitated at the use of these means to secure money. What is the moral in this case? We should not like to draw it as some would, but to the would-be partner it is this: have the books audited by a regular accountant before entering into partnership.

The outcome of the whole is, that except a man inherits, or somehow becomes heir to, a practice, money must be spent in acquiring it. But how to lay out money to the best advantage we cannot undertake to say. What may seem folly or madness in one case, may appear the most consummate prudence in another. The case varies with the circumstances.

But there is one mode of making an honest, and what used to be an honoured, livelihood by the profession of medicine, where little or no capital was required; where sound professional knowledge and gentlemanly conduct were the chief, if not the only, requisites: that was in the service of the country. But these days seem to have passed away. Each of the three most important Services—the Army, Navy, and Indian—has drawbacks; but in the Army, or Queen's, Service these seem to have culminated. The Navy never was a popular service with our profession. Within the narrow walls of a vessel so much depends on the men with whom one is of necessity brought in contact, that everything conducing to personal comfort may be said to be under the control of others. In the Army this was never so much the case. In the Navy, however, a careful man could save a good deal of money, which he could not in the Army; and if he had a pleasant set of messmates and a good captain, life could be made very tolerable; but all depended on the *if*. A brutal captain has driven many a good man to despair, and worse. Again, in the Navy, no man could look forward to marriage for many years; and this has drawn some of the best men from the Navy. Finding themselves engaged, the prospect of long waiting was too hard to bear; and the position of a wife left for years alone on shore was not one to be envied. Then, when the husband did return, the period of leave was so short that a further application would often be asked for, ending in the conferring and accepting of that curse of the naval system—half-pay. A ship comes home after years of foreign service, is paid off, and so many days or weeks of leave granted. Then follows half-pay. This does not press so hard on unmarried men—they can live on half-pay; it is hard for a man with a family to do so. Promotion comes; increased pay should come with the new rank, but instead of that—half-pay again. It is cheaper to employ men who earn a smaller income. And so some men rust out, and some men wear out, though it must be confessed that there are numerous fairly good appointments on shore even for naval doctors when they become seniors. It would seem almost passing to the ridiculous to mention next certain little drawbacks which seem to embitter men's lives. The naval medical officer, though wearing her Majesty's uniform, is never saluted, except it may be by his own men; and some feel this keenly. There are scores of little irritations of the most absurd kind which might be easily removed, but which remain and fester, apparently only to keep open that ill-concealed feud which has long existed between ordinary combatants and men of science.

If we turn to the Army, matters are still worse. In the olden time, when service was regimental, the surgeon next to the colonel, or often before him, was the "father" of the regiment. To him and in him all things were confided. He knew all his men personally, knew what maladies they were subject to—in fact, was in a similar but far superior position to that of an esteemed and skilful family doctor. But all this is no more. The Army is no longer even a career, for by the new regulations a man only enters for ten years, and may never reach a higher grade than that of surgeon. His pay—adequate, it may be, for a young man—is utterly inadequate for a man who is married; and marriage may appear to be the only relief to the solitude which promises soon to be the fate of aspirants for honour in the Army Medical Service. The ten most important years in the practitioner's career are to be squandered,—and for what? A miserable pittance by way of pay, and £1000 at the end of his career! But how many will have their £1000 intact. There are plenty of gentlemen who will be most happy to advance money on the contingency,—but at what rate? A good many men used to join the Army Medical Service for the sake of a pleasant life among pleasant companions. Where are they now? Cursing their fate, eager to withdraw from the Service, but unable to do so save at a loss they cannot afford. They have no longer their regiment as a home; they are driven about from place to place; in most garrisons they are simply honorary members of the mess, for the combatants only grant them the use of their mess out of charity,—they refuse to allow surgeons to pay like themselves. If any entertainments are going on, the surgeon has no share or lot in them, though a good-natured committee may send him a ticket, not personally, but merely to the surgeon for the time being. This may be looked upon as an extreme view, but it is not, for it is not long since a regiment in Ireland passed a resolution that thereafter no medical man should be even an honorary member of their mess. With such prospects how can men come forward to help to fill the vacancies in such a service? They must be wonderfully constituted. Of hope they must have much, of self-respect little. Where they come from, a table we published will help to show. We took the trouble to analyse the qualifications of those who had been successful at the recent examinations. These speak for themselves, but it may be useful to add that at the time of passing two were not even registered. We have no doubt they will meet from their brethren that cordial reception accorded by a starving man to another who comes to share his last crust. What of the Indian Service? Alas! that too is doomed. The advantages it presented were too patent when Queen's and Indian men were serving side by side; so that too is to be, it is said, "unified." The result is not doubtful. Good pay and good allowances enticed many men into a service which entails many privations and a good many discomforts. Prospects like these now offered by the British service will not induce men of capacity to enter on such a career. There is only one way of enforcing the claim of the profession on the military authorities—that is, abstention. Our advice is simple:—Keep out of such service.

Thus, unfortunately, we must end as we began. We may lament the fact, but fact it is: the prospects of the newly and duly qualified medical practitioner are not brilliant.

Syphilitic Cerebral Arteritis.—Under this name, M. Lancereaux read a paper at the late meeting at Havre, in which he stated that the special anatomical character of this affection is localisation at certain points of the arterial wall, the lesion commencing in the connective tissue of the artery, and proceeding on, in different cases, either to contraction or obliteration at such points, or to aneurismal dilatation. It varies from ordinary endarteritis by its tendency (like all syphilitic lesions) to remain circumscribed, and by its disposition to symmetry.—*Gaz. Hebd.*, September 7.

The Hospital Saturday Fund.—The amount collected in the boxes placed in the streets and large establishments of London on Hospital Saturday was £835, being a slight increase on the sum realised in the same way last year. Of this amount £685 12s. 5d. was contained in the boxes lodged at Messrs. Hoare's bank up to 11.30 p.m., and was made up as follows:—Gold, £60; silver, £461 18s. 5d.; copper, £163 14s. The boxes placed in the steamboats brought in £31 17s. Those kindly put up by Messrs. Spiers and Pond on the counters of their various establishments realised £26 13s. 6d., and those put up by Messrs. Faulkners £1 10s. 11d. The remainder was made up of money deposited in boxes at Covent-garden Theatre, Holborn Restaurant, sundry hospitals, etc.

FROM ABROAD.

Salicylic Acid in Rheumatism and Gout.

In July last, Prof. Germain Sée read an elaborate paper upon this subject at the Academy of Medicine, the conclusions of which are published in our number for July 21, page 72. These have been regarded by most persons as furnishing an exaggerated estimate of the benefits of the remedy—such as, in fact, is of frequent occurrence with most new medicines in the hands of sanguine experimenters; and the short discussion which has followed the reading of the paper has not given much encouragement to their unqualified adoption. Prof. Sée, however, is as confident as ever of the accuracy of his deductions, and attributes the want of corroboration which he has met with from some other observers to their faulty mode of dealing with the substance in question.

At the commencement of the discussion M. Oulmont (*Bulletin de l'Académie*, July 24) called attention to the antifebrile or antipyretic power of salicylic acid and the salicylates, which Prof. Sée seems to have overlooked. Given in large doses, they determine in from two to four hours a fall of the pulse from ten to twenty beats, and a diminution of temperature which may range from five-tenths of a degree to 2° or 3° C. It was at Basle that M. Oulmont had first observed these results produced by Prof. Immermann. He has himself since administered the salicylate of soda to a great number of patients suffering from a variety of febrile affections. Four or five doses of a gramme each are taken at intervals of half an hour, the temperature and pulse being examined every four hours. The medicine may have to be continued for several days, which, as it is easily eliminated, it can be without danger. So administered, M. Oulmont regards the salicylate as a very efficacious antipyretic in different febrile affections, and a specific in acute rheumatism. M. Guéneau de Mussy, as the result of the trials which he has made during two years, gives a guarded approbation of the salicylates in rheumatism, and does not venture to employ them in the large doses sometimes recommended; and he suspects that the greater frequency of cerebral rheumatism in recent times in some measure arises from the unguarded use of modern remedies. In gout, M. Guéneau de Mussy prefers the practice of watching and alleviating suffering rather than attempting to cut short the paroxysm; and in typhoid fever he uses the salicylate rather as an antiseptic than as an antipyretic, having found it in moderate doses very useful in several cases which threatened to prove fatal. In gangrenous sores of typhoid cases the external application of a solution of salicylic acid has proved rapidly beneficial. Upon the whole, M. Guéneau de Mussy has derived sufficiently beneficial results to encourage him to make additional trials. Prof. Jaccoud has employed the salicylate of soda in twenty-one cases of acute rheumatism, giving it in doses of from eight to twelve grammes distributed over the twenty-four hours; and he sums up the results of his experience as follows:—1. In febrile articular rheumatism, unaccompanied by any complication, it is one of the most powerful therapeutical means which we possess, producing a cure more rapidly than any other. 2. Although its action is sometimes so prompt as to effect a cure in from two to four days, yet we cannot assign a uniform duration of three days for the treatment. This would only cause disappointment, and damage a really valuable remedy in the cases indicated. 3. The salicylate does not prevent the cardiac, pulmonary, or cerebral complications of acute rheumatism. 4. When these complications exist before the remedy is employed, it exerts no influence upon them. 4. In spite of its antipyretic properties, the salicylate does not prevent the thermometrical ascension which reveals visceral complications in the course of the medication already instituted. 6. In febrile rheumatism with only very slight complications we may still employ the salicylate in order to take advantage of its antipyretic and analgesient power; but in order that nothing may be compromised, we should adjoin to this treatment the employment of revulsives, and even of stimulants. 7. In febrile rheumatism accompanied by serious complications, the salicylate cannot be relied on, and other means must be had recourse to.

In his reply (*Bulletin*, August 21 and 28), Prof. Sée observed that the five weeks which had elapsed since he read his paper had only corroborated by additional facts the views which he had brought forward, while the objections which had been made to these were chiefly of a theoretical character. He would first observe as to the method of employing the remedy. It was generally acknowledged now that the salicylate of soda is the best preparation to employ, and all it requires is to be dissolved in ten parts of water without any other addition. The salt should be absolutely pure, and free from carbolic acid, with which it is sometimes contaminated. The administration of salicylic acid in the solid form is a dangerous practice to be cautiously avoided. Large doses given at short intervals are not to be administered; but they should be spread over pretty equal intervals during the day. Less than three grammes daily (forty-five grains) of the salicylate are of no avail; but large doses given at one time, although they may reduce the temperature and the pulse, do so only for a few hours. In acute rheumatism the true dose is from eight to ten grammes in the twenty-four hours, and these doses must be begun with at once, and not gradually reached. In this disease abundant statistics show that in rheumatism so treated from the beginning, complications are of very rare occurrence, while the duration of the disease is enormously abridged. As to the specific antipyretic power claimed for the salicylate in rheumatism, Prof. Sée cannot admit it, for most of his cases were apyretic, and all he can say is that the remedy rapidly abates the pain, diminishes the swelling, and favours the elimination of urea and the urates. For these properties, and especially the first, it is that he has also employed it in neuralgia and all painful affections. He can also bring additional testimony in favour of its efficacy in chronic rheumatism, and especially in those acute accidents which graft themselves on chronic rheumatism; and if Prof. Jaccoud and others have not been so fortunate, it has been owing to their want of perseverance or the employment of insufficient doses. The fears of suppressing gout, entertained by M. Guéneau de Mussy and others, Prof. Sée regards as hypothetical and unfounded. At all events, the salicylate is no repercussive agent, but an eliminator of uric acid accumulated in the blood, as well as of extractive matter. In acute gout, as in acute rheumatism, eight grammes of the salicylate should be given per diem. Thirty grammes may be dissolved in 300 of water, of which four spoonfuls may be taken in water daily. When the pain diminishes, three spoonfuls may be taken per diem during a week or a fortnight longer; and then only two. In chronic gout we may commence with, but never exceed, three spoonfuls, continuing them until the swelling has diminished and the pains have ceased; two spoonfuls being then continued during an indefinite period. In this way relapses are almost certainly warded off. If the remedy has to be continued during a long period, it is better to give it at mealtimes; and if it gives rise to nausea, it may be diluted with Vichy or Seltzer water, or a spoonful of brandy may be added. Prof. Sée has received additional confirmatory evidence of the utility of the salicylate in neuralgia and other painful affections.

The Paris Hospital Mortality Returns.

M. Besnier, in his report for the quarter April to June (*Union Méd.*, August 9 to September 1) observes that the mean temperature has been the same as that of the corresponding time of year for several years; but that the variations between the maxima and minima have been remarkable. The *general mortality* in the hospitals is still greater than the mean of the quarter of prior years, but much less so than in the preceding quarter. The total mortality amounted to 3241, the mean of the quarter in the preceding six years having been 3043.

1. *Affections of Respiratory Organs.*—These have undergone the favourable influence observed at this time of the year—4000 cases having been admitted, with 1083 deaths. Of these, 1481 were cases of phthisis, with 745 deaths; 568 pneumonias, with 177 deaths; 1542 bronchites, with 120 deaths; and 409 pleurisies, with 41 deaths.

2. *Articular Rheumatism.*—As usual at this time of the year, there has been remarkable benignity in this disease. Nor is this the case in Paris alone; for at Toulouse the benignity of the disease and of the general medical constitution induces M. Bonnemaison to exclaim, "What a happy quarter! What mild diseases! What a magnificent time for the success of remedies, whether old or new!"

3. *Diphtheria.*—Although the diphtheritic affections have undergone their habitual attenuation at the approach of summer, the serious epidemic paroxysm dwelt upon in last

quarter's report has not yet passed away. The 728 deaths for all Paris during the first quarter of 1877 has descended to for all Paris during the first quarter of 1877 has descended to 592 for this second quarter. As to the hospitals, "there is always the same lamentable series; the same increasing progress of the number of cases; the same insufficiency of therapeutical agents; the same frightful mortality; the same disasters produced by the promiscuity of the children; and the same want of success of all demands for isolation." In this second quarter there were admitted 232 cases, furnishing a mortality of 184, or 79·31 per cent. The total admissions for the same quarter of the seven preceding years amounted to 788, with 566 deaths, or 71·82 per cent. Of 73 cases treated by M. Bergeron at the Ste. Eugénie, on 34 tracheotomy was performed, 5 only recovering; 39 cases of diphtheritic angina which did not invade the larynx were admitted, and of these 10 recovered. In M. Cadet's wards in the same hospital, of 36 cases 1 was an example of buccal diphtheritis, 10 were cases of diphtheritic angina without croup, and 25 were cases of croup, in 5 of which there was angina; of the 10 anginas, 9 succumbed; of the 25 cases of croup, 9 were cured; of 21 operations for croup, 7 were successful and 14 unsuccessful—*i.e.*, 33 per cent. of cures; of 4 not operated upon, 2 died and 2 recovered. M. Cadet is convinced of the utter uselessness of chlorate of potash in diphtheria and croup; but he has no better substitute to offer. At the Enfauts Malades, M. Archambaut had 18 cases of croup, 16 of which were operated upon, with only 1 recovery. These cases were all preceded by angina, and in all of them there was albuminuria present, sometimes in large quantities. Of 16 cases of diphtheritic angina without exteusion to the larynx, 5 died. One of M. Jules Simon's wards at the same hospital was invaded by a diphtheritic epidemic, only 2 out of 15 cases recovering.

4. *Variola.*—Not only has this undergone its habitual seasonal diminution, but it was also considerably below its mean prevalence as compared with the general mean since accurate records have existed. When the present mild epidemic began in 1875 there were for this quarter 181 admissions, with 36 deaths; in 1876 there were 170 cases, with 28 deaths; and in 1877, 105 cases, with 13 deaths. Partial as is the isolation carried on in the Paris hospitals, it still has been of great service in diminishing the number of cases; but it is an illusory measure as a means of preveuting the propagation of the disease, which can only be accomplished by the construction of separate hospitals.

5. *Typhoid Fever.*—According to the well-proved law of its progress, the epidemic of typhoid has reached in this second quarter of the year the lowest point of its seasonal curve, following in this a line that may be traced in advance, and that even in the severest epidemics. From 992 (the number of deaths from typhoid in Paris for the last quarter of 1876) the number descended to 361 during the first quarter of 1877, and then to 196 during this second quarter. The lowest point of the habitual curve is now attained, and the month of July will serve as a period of oscillation, and from the month of August the curve will mount up agaiu, to descend no more until the arrival of winter. We may affirm without hesitation that during August and the following months the number of deaths from typhoid will again increase. The existence of such increase is invariable, although its amount differs.

6. *Intermittent Fever.*—As is always the case, there has been in this spring quarter an increase in the frequency of intermittent fever, the *fièvre tellurique nostras*, which, usually benign, is sometimes pernicious in certain conditions of the individual or of the infection—localised in a *quartier*, a street, or usually in a dwelling, around which operations that have disturbed the infiltrated soil have been goiug on. M. Jules Simon has been much struck by the number of cases of intermittent fever occurring among children, aud relates some obscure cases of apparent cerebral disease which rapidly yielded to large doses of quinine.

7. *Scorbutus.*—The cases of scorbutus which have been met with in this and the preceding quarter bear much resemblance to those which may be termed prison scorbutus—*i.e.*, scorbutus due to confined and humid air, misery, and insufficient oxygenation and alimentation, without leaving out of sight the prevailing atmospheric constitution. M. De Beauvais states that since the cellular arrangement has been adopted at the Mazas Prison in 1852, the present is the second epidemic of scorbutus that has beeu observed, the first appearing during the severe winter of 1871, at the time of the siege, and the other during the first quarter of 1877. This last appeared quite unexpectedly, and attacked nineteen individuals, and seems to be explicable on no other supposition than epidemic influence. But neither at the St. Pélagie, where there are from 500 to 700 prisoners, nor at the St. Lazare, which contains from 1300 to 1600 female prisoners, was a single case of scorbutus observed. M. Lereboullet had a few cases which soon recovered, and the origin of which he attributed to the extremely damp coudition of the prison of the Chèrche-Modi. Two cases treated by M. Desnos at La Pitié also came from a prison.

7. *Puerperal Affections.*—These presented no great peculiarities this quarter. M. Siredey has contributed a note concerning the 458 lying-in women who were admitted during the first six months of 1877 into the Lariboisière Hospital. Of this number 12 died, but of these there were 3 whose deaths have to be abstracted from the general account. One died with hemiplegia occurring after an attack of typhoid; another of meningeal apoplexy and rupture of the liver after eclampsia, the day of her admission; and the third died also of meningeal apoplexy following eclampsia three days after delivery. The remaining 9 give, therefore, a mortality of 2 per cent. In 5 of these cases obstetrical interference, of more or less violence, was required; and the other 4 died after natural labour, proceeding apparently under the most favourable circumstances. An examination of these figures shows the considerable effect of obstetrical intervention on mortality. Thus, the 15 operations or manœuvres were followed in the six months by 5 deaths—*i.e.*, 1 in 3; while, abstracting the 3 cases mentioned above and this 15, there remained 440 deliveries, followed only by 4 deaths—*i.e.*, 1 in 10. Women in the poorer classes, when the subjects of abnormal conditions, are generally brought to the hospital, and that frequently after the failure of unskilful attempts at delivery.

Erysipelas of Infants.—In an interesting note M. Siredey relates his discovery of how this disease became endemic at the Lariboisière. For a long time past he has had numerous fatal cases (15 cases during this half-year, with only 2 recoveries), and has in vain sought for the cause of a prevalence which did not exist at the other hospitals. The disease did not affect exclusively cachectic and exhausted infants, but those who were robust aud healthy-looking. Every care had been taken with the infants, as with the women, to prevent washing in commou, each being supplied with separate implements. In spite of these and various other precautions, not a fortnight ever passed without a new case occurring. When beginning to despair of ever discovering the cause of this endemic prevalence, M. Siredey observed that in several of the cases the erysipelas did not commence around the umbilicus, but on the genital organs, the buttocks, the belly, and the loins. Now, at this time there was also a great number of infants suffering from diarrhœa, in whom erythema rapidly supervened, extending from the margin of the anus to the buttocks, genital organs, etc. From the wellnigh constant contact of urine and fæcal matters, the softened epidermis became removed, exposing the dermis aud giving rise to great suffering. The difficulty in so large an establishment, with an insufficient number of nurses, of bathing and changing the infants sufficiently often, induced M. Siredey to recommend that after they had been washed all the parts of the infant which were the seat of erythema should be smeared with cold cream or fresh cerate, and abundantly powdered with starch-powder, the napkins then being put on. The cerate having been found to be too liquid and difficult of application, fresh lard was substituted with the most excellent results. One of the nurses having observed this success, proceeded to apply the lard as a preventive, covering with it at each changing the buttocks and genitals of any infants whom, right or wrong, she suspected were about to have diarrhœa, aud usiug for this purpose old rancid and almost yellow lard. After this was discovered, and the old lard was discontinued, the endemic of erysipelas entirely ceased.

Death of Professor Gerlach.—This distinguished veterinarian and scientific observer died, after a long illness, on August 29. He was Director of the Royal Veterinary College at Berlin, and one of the first authorities on veterinary medicine. He was one of those who helped to place our knowledge of scabies on its present basis, and he investigated *inter alia* the effects of the meat and milk of tuberculous cattle on the human organism. He also wrote on hygienic subjects, and on "meat as a food for human beings."

REVIEWS.

Cyclopædia of the Practice of Medicine. Edited by Dr. H. von Ziemssen. Vol. VI., Diseases of the Circulatory System, etc. Translated by George W. Balfour, M.D., of Edinburgh; Edward G. Geoghegan, M.D., of London; Thomas Dwight, M.D., of Boston; J. Haven Emerson, M.D., and George G. Wheelock, M.D., of New York; and J. Solis Cohen, M.D., of Philadelphia. London: Sampson Low, Marston, Searle, and Rivington. 1876.

The first article in this volume is by Professor Rosenstein, of Leyden, and deals with the methods of physical examination of the heart. In a narrow compass it seems to us to contain all the most essential information on this subject, and the student may be interested in the descriptions of the "*pulsus trigeminus*" and "*pulsus alternans*" of Traube, and the "*pulsus paradoxus*" of Kussmaul and Griesinger. Professor Rosenstein also gives us the chapter on Diseases of the Endocardium, which he divides into—(1) acute ulcerative or diphtheritic endocarditis; (2) acute and chronic subacute verrucose endocarditis; and (3) chronic sclerotic endocarditis. A most excellent account is given of ulcerative endocarditis, a disease of quite modern discovery, and which appears to have been first described by the late Dr. Senhouse Kirkes. Rosenstein considers that the most important etiological factors in its development are—rheumatic fever, which is present in the great majority of the cases; puerperal processes, in which diphtheritic matter is found on the genitals; wounds whose surface is similarly affected; chronic valvular disease; and pyæmia. The existence of one of these factors he regards as the most important point in deciding whether ulcerative endocarditis is present in a given case. He decidedly thinks that we must only regard those cases as parasitic where there is the possibility of the introduction of diphtheritic matter *from without* through the surface of a wound. Acute or chronic nephritis appears to have no causal relationship to diphtheritic endocarditis.

In the section on acute endocarditis we notice with some surprise Dr. Rosenstein's dictum, that "the disposition to endocardial affections (especially after rheumatism) is, on the whole, smaller in childhood than after puberty." He refers to Dr. West, and other distinguished authorities, as opposed to his view; and, if our memory serves us rightly, an authority of equal weight—Sir William Jenner—would be also a member of the opposition. Certainly, in English children's practice the connexion between rheumatism and endocarditis is a very constant one; but there are striking exceptions, as in the case of a girl who was under the writer's care for her *ninth* attack of rheumatic fever, and who had not a trace of cardiac disease, although she had not exceeded her eighteenth year. In the treatment of acute rheumatism, Rosenstein inclines to the belief that Dr. Herbert Davies' blistering plan has the greatest claim to further trial, as a preventive of endocardial complication. In recent cases of endocarditis itself he recommends that Gerhardt's treatment by the inhalation of carbonate of soda should be further tested.

The subject of chronic endocarditis is fully treated, but there is nothing in the article to call for special remark. There are some thoughtful sentences under the head of treatment of valvular diseases, such as the following:—"Olympian calm, when its attainment is possible, should be warmly recommended as the mental dietary of a heart-disease patient. The patient's attention should never be attracted to his disease, either by those about him or by the physician" (page 167). Digitalis and iron (and especially the former) are the sheet-anchors of the practitioner in valvular disease, but Rosenstein speaks favourably also, from his own experience, of Waldenburg's treatment with compressed air in "correcting the symptoms of a deranged compensation."

Changes in the Position of the Heart and Diseases of the Heart-Substance are ably handled by Professor Schroetter of Vienna, well known to many Englishmen and Americans in his capacity of lecturer on the laryngoscope in the General Hospital. In the section on cardiac hypertrophy we notice that he rejects Traube's theory that the hypertrophy of Bright's disease is due to the elimination of a part of the renal capillary system, and that for reasons he gives he is inclined to the view that its true cause is to be sought in other concomitant conditions, such as disease of the heart-substance, an improper quality of the blood itself, and hence depraved nutrition, etc The observation that "the diagnosis of *dilatation* is just as difficult as that of hypertrophy is, as a rule, easy and sure," is one whose truth is at once felt when it is expressed, though it is perhaps too little insisted on in clinical teaching. It is worthy of passing note that Professor Schroetter considers *tea* of special value as a stimulant in the treatment of acute dilatation occurring in the course of inflammatory diseases, and where the object is simply "to maintain the *energy* of the heart's contractions only through a short period of time."

There is a good article on Fatty Degeneration of the Heart, in which, however, no mention is made of chloroform inhalation as an exciting cause of death in cases of fatty heart. Wounds of the Heart are treated at some length, but there seems to be little hope for anyone whose heart's wall has been perforated. "In the whole rich collection of cases (*here summarised*) there is no authenticated case of the cicatrisation of a ruptured heart" (page 275). We would especially recommend the article on Nervous Palpitation to our readers. The physiology of palpitation is very well done. Professor Schroetter seems to rely most on cold, applied either in the form of wet compresses or of an ice-bag, to relieve this troublesome symptom, the cause, of course, if possible, having been previously removed.

Congenital Diseases of the Heart are described by ex-Professor Lebert, and Diseases of the Vascular System (arteries, veins, and lymphatics) by Professor Quincke of Berne. Under the head of mesarteritis, or inflammation of the middle coat of the arteries, we find the following remarks on the antagonistic views of Dr. G. Johnson, and Drs. Gull and Sutton:—"Further observations of numerous cases are required to reconcile these contradictory observations, and the investigation is rendered all the more difficult that we have no positive knowledge of the actual size of the smallest arterioles in the various organs, while the varying degrees of contraction of these arterioles, and the varying amount of cadaveric rigidity (quite irrespective of diversities in the methods of preparing the specimens), introduce serious complications into any attempts at comparative measurements."

Aneurism, and the methods of treating this disease, are considered at considerable length, but Professor Quincke's survey of the latter is not encouraging. "It seems," he says, "that of all the local methods of treatment, next to ligature and compression, galvano-puncture is most deserving of confidence; but in most cases we are restricted to indirect and palliative treatment."

The section on Diseases of the Lymphatics is very complete, and we may especially call attention to the part dealing with rupture of the lymphatics, or lymphorrhagia. In the bibliography of chyluria we see that medicine is chiefly indebted to British observers for its discovery, and for the elucidation of its nature.

To Dr. Bauer, extraordinary professor of the Propaideutic Clinic at Munich, have been entrusted the articles on Diseases of the Pericardium. Our space will not allow us to do more than to say that few more graphic and carefully written accounts of pericarditis have appeared, especially in the important matter of physical signs. The subject of indurated mediastino-pericarditis and paradoxical pulse, here treated *in extenso*, will interest many scientific practitioners.

This gigantic volume—it exceeds a thousand pages—also contains a most comprehensive article on Whooping-Cough, by Dr. Steffen of Stettin; a long section on Diseases of the Lips and Cavity of the Mouth, by Professor Vogel of Dorpat; and an article on Diseases of the Soft Palate, by Professor Wagner of Leipsic.

Dr. Steffen rejects the idea that whooping-cough is either a neurosis or a zymotic disease, and considers that all we can at present say of it is, that "a catarrh of the respiratory organs lies at its foundation, and that this catarrh arises from infection, though we do not know of what kind the infectious substance is" (page 688). As to treatment, he considers that the results of inhalation of various substances (petroleum, carbolic acid, etc.) decidedly urge us to further experiment, and he believes that there is distinct proof that large doses of quinine (nine grains *bis die*) moderate and shorten the spasmodic stage.

Vogel's article closely resembles that on the same subject in his "Lehrbuch der Kinderkrankheiten," of which Dr. Jacobi of New York has published a translation, but it is fully brought up to the present time by the incorporation of the results of several new researches. The section on difficult dentition seems to us a particularly good one.

Among the diseases of the soft palate which Wagner describes, the greatest interest attaches to pharyngeal diphtheritis or diphtheria, the article on which is based on the writer's personal experience of about a hundred fatal cases, and a number of mild cases observed either in his own or Wunderlich's Clinic at Leipsic. We mention this because diphtheria has been already described by Oertel in vol. i. of this Cyclopædia; and Wagner, whose opinion on pathological subjects must carry great weight, differs from Oertel *in toto* on several theoretical points. Wagner's views of the essential nature of diphtheria may be summed up as follows:—"The specific poison which produces it is still entirely unknown; the evidence in favour of its parasitic nature is very weak. There is an intimate relation between croup and diphtheria." He has nothing better to offer in the way of treatment than Steiner in a previous volume had in the case of croup.

In conclusion we may say that Vol. VI. is quite up to the mark of the others which have come under our notice. Full justice is done to British authors, by whom our knowledge of the diseases included in it has been in no mean degree furthered. The appalling catalogues which embrace the whole literature of each subject will be of extreme value to future generations, though, if the truth were known, the credit of compiling them is probably mainly due to the editors of Canstatt's *Jahresbericht*.

Hints on Ophthalmic Out-Patient Practice. By Chas. Higgens, F.R.C.S., Ophthalmic Assistant-Surgeon to Guy's Hospital. London: J. and A. Churchill. 1877. Pp. 87.

This is a very useful little book, and a very practical one. It is just the sort of book a second year's man requires as an introduction to the subject of ophthalmology. It teaches, in very simple language, the most essential points of this all-important subject, and anyone who has got up this book well will be able to treat the ordinary forms of eye disease which he will meet with in practice, while he will learn sufficient of the more complicated and serious forms to diagnose them, and at the same time to see the importance of sending them off to a man who makes ophthalmology a specialty. The book is well got up, and its low price, no less than its subject-matter, will recommend it to a large number of readers.

Sanitas, Sanitatum, et omnia Sanitas. By Richard Metcalfe, F.S.S. Vol. I. London: Co-operative Printing Company, Plough-court, Fetter-lane, E.C. 1877. Pp. 334.

The author of this work states that he has often been an eye-witness to the discomfort and inconveniences to which the poor are subjected in washing and drying their clothes in the apartment in which they live and sleep; and he asserts that he knows that the evils resulting from the want of bath and washhouse accommodation are often far greater than the consequences of sanitary defects whose removal the law peremptorily enjoins. He has therefore been induced to invite public attention to the question, and he hopes by showing what has been done in providing baths and washhouses from the rates, Government may be induced to make the Bath Act compulsory. This is a very laudable object, but the author must be more sanguine than we are if he imagines that his volume will have any decided effect in promoting the object he has in view. The mass of statistical information which confronts one on opening its pages is not calculated to attract a large number of readers; and, moreover, the belief of the author as regards the relative prevalence of small-pox before the introduction of vaccination, etc., does not excite confidence in his idea or comprehension of statistics. And it would perhaps be the happiest thing for all parties if those into whose hands the work falls were to cast it aside unread. The author is harmless enough, although very wearisome, when writing on baths and washhouses; but after he has had his say on this topic he runs off on the subject of small-pox, and here he becomes positively and extremely mischievous, railing against vaccination and those who practise it. Small-pox, he says, was dying out when vaccination was introduced, and since its introduction consumption has increased, other diseases have been introduced into the body with vaccine matter. He would treat small-pox by means of the fluid sulphur bath, Condy's fluid bath, and the wet pack, and would be only "too glad to have an opportunity to practically illustrate the treatment of small-pox under the supervision of the medical board in any hospital." From small-pox the author descends to "dipsomania," and would have us believe that he is an authority on this subject also. But his style and tone of treatment will not command the respect of any who wish to consider the subject dispassionately.

OBITUARY.

JOHN MOLLAN, M.D. (Hon.) Dub., F.K.Q.C.P. etc.

Died at his residence, 60, Fitzwilliam-square, Dublin, in the eighty-seventh year of his age, on Monday, September 17. Dr. Mollan, a highly esteemed and respected member of the profession, had long since retired from practice. In his day he was much thought of, and in 1855 and 1856 he filled the presidential chair of the King and Queen's College of Physicians, to the Fellowship of which body he was elected in 1839. He was Consulting Physician to the Richmond Lunatic Asylum. He was also a member of the Royal Irish Academy.

MEDICAL NEWS.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, September 13:—

Low, Charles Arthur, 233, New Cross-road, S.E.
Pickup, William James, Bacup, Lancashire.

The following gentlemen also on the same day passed their Primary Professional Examination:—

Nicod, Louis Charles Napoleon, St. Mary's Hospital.
Wells, Charles, Middlesex Hospital.
Wolfe, James Lovett de, Charing-cross Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Barr, James, M.B.—Visiting Surgeon to the Kirkdale County Prison, Liverpool, *vice* W. Mitchell Banks, F.R.C.S. Eng., resigned.

Turner, Francis Charlewood, M.A., M.D. Cantab., Assistant-Physician to the London Hospital, and formerly Resident Physician at St. Thomas's Hospital—Physician to the North-Eastern Hospital for Children, Hackney-road, E.

NAVAL, MILITARY, &c., APPOINTMENTS.

Militia.—Medical Department.—Surgeon-Major George Curme, Dorset Militia, resigns his commission.

War Office.—Medical Department.—Deputy Surgeon-General Thomas Best to be Surgeon-General, *vice* R. Bowen, retired upon half-pay; Surgeon-Major William Sim Murray, M.B., to be Deputy Surgeon-General, *vice* Thomas Best, promoted.

BIRTHS.

Cox.—On September 12, at Theale, near Reading, the wife of Richard Cox, M.D., of a daughter.

Douglas.—On September 14, at Wootton Bank, Bournemouth, the wife of Justyn G. Douglas, M.D., of a son.

Farnfield.—On September 12, at Fir Grove, North Brixton, the wife of Walter E. Farnfield, L.R.C.P. Edin., of a son.

Flood.—On September 15, at Hopeton House, Reigate, the wife of A. W. Flood, L.R.C.P. Edin., L.R.C.S. Edin., Surgeon R.N., of a son.

Galton.—On September 13, at Woodside, Anerley-road, Upper Norwood, S.E., the wife of John H. Galton, M.D. Lond., of a daughter.

Haward.—On September 6, at Luton, Beds, the wife of F. R. Haward, M.R.C.S. Eng., of a daughter.

Perigal.—On September 14, at Lorne Villa, Nairn, N.B., the wife of Arthur Perigal, M.D., of a daughter.

Rolleston.—On September 15, at Oxford, the wife of George Rolleston, M.D., Professor of Anatomy and Physiology, of a son.

Southey.—On September 17, at 6, Harley-street, London, the wife of Reginald Southey, M.D. Oxon., of a daughter.

MARRIAGES.

Chant—Dibbin.—On September 13, at Capel, Surrey, Thomas Chant, M.R.C.S., of Lowestoft, to Laura Ormiston, second daughter of the late F. W. Dibbin, Esq., of Burton, Somersetshire.

Davies—Reed.—On September 12, at St. Leonard's Church, Streatham, Thomas Davies, M.D., of Machynlleth, N. Wales, to Marian, youngest daughter of Thomas German Reed, Esq., of Oakfield, Balham.

Iles—Hopkinson.—On September 13, at St. Mary's, Willesden, Alfred Robert Iles, L.R.C.P. Edin., M.R.C.S., of Taunton, Somerset, to Jane, eldest daughter of T. B. Hopkinson, Esq., of The Grove, Neasdon, Willesden, N.W.

Madden—Chadwick.—On September 10, at Holy Trinity Church, Birchfield, near Birmingham, Edward Monson Madden, M.B., M.R.C.S., of Birmingham, son of Henry R. Madden, M.D., to Elizabeth Leman, daughter of the late F. R. Chadwick, surgeon, of Burnham, Somerset.

PLETTS—BINKS.—On September 13, at St. Bartholomew's Church, Sydenham, John Menham Pletts, M.D., M.R.C.S. Eng., of Ryde, Isle of Wight, to Frances Harriet, only daughter of George Binks, Esq., of West Hill Lodge, Sydenham.

DEATHS.

BLACK, PATRICK ABERCROMBIE, Commander R.N., second son of Patrick Black, M.D., of 11, Queen Anne-street, at his father's residence, on September 13, in his 32nd year.

BRIDGE, S. F., M.D., F.R.C.S., at Old Court, Wellington, on September 12, in his 88th year.

BRUMWELL, JOHN ROBERT, M.D., at Homelands, Ryde, Isle of Wight, on September 7.

JONES, JOHN, M.R.C.P., F.R.C.S., at 53, Blenheim-crescent, Notting-hill, on September 13, aged 69.

MOLLAN, JOHN, M.D., Fellow, and formerly President, of the King and Queen's College of Physicians in Ireland, at 60, Fitzwilliam-square North, Dublin, on September 17, in the 87th year of his age.

TETLEY, JAMES, M.D., F.R.C.P., at Belmont, Torre, Torquay, on September 18.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made and the day of election (as far as known) are stated in succession.

BEDFORD GENERAL INFIRMARY.—Resident Surgeon. Applications, with testimonials, to the Chairman of the Weekly Committee, on or before September 27.

EAST SUFFOLK AND IPSWICH HOSPITAL.—House-Surgeon. Candidates must be single, qualified both in medicine and surgery, and registered according to the provisions of the Medical Act. Applications, with testimonials, to the Secretary, on or before September 26.

ROTHERHAM HOSPITAL.—Resident House-Surgeon. Candidates must be M.R.C.S. Eng., and Licentiates of the Society of Apothecaries or of the Royal College of Physicians, London, registered, and unmarried. Applications, with testimonials as to professional ability and moral character, to the Honorary Secretary, on or before October 15.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1871.

RESIGNATIONS.

Newent Union.—Mr. R. W. Ceely has resigned the Redmarley District; area 10,519; population 2956; salary £60 per annum.

Wellington (Salop) Union.—Mr. John Morgan has resigned the First Northern District; area 14,941; population 2500; salary £45 per annum.

APPOINTMENTS.

Alresford Union.—Joseph W. Ekens, M.R.C.S. Eng., L.S.A., to the Second District.

Guiltcross Union.—W. E. Soffe, M.R.C.S. Eng., L.S.A., L.F.P. & S. Glasg., to the Third District.

Oswestry.—David H. Richards, F.C.S., as Analyst for the Borough.

ROYAL COLLEGE OF SURGEONS.—The following analysis of the Calendar of this institution, which has just been published, will, no doubt, be read with great interest by some of our readers. It appears that the *Board* of Examiners in Anatomy and Physiology, which consists of nine members, annually elected by the Council from the Fellows of the College, have held four meetings for the Fellowship, and thirty meetings for the Membership. The following is a statement of the number of candidates who presented themselves for the Fellowship and Membership respectively, with the results of the several examinations, viz.:—At the Primary Examinations, for the first-named distinction there were 87 candidates; of this number 44 passed, and 43 were referred for six months. At the Pass Examination there were 37 candidates, 27 of whom were successful, and 10 the reverse. The *Court* of Examiners, which consists of ten members, also elected by the Council from the Fellows of the College, have held two meetings for the examinations for the Fellowship, and twenty-nine for the pass examinations for the Membership, during the collegiate year. At the Primary Examination in Anatomy and Physiology 792 candidates presented themselves, of which number 546 passed, and 246 were referred to their studies for three months. At the Pass Examination in Surgical Anatomy and the Principles and Practice of Surgery and Medicine there were 569 candidates, 356 of whom passed, and 76 were approved in surgery and required to qualify in medicine; only 50, however, did afterwards qualify in medicine, making the total number of diplomas granted amount to 406. Rejected candidates numbered 137. The Board of Examiners in Dental Surgery have examined 27 candidates during the past year, 20 of whom passed to the satisfaction of the Board. During the past collegiate year there have been sixteen meetings of the Council or governing body of the College. An *official* return of the number passed and plucked from the various recognised metropolitan and provincial hospitals appears in another column.

HUNTERIAN MUSEUM.—An interesting and valuable addition has just been made to this collection by the Hon. Charles B. F. Berkeley, in the presentation of the skeleton of a gigantic crocodile, shot by himself last winter near Hagar Silsilis, in Egypt. As every Nile voyager knows, these animals, once forming such a characteristic feature in the scenery of the ancient river, have become of late exceedingly scarce below the cataracts; and this one, which had long been known to the natives of the district in which it had taken up its abode, must have been one of the last survivors of its race—at all events, the last to attain such dimensions as this one, viz., nearly sixteen feet. Perhaps their absence will be less regretted by the inhabitants of the river banks than by naturalists and artistic travellers, considering the illustration of the manners and customs of this formidable creature afforded by the contents of its stomach, viz., the hoofs and halter of a donkey, and a boy's ear-rings. The natives stated that it had never been known to seize a woman, confining its attentions to the sterner sex. When examined, the animal was found to have been engaged in many a deadly strife, judging from the severe scars it exhibited, and also in the loss of one of its feet, leaving however, a very formidable stump.

COMPOSITION AND QUALITY OF THE METROPOLITAN WATERS IN AUGUST.—The following are the returns (by Dr. Meymott Tidy) of the Society of Medical Officers of Health:—

Names of Water Companies.	Total Solid Matter per Gallon.	Oxygen required by Organic Matter, etc.	Nitrogen: As Nitrates, etc.	Ammonia.		Hardness. (Clarke's Scale).	
				Saline.	Organic.	Before Boiling.	After Boiling.
Thames Water Companies.	Grs.	Grs.	Grs.	Grs.	Grs.	Degs.	Degs.
Grand Junction .	18·40	0·024	0·099	0·000	0·007	12·1	3·0
West Middlesex .	16·00	0·048	0·090	0·001	0·007	12·6	3·0
Southwark and Vauxhall . .	16·70	0·052	0·105	0·000	0·007	12·1	2·4
Chelsea . .	18·60	0·021	0·133	0·000	0·009	13·2	3·0
Lambeth . .	17·70	0·077	0·125	0·000	0·008	13·2	3·3
Other Companies.							
Kent . . .	28·00	0·003	0·375	0·000	0·002	19·4	5·6
New River . .	17·90	0·024	0·129	0·000	0·009	12·6	3·0
East London .	17·90	0·063	0·105	0·000	0·006	12·1	3·7

Note.—The amount of oxygen required to oxidise the organic matter, nitrites, etc., is determined by a standard solution of permanganate of potash acting for three hours; and in the case of the metropolitan waters the quantity of organic matter is about eight times the amount of oxygen required by it.

The water was found to be clear and nearly colourless in all cases but the following, when it was very slightly turbid—namely, in that of the Southwark and Vauxhall and the Chelsea Companies.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

An Anti-Vaccinationist.—Mr. F. Pearce, photographer, Andover, has just been fined for the forty-third time for non-compliance with the Vaccination Acts. He appealed to the Bench to impose a nominal fine, but the full penalty of 20s. in each case, with costs, amounting altogether to £4 2s. 6d., was inflicted.

Artisan.—The first Factory Act ever passed (42 George III., c. 73) was called specifically "The Health and Morals Act," and while the immediate cause of its enactment was the alarming spread among the manufacturing population of epidemic disease, this condition of things, it was stated, was chiefly brought about by the new conditions of industrial labour. The Factory Act, 1833 (3 & 4 William IV., c. 103), still forms the basis of all subsequent legislation on the subject. This is the statute often quoted as Lord Althorp's Act.

A Parent.—Bombay Island itself, though in general cooled by the sea breeze, is oppressively hot during May and October. From June to October travelling is difficult and unpleasant, except in Sindh, where the monsoon rains have little influence.

Botanist.—One of the earliest attempts at a methodical arrangement of plants was made in Florence by Andreas Cæsalpinus, a native of Arezzo, some time professor of botany at Padua, and afterwards physician to Pope Clement VIII. He is called by Linnæus *primus verus systematicus.*

Edmund.—Dr. W. S. W. Ruschenberger, while in charge of the United States Naval Hospital at Brooklyn, New York, 1843-47, organised the naval laboratory for supplying the service with unadulterated drugs, and in 1849 was made a member of the Board to draw up plans and regulations for the United States Naval Academy. In October, 1854, he sailed as Surgeon of the Pacific Squadron, and retired with rank of Commodore, September 4, 1869. He has written much on medical and scientific subjects, in various periodicals.

Sista.—Yes; The method of procedure for recovering the apparently drowned, as given in the Chinese official Medical Jurisprudence, is, like that which was formerly in common use in the Western World,—calculated to extinguish life; but Dr. Macgowan, the medical missionary in China, has recently published a pamphlet in Chinese, the English title of which is, "Directions for Resuscitating the Apparently Drowned, and for Recovering those Poisoned with Opium," which probably will be useful in saving life.

Hetty.—Miss Veitch's sensible warning against a sentimental view of the office of nurse was:—"To ladies who intend to make nursing a profession, I would say, do not undertake the work with any romantic ideas of being a 'ministering angel,' moving about your wards in a very becoming hospital dress, and followed wherever you go by loving looks and murmured blessings from grateful patients, or you will never have courage to face the reality of finding yourself always a hardworked, often a weary, worn, and sorely harassed woman."

THE NOXIOUS WEED.

Dr. M'Kendrick, of Glasgow, in conjunction with Professor Dewar, of Cambridge, has for some time past been conducting a series of investigations into the physiological action of what may be called the tobacco-smoke alkaloids, and their congeners. The complete series of researches is to be published. From official returns it appears there are eighteen manufactories of tobacco in France, 357 depôts, and 40,210 licensed shops for its sale.

COMMUNICATIONS have been received from—

THE SECRETARY OF THE APOTHECARIES' HALL, London; Dr. SPARKS, Crewkerne; Mr. JOHN INGPEN, London; COMMANDER CHEYNE, London; THE SECRETARY OF THE VICTORIA GALLERY, London; Mr. WHEELER, Nottingham; Dr. ROBERT LAWSON, Banstead; Mr. A. L. MEADE, Cavan; Mr. T. M. STONE, London; Dr. J. W. MOORE, Dublin; Dr. J. W. ROSEBURGH, Canada; Mr. C. F. MAUNDER, London; Dr. S. MACKENZIE, London; Dr. R. DRUITT, London; Mr. R. BRUDENELL CARTER, London; Dr. BARLOW, London; Mr. J. CHATTO, London; Dr. BYROM BRAMWELL, Newcastle-on-Tyne; Dr. C. HANDFIELD JONES, London.

BOOKS AND PAMPHLETS RECEIVED—

Thomas B. Peacock, M.D., F.R.C.P., On the Prognosis in Cases of Valvular Disease of the Heart—George Paddock Bate, M.D., Report on the Sanitary Condition of the Parish of St. Matthew, Bethnal-green—Elements of Chemistry, Theoretical and Practical (part 1, Chemical Physics), by William Allen Miller, M.D., D.C.L., LL.D., revised by Herbert McLeod, F.C.S.—Fownes' Organic Chemistry, revised and enlarged by Henry Watts, B.A., F.R.S.—Alfred Carpenter, M.D. Lond., Preventive Medicine in relation to the Public Heath.

PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Berliner Klinische Wochenschrift—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Gazette Hebdomadaire—Le Progrès Médical—Bulletin de l'Académie de Médecine—Pharmaceutical Journal—Wiener Medizinische Wochenschrift—Medical Examiner—The Louisville Medical News—Boston Medical and Surgical Journal—Nature—Philadelphia Medical Times—Iron—Cincinnati Clinic—Medical Enquirer—Indian Medical Gazette—Monthly Homœopathic Review—Home Chronicler—Canada Lancet—Boston Journal of Chemistry—New York Medical Journal—New Orleans Medical and Surgical Journal—La Province Médicale—Students' Journal and Hospital Gazette.

APPOINTMENTS FOR THE WEEK.

September 22. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 1½ p.m.

24. *Monday.*

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

25. *Tuesday.*

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

26. *Wednesday.*

Operations at University College, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex. 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 1½ p.m.

27. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing-cross, 2 p.m.; St. Thomas's (ophthalmic operations), 4 p.m.

28. *Friday.*

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m.; Guy's, 1½ p.m.

QUEKETT MICROSCOPICAL CLUB, 8 p.m. Meeting.

VITAL STATISTICS OF LONDON.

Week ending Saturday, September 15, 1877.

BIRTHS.

Births of Boys, 1189; Girls, 1179; Total, 2368.
Average of 10 corresponding years 1867-76, 2154·5.

DEATHS.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	29·769 in.
Mean temperature	58·9°
Highest point of thermometer	73·4°
Lowest point of thermometer	49·1°
Mean dew-point temperature	51·9°
General direction of wind	Variable.
Whole amount of rain in the week	0·16 in.

BIRTHS and DEATHS Registered and METEOROLOGY during the Week ending Saturday, September 15, 1877, in the following large Towns:—

Boroughs, etc. (Municipal boundaries for all except London.)	Estimated Population to middle of the year 1877.*	Persons to an Acre. (1877.)	Births Registered during the week ending Sept. 15.	Deaths Registered during the week ending Sept. 15.	Temperature of Air (Fahr.): Highest during the Week.	Lowest during the Week.	Weekly Mean of Mean Daily Values	Temp. of Air (Cent.): Weekly Mean of Mean Daily Values.	Rain Fall: In Inches.	In Centimetres.

At the Royal Observatory, Greenwich, the mean reading of the barometer last week was 29·77 in. The lowest reading was 29·57 in. on Tuesday afternoon, and the highest 30·00 in. at the end of the week.

* The figures for the English and Scottish towns are the numbers enumerated in April, 1871, raised to the middle of 1877 by the addition of six years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the number enumerated in April, 1871.

ORIGINAL LECTURES.

SELECT LECTURES ON MEDICAL JURISPRUDENCE.

By FRANCIS OGSTON, M.D.,
Professor of Medical Logic and Medical Jurisprudence in the University of Aberdeen.

Lecture XVIII.—WOUNDS, *Continued.*

Having concluded what I had to say of the *Diagnosis* of Wounds, as the term wound is understood in Legal Medicine, it now falls to me to notice, in addition, certain other inquiries calling for settlement by the expert in this extensive and important class of injuries.

These inquiries admit of being arranged under two heads; those deducible from, first, the progress of the cases in hand during life, where the injuries have not proved immediately or speedily fatal; and secondly, from the inspection of the body where death has resulted from their infliction: or, in other words, *the Prognosis of Wounds*, and *the post-mortem inspection*. The two lines of inquiry, I need scarcely add, may have to be combined in the same case where the party has been seen both before and after the fatal event. To begin with the *Prognosis of Wounds*. Here it behoves the medical jurist to have not only a familiarity with the more usual results of such injuries as they progress in the living, but also to be aware of, and to be prepared to take into account, the circumstances which may be found in certain cases to influence and control, so as to modify, their natural and accustomed course.

Taking up in succession these two points, I shall advert in the first place to the character and results of injuries in the living under ordinary conditions, or apart from the modifying circumstances to which I have just referred. And here it may be premised that little is to be gained by following the course of some medico-legal writers, especially abroad, of laying down for their guidance, in their prognosis, arbitrary and artificial schemes of classification, founded on the degree of danger of various injuries; such as *slight, severe, dangerous*, and *fatal wounds*—characteristics which are of too fluctuating and uncertain a kind to serve as a fixed and available basis for reliable distinctive tests. Thus, in practice, it is known that a slight wound may be converted into a dangerous one; a wound not usually considered mortal may terminate life, and *vice versâ*, from the occurrence of certain circumstances. In preference to this, I shall take for my guide in the prognosis the data deducible from the seat of the injury and the parts of the body which it may have involved, or both sources of information combined.

And first of the prognosis of *injuries of the nervous system*, including the brain, spinal cord, and the nervous ramifications. Injuries of the nervous system, I need scarcely say, deserve the greatest attention from the expert, as a frequent cause of both sudden and lingering deaths. Sometimes also they are found closely to resemble the effects of natural disease. Their progress is likewise occasionally influenced by natural causes affecting these organs. They may prove fatal, too, without leaving any very distinct trace of altered structure in the dead body.

The frequency of *railway accidents* has, of late, by multiplying this class of injuries, given added importance to them, both as regards the medical jurist and the profession generally, and, what is to be regretted, been the occasion of bringing out not a little conflict of professional opinion on the part of witnesses cited on trials originating in such accidents. This undesirable result has arisen from the circumstances of their serious character not being always apparent at the time of their occurrence; and from proper allowance not being always made for the possibility of their giving rise to secondary effects in individual instances.

(1.) *Wounds of the head* are important, chiefly from their liability to disturb the functions of the brain, or to involve that viscus in active disease. When strictly local, they heal without much trouble; but even in these circumstances they may be complicated with diffuse abscess, erysipelas, or irritative fever.

When the irritation such wounds give rise to is considerable, or even when they appear slight, the brain and its membranes may sympathise with injuries of this sort; or the party may be attacked with tetanus; and in either of these ways an injury, at first inconsiderable, may prove unexpectedly fatal. A *simple blow on the head*, with or without a scalp-wound, may sooner or later lead to mischief about the bones of the calvaria. Sometimes the diseased action thus set up ends in hypertrophy of the bones, which may go on for years, and the calvaria thus become enormously thickened. Again, the diseased action thus set up may lead to caries and necrosis of the calvaria. Here the disease may be limited to the original seat of the injury, or it may spread widely, affecting either one or both tables of the bone. Again, a blow on the head may be followed by acute inflammation, with its starting point in the diploë, the consequence of extravasation of blood, or of the breaking-down of the cancellous tissue, without injury to the cranial tables, though liable to spread to these or to induce pyæmia.

In either of these cases, the patient may not appear to suffer much, or not at all, *at first*; the illness, when it occurs either in a few days or only after weeks, may assume the chronic form, or it may prove rapidly fatal.—(Holmes, vol. ii., pages 298-9.)

Instances of such effects of apparently slight or trivial injuries, from their occasionally unexpected character, are apt to take the practitioner by surprise. They are by no means of very unfrequent occurrence, and such instances have been cited from my own practice in a previous lecture.

(2.) *Contusions of the head*, as a rule, are not dangerous, if unattended with such symptoms of violence as are set down by most surgical writers as the effects of concussion of the brain, but which, as we saw formerly, are by some recent authorities attributed in every case to contusion and mechanical injury of that organ.

(3.) *Punctures*, or even *simple fractures* of the bones of the head, when *unaccompanied with injury of the brain*, are not in general followed by bad consequences, though a guarded prognosis should be given, even in apparently slight cases, as the exact state of matters cannot always be known at the time. The brain, however, may be reached in this way, with or without much injury of the soft and hard parts encasing it. Death, as we saw under "Infanticide," may be caused in infants by punctures through the fontanelles, or the base of the skull. Again, the brain may be reached by penetrating instruments through the orbits or nostrils.

An interesting case of the latter kind led to a trial here in 1855. A person in Peterhead had been thrust at by "a walking-stick, not by any means a stout one, but armed with a small iron ferule, having a knob at the extremity about the size of a large pea." The stick had passed through the right lower eyelid, partially displacing the orbit. The man survived till the third day, at first conscious, but suffering great pain, though afterwards becoming comatose. On dissection, the instrument was found to have passed through the orbital plate of the frontal bone, and to have led to unhealthy inflammation of the membranes and surface of the right anterior lobe of the brain, in the vicinity of the fracture.—(*Monthly Journal of Med. Science*, June, 1855.) (The fractured bone, for which I am indebted to Dr. Jamieson, of Peterhead, is now in the museum.)

I had an opportunity some years ago of seeing a case at Banchory which terminated favourably, where, from the symptoms, it was probable that a large needle used for making farm-sacking had been pushed up through the nostrils and the cribriform plate of the ethmoid bone.

In those cases of *instantaneous death* which are usually known as *concussion*, but by some as *contusion of the brain*, death is found to be caused by syncope from the depression of the cerebral functions. Compression of the brain, where death follows more slowly, leads to death by *coma* or *comato-asphyxia*, the arrest of the respiration following the depression or arrest of the functions of the brain. At a later period, death may follow as the result of inflammation of the brain, originating in the injuries received—superficial injuries; commotion, whether without or with contusion; fractures of the skull, succeeded either by inflammatory or irritative fever, or compression from the products of the inflammation,—resolving itself into death by *coma*. In the same way, death is often produced by *disorganisation of the brain*, which does not necessarily imply compression of its substance. We have seen already that it was till lately held generally, that death may result from *the mere commotion of the brain*, without either *fracture of the skull*, *effusion of blood* within the head, or *any other change* being to be observed in dissection; and that this is denied by some later authorities. The dispute, however, is not of much practical importance; as, while the latter contend for the existence of structural change having actually occurred in every such instance, the former parties admit that such lesion may be inferred, though the suddenness of the fatal event has not allowed time for such subsequent changes as

hæmorrhage or inflammation, or the establishment of reaction. Injuries of this sort, whether we term them cases of *concussion* or of *contusion of the brain*, may prove fatal *instantly* and *directly*, or *indirectly*, after a lapse of days or even weeks, or still longer periods, from the consequences of the original violence. Thus, chronic inflammation and its sequence may go on progressively and terminate fatally, after the lapse of several weeks, months, or even, it is believed, of years. A case of this sort was given in a previous lecture.

Effusion of blood within the cranium, either upon the surface of the brain, into its substance, or into the ventricles, from laceration of the brain, or the rupture of one or more blood-vessels by a fractured bone, or by separation of its membranes, is a very common cause of death from violence producing commotion of the brain. This has even been found to occur when there was no external mark of injury on the head; and the frequency of *effusion within the skull without any apparent external injury* may lead to a very important medico-legal question in many cases of sudden death—viz., *whether the effusion has arisen from violence or from natural disease*. In some cases, particularly where the vessels of the brain are in a diseased state, or where there is a tendency to softening of the brain, continued intoxication, or a sudden burst of passion, or struggling with another person, or a fall, may occasion the bursting of a bloodvessel within the head, and cause a fatal effusion of blood. Such effusions, when *spontaneous*, are most usually in the *substance of the brain*, while *effusion from the effects of violence* is most commonly on *its surface*, or between the brain-matter and the skull.

4. Next in importance, though not in frequency, are similar *injuries of the spinal cord*. Those which wound, divide, compress, or disorganise any part of the spinal cord in general prove fatal either immediately or after an interval of more or less duration, according to the situation, extent, or nature of the injury. When the cord is deeply penetrated or injured at its upper part, death takes place immediately. But if the lesion is superficial, and at a point lower down in the cord, the injury, though not immediately fatal, is followed by less of pain and feeling below the injured parts, by which the patient sooner or later dies. Wounds of the medulla oblongata, or pressure from effused blood, or fracture and destruction of the vertebræ, prove instantly fatal in consequence of the circulation and respiration being brought to a stand. Hence the importance in all such cases of a careful inspection of the spine after death—a point too little attended to. It is important, however, to be aware of the fact that extravasation of blood upon the spinal cord is not necessarily the result of violence, but may occur spontaneously, as has been shown by Dr. Abercrombie.

It may be well here to direct your attention to a circumstance which bears chiefly, if not exclusively, on the class of injuries under consideration. I refer to the emptiness of blood in fresh bodies on both sides of the heart, and that so complete that the endocardium is not wet enough to stain a white cloth applied to it. The first instance of this sort which attracted my attention was in a man fifty-five years of age, who died instantly from the fall on the back of his head and the upper part of his spine, while in a stooping posture, of a chimney from the third floor of a house which was being pulled down in Castle-street, Aberdeen, in August, 1839. At the inspection, several fractures at the base of the skull appeared to have radiated upwards from the foramen magnum as a centre. The appearances otherwise were those of death by syncope. I have since met with two cases almost parallel with the above—one from the fall of a railway-arch, crushing the occiput and two of the cervical vertebræ; the other after a railway collision, dislocating the dorsal vertebræ.

(5.) The effect *on the nerves* of concussions received on the trunk have been already sufficiently illustrated. It may be proper, however, to remark here that blows on this part may be instantly fatal, by leading to the arrest of the heart's action, and consequently death by syncope, as in concussion of the brain, without leaving any morbid appearances in the body.—(Watson on Homicide, pages 27 to 88, *pass.*)

I have now to notice, in *the second place*, the effects of *injuries of the circulatory system*. Injuries of the circulatory system are frequent causes of sudden death, and are often the subject of medico-legal investigation. The fatal issue arises from the extreme exhaustion and depression of the vital powers consequent on extensive hæmorrhage, and the death is by syncope. Injuries of the circulatory organs may, however, prove fatal otherwise. Thus, a less effusion than would destroy life may prove fatal from the pressure of the effused blood impeding the functions of organs essential to life, such as the brain, the spinal cord, the heart, or the lungs.

By *the admission of air into the veins*, a wound of a blood-vessel may instantly destroy life.

It is impossible to say beforehand what amount of blood may be lost without leading to fatal syncope, as this varies with different states of the constitution, and with the habits of the party. The *rupture of a varicose vein*, or even *the extraction of a tooth*, in spanæmious individuals, may lead to dangerous, or even fatal, hæmorrhage; both of which occurrences I have witnessed in practice. I have twice had the opportunity of examining the bodies of persons who had bled to death from suicidal wounds of *the veins at the bend of the arm*. One, a seaman, was found dead some years ago in a court in the Gallowgate, Aberdeen, lying in the recumbent position in bed, with the wounded arm hanging down in front of it. The other, a cattle-dealer at Strathdon, in the spring of 1867, was found on a hillside, in a pool of blood, with a small superficial wound on the *right* side of the neck; and the left *median basilic vein* cut across with a penknife, a strap of leather surrounding the arm above the part, as in ordinary venesection. In the case of Christian Davidson, previously referred to, for causing whose death a person was tried here in 1854, *the division*, with the points of a pair of scissors, of *the frontal branch of the temporal artery* on one side had led to fatal syncope.

In each of these cases the parties were known to have been of very intemperate habits. From the state of matters, it is notorious that cases of slight wounds of the scalp, or incised wounds of no great depth in the limbs, lead to so copious a flow of blood that, if left to themselves, the parties, if they did not perish in this way, as in the two cases above, if unattended, would be left thereby in a state of great prostration. Such cases are not unfrequent at our police-stations, or in taverns where fighting has been going on.

The proofs of death from hæmorrhage are deducible from (1) the indications of the wound having been produced *during life*; (2) the *absence of blood* in the *larger vessels* and *important viscera*; and (3) *the healthy state of the principal organs of the body*.

So much for the prognosis of wounds *in general*. I have now to consider the consequences of *wounds* in *different parts of the body*.

I have nothing to add to what I have said of *wounds of the head*.

Wounds of the neck are often the subject of medico-legal inquiry. Cases of murder by wounds in this situation occasionally occur, though death from this cause is oftener the result of suicide than of homicide. In the Cults case, previously adduced (1854), the spinal cord was divided through the intervertebral substance betwixt two of the cervical vertebræ, which at once decided that the case was one of homicide. It should be borne in mind, however, that the extent of injury inflicted by a determined suicide may sometimes be very considerable.

In a seaman on board a vessel in Aberdeen harbour, to whom I was called some years ago, it was found that he had divided all the soft parts in front of the vertebræ, and the mark of the edge of the razor was noticeable on the surface of one of these bones.

In a sweep at Justice-street, Aberdeen, two such incisions and *two such impressions* were seen on the body of one of the cervical vertebræ.

Punctured wounds are occasionally, though rarely, made in this region with suicidal intent. It was in this way that Castlereagh destroyed himself, by plunging the penknife through the carotid artery (Holmes, page 466-7). In a previous lecture I mentioned a suicidal case which united the characters of an incised and a penetrating wound on the front of the neck.

Wounds of the chest may prove fatal in different ways. The most frequent cause of death is syncope, from the hæmorrhage occasioned. A less effusion of blood than would destroy life in this way may lead to the same result by compression of the heart, as when effused into the pericardium; or of the lungs, when the effusion is into the chest. A *rupture* of the heart or large vessels within the chest may take place, either from pressure or a blow upon it, without any appearance of external injury. The same injuries, however, it should be known, may occur spontaneously. I have already related one instance of spontaneous rupture of the aorta in a person free from aneurism or other previous apparent disease. *Wounds* of the heart and large vessels are not *necessarily instantly fatal*. Thus, in the case of a woman at Old Meldrum, in July, 1857, for the murder of whom a man (Booth) was tried and executed at Aberdeen, the heart had been transfixed with a deer-knife, notwithstanding which, the victim, after the receipt of the

injury, left the apartment (a shop), ran across the street, returned to the shop, and to the back of the counter there, before falling down dead.

In *injuries of the abdomen and pelvis*, death sometimes follows the division of the arteries of the viscera.

Wounds of the organs of generation occasionally lead to fatal hæmorrhage, without any of the larger vessels being divided.

A few years ago several remarkable cases occurred in Edinburgh and Glasgow from wounds in the labia of the female.

In 1826, a person of the name of Pollock was tried at Edinburgh for the murder of his wife, by inflicting two wounds of this sort. Two incisions of the inner side of the right nympha, penetrating to the depth of two inches and a half, were observed on dissection, and the clothes in the vicinity were stained with blood. The woman was intoxicated at the time of receiving these wounds. Pollock was convicted, and would have suffered death, but hung himself before the day of execution.

Two persons were tried in Edinburgh in 1831, for inflicting a wound in the labium of a woman. It was three-quarters of an inch in length, and three inches in depth. She died from loss of blood soon after its infliction. The parties escaped from a charge of murder from want of proof as to which of them had given the wound.

Two persons were tried in Glasgow in 1830 and 1831, for causing the deaths of their wives in this way, and both were convicted and executed.

A case of this kind was tried at Aberdeen in the autumn of 1849, but, from the impossibility of determining which of the two parties tried had inflicted the fatal wound in the vagina, a verdict was returned of "not proven." In this instance two incisions were discovered, one at the left labium, the other at the entrance of the vagina at its upper part, and the female (who was pregnant) did not survive above ten minutes.

In connexion with this subject, it is important to notice that at a discussion which took place (December 1, 1849) in the Edinburgh Obstetrical Society, it was suggested by the late Sir James Simpson that *the spontaneous origin* of such wounds in *pregnant females* is not by any means *impossible*. In support of this view, he refers to a case reported to him by Dr. Kyle, of Dundee, where a pregnant woman died from a rupture in one of the labia, communicating with a large vein, produced apparently by straining while on the night-stool. On the same occasion, Dr. Thomson brought forward a case from his own practice, where a woman, six weeks after delivery, had nearly perished by hæmorrhage from a wound "in the anterior wall of the vagina, at the union of its upper with the middle third," large enough "to admit the finger to a depth of about half an inch." It was believed by the narrator that the wound had occurred during an intercourse of the woman with her husband, (?) without any violence on his part.—(*Monthly Jour. of Med. Science*, February, 1850.)

Be this as it may, it should not be forgotten that it is quite possible that wounds of the *labia* may be produced *accidentally*. Several years ago I was called to a young woman who, while in drink, had fallen upon a chamber-pot and wounded this part, which bled profusely, and required to have the hæmorrhage arrested by pressure.

A curious anomaly occurred in the case of the woman Harvey, at Cults, in 1854, previously referred to as an instance of homicidal cut-throat. The assassin, after the girl's death from the extensive and deep wound in the throat, had inflicted a deep, penetrating wound of the vulva, from which, unlike that on the neck, which had bled copiously, only a little bloody serum had oozed. At the trial in the High Court of Justiciary in Edinburgh, I was asked by the judge (the late Lord Justice Clerk Hope) how I could account for this genital wound. The only hypothesis I could offer was that the assassin had wished it to be supposed that the woman had been violated, which, in case of the discovery leading in his direction, would avert suspicion from him, as it was known that the girl was his own concubine, whom it would not be supposed he would force.

I now come, in the third place, to make some remarks on the prognosis of *injuries of the respiratory system*. Amongst the most important of these are *wounds of the chest and lungs*. Contusions and fractures of the ribs, and wounds of the pleuræ and lungs, are not unusual forms of homicide, and prove fatal from the shock, by way of syncope; by the interruption to the functions of respiration, causing death by asphyxia; or they lead to the same result from the consequent hæmorrhage ending in syncope; or the inflammation and pain which are occasioned by the violence, destroy life more gradually. In penetrating wounds of the chest, the entrance of the air may cause collapse of the lungs, and death by asphyxia. The lungs may also be compressed from blood or other fluids in one or both cavities of the pleura. Wounds of the lungs, likewise, by broken ribs or other means, which produce emphysema of these organs, cause death by suffocation. Pneumothorax from lungs wounded in consequence of fractured ribs, or the decomposition of blood or other fluid effused into the chest, is speedily fatal by asphyxia when both sides are affected; when confined to one side, the patient may recover. "When both sides of the chest are open by penetrating wounds," even without injury of the lungs, "death takes place almost immediately by collapse of the lungs," and consequent asphyxia. "Wounds laying open the larynx and trachea are not necessarily fatal, but they may be so though no other important part is injured, by asphyxia from the hæmorrhage filling up the passage"; "or in cases of the complete division of the trachea by the retraction of the lower orifice impeding respiration. When the wound is situated between the os hyoids and the thyroid cartilage, fluids which are swallowed are apt to fall into the larynx and cause suffocation. Wounds of the larynx, particularly lacerated wounds, may also prove fatal by violent inflammation of the parts. Wounds of the larynx and trachea are rendered much more dangerous when the pharynx or œsophagus has also been wounded, in consequence of matter, either attempted to be swallowed or that may be ejected from the stomach, filling up the trachea. But even injuries of this kind are not necessarily fatal." "When death takes place from self-inflicted wounds in the throat, it is in general owing to injury to some of the large bloodvessels or nerves which lie contingous to the wind-pipe, also wounded in the attempt" on life.—(Devergie, pages 178-82 *pass.*, and 165-8 *pass.*)

This brings me, in the last place, to notice shortly the prognosis in *injuries of the abdomen*. Homicide has frequently been committed by injuries of the parts contained in the abdomen and pelvis by contusions and other injuries. These prove fatal in different ways: (1) by the shock or impression made upon the nervous system; (2) by hæmorrhage; (3) by inflammation; and (4) by interfering with the nutrition of the system. To some of these modes of death I have already alluded; to others I shall now briefly advert.

We have seen that blows or other injuries of the abdominal parietes, either without or with lesion of the deep-seated organs, may prove fatal immediately, or after a lapse of some time, without inflammation or other reaction having been set up. We have also seen the effects of exhaustion of blood on the contents of the viscera, in leading to death from sinking of the powers of life without reaction being established, or the occurrence of inflammation, in those cases in which these viscera have been injured seriously. In these instances the death is by way of syncope. Contusions from blows, and other injuries of the belly and pelvis, are likewise sometimes fatal by inducing inflammation, though the internal organs are not injured. Penetrating wounds of the abdomen, even where the intestine is wounded, are not necessarily fatal, for the effusion of their contents into the belly does not necessarily follow, and the consequent inflammation may be inconsiderable. The same remark applies to rupture of the intestines without external wound. It is to be kept in view by the medical jurist that, in some cases, death happens very suddenly from a *spontaneous* rupture of some part of the bowels, even without any previous disease. Injuries of the liver, spleen, kidneys, and bladder are often attended with the same fatal consequences as injuries of the bowels.—(*Id.*, pages 183-96 *pass.*)

This brings me, in the next place, to the consideration of, *circumstances which* are *occasionally* found to *interfere with the natural progress of injuries* in the living, so as to control and modify their accustomed course.

Such of these modifying circumstances *generally* as are applicable, more or less, to the whole or the greater number of the injuries which we have included under "Homicide," were considered under that head. Those which require to be adverted to here are such as specially refer to the subject under discussion (Wounds).

1. Of the first of these modifying circumstances, *age*, little need be said. It is known that while, on the one hand, children readily succumb to certain forms of violence, on the other, they show a wonderful power of recovery from the consequences of others of them; and it is equally known that adult age presents a better chance of escape than does old age from the severer forms of injury.

2. Equally marked differences distinguish the *sexes*, particularly during the child-bearing period of the female, who at other times, as a rule, succumbs less readily than the male to many forms of violence.

3. *Certain constitutional peculiarities*, natural or acquired, render injuries much more serious to some individuals than the same injuries would be to others. Thus, *the bones* in some are so *thin and brittle* as easily to be *fractured* by slight blows or falls. Two such cases have been already adduced. A skull in our museum is that of an old man, extensively fractured on one side by a blow, the skull being unusually thin at the seat of the fracture. Some people are of a preternaturally *phlogistic* or *hæmorrhagic diathesis;* hence dangerous inflammation or hæmorrhage may follow trifling blows or wounds. The same serious consequences may follow similar slight injuries in *persons of intemperate habits* or *broken-down constitutions*, besides the liability of the one to delirium tremens, and the other to gangrene. In such parties, too, and in *persons suffering under previous injuries and diseases*, death not unusually occurs suddenly in drunken quarrels, in which it may be difficult to say what share should be attributed to the blows which may have been received, what to passion, intoxication, the struggle, the enfeebled constitution, or previous disease. Cases of this sort might easily be multiplied, where dissection has pointed out a ruptured aneurism, apoplexy, with diseased state of the arteries at the base of the brain, disease of the heart, advanced phthisis, pneumonia, etc. *Subsequent injury or disease* may modify the result of the injury, as may the *neglect* of treatment or of hygienic precautions on the part of the patient or his medical attendant.—(Watson, pages 197-237, *pass.*)

Having now concluded our remarks in regard to the proper *diagnosis* and *prognosis of wounds*, and other injuries included in law under that designation, it only remains to treat of the *medico-legal inspection after death* from wounds. In cases of death from violence, several medico-legal questions may arise which can only be settled by a general survey of the body, and a carefully conducted external examination of the corpse and its accessories, in addition to the ordinary dissection of its internal cavities. The first point for the medical jurist to ascertain in those cases is *the nature of the wound*, whether contused, lacerated, incised, or otherwise. Secondly, he should endeavour to ascertain whether the wound has been *recently inflicted*, or has been of *longer standing*. Thirdly, he has to determine whether it had been *inflicted during life* or *after death*. Fourthly, any *weapon* found should be *compared with the external wound*, and *with the clothes* where they have been penetrated by it. Fifthly, any *foreign body* found in the wound should be *carefully preserved*. Sixthly, the length, breadth, and depth of the wound are to be carefully examined. Seventh, *the situation and direction of the wound* demand attention as affording evidence of the *intent* of the person who inflicted them, the manner in which the wound had been inflicted, and the relative position of the individuals concerned at the moment of their infliction. The situation and direction of wounds has been also of importance in ascertaining whether the fatal injury was inflicted by *another*, or by the *individual himself*. Eighth, the *probable manner*, *force*, and *weapons employed* for their infliction are to be ascertained by the nature and extent of the wounds, together with the known effects of certain weapons or wounding bodies, when applied with different degrees of force. Lastly, the question whether death has been the result of *accident*, *suicide*, or *homicide* may sometimes admit of being decided by the medical examiner.

Many of these various points have been necessarily anticipated; and others of them belong to the *legal* proof rather than to the *medical*, though they cannot be properly overlooked by the medical jurist, who is by his position best fitted to form a correct estimate of their bearing on the case in hand. Besides, *general rules* cannot be laid down which shall be applicable to the varying circumstances of individual instances of suspected homicide. Still, there are some data of a general nature which require the attention of the medical examiner, and are certain to be of essential importance towards the elucidation of the several points we have enumerated. These I shall therefore pass in review, as briefly as I can, not in the precise order in which I have stated them; but as they may be expected to come under the notice of the examiner at the post-mortem examination.

First, then, some *preliminary observation* may be demanded before proceeding to the *examination proper*, which may throw light on the case where little or nothing is known of the previous history, and when a body is found under suspicious or doubtful circumstances, such as (*a*) the precise *position of the corpse;* (*b*) *the sex;* (*c*) *the apparent age;* (*d*) *the general conformation of the body;* (*e*) *the clothing*, whether complete or otherwise, undisturbed or displaced in any way; if torn, soiled, stained with blood, dirt, or mud, or otherwise; (*f*) *the locality*, whether an open spot, or a concealed place; (*g*) *the ground*, whether showing traces of a struggle, marks of footprints different from those which might have been left by the deceased, and if so, in what direction they admitted of being traced; (*h*) *the probable period the corpse may have lain at the place*, etc. The data for the settlement of several of these points have been already discussed; as also certain inferences to be drawn from them; while to some of them we shall have again to recur presently.

This preliminary observation over, the

External examination of the body may be proceeded with; and first, the *nature of the wound*, whether incised, punctured, contused, etc., is to be determined by the data already laid down; as also, second, whether it had been inflicted *recently* or *more remotely*, and whether *during life* or *only after death*. Third. *The weapon*, if any had been found near the body, has to be compared with *the exterior of the wound*, and also with *the clothes* where these had been penetrated by it; these, along with the weapon, being carefully preserved and labelled for subsequent identification. Fourth. Any foreign body found in the wound must be noted and preserved, and note taken of its nature; whether clothes, fragments of wood, wadding, or otherwise. Fifth. The amount of blood which may have escaped frem the wound, and its distribution round its edges, on the clothes, or on the articles on the ground in the vicinity of the corpse, deserves attention. Sixth. In *gunshot wounds*, any *stains from gunpowder* should be looked for and noted, if present, either about the *lips of the wound*, or the *fingers and mouth of the corpse*. Seventh. The *size of the wound* should be carefully measured and noted. Eighth. Its *direction and depth* (points of great importance) demand a methodical course of procedure. For this purpose the inspection should not proceed *at random*, but *in a systematic manner*. A circular incision should with this view be carried around, about three or four inches from the wound, taking care not to interfere with it, and the integuments then dissected off from the circumference to the centre. The same mode of procedure should be adopted with the muscles, bloodvessels, nerves, and bones; in short, all the parts interested in the traject of the wound. In this way only can an accurate idea be formed of the tissues involved in the wound, the direction in which they have been divided, the foreign bodies which may have lodged there, and the relative position of the assassin and his victim at the moment of its infliction. By this means also, and by them alone, the examiner can ascertain whether the wound has, or has not, been necessarily mortal; how and by what instrument it has been caused; what period of time has probably elapsed between the receipt of the injury and the death of the party; and whether the person has suffered pain to any great extent or otherwise.

This stage of the examination completed, the inspector has only further to proceed to the dissection of the body, for which no special directions require to be given, in so far as the cavities are concerned. The distribution of the blood and the traeing of the extent of the wound or other injury are the chief things to be attended to. By carefully ascertaining the state and distribution of the blood in the heart, lungs, and brain, the mode of death will be learned—a point of some importanee.

Lastly, the *nature* and *circumstances* under which the body is found may enable the medical examiner sometimes to decide the question whether death has been the result of *accident*, *suicide*, or *homicide*. Thus:—

(*a.*) *Contusions* are very rarely *self-inflicted*, though exceptions to this occur. Suicide, for instance, is sometimes committed by the party easting himself from a precipice or window, instances of which we meet with in maniaes and drunkards. Prisoners and maniacs have also been known to dash themselves against a wall. A fatal accident of this kind occurred at Union-place, a few winters ago, by a tradesman, during a snow-storm, while running fast, coming forcibly against a projecting iron paling. Although, as a rule, contusions are very rarely self-inflicted, yet it is often very difficult, in many cases, to determine whether they have been the result of accident, or of injury inflicted by another person. The assailant usually strikes about the face or upper part of the chest, but these parts also suffer in an accidental fall. The ease is different when the contusion is met with in a part of the body which could not have been injured accidentally, as on the inner side of the arms or legs, on different sides of the legs, and the like.

Very severe eontusions or lacerations, which could only have been inflicted by means of an axe, hammer, or other such ponderous weapon, are almost always inflicted by another for the purpose of murder. In such cases, accident and suicide are generally both out of the question.

(*b.*) *Lacerated wounds*, as a rule, are the result of accident,

though maniacs have been known to inflict severe injuries of this kind on themselves.

(*c.*) A penetrating *wound* in a *concealed* part is highly suspicious of murder. The part of the body struck at by the assassin will be influenced by the character of the weapon he employs, and the mode in which it is handled by him. Thus, he will strike with a dagger or poniard, which he holds with the point undermost, downwards and inwards at the bottom of the neck or upper part of the chest of his victim; while, if he stabs with a long knife, he aims at the region of the heart.

Death by *stabbing* is generally the deed of another person for the purpose of murder. It occurs rarely for the purpose of suicide, and still more rarely by accident.

(*d.*) Incised wounds of a serious kind are very infrequent in purely medico-legal practice, except in instances of *suicide*.

It has been conceived that, in cases of suicide, wounds are seldom made steadily, so as to form a clean cut, unless the person is in a state of delirium. But few persons commit suicide who are not either in delirium, or in a state resembling it, at the time. Besides, a very clean cut may be inflicted with a sharp knife by a determined suicide without any delirium; while, on the other hand, a wound made by an assassin may be ragged and uneven from the struggles of his victim. No great reliance, therefore, is to be placed in this indication of suicidal wounds; neither is any confidence to be placed in the evidence deduced from the number of the wounds, which, in suicide, are said to be generally few in number. Suicidal wounds are, as a rule, very seldom inflicted in the back or left side of the body unless the individual is left-handed. Self-inflicted wounds also very rarely occur in a concealed part of the body. In cases of suicide, the situation of the wound varies with the kind of weapon used. Thus, if a suicide *shoots himself*, he generally shoots himself through *the head;* if he *stabs* himself, he does it in *the chest* or *belly;* if he effects his purpose by a cutting instrument or incisions, he selects the throat. Suicide *in females* is seldom, if ever, accomplished by *cutting instruments* or *firearms*. If there is a wound upon the body, and no weapon is found near it, or if the weapon is found concealed where it could not have been concealed by the deceased, accident and suicide are both out of the question. Murderers often use several weapons to despatch their victims, first employing one to stun, and then another to stab, shoot, or strangle them. Suicides, on the other hand, seldom use more than one method, though to this there have been some exceptions. If *gunshot wounds* occur in the back, they cannot have been self-inflicted.—(Watson, pages 249-78, *pass.*)

Oleo-calcareous Liniment in Fissure of the Anus.—Dr. Carrère relates a case of very painful fissure of the anus, in which, after failing with the usual means, it occurred to him to try the above liniment, which is found useful in burns. By means of a small hair-pencil the fissure was painted over with it three or four times a day, a few shreds of charpie moistened with it being also left in at night. The fissure was completely cured in a week.—*Rév. Méd.*

Glasgow Southern Medical Society.—The thirty-fourth annual meeting of this Society was held on September 20, when the following gentlemen were elected office-bearers for the ensuing year:—*President:* Eben Duncan, M.D. *Vice-President:* John Niven, L.F.P.S. *Treasurer:* Ed. McMillan, L.R.C.S. *Secretary:* Thos. F. Gilmour, L.R.C.P. *Editorial Secretary:* Andrew J. Hall, M.B. *Seal Keeper:* Robt. S. Wallace, L.F.P.S. *Court Medical:* John Dougall, M.D. (Convener); A. L. Kelly, M.D.; Neil Carmichael, M.D.; James Morton, M.D.; Robert Park, L.F.P.S.

Temperature of the Eye.—Dr. Galezowski read a paper at the Havre meeting, in which he stated that the temperature of the healthy eye, ascertained by a small thermometer introduced under the eyelids, is about 37·5° C. The disease which gives rise to its greatest elevation is catarrhal conjunctivitis, in which it may rise as much as 2°, as it may also in abscess of the cornea. In affections consequent on alterations in the fifth pair, there is rather a diminution of the temperature, although the inflammatory symptoms may be very intense. Dr. Galezowski has also sought to ascertain whether it is not also a general elevation of the temperature in certain affections of the eye. He has found this to be the case, but recognises the fact that the ocular affection is only a manifestation of a more general disease, and that when this is suitably treated the morbid ocular phenomena soon disappear.—*Rév. Scientifique*, September 8.

ORIGINAL COMMUNICATIONS.

THE NATURE AND THERAPEUTICAL VALUE OF ELECTRICAL TENSION.

By A. DE WATTEVILLE, M.A. Lond., M.R.C.S.,
Electro-Therapeutical Assistant to University College Hospital.

The object of the present paper is to elucidate a point of some theoretical difficulty, and which seems not to have received its proper amount of attention in the usual works on electro-therapeutics. We shall try first to dispel the obscurity which attends the idea of electrical "tension"; and next to explain the facts where it finds a practical application.

It is often said, but little remembered, that electrical currents—including the "spark" of the frictional machine, the momentary current of the induction coil, and the typical continuous flow of the galvanic battery—are governed by Ohm's law. Of course we speak here of currents only in reference to their strength; their effects vary widely, and, to speak of physiology alone, depend as much upon their duration and rate of intermittence as upon their strength.

What, then, says Ohm's law? The strength of an electrical current is directly proportional to the electro-motive force impelling it, indirectly to the resistance opposing flow. In other words, $C = \frac{E}{R}$. The researches of physicists have one and all confirmed the universality of this formula. But we find in it no reference to the "tension" of the current so often mentioned. It must, then, either denote an imaginary, or at least special, property of the current, or be implied in some one or more of the three terms of the formula. Let us examine them a little more closely. The strength of an electrical current is defined as "the quantity of electricity flowing in a unit of time," exactly as the strength of a stream of water is measured by the number of gallons it conveys in the second or minute. In both cases the strength of the current denotes the work it can perform.

The resistance offered by a body to the passage of a current of electricity depends upon its greater or less conductivity, of which it is the reciprocal. This, again, may be illustrated by a hydrostatical example, and compared to the diameter of water-pipes. *Cæteris paribus*, the quantity of fluid transmitted is proportional to the diameter of the pipe in the one instance, and to the conductivity of the body in the other.

Electro-motive force is not really a force in the same sense as heat, etc. It is only an abstraction—a name given to the hidden cause which, to continue our analogy between electricity and water, manifests itself as "difference of level" between two points. This difference of electrical level is called difference of potential, and is exhibited between the poles of a galvanic cell, or battery, between the terminals of an induction coil, between the knobs of a frictional machine, between two thunder-clouds, between the longitudinal and transverse section of a muscle; in a word, wherever electrical equilibrium is disturbed. Without difference of level there is no current, either of water or of electricity.

Now, tension is, in its only possible acceptation, but the older term for difference of potential. Difference of potential again is, as we have just said, the manifestation of electro-motive force at two given points. Hence, assuming one of the points at zero (that is, at the earth's potential), we are able to speak absolutely of the potential, or tension, of a point. Thus, the tension at any point in a circuit is simply the electro-motive force effective at that point to carry on the current. If, however, we examine a little more closely the word tension in its ordinary loose employment, as, for instance, in most books of electro-therapeutics, we find that another idea is mixed up in it with that of potential—the idea of resistance. This apparently depends upon two causes. First, it is evident that, in order to have two points at very different potentials, they must be separated by a resistance sufficient to prevent the immediate equalisation of levels. This is well illustrated by the phenomena of atmospheric electricity. Air, we know, offers an enormous resistance to the passage of a current. But as soon as the difference of potential between the earth and a cloud has reached a sufficient height to overcome that resistance, equilibrium is restored: the flash of lightning is the best possible instance of a current of high tension.

Secondly, the use of elements with high internal resistance

allows a larger number to be applied without increasing the current-strength, but only the "tension" of the current. This has undoubtedly led some medical writers to ascribe to that resistance the origin of tension.

To sum up: "Tension" in its strict sense has been replaced in the present school of electricians by "potential," which again may practically be used convertibly with "electro-motive force." The value of "currents of high tension" is given to currents impelled by a high electro-motive force through a large resistance. Thus, currents equal in strength are given by 1, 10, 1000, or any number of volts, provided the resistance in circuit be proportional to the electro-motive force, but the last will have a higher tension than the former. If we use in one case a battery of 35 Daniells to galvanise a patient, the resistance of whose body, including the electrodes, etc., may be taken at 3500 ohms (the resistance of the battery may be neglected, and the electro-motive force of each cell taken at 1 volt), the strength of the current obtained is $\frac{35\times1}{3500}=\cdot01$.

We obtain the same result by using 350 Daniells and introducing into the circuit an additional resistance of 31,500 ohms; for $\frac{350\times1}{31500+3500}=\cdot01$. Thus we gain nothing as far as the quantity of electricity flowing through the patient is concerned. But the following points must be noticed:—If, when we are using the thirty-five cells, we allow the moist electrodes to remain ten or fifteen minutes in contact with the same portion of the skin, the galvanometer shows during that period a marked increase of the current-strength. If we move one of the electrodes over different points of the body, the needle again shows variations in the quantity of electricity flowing. If, on different occasions, we use rheophores not equally moistened, or moistened with salt solution of varying strength, or if the rheophores and electrodes have become oxidised; or, again, if one day the patient's skin is cold and dry, and another hot and perspiring,—we shall find that each of these circumstances produces fluctuations in the current given by our battery, supposing, of course, no change has occurred in it. The reason is, that in every case there is an alteration of the resistances in the circuit. Suppose these variations make the original resistance range between 2500 and 4500, it is clear that the current will vary in the proportion of 5 to 9.

Now, if we use the battery of 350 volts with an additional resistance of 31,500 ohms, it is at once apparent that the variations just described have, practically, no influence upon the current-strength, which will vary in the proportion of 34 to 35 only. Nay, the resistance of the whole body, when placed in the circuit, produces a diminution of but one-tenth of the previous current-strength, for $\frac{315}{350}=\frac{9}{10}$. Hence we deduce the rule that the constancy of the current is inversely proportional to the ratio which the fluctuations of the adventitious resistances bear to the permanent resistance in the circuit; that is, *cæteris paribus*, the constancy of a current is proportional to its tension.

In the case of the induced current the well-known controversy between Duchenne and Becquerel, in which the latter showed that the alleged physiological differences between the primary and secondary currents were solely due to their respective tension, has attracted the attention of electro-therapeutists to this subject. Coils may be made either of a short thick wire, or of a long fine one. The electro-motive force generated in a coil is, *cæteris paribus*, directly proportional to the number of turns it contains, whilst the resistance is directly proportional to the length, and indirectly to the diameter of the wire. Hence, coils made of a long fine wire give currents of high tension. And the same observations apply to them as to galvanic batteries with a large number of elements and additional resistance. For instance, if I induce in a short thick coil of 5 ohms resistance an electro-motive force of 50 volts, and in a long fine coil of 8000 ohms an electro-motive force of 250 volts, and send the current through a portion of the body of, say, 2000 ohms, the current-strength in both cases is about ·0025. But whilst any variation in the resistance included (such, for instance, as when the skin is not moistened) is accompanied by corresponding changes in the first instance; no such effect is produced in the second. Whenever, then, in practice, currents of great constancy are required, high tension batteries and coils will be found preferable.

For instance, in electro-diagnosis, the utmost uniformity of current-strength is to be secured. For this purpose minute attention must be paid, when an ordinary galvanic battery is used, to the details of the operation, such as the degree of moisture of the skin on the two sides of the body, the amount of pressure of the electrodes, etc. It is evident that both time is saved and accuracy insured by the use of a high tension current; for, as we have just shown, even considerable oscillations in the external resistance, due to causes mentioned above, may be neutralised by the large additional resistance in the circuit. These remarks equally apply when constancy is required, either for physiological research or therapeutical application.

The effects of high tension currents upon the skin is to be noted. If a current of ·003 (produced in the one case by ten Leclanchés and no additional resistance, and in the other by 1000 through 50,000 ohms) be sent through the hand, for instance, exactly the same result is obtained when the rheophores are firmly applied to the surface. But if the negative pole be made to touch lightly the skin, a great difference in the sensations produced is observed. No pain is felt on the first application, but a very sharp stinging pain is felt on the second. The same phenomena are observed when induced currents of the same strength, but produced in different coils, are used. The epidermis offers, especially when dry, a considerable resistance to the current. This resistance increases proportionally to the smallness of the surface touched by the electrode. The ordinary low tension current is so much weakened by this resistance as to become unappreciable; the high tension current suffers no such diminution. Again, currents of the same strength have a local action proportional to their density. These two considerations explain the superiority of high tension currents when a powerful action upon the skin is required.

Similar considerations show, also, that high tension currents must be used when a localised action is to be exerted upon some deep-seated organ. Different tissues conduct electricity differently. For instance, the resistances of muscle, nerve, and bone are said to be in the proportion of 1 : 3 : 12. If, then, for instance, we have to influence the spinal cord, we labour under a double disadvantage: the current has to be sent through a moderately good conductor, enclosed in a tube of great resistance, itself surrounded by a mass of well-conducting material. It is evident, therefore, that with an ordinary battery powerful currents must be used, in order that a sensible quantity of electricity reach the cord. Much the greater proportion is wasted in the muscles surrounding the spine. On the other hand, we have a right to assume, on physical grounds, that the cord is more easily influenced by high tension currents. What happens in the case of the skin will happen to the bony protection of the cord; its resistance is small compared to the resistances in circuit, and is easily overcome. The course of the current will be more direct, its density greater; hence its action more localised. As an illustration we may take the action of the modern rifle-bullets: fired under great pressure, they readily pierce any obstacle in their course. A point to be remembered, also, is that high tension may be used weaker than low tension currents, and therefore allow of smaller electrodes being employed without producing pain or disorganisation of the skin. This is an important factor in the localisation of the current.

Before concluding, a few words about the apparatus may be found useful. The number of cells must, of course, be large—the larger the better,—but very good results are obtained with 100 cells. The additional resistance is obtained by means of a water rheostat, or set of resistance coils. The graduation of the current being effected by means of the latter, a collector is not necessary, but it may be found convenient to be able to work with half the battery at a time when very weak currents are requisite. Fifty Leclanchés through 50,000 ohms give a current of ·0015, which can be safely applied to the head. A properly graduated galvanometer should be used. The liquid rheostat allows of a very fine graduation of the current. An advantage of this method is that it does away with the multitudes of wires necessitated by a collector—a constant source of trouble with batteries. Nor is the bulk of the wear and tear thrown upon the first ten or twenty cells of the battery, but is evenly spread over the whole number. Not only there is no waste of material by using a high tension battery, but rather a saving, for the amount of chemical change in the cells is proportional not to the number of elements, but to the current-strength used. These changes having a larger surface upon which to develope themselves, are less intense at

any particular point, and the cells last longer. In fact, all the advantages of large over small elements are secured, in addition to the tension. When the action upon the skin is not required, the electrodes must be applied firmly, and the current closed after they are in position. An interrupting handle will be found exceedingly convenient for this purpose. Finally, the cells must be such as do not waste when not in use; Leclanché or chloride of silver elements answer very well, and there is no harm in their having a considerable internal resistance.

With regard to the induced current, what precedes sufficiently shows the desirability of using short thick, or long fine coils, according to the necessities of the case. Gaiffe, of Paris, has supplied me with a Du Bois-Reymond's apparatus, and three coils. The wire of the first is 66 metres in length, 1·4 millimetre in diameter; of the second, 198 metres in length, 0·7 millimetre in diameter; of the third, 600 metres in length, 0·225 millimetre in diameter. The first is useful for treatment generally, with thoroughly moistened skin; the second for diagnosis and powerful effects; the third for cutaneous electrisation. In the usual apparatus the primary (short thick wire) and secondary (long thin) fulfil these indications more or less completely. But it is physically impossible to produce, as some authorities pretend, all the required effects with different lengths of a single coil.

STATISTICS OF DISEASE IN KING WILLIAM'S TOWN, BRITISH KAFFRARIA.

By CHAS. JAS. EGAN, A.B.T.C.D., M.R.C.S., etc.

No. IV.

To render my account of the principal diseases of Kaffraria more complete, I must allude to the fevers and zymotic diseases usually met with here.

In former papers published in this journal (*Medical Times and Gazette*, January 27, 1872, and June 28, 1873), I have given an account of typhus and typhoid fever, small-pox, and scarlatina. Since then no case of true typhus has been met with by me, but typhoid is, as heretofore, met with under the same conditions as those mentioned by me in a previous paper—*i.e.*, occurring often sporadically, among persons constantly inhaling air, or drinking water, contaminated by exhalations from, or mixture with, human excreta, whether such excreta be derived from persons suffering from typhoid fever, or from healthy individuals.

During the six years 1870 to 1875 eighty-four cases of typhoid have been attended. The following table shows the order in which they occurred in each quarter of the year:—

Table I.—*Typhoid Fever.*

	1870.	1871.	1872.	1873.	1874.	1875.	
Spring	4	1	3	1	—	8	= 17, or 20·23 p. cent.
Summer...	—	7	6	6	13	1	= 33, or 39·28 p. cent.
Autumn..	1	3	8	5	4	1	= 22, or 26·19 p. cent.
Winter....	—	—	4	1	5	2	= 12, or 14·28 p. cent.
	5	11	21	13	22	12	= 84

Among these cases seven deaths occurred, equal to 8·33 per cent. It will be seen, by referring to a previous paper, that both dysentery and diarrhœa were much in excess in 1874 over other years, and in that year the rainfall was higher than in any of the other years, exceeding the average of ten years by ten inches.

A few cases of scarlatina have been met with, occurring sporadically, of a very mild form; no death from this disease having taken place. Children in many instances go through a fever in all respects similar to scarlatina—with sore throat, red palate and fauces, strawberry tongue, but without any eruption on the skin, though followed by desquamation. Some cases were followed by œdema and albuminuria, easily amenable to treatment, and not leaving any bad effects behind.

Small-pox has not visited the colony since the epidemic of 1859, and I think that by proper quarantine regulations it can be permanently kept out of the country. On two or three occasions since then ships with small-pox on board have come into ports in the colony, but, by being placed under quarantine, no case of the disease has occurred on shore.

Since I wrote in 1872, a wide-spread epidemic of measles has passed through the colony, and I here give the statistics of it, as it occurred in my practice in King William's Town. The epidemic began in December, 1873, and continued during the summer, autumn, and winter of 1874, as shown in the following table:—

Table II.—*Measles.*

December, 1873	76	cases
January and February, 1874 (summer)	182	,,
March, April, and May, 1874 (autumn)	92	,,
Winter	46	,,
Total	396	cases

Among these, six deaths occurred, or a percentage of 1·51. Three of these deaths were produced by congestion of the lungs, and would have been prevented if ordinary care had been taken of the patients. One was carried off by congestion of the kidneys brought on by cold, the patient having been allowed to get out of bed and go to a yard to relieve the bowels when the eruption was fully developed. Other members of the family had got through the disease so easily, that this child, a boy of ten years of age, was allowed to do just as he liked, as if nothing was the matter with him.

I have not met with any serious secondary affections of the eyes or mucous membranes remaining after attacks of measles, as is so often found at home, except in one case, where a boy, aged fourteen, got lupoid ulceration of the tonsils and palate, which eventually killed him after two years' suffering. Two other members of his family were affected with lupus exedens of the face, and all the family were highly scrofulous.

Intermittent fever and diseases of malarious character do not originate here, and all cases of the kind that have been met with were first contracted by residence in other countries.

No case of cholera morbus has so far been met with here; the disease has never extended further south of the line, on the African coast, than the latitude of Mauritius.

Another disease of which no case has ever occurred in South Africa is hydrophobia; its absence from this country seeming to prove the correctness of the opinion of Mr. Youatt, that it is a disease now only propagated in the dog by direct infection from a rabid animal. The distance of this colony from Europe, and the expense of importing dogs by steamer, act as efficiently in keeping out the disease as a regular system of quarantine.

Both acute and chronic rheumatism are very common; the following table shows the frequency with which they occur:—

Table III.—*Acute Rheumatism.*

	1870.	1871.	1872.	1873.	1874.	1875.	
Spring....	4	6	3	3	16	8	= 40, or 32·26 p. cent.
Summer..	5	2	—	3	11	11	= 32, or 25·80 ,,
Autumn..	6	5	5	—	2	9	= 27, or 21·77 ,,
Winter....	3	5	1	1	9	6	= 25, or 20·16 ,,
	18	18	9	7	38	34	= 124

These were not all of them actual cases of rheumatic fever, many of them being only acute attacks of rheumatism, affecting one joint, and not lasting very long; in some cases removed by a blister, etc.

Five cases of rheumatic inflammation of the pericardium, and three of the endocardium, occurred—of which one died. This case was that of a very delicate girl, aged twelve years, who went through a severe attack of rheumatic fever affecting all the joints, and also the endocardium, especially the mitral valves; on the subsidence of the rheumatic fever, violent chorea set in, and the child died after ten days utterly exhausted; all the usual remedies for chorea, and narcotics having been ineffectually tried.

The cases of chronic rheumatism treated are shown in the following table:—

Table IV.—*Chronic Rheumatism.*

	1870.	1871.	1872.	1873.	1874.	1875.	
Spring....	6	7	3	19	2	4	= 41, or 24·11 p. cent.
Summer..	3	11	7	13	12	5	= 51, or 30·00 ,,
Autumn..	1	3	11	10	3	7	= 35, or 28·80 ,,
Winter...	4	6	3	10	7	13	= 43, or 25·03 ,,
	14	27	24	52	24	29	= 170

This return does not show the proper relative proportion of chronic to acute rheumatism, for many persons suffering from it do not apply for medical assistance, using instead household remedies and various kinds of liniments. But many of these persons suffering from chronic rheumatism have also valvular disease of the heart, the affection of the heart appearing to come on gradually, and not originating in any acute attack of endocarditis.

In the following table I give a summary of the statistics of those diseases brought forward in these papers, and I think

they will compare favourably with similar reports taken in other countries.

The death-rate is low, only 2½ per cent. on the total number of cases treated; and, as far as I can judge, if the death-rate of the entire population of the district could be ascertained, it would not exceed 25 per 1000. However, as yet I am not in a position to determine this point accurately.

Table V.—*Summary of Preceding Tables.*

	No. of cases.	Deaths.	Percentage of deaths.

A CRITICAL REVIEW OF THE

PREVAILING THEORIES CONCERNING THE PHYSIOLOGY AND THE PATHOLOGY OF THE BRAIN:

LOCALISATION OF FUNCTIONS, AND MODE OF PRODUCTION OF SYMPTOMS.

By EUGÈNE DUPUY, M.D. Paris, of New York;
orresponding Member of the Paris Société de Biologie; Member of the American Neurological Association, etc.

Part II.

The oldest precise localisation known was established fifteen years ago by Professor Broca. His theory teaches that the faculty of speech is localised in the third frontal convolution of the left hemisphere. There exist a great number of pathological cases which show a very frequent coincidence of disease of that convolution with loss of speech. But ought we to adopt the theory of Broca, so ably maintained by Hughlings-Jackson, and which is even said by Dr. Ferrier to derive support from his experiments on the brains of monkeys?

First, there are cases of aphasia which have occurred with destruction, not of the left, but of the right frontal convolution. It has been answered against this fact that the patient must have been a left-handed person; hence the rule holds true. But, secondly, there are cases of aphasia with lesions seated in other parts of the left hemisphere than the left frontal convolution, or even of the island of Reil, which, according to the greater number of authorities, also is concerned in the faculty of speech; and, thirdly, there are cases in which the island of Reil and Broca's convolution have been found diseased, and no aphasia observed. There are numerous cases enough of this last description, and of the preceding one, to enable me to state at least that if Broca's convolution is the seat of the faculty of speech, it is not the only one; but of course this is only a *pis aller*, because, if we look more into the subject, it will very soon appear that Broca's convolution is not, more than any other convolution, the organ of speech.

The proofs which I can adduce to support this statement are numerous, and, I believe, have some value. It is necessary for me to state at once here that I cannot consider the six or seven different kinds of aphasia usually treated of by authors; physiologically, they are only several degrees of one kind of aphasia.

The cases which I will report now have been well observed, and published by physicians of merit who have recorded them for the purpose of elucidating the subject of aphasia. I shall, therefore, not mention the old cases contrary to the would-be speech-centre, found in the book of Dr. Bateman, and in the works and papers of other authors.

The first and most striking case of destruction of the so-called speech-centre without consequent aphasia is the celebrated American crowbar case. I believe that I was the first to report that extraordinary case in France. Dr. Ferrier, in commenting on it, lays it down that only the anterior portion of the frontal lobe was destroyed by the accident. It is well known that the subject of that observation, while occupied in blasting a rock, was wounded by the unexpected explosion of the blast at which he was engaged. The tamping-iron which he was using was several feet long and *an inch and a quarter* in diameter; it passed, according to measurement which I have made, through the brain on the left side, in such a manner as not only to destroy the left Sylvian artery, which sends a special artery to Broca's convolution, but it actually destroyed the greater part of the island of Reil. A great quantity of brain-matter was discharged for several days after the accident, in consequence of sloughing. I had an opportunity of seeing that cranium in Boston last winter, and also the iron bar. That man (Gage) was never aphasic, nor paralysed. There is another case, recorded by Theodore Simon,(a) which proves that a notable loss of substance of the brain-matter in the orbital region can exist for years without giving rise to appreciable symptoms, and that the destruction of the *insula* on the left side is not necessarily followed by loss of speech.

There is a case recorded by my excellent friend Dr. Troisier, in which aphasia has existed with no other lesion but one found in the postero-parietal region. The following case is also very interesting, as it shows partial aphasia with very limited paralysis in a patient, observed by one who took the notes for the purpose of elucidating the subject of localisation of functions in the brain. The patient was observed in the wards of Dr. Luys. There was right paralysis of the tongue and of the face; sensation intact.(b) "The left arm and hand are paralysed to a slight degree as to motion and sensation. The right eye and ear are impaired; there is no apparent lesion of the transparent media of the eye. The vocabulary of the patient is exceedingly limited, and consists of only a few words, which are used for all purposes. There is impossibility of reading; A is taken for B, etc. Cannot write her name. Cannot write, although the pen is well held; writes Coroline for Caroline; her name being Madame *Cohadon*, she writes Madame *Adon*, and then Madame *Coadon*, etc." The autopsy discovered in the left hemisphere a yellow (ochre-coloured) softened patch having destroyed the first and second temporal convolutions; "above and forward the lesion is limited exactly by the sulcus which separates the insula from the sphenoidal lobule; behind, it bends round the posterior extremity of the fissure of Sylvius, leaves untouched the whole third convolution, but ascends on the *pli courbe* (gyrus angularis), of which the greater part is so destroyed, and is found a little further in the sulcus which separates the superior parietal lobule from the inferior one. On the occipital lobe it penetrates a little in the parieto-occipital sulcus, destroys a part of the internal and of the external portion of the cuneiform lobule." In the hemisphere itself there was detected a *lacuna* in the white substance, with very neat lining, corresponding in site to the junction of the first temporal convolution with the lobule of the gyrus angularis; also, a very small *foyer* (spot of softening) with yellow borders in the posterior portion of the thalamus opticus. In the right hemisphere there was nothing in the convolutions; but in the white substance there were two pisiform lacunæ close together, above the internal capsule, one centimetre and a half from the base of the corresponding convolutions. In the lenticular ganglion of the corpus striatum

(a) Theodore Simon, *Deutsche Klinik*, 1873, Nos. 17 and 18.
(b) Sabourin, Société Anatomique, rapporté dans *Le Progrès Médical*, 1877, p. 70.

there was also a yellow matter resulting from old disease, extending from behind forward, exactly on the limit of that nucleus and the external capsule. The softening extended up to the most distant portion of that nucleus lenticularis. There was also in the centre of the thalamus opticus another old lacuna, as large as a hempseed. In the pons, on the right side, above the large inferior fasciculus, there was a small darkish patch five millimetres by one centimetre in size. All the other organs were healthy.

This observation is remarkable in more than one aspect. But I desire only to observe here that there was aphasia without destruction of the third frontal convolution or of the insula.

Dr. Brown-Séquard, in his Lectures in course of publication in the *Lancet*, will doubtless bring out such a large number of similar facts, that I have no occasion for reporting more here. I beg to observe that I have given cases well observed and well recorded by physicians of ability, which prove the postulate written above—that aphasia may exist without or with lesions of Broca's convolution, and also with or without lesions localised in other parts of the brain.

The experimental proofs of localisation of the speech-centre in the left third frontal convolution in its posterior part where it overlaps the insula, Dr. Ferrier pretends to have discovered; for he says that this region in the brain of man "corresponds with the situation of the motor centres of articulation in the monkey." Now, in the monkey, on the irritating only of one side, he has had movement in both sides of the tongue and in the orbicularis of the lips; but on what grounds a similarity is established between the two phenomena, contraction of the muscles of the tongue and aphasia—the first in the monkey, and the second in man,—I fail to see. It must not be forgotten that man may suffer from loss of speech through paralysis of the tongue, the aphasia then being apparent only; and that if the experiment on the monkey proves anything, it proves only that last point, judging by analogy. Now, if aphasia is not due to loss of function of a speech-centre situated in Broca's convolution, how are we to explain it? I believe that it is due to a reflex process—a process of inhibition. That there is a reflex inhibitory element in it can be seen by reading carefully even the old authors. Trousseau has recorded several instances to the point. Indeed, his lecture on that subject of aphasia contains nothing but cases which, when properly analysed, go a good way to overthrow Broca's theory. One patient who could say nothing but "*Oui*," one day, having let fall his handkerchief, a lady who was near him picked it up; upon this he said "*Merci*" (*i.e.*, Thank you) in a high and intelligible tone. He was asked to repeat the word; it was several times uttered before him, but in vain—he never afterwards could say it.(c) Again, another patient, who for three months after the onset of the disease could say only a few words with no meaning, and the same in all circumstances, yet one day, two weeks after the stroke of disease, said to his wife, "My dear." Again it was in vain that he was asked to repeat it.(d) In that same celebrated lecture Trousseau has recorded Professor Charcot's case of aphasia as complete as it could be, existing with the integrity of Broca's convolution. Professor Broca had himself examined the brain of that patient microscopically. So that when Professor Charcot said last year, in the Société de Biologie, that he rejects all his former cases up to that time as being incompletely observed, he begged leave to retain this one, because a double examination was made by himself and by Broca, and microscopically. It is needless for me to state that this case was a reflex inhibited instance like the others; but the following is more authentic still. It is reported by Dr. William Wadham.(e) A boy, who was the subject of hemiplegia of the left side, and who was ambidextrous, was subsequently affected with aphasia, which continued complete for three months. The only lesion found was a nearly complete destruction of the island of Reil on the right side. The author, in arguing on this case, very properly shows that this aphasic does not come into the category of left-handed persons because he was *ambidextrous;* and also of his *subsequent* recovery of speech, that it was not a paralysis of the tongue, notwithstanding appearances detected at the time, because his mother had to teach him the words after a long process, consisting in making him repeat after her each word. Moreover, if it was paralysis of the tongue, and not aphasia, having recovered from that paralysis sufficiently to articulate, however imperfectly, one word or phrase, he would quite as readily have given expression to his thoughts, whereas "Yes" and "No," "Good morning," and "Dr. Wadham," were the only words he had succeeded in learning. He was, however, able to write and spell correctly. He was only deprived of the power of converting his thoughts into words.

Dr. Wadham has very judiciously observed also that this case cannot be considered as a "left-handed case" in which the seat of speech is transferred to the right hemisphere, because the recovery of speech took place without any repair of the cerebral lesion, as shown at the post-mortem examination. He believes that the boy, although strongest in his left hand, being ambidextrous, the other (left) speech-centre came somewhat to fulfil the function which was only partially developed in it. Here I no longer agree with Dr. Wadham. First, it is to be observed that Broca's convolution, or its analogue on the right side, is said to have been healthy; and, secondly, there must have been reflex or inhibition processes in the case, because the parts destroyed cannot account for the presence of hemiplegia.

Another very interesting case is recorded by Dr. Schalz.(f) A patient had at one time, after a traumatism in the left parietal region, vertigo, pains, etc.; fifteen days later, paralysis of the arm and leg on the left side, loss of speech. Eleven days later, right hemiplegia with exaggerated reflex sensibility; after lasting one day, that hemiplegia disappeared. On the seventeenth day the aphasia, which was absolute, began to pass away; after three weeks there was nothing left of it. Three weeks after his entry into the wards, an operation was performed in order to remove the pus, of which the presence was shown by manifest signs and the presence of a tumour as large as a hazel-nut. On that (left) side of the head, nine centimetres below the sagittal suture, and on the tract of the coronal suture, some pus was discharged, together with white matter. He, two months and a half afterwards, was well to all intents, except that there was a slight prolapsus of the left superior eyelid. He began to recover even a quarter of an hour after the operation.

Certainly in this case, again, there was another influence at work than destruction of the island of Reil, or of Broca's convolution, or of pressure by pus. Firstly, if those causes were at work it would show that the aphasia depended upon the lesion of the speech-centre; but how explain the *left* hemiplegia then? And if this *left* hemiplegia is due to a reflex action, why not the aphasia also, since the speech-centre was not touched, or, if it was touched, how could the patient recover speech so speedily after the operation?

Another case by Dr. Proust.(g) A young man, in a fight with some soldiers, received a bayonet-wound in the left parietal region on October 8, 1876. He never had any symptom till after several days, and then even only headache. On the 19th and 20th of the same month Dr. Proust saw him in his ward, having then aphasia and paresis of right superior limb, and facial hemiplegia. The three symptoms increased slowly. (Dr. Proust watched the patient with great care; he is well known for having contributed to that special subject of aphasia a very valuable memoir.) Trephine was applied *loco dolente*. The fractured bone was taken away, and, at the same time, all the symptoms diminished. The dura mater was not even perforated. The operation was hardly terminated and the wound was not yet dressed, when the patient was already cured. On comparing by measuration the region of the seat of the injury in his patient with data obtained upon crania of other deceased patients, Dr. Proust was able with almost mathematical precision to localise the injury received by his patient only in the left ascending parietal convolution in its middle part. The Doctor adds, besides, that probably it engaged the frontal convolutions by nutritive troubles of neighbourhood; hence the ready explanation of the aphasia, the right paresis, and the paralysis of right face. But of course this view cannot be entertained. How can such be the case, since the patient recovered so rapidly? The nutritive changes cannot have disappeared in such a short space of time.

All those cases, I believe, go far to show that loss of speech does not depend upon destruction of a would-be speech-centre, but to an inhibitory reflex action. Language—speech—is essentially a reflex process altogether. It is verily an "organisation of past experience." Speech in man is not different from speech in birds; the only difference said to be detected between acquired speech in a bird and in a boy, is

(c) Trousseau, "Cliniques de l'Hôtel-Dieu," t. ii., p. 556, deuxième edition.
(d) Trousseau, *loc. cit.*, p. 592.

(g) Proust, *Bulletin Général de Thérapeutique*, t. xci., 11 liv., December 15, 1876.

that the boy has the advantage of being able to associate a certain idea with a certain speech, whereas the bird is said to be deprived of that faculty—by some altogether, by others to some degree. I have had opportunity to watch speaking birds several times, and I repeat it, I can detect no difference. We must remember that in a child speech is evoked by external circumstances; so with the bird. It is only when a child has grown that speech appears to be spontaneous; but even then, after all, it is brought about by a reflex process or a process from past organised experience acting upon articulatory centres. The bird when well educated does perfectly associate the words "Good morning, sir!" with the presence of a stranger or of somebody coming into a room; and a child does nothing else.

That a reflex action is at the bottom of all that process can be found out by a series of considerations which many can confirm for themselves. My friend Dr. Onimus has studied cases of aphasia in that direction, and he has recorded some very interesting instances.(h) A concierge (janitor), who was suffering from a stroke of paralysis and aphasia, was recovering to some extent, and words were being taught to him. One day Dr. Onimus pointed out to him a statuette made of plaster-of-Paris which was on one of his tables, and asked him to call it by name. He could not do it. The Doctor then discovered that if some other object was pointed out to him, and only the first syllable said, he would repeat it readily, and, as if moved by a spring, the whole word would come out. He therefore told him again to name the statuette, and said, by way of prompting, *sta*, the first syllable of "statue," but the patient could not finish the word. His wife, who was present, said, "Why can't you say an *e*statue?" He at once said an *e*statue. Now, the uneducated people in Paris do not say a *sta*tue, but an *e*statue. That aphasic patient, therefore, with many other examples known to all, shows very conclusively that speech in man, as well as in birds, is acquired by the same process. I beg leave to submit that perhaps when birds have been educated to talk for several generations consecutively, uninterruptedly, the subject of aphasia will receive a great deal of light.

What I have said of aphasia applies, I believe, as well to other paralyses from brain diseases. I am of opinion that even the *so-called* hemianæsthesia following destruction of the internal capsule is a reflex inhibitory phenomenon. I have said so already. I will now prove it. Professor Charcot has insisted very much on that one localisation. Veyssière and Carville and Duret, and Ferrier, have all based upon experimentation the same theory, that the internal capsule is the corner of nerve-matter which, when it is the seat of disease, causes loss of sensation for half of the body. Besides the arguments which I have already given to show how such a loss of sensation could happen, I will say now that Professor Charcot has himself within a few months shown that that anæsthesia is not an absolute one. While experimenting on the so-called metallo-therapic method, he has found that sensation, general and special, can be recalled in paralysed parts by the application of a gold coin or ring to the limb deprived of sensation.(i)

Now, it is clear that if in those cases of undoubted destruction of the so-called internal capsule-centre, of old standing—more than ten years—sensation can have been awakened even for only a few hours, the non-permanent manifestation of that sensation is not dependent upon destruction of a centre, because it would be impossible to have the results now obtained.

Again, in the cases published by Dr. Lepine, and of which I have already spoken, and in the case of Dr. Wadham reported above, and the case of Dr. Sabourin, certainly the phenomena observed during life did not correspond with the lesions detected. Let anyone think over the last case in particular, and he will see how impossible it is to make it agree with the theory of localisation.

Moreover, it is denied by nobody that some cases of undoubted destruction of brain-substance can exist, and yet the function, temporarily absent, appear again. Dr. Hughlings-Jackson has written on that subject—"The slightness and transientness of a paralytic symptom depend on the slight extent of lesions of nervous organs, not on slight *degree* of change. . . . (The patient) recovers, because he has lost only *a small quantity* of that tract (motor). For it is manifest to those who make post-mortem examinations that recovery from paralysis occurs when a part of the motor tract is permanently wanting."(k)

It is evident from that quotation that the paralysis must have some reflex element in it. For, during its existence, as well as after its disappearance, the same lesion existed in the motor tract; and if it is not so, how account for the paralysis or for its disappearance? I know how unbecoming of me it is to criticise the opinion of such a distinguished physician and such an acute clinician as Dr. Jackson, but I am impelled by facts to urge that the size or extent of the lesion has no influence on the transientness or slightness of a paralytic attack. There are numerous instances of what I advance here. Let us only remember the magnitude of the brain in the case of Dr. Sabourin. Some other element is concerned in that production of disorder and its duration. It is proved that the nature of the lesion, tumour, softening, hæmorrhage, traumatism, etc., have no influence. Considered specifically, it remains only to admit that the lesions do create an influence by the mere fact of their presence, which influence is the agent at work: that is to say, that, irrespective of size, the lesion acts just as an irritant applied to the skin does—to awake a reflex process. It is by the foregoing theory also that those cases can receive interpretation in which we see that a lesion localised in one hemisphere will cause simultaneously, or one after the other, paralyses on either side of the body.(l)

I am aware that it has been stated with regard to those cases which appear to the advocates of localisation contrary to their theory, that the observations were incompletely taken, or that an unseen lesion may have existed, or that there was an anomaly, just as when the heart is situated to the right, etc. Those objections are more apparent than real. To give only two instances, the American crowbar case and the case of Dr. Sabourin militate against such a view. And how can we attribute to an unseen lesion the paralysis observed, without at the same time admitting that the large lesion seen in a motor (so-called) centre, but on the corresponding side, has caused no symptom, and in this way destroy our very argument? And, moreover, a case of anomaly cannot be considered, because we know of cases in which one lesion in one hemisphere has caused paralysis on the corresponding side, which was cured to some extent, and later another lesion occurring in the other healthy hemisphere has again brought on paralysis, not only on the formerly paralysed side, but also on the one which was not originally so affected.(m) The loss of sight, amaurosis, is amenable to the same reasoning. Let me only say here that two of the very ablest pupils of Professor Charcot have just published researches which demonstrate very plainly two very different things. I explain: Dr. Ferrier has localised the sense of sight in the angular gyrus in man. Dr. Féré has observed a patient who for three years has had pain, etc., consequent upon a fall, which was followed by a wound in the right parietal region; the only symptoms now remaining are contractions, which specially show themselves when the patient does not pay attention, in the orbicularis palpebrarum, the muscles of the eye, and the zygomatic muscles. Dr. Féré made an attentive study of that patient, and by means of careful measuration and comparison, after Broca's method and his own method, with a number of crania, arrived at the conclusion that the spot of the bone depressed by the fall coincided with the posterior portion of the *pli courbe*, or at the very least with a region very near that spot; which is concordant with Dr. Ferrier's views.(n) But Dr. Pitres, another pupil of Professor Charcot, shows(o) ten cerebra marked by cortical lesions, from which (the symptoms during life being kept in mind) he concludes that the destruction of the *pli courbe* (gyrus angularis) is accompanied by *no symptom in the muscles of the eye*;(p) that destruction of the three superior quarters of it gives rise to paralysis of the face, but not of the limbs.

THE CHINESE TREATMENT OF AGUE.

By J. DUDGEON, M.D., Pekin.

This affection is one of the most common in the centre and South of China. After extensive and long-continued inundations, with the great heat that prevails, it becomes also in North China one of the most prevalent diseases. In ordinary circumstances the sandy nature of the soil grants immunity from its

ravages. It is a fruitful cause of much of the anæmia, and its consequent disorders, which is so rife in China generally. The floods in the North, beginning in 1870, and continuing for several successive years, produced commonly, in the summer and autumn months, about 60 per cent. of ague cases as compared with other affections. The inundations exist sometimes for a series of years consecutively, the floods of one year not disappearing before the heavy rains of the next. It is in this way that ague prevails so endemically and persistently in these regions, the severity of the disease, and consequently the number of victims, increasing or diminishing according to degree of heat, but hardly at all disappearing. Deaths among the old from ague are not uncommon. The book-name for it is so called from its resemblance in its treatment of people to a harsh and cruel man. The different forms are arranged according to their supposed causes, such as cold, heat, damp, phlegm, food, over-exertion, demons, pestilential exhalations, and old or mother-ague. This latter form is caused by water, phlegm, and blood getting coagulated together, and thus causing enlargement. The demon form is caused by sleeping with or watching by a corpse. The cold and hot stages are explained, according to Chinese philosophy, by want of harmony between the male and female principles of nature. The various forms are explained by the quantity of air furtively introduced at the time the patient was exposed to the causes. They admit a somewhat long latent period, the disease being, in many cases, caught in summer but not developed till autumn. The remedies in this, as in all other diseases, are legion. Every work repeats what every preceding one contains, the author merely adding his own views or comments. As a rule, the older the book, the better and more valuable the observations. Ginger, peppermint, liquorice, ginseng, and cinnamon enter largely into their remedies. Powdered tortoise-shell, a compound of centipedes, the skull of a tiger, the excrement and flesh of foxes, etc., could not, of course, be omitted. In mother-ague (enlarged spleen), assafœtida, realgar, and vermilion are relied upon. Several celebrated recipes are styled *barrier* prescriptions, because of their great efficacy in cutting short an attack, and curing the patient for ever by one administration, and on this account are therefore said to be divine. Tonic medicines are highly lauded. An ordinary formula, to be taken warm on the morning of the day of attack, is—rad. lysimachiæ, betel-nut, cloves, and spirit. Remedies of a magical character find a natural place in all Chinese medical works. A combination of arsenic, spiders, and beans is highly extolled when it is desired to cut short an attack in a spirit-like manner. It is somewhat remarkable that the Chinese should for thousands of years have been following a tonic and arsenical treatment. The confidence with which these remedies are administered would indicate the benefit that has been derived from them. Some of the prescriptions are designated by such epithets as "the great, instantaneous, godlike, infallible, speedy, sure, once-to-be-taken remedy for ague." Quinine, wherever known, has superseded all the native remedies; and there must be a growing demand for this Western specific. From the large dose which can be given with safety and efficacy, quinine is the most valuable remedy, but its great expense is a serious objection in a large dispensary practice. Fowler's solution proves highly serviceable, and may be substituted in every case for quinine, and in some cases where the quinine seems to fail. The comparative slowness of its action, and the smallness of the dose required to be given, however, militate against its free use among the natives seen at the public dispensaries. The carbazotate of ammonia may also be used with good results. I have had no experience of the hypodermic injection of carbolic acid as recommended by some French surgeons. In Mongolia ague is hardly known. It has, however, more than once greatly alarmed some of the tribes by its spreading among them; and the lamas (priests) concluded that it was a contagious disease introduced by soldiers returning from China. The popular account states that when Mongols take it and become delirious, *they rave in Chinese*. From its regular periodic character, the common Chinese suppose it to be caused by demons; and to elude their visits, and thus effect a cure, they frequently change their abode, or at least leave home, about the time the attack is expected.

It is stated that between 8000 and 10,000 glass eyes are sold annually in the United States. An eye-maker gives one in 125 as the proportion of one-eyed people.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

CASES OF ABDOMINAL ABSCESS.

LONDON HOSPITAL.

Case 1.—*Abdominal Abscess, probably communicating with Transverse Colon by a Small Aperture—Opening made—Recovery.*

(Under the care of Mr. RIVINGTON.)

J. M., aged fifty, a printer, of sedentary habits, was admitted into the London Hospital on May 24, 1874. He was affected with a swelling in the abdomen, immediately below the umbilicus. This swelling was larger than a fœtal head, but flattened. Its long diameter was transverse and measured eight inches; its short diameter vertical and measured four inches. It engaged all the soft tissues of the abdominal wall, and they could not be moved over it. It seemed to extend deeply into the abdominal cavity. The skin was adherent and showed a brown discoloration. An obscure feeling of fluctuation could be elicited. It had been growing rapidly during the last few days, and had extended at least two inches further across the abdomen. It had commenced five weeks previously, when the patient felt a sudden severe pain an inch below the umbilicus, and this remained from eleven o'clock on Saturday morning till five o'clock on the following Sunday afternoon. Two or three days later he felt a small tumour in the spot where the pain had been; it was then larger than a marble, and was close underneath the skin. For three weeks it did not increase in size, but then it took on rapid increase. There was some dull, dragging, intermittent pain in the part, but no shooting pain. The question of diagnosis rested between abscess and malignant tumour. In reference to the latter it was ascertained that there was no history of tumours of any kind in the family. He had had no serious illness. Now he had a slight inclination to sickness; his appetite was failing; tongue slightly furred; bowels regular; heart and lungs sound; no albumen in his urine; he had no rigor or chills.

May 27.—Evident fluctuation in the tumour. An exploratory incision an inch long was made through the soft tissues below the umbilicus and in the middle line. Pus and gas commingled, and possessing a most decided and offensive fæcal odour, issued. A charcoal poultice was applied. During the next few days the discharge of pus continued freely. The pus was dark and offensive.

May 31.—The pus to-day became healthy and free from smell. The patient was decidedly better: appetite returning, and sleep undisturbed.

June 1.—A sharp rigor. Face pallid; pulse quick and small; respiration hurried. Nothing about the wound or swelling to account for the rigor. Perspiration profuse; no pain; vomiting. The rigor lasted more than half an hour.

2nd.—Better; less discharge.

7th.—No shivering since the 1st. No tenderness; tumour becoming smaller.

9th.—Mr. Rivington pressed out some pus and gas, and a large quantity of dark-coloured stuff looking and smelling like fæces, with relief.

10th.—Going on very well.

Nothing further worth noticing occurred. The swelling decreased in size day by day, and the wound had closed before the 23rd, when he was discharged cured.

CLEVELAND-STREET ASYLUM.

Case 2.—*Abdominal Abscess discharging through Bladder.*

(Under the care of Dr. LEDIARD.)

H. V., aged forty-nine, porter, formerly a bandsman in the Navy, was admitted into the Cleveland-street Sick Asylum on January 19, 1877.

History.—Father died of liver complaint at seventy-two. Mother died from a "gathering" which came from the navel at forty-six. Patient was in the Navy ten years. Served in Crimea, Peru, and Pacific. Formerly suffered from dysentery. Had drunk freely, but not to a great extent, and was fairly well up to last September, when he had some griping in the abdomen, but he did not give up work until December.

On admission he was found to be somewhat spare, and suffered from diarrhœa and abdominal pain. Passed blood

per rectum before admission. The abdomen was natural except some enlarged glands in either groin; heart and lungs normal; no albumen in urine; no blood with stools; slept and ate well.

January 31.—To-day the patient first passed pus with his urine, and had some difficulty in micturition, but no rigors. Then micturition became frequent and painful, he began to cough and spit, and the diarrhœa abated.

February 17.—Complains of persistent pain in right hip-joint. Pus continues to pass with urine freely. No rigors, night sweating, or diarrhœa. Cough continues. A sound passed into bladder detects nothing. There is some lumbar pain. Body is getting emaciated; glands in groin continue enlarged; no supra-pubic tenderness, and abdomen can be handled with freedom; the spleen and liver are not enlarged; the skin is generally dry, and varies from coolness to slightly increased heat.

In March some improvement of a temporary character was noted, and less pus was passed with the urine.

March 12.—Abdominal pain has returned, with pain on passing water; rectum seems healthy; face has a yellowish hue, but no jaundice; bowels are not loose now.

17th.—The pain previously complained of in the right hip has returned, together with pain in the loins.

A few days after, the diarrhœa recommenced, and the urine was solid on boiling from the amount of pus. The bladder was washed out with a double catheter and always seemed free from disease, and it was thought possible that there might be some pyelitis at this time.

In April, urine was very offensive, and passed in small quantity at a time; the diarrhœa continued on and off. In short, his symptoms were much the same, but aggravated.

In May, his mouth became parched. Scalding with micturition appeared. Pyuria as before, and diarrhœa; then latterly he had extreme agony on passing water, and the pain in the hip returned, with some contraction of the right thigh.

He died on the 28th, exhausted.

Post-mortem.—Body emaciated; abdomen discoloured; no peritonitis, ascites, or general dropsy. Liver tolerably healthy, but adherent to spleen by the under part of the left extremity. Heart healthy. Lungs thin; small cavities at upper part of each. Left kidney large, a little fatty, but otherwise healthy; right kidney somewhat atrophied and discoloured on posterior surface from continuity to abscess in psoas muscle. Bladder and rectum cut out of pelvis with difficulty, from thickening and adhesion of parts to the pelvic cavity on the right side. Ureters natural. Right psoas and iliacus muscles discoloured and destroyed, partially from presence of pus burrowing in all directions and passing up as far as the origin of the former. Vertebræ healthy. Sacro-iliac and vertebral articulations normal. Pus burrowing in all directions on the right side of the pelvis, passing into the hip-joint through the obturator foramen. The cartilages of the joint were discoloured, but scarcely altered at all structurally. On opening the bladder, the mucous membrane was greenish-looking, coats thickened, no ulceration, and not much cystitis; on the right side of the bladder was a small perforation, through which the extensive psoas, iliac, and pelvic abscesses had discharged. The lower end of the rectum was healthy, but the upper part congested, thickened, and ulcerated here and there; and this thickened condition existed, together with contracted calibre, more or less, up to the valve, the "shaved-beard" appearance being constant throughout. The most active disease was situated at the sigmoid flexure and upper rectum, with here and there old cicatrices. There was a small secondary abscess in the liver. There was no evidence, clinically or pathologically, of osseous disease, and it is probable that the abscess originated in peri-intestinal inflammation at the brim of the pelvis, from whence pus passed in the three directions noted.

CHARING-CROSS HOSPITAL.

PLEURITIC EFFUSION AND ULCERATION OF LUNG IN A PATIENT THE SUBJECT OF ACQUIRED SYPHILIS AND OF GRANULAR KIDNEY DISEASE.

(Under the care of Dr. THOS. BARLOW.)

R. B., aged forty-eight, a commercial traveller, came under treatment February 28, 1875. He stated that six weeks before, whilst in the country, he had been taken with sharp pain below the right shoulder-blade, cough, and shortness of breath. He had consulted a medical man, who told him he had congestion of the lung; and he had been obliged to stop in the house for more than a week. Although he had improved, he said that he still felt feeble, and that his breath was a little short yet. He had the signs of a very slight effusion into the right pleura. Otherwise, physical examination revealed nothing abnormal with the exception of slight emphysema. His tongue was flabby, but nearly clean, and his skin cool. But it was impossible to resist the conviction that the pleurisy was quite a fractional part of his morbid condition, and that, in fact, he had some diathetic disease at the back of it; for although he was a well-built man, he had a quite unnatural sallowness of face, with an anxious expression, and moreover, though not emaciated to any great extent, he was "pulled down" more than a simple resolving pleurisy would account for. He was examined again and again for mediastinal dulness, but none could be made out. There seemed some reason to suspect granular kidney, although at that time there was no albumen in the urine, nor on several occasions subsequently was any to be detected. Moreover, it was impossible to establish any distinct cardiac hypertrophy.

On inquiry it was found he had had several attacks of gout, and so had his father. This, together with the fact that at a former period he had drunk a great deal, gave a certain probability to the granular kidney hypothesis. There was one other diathetic condition to be considered, viz., syphilis. He had had, nearly thirty years before, a chancre, followed by bubo, slight sore throat, and rash, but had not suffered, so far as could be ascertained, since. He was ordered tonics, and some slight counter-irritation to the right back.

In a fortnight's time he had an attack of gout in his big toes, and at the same time some bronchitis. After this he suffered a great deal from constipation and flatulence. The effusion certainly diminished, but there was still impairment of resonance.

During the month of May he did not attend, but in June, when he was seen again, he was still losing flesh. The chest-signs were not materially changed, but he had on several occasions expectorated slight streaks of blood. There were no adventitious sounds to be heard, with the exception of some faint friction and a little sibilus here and there.

In July there was evidence of a little fresh effusion at the right anterior base. The heart's apex-beat was displaced a very little to the left of the nipple-line; though, as the sequel proved, this was partly due to dilatation.

On July 5, Dr. Douglas Powell examined the patient. He also was unable to find any evidence of mediastinal disease, and he suggested that the cachexia of the patient was the joint product of his old syphilis and his gouty condition. He had had some iodide of potassium for a short time before, but he was ordered it again in four-grain doses to start with. Within three weeks afterwards he became, however, much worse, with vague symptoms, which, for want of a better name, must be called uræmic.

He passed the usual quantity of urine, but there was at length a distinct trace of albumen. He got a brown tongue, had frontal headache, repeated vomiting, and ultimately sank from exhaustion. No fresh physical sign was made out, except the diminution of the pleuritic effusion and some enlargement of the spleen.

The post-mortem was made, thirty-six hours after death, by Dr. Powell and Dr. Barlow at the house of the patient, and was not so complete as could have been wished. In the right pleura there was adhesion posteriorly, and anteriorly there was slight serous effusion, with very thin strands of lymph. There was not more than an ounce and a half of fluid. The lower lobe of the right lung was slightly indurated, and also congested. On examining the root of the lung a quantity of semi-gelatinous, ill-defined cicatricial stuff narrowing and investing all the structures of the root was found. This stuff appeared to be inflammatory rather than of the nature of a tumour. On slitting up the bronchus, its inner surface was found much puckered, though not showing signs of *recent* ulceration. Immediately after its entrance into the lung, there opened out of it a rounded smooth-walled cavity the size of a Spanish chesnut. It was not at all like a tuberculous cavity; neither in its neighbourhood, nor indeed in any part of the body, was any grey or yellow tubercle to be found. There were no nodules of any kind in the lung, and no fibroid bands. There was slight emphysema of the other lung, and there was a dilated heart; no valvular disease, and no atheroma of aorta. The spleen was large and flabby, and the kidneys large, red, slightly granular on the surface, with considerable

adhesion of the capsule, and some diminution in the thickness of the cortex. The liver showed nothing abnormal. Brain not examined.

SATURDAY, SEPTEMBER 29, 1877.

ITALIAN HEALTH-RESORTS.

No. IV.—Nervi and Rapallo.

The health-resorts of the Riviera di Levante, that is of the strip of coast which runs in a south-easterly direction from Genoa to Spezia, are as yet but two in number—Nervi and Rapallo. Nervi has been a recognised sanatorium for several years, but Rapallo is very little known, probably because it, until lately, lay out of the ordinary route of travellers, and was only accessible by *diligence*. Since the railway has been completed between Genoa and Spezia, both Nervi and Rapallo are on the direct line from Genoa to Leghorn, Pisa, and Florence. The Mont Cenis Tunnel now renders this part of the Mediterranean coast as accessible as the Western Riviera to comers from the north. From such places as Cannes, Mentone, and San Remo, Nervi and Rapallo are distinguished by their moister climate. Much more rain falls on that part of the coast where they are situated than further west, though unfortunately, at present, in consequence of the absence of statistics, one can only make this general statement, without being able to adduce figures in proof of it. (See, however, *footnote* as to this point.) Mr. Brown, her Majesty's Consul at Genoa, informs us that Rapallo, owing to its situation on the south side of the high promontory of Porto Fino, is especially favoured by the rain, and the luxuriance of the vegetation there bears out his observation.

Nervi lies in 44° 22′ North latitude, about eight miles by rail S.S.E. from Genoa. About half a mile to the west of the railway-station the coast-line, which previously ran nearly due south, turns round, so as to take a direction nearly due east. At the same time, the near hills—outliers of the Apennines, and possibly 700 to 800 feet high—bend round parallel to the shore, and form a steep protecting wall on the north, at less than a quarter of a mile from the sea. At the foot of these hills the carriage-road from Genoa to Spezia is placed; and on either side, in straggling fashion, stand the houses, shops, etc., which make up the town of Nervi. The most sheltered part, and consequently that most suitable for invalids, is nearly opposite the station, and a little to the right looking from the sea. Here the ground rises somewhat, and the street approaches very near the hill. At this point the chief hotel—the Pension Anglaise (so called on the *lucus a non lucendo* principle, because most of its visitors are Germans)—is situated. It is a fine building, with four storeys facing due south, and with more than fifty south windows. The *salle à manger* runs along the front of part of the first floor, on a level with the street, and outside it there is a large verandah, with a fine view over cypresses, pines, olives, etc., to the sea. Below the house there is a good-sized garden, in which we noticed some well-laden and healthy lemon trees, and into which you descend from the verandah by a flight of steps. Inside the hotel everything is in excellent style, and the management is very well spoken of. The great drawback is the narrow, sunless, draughty, and not over-clean street at the back, which is the only possible means of approaching the hotel. The north-east wind sometimes blows with considerable force through this street, so as to be a source of danger to the invalid as he leaves his warm room or the sunny garden. The prices at the Pension Anglaise are sufficiently high; and, owing to the want of much competition, and to the fact that the demand for rooms is sometimes greater than the supply, applicants for admission have, it is said, been occasionally treated with unnecessary brusqueness. The *pension* on the first and second floors is twelve francs, and on the third and fourth ten francs, a day.

A second, and less pretentious, hotel—the Hôtel Oriental—stands a little more to the west, nearer the sea and the station, close to the new road from the latter to the town. The rooms are smaller than at the Pension Anglaise, and some at least have no fireplaces; there is a garden in front. The landlord, an Italian, is very obliging, and desirous to give satisfaction; and the only complaint that we heard from residents was that there was a tendency sometimes to be stingy with the food.

The ground between the main street of Nervi and the shore is nearly level—or, at any rate, only has a gentle slope—until the railway (which skirts the shore) is passed, and then there is a rapid fall of thirty or forty feet or more to the sea itself. This level space is covered with the gardens belonging to the villas of some of the inhabitants of Nervi—of which that belonging to the Marquis Gropallo, close to the Pension Anglaise, is one of the finest,—and with orange and lemon orchards. Seen from the railway, Nervi with its gardens has a most picturesque appearance. Below the railway, and just before the rocky shore takes its steep descent into the sea, a path a few feet wide has been cut along the edge of the rock for the use of the coastguardsmen, and as it accurately follows the indentations of the coastline, and is absolutely protected from the north by high garden-walls, or by part of the rocky slope, or the railway embankment, while it gets all the southern sun in its full force, it is naturally an excellent promenade for invalids. Here they can walk or sit, or, if they choose, at certain points descend close to the sea, and enjoy a temperature of 64° to 68° Fahr., while in the High-street of Nervi the thermometer at the same time is not higher than 43° or 44°. Naturally great care is necessary to be provided with plenty of wraps to put on on returning from the shore to the town. The neighbourhood of Nervi offers but a limited field for excursions, owing to the nearness of the high hills at the back of the town. There is no drive along the shore close to Nervi, though further west the road at some places

nearly overhangs the sea. In fact, even for foot-passengers the promenade above mentioned is only accessible by two or three narrow lanes which run down from the main road between high walls, and pass by a small arch under the railway. The authorities have been very slow to promote the comfort of visitors at Nervi, and even as late as last December there was no carriage-road fit for anything but a steam-roller, connecting the railway-station with the town. It is true that a broad road up from the station was partly finished, but it was so covered with a layer of gigantic "metal," that even to cross it by day on foot was to risk the chance of a sprained ankle, while after dark it was absolutely dangerous. On our arrival at Nervi in the evening, we had to traverse a series of narrow and most dimly-lighted lanes, in which it was difficult to make out the position of our guide, except by his footfall, in order to reach the hotel. On leaving, on another evening, after foolishly rejecting assistance to put us in the way to the station, we had the utmost difficulty in reaching the latter, after being precipitated into a sandpit, and undergoing other annoyances, on account of the abominable state of the roads, and the want of proper illumination. In addition to its protection by hills on the north, Nervi is, to a considerable extent, sheltered on the east by the high ground of the coast, as it bends round southward towards the promontory of Santa Marguerita. The north-east wind, however, as we have already mentioned, and as we can personally testify, is at times strongly felt. The only thermometric observations which we have obtained as to the winter temperature of Nervi we owe to Herr Schulze ("Die Klimatischen Curorte der Riviera," etc.; Frankfort, 1875), who has compared the daily temperatures at 8 a.m. and 2 p.m. at Nervi and Mentone during the winter of 1874-75.(a) We have taken the mean for each month from his tables, and reduced them from Réaumur to Fahrenheit, and have also given the maximum and minimum temperatures for each month at the two places. It is only necessary to warn our readers against drawing any very positive conclusions from the observations of a single winter made by different observers, and possibly not under precisely similar conditions. An Englishman whom we met at Nervi, and who had spent some time there as well as two or three winters at Mentone, told us that he believed Nervi was the warmer of the two places. All things considered, the social advantages of Nervi are at present much inferior to those of Cannes, Mentone, or San Remo.

Winter of 1874-75.

	Nov.	Dec.	Jan.	Feb.	Mar.
Mean Temperature at 8 a.m.—					
Nervi	56°	52°	51°	44°	49°
Mentone	54	48·2	50·5	44·5	49·3
Mean Temperature at 2 p.m.—					
Nervi	59·5	56·5	58	50·3	55·9
Mentone	59·2	53·6	56	49	57·8
Maximum Temperature—					
Nervi	70·5	66	66	61	64
Mentone	70·5	64	64	55	66
Minimum Temperature—					
Nervi	44	41	44	36	44
Mentone	46	42	46	36	48

There is still less to be said about Rapallo than about Nervi, and the following remarks scarcely pretend to do more than call attention to its existence, and to the possibility of its future development. It is a town of 4000 or 5000 inhabitants, built on the north side of a small bay about twenty-two miles south-east of Genoa, in latitude 44° 15′. The bay, which has quite a narrow entrance, is much shut in by two promontories on the west and east, and by a semicircle of hills which connect them on the north. The hills are covered with olives, chesnuts, and figs. They are highest towards the north-east, and may reach 1000 feet or more. One or two streams run down from them to the sea, and on the left bank of one of these, not far from the sea to the east of the town, stands the (at present) only available hotel, a great square-looking building, probably an old palazzo—the Hôtel de l'Europe. It has a small garden, with orange-trees in front separating it from the main road, which crosses the stream by a bridge very near the sea. The accommodation is not great, and there is not room, we should think, for more than thirty or forty people, but everything appeared very comfortable when we were there. There is a good *salle à manger*, and a large *salon* looking over the sea; but there are unfortunately only six south bedrooms, the remainder having an east and westerly aspect. The best rooms are on the first and third floors, those on the second having low ceilings. *Pension*, first floor eight francs, second floor seven francs and a half, and third floor ten and nine francs. The wine of the country is good and moderate in price, and the feeding is well reported of. The landlord is extremely civil and attentive. There is an English chaplain of rather High Church proclivities, who performs service in a small room twelve feet by ten, lighted by a door-window, and tenanted by a dozen chairs, "three times a day," as we were told, "in the week, and all day on Sunday"! Both at Nervi and Rapallo the inhabitants, or rather the chief proprietors, are not at all anxious to encourage the advent of visitors, and at the latter place it was stated that impossible prices were asked for land on which to build a more commodious hotel, chiefly to prevent the increase in the cost of living which the presence of many strangers would entail.

The town of Rapallo is much like many other small Italian coast towns. There is one long main street, with a number of small back streets, and a kind of square, or market-place. Part of the main street has arcades on either side. The town is pretty clean, and is well paved. The inhabitants live, the men by fishing, and the women by making a coarse kind of lace with cushions and bobbins. There are well-cultivated gardens and fields round the town, especially to the north-west; and there are a number of pleasant walks inland in various directions, as well as along the coast road to the east, parts of which are planted on either side with olive-trees in a way that was new to us. The soil is clay-slate, or something very similar, and appears to dry rapidly. Rapallo is a good place for flowers in spring, and we saw a fine specimen of the *Pteris cretica*, which had just been picked wild (December) in the neighbourhood. The beach at Rapallo, unlike that of Nervi, is sandy; and, from the sheltered position of the bay, there would probably be excellent opportunities for boating.

(a) Since the above was written, Dr. H. J. Thomas, of Baden-Weiler, has published some statistics about the climate of Nervi (*Berliner Klin. Wochenschrift*, No. 22, 1877, s. 317), a short abstract of which we append. The mean temperature in the winter of 1876-77 was as follows at 8 a.m.:—

Dec.	Jan.	Feb.	Mar.
51·5° Fahr.	49·3° Fahr.	47·2° Fahr.	47·4° Fahr.

The lowest readings were taken in the first fortnight of March, 1877, when 35·2° was noted on March 2 and 35·8 on March 11. The mean diurnal variations were:—

	Dec.	Jan.	Feb.	Mar.	April.
In 1875-76	4·5°	5·2°	4·6°	5·2°	4·3°
In 1876-77	4·1	5·4	7·0	6·5	—

The mean relative humidity, measured by an August's psychrometer, gave the following results:—

	Dec.	Jan.	Feb.	Mar.	April.
In 1875-76	64	60·0	64·8	65·7	72·7
In 1876-77	75	63·2	61·4	68·5	—

—*total* saturation being represented by 100. According to Thomas, the air of Nervi is *moderately dry*, and not, as has been generally asserted, moist. The following table, however, which we are able to compare with similar observations of our own for Mentone, shows that considerably more rain falls at Nervi than at the latter health-resort. The sixty-two "clear" days credited to Mentone were those which were almost absolutely free from cloud:—

Number of Days.

	Clear, or partly so.		Cloudy.		Rainy (including slight showers).	
1876-77.	Nervi.	Mentone.	Nervi.	Mentone.	Nervi.	Mentone.
December	13	10	18	9	16	12
January	21	17	10	9	9	5
February	21	22	7	4	5	1 (few drops)
March	20	13	11	8	18	9
Totals	75	62	46	30	48	27

On the whole, if only there were more accommodation, Rapallo is a place which might be safely recommended to that class of invalids with whom a warm and rather moist climate has been found by experience to agree. No doubt it, in some respects, resembles Pisa; but it has an enormous advantage over that dullest of dull places, in its cheerful situation and its ready accessibility. We have heard of one lady who has spent three winters at Rapallo, and has derived great benefit from doing so.

We may mention, in conclusion, the fact of the existence of *Santa Marguerita*, a small and extremely picturesque town between Rapallo and Nervi, close to the sea. We have no personal knowledge of it, except from passing it in the train, but it is said to command some of the finest scenery in Italy. There is a new hotel, which is stated to be large and clean, and in the hands of obliging proprietors, ready to adapt themselves to the requirements of English visitors. The cooking is fair, and the charges are moderate. Mr. Brown, the courteous and obliging British Consul at Genoa, has a house very near Santa Marguerita. We should for the present advise only those persons to try it who have acquired some previous knowledge of Italian life, and some acquaintance with the language.

THE MADRAS FAMINE.

Since our last note, a month ago, on the subject of the famine in Madras, matters have, we are happy to say, assumed a much less disheartening aspect as regards the future. The correspondent of the *Times* was able, on the 23rd of the present month, to say—"The dark cloud of the Madras famine is at length beginning to exhibit a silver lining. The news of last week is good, and future prospects are hopeful. Plenteous rain has fallen in many of the worst famine districts, agricultural work is active, and the crops are making rapid progress." The natives who were strong enough to work were rapidly deserting the relief camps in Madras, and hurrying away to their homes; but the relief camps up the country were not being thinned so quickly as in Madras, great numbers of the people having been so reduced in condition that they would not be able to work for a considerable period. The telegrams received at the Mansion House from the Relief Committee at Madras also give more cheering reports than could be sent a short time ago. "In some districts," we are told, "there is a prospect of a quarter or half the usual crop over such extent as is cultivated. This will be ready to be reaped in a few weeks, and will help to mitigate, more or less, the great pressure on the food supplies." But in some parts there is still very serious failure of rain, and an increase of distress. In Salem, for instance, "large numbers are coming on relief, owing to increase of famine"; in Bellary there is "no harvest"; and everywhere there is great distress, and food is at famine prices. The mortality was, according to the latest reports, still fearful. The Madras Committee, in their telegram dated September 18, gave the death-rates of July in some municipal towns in the famine districts, compared with the average death-rates in the same month for three previous years. In Nellore the rate was 74 per 1000 per annum, against 22; in Kurnool, 211, as against 81; in Vellore, 119, as against 41; in Madras, 139, as against 36; in Bellary, 74, as against 23; in Bangalore, 120, as against 20; in Wallajapet, 131, as against 31; in Conjeveram, 188, as against 26; and in Errode, 611, as against 41. While in the telegram dated the 23rd inst. the total mortality in all the famine districts for the month of July is put at 80,052 above the average mortality of the same month during the last five years; and "the number of persons on relief works, fed by the Government," was, at the date of the message, estimated to be nearly 2,500,000.

Terribly sad as all this is, however, it is satisfactory to think how very different the position is now compared to what it was when we first called attention to the Madras famine in May last, and again in June. The Temple rate of relief wages has long been abandoned, and we have no longer to wonder at and remonstrate against the indifference and apathy with which our statesmen and the English public apparently looked on the sufferings of our fellow-subjects in India. The subject was given a prominent place in her Majesty's Speech on the prorogation of Parliament; Lord Northbrook, a former Viceroy of India, declared in his speech on the East India Loan Bill, that "in famine, as in war, where the safety or the honour of the country is concerned, the great object to aim at is success, and not economy"; the sympathy of the English people has been thoroughly awakened from one end of the country to the other; and the donations to the Mansion House Indian Famine Relief Fund amount now to more than £250,000, of which £200,000 has already been transmitted to Madras, while contributions are still pouring in to the amount of some thousands of pounds a day. The Viceroy of India has also personally visited the famine-stricken districts, and, in confereuce with the Duke of Buckingham, the Governor of Madras, has settled the futuro famine policy. "All friction between the two Governments has," we are told, "apparently been quite removed, and they are now acting together with complete accord," with consequently the important results of—uniform relief wages, and food-rates unsupervised; large and important instead of petty relief works; and, as "the strength of the people is so reduced that possibly the call for hard work may prove destructive," the officials are enjoined that enfeebled persons aro to have special consideration, and, it is said, "they will probably be further vested with large powers and ample discretion." And all famine questions coming before the Madras Government are to be disposed of by the Governor alone, his orders having the force of Orders in Council.

One of the great difficulties in the way of affording relief has been, and still is, the impossibility of obtaining anything like sufficient means of carrying food into the famine-stricken regions; and a Madras correspondent of the *Times* has described, under date of August 13, how, covering for acres the Madras beach, might be seen great mounds of bags of rice which it was impossible to carry away fast enough to the famishing crowds in the interior of the country. Since then, however, the carriage means have been improved, and a double line of railway between Madras and the Arconum Junction, where the north-west and south-west lines of the Madras Railway diverge, has been lately opened—an arrangement which will greatly facilitate, it is said, the despatch of goods trains. This doubling of the line was undertaken as a famine relief work, and it is certainly very satisfactory to know that so much good has resulted already from the employment of famine-labour.

It must be hoped that the terrible experiences of this famine will impress upon the Governments and their Councils, at home and in India, some important and fruitful lessons. We can hardly believe that it cannot be possible to find out some means of at least lessening, if not preventing, such calamities; and if such a thing is possible, it must be done. As to whether a tank system, a canal system, or an irrigation system should be adopted, or a combination of all these (which appears most likely), we cannot say, and Indian authorities seem to be greatly at variauce on the subject. But whatever plan, or plans, may be decided on, we suspect that an extensive and scientific system of the planting of such forest trees as can be made to grow in the various regions of India must play an important part. Proof can be obtained in abundance, we believe, from America and from our own colonies, of the injurious effects on climate, on fertility of the soil, and on water-supply, of the continued and extensive destruction

of forests, unaccompanied with a regular and proportionate planting of young trees.

But we are most concerned with insisting that there shall not on any future famine occasion be any experiments made as to how little food human beings can be kept alive on. The Madras famine ought, at the least, to make that impossible. We have no wish to again go into the history of the Temple experiment. Sir Richard Temple was, without doubt, actuated by the laudable desire to prevent any avoidable addition to the financial burdens of a poor country, India, by guarding against a higher rate of work-wage than was necessary; and hence the relief-rate imposed on the Madras Government till the Duke of Buckingham, taught by its disastrous consequences, rebelled against it; and the Supreme Government was forced to admit that he was right. The *Times* approved of the action of the Madras Government, and their correspondent at Bellary describes in vivid and graphic terms the falling away of the men in the working gangs. It was not only that they were emaciated; they bore on their skin the particular famine marks described by Dr. Donovan in his account of the Irish famine, thirty years ago; and said the correspondent, "If we look at thousands of people collected on our relief works, these 'famine marks' are of almost universal prevalence." Yet the great leader and exponent of public opinion, at the same time (August 15), asked, "Was the relief given, in fact, too low?" and went on to remark, "Medical men may dispute over the number of grains of nitrogen and carbon necessary to sustain life, but their wisdom can only be the fruit of experience, and it is by experience that it must be tested. If men do not keep alive on the rations allotted them, it may be concluded that the rations are insufficient"; and they add, "If there has been a deficient allotment, it was from a miscalculation of the medical authorities, coupled, perhaps, with some forgetfulness of Lord Northbrook's principle that the great object to aim at is success, not economy." Now, we must protest most strongly against such statements as these. There was certainly no miscalculation *by* medical authorities, and we have no proof that there was in the first instance any miscalculation or misunderstanding by anyone of statements made by medical authorities, for we have not seen it stated anywhere that Sir Richard Temple based his experiment wage-rate on or after consultation with any medical authorities. Indeed, Sir Richard Temple himself stated that his opinion that his new rate would be sufficient "was not based on so-called scientific evidence," but "rather on probabilities practically deduced from the condition of the poorer classes in ordinary times, and on the results of general experience." The "wisdom of medical men" on the subject *is* the fruit of experience, and has been tested by experience over and over again in communities and masses, large and small, as was well shown by Surgeon-Major Cornish, the Sanitary Commissioner of Madras, in his strongly worded and admirably argued protest against Sir R. Temple's first Minute on the subject, and in the controversy that followed. The experiment was decided on without consultation with, and was carried on in spite of the remonstrance of, medical authority; and what we care for especially now in the matter is that its predicted failure shall be so officially and authoritatively recorded that there shall be no danger of any like experiment being tried at any future time.

PHYSIOLOGY IN THE SCOTTISH UNIVERSITIES.

After considerable delay, due, no doubt, to the engrossing nature of wider public interests, the Home Secretary has begun to direct his attention to the vacancies in the Scotch Universities, and has appointed Dr. Stirling to be the Professor of the Institutes of Medicine in the University of Aberdeen, as we last week informed our readers. The satisfactory nature of the appointment is so evident to all who are conversant with the progress of physiology, that the nomination itself requires no comment; but the opportunity is a fitting one for drawing attention to the fact that the Scottish Universities are now in a position to speak with some pride of the manner in which their physiology chairs have been distributed amongst men who, having already attained to no small reputation, may still be regarded as having only stepped over the threshold of life, so that the repute which they have won for themselves may be looked upon more as the promise of future usefulness and fame than as the justification of the practical recognition of their patrons.

While recently commenting upon the British Association addresses of Dr. Allen Thomson and Dr. Gamgee, we took occasion to endorse the opinions of the latter regarding the importance of Physiology as the helpmate of Medicine; and it is especially gratifying to think, that in the Scottish Universities, where Physiology has from the first been entitled and regarded as the Institutes of Medicine, the provisions made for the teaching of that branch of science should be so adequate to the modern requirements of the task. Never more than at present has physiology been the only sure foundation of rational medicine; and at no time in the history of science has one branch of investigation been able to bestow a greater wealth of discovery and suggestion upon another than Physiology is now daily conferring upon the Science of Medicine and of Therapeutics. Not only so, but the earnest and patient pursuit of physiological science and of the allied science of biology has placed in the hands of psychologists the means of detecting the physical nature of much that had hitherto been regarded as metaphysical and hopelessly obscure, and of drawing a visible line between that knowledge which is attainable, and that which on scientific grounds must be regarded as beyond our present means of research.

The men who can best maintain the dignity of such a science, and add new triumphs to those it has already secured, are those in whom special aptitudes have been aided by early and special education. The modern physiologist who excels as a teacher and investigator must combine in himself the accuracy of a microscopist, the profound skill and clever knack of a chemist, the precision of a logician, and the fluency of an orator. He must be a physicist; it is necessary that he should be an anatomist; and he must be on intimate terms with pathology and medicine. One thing essential in the physiologist of to-day as a teacher is that he should be a demonstrator as well as a lecturer. Physiology is nothing as an attainment unless when it is practical, and the aim of the modern teacher of physiology should be to make his more formal teaching go hand in hand with practical example. The consequence of such teaching is that the pupil is safe to learn enough physiology to constitute a sure basis for his knowledge of medicine and of therapeutics. In this connexion there is one thing which has almost risen to the dignity of a feature of the Edinburgh School of Medicine during the past ten years—namely, the enthusiasm which has been shown by students in their attendance upon special practical classes. The natural tendencies of the late Professor Bennett led him to throw all his influence into the advocacy of what may be called the demonstrative system of teaching. "See for yourself!" might almost be accepted as the essence of the principles which he used to promulgate with such energy, humour, and eloquence; and if his own stage of existence and condition of life prevented him from taking full advantage of the modern tendencies of physiological science, those who were associated with him have shown their appreciation of the spirit which actuated him; and the result is that Rutherford at Edinburgh, M'Kendrick at Glasgow, Stirling at Aberdeen, and (indirectly) Pettigrew at St. Andrews, constitute a group representing physiology in the Scotch Universities in a manner which any country might envy. Every one of them has shown himself an adept

in the intelligent interpretation of nature, and in the exact and grateful transmission of his knowledge to others. All have availed themselves of the highest forms of scientific culture; and their success has shown that their spirit is the spirit of the age, which, recognising that they are treading the path of progress, has adopted them as its representatives.

It speaks well for the influence of Scotch Universities on the Medicine of the future, that Physiology, which above all others is the typical science of the time, should be in the hands of men who, with the ardour of early life, combine the ripeness of scientific maturity, and have the inspiration to know how, in a professional sense, to adopt the principle which Disraeli, in his Glasgow Rectorial address, so adroitly modified from Rochefoucauld's maxim, when he said that the essence of progress consisted in interpreting the spirit of the age and acting upon it.

Scotchmen should be grateful that the preliminary education of men intended for the medical profession is in the hands of such professors. The British Constitution, liberal to profusion in everything else, is niggard to science; and with regard to original physiological observation, sentiment has done its best and worst to paralyse honest endeavours to ameliorate the sorrows of the human race, by arresting attempts to understand them. And as, at present, men in the position of professors of physiology are amongst the very few whom the State will trust as sufficiently capable and humane to perform experiments on animals for the good of the human race, it is well that the Professors of Physiology in all the Scottish Universities are men who, by nature, education, and position, are recognised as distinguished in their profession, cognisant of their great responsibilities, and (as science has not yet soared above malevolence) superior to calumny.

THE WEEK.

TOPICS OF THE DAY.

The first inquiry under the Rivers Pollution Prevention Act of 1876 was opened at the Town Hall, Canterbury, on Monday last, when Mr. Robert Rawlinson, C.B., C.E., Chief Engineer to the Local Government Board, attended for the purpose of inquiring into the alleged pollution of the river Stour by the discharge therein of the town sewage. The Canterbury Town Council had applied for a certificate under the above-mentioned Act, to the effect that the means used by them for rendering harmless the sewage matter flowing or carried into the river Stour from their sewage outfall at Fordwick were the best or only practicable and available means under the circumstances of the case. The Town Clerk applied for the certificate, and it was opposed (on behalf of the Commissioners of Sewers for East Kent, who keep clear the watercourses in that part of the county) by Mr. Douglas Kingsford, barrister. Mr. J. G. Hall, the City Surveyor, described the process at present in use for purifying the sewage previous to its being discharged into the river, which consisted simply of passing it through layers of faggots, gravel, and flints. He admitted that the water for a short distance down the river below the outfall was often discoloured, but added that when the water was at times darker than usual it was caused by the discharge from the tanneries and dye-works in the city; he, however, maintained that for all practical purposes the method was a success. Colonel Cox, a resident in the neighbourhood of the outfall, called by Mr. Kingsford, described the river as being very foul, owing to the discharge of sewage, while the stench arising from the sewage-matter floating down the stream was abominable. Three other witnesses were also called in corroboration of the statements made by Colonel Cox; and Dr. Robinson, Medical Officer of Health for East Kent, also stated that he had received frequent complaints from people living in the district. He gave it as his opinion that the sewage works were utterly inadequate for the purpose for which they were intended. Several samples of water taken from the river at different times when it had been discoloured were also produced by Mr. Kingsford. The inspector subsequently visited the sewage works himself, and his report will be rendered to the Local Government Board. During the course of the proceedings Mr. Rawlinson stated that similar inquiries were about to be opened by him, almost immediately, at Ventnor and Salisbury.

At the meeting of the Whitechapel Board of Works, held last week, the Sanitary Inspector reported that upon inspection of Emery's-place, Butler-street, Spitalfields, he found upon the ground-floor of one of the houses a room containing 1215 cubic feet of space occupied as a school by a person who also dwelt and slept in the same room. On the occasion of his visit the room was very much overcrowded, there being no fewer than twenty-three children huddled together on the bare floor, and the stifling atmosphere of the place was most sickening. On reporting the facts to the medical officer, a second visit was paid the following morning, when they found thirty-five children in the room, which allowed only thirty-four feet of cubic space for each child, and even this was further reduced by the bedstead which stood in the room. Even a worse case was discovered at a school at 24, Freeman-street, Spitalfields; in this overcrowded room, containing only 630 cubic feet of space, the sanitary officers found twenty-nine children, all huddled together on the floor. The place was in a very offensive and improper condition, and the space for each child was only twenty-one cubic feet. The children in both these schools appeared to be under five years of age, and to belong to Jewish families; and although the places were called "schools" the sanitary officers believed that the children were simply placed there by their parents to be taken care of during their absence at work during the day. Many of the children looked ill and delicate, as was to be expected. By order of the Sanitary Committee of the Board and the Medical Officer of Health, notice had been served upon the two women owning the establishments, to abate the overcrowding, and compulsory orders were prepared and signed by the Chairman of the Board, so that the sanitary officers might be in a position to institute legal proceedings immediately, if such a step proved to be necessary.

A case of much importance to the public was heard before the magistrate at the Lambeth Police-court last week. George Parker, house agent, was summoned at the instance of the Vestry of St. Giles's, Camberwell, for having let a house in Crown-street, Camberwell, in which persons had been suffering from scarlet fever, without having first carried out the regulation for disinfecting such premises. Mr. Marsden, on behalf of the Vestry, said three children were seized with scarlet fever in the house, and after their removal to the hospital the defendant neglected to disinfect the rooms previous to re-letting them. The defendant said he did not wish to act contrary to the law, but in this case an error had been committed. Mr. Ellison said such an excuse could not be admitted, especially when the public health had to be considered. The defendant had rendered himself liable to a penalty of £20; he should, however, require him to pay a fine of £5 and costs. John Carpenter, the father of the children referred to in this case, was also summoned for exposing in a public place bedding, etc., used by the sufferers from fever. The evidence showed that the defendant had removed the bedding and clothing to another house without having had it previously disinfected. The defendant was fined 40s. Culpable negligence of the foregoing description is responsible for much of the spread of diseases of the zymotic class.

In the Health Department of the Social Science Congress, held at Aberdeen last week, Dr. Hardwicke, the Coroner for

Middlesex, read a paper on the mode of providing dwellings for the wage classes in large towns. He referred to a block of buildings erected by a large manufacturer at Guise, in France, which he described as having far superior arrangements, social and commercial, as well as sanitary, to the workmen's dwellings lately constructed in the British metropolis. These he criticised as being very defective in details, and susceptible of considerable improvement. As open spaces for the children of the wage classes he advocated the utilisation of the squares in the metropolis, and also the graveyards, which, since the abolition of intramural interments, were kept in a most neglected condition. At the end of the discussion which followed, a resolution was adopted recommending the Council to memorialise the Legislature for an extension of the existing law for providing open spaces for suburban populations.

It is stated that Liverpool is about to follow the example of Manchester in going to a distance for its water-supply in order to insure greater purity. It is proposed to make Wales the fountain-head by impounding the waters of the river Vyrnwy at Llanwddyn, Montgomeryshire, and those of the river Tarrat at Llangedwyn, embracing together a watershed of quite 80,000 acres, and capable of yielding more than eight times the quantity of water now daily supplied to Liverpool. The distance the water will have to be brought is sixty-six miles, and the engineering difficulties connected with the undertaking are said to be trifling. The originator of the scheme, Mr. H. Williams, C.E., of Wigan, has devoted two years to maturing plans for its development.

The *Sanitary Record*, which has lately been recording the results of the analyses of water at different seaside towns, reports that the Eastbourne supply has the advantage of great organic purity, whilst the Brighton water is better than any sample analysed, unless it be that of Dover. At Cromer the water is described as of a yellow-green colour, with very offensive smell and nauseous taste, swarming with animalcules, and concentrated but fairly oxidised sewage. Worthing has a good water-supply, but that of Littlehampton was found to be full of living organisms; and the same description applies to the water supplied for consumption at the neighbouring town of Bognor.

The town of Keighley seems determined to offend on the old subject of vaccination. At a meeting of the Board of Guardians held last week, a letter was read from the Local Government Board, enclosing correspondence which had been published in the local papers. It appears that Mr. H. Shuttleworth was appointed Vaccination Officer on June 27, and on July 20 he wrote to Mr. Hume Rothery, offering to write articles for the *Anti-Compulsory Vaccination Reporter*, and also offering to distribute leaflets when making his professional visits. It further transpired that Mr. Shuttleworth was a member of the Anti-Vaccination League, and had two children not vaccinated. It was resolved to inform the Local Government Board that his children were not vaccinated, and also to ask them to cancel his appointment.

The Ottoman Government has made known, through the Consulates, its want of doctors and surgeons, as well as other sanitary officers, for its Army Medical Service. The conditions under which such sanitary assistance will be engaged are to be ascertained at the various Consulates. It is notified that twenty surgeons are immediately required, who will be despatched forthwith to the seat of the war, and early application on the part of those who elect to accept such service is requested. That increased surgical assistance is urgently needed is only too apparent from the accounts which reach us from the different points where active operations are being carried on. Assistant-Commissary Young, whose services have been placed at the disposal of the National Society for Aid to the Sick and Wounded in War, reports that from all divisions of the medical staff furnished from this country he continues to receive accounts of splendid work done for the sick and wounded. Large numbers of wounded are reported to be pouring into Constantinople daily, and the Red Crescent Society are taxed to their utmost to meet the immense calls upon their services, not only in the capital, but at the front, by means of flying ambulances, transport, etc. One of the Sultan's palaces at Beylerbey has been placed at their disposal for the reception of the wounded.

The monthly return of the Registrar-General of Scotland for the eight principal towns of Scotland (containing fully a third of the population of that country) shows 2048 deaths in August, being 480 under the average for the corresponding month during the last ten years, allowing for increase of population. The deaths from zymotic diseases amounted to 326, or 15·9 per cent. of the whole mortality; and this also is the smallest number and smallest proportion from that class of diseases in any August since the registration was commenced in the year 1855.

THE DESTRUCTION OF CONDEMNED MEAT.

Dr. Sedgwick Saunders has presented to the Commissioners of Sewers his report on the method proposed by him for destroying meat condemned as unfit for consumption. The deodorant suggested by him to be employed is a mixture of water, "Cooper's salts," protosulphate of iron, and picric acid. "Cooper's salts" are composed of the waste chlorides of commerce, and contain, approximately, 80 per cent. of powerful antiseptic substance, and about 20 per cent. of water; they are described as being inodorous, perfectly harmless to man or animals, free from deleterious ingredients, and with no chemical action upon metals or fabrics. They act in virtue of the power the chloride of sodium is known to possess of arresting change in albuminous substances; and the chloride of calcium is added, because it exercises a specific action upon animal tissues undergoing incipient decomposition, inasmuch as it forms the insoluble and inert albuminate of lime under these conditions. Any putrid or stinking meat is immediately deodorised by immersion in a watery solution of these salts alone, but it is not thus rendered unfit for manipulation for food by dishonest operators. To accomplish this the picric acid and the sulphate of iron are added, which discolour the meat and render it so disgusting to the taste, and so entirely unfit for human food, that no fear need exist as to its improper appropriation. Even then, however, it has to be got rid of in some manner, and Dr. Saunders suggests that it might be sold to be converted into a substance useful in the arts, or, as a last alternative, that it should be taken down the Thames and sunk below the Nore Light-ship. After considering the report, we are still of opinion that the suggestion we put forward last week for getting rid of this putrid meat—namely, by scientific cremation—might be found to be the most effective, and certainly less expensive than the method propounded in Dr. Saunders' report.

THE EARLSWOOD ASYLUM FOR IDIOTS.

In noticing the thirtieth annual report on the Asylum for Idiots at Earlswood, for the year 1876, it is only necessary to remark the fact that the watchfulness and experience of those entrusted with the management of the institution have conduced to continued improvement in the mental and physical condition of the inmates. The general health throughout the year has been remarkably good; and as every precaution is adopted to prevent the entrance of infectious disorders, the Medical Superintendent, Dr. G. W. Grabham, is able to report that no case of epidemic disease has occurred amongst the inmates during the period under notice. The highest number accommodated at one time has been 621; the average number resident during the year having been 605. This has taxed the

resources of the Asylum almost to its limits; but when the detached infirmary, now being added to the establishment, is completed, many rooms now occupied in the main building will be set free, and it will then be possible to accommodate even a larger number than 620 patients. Finally, it is shown that the number of those at present in the Asylum who have made material improvement is much larger than in the previous year, viz., 146. Of those who have remained stationary as regards mental condition, a large number are usefully employed; while deterioration in only eighteen cases has been generally due to epilepsy or other diseases. The institution may justly be said to have maintained its usefulness; and it unquestionably affords an excellent model for similar asylums, whether in this or in other countries.

DEATH UNDER ANÆSTHESIA.

We are informed that in the fatal case of anæsthesia which we reported last week as having occurred at the Radcliffe Infirmary, Oxford, the anæsthetic employed was chloroform, and not the bichloride of mythelene, as we had then by mistake been informed. The operation (for disease of the bones of the foot) was, we are told, a somewhat tedious one. The former death, to which we alluded, was six, not five years ago, and in that case also chloroform was used.

THE PENGE MURDER.

The Penge mystery, with all its revolting details and revelations, no longer disfigures the pages of our daily papers, to the great relief of all newspaper readers, save such as love to sup on horrors. The case is, however, an important and somewhat interesting one from the medical-jurisprudence point of view; and we shall, therefore, next week deal fully with the medical points in it.

FROM ABROAD.

Prof. Schiff on the Functions of the Spleen.

The following are the conclusions of a paper read (*Gaz. Hebdomadaire*, September 21) at the recent Medical Congress of Geneva:—

1. Extirpation of the spleen has no durable influence on the absolute or relative quantity of the white or red globules of the blood. 2. During the early periods after the operation there is observed a considerable increase in the white globules, with or without a diminution of the red globules. But these changes do not depend upon the absence of the spleen, but only upon the operative procedures necessary for its ablation; and the phenomena remain very much the same when these preparatory acts are not followed by the removal of the spleen. 3. After the removal it is quite exceptional for any swelling of the lymphatic glands, or increase in the size of other glands, to take place. The so-called supplementary spleens are not produced even when the animals are allowed to live for more than a year and a half, and when the operation has been performed only a few weeks after birth. 4. The swelling of the mesenteric glands, which is very exceptionally met with in animals from which the spleen has been removed, appears to be due to a prolonged partial peritonitis, which sometimes is a consequence of the operation. 5. The spleen appears to increase in size from the fourth to about the seventh hour of a sufficient stomachal digestion. 6. The spleen during digesting, or rather during stomachal absorption, prepares the ferment which, entering with the blood into the tissue of the pancreas, transforms in this gland a special substance (probably an albuminoid) into *pancreatopepsin* or *trypsin*—that is to say, into a substance apt to digest albuminoid bodies. 7. After the extirpation of the spleen the pancreatic fluid loses its digestive influence upon albuminoid bodies, while retaining its other digestive properties. The duodenal digestion of albuminoid bodies is no longer distinguished by its energy and rapidity, but becomes feeble as in other parts of the small intestine. 8. After the ablation of the spleen the substance destined to form pancreatopepsin accumulates in great part in the pancreas, and may still be transformed into pancreatopepsin by means of the chemical influences which after death accompany the commencement of putrefaction. 9. After the destruction of its nerves the spleen remains flaccid, and, undergoing turgescence no longer, becomes atrophied, as do erectile tissues in general, the vascular nerves of which have become paralysed.

The Weighing of Infants.

Dr. Eisenschitz, Privat-docent in the Vienna University, issues in the *Wiener Med. Woch.* (No. 28) what he calls a *Hilferuf*, or call for co-operation in the matter of weighing young infants. It is only, he says, by the accumulation of a great number of data that the great practical value of this procedure can be demonstrated. However opposed to this, as to all other innovations, the ignorant may be at first, Dr. Eisenschitz expects to receive the support of educated persons, and that the infants of the profession, at all events, will be at once utilised. Even with our present experience the great importance of the practice may be easily shown as regards the symptomatology of infants, as also the probable great extension of the scope of the inquiry. The weighing of sucking infants is, in fact, a most useful and certain guide for the practitioner in judging of their development and nutrition; and it does not require to be shown how welcome such a guide must be, by enabling him to give a precise and speedy answer in questions of this kind, which are often attended with doubt. By the use of the scales we may in less than a week determine whether the mode in which the child is nourished requires to undergo a change, and whether such change is urgent or may be delayed awhile. The remark may here be made that a cause of dyspepsia in infants is very frequently overlooked—viz., that while dyspepsia, from whatever cause arising, is prejudicial to nutrition, so may not merely a qualitative faultiness, but a quantitative deficiency, of food become a cause of dyspepsia in sucklings, and induce catarrh of the stomach and intestinal canal. Moreover, the secretion of the breasts, from which a sparing supply of milk is produced, is usually of difficult digestion. An infant who has for some time been insufficiently nourished from this cause, and one who has obtained only milk of a bad quality, will, upon the whole, exhibit a similar diseased condition, which, at first consisting only of slight dyspeptic symptoms, sooner or later are converted into signs of serious disease of the intestinal passages. When a suckling, who from one or other of these causes, has had its nutrition damaged, obtains access, while yet there is time, to suitable food, its weight-curve rises at so rapid a rate that it gives the impression of an effort having been made to supply the lost weight, so as to hasten the weight-curve up to the proper point for a child of that age. The phenomenon is apparently explained by the fact, which careful clinical observation supplies, that such infants, analogously to individuals who have suffered from starvation, reproduce most rapidly, when suitable qualitative and quantitative aliment is supplied, the tissues that first and most speedily disappeared. The first rapid increase arises from the retention of water, for which the tissues, on account of their prior great transpiration, exhibit increased attraction as soon as their normal conditions of absorption are restored. The daily increase of weight which is observed under these circumstances exceeds very considerably the mean increases set down by authors; and, in fact, these mean numbers have proved so little reliable, that the necessity is obvious, in order that a secure basis for practice may be obtained, that numerous and exact weighings should be undertaken.

Dr. Eisenschitz own observations entirely relate to infants at the breast; and in those who are artificially nourished such rapid increase of weight, under the above circumstances, is quite exceptional. But it is precisely in infants so brought up, in whom from any cause the nutrition becomes deficient, that the scales obtain their greatest triumphs. It is now an admitted fact that the chemical composition of an infant's food will not alone, in certain cases, enable us to decide whether such food will prove suitable; and it is also certain that the same aliment which for a long time has furnished the most satisfactory results, will at last—we know not why—no longer agree with the same child. Every practitioner, even the most experienced, is aware of the great difficulties in children-practice which thus arise. By the aid of the scales we are enabled, and (which must be emphatically stated) with sufficient promptitude, to direct the choice of aliments upon which the child will best thrive. Frequently, for infants

several months or even weeks old, who do not obtain sufficient nutriment from the breast of their mother or nurse, we may be enabled to suggest a supplementary aliment that will be attended with the best results, and with the great advantage of preventing premature weaning. The possibility of thus supervising, by weighing, a mixed alimentation with such certainty, will give a great impulse to the practice of maternal suckling, and thus diminish a social reproach of our time. While, on the one hand, the mother, encouraged by the results obtained by observing the scales, perseveres in her duty; on the other, when she would almost obstinately continue the attempt after it has proved injurious, the practitioner is placed in the possession of a convincing reason for her abandoning it.

For the determination of the time for weaning, the repeated weighing of the child furnishes a truly physiological basis. On examining the normal weight-curve of an infant that has been suckled in the second half of its first year, we find with the increase of age (the exceptional conditions of the first two weeks being left out of consideration) a progressive diminution of the daily increase of weight, without the child manifesting ill-health, or without there being any visible disturbance in the progress of its development. If such a condition of the weight-curves occurs earlier, it must be looked upon as an indication for suitable supplementary aliment; while if it is observed at a later period, it is an intimation on the part of nature that weaning should be commenced. But it is quite certain that if an infant, kept exclusively at the breast, continues at the end of the seventh month to increase daily fifteen grammes in weight, it may be allowed to suckle longer with advantage. The execution of these weighings need not give much trouble. The decimal balance is that which is most convenient, and fifty kilogrammes is the highest weight wanted. The parents, if intelligent, might be trusted, under the supervision of the practitioner, to take the weights; and mothers readily undertake a task which they find is so advantageous to their infants. The results should be collected and tabulated, with the dates. The net weight must be accurately determined; and by the side of the weekly entries should be stated all the circumstances which may have influenced the development of the infant—as the sickness of itself or nurse, change of nurse, change of aliment, etc.

REVIEWS.

Cyclopædia of the Practice of Medicine. Edited by Dr. H. von Ziemssen, Professor of Clinical Medicine at Munich, Bavaria. Vol. VII. Diseases of the Chylopoietic System, etc. English Translation edited by Albert H. Buck, M.D., New York. London: Sampson Low, Marston, and Co. 1877.

The first article in this volume is by Professor Wendt, of Leipsic, and deals with Diseases of the Naso-Pharyngeal Cavity. It is scarcely as satisfactory as some of the others, partly on account of the extreme baldness of the translation, and partly because some of the affections described have not received characteristic names in this country as they have in Germany, and it is not always easy at first sight to know what condition the writer is speaking of. Thus, "pharyngeal phlegmon" would not convey the author's meaning to many English practitioners, any more than "rarefying dry catarrh of the naso-pharyngeal cavity" would. The translator should have seen to this, and not allowed any loophole for obscurity.

Diseases of the Stomach and Intestines, by Professor Leube, of Jena, fully maintain their author's character for thoroughness and originality. His introductory remarks are worthy of attention by those who wish to study abdominal disorders with any profit:—"A thorough knowledge of the anatomy and physiology of the parts is absolutely indispensable in the investigation of diseases of the stomach and intestines. It may, indeed, be asserted that in these affections a knowledge of physiology is the more important, because the products of the organs which are acting under abnormal conditions may themselves be submitted to direct examination." We quote these sentences, not because they contain anything new, but only to insist on their importance, because we know that extraordinary ideas as to the physiology of digestion are still too rife among practitioners. Professor Leube gives a good *résumé* of our present knowledge on this subject, and then goes on to consider Acute Gastritis, or acute gastric catarrh, Cholera Infantûm, Gastritis Phlegmonosa, or interstitial purulent inflammation of the walls of the stomach, and Chronic Gastritis, or chronic gastric catarrh. His view as to the causation of sporadic cholera, or cholera infantûm, is as follows:—"That the nerves of the gastric and intestinal parietes become irritated to a high degree, sometimes by the action of certain excitants, but more particularly by that of fermenting food, thus giving rise to excessive peristaltic action of the intestine and vomiting," and he explains the frequency and severity of "sporadic cholera" among infants by the greater sensitiveness of their nervous system. It is worth notice that he does not agree with the recommendations of Trousseau and others to give raw meat in this affection, and he says, "To give *meat* to infants less than a year old, whether in the shape of scraped raw meat, or as beef-tea—which latter is in every way preferable to the former, as being more digestible—I do not think advisable, since its clinical (? *chemical*) composition is too widely different from that most appropriate to the infantile digestive organs."

Under Chronic Gastric Catarrh the observation that "we should not be satisfied, as a rule, with the diagnosis of a primary chronic catarrh until the various other chronic affections of the stomach giving rise to dyspepsia can be excluded with tolerable certainty," is an excellent one, and well worth remembering in practice. Like most writers, Professor Leube speaks of butyric acid fermentation and the presence of butyric acid in the stomach as if it were only prejudicial to the digestive process; but from some experiments made by Dr. Burdon-Sanderson for Mr. Darwin in reference to the digestive secretion of *Drosera rotundifolia* ("Insectivorous Plants," page 90), it appears that butyric acid in the presence of pepsin has a solvent action (at least on fibrin), equal to about one-third of that of hydrochloric acid. Hence its presence in the stomach cannot, it would seem, be altogether injurious to digestion.

The chapter on Ulcer of the Stomach is a very interesting one, and the etiology of this affection is discussed in a fuller way than we remember to have met with elsewhere. Its embolic origin Professor Leube accepts only with considerable modification, and he adheres to Virchow's original general proposition that "gastric ulcer is due to a great variety of causes, all of which act by interrupting the circulation in circumscribed portions of the wall of the stomach." For the anæmia thus caused to be efficient he believes that a second factor is essential—namely, "a temporarily increased acidity of the gastric juice,"—though this view is more hypothetical than real. Leube treats ulcer of the stomach by what he calls his method, which is as follows:—The patient is confined to bed, and has hot poultices applied to the abdomen, or ice if hæmorrhage threatens. He takes one tablespoonful of Carlsbad salt (chiefly sodic sulphate) in a pint of warm water every morning for the first few days, and his diet consists of a solution of beef, of which the daily allowance is equal to half a pound of beef, and which is made by digesting beef with a strongly acid solution of pepsin in hermetically sealed vessels at a temperature above that of the human body. Nothing else is at first allowed except a little milk and some soaked rusk. Everything is given *lukewarm*. After two or three weeks the patient is allowed light diet, consisting of pigeon, chicken, mashed potato, soup, etc.; and in another eight days he is allowed to return to still coarser food. Professor Leube declares that since he adopted this method he has never found it necessary to resort to any other remedies, not even to morphia. We observe that he is very sceptical as to the value of bismuth and nitrate of silver in cardialgia, and also of bismuth in gastric catarrh. Our personal experience is opposed to his opinion as to its value in the latter affection, and especially in its subacute form, for we have found decided benefit from it.

We must pass over the subjects of Cancer of the Stomach, Hæmorrhage of (? *from*) the Stomach, and Gastralgia, without comment, and say a word or two about the treatment of Dilatation of the Stomach, on which Professor Leube is an authority. In this disease, as well as in gastric catarrh, whether acute or chronic, he is strongly in favour of the use of the stomach-pump to remove irritating ingesta and give rest to the diseased mucous membrane. He prefers it even to emetics, but he is opposed to the use of the *syphon*-tube by the patient himself, and thinks that the same form of pump as is in ordinary use in cases of poisoning is the best form of apparatus. In dilatation of the stomach due to pyloric cancer, or cicatricial contraction, he claims for the stomach-pump (1) that it relieves the strain of undigested food on the wall of the stomach, and "prevents the food taken from being constantly decomposed, as heretofore, by the fermenting substances retained in the stomach"; and (2) that it enables the stomach

to recover the power of completely absorbing the products of digestion, and so relieves the vomiting and obstinate constipation, with a very striking improvement in the subjective condition of the patient. He confesses that, though his five years' experience of the treatment of gastrectasia by pumping out the stomach has been, upon the whole, gratifying, there are *limitations* to *its effectiveness*, and that there are cases where the use of the pump is either unjustifiable or entirely impracticable—*e.g.*, if there is a suspicion of recent ulcers; or if the patient strongly objects to being pumped; or, lastly, if the attempt to introduce the tube causes intense alarm, and spasm of the muscles of deglutition.

The Diseases of the Intestines, Intestinal Catarrh, Intestinal Hæmorrhage, and Enteralgia or colic, are all excellently treated; but we can only remark in passing that Professor Leube scarcely believes in anything but *ergotin*, hypodermically administered in doses of one grain and a half, to stop bleeding from the bowel. He is very sceptical as to the value of perchloride of iron in such cases, and also in gastric hæmorrhage.

Constrictions, Occlusions, and Displacements of the Intestines are most exhaustively handled by Dr. O. Leichtenstern, of Tübingen. The account of the methods of diagnosis of constrictions is very good, and deserves careful study. The author considers that Simon's method of introducing the whole hand into the rectum "is by no means an indifferent operation, and that it should only be used when there is actual need of it—when important diagnostic information can, with a great degree of probability, be expected from it, or therapeutical ends obtained, as in the case of a foreign body, or before the performance of laparotomy or colotomy, etc." The number of ways in which internal strangulation of the intestine may arise is very startling, and when we look over the long list which Dr. Leichtenstern enumerates we feel almost surprised that anyone escapes a strangulation at some period of his existence. The causes of habitual constipation are discussed at great length, and the information embodied under this head cannot fail to be of great use to practitioners struggling with one of the unsatisfactory examples of this condition. In the section on treatment we notice with pleasure the position which Amussat's method of lumbar colotomy has taken in the hands of English surgeons, the mortality being only 33 per cent. according to the latest statistics of Erskine Mason.

Intestinal Parasites receive all due attention from Professor Heller, of Kiel; and we may especially notice the chapter on *oxyuris vermicularis*, as conveying a great deal of interesting, and at the same time valuable, information as to this parasite which is not to be met with in the ordinary text-books. Others will, no doubt, be surprised (as we were ourselves) to find that the true habitat of the oxyuris is NOT the rectum, as we have all been taught, but *the cæcum*, and the *vermiform appendix!* Professor Heller calls attention to the fact that the idea that the oxyuris mainly inhabits the rectum is upheld in all the books (and, certainly, the few we have referred to since reading this statement confirm it); and he points out that the difficulty of completely expelling the worm from the intestines is due to this long undetected fact. We strongly recommend a perusal of the few pages devoted to this particular subject.

The editor of the "Cyclopædia," Professor von Ziemssen, follows Professor Heller with the subjects of Laryngitis Phlegmonosa, Perichondritis Laryngea, Ulcerations, Tumours, and Neuroses of the Larynx. The term *laryngitis phlegmonosa* is applied to those inflammations in the larynx which run their course principally in the submucous connective tissue, without, however, being exclusively limited thereto. It is ordinarily known as *œdema laryngis*. In the section on Laryngeal Phthisis, Professor Ziemssen strongly maintains the truth of Louis's law—that *pulmonary* phthisis almost invariably precedes the laryngeal affection. He has paid special attention to the subject for years, and thus far has "*not met with a case* of phthisical ulcers of the larynx in which he could not demonstrate either fresh or old consolidations in the lungs, especially at their apices." The subject of Laryngeal Growths is capitally done, as is also Neuroses of the Larynx, on which latter von Ziemssen is an established authority. This part of the volume contains a number of well-executed woodcuts, which add considerably to its value. Bilateral paralysis of the *erico-arytænoidei postici* muscles (a well-characterised lesion, of which, however, as yet, only nine cases have been reported) is dealt with very fully, and illustrated by a succinct account of each recorded case.

Dr. Steffen, of Stettin, winds up the volume—which is one of the most generally serviceable of the series which has as yet appeared—with a good article on Spasm of the Glottis. The various articles are translated by Dr. A. V. Macan, of Dublin; Dr. E. W. Schauffler, of Kansas City; Dr. Ball, and Dr. L. A. Stimson, of New York; and Dr. J. S. Cohen, and Dr. A. van Harlingen, of Philadelphia.

An Essay on Hospital Mortality, based upon the Statisties of the Hospitals of Great Britain for Fifteen Years. By LAWSON TAIT, F.R.C.S., etc. London: J. and A. Churchill. 1877. Pp. 136.

THE subject of hospital mortality is one which well deserves, and indeed imperatively demands, our closest attention. Mr. Lawson Tait, following in the lines of the late Sir James Simpson, has collected from every hospital in the country information as to its rate of mortality; and the results of his labours are embodied in the little work before us. He sums up the lessons which his statistics teach as follows:—"The figures show incontestably that a most stringent inquiry is demanded as to the possibility of reducing the number of deaths in at least some institutions for the treatment of the sick poor." Though we are scarcely prepared to accept all the views which Mr. Tait formulates in the course of his book, we do, nevertheless, agree in the main with the above conclusion at which he has arrived. That hospital mortality is very high, cannot be doubted; that it is higher than it ought to be, is possibly true; but that it depends on aggregation, *per se*, is, in our mind, to say the least, doubtful. First, Mr. Tait's figures, which are very large, demonstrate that a very large number of persons die annually in our hospitals, but there is not one particle of evidence to show that any part of this mortality is other than the *natural result of disease or accident*. It would, indeed, be putting figures to bad use if an attempt were made to *explain* the number of deaths by mere statistics. But if Mr. Tait's *general statements* concerning hospitals *en masse* should lead to a *special* inquiry into the working details and results of *each one*, then undoubtedly some good would result from his work, and it might, and probably would, lead to improvements.

Mr. Tait says (page 83), "Large hospitals are not more unhealthy because of their greater size, but because they want more looking after, larger bed-areas and cubic spaces—conditions which they do not obtain, because, in places where they exist, time, labour, and space are so much more valuable than in the small hospital areas." We agree with our author as to the need of more careful surveillance, but we cannot without qualification accept his opinion concerning the larger amount of cubic space—indeed, his own statistics and our experience alike refute it. We have seen, over and over again, brilliant results obtained in small, dingy-looking hospitals, where scientific sanitation, such as Mr. Tait would advocate, had been palpably prominent by its absence. Large, handsome hospitals, well known by the public to be supplied with every kind of scientific appliance for warming, ventilating, purifying, and keeping clean and wholesome the atmosphere, are courted especially by those who are the subjects of serious, and probably incurable disease, in the hope of there finding some possible mitigation of their diseases; and hence it is that in some hospitals where there should, on *à priori* grounds, be a low mortality, there is a very high one, and the place is at once condemned, its statistics of mortality alone being considered. Let us look at a high death-rate from another point of view. We will this time choose some large, poor hospital, whose foundation dates long before sanitary matters were ever dreamt of. The size of such a hospital is usually commensurate with the amount of illness, disease, or accident of its immediate district. The amount of illness depends on local causes—poverty, neglect, or the aggregation of large (and dangerous) manufactories; and wherever these local causes are active outside a hospital, they are as naturally active within it. Poverty always implies a lowered health-standard—a less recuperative power after disease or injury—less of the reserve force necessary to recover either from accident, operation, or disease; and hence the results of hospital work vary with the class of people who undergo treatment within its walls. This is, to our mind, the key of the whole argument. Herbert Spencer reconciles greater apparent discrepancies than even those to which Mr. Tait's book refers, to the ever-varying agencies which act on matter: no two particles of matter are constantly acted upon by the same agencies under the same circumstances and conditions for similar periods, and to this fact is to be ascribed the amazing variations under which matter presents itself to us.

We may venture on a third variety of hospital. Let us imagine ourselves in a fine modern palatial building, situated within its own grounds and surrounded by open fields. Would Mr. Tait ascribe the low death-rate of such a place to better "looking after, larger bed-areas and cubic spaces"? We fancy not. It is well known that the few such places which do exist are more or less of a failure from a scientific point of view. The sick poor do not care to be carried far away from home; they cannot be so conveniently visited by their friends, and they do not care to die away from them: and as for accidents, it is well known that the patients could not be transported to a distance without grave additional risks. In the London hospitals a large number of patients are taken in to die; humanity and science alike prompt to such admissions, and until all such cases are scratched off the mortality tables, no true estimate of their relative value can be obtained.

We will now pass on from these general conclusions to one or two special points. After what we have said, the reader will scarcely expect us to enter into any discussion on the figures which Mr. Tait adduces as the results of his inquiries. We will glance rather at the subject than at details. First, as regards amputations. He says (page 117), "It certainly is somewhat disappointing to find that of *all* the amputations performed in hospitals more than *one in every four dies;* and that even of *all* amputations for disease the results are not so good as to secure the recovery of four out of five"! Mr. Tait has done well in choosing the word "disappointing," for it aptly expresses the feelings with which every surgeon will read this statement. We regret to read further on in the same paragraph the opinion that this "*ought* to be greatly reduced" (the italics are our own); for this implies a culpable negligence on the part of the hospital staff, both lay and professional, which is not deserved. We have already entered into a few of the causes which tend to modify the results of treatment, including the previous surroundings of the patients—their previous habits of life, and their inherited as well as their acquired idiosyncrasies. We would now add that before any slur can be implied, and still less cast, on a hospital in consequence of a high mortality, all these circumstances must be carefully weighed *in each individual case*, together with the nature of the disease or accident which necessitated each operation. Until all these points have been carefully weighed and balanced, and until post-mortem examinations in the fatal cases reveal or negative internal injuries or disease, the mere record of "Died" or "Recovered" is absolutely valueless.

Turning to Ovariotomy, we are pleased to be able, with Mr. Tait, to admire the gigantic success of some two or three special operators, and we congratulate them on their results. Nevertheless, we are utterly unable to find any parallel between the *individual* practice of two surgeons in ovariotomy, and the *aggregate result*—acknowledged by the author to be imperfect, because of the imperfect nature of the data and statistics on which they are based—which Mr. Tait deduces from 4948 *collected* amputations. It is "disappointing" to learn that "one in every four dies,"—and that we have regretfully conceded. But it is none the less a useless piece of information until we know *why* "one in every four dies." After we have excluded a large proportion of patients who die of the accidents *subsequent* to amputation (*but not of it*), or of disease which has exhausted the patient before he comes under treatment, or of metastatic recurrence which is beyond the reach of the knife, we venture to believe that a different statistical result would be arrived at. It would not be fair to contrast fifty thigh amputations done by one man, with fifty ovariotomies done by some other individual surgeon, unless we could by a kind of second-sight know what would have been the final result of the two series of cases if left to themselves. We will briefly glance at one more point—the mortality in children's hospitals. Speaking of Great Ormond-street, the author thinks that the mean residence (37·2 days) is too great, "if we bear in mind the rapid course which diseases usually run in children." Can Mr. Tait have left out of his consideration the so-called scrofulous diseases of children—the cases of hip-joint disease, of knee-joint disease, scrofulous disease of glands or of the lungs—so fatally common in young children, or has he discovered some remedy to cut them short? In the Birmingham Hospital for Children, he tells us, the mean residence is 24·2 days, "facts which are sufficient alone to indicate this hospital as a thoroughly well-managed institution." What a fallacy! The Birmingham Hospital draws its patients, most probably, chiefly from its own immediate district, and no doubt does good work. Great Ormond-street receives patients from the whole country; its resources are heavily taxed, and its benefits are eagerly sought by those who suffer from the more serious diseases incidental to childhood. Mr. Tait says (page 75) "When the mortality of a children's hospital is found to be so low as 2·3 per cent., I think it may be fairly inferred that such an institution is not doing the work it ought to do; for such a mortality can only be arrived at by the exclusion of acute cases." Surely this is contradictory of the theory which the book was written to substantiate, for Mr. Tait's whole argument is that hospital mortality is excessive, and that it depends on preventable causes. Why not say it is excessive because *too many acute cases are admitted.* He speaks very highly of the Birmingham Children's Hospital. We fancy he does so because he knows more about it than of some of the hospitals of which he has written so much. We believe that a more extended personal acquaintance with the management of some of the large London hospitals, and with the nature of the cases, would convince Mr. Tait that he had been unjust to at least some institutions.

In conclusion, we regret that Mr. Tait was unable to procure, as fully as he wished, the statistics of some hospitals. We would advise him, and everyone who asks such favours, to be thoroughly courteous in their communications. It does not do nowadays to *demand* information, which, to be of service must be accurate, for it must be remembered that such details asked for from large hospitals, would occupy a very considerable time in their preparation. We do not think that Mr Tait's communications always were quite as courteous as they might have been; and we have reason to know that this fact explains the difficulties he met with on more than one occasion.

A Practical Treatise on Diseases of the Skin. By Louis A. Duhring, M.D., Professor of Diseases of the Skin in the Hospital of the University of Pennsylvania, etc. Philadelphia: J. B. Lippincott and Co. 1877.

We must congratulate Dr. Duhring on having produced a thoroughly workmanlike, practical, and comprehensive treatise which cannot fail to increase his reputation as a dermatologist, both in the United States and in Great Britain. Although intimately acquainted with the views of British and Continental authorities on diseases of the skin, he has wisely elected to work, in the main, on the lines which Hebra has laid down, and has adopted the classification of the latter with but slight modifications. It might be a nice question whether *Acne vulgaris* should not, as a condition in great measure dependent on the pre-existence of *comedones*, be included under the head of disorders of sebaceous secretion, and not under pustular diseases; but perhaps Dr. Duhring has done rightly in placing it where he has.

Where all articles are so excellent we have a difficulty in singling out any for special mention. Perhaps the chapters on General Diagnosis and Treatment may be referred to as particularly good, and well worthy of the attention of anyone who wishes to become skilful in distinguishing between different skin diseases. It is, however, going rather too far to say that "we need not entertain the occurrence of psoriasis before the sixth year" (page 75). We have before us the notes of a case under our own care in which it began at *four years and a half*, and, though very rare, others have been recorded still earlier. Acne is carefully treated of, and special stress is laid on "dyspepsia in all its forms, as one of its most prolific sources." We notice that Dr. Duhring believes that arsenic does decided good in the papular variety, and in acne where the lesions are imperfectly developed. We have ourselves seen benefit from it in the same class of cases. In a note on *Herpes gestationis*, Dr. Duhring has fallen into a mistake which might have been avoided by a simple comparison of dates. The note is as follows:—*Wiener Med. Wochenschrift*, No. 48, 1872. *Abstract to be found in the Lancet*, March 23, 1872." This implies that the so-called "abstract" was published several months before the article from which it is supposed to have been condensed, and which must have appeared either at the end of November or beginning of December, 1872. As a matter of fact, we know for certain that the reputed abstract was specially reported at Vienna for the journal in which it appeared, and it was, we believe, the first notice of the remarkable case described which appeared in print.

Under the heading "Prurigo," in which Hebra's description

is followed, we are surprised to find no reference to *Lichen urticatus* as the representative of prurigo out of Austria, and as one of the most troublesome—though, happily, not the most common—of the skin diseases to which children are liable. A short mention is made of the disease under "Urticaria," with which its chronicity alone should, in our opinion, prevent its being classed. The only cases we have seen in England, to which the term "prurigo" may be correctly applied (excluding Prurigo hiemalis, which we have met with exactly as described by Duhring), are those of Lichen urticatus, and they agreed with Hebra's Prurigo in being accompanied by severe secondary lesions due to scratching, in chiefly involving the lower limbs, and in resisting treatment, though most benefit was derived from lotions containing tar, or sulphur-baths. Contrary to Dr. Duhring's experience, the children were well nourished, and not ill cared for; on the contrary, they belonged to the better class of poor.

The subject of treatment is in all the chapters well handled; and though there is not much that can be called new in what is suggested, yet nothing of importance is omitted, and the ideas of others are (as also everywhere else throughout the volume) accorded full justice whenever they deserve it. Dr. Duhring is not one who parades wonderful cures, or vaunts miraculous panaceas, and his modest opinions are all the more worthy of attention and respect.

There is one point more we should like to mention before concluding our review. It refers to the differences between the skin diseases of Europe and North America; and we may quote the author's own words to illustrate it. He says:—"Having had some few years ago favourable opportunities for observing a large number of cutaneous affections in the various countries of Europe, and since then of studying these diseases in the United States, I can state that in many instances they differ materially in type as they are seen on the two Continents, and that the diseases met with here resemble more closely those of Great Britain than those of either France or Germany." This is an observation of great interest, and points to the relation of skin diseases rather with *race* than climate. We know of no similar generalisation with regard to Australia, New Zealand, or the Cape, and have mentioned Dr. Duhring's remarks partly to call the attention of surgeons in those parts to them. The predominance of the Anglo-Saxon element in the United States helps to explain the similarity of its skin diseases to those of Great Britain. Possibly in a few centuries the original types will become considerably modified from their European forms. Skin diseases apart, are the types of disease prevalent in Britain replacing indigenous types abroad, as the Anglo-Saxon replaces the New Zealander or the American Indian? We know how measles have decimated the Fijians, and small-pox the Red Indians, and how our sailors syphilise and our "fire-waters" degrade the inhabitants of all the ports they enter. Do we colonise new countries permanently with diseases as well as with people, or do we stamp out aboriginal inhabitants and aboriginal diseases, and leave no fresh diseases in their place? These are important questions, and they open a wide field of inquiry. Let us hope that Dr. Duhring will continue to devote his attention to the variations of type in imported skin diseases, and give us fuller details on the subject at a future day. Meantime we can heartily recommend his book as a solid, reliable, and painstaking production.

Transactions of the Obstetrical Society of London for the Year 1876. Vol. XVIII. London: Longmans, Green, and Co., Paternoster-row. 1877. Pp. 355.

Although smaller than some of its predecessors, the eighteenth volume of the *Transactions of the Obstetrical Society of London* is not wanting in matter of interest and value to the obstetrician and gynæcologist. Abstracts of the papers and reports of the discussions to which they gave rise were duly published in our columns after each meeting; it is therefore unnecessary to consider them at length in the present notice. Among the more important papers are the annual address of the President of the Society, Dr. Priestley, in which he gives a very careful and elaborate summary of the debate on Puerperal Fever; Dr. Routh's paper on a case of Extra-Uterine Fibroid successfully treated by Gastrotomy; Dr. Williams's on the Mechanical Action of Pessaries; Dr. H. Cooper Rose's and Dr. Clement Godson's contributions to the Statistics of Midwifery in General Practice; Dr. Galabin's papers on two cases of Cæsarean Section; Mr. Jessop's report on a successful case of Abdominal Section for Extra-Uterine Gestation; and Dr. Langdon Down's on the Obstetrical Aspects of Idiocy. The present volume of *Transactions* shows that the Obstetrical Society is in a very flourishing state, and that its present members are equal to maintaining its high reputation.

GENERAL CORRESPONDENCE.

DR. EUGÈNE DUPUY (PARIS) ON THE PHYSIOLOGY OF THE BRAIN.

Letter from Dr. Roberts Bartholow.

[To the Editor of the Medical Times and Gazette.]

Sir,—In a communication to the *Medical Times and Gazette* of July 28, 1877, under the above heading, Dr. Dupuy refers to me in a way which calls for some comment on my part. It is with no intention to obtrude my opinions on the medical profession of Great Britain that I ask for a small part of your valuable space, but simply to expose a singular mistake made by Dr. Dupuy, by which he has given an altogether erroneous view of a case of mine that has obtained an unfortunate notoriety. This mistake is all the more remarkable because Dr. Dupuy makes much proclamation of the precautions taken by him to secure accuracy. It is perhaps less singular that this mistake furnishes him with an important argument.

Dr. Dupuy refers to the "much-to-be-regretted experiment of Dr. Roberts Bartholow, of Cincinnati," on the brain of a living woman. He professes to give "Dr. Bartholow's own phraseology all through in order to be more accurate," and he "doubts whether all those who have quoted it have read it." I shall have something to say presently of the humanitarian aspects of this case which so shocks the sensibilities of Dr. Dupuy; but just now I purpose to show what an extraordinary liberty he has taken with my report.

As a justification of the experiments, which I do not now pretend to justify, I remarked (*American Journal of the Medical Sciences*, vol. lxvii., page 309) that, "as portions of brain-substance have been lost by injury, or by the surgeon's knife, and as the brain has been deeply penetrated by incisions made for the escape of pus" (*i.e.*, cases narrated in surgical literature), "it was supposed that fine needles could be introduced without material injury to the cerebral matter" (in this case). Anyone at all familiar with surgical literature will be able to recall numerous examples of the injuries to the brain, just mentioned, which were not followed by ill effects of any kind. No surgical interference of any kind had been attempted in the case of the woman the subject of the experiments; and, indeed, the account given of the excavation which laid bear the dura mater shows that no surgical operation which promised any relief or benefit was possible. Dr. Dupuy assumes, and absolutely without justification, that various surgical operations had been performed, that portions of this woman's brain had been removed by the surgeon's knife, and that incisions had been made for the escape of pus, etc. His words are as follows:—

"I only beg the reader to notice that the needles being insulated up to their extremities, and introduced to a depth of an inch and a half into *the substance of the brain which had so much suffered by the surgeon's knife*, etc., the aim of the experiment has been lost sight of, as *no cortical matter could possibly have been irritated*." (Italics Dr. Dupuy's.)

There was absolutely no warrant for this assumption, on the part of Dr. Dupuy, that the brain had been so maltreated by a surgeon.

I beg leave to add a few words on the humanitarian aspects of this case. Every writer who has noticed the experiments made on this poor patient has expressed a strong disapproval of them on strictly humanitarian grounds. Dr. Dupuy has implied that great wrong was done. It is a nice question of casuistry, which such humanitarian philosophers as Dr. Dupuy may properly decide—whether it is more inhuman to practise vivisections on dumb brutes, who can only protest by cries and struggles against the proceedings of the experimenter, or to operate on a poor woman, whose race being nearly run, consents to have some experiments made. In the very paper in which he implies a strong condemnation of my experiments, we read that he "was successful enough to keep one dog alive several weeks" after having removed a part of

the animal's brain. We believe that Dr. Dupuy is a pupil and follower of Dr. Brown-Séquard, who has used hecatombs of animals in his vivisections. That the results achieved in these experiments justify the sacrifice of life, I am fully persuaded; but gentlemen engaged in such researches ought to be charitable in their view of my case—if for no other reason, because the patient submitted to them of her own volition.

In my original report of the case of experiment on the human brain, I stated the facts without any attempt at special pleading to forestall the judgment of the medical profession. I said nothing of the unwearied care of which this poor woman was the recipient at the hands of the devoted Sisters of Charity during many months preceding her death. I said nothing of the numerous attempts which we made to stay the progress of the destructive ulceration, which threatened an early extinction of life. In part, gratitude, I think, for our attention to her comfort induced the woman, so near her end, to yield a cheerful assent to the proposed experiments. That it was not right to make these experiments, the result has proved. I do not defend them; but those who quote them hereafter, ought to quote them for what they are worth scientifically, and spare those moral sentiments aud reflections, which, however admirable in themselves, have really nothing to do with purely scientific questions. I am, &c.,

ROBERTS BARTHOLOW, M.A., M.D.,
Professor of the Theory and Practice of Medicine and of Clinical Medicine in the Medical College of Ohio, etc.

JUSTICE TO MANCHESTER WORTHIES.

LETTER FROM DR. LLOYD ROBERTS.

[To the Editor of the Medical Times and Gazette.]

SIR,—Will you kindly allow me a brief space in your journal to reply to a letter headed "Justice to Manchester Worthies," from your correspondent "R. D.," in your impression of the 15th inst. He there assumes that Dr. Priestley has mentioned Mr. Ward, meaning Mr. Kinder Wood. I have to say that Dr. Priestley is quite correct in his reference. Mr. Ward's case occurred fourteen years before Mr. Kinder Wood's paper was written. I am, &c.,

Manchester, September 24. LLOYD ROBERTS.

OILING THE URETHRA.

LETTER FROM MR. T. MARK HOVELL.

[To the Editor of the Medical Times and Gazette.]

SIR,—In the *Medical Times and Gazette* for August 25, I noticed a paragraph headed "Oiling the Urethra," in which it is stated that M. Desprès, "after trying various substances for greasing instruments intended to be passed into the bladder, now always injects oil into the urethra by means of a glass syringe, thereby oiling the passage and not the instrument." This method is by no means new. At the London Hospital, Mr. Maunder has successfully employed it for the last four or five years to my knowledge, and the practice was with him a very old one when I first became acquainted with it.

I am, &c., T. MARK HOVELL, House-Surgeon.
London Hospital, September 17.

ANTIHYDROPIN FROM COCKROACHES.—Dr. Unterberger gives details in the *Petersburg Med. Woch.* (September 1) of four cases of *nephritis scarlatinosa*, in which the *Blatta orientalis* proved of great utility. It is, in fact, a very old Russian popular remedy in dropsical effusion. In these cases of scarlatinic dropsy (as also one of dropsy after measles), as in those of dropsy in the adult, formerly published by Dr. Bogomolow, it certainly proved highly efficacious as a diuretic. The œdema and albumen diminished as the urine increased; and there was no irritating action produced in the kidney or intestinal canal. As the alkaloid antihydropin cauot be obtained in trade, tho powder of the *Blatta orientalis* or *Blatta germanica* is employed in doses of from 0·18 grammes to 0·3 grammes three times a day. It is a brown powder, without disagrecable taste or smell, and is readily taken by children.

NEW INVENTIONS AND IMPROVEMENTS.

NEW ILLUMINATING LAMP FOR MEDICAL PURPOSES.

IN reference to the above lamp, Messrs. Coxeter and Son write as follows:—"Will you kindly allow us to correct a statement that appeared in your issue of the 15th inst. under the above heading. The lamp claimed to have been brought out by Messrs. Salt and Son has now been sold for some years, and was exhibited by us at the late meeting of the British Medical Association in Manchester. We append an engraving showing the complete apparatus as originally procured by us from Paris.

FIG. 1.

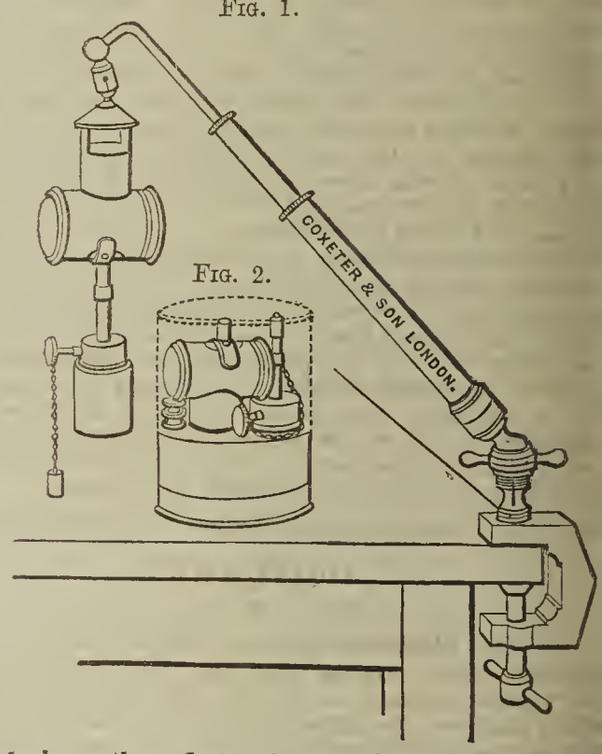

FIG. 2.

"Fig. 1 shows the reflector, lamp, and bracket as in use; and Fig. 2 the reflector (inverted) and lamp packed away in its case, part of which serves the purposes of stand, and reservoir for spare benzoline."

PORTABLE TURKISH AND VAPOUR BATH.

THE Portable Turkish Hot-Air and Vapour Bath manufactured by Allen and Son, Marylebone-lane, Oxford-street, deserves to be much more widely known and used than it seems to be at present. The apparatus is very convenient, ingenious, and well made. The representation of it appended to this notice shows it as used for giving a hot-air bath in bed, the nozzle of the tube being introduced underneath the bedclothes; but each bath can be used for hot air only, hot air and vapour combined, or for a medicated bath of poppy-heads, camomile-flowers, etc. With the funnel-head and tube a stream of hot air, or hot air and vapour, can be directed on to any selected part only of the body, or made to act as a foot-bath. Or by removing the funnel-head and tube and putting on a "distributor," the apparatus can be used under a chair, and, a flannel cloak or a blanket being thrown well round the body, a hot-air or vapour bath may be given in that way. Or, by help of a plate lately added, a mercurial bath may be given. The required bath can be thus obtained in a few minutes, and at a trifliug expense. The apparatus may be employed with safety, we believe, and readiness in the bath-room, dressing-room, or nursery; and may be confidently recommended as an important auxiliary in the sick-room.

ALMONDISED COD-LIVER OIL.

This is an agreeably flavoured cod-liver oil, introduced by Messrs. Leslie and Co. (Limited), of Walbrook, London, E.C. It is much less disagreeable, both to the palate and to the nose, than the ordinary oil; and we think that this quality will recommend it to many who find difficulty in taking this useful medicine. The taste is decidedly masked by the almond flavouring, but it is still cod-liver oil for all that. The cold season is coming on fast, and large quantities of the oil will be consumed. Great credit is due to those who endeavour to render a rather nauseous medicine palatable and agreeable.

THE RESPIRATOR VEIL.

We are very close upon chill October, and we have already had a foretaste of the raw foggy days supposed to belong especially to November, and of wintry-feeling north and easterly winds. We therefore take an opportunity of noticing with commendation the Respirator Veils manufactured by Messrs. Marshall and Snelgrove, of Oxford-street. The veil is made of plain net, but the lower border, in all its length and for a depth of from three to four inches, is thickened by a double fold of silk gossamer, and the part that hangs before the nose and mouth is made stiffer, and slightly thicker still, by the insertion of a layer of very fine wire-gauze. Additional protection against cold is thus given to the nostrils, mouth, and ears; the air is warmed before inhalation during its passage through the layers of blonde, gossamer, and wire-gauze; and the veil differs so little in appearance from an ordinary veil that it cannot be considered unsightly. Very many ladies may therefore be willing to (and would with much benefit, we think) employ these veils, who would greatly object to use any of the ordinary kinds of respirators. We will add that these veils will also give very useful protection against dust.

OBITUARY.

CHARLES MAYO, M.D., etc.

Charles Mayo was the eldest son of the Charles Mayo, the veteran Surgeon to the Winchester County Hospital, whose death we chronicled at the end of last year. He was born on January 13, 1837, and was educated at St. Mary's College, Winchester, on the foundation of the venerated William of Wykeham. Thence he was elected to New College, Oxford, of which he became a Fellow in 1855. Whilst finishing his Oxford course, and before exploring the depths of medical study, he yielded only too willingly to the fascination of archæology, ecclesiology, music, and architecture. These are branches of study which are pre-eminently distinctive of an elegant literary education, and they give a liberal tone to the mind by showing that the religion, customs, artistic taste, and constructive ingenuity of our ancestors during what are called the darkest ages were not so despicable as some persons pretend. But it was probably a mistake to carry the pursuit of them so far as did the subject of our sketch.

We find that his first literary effort was "A History of Wimborne Minster," published by Bell and Daldy in 1860, to which, from a mixture of pride and shyness, he did not put his name. At Wimborne, where many members of the Mayo family resided, is an ancient and curious church of the eleventh century, which, after mouldering for some years, as Dr. Johnson says, "in unregarded dilapidation," was submitted to elaborate restoration. This furnished an unhappy opportunity for the exercise of Mayo's favourite tastes and acquirements. His book is one which, from the fulness of detail, from the skill and perspicuity with which the successive stages in the construction of an ancient church are described, would have done credit to any antiquary or architect.

As usual in local histories, he gives copious extracts from the ancient records and churchwardens' accounts. We will only mention two as having a faint medical interest. One relates to the status of physicians in the fifteenth century, and the manner in which their salaries were made up; that is to say, they were generally persons in holy orders, and were remunerated by ecclesiastical sinecures. Thus, we find that "Peter de Altobello or Altobasso, an Italian, the King's Physician, was admitted Dean of Wimborne on the 29th April, 1412." Most likely the clergy were the only persons skilled in medicine, and an ecclesiastical benefice the surest way of finding them remuneration. The other point that strikes our eye is the Latin in common use, or rather falling into disuse, in the fifteenth century, for letters and ordinary accounts. We are reminded painfully of the kind of Latin we meet with in some prescriptions at the present day, when we read Mayo's extracts from the churchwardens' accounts at Wimborne for the year 1464. "Solut' pro querend' unum glaziatorem—iv.*d.*" "Et in expensis dicti glaziatoris cum equo suo per v. days—iv.*s.*" This in plain English signifies, "Paid for fetching a glazier 4d., and for the costs of the said glazier and his horse for five days, 4s."

We must not, however, linger on the history of Wimborne Minster, which we regard as an example of liberal pursuits carried almost to excess, but must go on to mention an invention for propelling ships, of which he had models made, and for which he took out a patent.

We next find him taking up his professional work warmly, becoming M.R.C.S. in 1861, and then going to Vienna for some months of study. He proceeded also to Prague, where he studied the laryngoscope under Czermak and Türck, and before his return to England visited all the chief hospitals in Germany, and made himself complete master of the theory and practice of hospital construction. On his return he served a short time as House Surgeon to the Radcliffe Infirmary, Oxford.

But now the great Civil War was raging in America, and thither he bent his steps in October, 1862, where his credentials procured him a hearty reception. Of his life and adventures at this period he has given a full account in a paper contributed to the "Vacation Tourists and Notes of Travel in 1862-63," edited by Francis Gatton," and published in 1864. He underwent a week's examination by the Surgeon-General's Department, which was essential for taking a staff appointment, and then was fortunate enough to obtain one of the best appointments in the service—that of taking charge of sick and wounded volunteer officers in Washington itself.

During an interval when work was lighter than usual, he had the opportunity of visiting the army of the Potomac, under General Hooker, opposite Fredericksburg; and soon after his return to Washington he obtained the position of Staff Surgeon-Major and Medical Inspector of the 13th Army Corps, and was ordered to Vicksburg to join Grant's army besieging that place. He speaks in the highest terms of that great Sanitary Commission, which, with a rare union of skill, thoughtfulness, and munificence, supplemented the shortcomings of the official machinery for supplying comforts and luxuries for the sick of the American army. Diarrhœa and malaria, which ravaged the armies on both sides, did not spare the doctors, and Mayo was obliged to resign in order to save his life. After a narrow escape from being blown up with a steamer in which he was to have travelled, and a visit to Saratoga Springs, he returned to England in a very dilapidated condition in October, 1863. The next few years were spent partly in Oxford in his congenial pursuits, and partly in London, where he became Physician to the General Dispensary in Bartholomew-close; studied midwifery for some time in Dublin, where he took a Doctor's degree, became M.R.C.P. London in 1869, and M.D. of Oxford.

On the breaking out of the Franco-Prussian War, he was not slow in obtaining employment on the German side; and this, we suspect, was the happiest part of his life. He had the good fortune to be sent to Darmstadt, where he came under the notice of the Princess Alice and her sister, the Crown Princess of Prussia, whose practical good sense and active kindness were always mentioned by him with admiration and gratitude. Here he had ample scope for his ingenuity and skill in construction. He superintended the building of a hospital, which he was proud to be permitted to call the Alice Hospital, and piqued himself on the abundance of good ventilation. He also invented some sick-transport carts. With these he was sent, through the influence of the Crown Princess, to Lagny, near Paris, in January, 1871. From this place he went with his letter to the Crown Prince at Versailles; and there he had the honour of receiving hospitality from the men upon whom the eyes of all Europe were fixed. In a letter of January 13, 1871, he says—"10.30 p.m.: I have come back from dining with the Crown Prince. There were about eighteen or twenty to dinner;" on one side, the Crown Prince, between Bismarck and Moltke, besides many generals and colonels, and Generalarzt Wagner. "During dinner we could hear the great guns firing away. . . . . A telegram was brought in saying that Chanzy's army was defeated, with the loss of

18,000 prisoners and twelve guns. This was treated as improbable. Bismarck said jocosely, 'Probably the correspondent has made a mistake—he meant to say 18,000 guns and twelve prisoners!' But, about an hour afterwards, a French telegram was produced, in which precisely the same numbers were given, with the addition that Le Mans was occupied by Prince Frederick Charles, and that the Grand Duke of Mecklenburg was in pursuit. I explained my photograph of carts to the Crown Prince. Moltke afterwards took them up and examined them, and I tried to engage him in conversation, but failed. He seems to say but little to anybody. The Prince came and talked to me for a quarter of an hour about various things, including the Alice Hospital."

Mayo remained in the German service till their subsidiary military establishment was broken up after the peace. He brought back with him the decorations of the First Class of the Order of Philip the Generous, and the Third Class of the Order of the Prussian Crown, the Imperial German War Medal, the Bavarian Cross of Merit, and the Hessian Cross for Medical Service in the Franco-German War.

On his return he meditated remaining in England and settling in practice, but such a thing becomes more and more difficult in proportion to the age of the candidate, who is apt to be too impatient and critical to submit to the drudgery necessary for gaining a footing on the lower steps of the ladder of promotion. So we are not surprised to find that in the year 1873 Mayo entered the service of the Dutch, and joined their army in the swamps of Atchen. Here, of course, he was witness to all the discomfort and dangers which sun and swamps, and utter disregard of sanitary measures, can inflict on an army in the presence of an astute and implacable foe. He wrote the accounts of the war which appeared in the *Times* newspaper.

In July, 1874, he returned to England, and resided chiefly at Oxford, where he published a pamphlet on the Organ of New College Chapel, without name or date, although we know from private sources it was in 1875. It is just such a publication as might have come from the pen of a professional organ-builder. In fact, we may apply to Mayo the epithet on the tombstone of Dalham, who built the New College organ after the Great Rebellion—

"Instrumenti Pneumatici
Quod vulgo Organum nuncupant
Peritissimus Artifex."

He was the author of several inventions for coupling the different stops, and otherwise improving the mechanism of organs, and had collected a large number of organ-pipes from various sources, which he intended to put together some day when he should have leisure to construct a perfect instrument.

We have omitted several of the minor appointments which he held, such as the Coronership of the University of Oxford. He was also Surgeon to the Inns of Court Volunteers, and to the National Rifle Association, in which capacity he attended the annual rifle matches at Wimbledon. He was occasionally consulted on sanitary questions, and sometimes contributed articles to this paper, of which we may mention—An Analysis of Cohn's book on Embolism (*Medical Times and Gazette*, vol. i. 1862) as the first.

But we must hasten on to the last scene of the tragedy. Impatient of the conditions necessary for professional success at home, the man who had received the most costly and refined education which this country affords, who piqued himself on the nicety of his scholarship, who could judge of the age and style of every order of church architecture and ornament, who had studied his own profession minutely, and was possessed of unusual mechanical skill, an accomplished artist, and a skilful musician, a genial and witty companion—throws himself away amongst the savages of Fiji. He sailed for that place as one of the Government medical officers, in the suite of Sir A. Gordon, on March 25, 1875; and almost all that we know of him since that date is that he was relegated to a distant island, with a miserable hut to live in, with no roads, and no boat; no books, and no companions; with all the decencies of life only to be obtained at four times their real value. His latest letters displayed utter prostration of mind and body—so different from the cheeriness with which he encountered the discomforts of Vicksburg and Atchen. He pined for the time when his term of service should expire, and he should be at liberty to take service in one of the great European wars, the first mutterings of which had reached the distant and detested settlement of Fiji.

At last he was seized with acute dysentery, and was moved to the hospital at Lavuka, where he was put on board the ss. *Lyce Moon*, in the hope that his life might be saved by a sea-voyage. But a kind-hearted letter from Captain Saunders announced his death on July 15, 1877, and his burial at sea 200 miles south-west of the island of Kandavau.

"Requiescat in Pace."

MEDICAL NEWS.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, September 20:—

Davidson, Alexander Deas, Erith, Kent.
Hornsby, George Harcourt, Bromsgrove.
Macdonald, Henry Murray Wyle, Madras, E. Indies.
Newman, Arthur Joshua, 37, Southwick-street, W.
Prior, Edward Thurlow, 11, Talbot-square, W.
Taylor, Frank, Stoke Croft, Bristol.
Weston, Edwin, Madras, E. Indies.

The following gentlemen also on the same day passed their Primary Professional Examination:—

Alden, Ebenezer Wenham, Middlesex Hospital.
Jeffreys, James Graham, St. Thomas's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Newton, James, M.R.C.S. Eng.—Junior House-Surgeon to the Carlisle Dispensary, *vice* Mr. Steele, resigned.

NAVAL, MILITARY, &c., APPOINTMENTS.

Admiralty.—Staff-Surgeon Charles H. Slaughter has been promoted to the rank of Fleet-Surgeon in her Majesty's Fleet, with seniority of August 21, 1877.

BIRTHS.

Allen.—On September 15, the wife of B. H. Allen, M.D., of Hastings, of a son.

Skimming.—On September 20, at Tudor Lodge, East Molesey, the wife of Robert Skimming, M.D., F.R.C.S.E., of a daughter.

Stewart.—On September 10, at Mount Hope, Sneyd-park, near Bristol, the wife of James Stewart, B.A., L.R.C.P. Edin., ex-R.N., of a daughter.

MARRIAGES.

Cock—Liebreich.—On September 20, at the parish church, Weybridge, Surrey, Alfred Cock, of the Middle Temple, barrister-at-law, to Eva, only child of Richard Liebreich, M.R.C.S. Eng., Ophthalmic Surgeon to St. Thomas' Hospital, of 16, Albemarle-street, Piccadilly.

Foulis—Fraser.—On September 19, at St. George's Episcopal Church, Edinburgh, James Foulis, M.D., to Henrietta Baird, third daughter of William N. Fraser, Esq., of Tornaveen, Aberdeenshire.

Hainworth—Tuckwood.—On September 19, at St. Thomas's Church, Camden New Town, N.W., John Hainworth, F.R.C.S., to Emma, youngest daughter of the late John Tuckwood, of London.

Hart—Burt.—On September 20, at the parish church, Harborne, George Henry Hart, M.R.C.S., second son of Charles Hart, Esq., of The Hall, Harborne, to Mary Louisa, only daughter of Major Burt, of Englefield, Harborne.

Lawrence—Wood.—On September 18, at Old Widcombe Church, Bath, George Edgar Lawrence, L.R.C.P. Lond., M.R.C.S. Eng., of 31, Claverton-street, to Rosalind, second daughter of Bennett Wood, Esq., of Abbey View House, Bath.

Leftwich—Kilburn.—On September 19, at the parish church, Hampstead, Ralph Winnington Leftwich, M.D., of 231, Kennington-road, third son of George Leftwich, Esq., of Tufnell-park West, to Ada Elizabeth, second daughter of Charles Kilburn, Esq., of Alvaston, Arkwright-road, Hampstead.

Marshall—Pryn.—On September 20, at the parish church of St. Stephen's-by-Saltash, Cornwall, John Marshall, M.R.C.S.E., of Bermondsey, to Amy Maria, only daughter of W. Pryn, Esq., of Tredown-street, St. Stephen's-by-Saltash.

Simms—Stanistreet.—On September 19. at St. Peter's Church, Rock Ferry, James Simms, L.K.Q.C.P. Ire., Surgeon Royal Navy, to Anna Maria Harriett, youngest daughter of George Stanistreet, of Highfield, Rock Ferry, Cheshire.

Steele—Trench.—On September 13, at The Castle, Ballyraggett, the residence of Lady Harriet Kavanagh, James Peddie Steele, B.A., M.D. Edin., to Sarah Louisa, youngest daughter of the late Rev. William and Lady Louisa le Poer Trench.

Taylor—Maberly.—On September 20, at St. Aldate's, Oxford, Thomas Taylor, B.A., of Holmleigh, Oldham, to Maude, daughter of G. F. Maberly, M.R.C.S., of Leamington.

DEATHS.

Allen, A. B. de Lisle, M.R.C.S. Eng., of Sutherland-gardens, on September 21, aged 60.

Fletcher, Thomas Swindell, L.R.C.P. Edin., M.R.C.S. Eng., at Broxbourne, on September 24, aged 66.

Herrans, James George, M.R.C.S., L.S.A., at 7A, Wyndham-place, Bryanston-square, on September 21, aged 84.

Meryon, Charles Lewis, M.D., F.R.C.P., at The Grove, Hammersmith, on September 11, aged 94.

Tanner, John, son of Robert Tanner, M.D., of Ledbury, Herefordshire, lost in the ship *Avalanche*, off Portland, on September 11, aged 12.

Tanner, Robert, M.D., of Ledbury, Herefordshire, lost in the ship *Avalanche*, off Portland, on September 11, aged 39.

Walter, John, M.R.C.S. Eng., late Surgeon to the Kent Artillery Militia, on September 24.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made and the day of election (as far as known) are stated in succession.

Brighton and Hove Lying-in Institution.—House-Surgeon. Candidates must be Members of the Royal College of Surgeons of Great Britain or Ireland, and Licentiates of the Royal College of Physicians, or of the Society of Apothecaries', London, and registered according to the Medical Act. Testimonials to be forwarded before October 5.

Rotherham Hospital.—Resident House-Surgeon. Candidates must be M.R.C.S. Eng., and Licentiates of the Society of Apothecaries or of the Royal College of Physicians, London, registered, and unmarried. Applications, with testimonials as to professional ability and moral character, to the Honorary Secretary, on or before October 15.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1871.

APPOINTMENTS.

Guiltcross Union.—Charles D. Fenn, M.R.C.S. Eng., L.S.A., to the Fifth District.

Tamworth Union.—H. J. Fausset, B.M. and C.M. Dub., to the Tamworth District and the Workhouse.

Wareham and Purbeck Union.—James Bartlett, L.R.C.P. Edin., L.S.A. Lond., L.F.P.&S. Glasg., to the Winfrith District.

Wigton Union.—Wm. P. Briggs, L.F.P.&S. Glasg., L.R.C.P. Edin., to the Allonby District.

At the recent annual meeting in connexion with the West of England Sanatorium at Weston-super-Mare, the Right Hon. Stephen Cave, M.P., was elected president for the ensuing year. The buildings have cost £12,000 in the erection, and during the coming year an effort will be made to complete the original design, for which £5000 is still required.

The Congress of the Sanitary Institute at Leamington will be opened on October 3 by Dr. Richardson, F.R.S. The exhibition in connexion with the Congress will be opened on the same day by the Worshipful the Mayor of Leamington, when Mr. Lawson Tait, F.R.C.S., will give an account of the work of the Interception Sub-Committee of the Birmingham Corporation, illustrated by working models of plan.

Lotions in Pruritus.—The following are M. Delioux's prescriptions:—1. Borate of soda eight parts, and distilled water 100 parts; 2. Borate of soda ten parts, glycerine twenty parts, and distilled water 80 parts. These are recommended for pruritus, epihilides, pityriasis, and other herpetic appearances.—*Union Méd.*, September 15.

The Growth of Children in the United States.—The recently published Eighth Report of the State Board of Health, Massachusetts, contains an elaborate paper by Dr. Bowditch on the "Growth of Children," derived from 24,500 observations in schools. The following are the conclusions drawn:—1. The growth of children takes place in such a way that until the age of eleven or twelve boys are both taller and heavier than girls of the same age. At this period of life girls begin to grow very rapidly, and for the next two or three years surpass boys of the same age in both height and weight. Boys then acquire and retain a size superior to that of girls, who have now nearly completed their full growth. 2. Children of American-born parents are in this community taller and heavier than children of foreign-born parents—a superiority which seems to depend partly on the greater average comfort in which such children live and grow up, and partly upon difference of race or stock. 3. Pupils of American parentage at the Public Latin School, Private Latin School, and Institute of Technology are (apparently for similar reasons) superior in weight and height to the generality of boys of American parentage attending the public schools. 4. Pupils of the same selected schools are also taller and heavier than English boys of the non-labouring classes attending public schools and universities, the superiority in weight being, as a rule, more marked than that in height. 5. The relation of weight to height in growing children is such that at heights below fifty-eight inches boys are heavier than girls in proportion to their stature; at heights above fifty-eight inches the reverse is the case.

Palmar Temperature.—M. Courty, at the recent meeting at Havre, states the following results of more than 3000 temperatures taken by placing the thermometer in the middle of the palm:—1. In the normal condition each individual has a palmar temperature, the variations of which are limited. In some they range from 26° to 30° C., in others from 35° to 36°, and in others they are intermediate. 2. These physiological variations depend for the same individual on conditions, some of which (as repose, external temperature) can be studied. The causes of the differences between different individuals remain, on the other hand, quite unknown. 3. In the pathological condition, in all febrile diseases the increase of temperature is greater at the peripheric than at the central parts, and the palmar temperature becomes equal to the axillary. This equality remaining in most cases persistent and durable, in fever the local increase of temperature is therefore greatest at the extremities. 4. This equalisation of palmar and axillary temperature ceases at the period of convalescence, the temperature of the hand then falling to 34°, 32°, or even to 28°. But in certain affections, as pneumonia, pleurisy, and typhoid, the palmar defervescence accompanies or even precedes the axillary; while in articular rheumatism, erysipelas, and measles the palmar temperature remains equal, or nearly so, to the axillary for several days, or even several weeks. M. Potain stated that in hysterical subjects a remarkable phenomenon is observed which might sometimes give rise to error. Their pulse is often very rapid, and their peripheric temperature, in place of being lower than the axillary, nearly equals it, so that a superficial examination might lead to the supposition of fever when the temperature is nearly normal.—*Rév. Scientifique*, September 3.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Associate, King's College.—A good portrait and life of the late Sir William Fergusson appeared in the *Illustrated London News* of February 24, 1866.

A Demonstrator.—There ought not to be the scarcity of subjects in this metropolis which you anticipate; we believe that Mr. Hawkins does his best to remedy the evil. The College of Surgeons has no power in the matter. Some years ago the College claimed the bodies of all murderers executed at the Old Bailey. The last body was that of Smithers, executed for causing the death by burning of two ladies who lodged at his house in Oxford-street—an event which he did not anticipate when he set light to his house to defraud the insurance office.

A "Bet."—That subtle poison "woorari" has been tried in cases of hydrophobia, and the late Mr. Waterton, the naturalist, published the result of his experiments with it. The Abbé Salvador Gilii states, in his "History of America," that he has seen the strongest animals succumb instantly when wounded with arrows tipped with the "woorari," but the poison does not produce any effect on their flesh.

Dr. Campbell.—The paper on "Ephidrosis Cruenta," or bloody sweat, was read by Dr. Anderson. The celebrated Dr. Richard Mead refers to it in his "Medica Sacra."

Dens Sap.—There will be an examination for the Licence in Dental Surgery of the College of Surgeons in the ensuing month. Write to the Secretary.

H. M., and A Guardian.—Having been successful at the recent Preliminary Examination of the Royal College of Surgeons, you can commence your professional studies at once, and register them from October 1 to 15 at the College.

Rahere.—The "introductory" has been discontinued at St. Bartholomew's for some years past, instead of which an annual dinner of old students and friends takes place in the fine old hall of the Hospital. Sir Trevor Lawrence, M.P., will take the chair on the 1st prox.

Good Templar.—The third report from the Select Committee of the House of Lords on Intemperance, together with the proceedings of the Committee, minutes of evidence, etc., has recently been issued.

Restless.—Yes; the supply of surgeons in the Servian army is scanty. During the campaign of 1876 more than 200 medical men from England, Russia, Austria, Italy, and Switzerland took service in the Servian forces.

G. G.—The London Temperance Hospital was opened in 1873. The medical officers are not *ex officio* total abstainers in their own persons.

Sophistication.—"The Sale of Food and Drugs Act," 1875, was the result of the deliberations of the Select Parliamentary Committee, which sat during the summer of 1874 to inquire into the operation of the Adulteration of Food Acts, 1860 and 1872, which were repealed.

Ken.—Tiberius Cavallo, F.R.S., etc., was born in Naples. He died in London on December 26, 1809, and his remains were interred in St. Pancras Churchyard, in a vault constructed for the purpose, close to the monument of his intimate friend General Paoli.

Salus.—1. Swiss and Pyrenean sanatoria vary from about 3000 to 5500 feet in elevation. 2. Mr. Alfred Haviland had a Government grant accorded to him for his "basis map." It was employed in collecting the facts included in the last census. The engraved copper-plate of the map is available to medical officers of health and to sanitary authorities desiring to procure an outline map of their areas of administration.

M. L. M.—The University of Glasgow has bursaries in the patronage of (1) the Senate, (2) the Duke of Hamilton, and (3) the Town Council and other public bodies. The bursaries in the gift of the Senate are now given wholly by open competition; up to 1870 they were given partly by competition and partly by selection.

Numerist.—The Irish Census Commissioners did not present to Parliament their general report of the census taken in Ireland in the year 1871, until February, 1876. In 1821, the year of the first authentic census, Ireland had 6,801,827 inhabitants; in 1871 there were 5,412,377.

COMMUNICATIONS have been received from—

Dr. Barlow, London; Mr. J. Chatto, London; Mr. W. E. Poole, London; Mr. R. Brudenell Carter, London; Mr. Herbert Page, London; Dr. Robert Druitt, London; Mr. J. Mark Hovell, London; Dr. Cornelius Fox, London; Dr. Robert Lawson, Banstead; Dr. R. Bartholow, Cincinnati; The Registrar of the Apothecaries' Hall, London; The Treasurer of Guy's Hospital, London; The Secretary of the Local Government Board, London; The Secretary of the Hospital Saturday Fund, London, Mr. Wm. H. Heaton, London; Messrs. Calvert and Co., Manchester; Mr. Gilmour, Glasgow: Dr. Gillespie, London; Dr. Edward Sparks, Crewkerne; Messrs. Wyld, London; Dr. Edis, London; Mr. Kershaw, London; Mr. E. Sargeant, Bolton; The Secretary of the Birmingham Lying-in Charity; Dr. Beard, New York; Dr. O. H. Allis, Philadelphia; Dr. Lloyd Roberts, Manchester; The Dean, King's College, London; Mr. T. M. Stone, London; President and Council of the London School of Homœopathy; Dr. Leared, London; Chairman of the Radcliffe Infirmary Committee; The Council of the Sanitary Institute; Mr. C. Martin, London; Messrs. Ferguson and Co., West Smithfield; The Secretary of the Clinical Society of London; The Secretary of the Royal Medical and Chirurgical Society of London.

BOOKS AND PAMPHLETS RECEIVED—

Thirty-first Report of the Commissioners in Lunacy to the Lord Chancellor—Reports of the Medical and Surgical Registrars of the Middlesex Hospital for the Year 1875—W. APPOINTMENTS FOR THE WEEK.

September 29. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 1½ p.m.

October 1. *Monday*.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

2. *Tuesday*.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

3. *Wednesday*.

Operations at University College, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 1½ p.m.

Obstetrical Society, 8 p.m. Specimens, by Dr. Galabin and others. Dr. W. T. Greene, "A Synopsis of 1500 consecutive Labours."

4. *Thursday*.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing-cross, 2 p.m.; St. Thomas's (ophthalmic operations), 4 p.m.

5. *Friday*.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1½ p.m.; Guy's, 1½ p.m.

VITAL STATISTICS OF LONDON.

Week ending Saturday, September 22, 1877.

At the Royal Observatory, Greenwich, the mean reading of the barometer last week was 29·89 in. The highest reading was 30·16 in. on Monday evening, and the lowest 29·60 in. on Thursday evening.

* The figures for the English and Scottish towns are the numbers enumerated in April, 1871, raised to the middle of 1877 by the addition of six years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the number enumerated in April, 1871.

INTRODUCTORY ADDRESS

DELIVERED AT THE OPENING OF THE ST. MARY'S HOSPITAL MEDICAL SCHOOL

By HERBERT W. PAGE, M.A., M.C. Cantab., F.R.C.S.,
Assistant-Surgeon and Lecturer on Practical Surgery.

STUDENTS OF ST. MARY'S HOSPITAL,—My first duty and greatest pleasure, on the opening day of another session, is to bid you welcome, and to offer you, in the name of my colleagues, and in my own, the hand of friendship and fellowship—of friendship, sometimes lasting, always, be it hoped, sincere; of fellowship in the great and noble work which is common to us all. Let no man delude himself that the work before him is easy, and that his student-days are to be spent in merely gaining enough knowledge to pass a few examinations, so that then he may be fitted to begin life. There may lie a gross deception in the phrase *beginning life*. Nothing is so comforting for one's own mind, or so likely to be dangerous, as to fix a future time when life shall begiu. Your life is beginning now; and no barrier must be allowed to separate the work you do here from that which you will do when you have left us. It is false to assume that the four years to be passed here are the only years of student-life, differing somehow from those which are to follow.

Anatomy and physiology, the very grammar and groundwork of all, you must kuow well; for without a knowledge of the normal structure and functions of the human body, how can anyone deal with those aberrations from them which constitute disease? It is your mission to be constantly at warfare with a desperate enemy, one to be watched closely lest he elude the grasp, to be known and tracked through all the subtle paths wherein he lurks. No man can teach you to fight the battle. You must do it all yourselves. It is not less true for us than for those to whom Sir Joshua Reynolds spoke in one of his beautiful "Discourses," which you would do well to read:—"Few have been taught to any purpose who have not been their own teachers. We prefer those instructions which we have given ourselves, from our affection to the instructor; and they are more effectual from being received into the mind at the very time when it is most open and eager to receive them." Close observation at the bedside, the storing of clinical facts, familiarity with the daily variations in disease, an iutelligeut use of the different aids to diagnosis, the teaching of the eye, and hand, and ear, all must bc incessantly cxercised if a man would become conversant with the work he has to do. Experience gained at the bedside must bc accompanied by work in the post-mortem room. It is impossible to become intimate with disease unless we see the marvellous ways in which it acts. You should never miss a post-mortem examination. My own master, an eminent pathologist, used to say that he never made a post-mortem examination without learning something; and to that I would add, few things are more likely to excite in you an interest in your work. It is obvious, then, that if the power of observation is to be cultivated, each one must do it for himself. No man can see with the eyes of another, or know with another man's understanding.

Beware of books. The most learned student, with the best book-knowledge at his fingers' ends—knowledge astounding, perhaps, to the strictest examiner—will be simply paralysed and helpless when he comes to stand face to face with disease at the bedside. "Actual experience," wrote a distinguished man, "with a sense of responsibility attached to it, is the sole school in which to make a good physician. One of the most learned men I cver knew in the literature of medicine, as well as in physical science, was one of the worst practitioners, borrowing his diagnosis from books, not from that happier faculty, almost an instinct, which enables a man to interpret and act upon signs which no book cau describe." If you are to be of any real use in your day and generation, you must learn your profession by actual experience in the hospital wards, for no amount of reading can supply its place. But I have been warned not to speak for much more than half an hour, and I must not weary you with these matters. I will only beg of you, if there be any truth in what I have said, not to forget it when hurrying along in the paths which custom and routine have laid down.

My second duty is to ask your attention for a short time to some of those questions which concern us as members of the medical profession, to something perhaps of moment in the course and conduct of our lives. The labour of others who have preceded me here and elsewhere as readers of introductory addresses renders this duty somewhat of a task; and I would it had been given to some one of riper judgment and years.

You have done your best, then, to gain a well-grounded knowledge of your profession and its aims, and are fitted to become the healers of your fellow-men. I hold you should be something more—you must be the teachers also. But he who would succeed iu this must bc not only a good doctor, but also an educated man. Most of you come here fresh from school life. Has the work done there been such as will be of much use to you in the calling which you have chosen? I know not whether, after all the talk of improvement, school commissions, and the like, there has been any material change in the general course of au English school education. A smattering of Latin and Greek, taught as dead languages; a tedious reading of ancient authors for the sake of grammar, forgetful of the light and interest which they shed upou the times aud peoples when they lived; hours passed in the weary rendering of some splendid English into execrable Latin prose, or of some beauty of an English poet into unimaginative and barren verse—a labour entailed on all, though perhaps only one boy in a thousand has an aptitude or pleasure for the work; an acquaintance with so-called history, of which the dates of the births and deaths of kings form no inconsiderable part; and a continuous effort to instil higher mathematics into growing minds which instinctively recoil from the infliction: such may not have been your misfortune! But the times are, indeed, not what they were, if in any of our schools an intelligent appreciation of the beauties of literature, of art, of painting, of music; if some knowledge of the physical sciences, of countries and peoples, of governments, of the principles of law, of the science of history and of languages—be open to any who have a natural bent thereto. Happy is that man who finds when he has left school that he has learned something of real value to him in the world in which he moves!

It has often been urged that the medical profession loses much from having no connexion with the great centres of enlightenment and learning. An anonymous writer in one of the weekly journals, commenting on an able address delivered two years ago at another school, says:—"There is quite an unnecessary divorce between the great training schools of Oxford and Cambridge and the profession of medicine. . . . The old Universities have grievously neglected their duty towards this important profession. . . . It is from their connexiou with the Universities that Law and the Church derive much of that social influence which is desired for the medical profession." There are many who may doubt the truth of these remarks, but noue that there is much of truth, eveu if there be some severity, in that which follows:—"Hitherto," he says, "or at least lately, doctors have hardly been educated men. The beneficence of their profession ought to give them immense influence, and their scientific training should make them the leaders in the enlightenment of society. Of course they have also great temptations to acquiesce in the prejudices of others of the time, but we believe they yield to them more easily than men of higher intellectual spirit. Probably no profession or trade in the world makes so little use of its opportunities."

While, theu, our school education is doing so little for us; while it is impossible for us all to enjoy the social life of Oxford and Cambridge, and there seems but small prospect of any other and future union with our ancient seats of learning; while, too, the enlarging influences of foreign travel can only be for the fortunate and few,—we must fall back on our own resources, and depend upon ourselves instead. I cannot help thinking there are many who in after-life must regret the wasted opportunities of self-improvement which surround them here. Social and intellectual good may be derived from early years at our universities; but our advantages, while we have them, are in many respects greater. It should be couuted a high privilege that you pass four years of your life in Londou; and there is no reason on earth why the most diligent work at your own special hospital studies should be hampered by au intelligent endeavour to know and profit by the treasures which this great Babylon contains. In that inimitable piece of portraiture which brings one of the most striking figures of the last century in very life before us

in this, we read that his biographer, having suggested a doubt that if he were to reside in London the exquisite zest with which he relished it in occasional visits might go off, and he might grow tired of it, drew from Johnson the characteristic reply—"Why, sir, you find no man at all intellectual who is willing to leave London. No, sir, when a man is tired of London he is tired of life; for there is in London all that life can afford." You may urge that there is no time for such things. I do not believe it. The man who is always talking about want of time generally wastes the time which he has got. "Men waste half their lives from want of method," said Sir Charles Bell, one of the greatest lights and most accomplished men in our profession. True, the advantages of life in London cannot be enjoyed by the students of every school; but the fountains of literature and the researches of science are open for all. If real culture be helped by a *knowing of the best that has been thought and said in the world*—and this definition we may accept as not very far from right—such culture is not withheld from any man. "A cultivated mind," wrote one of the leaders of thought in his day, "I do not mean that of a philosopher, but any mind to which the fountains of knowledge have been opened, and which has been taught in any tolerable degree to exercise its faculties, finds sources of inexhaustible interest in all that surrounds it—in the objects of nature, the achievements of art, the imaginations of poetry, the incidents of history, the ways of mankind past and present, and their prospects in the future." There is no profession in which a good training of the mind is so likely to be of service as in our own. Brought into contact as we are with all classes and sorts of men, who perhaps have but little sympathy with our calling and our work, how essential it is that our thoughts and feelings should not run always in the one groove of our own pursuits! A cultivated mind will do something more for us even in our special walk in life. It will make us better reasoners on the facts which daily crowd upon us in the investigation of disease; it will make us less selfish, more tolerant and charitable to the opinions of others; there will be less of professional rivalries and jealousy, and less thought of what we do ourselves, only so much as it is in the cause of humanity and truth. Thus endowed, a man may turn from the weariness of life, which must inevitably be his lot, to a sure source of refreshment and purest rest, whether he be toiling amid the busy and sunless gloom of a populous town, or in some remote village where he feels himself friendless and almost banished from the world.

There is, moreover, no isolation in our work. How much of deepest concern to ourselves is of interest to the educated men of every class? The greatest minds of all countries and ages have speculated on the foundations of thought and reason, and on the action of the human brain. Elaborate treatises in many tongues tell of the profound interest which this, the greatest mystery of our being, has always excited in the breast of man. For this age, and for our profession, it seems to have been left to throw some ray of light on this which is most dark and obscure. Careful observation of the results wrought by disease on the human brain, and the marvellous facts revealed by experiments on the brains of animals, are doing something to unravel the problems of thought, and to make clear the functions of the organ of mind. We stand only on the threshold of the inquiry, which none but those of high mental cultivation are fitted to comprehend or carry on. The keenest powers of reasoning are needed to keep us from falling into error, and grasping at the shadow when the substance is yet far off.

Theologians, and those who are familiar with the supernatural and unknown, may lucubrate on the origin of sin; we are more concerned with the origin of life. The last few years have seen a great increment in our knowledge of the sources of disease, and of our control over the many vital elements which combine to set it up. Nothing can be of greater moment to mankind than a solution of the ways in which preventable disease may originate or work. Whether, under certain conditions, the lowest organisms may start spontaneously into being, or all life proceed from life which has gone before, is one of those questions which the best scientific workers of the medical profession, not less than the leading physicists of the day, are labouring to unfold. Among those who deserve the highest praise for the work they have done in these branches of science, what men in our own, or in any country, occupy more foremost places than Ferrier and Hughlings-Jackson, Bastian, Roberts, and Lister? And here let me not forget that the distinguished surgeon whom I have last named to-day enters upon a new and larger field. There is no surgeon in London who cannot well afford to be glad that Professor Lister has became Surgeon to King's College Hospital. It is a sign of the times that now, as it has not always been before, there has been so little ill-feeling and jealousy aroused by his coming. And it is right that it should be so. The work of a wise man seeking after knowledge is not here nor there, but for every country, and through all time.

I have said we must be teachers as well as healers. When, amid the vast changes and revolutions taking place around us, peril has seemed to beset the establishment of the English Church, we have been told of the wondrous influence for good which lies in the presence of an educated gentleman in every parish. No man can be insensible to the zeal of the clergy in their exalted work, but while there are hundreds of homes and families in which they are never seen, there are very few, while misery and disease have mastery, from which the doctor can long be absent. How immeasurably great might be the influence of so widespread a body as our own, if to the full, and in something more than in name, we were worthy to be called an educated profession! The primary truths and laws of physiology which govern health, and the infringement of which brings on disease; an attention to simple sanitary rules, the neglect of which may be dangerous not only to individual households, but also to whole communities; a proper training of the young; a breaking down of the ignorant prejudices which have long combined to make men regard mental disorder as a disgrace to be concealed, rather than as a serious and lamentable disease, calling for treatment in its earliest stages,—these are but a few of the matters concerning which the doctor ought, in the routine of his daily work, to make a deep impress on the people at large. More important even than any one of these is that great social question, the solution of which is a parodox to legislators and divines. It has been pithily said, and I think with truth, you cannot make men sober by Act of Parliament. It may be said with no less truth, you will never make them sober by holding out the rewards of sobriety in this life or the next, or by talking of the pathological horrors to which excess in alcohol gives rise, and of the virtues which are the charm of pure water. There is a moral in the story of the drunkard, who, thinking to cure him of his drunkenness, turned to the Sacred Book for guidance in the right way, and having searched it through, found mention of only one man who had asked for water, and he was in hell. Nor will much lasting good ensue from cutting off the means of evil. Hear the strong and vigorous language of Milton: "Wherefore did God create passions within us, pleasures round about us, but that these, rightly tempered, are the very ingredients of virtue? They are not skilful considerers of human things who imagine to remove sin by removing the matter of sin. . . . . Though ye take from a covetous man all his treasure, he has yet one jewel left, ye cannot bereave him of his covetousness." Drinking and drunkenness are serious maladies which afflict our national life. I have no startling panacea, but I hold they can never be cured unless our people be taught a new habit—the habit of thrift. It is a grievous failing, which lies at the root of this disease, that our poorer classes do not know how to save. The man who has once felt the good effects of putting by something for a future day for himself and his children, will find a healthier eagerness for getting and saving, and will pause before he squanders all his substance in the public-house. Drunkenness is but rarely to be found in those countries whose people know the wisdom of providence. The absence of it in our land may be much fostered by so-called charity; and I am not sure that the lavish and indiscriminate charity, public and private, met with in England is not one of the crying evils of the day. Great ought to be the influence of our profession, for who more than its members have the opportunity of giving encouragement, advice, and sympathy, which many a human creature needs? To do it we must be equal to the task, and our own lives must not fall short of the lofty aims which should be our glory.

We live in times of wide speculative thought, of far-reaching mental activity. On all sides are change and progress—change in ancient views of man's origin and destiny; progress in our knowledge of the immutable laws which govern the universe around. There is a great stir among our hospitals and schools. St. Bartholomew's, with its magnificent scheme for a hospital college, resolved to be, as ever, in the foremost rank; the London Hospital, with its vast size and unrivalled organisation, determined to overcome the disadvantages under which it has seemed to lie from its position in the far east; King's

College Hospital, building new wards, and repairing its loss of the great practical surgeon by calling to it the eminent scientific surgeon who takes his place; University College, Charing-cross, the Westminster Hospitals—all enlarging or renewing their wards, and thereby increasing the attractions to be offered to students, and the good to be done to suffering man. Matter for the earnest consideration of the government of St. Mary's Hospital! If this Hospital is to hold its own in the great struggle which is going on about it, it must fit itself to do the utmost it can for the vast and growing district in which it stands. And no interests of place or power should prevent those who are more intimately concerned in its management from making its organisation as perfect as any to be found.

Would that our Royal Colleges would wake from the slumber which enshrouds them, and do something more for the higher professional education of those who flock to them for a diploma! It is impossible to expect the best teacher in every subject at each one of our many schools in London; and it is mournful that the lecture-rooms of the Colleges of Physicians and Surgeons should be occupied for some two dozen hours only in the whole year, when they might be open to all to hear in them the wisdom and experience of the chief living masters of their art. How many London students are there who have never once entered the splendid museum created by the industry and genius of one great man—simply because there is no systematic means of drawing men to profit by the teachings it contains? The profession has a right to look to its great corporate bodies to do something better for it than elaborate the machinery of examinations.

In the advancement of knowledge there is not one of us who may not play his part. The intricate questions which involve the evolution of disease, and the hereditary influences ever tending to modify it and call it into existence, can only be solved by those who have the opportunity of observing the life-history of whole families. It is not to those only whom custom attaches as surgeons or physicians to a hospital, but to the great body of practitioners throughout the country we must look for light on these subjects. The general practitioner who will exercise a well-trained mind by the careful record of observations in his daily work will find a vast scope for study and reflection, and will confer a great boon upon mankind. You say, I offer you only vague generalities, instead of some striking example of what I mean. Who then, sufficiently burthened, it might seem, with a large general practice, has made a more distinguished name in the ranks of science than the Hunterian Professor of the Royal College of Surgeons, Mr. W. K. Parker?—a man whom all must honour and regard, not less for his brilliant work, than for the noble spirit of humility in which it has been achieved.

Let no man despair because he has not the gift of great talents or abilities, or be cast down that his own light appears dim beside the genius of great men. It is not given to every man to be a Hunter, Brodie, Astley Cooper, or Charles Bell; but it is some consolation to know that no great genius has ever yet been born whose name and fame have not been builded to a large extent on the work of lesser men who have gone before them. "Society has its great men and its little men, as the earth has its mountains and its valleys. . . . The sun illuminates the hills while it is still below the horizon; and truth is discovered by the highest minds a little before it becomes manifest to the multitude. This is the extent of their superiority. They are the first to catch and reflect a light which, without their assistance, must in a short time be visible to those who lie far beneath them."

Let each man do his duty, fearlessly, honestly, and with singleness of purpose. He shall not work in vain. It is an ennobling thought, the solace of some of the wisest and best amongst us, that what we so do here may be consummated and made perfect in the life which hath immortality.

"Foil'd by our fellow-men, depressed, outworn,
We leave the brutal world to take its way;
And *patience! in another life*, we say
The world shall be thrust down, and we up-borne!

"And will not, then, the immortal armies scorn
The world's poor routed leavings? Or will they,
Who fail'd under the heat of this life's day,
Support the fervours of the heavenly morn?

"No, no; the energy of life may be
Kept on after the grave, but not begun!
And he, who flagged not in the earthly strife,

"From strength to strength advancing—only he
His soul well-knit, and all his battles won—
Mounts, and that hardly, to eternal life."

ABSTRACT OF INTRODUCTORY ADDRESS

DELIVERED AT THE OPENING OF ST. THOMAS'S HOSPITAL MEDICAL SCHOOL

By W. W. WAGSTAFFE, B.A., M.B., F.R.C.S., Eng.,
Assistant-Surgeon and Lecturer on Anatomy at the Hospital.

After alluding to the loss the institution had sustained by the death of the late Treasurer, Sir Francis Hicks, and of Mr. R. G. Whitfield, who for more than fifty years had been connected intimately with the School, he referred to the relation of hospitals to schools.

It could not be overlooked that, in the present day, one object in the foundation of a hospital, which, if it existed at all originally, was then a very subsidiary one, had now, by advance of education, become one of its most important functions. Hospitals were not mere almshouses; but, as schools for the education of those who would have to look after the health of the nation, as well as institutions for the skilful care of those whose injuries or diseases required more than ordinary attention, such hospitals as St. Thomas's were specially adapted, and the responsibility of the governing body was associated with one almost as much as with the other. Mr. Wagstaffe addressed a few words of advice to those who had just determined upon beginning their medical studies, and urged beginning well to be more than half the battle. He then addressed all students of all ages upon what they were striving for and what was their chance of success. The first condition of success was to understand clearly what they wanted to do. To some, the accumulation of knowledge for the purpose of satisfying examiners was made the object; but he warned them against this, and condemned cramming. To gain a livelihood was another object, and this was a justifiable one, but, though first in the order of necessity, not the highest. That his profession would give him the means of living there should be no question, for times had changed, and the position of doctors had altered; and so also had that of students. Quoting from Froude, he compared the student of three centuries ago with that of to-day, and referred to the fact of medical science being fashionable, when novelists, ladies, and royal dukes took to writing on medical matters.

The main object of a student's work and life should be Truth. The practical question which followed was, What qualities should be specially cultivated to gain this object? The first was honesty—honesty in using the means in his power to prove the truth of a statement when it was provable. There were a thousand-and-one supposed facts he would have to swallow as a student, and to disgorge as he grew older and wiser; but there were ten-thousand-and-one facts laid before him of which he could prove the truth or falsity if he liked to use his senses. Incomplete or mis- statements, false theories, half-truths due to the want of honest observation and judgment, were often more pernicious than whole untruths, for they attracted less attention at first, and blended and grew into gross unrealities. Carefulness was insisted on as an essential. A truth had to be looked at on all sides, to be tested in a variety of ways; and the exercise of caution might prevent him finding many mare's nests, might save him trumpeting imaginary discoveries and worrying the literary world to no purpose. There was already too much literature for any man to read honestly; and too often he ran the risk of becoming a literary sewer, much rubbish passing through him, and very little sticking. Perseverance was the third essential. What Dr. Arnold said of boys was equally true of men: that the difference between any two consisted not so much in talent as in industry. Few modern biographies showed better what perseverance was than that of Thomas Edward, the naturalist; and if such a man regretted his lost opportunities, how much more must anyone who has wilfully wasted them have occasion to condemn himself? And who could tell how far others might be injured by his ignorance? Courage was the last, but not the least important quality—courage in himself and in his own opinions when honestly worked out. John Hunter had said: "Is there any whom difficulties dishearten, who bends to the storm? He will do little. Is there one who *will* conquer? That man never fails." Nowadays, difficulties were much smoothed down; facilities for education were provided; and the fear was, that self-dependence was endangered.

Mr. Wagstaffe then cautioned students against the excesses or perversions of these qualities—against coarseness, want of

consideration, and brusqueness. "And," he said, "particularly steer clear of that disbelief which apes originality. You are seeking the truth in things attainable. There are many things of which the proof lies far away, and only comes from patient, long-continued search,—things made a part of ourselves by being worked into our mind from childhood's earliest time. As time goes on, and Reason tries to grasp what Memory has received, she often fails to seize the whole. But, if some part of what tradition holds is false, and much perchance is hard to prove, why cast away the whole and disbelieve in all tradition and authority?" The importance of personal influence was then adverted to. Few realised this, and few recognised how many a light word blossomed for good or evil when least expected. Our stray words and thoughts were not lost.

"Being rooted like trees in one place,
Our brain-foliage tossed
Like the leaves of the trees that are caught
By the four winds of heaven, some thought
Blown out of the world into space
And seems lost.
Being fallen like trees in one place,
Hid, buried, embossed,
Our dead leaves are raked up for mould;
But some that are sunbright and gold,
Blown out of the world into space,
Are not lost.

In conclusion, he trusted that, when their sunset was come, they might be able to say like Thierry in his last moments, "There is something in the world better than sensual enjoyment, better than fortune, better than health itself; it is devotion to knowledge, it is devotion to truth."

ABSTRACT OF INTRODUCTORY ADDRESS

DELIVERED AT THE OPENING OF UNIVERSITY COLLEGE MEDICAL SCHOOL

By JOHN WILLIAMS, M.D. Lond., M.R.C.P.,
Assistant Obstetric Physician to the Hospital.

During recent years the progress of medical science has been great and rapid. This has been the case in all departments of medicine. It is seen in the invention of new instruments for scientific and clinical investigation, in the discovery of new remedies, in the enunciation of pathological laws, in the perfection of the art of surgery, in a more intimate knowledge of the natural history of disease, and in the development of hygienic and preventive medicine. At first sight it may seem that progress has been greater in the art of surgery than in the sciences into which medicine is divided; but this is only apparent. The progress of surgery has not surpassed that of medicine. To appreciate this the present should be compared with the past. Medicine has now entered upon its ultimate phase, and has assumed a preventive character. Gynæcology has not, in this respect, kept pace with general medicine; and yet it has made great progress.

No apology is needed for making gynæcology the subject of an introductory address, for it now takes rank with medicine and surgery as a branch of special study. It is of the greatest importance in practice, and its bearing on certain social questions which at present agitate the public mind is such that, in the future, it must command greater attention than it has received in the past.

The ancients held curious views with regard to the female organs of generation, and some of the theories invented by them to explain certain phenomena were simply absurd. No progress was made in the study of gynæcology until long after the revival of anatomy in the fifteenth century. The muscular structure of the uterus was unknown until Sartorini asserted it in the beginning of the eighteenth century. Harvey was ignorant of the existence of the mammalian ovary, though he recognised in the fœtus and its membranes a true ovum. His views with regard to the formation of the ovum, however, were purely fanciful, for he thought it was formed from the juices secreted by the uterine cotyledons, which became swollen after intercourse.

The ovarian follicles were observed by Vesalius, and Van Horne called them "ova," while De Graäf gave the first full description of them, and with Van Horne regarded them as ova. There were great objections to this view—some of them insuperable, and in consequence Hahn stated that the ovum was formed in the Fallopian tube from the expelled contents of the Graäfian follicles. This view was accepted until the end of the last century. William Cruikshank published the results of his experiments confirming De Graäf's theory in 1797. The ovum was discovered by Baer in 1827, but his error with regard to it was dissipated in 1834-35, only when Coste, Wharton Jones, and Rudolph Wagner discovered and described the feminal vesicle and spot.

In 1821 Dr. John Power enunciated the law of spontaneous discharge of ova. His conclusions were drawn partly from analogy, partly from observations made on the humane female. His observations were, however, scanty; but ample proof of the laws was supplied during the twenty years following the publication of Power's book by the researches of Girdwood, Seguin, Bischoff, Raciborski, and others. At the same time, the view that the functions of the uterus are dependent on the growth and rupture of a Graäfian follicle was promulgated. This was strenuously opposed by Ritchie, but it became generally accepted, and was received until the last few years, when the evidence against it has accumulated so that it can no longer be maintained. Moreover, much evidence has been brought to light to prove the independence of the uterine functions not only of the growth of ovarian follieles, but also of ovarian influence.

Changes in the mucous membrane of the uterus were first noticed during pregnancy. William Hunter described the decidua accurately. His brother, John Hunter, soon afterwards described it as an exudation of plastic lymph. The latter view was accepted and taught until Hartz and Weber discovered the true nature of the decidua, and demonstrated its histological structure. The changes in the uterus during menstruation were comparatively unknown until within the last few years. It has been shown that they consist not in a congestion, but in a periodical development and removal by disintegration of a decidual lining.

The views maintained with regard to uterine pathology were briefly sketched, and it was pointed out that in the formation of such views too little regard had been had to the physiology of the organs of generation.

Pathology should be based in great part on physiology; and it is by increasing our knowledge of physiology that we may extend and widen our pathological doctrines. These inquiries, moreover, have a direct bearing on the employment of women. The latter question cannot be decided by prejudice nor yet by the intellectual caprice of a few experimenters in moral and social science. The problem must be solved on physiological and pathological grounds. Uterine disease is in great part the penalty of a high civilisation. It is by a knowledge of its causes and their mode of action that we can hope to arrest disease, and make gynæcology a preventive science.

Dr. Williams concluded by welcoming his hearers to University College, and with an exhortation to hard work.

ABSTRACT OF INTRODUCTORY ADDRESS

DELIVERED AT THE OPENING OF MIDDLESEX HOSPITAL MEDICAL SCHOOL

By ARTHUR HENSMAN, M.R.C.S. Eng.,
Lecturer on Botany and Comparative Anatomy at the School.

The lecturer, Mr. Arthur Hensman, commenced with a short review of the early history of the Hospital and its Medical School. In speaking of the ceremony which took place on May 15, 1755, when the Earl of Northumberland laid the first stone of the new Hospital, he said:—

"That stone, history informs us, was being laid while a fierce thunderstorm raged over London, and the painting by Pine in the Board-room depicting the ceremony truly represents this; but the painter, with that suggestive genius belonging to his art, has, I see, introduced into his work a distant gleam of sunshine, fit emblem of the light of that skill and the warmth of that charity which ever characterise the noble profession you are entering to-day, and which we know has not been lacking in those who for more than a century have manfully striven within these walls to dispel the darkness of sin and the gloom of human misery and suffering. The names of Handel, the composer, and of David Garrick, the actor, were mentioned by the lecturer, both having closely identified themselves with the Hospital as its benefactors." Alluding to the address which the medical officers presented to the Governors, urging the formation of a medical school, to which, among other names, were attached those of Thomas Watson

and Charles Bell, he said—"But these names must suggest memories of the past, and to those of us who are youngest become

"'A link among the days to knit
The generations each with each.'"

After a graceful allusion to the death of Sir Charles Bell's widow, and an expression of the pleasure it gave to be able to speak of Sir Thomas Watson as still able and willing to attract by the charm of his writing and the weight of his long experience, Mr. Hensman said—"I need trace no further this meagre outline, but I will remind you that until a comparatively recent period science was nowhere systematically taught, if we except the medical schools. The older universities, unable to embrace these new wants, the birth of a new era, clung to the old traditional method of teaching, and only now are beginning heartily to recognise the real value of natural science as a branch of general education and culture. We should all remember that it is to the long-continued efforts of men of science imbued with the pure spirit of research that we owe in large measure our advance in civilisation and our greatness as a nation. While the medical schools have grown up as necessary offshoots of those charitable institutions which everywhere mark the progress of a civilised people, having been created for the education of a special class of the community, we must never forget that they have had a still wider influence and use, for have they not found fitting employment for the energies of many who in their own departments stand in the foremost rank of scientific investigators? The scientific discoverer must ever lead the way; applied science, coming after, takes up the thread of discovery, and, once guided into a useful channel, industries are created and commerce spreads." Illustrations of this order of evolution were exemplified by the discoveries of the properties of steam and its application as a motive power. The spectroscope was shown by the speaker to have its origin in the early researches of Sir Isaac Newton, followed later by those of Wollaston and Frauenhoffer. Chemistry in this connexion was referred to as a science exercising a kind of creative power over the elements, setting them free or cementing them into new relations, and as an art vital to the right progress and development of manufacturing industry. He might weary his hearers, he said, with illustrations all tending to show how the purely scientific workers often supplied the material which later on others had utilised. Great discoveries were not made at a leap; they came slowly, after years of patient labour. In speaking of anatomy the lecturer said this must ever remain one of the great central subjects of medical study—like the keystone of the arch, touching both halves of their work, medicine on the one hand, surgery on the other, and fitly crowning the span of their knowledge; for without it neither side could stand secure. All that by their skill as dissectors they could demonstrate and verify was valuable; much of the knowledge they gained by reading alone was useless. The difference between seeing a thing and reading about it was not to be measured. The knowledge gained by the one method was practical and lasting; that gained by the other was theoretical and fleeting. Therefore he urged them to work diligently in the dissecting-room, for, though they would forget much, they would learn more, and if they did not become accomplished anatomists he promised them they would have learnt enough to make them cautious hereafter. "Remember," he said, "while you dissect you are gaining habits of observation, you are training the eye and you are educating the hand. The value of sketching in outline will assist you much in your work; you should, if possible, sketch all you see under the microscope and make outline drawings of your dissections. The art of drawing, I believe, may be a great aid to a medical man throughout his whole professional career. A careful drawing of a well-prepared dissection or a microscopical preparation may save hours of book-drudgery, and must lead to clear and accurate ideas. To the busy practitioner a rapid sketch of a morbid growth or the mere outline of a diseased limb may convey to the mind more than pages of careful notes. Drawing may be said pre-eminently to cultivate the eye as to form, size, and relation, and it certainly educates the touch in a manner scarcely second to the use of the scalpel in the dissecting-room. When it is remembered that in many surgical operations the knife is carried in curves or in straight lines, surely it must be some satisfaction to the surgeon to feel that his eye has been previously educated in these things, and will safely guide his hand." The address concluded as follows:—"Contrasting our own profession—the profession of medicine—with the other so-called learned professions, it must be obvious, I think, to all of you that while the faculties and powers of the mind are exercised alike in all, the special cultivation of the senses is necessary in ours alone. Those senses, which are the avenues through which alone a knowledge of the outer world flows into and becomes a part of our higher being, must be taught to do their work as highly trained and willing assistants. We should endeavour, then, to educate our senses, for their capabilities are great. As the blind man acquires a touch surpassing our experience, so should we strive to develope these half-expanded powers. I have often thought that John Hunter owed much of his great fame to the manual skill he gained as a cabinet-maker. Bear in mind that, although the skill of the optician gained for us a new realm outside the range of unaided vision when he constructed the microscope, yet to see aright the eye must have a special training. The murmurs of respiration, or the rush and reflex of the blood as it flows through the great centre of the circulation, are heard to no better purpose by the use of the stethoscope if the ear be untutored. While we extend the sweep of our knowledge by means of the microscope, the ophthalmoscope, and the thermometer, let us watch lest our own organs of perception—best instruments of all, created by an Eternal Will, and step by step evolved through lower forms towards perfection—be unequal to the requirements of these higher duties. Every side of the intellect must be trained, every right capacity of the body must be developed, if we would work to good purpose. Those higher faculties and nobler aspirations which express the moral side of our nature can never flag if the object and the end be so good. Remembering the history of the past, it requires, I think, no prophet to predict in what direction we may hopefully look for advance in the future. We should ever remind ourselves that cause and effect work out their end with untiring round for good as well as for evil; and a wiser generation, more in harmony, because more fully understanding the laws which govern men and the world on which they exist, will better escape those ills which surround us to-day."

ABSTRACT OF INTRODUCTORY ADDRESS

DELIVERED AT THE OPENING OF THE LEEDS SCHOOL OF MEDICINE

By JOHN A. NUNNELEY, M.B. Lond., etc.,
Lecturer on Anatomy, and Senior Ophthalmic and Aural Surgeon to the General Infirmary at Leeds.

After referring to the appropriate opportunity presented by an introductory address for bringing all interested together and for taking a preliminary survey of the commencing session, and expressing the responsibility he felt at offering, in the name of the Council, the official welcome at the opening of the forty-seventh session of the Leeds School of Medicine, the lecturer proceeded to address the students, both old and new. "To the latter, those who now make their appearance in this lecture room for the first time to-day," he said, "let not the difficulties which you will at first inevitably encounter on the threshold of this, as of every other profession, dismay you, nor induce you to turn in disappointment from subjects which must seem to you, in the first instance, incomprehensible, because you find that those who sit on the same benches with you have no difficulty about them; rather remember, and be comforted by the remembrance, that only a very short time ago they were in the same position as that in which you now find yourselves. Let this prove to you that steady industry and perseverance will meet with their usual reward—success."

"To you, then, gentlemen, who to-day make your entry into the profession of medicine, I shall mainly direct the few remarks I have to make, as I believe by so doing I shall best fulfil the purpose for which an introductory address like the present is designed.

"I propose shortly to offer you such advice on a few points as my own experience and observation of students leads me to think may not be without some little use in directing you as to the best means of acquiring and utilising the knowledge necessary to enable you to qualify yourselves as reliable medical men; for the extent and variety of the subjects that will be placed before you as the objects of your future study is so great, and is moreover yearly increasing, and the time which with most of you is available for their acquirement is so short, that the beginner is likely enough to be oppressed

with a feeling of perplexity and discouragement. There is no reason for this—but you must expect to find that the study of medicine is now, as it has always been, a laborious business, when compared with the course necessary to obtain entrance into other professions; and it is certainly likely to become each year more and more laborious, for, thanks to the General Medical Council, many of the defects in the curricula of the various licensing bodies have been exposed, and consequently removed, and these are now much more in accordance with modern scientific knowledge than they were a few years ago: the natural result is, that the requirements have become much more extensive, and the examinations more searching and comprehensive than was the case formerly, and it is now hopeless for anyone to expect to qualify himself without earnest and thorough work." The lecturer next proceeded to speak of the great improvement in the general education of the student of medicine during the last few years, and the necessity for even farther progress in this direction; and quoting Mr. Spencer Wells' opinion on this matter as expressed in his late address before the British Medical Association at Manchester—"the surgeons of the future must be educated gentlemen, and we should so order our schemes of education as to bring into the profession, as far as possible, young men who have had the advantage of the highest general culture to be obtained by an English education,"—he then passed on to insist on the necessity for method and thoroughness in the student's work, and, discussing the value of lectures as a means of learning, and the different opinions held on this subject, said: "No doubt there are portions of every branch of learning which can be more easily and completely learnt from books by each student privately than in this room, and, of course, allowances must be made for individual differences and capacities, but altogether I am satisfied that if a due proportion of tutorial instruction and supervision be combined with it, the system of lecturing, as now required by the examining boards, offers, on the whole, greater advantages than any other method of learning, and a proper amount of private reading being superadded, enables a student to gain a knowledge of a profession like ours as readily and pleasantly as it is possible to do. The great business of your first winter session will be to master the main outlines of anatomy and physiology, especially the former; and you will also have to devote a certain amount of time to chemistry. You will probably not be required to attend more than three lectures in a day—usually I believe not more than two, of which one will generally be on anatomy. And I am sure that I shall not be contradicted when I say that if there be one subject which demands more time and attention than others, it is anatomy; for indeed this, with its dependants physiology and pathology, must form the foundation of your knowledge of medicine and surgery: upon it your entire medical education will have to be constructed. It is a subject, too, which must be mastered early in your career; later, the 'romantic region' of the hospital will to many prove more attractive than the dissecting-room, and in the dissecting-room a large part of every day must be spent. And recollect, once for all, anatomy can be learnt nowhere else than in the dissecting-room; books and slates are a help, a great help, but nothing more." Next referring to physiology and pathology—"The vast advances made in these sciences, and in microscopic and experimental research, have undoubtedly been mainly instrumental in causing the remarkable progress which medicine and surgery have made of late years, and have done much to establish them upon a sure and scientific foundation. The area, however, of chemistry is so vast, that it is not possible for a student to obtain a knowledge of the whole; nor, so far as chemistry, at any rate, is concerned, is it necessary for the purposes of medicine simply that he should do so. It seems, therefore, exceedingly desirable that the examining boards should within certain limits define their requirements on these subjects, as recommended by the Medical Council, in order that the time of the medical student, far too short already, may not be occupied with what is unnecessary or not practically useful." On the subject of the amount of time which it is desirable for a first year's student to devote to hospital work, Mr. Nunneley remarked—"No doubt the attractions of the hospital are very great, and some men may be tempted to spend too much time in the wards and out-patient room, to the neglect of their proper work; but, on the other hand, I certainly hold that the opposite course of neglecting hospital work wholly during the first winter session is equally a mistake for most students. Those who intend to spend some years at this or other hospitals, as well as those who are preparing for the University of London, may advantageously postpone their hospital work, and give their whole time to elementary subjects; but, with these exceptions, I think everyone should attend the surgical practice of the hospital regularly, even during his first session, especially as apprenticeship to some busy practitioner, where much practical knowledge was obtained, is not by any means so general as it formerly was. It therefore becomes all the more essential that every opportunity for practical work at the bed-side side, and especially perhaps among the minor ailments in the out-patient room, should be sought. Besides, just as an apprentice to any trade gains by practice facility in the use of the appropriate tools, you must train your eyes, your hands, indeed all your senses. More than this—and it is of even greater importance to your future career—you should gain the knowledge of how to deal with patients, and so to obtain that mental control over them, that tact, without which all your skill may often avail you little."

Speaking of hospital practice, the lecturer dwelt on the necessity of working out cases thoroughly. "One case thoroughly worked out is of far more value than twenty only half mastered: the one case, so far as it goes, at any rate, will guide you aright; the twenty are likely enough to mislead you. While on this subject, let me warn you against an error into which I notice some students are liable to fall—viz., of running after great cases only, and neglecting the minor ones. This is a serious mistake; for, let me remind you, the lesser ailments are those which you will far the most frequently have to deal with in your after-life, and it is a perfect knowledge of these, therefore, which for a young man is of the most consequence. I fancy also some students devote themselves too exclusively to the surgical wards, neglecting somewhat the medical ones. This is an error, the more important nowadays on account of the many instruments tending to precision in diagnosis which are now used by the physician, and a knowledge of which is indispensable."

After insisting on the importance of note-taking in the wards as a valuable means of training the powers of observation and impressing the cases on the memory, and the use which a well-recorded set of hospital cases would be found in after-life, the lecturer said:—"Among the matters which are occupying and interesting the mind of the profession at present, and which cannot be without some importance to you as future members of it, is the question of admission of women to medical degrees in England. Most of the difficulties which have prevented more than a very few women from complying with the requirements of the licensing bodies and obtaining a place upon the Register are being smoothed away; and there can be no doubt that the decision of the Senate of the University of London to provide a modified curriculum and examination, and to admit women at once to medical degrees, will, if carried out, as seems likely, give great impetus to the movement. This step on the part of the Senate, however, is opposed by Convocation as an infringement of the privileges of that body and contrary to the constitution of the University, and by the great body of the medical graduates, because, as Dr. Barnes has said, 'it is a fundamental principle of the University that its degrees imply full and equal knowledge in all departments'—a principle which certainly could not be carried out in the modified course proposed, because of the impossibility of women obtaining the same professional instruction as men. We should, of course, all agree that if a new sphere of employment could be found for the large number of well-educated women who are now barely able to earn a living by teaching, etc., it would be a most desirable thing. But then comes the question, Is the practice of a profession like ours a proper vocation for women, and one which they would be likely to pursue successfully? Perhaps this question, time only can fully solve; but one thing is certain, that if it is to be decided in any degree affirmatively, it is absolutely essential that women should receive a medical education equally thorough with men upon the same examinations. 'This (I again quote Dr. Barnes) seems impossible, so long as men and women retain the physical and mental attributes which have distinguished the sexes from the time of the Creation.' From ordinary general practice, as well as from nearly all appointments, the medical woman must of course by circumstances be cut off, as also from any position involving the charge of a mixed population. She must of necessity almost be confined to large towns, as a special consulting practitioner among women and children; and here no doubt a few with unusual ability and determination may succeed, but their

number can never in all probability be large, and will not take any great share in satisfactorily removing the difficulty of finding occupation for ordinary women. And although we, I think in common with most men, both medical and others, believe that of all professions that of medicine is the one least fitted for women, such a feeling will not, I am sure, prevent us from welcoming the few whose talents and energy enable them to enter our ranks.

"In conclusion, gentlemen, I have said something to you of the work which you must undergo to fit yourselves for the noble calling which you have chosen. What is the return for this work which you may fairly look forward to? With ordinary ability, industry, and determination there is no profession in which you may so certainly expect a moderate independence—but not more; its prizes with reference to honours or public distinctions are few; your greater and more lasting return will be the gratitude of your patients, and the satisfaction of your own conscience. In order to obtain these, you must realise the responsibility of what you are undertaking. To your hands will be committed vast opportunity of doing either good or evil, for no man is so universally trusted as the doctor. Medical men are truly under the heaviest burden of responsibility that it is possible for men to be placed under: the patient resigns himself wholly into his medical adviser's hands; his—the patient's—future comfort, his very life, may depend upon the way in which this unbounded confidence is met. The manner in which you will be able to discharge this great responsibility, and the character of your whole future career, will depend upon the advantage which you take of the great facilities for acquiring a competent knowledge of your profession which will be offered to you here. Should you fail to obtain this now, the opportunity can never return."

ABSTRACT OF INTRODUCTORY ADDRESS

DELIVERED AT THE OPENING OF THE SHEFFIELD SCHOOL OF MEDICINE

By HENRY FRENCH BANHAM, M.A., M.B.,

Lecturer on Medicine at the School.

After a few preliminary remarks, Dr. Banham congratulated the students upon their choice of a profession, assuring them that they would not be likely to regret that choice if they were able to endure the inevitable hardships which it involved. He proceeded to enlarge upon the value of a preliminary training, even in cases where it had not been of a scientific character. "Indeed," said he, "not only are you not the worse for a training specifically different from the scientific work which henceforth is to be your chief business, but you are distinctly the better."

He then made some reference to the interdependence of all branches of knowledge, and showed the necessary truth of the seeming paradox that a man must know many things before he can thoroughly know one.

He next explained to them that whether fitted for their work by unusual intellectual powers, or by a suitable preparatory training, the all-important work for them was the practical study of disease—a study which must be supplemented, but could not be superseded, by the theoretical study of books. "The knowledge required," he said, "is not simply that bookish knowledge which enables you to describe a disease, but that practical knowledge which enables you to detect it—a knowledge gained at the bedside of your patient, requiring for its development trained eyes, trained ears, and trained fingers."

He proceeded to give a detailed account of the manner in which they should prosecute the practical study of medicine, quoting Lord Bacon's dicta on the necessity for the removal of all the idols of prejudice or authority from their minds, in order that an accurate observation may lay the foundation for a useful induction. Here, in illustration, he traced the changes in medical fashion by which the cupping and drenching custom of one age had revolted the common sense of the next, only to give place to an authorised but excessive stimulation by inordinate doses of alcohol.

A feeling allusion was then made to the loss that the School had sustained in the removal by death of two of the most accomplished members of its educational staff—Dr. J. C. Hall, one of the Lecturers in Medicine, and Physician to the Public Hospital and Dispensary; and Mr. Samuel Parker, one of the Lecturers on Surgery, and a Surgeon at the Infirmary.

A few remarks were then directed to those students who were about to leave the School and enter upon the responsible duties of medical practice, and special reference was made to the department of preventive medicine, to which so much of their attention would have to be directed.

He urged them to perform earnestly and faithfully their duties, remembering that it was not for themselves alone they toiled, but for the world around, needlessly wasted by sickness and death.

ORIGINAL COMMUNICATIONS.

NEURALGIA AND ITS TREATMENT.

By EVAN MARLETT BODDY, F.R.C.S., etc.

So many authorities are at variance regarding the treatment of this painful debilitating affection, that a few remarks on it will not be superfluous; for it is a malady which up to the present time has resisted nearly every remedy, so that it is considered by many as incurable. Indeed, so perplexing and unsatisfactory has its treatment been to the profession, that we can hardly find two authors of the same opinion, each having his own favourite remedy or specific, of course advocating it in preference to any other, and endeavouring to prove its superior excellence by advancing certain hypotheses; so that many are at a complete loss what drugs should be employed in its treatment.

Some, for instance, advocate aconitine; others chloroform. The valerianate and the hydrochlorate of ammonia are considered by many to be of marked efficacy. The latter drug is advocated by Dr. Hawkes Tanner, who advises its administration in drachm doses during the paroxysm. Dr. Aitken asserts that "the remedies of most value are the diffusible stimulants." Dr. Radcliffe is in favour of the hypophosphite of soda. Wood, of Edinburgh, introduced the hypodermic injection of morphia; but as regards giving permanent relief, this operation is futile; besides, it is apt to act injuriously on the cranial contents. Of late, croton hydral has been tried and found of none effect, though it was considered at first to be a specific. In fact, many other supposed remedies could be mentioned, but the enumeration of them would be useless.

In France and Germany there is the same variety and divergence of opinion as there is in our own country. Monsieur Gubler, in the *Journal de Thérapeutique*, asserts that aconitine may be looked upon as a specific in what is sometimes called facial neuralgia, but that it is useless in its other forms. Trousseau recommends a compress steeped in a solution of the sulphate of atropine. Niemeyer believes in electricity, and devotes several pages of his book to prove its superiority over all other remedies. Thus we see in England, France, and Germany, the treatment of neuralgia is a disputed point.

The origin of neuralgia is comparatively obscure, many authors ascribing it to certain lesions or local derangements. Dr. Hawkes Tanner affirms that it may arise from decayed teeth; which Sir Benjamin Brodie denies, and I think with truth. Others, for instance, say it may arise from diseased bone, or from a tumour pressing on a nerve, or from a syphilitic taint. I think that pain arising from these lesions, though simulating neuralgia, cannot justly be termed so, for the pain is nothing more than a symptom originating from some local derangement, which is remedied by surgical treatment alone. It is true that Niemeyer and others affirm that pain extending along the course of a nerve must of necessity be neuralgia, leaving the origin of it altogether out of consideration; but I hold that such is not the case, for how can we correctly term symptoms which are dependent on different causes to be one and the same disease?

If we accept the theory that neuralgia arises from some local lesion, it cannot possibly be cured by any therapeutic agent, for if a decayed tooth is the cause, the extraction of it gives relief; medicine we well know in such a case is useless. Supposing, as some authors say, it arises from diseased bone, the removal of it effects a cure generally; the administration of medicine is of no avail. Therefore I decidedly think that we are in error when we call so many different lesions neuralgia, for pain arising from a decayed tooth can be no other than simple toothache, and pain arising from diseased bone is what one may naturally expect from such a lesion. In my opinion, neuralgia is pain devolving on some obscure lesion of a nerve, unaccompanied by any local derangement. If this theory is correct, it is certainly amenable to medical treatment; but if we conclude that toothache is neuralgia, and that it may

also arise from diseased bone, we make the cure devolve upon surgical, and not medical means.

The most common form of neuralgia, which is usually called facial neuralgia, is that arising from some obscure irritation of the fifth pair of nerves, or from some inflammation of its neurilemma, giving rise to a lancinating and excruciating pain occurring at certain intervals, though I have known some cases where it has been continual.

Romberg, somewhat quaintly, though poetically, designates the pain of neuralgia as "the prayer of a nerve for healthy blood," thus making this affection arise from an impure and weakened condition of the whole system.

The following appears to me to be a true definition of neuralgia—*i.e.*, pain occurring in paroxysms arising from some obscure lesion of the fifth pair of nerves, accompanied sometimes by nocturnal exacerbations, and generally affecting one side of the face. This definition appears to me to be of some utility, for it enables us to diagnose it from neuralgic pain arising from some local lesion, which I hold is not real neuralgia, for I decidedly think that pain originating from carious teeth, etc., is nothing but a false or spurious variety.

We must now direct our attention to the treatment, and we must do so more particularly on account of so many conflicting opinions regarding it.

As neuralgia occurs in paroxysms, and periodically, and as we are cognisant of the fact that it is very often accompanied in the female sex by some uterine disturbance, and that in some instances it is dependent upon debility and anæmia: antiperiodics combined with sedatives must be administered in conjunction with tonics. Now, if we accept the several theories which owe their origin to the authorities I have quoted, such treatment would not be of the slightest avail. What medicine, for instance, would cure toothache, or even assuage its agony permanently? What drug can we administer to eradicate the pain consequent upon the pressure exercised on a nerve by the presence of a tumour? We may alleviate the suffering, but we are perfectly powerless as regards its curability medicinally. If we give to a patient, suffering from what I nuncupate false or spurious neuralgia, any amount of sudorifics and antiperiodics, we modify the pain, but there we stop; for when we omit their administration the pain instantly returns, and the patient is as bad as before. I cannot, therefore, help thinking that, as we are often prone to confound false or spurious neuralgia with definite neuralgia, we may account for the variety of treatment advocated; as the former kind invariably requires surgical aid, and the latter I know from experience is amenable to medical treatment.

Dr. Elliotson says that "in all cases of neuralgia, whether exquisite or not, unaccompanied by inflammation or evident existing cause, iron is the best remedy." This method of treatment is not to be depended on, the process of cure being very slow and uncertain. Another reason which demonstrates its comparative uselessness in the majority of cases is that the pain is sudden, severe, and excruciating, and the sufferer demands and requires immediate relief; and iron, however good it may be as an adjunct, is altogether powerless in relieving pain. To soothe the pain and to arrest its intermittent attacks must be our first endeavour; and when that is accomplished we may then direct our attention towards improving the general health.

If we merely administer a sedative, the relief is only temporary; if we give an antiperiodic, some period of time must elapse before the drug can take effect; consequently, if the two are combined, we give instant and permanent relief—that is, if the patient is suffering from definite neuralgia; if afflicted with a spurious form, the aid of a surgeon is required.

The question now arises, What two drugs can we combine? whether the combination is compatible, and whether the administration should precede or succeed a meal? If possible, the patient should endeavour to eat a full one; if unable to do so, *some* food at any rate should be in the stomach previously, to obviate any chances of injury to the coats of that viscus.

The most efficacious antiperiodic we can employ is the arsenical solution, and the sedative which should be combined with it is the tincture of opium. By so doing we alleviate the pain, and prevent its recurrence. As regards the compatibility of these two drugs, a flocculent sediment is precipitated if the mixture is kept for any length of time. Supposing the tincture of opium is impure, the same flocculent sediment is precipitated almost immediately. This decomposition does not detract from the efficacy of the remedy.

The reason why the administration should take place after a meal is obvious, for symptoms of arsenical poisoning are very liable to show themselves if the remedy is taken on an empty stomach.

I have employed this remedy in every case which I have had under my care, and the results have been such as to make me consider it as a specific in all cases of facial or definite neuralgia.

Camberwell-road.

THE TREATMENT OF DIPHTHERIA.

By W. R. MACDONALD, M.D., M.R.C.S.,
Medical Officer of Health, and late Resident Physician of the Ayr Fever Hospital and Dispensary, Ayr; etc.

Diphtheria, with its insidious approach, its prostrating effects, and its often sudden and fatal termination, holds a high place in the records of the causes of mortality. Its great fatality seems to point to the inefficacy of the treatment which is still employed by many; and therefore the experience of a treatment which seems to be almost, if not altogether, a specific for this disease, will, I have no doubt, be acceptable to the profession.

In the month of May, 1868, I was called to see a boy about six years of age, and found him in bed complaining of a slight pain in the throat, headache, and pain in the limbs, with great weakness. His pulse was weak and above 100, his tongue slightly furred, and his appetite gone. On examining the throat, I observed the tonsils congested, and a whitish spot about the size of a threepenny-piece on the upper part of the right tonsil. From these symptoms I concluded that I had to deal with a case of diphtheria; and not having any confidence in the ordinary treatment of this disease, I prescribed a mixture which I had previously employed in cases of tousillitis and scarlatina with very good results, consisting of potass. chlorat. gr. lx., tinct. ferri mur. ʒij., aquæ ʒiv.

Of this mixture I gave a teaspoonful every two hours, with a diet of farinaceous food—eggs, beef-tea, and milk, *ad libitum*. On examining the throat, about six hours after, there was no increase in the severity of the symptoms, and I strictly enjoined the continuing of the same treatment during the night. On calling next day, the general symptoms were improved; the spot was no larger, and was thinner in appearance. On the third day the pulse was 96, the tongue cleaner, appetite better, and the spot about half its previous size. On the fourth day I found the patient sitting up in bed; the spot had completely disappeared from the tonsil, and he was complaining of nothing but weakness, from which he steadily and speedily recovered.

Not long after, I was called, in consultation with another practitioner, to see a gentleman, whose child had died of diphtheria. His throat was considerably congested, and there was slight pain, with great depression of the system, but no spots on the tonsils. I prescribed the same mixture, and the symptoms at once began to subside; and in three days he was almost quite well. In two weeks one of the daughters of this gentleman was seized with the disease, and I was asked to undertake the treatment. I found her suffering from slight pain in the throat, which was congested, and showed two spots on the right tonsil, and a small one on the left; also headache and pain in the limbs and back, with great depression of the system. The same medicine was prescribed, with a similar diet; and on the fourth day the spots had disappeared, and speedy recovery followed, as in the previous case.

About the same time, a gentleman who had attended the funeral of a child that had died of diphtheria was seized with sore throat, and consulted me. There was considerable congestion of the tonsils, but no spots, so that after a few doses of the medicine the symptoms were allayed and he continued at his employment. Three days after this, when driving on a cold night, he felt a pain in the throat, and had an attack of shivering. On getting home he took a dose of castor oil on his own responsibility, thinking he had an ordinary cold. During the night I was called to see him, and found him in a very prostrate condition. His pulse was 104, weak; he complained of pain in the head, throat, limbs, and back, and on his congested tonsils there were several characteristic spots. I prescribed the mixture every two hours, but it was taken oftener on account of the relief experienced after each dose. The next day there was still great congestion of the throat, with a tongue slightly swollen and much furred; also slight delirium; but the spots had not increased. Egg-flip, with a few teaspoonfuls of sherry, was prescribed every two hours. On the following day the symptoms were much abated, and the dose of the medicine was gradually reduced, while the recovery progressed as in

the other cases. All the family, consisting of five children, took the disease successively, the youngest being nine months old; and all recovered with the same medicine. In a few of the cases I used a local application of a weak solution of nitrate of silver; but I gave this up, and found that they got on quite as well, if not better, without it.

Since the first case described, I have treated sixty-five with this medicine, only one of which had a fatal termination, and this under exceptional circumstances. It was a child about eight months of age, the last of three, two others having just died of diphtheria. The child had the peculiar metallic cough, but no expectoration. There was a discharge from the nostrils, with whitish spots on the throat and pharynx, and difficulty in swallowing. There was some delay in getting the medicine, as the patient resided a good way in the country. Notwithstanding, there was considerable improvement after getting the medicine, and the case progressed favourably for about eight days, the spots disappearing from the throat. On the eighth night, when the bitter blast of January was raging without, the child was placed near the window in its cradle, where it was exposed to a draught of cold air between the window and the fire. Next morning the submaxillary glands were much swollen, and the whitish membrane reappeared on the throat, and seemed to be further down the air-passages. The child became comatose, and died on the third day after the relapse, or the eleventh day after being under treatment.

In most of the cases I prescribe the first three or four doses of this medicine every half-hour, and every two hours afterwards, till the spots have disappeared from the throat, when it is gradually reduced to a teaspoonful three times a day, at which it is continued till the patient's strength is restored. The depressing and exhausting nature of the diphtheric poison renders the administration of stimulants and nutritious fluids necessary; of these I have found the best to be sherry and eggs, or brandy and milk, at such intervals as the urgency of the case may require. In medicine, it has been said that the most useful knowledge is the knowledge of what not to do. Be this as it may, it certainly holds good in the treatment of diphtheria, as nothing is more prejudicial than to pursue a wrong course of treatment in this disease. The poison of diphtheria seems to be of so subtle a nature, and to increase in virulence with such marvellous rapidity where the vitality of the system has been lowered, that the exposing of a patient to any depressing cause, or the administration of any depressing medicine, may be sufficient to convert one of the mildest cases of this disease, which might have recovered without any special treatment, into one of such severity as to have a fatal termination. And this remark applies specially to the administration of purgatives, even of the mildest nature—such as castor oil. I have not prescribed purgatives myself, but in cases where they had been employed by others the results were very serious. After the administration of castor oil there has always been increased depression of the system and an aggravation of the disease; while those patients have got on very well whose bowels were left to take care of themselves.

The action of chlorate of potash and iron in diphtheria seems to be both local and general. Locally, it acts as an astringent and disinfectant, causing contraction of the capillaries of the throat, and destroying the life in the diphtheric exudation. Generally, it acts as a stimulant and disinfectant. By giving oxygen and chlorine to the blood it stimulates the vital powers, and destroys the poison of diphtheria. This is my theory of the action of this medicine, for the discussion of which a more extended space than at present available would be required. Whatever the theory may be, there is no doubt of the rapid and beneficial effects of the preceding treatment in diphtheria.

THE NERVE THEORY OF HAY-FEVER.

By G. M. BEARD, M.D., New York.

THERE have been of late a good many references to the action of pollen in the causation of hay-fever. The whole discussion seems to come from looking exclusively at one side of a complex subject. Pollen of various kinds is one of an infinite number of exciting causes, mechanical and chemical, of hay-fever, as has been well known in this country for at least ten years. It is not, however, the disease, any more than the friction which lights a match is the fire that results from that friction. Hay-fever, as I have shown in my work on that subject, is a subjective constitutional disease, a neurosis or functional disease of the nervous system, very frequently hereditary, while the exciting causes (of which pollen is but one) are only secondary and tertiary. The prime and constant factor is the nervous sensitiveness, while nearly every irritating influence on the earth or in the air may act as an exciting cause. Everything depends on the idiosyncrasy. Irritants that are poisons to one hay-fever subject have no evil effect on others. Heat and dust are far more frequent exciting causes than pollen. These conclusions briefly stated here, but argued more in detail in my writings on this subject, are derived from the study of at least 500 cases of hay-fever.

The pollen theory, as an exclusive theory of the disease, is absolutely overthrown by the fact that in this country hay-fever appears in the *winter* as well as in the summer—indeed, at all seasons of the year. I have seen scores of patients who, in *any month* of the year are liable to attacks, with all the characteristic symptoms, whenever they remain long in a closed and over-heated room, or are exposed to the odour of flowers, fruit, ipecac or other pungent powders, to dust of any kind, or to certain animal odours, as that of a horse. I know a physician who cannot in winter or summer approach a horse without suffering from hay-fever symptoms—itching of the nose and eyes, sneezing, profuse nasal discharge, cough, and asthma. In the winter, snow sometimes acts as an exciting cause, its presence at once inducing an attack. Some persons always suffer from hay-fever when there is snow on the ground.

Here we have in the summer three different seasons for the regular attacks of hay-fever—May and June the early form, July the middle form, and August and September the later form, or autumnal catarrh. Scores of patients, whose cases I have studied, have all three of these forms; while others have but one, or in some instances two—the early and later forms. The later form is frequently extended late into the autumn, and even through the winter.

The chief exciting cause of the early and middle forms appears to be odour and pollen of grasses, hay, roses and other flowers. The exciting causes of the later form are the pollen of ragweed (Roman wormwood, *Ambrosia artemifolia*), golden rod (*Solidago odora*), Indian corn, and the odour of our fall fruits, as the peach, musk-mellon, pear, and grapes. I have seen a large number of hay-fever subjects who are obliged to leave the table at any season of the year when fruit or flowers are brought on.

No other disease that has been scientifically investigated is so markedly hereditary as hay-fever. I know of a family in which there have been ten cases of the different forms of the disease. I found fifty cases in fifteen families. Fully one-third of the sufferers have relations similarly afflicted.

It is impossible to get full statistics on subjects of this nature; but, judging from extensive personal observation and correspondence for a number of years, and from all sources of information, it is within limits to say that there are 50,000 cases in this country—probably more than in all the rest of the world. The malady is most common in the north and east, and diminishes in frequency as we go south—in this respect following the analogy of general neuralgia, sick headache, nervous dyspepsia, and other nervous diseases of the family to which it belongs. Hay-fever, like these other functional nervous diseases, appears to be increasing.

The disease is here known by different names, according to the season of the year in which the attack comes on, the special irritant that excites the paroxysms, and so forth. Thus we have the names, "ragweed fever," "peach cold" (it is quite common in the vicinity of peach-orchards), "rose cold," "June cold," "July fever," "autumnal catarrh," "strawberry cold," "snow fever," and "summer catarrh."

"Dust fever" would be a more appropriate name, since dust indoor and outdoor acts at all seasons of the year as an exciting cause more frequently than any other irritant. Some patients trace their attacks to sexual excess and to seminal emissions. The evidence on this subject is, in my mind, conclusive. Here, as everywhere, hay-fever is most commonly found in the indoor and brain-working classes. It is, in short, a disease of those who do *not* work in hay, being very rare in these latter, although I have seen ten cases in the agricultural population.

The treatment now chiefly used in this country consists of sedatives, tonics, and anodynes, used generally and locally, arsenic, quinine, nux vomica, bromides of ammonium and potassium, chloral, camphor, belladonna, electricity, Turkish baths, alcohol, and morphine. Under this plan of treatment some have their attacks rapidly broken up; others have various

degrees of relief; others still can only be helped by hypodermic injections of morphine, or by inhaling chloroform. The treatment by injections of quinine helps some cases, but frequently fails.

If Helmholtz and Tyndall and Bulkeley, and others, who have advocated parasitic, or germ, or pollen theories of hay-fever, could visit the White Mountains in August and September they would then find hundreds of sufferers from every form of hay-fever, and they would soon see that it is a subjective constitutional and nervous disease, each case differing more or less from every other case in susceptibility to external irritants; and they would then also find an unusually rich field for the study of all other functional nervous disorders.

Relief is found in the White Mountains and other extensive forest regions of the north, where the air is cool and comparatively free from vegetable irritants. Those who visit Europe at the season of an attack are usually, though not always, free.

Hay-fever also acts vicariously very frequently, taking the place of dysentery, diarrhœa, sick headache, neuralgia, dyspepsia, and being replaced by these diseases sometimes suddenly. The accumulating facts on this branch of the subject are very interesting.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

CASES OF APEX PNEUMONIA.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

[For notes of these cases we are indebted to Mr. J. A. Kempe, L.R.C.P., Senior House-Surgeon.]

(Under the care of Dr. GEE.)

Case 1.—Louisa P., aged five years, was admitted June 18.

Family History.—No phthisis. One other child has had to attend Chest Hospital on account of cough. This child had measles when two years old, but has not been subject to cough since.

Present Illness.—Quite well till June 12. Came home from school tired; went to sleep, and at 8.30 p.m. became convulsed on both sides of the body. She lost her senses, bit her tongue, and twitched for ten minutes. Mother says right half of face was more convulsed than left. Was very pale when she recovered from the fit. She was very thirsty; not paralysed; soon fell asleep again, but in about half an hour had another fit, and between then and 4 a.m. had four more of similar character and duration to one described. No return of fits since. On the following morning (July 13) it was noticed that she breathed very quickly, and had a slight cough; was thirsty and very restless. Diarrhœa; bowels opened about six times in twenty-four hours. The following day she was delirious, and, continuing to get worse, was brought here, and admitted on the 18th.

Present History.—Pale; fingers cyanotic; skin pungent; temperature 105·2°; lies low in bed, prostrate; alæ nasi working; respirations 60; pulse 150. Enlarged glands in both posterior triangles, not above clavicles. Tongue moist, coated with thick yellow fur, through which enlarged red papillæ project. Chest: Apparent fulness of whole front. Right front and lateral region, deficient mobility. Percussion—Marked dulness over right front as far as nipple-level; right axilla, resonance altered over upper quarter, not below; left front and axilla, resonance good. Auscultation—Over dull area very fine râles are heard with inspiration; respiration bronchial; vocal resonance bronchophonic; in axilla respiration is almost tubular; rest of fronts and lateral regions natural. Backs: Percussion—Right supra-spinous fossa dull; rest of both backs natural. Auscultation—Very fine râles heard with inspiration; bronchial respiration and bronchophony over dull area; rest of back free. Heart beating indistinctly at epigastrium; no impulse in natural position; sounds feeble and distant. Abdomen full; spleen and liver not palpable.

June 19.—Temperature 100·2°; pulse 124; respirations 44. Child evidently better. Diarrhœa three times in twenty-four hours. Ordered mist. hæmatoxyli co. ℥ij., quartis horis. Urine acid; trace of albumen; no diminution of chlorides.

20th.—This morning temperature 98°; skin cool; pulse fuller, 104; respirations 36; still marked loss of resonance at right apex, and at right supra-spinous fossa bronchophony; weak bronchial respiration, and occasional fine râle. Diarrhœa better.

29th.—Temperature has been normal since last note. Child's appetite good. Dulness on percussion has almost gone; respiration is vesicular, no adventitious sounds. Urine acid; no albumen.

July 2.—Got up to-day.

5th.—Went to Highgate, quite recovered.

(Under the care of Dr. CHEADLE.)

Case 2.—William G., aged three years and a half, admitted June 15.

Family History good. Child had whooping-cough at three years old, but got quite well of it.

Present Illness.—Considered in excellent health before 5 p.m. on June 9, when he came indoors, and lay down on the bed, complained of his head, put his hand to his forehead, and tossed about. At 7 p.m. vomited; brought up food and mucus. His head then seemed better, and he slept well that night. On the 10th he complained of pain in the stomach; bowels were natural. He was very drowsy—could not sit up, and cried if raised; very thirsty; not noticed to breathe quickly. Continued in this state till June 13, when he was admitted here.

Present State.—Pale; skin very hot; temperature 104·2°; irritable, prostrate; pulse 160; breathing hurried; respirations 52. Tongue red and irritable, coated with white fur. Chest: Impaired mobility at right apex. Percussion—Right front dull as low as nipple; right axilla dull over upper half, and note altered below. Auscultation—Right front, over dull area respiration is weak, but distinctly bronchial; vocal resonance, but not bronchophonic; no adventitious sounds. In right axilla, respiration over dull area suddenly becomes distinctly tubular. Left front and axilla natural. Heart natural. Backs: Percussion—Right supra-spinous fossa dull; elsewhere over both backs, good resonance. Auscultation—Right supra-spinous fossa, respiration harsh, but not much altered; no râle; over rest of back, good vesicular respiration. Abdomen: Spleen two fingers' breadth below margin of ribs. Liver just palpable; no *tache cérébrale;* no retraction.

June 16.—Urine acid; albumen; copious deposits of chlorides. Temperature 103·4°; respirations 44; pulse 152; heart beating at epigastrium. Constantly trying to get out of bed; screams. This evening, temperature 104°; delirious.

17th.—Temperature 103·6°; pulse 140; respirations 68. Had a very restless night; delirious; spleen very tender. Temperature this evening 103°. Still constantly trying to get out of bed. Pulse 160, feeble. Ordered brandy ℥j.

18th.—Temperature 102·4°; pulse 136; respirations 44. A little better. Constant cough; had a better night; not delirious; sordes on lips. Signs in lungs the same as on admission.

20th.—Breath very offensive; tongue coated with thick yellow fur; temperature 101°. Chest: Intense bronchial respiration all over upper part of right front, extending down to nipple; fine crepitation; in right supra-spinous fossa, respiration bronchial with fine crepitation. Bowels opened three times in twenty-four hours. Ordered mist. hæmatox. co. ℥ij. quartis horis, brandy ℥ij.; tent bed with carbolic steam. An ulcer about the size of a sixpence on inner side of right cheek. Glycerini acidi carbolici ♏xxv., glycerini acidi tannici ♏xv., aquæ ℥j., to be painted on ulcer.

23rd.—Temperature 98·4°. Râles at apex are coarser; a few fine râles at end of inspiration about nipple; abdomen distended; breath less offensive; sits up in bed; evidently much better.

July 7.—Still little impaired resonance at right apex; no râles; respiration faintly bronchial; back and axilla natural. Temperature normal. Ulcer on cheek healed.

17th.—Signs in chest have quite disappeared; temperature normal; urine no albumen; spleen still distinctly enlarged. Sent home to-day.

UNIVERSITY COLLEGE HOSPITAL.

(Under the care of Dr. RINGER.)

[For notes of this case we are indebted to Mr. Judson Bury, M.R.C.S., Physician's Assistant.]

Case 3.—Claude F., aged ten, admitted August 15. Mother died, aged forty-five, of consumption; one sister said to be consumptive. Boy had a cough last winter, had poor food, and not enough clothing. He was taken suddenly ill on August 11, whilst at school. He got home with difficulty, and fell down when he reached the house; he complained of pain in the head, neck, back, and right side of the chest. Since then he has had

a slight cough, and has not been free from pain in the right side. There has been no vomiting; bowels opened six or seven times on the 14th, not since.

Present State (August 15).—Lies on his left side; complains of pain in right side, especially under the collar-bone. Is very prostrate: cannot sit up in bed. Pale, with blue lips; alæ nasi work with respiration; temperature 102·2°. Has a slight dry cough, attended with much pain on the right side; respirations 48—the ratio to pulse is as 1 to $2\frac{3}{4}$. Right front, fair expansion; dull at apex; impaired below and in axilla. Right back, deficient resonance all over; dull at supra-spinous fossa. Left back hyper-resonant. Bronchial breathing right apex front and back, with a little metallic râle accompanying inspiration in a few places. Vocal resonance and fremitus increased over right upper part of chest. Heart-dulness normal; pulse 133, weak. Tongue bright red at tip and edges, elsewhere covered with thick yellow fur. Constipated. Patient was ordered carbonate of ammonia, ipecacuanha, quassia, three ounces of brandy, spoon diet, and spongio-piline to be applied over right front.

August 16.—Less pain. Breath-sound at right apex now quite tubular. Pulse 116; respirations 46; temperature 99·4° morning, 101·4° evening (7 p.m.).

17th.—Some vomiting. Cheeks flushed—equally on the two sides. Temperature 100·6° in the morning; pulse 94; respirations 48. In the evening, temperature 98·4°.

18th.—A little more resonance at the right apex. Temperature normal.

22nd.—Good resonance both sides—right side a shade less than left; and breath-sound at right apex a very little weaker than at left. Feels well; on full diet.

September 8.—With exception of slight deficient resonance at right supra-spinous fossa, physical signs natural. In good general health. Since August 22 he has had pyrexia, without anything to account for it so far as could be ascertained.

Secondary Rise of Temperature (10 a.m. and 7 p.m. where time is not specially noted).—August 22, 99·0°, 99·4°; 23rd, 99·4°, 100°; 24th, 99·8°, 100·2°; 25th, 99·8°, 100·2°; 26th, 101·2°, 100·6°; 27th, p.m., 101·8°; 28th, 99·2°, 100·1°; 29th, 100·5°, 103·3°; 30th, a.m., 100°; 31st, p.m., 101°; September 1, a.m., 102·2°; 2nd, 100·2°, 101·2°; 3rd, 99·4°, 100·6°; 4th, 99·8°, 102·4°; 5th, 100°, 100·7°; 6th, p.m., 99·2°; 7th, 100°, 99·2°; 8th, p.m., 99·4°; 9th, 100·6°, 99·4°; 10th, a.m., 98·2°. Till September 13 normal, when the boy was discharged.

Note.—These are typical cases of apex pneumonia—the first especially so, on account of the nervous phenomena attending it, and which have given rise to the term sometimes applied of cerebral pneumonia. The last case is of importance on account of the secondary pyrexia after physical signs had cleared up, with the exception of a very slight impairment at the supra-spinous fossa. The same condition was observed in a case of apex pneumonia reported recently in this journal, and is also noticed sometimes to last for weeks after pleurisy which is cured so far as physical signs determine. It is difficult to understand the cause of such pyrexia. Does it possibly depend on the slow absorption of local inflammatory products, and so far find its analogies in septicæmia? Signs of tuberculosis elsewhere were carefully looked for, but without result.

ST. THOMAS'S HOSPITAL.

CASE OF SPINDLE-CELLED SARCOMA INVOLVING THE SUPERIOR MAXILLA—REMOVAL—RAPID CONVALESCENCE.

(Under the care of Mr. FRANCIS MASON.)

[For the notes of this case we are indebted to Mr. Tebbitt, the dresser.]

The subject of this case was a married woman, aged forty-eight, who, two years before admission, noticed a small lump on the right side of the hard palate. This gradually increased in size for a period of six months, when it was about as large as a filbert. In another month some ulceration took place, when she became alarmed, and subsequently applied to the hospital for relief in October, 1876. The patient remained under observation for some time, and up to about March last the growth enlarged very gradually, and never gave her the slightest pain or annoyance. It then made rapid progress, and she was therefore admitted into the hospital on April 19, 1877, when the following notes were recorded:—

"On examining the affected part there is an upraised elastic growth situated on the right half of the palate, involving both the hard and soft parts. At the junction of the hard with the soft palate there is an irregular excavated ulcer about the size of a sixpence, having hard edges, but painless to the touch. On making firm pressure on the external or facial surface of the superior maxilla the bone is found thin, leading to the supposition that the growth extends into the antrum, but there is no bulging of the cheek, nor any prominence of the eyeball, nor is there any obstruction of the right nasal fossa. There is no family history of similar disease."

On April 28, the patient having been placed under the influence of ether, the growth was removed in the following manner:—The right lateral incisor of the superior maxilla having first been extracted, an incision was made through the upper lip exactly in the median line. The right cheek was separated from the bone; and a narrow-bladed saw having been introduced into the right nasal fossa, the alveolar border of the superior maxilla was notched at a point opposite to the lateral incisor that had been removed. The saw was then applied to the malar process, which was very thin, and then to the nasal process of the superior maxilla. With the cutting pliers the upper jaw was loosened, and the greater part of that bone, together with the tumour, removed with the lion forceps. Further examination showed that the tumour extended into the antrum, and this part was readily enucleated by means of the gouge. The removal of the remainder of the growth was completed by grasping a portion about the size of a walnut, which invaded the soft palate far back. There was free hæmorrhage, but no more than is usually noticed in such operations. All bleeding having ceased, the edges of the upper lip were brought together by means of silk sutures, and the patient was taken back to the ward.

On a microscopic examination of the tumour, it proved to be a well-marked example of spindle-celled sarcoma. It was for the most part firm to the touch, but here and there were softer portions which broke down under pressure of the finger.

The subsequent history of the case may be very briefly told, for, beyond being somewhat weak for a day or two after the operation, the patient made a rapid rally, and was up on the fifth day. The sutures applied to the lip were removed on the second day, and the scar of the incision was even then scarcely perceptible. In a few days she was sufficiently convalescent to leave the hospital, but she remained to have an artificial palate applied, which was admirably constructed by Messrs. Elliott and Ranger, the surgeon-dentists to the hospital. She was discharged on June 1.

Remarks.—In speaking of this case Mr. Mason dwelt upon the facility with which such operations are performed, if something like method is employed in their execution. There was no necessity to use undue haste; but the operation should be completed as rapidly as was consistent with the removal of the tumour. The application of the saw and cutting-pliers in the proper and in telling situations was all-important, and the student had only to look at the skull to understand that the superior maxilla could be readily removed by making such incision as had been employed in this case. Mr. Mason alluded to the extra room afforded by the division of the upper lip, and remarked on one point of importance, which was that in making this incision he first notched the skin with a sharp scalpel, so as to get a perfect line superficially. The completo division was effected by a second incision through the deeper structures. He also referred to the method of bringing the edges together with ordinary silk sutures, which he was in the habit of using, and preferred to the application of the harelip-pins and twisted suture. Hæmorrhage was known to be in some instances very free; but it was seldom alarming, for, as a rule, the bleeding ceased directly the growth was removed. It was so in this case, the application of the cautery or ligature being unnecessary. At one part of the operation the patient became faint, but revived on the application of smelling-salts to the nostrils. Reference was also made to an interesting point respecting the vision of the patient, for in the right eye there was after the operation a trifling external squint, which was probably due to some slight paralysis of the third nerve. The orbit itself was not opened, and as the adjustment of muscles was daily improving, it was believed that the palsy arose from pressure, due possibly to temporary inflammatory thickening, and that the harmony of muscles would soon be completely restored. The prognosis in many of these cases was not favourable; but, inasmuch as, in this instance, the growth appeared to be entirely removed, that it was more encapsuled than usual, that there

was no lymphatic enlargement, and that the patient's general health was good, there was great hope that a radical cure had been effected.

HOSPITAL FOR DISEASES OF THE CHEST, BROMPTON.

[For the notes of this case we are indebted to Mr. H. Lighton, House-Physician.]

(Under the care of Dr. DOUGLAS POWELL.)

J. L., aged thirty-nine, widow, admitted into the hospital on June 12, under the care of Dr. Douglas Powell, suffering from severe cough, accompanied with abundant muco-purulent expectoration. Dyspnœa on slight exertion, and profuse night-sweats.

There appeared to be no inherited tendency to phthisis, and the patient stated that she had always enjoyed good health until January, 1874, when she had a sudden attack of profuse hæmoptysis (about one pint). Since that time the cough had been gradually increasing, accompanied by night-sweats, occasional attacks of diarrhœa, and considerable emaciation. On admission her pulse was 108; respirations 32; temperature 101·1°.

Physical Signs.—Right: Dulness in front, with amphoric breathing at apex extending to third rib, together with coarse gurgling sounds; vesicular breathing at base. Left: Respiration harsh, with prolonged expiration in front, and scanty moist crepitation after cough. Behind, amphoric respiration with gurgle in supra-spinous fossa and over upper third of scapula, moist crepitation extending to base. For the first six or eight weeks after her admission to the hospital the patient's general condition showed little marked alteration, though the physical signs gradually increased.

The temperature continued considerably above the normal during the greater part of the time (varying from 99° to 102·8° Fahr.), notwithstanding the exhibition of salicylic acid, of which drug the patient seemed very intolerant (four-grain doses given every six hours as a pill causing headache, nausea, and other symptoms of salicylism).

The cough continued troublesome throughout, and occasional attacks of diarrhœa proved very obstinate. The patient, however, was not confined to bed for any length of time, but was able to get up and walk about the ward.

August 12.—Whilst sitting in the corridor this evening, she was suddenly seized with an attack of intense dyspnœa, and at present (half an hour afterwards) appears to be almost in a state of collapse. Pulse very rapid and weak; respiration hurried, shallow, and accompanied by a low moaning sound. Hands and feet cold; lips blue.

13th.—Pulse 116, very weak; respirations 56. Dyspnœa less urgent. Complains of no pain. As far as any examination of the chest was practicable, no marked alteration in the physical signs could be detected.

14th.—Slept at short intervals during last night, and is breathing rather more easily this morning. Complains of pain in right scapular region. 9.30 p.m.: Had another sudden increase of dyspnœa this evening. Respirations 52; pulse 132.

15th.—Is suffering from a third attack of same character as the preceding. Respiration hurried and shallow; pulse small, rapid; face livid; lips blue. 10 p.m.: Breathing more quietly. Otherwise as yesterday.

19th.—Condition unchanged. Pain in right side as before. Respirations 44; pulse 112; temperature 99·2°.

21st.—Very weak and low. Unable to move in bed without assistance. Cough troublesome; expectoration abundant, fetid.

22nd.—This morning a localised patch of gangrene, about the size of a crown-piece, appeared in the hollow between the great trochanter and the tuberosity of the ischium; on the right side it is distinctly circumscribed; is hard and dry. Patient complains of no tenderness on pressure over the part. The bony prominences around the part have been of late painted daily with stimulating lotions, and no discoloration has appeared until this morning. Patient complains also of pain over the left side of the face, which is somewhat swollen.

23rd.—Circumscribed patch of gangrene as before, except that a line of demarcation appears to be forming around the slough. Great pain of a dull aching character over left side of face, which is considerably swollen. There is slight drooping of the left corner of the mouth, and partial ptosis of left lid. Breathing easier; pain in the right side as before. No fresh signs on auscultation. Urine acid, no albumen, specific gravity 1018.

24th.—Cough more troublesome; expectoration abundant, very fetid. General condition unchanged.

26th.—Respirations 40; pulse 116; temperature 99°. Line of demarcation has formed round greater part of slough (which has been daily dusted over with oxide of zinc, and wrapped in oakum). The left eyeball appears to be rather more prominent than the right, and there is considerable œdema of the conjunctiva on same side. There is distinct drooping of left corner of mouth, and partial ptosis on same side; also some anæsthesia on the left side of the face. No other symptom of paralysis.

27th.—Slight delirium last night; perfectly conscious this morning. General symptoms unchanged, except that the prominence of the left eyeball is more marked, and the œdematous condition of the conjunctiva considerably increased.

28th.—Appears to be sinking. Pulse very small and weak. Cough troublesome, with inability to expectorate. Breath very offensive. Protrusion of left eye is still more marked. Anæsthesia has disappeared. The slough in gluteal region in much the same condition as on last note. Complains of no pain.

29th.—Death.

The treatment of the case consisted in general stomachic stimulants, and sedative mixtures for the cough. Night-sweats were checked by a pill of two grains of oxide of zinc, combined with hyoscyamus; and occasional attacks of diarrhœa were treated with bismuth and opium.

Post-mortem, twenty-eight hours after Death.—Rigor mortis absent. Convolutions of brain somewhat flattened; small quantity of fluid beneath arachnoid; ditto in ventricles; brain-substance pale; left middle lobe much discoloured and greenish, though not softened; circle of Willis full of dark semi-clotted blood. The left anterior cerebral artery contained a small decolorised semi-adherent clot. The orbit was opened, and the left eye carefully examined, but no pus was discovered. Lungs: Left adherent at apex, and in axillary region. A large ragged-walled cavity occupied upper two-thirds of upper lobe, the walls of which were extremely vascular, and lined with a patchy membrane. Below the floor of the vomica were numerous tubercles, solitary and closely studded in proportion to their approximation to the cavity. The right also contained a large ragged vomica. Middle lobe emphysematous. Lower lobe in a condition of catarrhal pneumonia, with recent solitary tubercle sparsely scattered. On examining the pulmonary artery the three main divisions were found blocked by decolorised adherent clots, which were larger than the apparent calibre of the vessels. In one branch there was a thread of decolorised fibrine connecting two blocks. Heart very small, five ounces in weight. Both ventricles dilated, containing semi-decolorised clots. Beyond the valves the clot was without colour; in the ventricles it was dark black. The valves were healthy, and no fibrine was detected attached. Liver pale, weighing two pounds six ounces. Spleen very small, weighing two ounces and a half. Kidneys together weighed eight ounces and a half; capsules adherent; fatty. One small block of fibrine found in left renal artery, but this was non-adherent (about the size of a mustard-seed). Vessels of pelvis carefully examined, but nothing abnormal discovered.

THE SECRETION OF SWEAT IN SKIN DISEASES.—M. Aubert read at the Havre meeting a paper on this subject, in which he first described his mode of ascertaining the normal conditions. Having applied papers opposite the glandular orifices, they became moistened, but the traces left were invisible. In order to reveal them, he resorted to various procedures, and found the best of these to be the passing over the papers of a pencil of nitrate of silver, which, by acting on the chloride of sodium in the sweat, gave rise to violet points, each of these corresponding to the orifice of a sudoriparous gland. By this means he then proceeded to examine the modifications produced in the sudoral secretion by various diseases of the skin, as nævus, wine-stains, ichthyosis, erysipelas, psoriasis, etc. In all these he was able to make out the general law that irritations of the skin completely suppress the sudoral secretion, and that even after the irritation has disappeared, a certain period of time is required before the secretion reappears. In cicatricial tissue a very large number of glands are destroyed, but those which remain possess an exaggerated secretion.—*Gaz. des Hôp.*, Sept. 25.

SATURDAY, OCTOBER 6, 1877.

THE INTRODUCTORIES.

One of the pages of our great contemporary, the *Times*, began on Tuesday last with the statement that, "Yesterday being the commencement of the academical year of the English Schools of Medicine, inaugural addresses were as usual delivered in the schools attached to the various metropolitan hospitals, with the exception of St. Bartholomew's, the London, and Guy's." Then followed some columns of abstracts of the "inaugural addresses" which had been delivered; and in several of the other daily papers considerable space was devoted to the same purpose. It would be somewhat interesting and curious, though not instructive, or, as some would say, edifying, to speculate on how few or how many years will pass before like announcements will disappear from all our journals, daily and weekly, and the "Introductory Lecture" at our medical schools will have become a thing of the past. But a very few years ago, an "introductory lecture" was given at each of the eleven metropolitan schools, and the School of St. Bartholomew Hospital was the first to make a breach in the time-honoured custom, in the first year of the present decade of 1800. We believe the last "introductory" at that school was delivered in 1869. Guy's School followed at an interval of a few years; and now the lecture has been given up at the London Hospital School also. Three schools out of eleven have abandoned the custom in eight years; how many years will elapse before the eight other schools follow the example set by the three largest hospitals? Not many, we suspect. It is true that this year there have been ten Introductories delivered—Mrs. Garrett-Anderson, M.D., having delivered an inaugural address at the London School of Medicine for Women; and Dr. Cockle an introductory lecture at the opening of the clinical branch of the same school, at the Royal Free Hospital; but nevertheless we doubt much whether the Introductory Lecture will remain for many years longer a feature of the opening of the winter session at the metropolitan medical schools. It seems highly probable that, should one or two of the smaller schools follow the example of the large ones, the custom will everywhere be rapidly abandoned. We still hold, as we have before this said, that for some reasons the innovation is to be regretted. The Introductory served several good purposes. It drew together again at each school the old students and their former teachers; was a meeting-point in the year for old friends and co-workers; and it introduced the new students to their teachers and their work, while to the lecturer it afforded an opportunity of giving to the new men some general idea and plan of the studies upon which they were entering, of warning them against the temptations that would most beset them, of encouraging them to face boldly and wisely the difficulties they would encounter, and of assuring them of the ever-ready sympathy and help of their teachers. The *conversazione*, which at Guy's and at the London Hospital has taken the place of the old Introductory, answers some of its purposes well, and affords a very pleasant reunion-ground for old friends and new; but it does not fulfil the more important function of introducing the new student in a like way to his new work. It must be confessed, however, that of late years there has been exhibited on some occasions a tendency to forget or ignore the special intention and function of the "Introductory." In these days of universal reporting and publicity the lecturer has a much larger audience than those whom he directly addresses, and it is well that he should remember this, and make a wise use of the opportunity of telling the public somewhat of what medicine is, or should be. But it is not well that he should altogether, or almost altogether, forget that his address was originally intended for the students, and specially for the youngest of them. And this has sometimes been the case. The lecturer has been ambitious, and, forgetting the medical student, has addressed the public, chiefly or entirely, on some point or points concerning the public health, or on some of the links between them and the profession; or he has delivered a discourse on some scientific question; or he has felt disinclined to reiterate to the student truisms about steady, persistent, hard, honest work, the necessity of being constantly on guard against waste of time—and so on; or he has been unwilling to offer advice and warnings which have not always been listened to courteously or respectfully; and so the Introductory Lecture has lost its speciality, and become but "one lecture more." If such a change is a necessary growth of the days we live in, the abandonment of the "Introductory" is not much to be regretted. And it may perhaps be said that so much more watchfulness and supervision is now exercised over the student than in former times; so much more care bestowed upon him individually, especially in the principal schools, through their colleges and increased staffs of professors and tutors, that the *raison d'être* of the special introductory lecture has ceased to exist. Anyhow, we suspect it is doomed, unless perhaps in such schools as may not be large enough or strong enough to replace it by a *conversazione*, or some similar mode of opening the winter session. If, however, the old custom is to be continued, we would suggest that the duty of giving the lecture be always undertaken by a senior physician or surgeon of the hospital, or lecturer in the school, and not entrusted, as is so generally the case, to the man last appointed on the hospital or the teaching staff; the counsel and advice given would then carry greater weight, and would more probably be listened to with attention and profit.

We do not propose to say much about the Introductories delivered this year. We publish one *in extenso*, and abstracts of others, elsewhere in our columns, and may well be content to recommend them in that way to our readers. The inaugural address at King's College, delivered by Professor Lister, was a purely scientific discourse, and therefore, though very able and interesting, is not, according to our views, an Introductory

Lecture properly so called. At St. Mary's Hospital, Mr. Herbert Page found great fault with the instruction given in our schools for general education, and came to the conclusion that "Happy is that man who finds when he has left school that he has learned something which will be of real value to him in the world in which he moves"; but we venture to think that he much underrates the value of even the classical instruction that a boy receives there, and that he forgets the education. The boy was learning how to learn; and without the instruction he gets in the dead languages, he would be pitiably at fault when he comes to read scientific and technical works. From this subject of general education Mr. Page passed on to give some excellent advice as to the spirit in which, and the ends for which, medical students and medical men should work. He spoke much of the wide-spread and powerful influence for good that medical men ought to be able to exert over their fellow-men, dwelling with especial earnestness on the work they might do in helping to teach the virtues that will prevent intemperance. We do not feel at all sure with him that the habit of thrift will cure or prevent drunkenness, but we are quite in accord when he says, "Great ought to be the influence of our profession, for who more than its members have the opportunity of giving encouragement, advice, and sympathy which many a human creature needs? To do it we must be equal to the task, and our own lives must not fall short of the lofty aims which should be our glory."

At University College the Introductory Address was delivered by Dr. John Williams, who spoke of the great and rapid progress made in medical science, as a whole, during recent years, especially in medicine and surgery. Gynæcology, which he defined as that branch of science which treats of the changes, healthy and morbid, in the female body, had not kept pace with general medicine—not, at least, in gaining the power of preventing disease. He then sketched the progress made in gynæcology, described the views taken at successive periods of time of the physiology and pathology of the female body; spoke of the advances made in the diagnosis of diseases; and referred to the labours of Brown, Wells, Keith, and others in rendering curable diseases which thirty years ago were incurable, and the operations for them fatal. He then exhorted the student of gynæcology to study pathology, to trace back the course of disease to it, to discover its causes; and so give gynæcology a preventive character. Such inquiries, he observed, had a most important bearing on a social question lately and now much discussed—the employment of women. "Persistent and strenuous efforts had been made to admit women to professions which demanded from their members strength, energy, and a power of continuous and severe effort and application. The importance of this subject could not be over-estimated, not to the few women for whose sake such clamour had been made, but to society and to the race. It could not be decided by prejudice—if that were prejudice which had existed for ages,—nor yet by the intellectual caprice of a few experimenters in moral and social science. It was a physiological and pathological problem, which could be solved on physiological and pathological grounds only."

At the Westminster Hospital, Dr. Chapman Grigg spoke of the way in which the profession discharges its duties with regard to general medicine, and of the impediments offered to science by the Vivisection Act; and then went on to enlarge on the subject of State medicine, and on its immense value and power to prevent sickness and to save life in peace and in war. He dwelt on the uselessness and irritating effects of half measures in sanitary legislation—and there we agree with him; but when he declared that "it is doubly necessary that a well-digested, carefully-matured measure, one that may last a generation, should be, without further delay, brought before Parliament, and should, if possible, be approved of in all its essential bases by the heads of both parties in the State," we cannot quite go along with him; for we greatly doubt the possibility of such a measure—a measure that would or should last a generation—being either matured or passed yet. We do not believe that either our legislators or the public are educated enough yet in sanitation, or sanitary science itself sufficiently assured for that. At any rate, we do not think that such legislation can be forced on the people yet; and Dr. Grigg himself declares that "the difficulties that exist in impressing on the public mind the necessity of sanitary improvements are very great, confounding statesman and philanthropist alike." Dr. Grigg concluded his lecture with some words of welcome and encouragement to the students. We observe, by-the-bye, that in speaking of the benefit "to students and the public" of the practice of giving introductory lectures, Dr. Grigg expressed the opinion that the relinquishment of that practice at some of the principal London hospitals was due "to the severe criticism of the public press." We must beg to differ from him entirely. We do not believe that the public press had anything whatever to do with it.

Mr. Wagstaffe, at St. Thomas's Hospital, made a few sensible observations on the immense importance of health to the students, and expressed a hope that a serious effort would be made to provide them with suitable dwelling-houses, "upon some such plan as that adopted at the Colleges in Oxford and Cambridge"; but he devoted his lecture almost entirely to advising, warning, and encouraging the student, and to telling him what his life should be as a student and as a practitioner. He warned the students against mistaking knowledge for wisdom. He said, "One thing that would make them honest in their work, and careful, persevering, and courageous observers—that would make them do their duty to their profession, their fellow-creatures and themselves, was to take as their aim in all their work, simply—truth." Then he enlarged on the meaning of this text—so to call it, and also warned them not to let their honesty be marred by their coarseness, to be considerate in their relations with others, and not to allow "over-carefulness or caution to prevent their ever making a step forwards, or to lead them to become the victims of care." His address is an admirable one, of the old introductory-lecture kind.

The introductory lectures given by Mr. T. P. Pick at St. George's Hospital, and by Mr. A. Hensman at the Middlesex, were likewise very good. Mr. Pick, taking for his text, as it were, the boyhood and early career of Hunter, Astley Cooper, and Brodie, entreated the students, with their immeasurably greater advantages, to endeavour to follow in the steps of those men, and, like them, do some good in the world. He pointed out that they could succeed in such endeavours only by steady, earnest, and thoughtful work, and by a just appreciation of the value of time, showed how to do this, and warned them especially against superficial and hurried work. Mr. Hensman, in his finished and excellent address, dwelt particularly on the necessity that "every side of the intellect shall be trained, every right capacity of the body be developed, if we would work to good purpose; and spoke at some length on the importance of training the eye and educating the hand. "The value of sketching in outline," he told the students, "will assist you much in your work; you should, if possible, sketch all you see under the microscope, and make outline drawings of your dissections. The art of drawing, I believe, may be a great aid to a medical man throughout his whole professional career. A careful drawing of a well-prepared dissection or a microscopical preparation may save hours of book-drudgery and must lead to clear and accurate ideas. To the busy practitioner a rapid sketch of a morbid growth, or the mere outline of a diseased limb, may convey to the mind more than pages of careful notes. Drawing may be said pre-eminently to cultivate

the eye as to form, size, and relation, and it certainly educates the touch in a manner scarcely second to the use of the scalpel in the dissecting-room."

We cannot afford space to say anything concerning other lectures, except that at the Charing-cross Hospital Mr. Astley Bloxam delivered a good practical address; and at the Royal Free Hospital, Dr. Cockle gave to the students of the London School of Medicine for Women an introductory lecture to clinical work, replete with wise and sound advice. An abstract of this lecture we hope to give our readers next week. And we must mention that in delivering an inaugural address at the School of Medicine for Women itself, Mrs. Garrett-Anderson, M.D., spoke with the sound good sense and moderation she almost invariably displays when speaking in public. She warned her hearers not to forget how much depended on the judgment, moderation, and good taste of the earliest supporters of a new cause, and how necessary it is that they should carry the community with them; she urged them to remember that henceforward they would be not merely women who desire to help the best interests of all other women, but also members of a noble profession, and that they had the responsibility which is linked with comradeship towards every other medical person, man or woman; and she said—"Whether women can be trained into first-rate doctors or not, and whether it is a solid advantage to society to have them so trained, are questions which can only be answered by experience on a somewhat large scale. A good many of the objections might doubtless be dismissed as imaginary. Women could certainly do as well as men as students, while in examinations they were also quite equal physically to what was needed of them. But, on the other hand, some of the advantages sometimes claimed by the advocates of the change would not be found to exist. The argument that women would understand women's ailments much better than men, was, in her judgment, misleading. Women would understand disease in proportion to their knowledge and intelligence, and not through any occult or mysterious sympathy with its subject." But she did think, she said, that women would understand better than men the conditions of life which underlie much chronic disease and debility among women.

THE PENGE CASE.

It is with a certain amount of reluctance that we approach this case, to deal with which, however, is a duty. It is no part of the business of a medical journal to deal with questions of ordinary morals, and when such are mingled with details which do concern us, we have to encounter the difficulty of keeping them distinct in our own minds, and of keeping them separate in endeavouring to form a sound judgment. To a well-trained mind this is not difficult, but the majority of minds are not well trained, and we are much inclined to believe that such must have been the case when four people notoriously and obviously culpable in different degrees were all found guilty of a crime to which there is but one punishment, and that punishment is death.

Looking at the conduct of the case in its broader aspects, there were two features which forcibly struck us. These were the behaviour of the judge and of the Attorney-General, who acted as prosecutor. Mr. Hawkins was a most distinguished and successful advocate; it will require other behaviour than that in the recent case to secure him the reputation of a distinguished judge. There is a sound maxim in our profession that "meddlesome midwifery is bad"; a meddlesome judge is worse, and one who will play the part of both judge and counsel must infallibly land in mischief. Illustrations of this in the Penge case are abundant. Neither can one keep from admiring the conduct of Sir John Holker in this painful case. It was worthy of the best and highest traditions of the English Bar. Everything was stated against the prisoners with the most studious moderation; if a point could be safely waived, it was waived in their favour. As it seems to us, the moderation of the prosecutor was in marked contrast to the meddlesomeness of the judge. But it is time for us to turn to what more especially concerns us, the medical evidence. That resolves itself into two parts—the few symptoms noted during life by Mr. Longrigg, and the details of the post-mortem examination made a week after death.

When seen by Mr. Longrigg, Harriet Staunton was perfectly insensible; the pulse was weak, but quick—110 per minute; her breathing was stertorous and laboured; her arms were rigid; the pupil of the right eye was dilated, that of the left contracted to a pin's point. These were the essential facts noted during life. From their observation Mr. Longrigg came to the conclusion that the patient was suffering from cerebral disease; and, when death happened, gave a certificate to that effect. No thought seems to have crossed his mind that the cause of death was other than here stated.

Next came side-information—not as to the medical history of the case, but statements of relatives; and the certificate founded on medical observation was withdrawn.

The next phase of the case that concerns us is the post-mortem examination, of which the following are the main facts, separated from the mass of inference with which they were interlarded:—

Body much emaciated; skin, especially on the abdomen, dry and harsh, very dirty; hair full of pediculi; thighs dirty, shrunk, and skin very dry; ecchymoses on both ankles and legs; feet very dirty and very dry; eyes sunk, conjunctivæ not injected; mouth open, dilated, containing food at back; tongue coated with thick dry fur. Measurement from vertex to heel of foot, 5 feet $5\frac{1}{4}$ inches; weight, 74 lbs. (5 st. 4 lbs.). On removal of the skull-cap, adhesions were found between it and the dura mater and arachnoid, and between this last and the pia mater; no appearance of lymph or of effusion into the ventricles or cavities of brain. There were some small patches of rough millet-seed-like deposit in the meshes of the pia mater, probably tubercular. There was well-marked and universal congestion of all the external bloodvessels of the brain, of the membranes, of the sinuses, and also of the internal vessels of the skull, especially of the longitudinal and lateral sinuses—*i.e.*, the bloodvessels appeared as if injected. Brain firm, healthy, and remarkably well preserved. No adhesions between the pleura and lungs. Pericardium contained about 1 oz. of fluid, but was not adherent to surface of heart. Heart small and contracted; weight $7\frac{3}{4}$ oz.; both auricles and ventricles empty and contracted; no trace of any valvular disease. Lungs free from disease except at left apex, where a small patch, about $1\frac{1}{2}$ in. to 2 in. square, contained tubercular deposit (grey and hepatised). Liver very small, healthy-looking, smooth, no adhesions; weight 2 lbs. $2\frac{3}{4}$ oz. Gall-bladder full. Spleen small and congested; weight $4\frac{1}{2}$ oz. Kidneys healthy, no adhesions, smooth; weight—right $3\frac{3}{4}$ oz., left 4 oz. Bladder healthy; contained about 3 oz. of urine. Uterus: Weight $1\frac{1}{2}$ oz., length $2\frac{1}{8}$ in., breadth (at fundus) $1\frac{3}{4}$ in.; internal surface congested; os uteri patulous; muco-gelatinous fluid exuding. The stomach contained food undigested, in which could be recognised egg and bread, and meat, and grey fluid. There was very marked and intense congestion of the internal lining, especially along the upper curvature. This congestion was unlike ordinary post-mortem congestion. The intestines, both small and large, were quite empty and contained no food or fæcal matter whatever. The duodenum was much congested throughout the whole of its upper part. The omentum was shrunk and contracted; it contained no fat, and no fat whatever surrounded the intestines, or any other organ—neither heart nor kidneys. The rectum was much congested throughout the last four inches.

From these facts the inference was plainly and clearly justified, that the deceased had been grossly and shockingly neglected. This was evident from the condition of the surface of the body.

The body was greatly emaciated, and was unusually light. The emaciation and loss of weight were incompatible with health. It would be very hard to say whether they were incompatible with life. Cases of extreme emaciation have been known to recover. It is not long since several such cases were brought before the Clinical Society.

On the surface of the brain were found many bodies described as tubercles, visible to the naked eye; but little or no effused fluid, though the vessels were congested.

In the apex of one lung were found tubercles again.

The stomach was congested; the bowels completely empty.

Such, we believe, were the main medical facts on which a purely medical opinion had to be founded. Let us suppose this body had been found under conditions which precluded any history being obtained—a not unfrequent occurrence. What would have been the conclusions to draw from such post-mortem appearance? We think it is hardly possible to arrive at any other inference than that the actual cause of death was tubercular meningitis. True, there was the additional evidence of a gross want of personal cleanliness, but not greater than is to be found among scores of casuals. True, again, the emaciation might have been due to want of food. But such emaciation has been known, as we said before, when the supply of food has been unlimited, and when it has even had to be forced on the patient.

Taking, therefore, the whole case on its purely medical bearings, the statement that death was due to wilful neglect and starvation is, as it seems to us, totally unjustifiable. If starvation was proved as the cause of death, it was not by medical evidence; and when we come into the wilderness of the ordinary evidence, we simply hold our hands. Opinions are hopelessly divergent, and it is not for us to attempt to reconcile them.

Two points more, and we have finished. We have not gone into the detailed evidence of each medical witness; but it, on the whole, conveys the idea of a degree of mismanagement and weakness, on the side of the prosecution, hard to conceive. It shows the utter folly of leaving such inquiries in the hands of men not specially trained to, and skilled in, such inquiries. Perhaps the height of absurdity was reached when, if we are to believe the reporter, a witness deposed to the post-mortem appearances being very similar to those the result of chronic poisoning by sulphuric acid: as if sulphuric acid ever formed tubercle in the lungs or brain! It is high time the system of medical evidence in criminal cases was reformed.

Again, we think the judge was quite right in rejecting Dr. Greenfield's evidence. Evidence in such cases, founded on "ifs," and "ands," and "buts," is unworthy of reception. Human life is at stake, and the fate of prisoners on their trial should not be thus decided.

THE FLESH OF CATTLE AFFECTED WITH CONTAGIOUS PLEURO-PNEUMONIA.

The question of the wholesomeness or otherwise of the flesh of oxen affected with contagious pleuro-pneumonia is causing no little excitement in Ireland at the present moment. We lately reprinted two queries addressed by the Public Health Committee of the Corporation of Dublin to every registered medical practitioner, and commented on the more than dubious results likely to be gained by an inquiry so conducted. The question has now reached a further stage; and this week a lengthy Report, prepared by direction of the Committee of the Irish Cattle Trade Defence Association, has been widely circulated in Ireland. This Report has been drawn up by Dr. Rawdon Macnamara, Surgeon to the Meath Hospital, Dublin; Dr. Alexander Macalister, Professor of Zoology in the University of Dublin; and Dr. J. Emerson Reynolds, Professor of Chemistry in the same University. These gentlemen are unquestionably distinguished men in their several callings; but we should have been better pleased to see one or two pathologists and one or two sanitary experts associated with them in an inquiry which certainly demanded much special knowledge. The unfavourable impression excited by a consideration of the qualifications of the reporters is not removed by a perusal of their Report, which seems to us to be little more than a clever bit of special pleading, and by no means a satisfactory solution of the questions involved.

The Report opens with a historical review of the disease epidemic pleuro-pneumonia. Its stages are then described in popular language, the fact of the constitutional, as distinguished from the local, nature of the malady from the beginning being throughout kept out of sight. The authors say—"The disease presents itself in two widely different stages, in the first of which the animal seems but to be out of sorts, its condition is unimpaired, and it presents but little, if any, symptoms of fever. In fact, it would require an experienced eye to detect the difference, whilst living, between such an animal and one in health; what amount of difference is observable after the animal is slaughtered we shall allude to further on, contenting ourselves here with remarking that none such can be observed in the flesh of the animal by the most experienced butcher, or the most skilful chemist, microscopist, or pathologist. In the second stage the symptoms during life are far more easily recognised, but the flesh of the slaughtered animal is not distinguishable by any known means from the flesh of any other animal *similarly reduced in condition. It is almost unnecessary, however, to add that animals, from any cause, so reduced in condition should not be looked upon as marketable commodities.*"

To most minds, we imagine, the passage marked by us in italics would seem to tell altogether and most forcibly against the view maintained by the writers. The mode of propagation of the disease, and its pathology, are next considered; and an argument as to the innocuousness of the flesh of cattle affected with pleuro-pneumonia is grounded upon the fact that the disease is infectious only through the medium of the air-passages. The authors observe—"The conclusion from this is plain—the disease is a local one, and, though contagious, yet is limited, as far as its specific nature is concerned, to the lung affected. This Dr. Burdon-Sanderson has also verified, by showing that the blood and other juices of cattle which are affected with pleuro-pneumonia, even in the most advanced stages, are incapable of producing any specific effect by inoculation, that power being limited to the fluid taken from the diseased lung (see the Official Report to the Medical Officer of the Privy Council, 1876)." In endeavouring to ascertain the effects produced on man and healthy animals by the consumption of the flesh of cattle affected with pleuro-pneumonia, the authors have consulted many authorities, from whose works they quote copiously; and they sum up by saying that from the considerations advanced they have arrived at conclusions of which the following is the pith:—"That the consumption of the flesh of cattle slaughtered in early stages of pleuro-pneumonia is perfectly harmless, and the destruction of such meat is a wasteful expenditure of a material which is capable of supplying a perfectly wholesome animal food."

We are further told that "it would appear, then, that the opinions of some sanitarians on the subject, and of many medical men who have not had time to specially investigate this important question, are in part founded upon the Livingstone cases and the hypothesis of the Scotch Registrar-General, of both which we have completely disposed; and in part on inferences hastily drawn from experience of the well-

known ill-effects which attend the consumption of the meat of animals affected with anthrax, milzbrand, etc.—diseases which are essentially different from pleuro-pneumonia in their nature and effects upon the animal tissues. Notwithstanding the fact that these inferences have no foundation in common experience or scientific investigation, they have been acted upon as if their truth had been established, and have been accepted by the popular mind, doubtless because they are in accord with the natural feeling of dislike to contact of any kind with diseased animals, and of aversion to the consumption of their flesh."

The Report concludes with a consideration of the nutritive value and quality of the meat of pleuro-pneumonic animals, which goes to prove that "the fresh and unchanged meat of animals slaughtered during an attack of pleuro-pneumonia may be safely consumed, and that such meat is not sensibly less in nutritive value than that of other animals unaffected by any disease, but that it is of lower quality, owing to its greater tendency to undergo change." We do not question the industry, skill, and time which have been spent upon the compilation of this Report, yet we must observe that it is admitted that the flesh of the pleuro-pneumonic animal has an unnatural tendency to undergo changes which would make it admittedly unwholesome; that the dislike to eat the flesh of diseased animals is a natural and healthy dislike; that it is very difficult indeed to *prove* direct results from feeding on the flesh of diseased animals; and, finally, that such a question as that here dealt with certainly cannot be solved by any *ex parte* report.

THE WEEK.

TOPICS OF THE DAY.

Amongst the numerous and varied adulterations in articles of our food supply, the question of the purity of the bread daily supplied to us has not yet been sufficiently considered. One day last week a baker of Pitfield-street, Hoxton, was summoned at the Worship-street Police-court for having sold bread adulterated with alum. Mr. Walker appeared to prosecute on behalf of the Vestry of the parish of St. Leonard, Shoreditch. He produced the certificate of the public analyst of the parish, showing that the bread submitted to him, which had been purchased from the defendant, contained fifteen grains of alum per two-pound loaf. The solicitor for the defendant said that his client had trusted the bread-making to his foreman, and, from what he had since learnt, he would submit to the judgment of the court; but he added that there was a disagreement between the professional gentlemen as to the bread being injurious to health, Professor Wanklyn, who was in court, stating the contrary. The magistrate said he should like to ask the Professor a question, and Mr. Wanklyn was accordingly sworn. He deposed that there was no evidence to show that in this case the quantity of alum used would be injurious to health. The danger from alum was in producing constipation; here it was not in sufficient quantity. Mr. Bushby asked the object with which alum was used in bread. The witness explained that it enabled sound bread to be made from unsound flour; flour that had begun to "go" would not make good bread. Mr. Bushby supposed that "go" meant "ferment," and asked if the flour had begun to ferment what would be the effect of alum on it. Professor Wanklyn replied that it would arrest the change, and further explained that alum was used to arrest the metamorphosis of nitrogenous substance, which the incipient fermentation set up would destroy. Mr. Bushby was obliged to the Professor for the light he had thrown on the matter. This case, he said, was not particularly affected by the question whether or not fifteen grains of alum per two-pound loaf was injurious to health; it was clear the bread was of inferior quality from the fact of alum being in it, and inferior from the loss of nitrogenous substance. He would deal with the case on that point, and as the defendant had pleaded guilty he would not impose upon him the heaviest penalty, but fine him 20s. and costs. Mr. Walker intimated that on a future occasion he would be prepared with scientific evidence to support the statement as to the injurious effect of alum.

It is singular to imagine why the uneducated classes should be so credulous on the subject of medical treatment, but it is a fact that the more impudent the imposture the more readily they become dupes. A proof of this was afforded by the proceedings which took place at an inquest held last week before Mr. Carter, at Camberwell, on an infant aged twenty months. The mother of the child was called, and said she was induced to go to a Mr. Stokes, a herbalist, of 105, Southampton-street, Camberwell, to get a mixture for her child, after reading a pamphlet entitled "Truth *versus* Error," alleged to show in a few brief extracts "the danger of using poison as a medicine, and the doctors' inability to cure diseases, and showing a brief way how to cure by the use of herbs as a medicine, by W. D. Stokes, medical herbalist." She saw Mr. Stokes's assistant, who prescribed for the infant, with the usual results. At the last moment, of course, a qualified medical practitioner was called in—too late to save the life of the child, sacrificed through the folly of the mother. The result of a post-mortem examination showed that the child died from exhaustion consequent upon a severe attack of diarrhœa. The mixture supplied by the herbalist had been tested, and it was not a proper medicine to give a child suffering from that complaint. In answer to the coroner, Mr. Stokes's assistant said two tablespoonfuls of the stuff was not an overdose for an infant; he generally gave an adult half a pint as a dose! A verdict of "Death from exhaustion" was recorded; and there does not seem to have been the slightest comment from the jury on the practices of the "herbalist," who is left to circulate his pamphlets, and trade on the credulity of the silly public, without so much even as a reprimand.

At a meeting of the Court of Common Council of the City of London held last week, £100 was voted for Queen Charlotte's Lying-in Hospital, £105 to the Royal General Dispensary, and £210 to the Westminster Hospital. Some rich prospective legacies have been left to different charities by the will of Mr. John Miland, late of Clairville, Wimbledon. At the death of his wife, the Metropolitan Convalescent Institution (Walton-on-Thames), the Royal Free Hospital (Gray's-inn-road), and the Charing-cross Hospital, are each to receive £1000; and the Seaside Convalescent Hospital (Seaford), the Westminster Hospital, King's College Hospital, the Ophthalmic Hospital (King William-street, Strand), and the Hospital Sunday Fund, £500 each.

It would be too much to expect perfection in the laws of any country, but what must be the reflection of everyone on reading the following case? Mr. C. E. Merrington, barrister-at-law, at present residing at Ventnor, was recently summoned before the Newport (Isle of Wight) county magistrates for an assault on Sidney Axhorn. The complainant was engaged by a quack doctor of Ryde, to distribute objectionable medical pamphlets, and the defendant having observed him giving them away to ladies, young girls, and children, struck him several blows with a stick, and finally knocked him down. The Bench, after regretting that the law did not give them power to prevent the circulation of such pamphlets, convicted Mr. Merrington of the assault, and fined him £1 0s. 6d., including costs.

It is stated that Mr. Alderman Stone, at the request of an influential body of the governors, has decided to allow himself to be nominated for the Treasurership of St. Thomas's Hospital, vacant by the death of Sir Francis Hicks. In the

face of the discussion which has recently taken place in the papers on this appointment, and what is expected of the gentleman who undertakes the duties of it, it argues that Mr. Stone is thoroughly determined to give up a sufficient amount of time to insure the success and prosperity of the Hospital, so far as the efforts of his department are concerned.

Ignoring the question of the importance, from a sanitary point of view, of hanging pictures on the walls of hospitals, Mr. Joseph Moore, chairman of the Committee of Management of the Seamen's Hospital, Greenwich, has, through the medium of the press, made an appeal to the public to assist him in decorating the wards of that institution with pictures, so as "to dissipate the depressing monotony of dead walls upon the patients." There is ample space, Mr. Moore reports, to put up 250 specimens. Towards this number fifty have already been received from the residents in and around Blackheath and Greenwich; and, as the institution is free to seamen of every nation, and therefore truly national, it is hoped that very many of all classes will respond to this call. It is desired that the pictures should be simple in character, coloured prints and chromo-lithographs being preferable to engravings.

The new reservoir, situate at the top of Heddington-hill, to supply the University and city of Oxford with water, was formally opened last week by the chairman of the Waterworks Committee, Mr. John Gilpin, in the presence of the Mayor and Corporation, and a distinguished company. The new reservoir has been built, from the plans of Messrs. L. and C. Hawksley, by Mr. Dickinson; it will contain a million and a half gallons of water, which will be supplied from the Lake at Oxford. The pressure from the new service will be so great that in case of fire a copious supply of water will be able to be produced capable of reaching the highest tower in Oxford.

Another discussion has taken place at the West Derby Board of Guardians respecting the administration of stimulants to paupers. Mr. Bradford expressed his surprise at the large amount (upwards of £1000) spent for the Workhouse in stimulants last year; and he added, that on speaking to the medical officers on the subject they were likewise astonished at the largeness of the sum. The two doctors attached to the institution were called in, and Dr. Little remarked on the fallaciousness of a comparison of statistics between one workhouse and another in this matter, and pointed out that there were in Mill-road Hospital during a limited period 3000 patients, 2000 of whom suffered from small-pox. Dr. Little added (Dr. Archer afterwards concurring), that the prescription of stimulants in cases of life and death ought to be left entirely in the hands of the medical officer. The explanations and statements of the doctors were ultimately pronounced satisfactory, and the debate ended in a resolution to the effect that a return on the subject should be placed on the table.

The number of accidental poisonings by carbolic acid must strike everyone as very large. Its smell is strong and peculiar —sufficient, it might almost be thought, to warn anyone against a mixture containing it; yet, recently, numberless lives have been sacrificed through it. An inquiry was held at Liverpool, on Saturday last, respecting the death of Emma Greenwood, forty-four years of age, an inmate of Brownlow-hill Workhouse. A bottle that contained cough-mixture was partially refilled, accidentally, with carbolic acid. The mixture in this state was taken to the wards. The deceased took a drink of it, and found she had been poisoned. Dr. Goshan attended her, using the stomach-pump and restoratives, but she died in six hours. The jury found that the deceased had been accidentally poisoned, and added that in a public institution like the workhouse people should be more careful.

It is satisfactory to find that after the recent epidemic of small-pox which visited the East-end of London with so much severity, the health of the Hackney district is now reported by the medical officer in charge there to be "singularly good." During the past fortnight only eighty-three deaths have been registered, being at the rate of only 16·6 per 1000 of the population, and the smallest proportion ever recorded for Hackney, except in the first fortnight in October, 1876, when it was 13·2 per 1000. It should, however, be remarked that, during the same period, the death-rate for all London was only 18 per 1000 of the population.

We learn from *Nature* that a Swedish paper has published "an interesting article under the heading, 'Why is the Climate of Europe growing Colder?'" We are tempted to ask, as King Charles did with regard to the famous question about the fish and the bowl of water, "Is it a fact?" But the writer of the article has no doubt on that score. He says that "in the Bay of Komenok, near Koma, in Greenland, fossil and very characteristic remains of palm and other trees have been discovered lately, which tend to show that in these parts formerly a rich vegetation must have existed. But the ice period of geologists arrived, and, as a consequence of the decreasing temperature, this fine vegetation was covered with ice and snow. This sinking in the temperature, which moved in a southerly direction, as can be proved by geological data—*i.e.*, the discovery of fossil plants of certain species—seems to be going on in our days also. During the last few years the ice has increased far towards the south; thus between Greenland and the Arctic Sea colossal masses of ice have accumulated. On European coasts navigators now frequently find ice in latitudes where it never existed before during the summer months, and the cold reigning upon the Scandinavian peninsula this summer results from the masses of ice which are floating in the region where the Gulf Stream bends towards our coasts. This is a repetition of the observations made in the cold summer of 1865. The unaccustomed vicinity of these masses of ice has rendered the climate of Iceland so cold that corn no longer ripens there, and the Icelanders, in fear of a coming famine and icy climate, begin to found a new home in North America."

LONDON HOSPITAL MEDICAL COLLEGE.

THE opening of the present session was inaugurated on the evening of the 1st inst. by a *soirée*, the old-fashioned custom of an "Introductory Lecture" having been set aside for the first time. We hear that it is contemplated alternating the *soirée* and lecture method of opening. The *soirée*, as such, was a very successful one indeed, the various rooms and theatres of the Medical College being thronged with a company of which a large proportion consisted of ladies. *Soirées* have this undoubted advantage over introductories—that ladies can be invited; and their presence undoubtedly conduces much to the success of such entertainments. But we see no reason why these methods should not be combined. We agree with some remarks made by Mr. Hutchinson at the Hospital Biennial Festival, held on Tuesday, October 2, that these lectures are looked forward to with great pleasure by a considerable number of the new, and not a few of the older, students; and that, although they may be somewhat stale and common-place to those who listen to them for a number of years, yet that there is always a new congregation of listeners present for the first time, and that the words of welcome and kindly advice thus given are valued and not seldom acted on. For our own part, we should regret to see the annual custom die out. It is one of the very few occasions on which the medical profession as a body comes before the outside world, and it ought to be a great inducement to come out well. It is certainly an opportunity of which not a few make good use; and if the orator be chosen early on in the year, it gives him both time and opportunity to prepare that which ought to be neither common-place nor stale. Might

not a short introductory lecture be given, and the gathering then resolve itself into a *soirée?* The undoubted advantages of the two now distinct methods of procedure would be gained. The *soirée* was very well attended, and the large number of new faces promised a good entry for this enterprising school. There was an excellent concert, including pieces by Mendelssohn, Haydn, and other classical composers. Mr. J. Gardner gave a clever ventriloquial performance, and Dr. Tidy demonstrated the beauties of polarised light. There was an exhibition of microscopic, scientific, and medical instruments and appliances; articles *de vertû* also were lent for the occasion, including some magnificent autotypes by the Autotype Company, chromographs by Messrs. Hanhart, graphoscopes and stereoscopes by the London Stereoscopic Company. The medical and lay staffs were well represented, though some of the most distinguished were unavoidably absent. On one point only have we any fault to find—the arrangement for coats and hats was very defective indeed, and the crush which preceded the break-up considerably ruffled the tempers of not a few, and somewhat marred what would otherwise have been a most agreeable evening. The refreshment-stall was not managed much better. On subsequent occasions the authorities will no doubt provide a better refreshment-room, which, as is well known, is always largely visited. Mr. Kershaw, the Medical Secretary of the College, must be congratulated on the success of the *soirée* as a whole; we hear that the organisation was entirely under his supervision.

RUSSIAN AND ROUMANIAN HOSPITALS.

The following remarks of the special correspondent of a contemporary, on medical arrangements around Plevna, are interesting and instructive:—"No war of modern times has paralleled this for ferocity, nor for human suffering. No medical service, however well provided, could supply the need of these armies. Russia has done her best, and spent money on the ambulances as freely as on her combatant army. The doctors are well paid, even extravagantly in the higher ranks; there is abundant provision of necessaries, and the hospital attendants show great courage in picking up wounded men, the ambulances going as far forward as could possibly be called prudent. Upon the other hand, the carelessness visible all through the Russian army is prominent here. Under the most thoughtful arrangements, thoroughly carried out, the hospitals could not bear the strain put upon them; but when good-humoured carelessness reigns supreme, the breakdown may be expected to be painful. Some doctors lose their heads before the flood of work, and in hurrying and fussing imperfectly treat the cases that fall under their eye, and neglect more than they treat. Most of the doctors are untrained to the work; stores and instruments, though there be plenty of them, are not forthcoming at the right place at the right time; the essential condition of cleanliness is not fulfilled, and the neighbourhood of a field hospital is almost as foul as that of any other camp. As an exception, under immense difficulties, the hospital at Gabrova is kept as clean as may be, and the chief doctor is never too much occupied to say a cheering word to each patient. But if grave fault must be charged against the Russian hospitals, the Roumanian are yet more open to stricture. It is reported on good authority that the Government intends to make an example of those doctors who conspicuously shirked their work on the battle-field, and of those stretcher-men who refused to take up the wounded under fire. The whole system, of which the head surgeon, M. D'Avila, was so proud, has tumbled to pieces at the touch of war. Rarely has been beheld a sight so pitiful, shocking, and scandalous as that in the Grivitza redoubt on the afternoon following its capture. The wounded lay in the sun without notice or attention. There was not a drop of water for them, nor had there been all night. Nobody even looked at them; the blood and dirt curdled over their wounds. Even of those 400 slight cases sent to the Princess's Hospital at Bucharest, none had had their bandages changed since the first dressing, nor their clothes removed. I am told that the average of those who survive amputation in Russian hospitals is about 3 per cent The same competent authority informs me that in the Roumanian ambulances, scarcely a fortnight in real service, amputation would be but another name for execution."

THE FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

At a meeting of this Corporation, held on the 1st inst., the following office-bearers were elected for the ensuing year, namely:—*President:* Andrew Buchanan, M.D. *Visitor:* R. Scott Orr, M.D. *Treasurer:* John Coats, M.D. *Honorary Librarian:* James Finlayson, M.D. *Vaccinator:* Hugh Thomson, M.D. *Councillors:* The President, *ex officio;* the Visitor, *ex officio;* the Treasurer, *ex officio;* J. G. Fleming, M.D.; Henry Muirhead, M.D.; J. D. Maclaren, M.D.; James Morton, M.D.; Andrew Fergus, M.D. *Board of Examiners:* R. Scott Orr, M.D., Medicine and Materia Medica; James Dunlop, M.D., Clinical Surgery; Alexander Patterson, M.D., Clinical Surgery; P. A. Simpson, M.D., Medical Jurisprudence; James Dunlop, M.D., Surgery and Surgical Anatomy; Joseph Coats, M.D., Physiology; Alexander M. Buchanan, M.D., Anatomy; H. C. THE SOCIAL SCIENCE CONGRESS AT ABERDEEN.

In the "Health Section" of the Social Science Congress, the proceedings of which were last week brought to a termination at Aberdeen, one of the special questions set down for discussion was "The present state of house-accommodation in rural districts, and can its evils be remedied?" Dr. Haviland, medical officer of health for one of the Northamptonshire districts, opened the proceedings, but his remarks were objected to, as applying to England and not to Scotland. Dr. Stevenson Macadam, of Edinburgh, also read a paper in which he dealt with the air-space, water-supply, and drainage that should be provided in cottages. On the following day the latter gentleman contributed another paper on the ventilation of drains and sewers, which was followed by a discussion in which the President (Mr. Edwin Chadwick, C.B.) and others took part. Mr. E. J. Watherston, of London, read a paper on "The Laundry as a Source of Contagion," in which he showed the mischief done by washing being undertaken in dirty and unhealthy places, the remedy suggested being the establishment of proper washing depôts; and Dr. Cornelius B. Fox wound up the proceedings in this department with some remarks "On the Mode of Registering Sickness."

SANITARY ORGANISATION IN IRELAND.

The representations on this subject recently made to the Government by the Irish Colleges of Physicians and Surgeons, the Irish Medical Association, and the Dublin Sanitary Association, have already borne fruit. At the meeting of the Corporation of Dublin held on the 1st inst., a letter was read from Mr. B. Banks, Secretary of the Local Government Board

for Ireland, in reference to representations made to the Chief Secretary for Ireland, as Chairman of the Local Government Board, that in the large towns in Ireland sanitary administration would be better conducted under the superintendence of one medical officer of health. The letter pointed out that the 10th section of the Public Health (Ireland) Act, 1874, authorised the Corporation, as the urban sanitary authority, to make such an appointment as they thought fit. The Corporation were requested to consider whether, in their opinion, the appointment of such an officer was necessary, and to state the conditions as to salary, etc., upon which (if at all) they proposed to appoint him. After consideration the letter was referred to the Public Health Committee.

DEATH FROM OVER-STRAIN IN WALKING.

Our contemporary, the *Globe*, says that the pedestrian feat by T. Hunter, aged thirty-five, of Sunderland, has terminated fatally. On Thursday Hunter commenced walking 160 miles in forty-eight hours, ten miles further than Weston; and on Saturday evening he completed the distance, with thirty-five minutes to spare. On Sunday afternoon, while in bed, he was discovered to be ill, and speedily died from heart disease through over-exertion and excitement. We trust that this sad occurrence may stop, or at least lessen, the rage for pedestrian feats. Medical advice and warnings have been uttered in vain against these and other senseless and dangerous ways of straining to the utmost man's powers of physical endurance. Rapidly fatal disease will speak with a louder and, we hope, more effective voice.

MADEMOISELLE TITIENS.

We deeply regret having to announce the death of Mdlle. Titiens. It has long been known in medical circles that she was suffering from a malady the cure of which is as yet beyond the reach of our science and art, however much we may be able to do in relieving the sufferings caused by it, and in delaying its fatal termination; but we were very loth to believe that we should never again hear the great singer, or again see her on the stage. She died on the morning of Wednesday, the 3rd inst. This is not the place to speak of her glorious gift of song, and her grand powers as an actress; but numbers of us will cherish a most grateful memory of delight and recreation derived by us through the exercise of her talents.

THE CHAIR OF ANATOMY AND PHYSIOLOGY IN THE UNIVERSITY OF GLASGOW.

Dr. Cleland, F.R.S., who has held the Chair of Anatomy in Queen's College, Galway, since the appointment of Dr. Croker King as Inspector of the Local Government Board, Ireland, in 1863, has just been appointed to the Chair of Anatomy and Physiology in the University of Glasgow, *vice* Professor Allen Thomson, resigned. Dr. Cleland enjoys the highest reputation in his special department. He received his education in Edinburgh University, of which he is a graduate in medicine.

LONDON HOSPITAL MEDICAL CLUB.

A large gathering of the members of this Club was present on October 2 at the opening dinner of the session. Dr. Little was in the chair, supported by Dr. Davies, Dr. Rygate, Mr. Ernest Hart, Mr. Hutchinson, etc. Upwards of a hundred members of the Club mustered on this occasion, including past and present members of the staff, as well as old and actual students of the Hospital. A very good dinner preceded an unusually successful and enjoyable evening.

Preservation of Solutions of Morphia.—Solutions of hydrochlorate of morphia cannot be long preserved in a transparent condition, and their turbidity prevents their being then employed for subcutaneous injections. If to one part of morphia a hundredth part of salicylic acid be added, no change will be found to occur in the solution for a month.—*Wien. Med. Zeit.*, No. 32.

A CASE OF HYDROPHOBIA CURED BY CURARE USED SUBCUTANEOUSLY.

The following case we give entirely on its own merits, and without venturing on any judgment as to the exact nature of the disease. It is, however, so important in itself that we feel bound to submit it to the judgment of the profession. The narrator is a Dr. Offenburg, belonging to Wickrath, in Rhenish Prussia, and the patient was a country-girl, aged twenty-four, belonging to a healthy family. She was bitten by a dog, strongly suspected to have hydrophobia, on July 28, 1874. The wound was burnt with caustic soda, but not until three days after the injury; suppuration was then promoted. She was admitted into Münster Hospital on account of the wound, and with a view to its being healed. One evening about 8 p.m., eighty days after the bite, some very characteristic respiratory and swallowing spasms occurred quite suddenly on her attempting to drink. About one hour before this some irritability and a tendency to cry had been observed. In the course of the next two hours the whole train of symptoms of ordinary human hydrophobia came on. The spasms, with difficulty of breathing, were repeated about every two minutes; they were especially severe when any attempt to drink water was made, or even at the sight of the glass. She was excited also by light, and there was hyperæsthesia both of the sense of smell and of the skin. She complained of great thirst, and was greatly depressed by the knowledge that she was hopelessly ill with hydrophobia.

After having tried the injection of morphia and inhalations of chloroform without any benefit, it was decided to try full doses of curare, seeing the good results which had been obtained in tetanus. A subcutaneous injection of two centigrammes of curare (about one-third of a grain) in water was administered. This was three hours after the sudden onset of the disease. A quarter of an hour later, there having been no visible effect, the dose was repeated, after which the condition began slightly to improve—that is, there were longer intervals between the spasms, and the muscular movements became less, and finally ceased.

This result induced to a continued trial of the same treatment. The injections were continued, a somewhat larger dose (three centigrammes) being used. They were timed in such a way that an interval sufficiently long between the doses was allowed for the physiological action of the drug, and for any manifestation of the curare-intoxication to be obtained. Thus, at twelve o'clock the third injection was given, and the intervals of spasm became longer. In an hour another injection was ordered, and the intervals again became longer. At the same time the feeling of anxiety and oppression was less intense. A fifth injection was given at 2 a.m., and a sixth at 2.30. The intervals between the spasms now extended to ten minutes, and the pain in the chest and throat was almost gone. Indeed, there was a peculiar condition of hilarity and talkativeness, instead of the previous anxiety. Then the first appearances of loss of voluntary power just began to show themselves. After one more injection (the seventh) at 3.20 the spasms ceased entirely, and symptoms of a general paralysis of all voluntary movements became quickly apparent. The eyelids could only be moved with difficulty; there was difficulty also in speaking. Breathing continued normal; only twice was there any arrest of respiration, and this was overcome easily by making one or two rhythmical movements with the abdominal parietes; the breathing then continued regular. After these toxic effects had lasted with this intensity about two hours, movements again became freer. Some hours after the last injection of curare, it was seen that the dread of water no longer existed, as the girl could drink freely without any difficulty whatever. The sensitiveness to light also disappeared, and indeed all the symptoms of hydrophobia subsided. Thus within four hours and thirty-five minutes seven injections had been administered, representing altogether nineteen centigrammes of curare. During the course of the next few days, a mixture of symptoms, partly arising from the curare, and partly from the effects of the recent disease, developed. The latter consisted of slight muscular movements and involuntary spasmodic respiratory troubles, which for the most part were produced by the irritation of drinking, or fright, though they occurred spontaneously every now and then. On the

evening of the next day but one, some of these symptoms assumed a serious aspect, and another injection of curare was at once ordered, after the administration of which they disappeared. These symptoms, though of much less intensity, continued to recur until the eighth day, after which they finally disappeared.

The girl was discharged cured on December 3 of the same year, and went into service a few weeks later. She is now in perfect health.

Remarks.—The favourable action of curare in human hydrophobia may be explained as follows:—The chief symptom certainly is the frequent spasms. These spasms, which become more violent after each attack, are the cause of the constantly increasing danger of the disease, and they are finally the cause of death, which results either from exhaustion or from acute asphyxia. Curare, unlike other narcotics, does not act directly on the nerve-centres, but seems to act rather on the peripheral nerves. Its chief action seems to consist in paralysing the motor nerves, and especially (and soonest) those of the voluntary and striped muscles; then, after large doses, those of the involuntary muscles. An animal to which large doses of curare have been administered cannot move about voluntarily, neither can reflex movements be produced. If the motor nerves or even the spinal cord are irritated by a very strong electric current during the action of curare, muscular contractions cannot be produced; the muscles seem to be cut off entirely from the nervous system. The administration of curare in hydrophobia is not new. Niemeyer seems to have been the first to have tried it. He injected in his case five milligrammes, and then one centigramme, at intervals of three or four hours. "This treatment seemed to be of temporary service, and to produce greater relief than very large injections of morphia." Niemeyer strongly urged a further trial of this drug in larger doses in other cases of hydrophobia. No other successful results seem to have been obtained. Gualla has used curare in four cases of hydrophobia, and without success, but it is doubtful whether his doses were large enough. Theoretical arguments, no less than the above case, seem to indicate that the paralysing effect of curare is necessary to secure success. This case also proves that life may be sustained in spite of general muscular paralysis, the chief effort being, of course, to keep up respiration by artificial means. There is less danger of cardiac paralysis. It is a misfortune that a definite dose of curare cannot be indicated, the doses variously allowed by authors ranging from one milligramme to fifteen centigrammes. The difference depends, probably, on the quality of the drug. Another explanation, however, may be given. The action of curare depends chiefly on the excitability of the nervous system. The greater, then, the excitation and the excitability, and the greater the psychical exaltation, the more violent and intense will be the spasms, and the greater, therefore, must be the amount of the curare to hold these spasms in check. Thus, not only in different cases, but also at different periods in the course of the same case, entirely different doses of the same preparation will be indicated. A dose of curare such as in a healthy individual with a normal nervous system would produce decided effects on the motor powers, would produce scarcely any effect whatever on one who is the subject of hydrophobia. The knowledge of this circumstance is of great importance, and we may commence at once with larger doses than we should probably otherwise employ; yet the difficulties of administering the drug are only partially overcome, especially as we have to administer it until we get paralysing effects. Obviously the safest way, then, to administer curare is to give small doses, and to repeat them at short intervals until the effects we desire are brought about; and as a subcutaneously injected dose is absorbed and commences to act in a few minutes, and further, as (according to Demme) the action of a dose of curare only lasts from four to five minutes, so then we may most surely and safely obtain the effects of curare by oft-repeated small injections. Thus, if an injection be practised every half hour—a period of time which largely suffices in order to get the action, and the whole action, of an injected dose of curare—we shall be able within four or five hours to make eight to ten injections. In using curare in this manner, we not only secure its physiological action, but also guard ourselves against any sudden and too energetic manifestation of its toxic qualities. The action of small doses is proportionate both in intensity and duration, and so soon as any dangerous symptoms show themselves we should withhold its further administration, and take precautions suitable to the occasion, as in the case just given. It is of importance to commence this treatment early on in the disease. If the spasms are still slight, very small doses will suffice; if they have become more intense, a corresponding dosage will be indicated. It must be remembered, however, that any possible toxic effect will also be proportionate to the dosage. Nor must it be forgotten that the administration of such a remedy itself produces spasms; the irritation of the injection-puncture may sometimes be so great that the patients will seriously dread it. The various precautions to take, then, and the dosage, will depend on the individual case, and must be left to the discretion of the surgeon in charge.

FROM ABROAD.

Professor Broca on Cerebral Thermometry.

We have already published a short notice of Prof. Broca's paper on this subject, but we believe that our readers will be pleased to see it in fuller detail as it has appeared in the *Révue Scientifique* (September 15):—

Prof. Broca closed the session of the French Association at Havre by a very remarkable communication on cerebral thermometry, and the part which it may play in the diagnosis of diseases of the encephalon. To obtain the temperatures he employs thermometers one side of the bulb of which is applied against the cranium, while the other is supported in a kind of pocket covered with layers of wadding, so that the external temperature may not influence the thermometer. In general, he employs six thermometers placed side by side, forming a kind of crown around the head. The temperature is thus taken at six different points, two of each being symmetrical. The two anterior are placed directly behind the external orbital apophysis; the two middle ones above the ear in the temporal region; and the two posterior in the occipital region. For brevity sake, the three thermometers on the left side are designated F, T, O, and those of the right side F′, T′, O′. When the figures derived from the six are added and divided by 6, the mean temperature is obtained; but as each thermometer indicates the temperature of the point to which it is applied, its figure may be compared with those of the other thermometers. It is this comparison alone which can furnish important indications.

M. Broca's researches on this subject were commenced about 1865; but it is especially since 1873 that he has applied them to the diagnosis of cerebral affections. In order to obtain a fixed basis it was first necessary to ascertain the normal temperature of different regions of the brain. To obtain this he had recourse to those of the students in his service who were of about the same age and intellectual development, so as to conduct his experiments under conditions as identical as possible. He desired to obtain the mean temperature of the brain, the temperature of the right compared with the left hemisphere, and the temperature of the frontal, temporal, and occipital lobes. An objection at once arose. The thermometer in these different regions is separated from the brain by very different thicknesses. Thus, F and F′, situated at the anterior part of the temporal fossa, are only separated by a thin muscular layer and by the bone, the laminæ of which are inconsiderable. T and T′ have no separating muscle, and bone only of very slight thickness, but the hair (which is pushed away as much as possible) is a bad conductor. O and O′ are also covered with hair, and the occipital is of considerable thickness. But still, these causes of error are too slight to explain the notable differences of temperature observed in the different regions.

The observations were made on twelve students, in as nearly the same physiological conditions as possible, and the thermometer was always left *in situ* for twenty minutes. The maximum temperature of the brain was found to be 34·85° C. and the minimum 32·80°; so that the mean temperature would be 33·82°. But if the left thermometers, F, T, O, be compared with the right, F′, T′, O′, it is constantly found that the temperature of the left side is sensibly higher than that of the right. Thus, while the mean temperature on the right side is but 33·90°, that of the left is a little more than 34°. There is, therefore, in the normal condition a somewhat higher (about one-tenth of a degree) temperature on the left side. But, strange to say, this inequality exists only in a state of rest; when the brain is worked, an equilibrium between the two hemispheres is established, the temperature being alike in both. Must we not admit with Prof. Broca that the left hemisphere is better

irrigated, receiving a larger quantity of blood; but that when the brain works, as the right hemisphere, less prepared, and *plus malhabile*, has to make great effort, the arrival of blood becomes more considerable on that side, and the equilibrium tends to establish itself between the two hemispheres.

Pursuing the investigation, Prof. Broca, comparing the different lobes of the same hemisphere, found that the temperature of O was 33·92°, of T 33·72°, and of F 35·28°. These figures exhibit to what an extent the functional activity of the frontal lobe surpasses that of the occipital and temporal lobes. These results are obtainable when the brain is in repose; but the figures are no longer the same when the organ is in a state of activity. It was not an easy matter to give to the brains of the different subjects experimented upon work which was identical and not more difficult for one than another. Prof. Broca resorted to reading as equally familiar to students of medicine. The result was, that while the temperature in a state of repose was 33·92°, after reading aloud for ten minutes it attained 34·23°—a difference, therefore, of nearly half a degree in favour of the brain at work. Another result, already indicated, was obtained, viz., the equilibrium between the right and left hemisphere. While, in order to pass from the state of repose to that of activity, the temperature on the left side was raised by twenty-two hundredths, on the right it was raised by thirty-four hundredths.

Prof. Broca's clinical researches are not less important, and he is enabled by thermometry to furnish a certain sign of cerebral embolism, and to determine the part of the brain deprived of sanguineous irrigation. Long since he demonstrated that in embolism of the limbs curious phenomena as regards temperature may be observed. As might be expected *à priori*, he showed that the general temperature of the limb was lowered; but, at the very level of the point where the vascular obliteration had taken place, there was an increase of temperature. It was sought, in the case of ligature, to explain this paradoxical condition by the constriction of the nerves which surrounded the artery; but such an explanation is of no worth in cases in which the obliteration is spontaneous, as in embolon, the nerves surrounding the artery being in nowise injured by the clot. Prof. Broca explains this elevation of temperature at the level of the embolon by the collateral circulation which becomes established. The blood not being able to pass by the deeper vessels penetrates into the superficial ones, and dilates them, and the peripheric circulation becoming more active, the temperature is raised. *The maximum of temperature in the limbs will therefore be found opposite the embolon.* In the encephalon nothing of this kind can take place, because the vessels of the collateral circulation are not sufficiently abundant. When a cerebral embolon occurs, seven times out of ten the clot occupies the left sylvian (middle cerebral artery), and obliterates it entirely or only one of its trunks. What ought to take place theoretically in this case? The blood no longer penetrates into the territory of the sylvian, and the temperature of the corresponding thermometer ought to fall; but the irrigation becoming more active in the frontal and the occipital lobes, where the compensatory afflux of blood takes place, so the temperature ought to rise in the occipital and frontal thermometers. Prof. Broca produces two cases in illustration of these facts. The first of these related to a rheumatic woman, who was suddenly seized with hemiplegia and loss of speech, and on applying the thermometer the following temperatures were observed:—Left side: frontal lobe, 35·2°; temporal lobe, 34·3°; occipital lobe, 35·6°. Right side: frontal lobe, 34·8°; temporal lobe, 34·8°; occipital lobe, 32·9°. A diminution of temperature is thus observed, and most decidedly at the left temporal lobe, the blood of which comes from the sylvian. It will be seen that the temperature of the corresponding lobe is higher on the right, although this is contrary to what takes place in the normal state. Moreover, the temperature of the frontal lobe and of the occipital lobe, especially the latter, is very superior to that which is generally obtained. Theory and clinical observation are in this case in complete agreement, and we must admit that opposite the embolon a diminution of temperature takes place. In the same way the second case also shows that the left temporal exhibits a lower temperature than the right, and that the temperature of the left frontal and occipital is sensibly higher than in the normal condition.

American Diplomas Abroad.

Under this heading the *New York Medical Record* (August 4) has an article which we reproduce, believing the reproach it contains has in some measure a just foundation:—

"It would appear that our English cousins are never to learn what constitutes a true medical diploma in this country. The name 'American diploma' is so constantly associated in their minds with the bogus certificates which are sold by *quasi* institutions here, that it is difficult for them to understand that we have any other legal guarantee for medical education. The facts of this abominable traffic have been brought to the notice of the profession across the water time and time again, and it should be pretty generally understood that the quacks who settle in London, and who claim to be 'American' physicians, are no more recognised here than they are there. The profession here has done its best to check the bogus diploma trade, and to a certain extent it has succeeded. It should not be held accountable for what it cannot control; and further, it is hardly fair to class what are really well-educated medical men here with a class whom even our English brethren acknowledge are transparent frauds. Every little while a new case comes into the London courts under the sensation caption, 'Another American Physician in Trouble,' and we read the account to find that a 'Dr.' Hamilton or 'Dr.' Jones has been guilty of unlawful conduct in assuming a spurious title, etc., etc.; and then, in the course of the comments upon the value of American diplomas, and the laxity of requirements for a medical degree, the usual absurd questions are asked if there be such a recognised medical school in the United States as the Metropolitan Medical College, the School of Medicine of New York, the Medical University of Philadelphia, *et id omne genus*. We protest that we have had enough of this, and think it about time that our critics should inform themselves of the true state of medical affairs in this country before indulging in further remarks."

REVIEWS.

On Curvatures of the Spine: their Causes and Treatment. By Richard Barwell, F.R.C.S., Surgeon to Charing-cross Hospital. Third edition. London: Macmillan and Co. 1877. Pp. 238.

Mr. Barwell, in the preface to this, his third edition, affirms that "a large number of deformities depend on muscular conditions; their cure, therefore, is better and more perfectly effected by causing the muscles to act aright than by preventing their acting at all." Few surgeons will be disposed to disagree with this dictum, as far as it goes; but it very imperfectly describes what is needful in a large proportion of cases of spine disease; for it is well known that the muscular conditions, even when they are the primary cause of curvature, do not long remain, if they *ever* constitute, the only pathological changes. Indeed, deformities (so-called) could not be brought about were it not for certain alterations in the bony structures which result from unnatural muscular action. Thus, then, something more is required than simply "causing the muscles to act aright," and unless this "something" is properly recognised and applied, there are many cases where it would be better for the muscles not to act at all. This principle is recognised by the majority of surgeons, and tenotomy and myotomy are the results of this doctrine. Dr. Sayre has well laid down, during his recent and frequent demonstrations in this country, that, when muscles and tendons are simply contracted, stretching often suffices to overcome it; but when there is pathological shortening, then any attempt to stretch acts as so much additional irritation, and leads to a result which is diametrically opposed to what is desired. This, by the way, is no new doctrine, though, even now, there are a few surgeons who seem to disregard it.

The work before us is practically a re-issue of the last edition; certainly there are a few alterations, but they are rather in manner than in matter. The most noteworthy addition to the book is Chapter x., "On Angular Curvature of the Spine, and its Treatment by Plaster of Paris." This is an account of the new method of treating spine disease which was devised by Dr. Louis Sayre, of New York, and it professes to be "a fuller narrative of his procedure than is contained in his work on 'Orthopædic Surgery.'" Mr. Barwell, though his experience of this new method extends "only over a few months," ventures to say of it, "This plan offers the one desideratum so long sought—a means of enabling persons suffering from spinal disease to sit up instead of lying in bed; to take a

healthy amount of exercise in the open air, instead of being dragged about in a wheel-couch, and to get well with as little, instead of with as much, deformity as possible." Mr. Barwell says he has made "a few minor modifications in the management."

Our own experience quite confirms that of Mr. Barwell, and we look with confidence for greater and more substantial successes in the treatment of spine disease as the result of Sayre's method than of any other hitherto proposed.

GENERAL CORRESPONDENCE.

THE TREATMENT OF SPINA BIFIDA.

LETTER FROM DR. J. W. ROSEBRUGH.

[To the Editor of the Medical Times and Gazette.]

SIR,—In your journal of July 28 there is a review entitled "The Treatment of Spina Bifida by a New Method," by James Morton, M.D., Glasgow. I have been expecting some writer on your side of the water would call in question Dr. Morton's claim to priority as the originator of what you are pleased to designate his "new method." The concluding paragraph of your review is as follows:—"The book is very suggestive, and we hope the success which Dr. Morton has had may induce others to try his 'new method,' for the invention of which Dr. Morton deserves no little credit, the treatment of spina bifida having hitherto been a very thankless task."

In March last year the *Canada Lancet* reproduced a part of an article concerning this "new method," which did not mention the name of the author. Upon inquiry, I was informed that the writer was Professor Watson, of Glasgow, and upon this information I addressed a note to the editor, which he kindly published.

If Dr. Morton has been pursuing this treatment further than any previous investigator, and has given the profession the result of his experience, we all must join in returning him our thanks; but, at the same time, it is to be presumed he will not wish to take the credit of originating the plan of treatment, which had been successfully practised and recommended in the medical journals several years previously.

Inclosed is a copy of the note published last year by the *Canada Lancet* anent this question, and I trust you will be kind enough to give it a place in your journal, in order that we may ascertain how far Dr. Morton is entitled to credit as the originator of this procedure. I am, &c.,

Hamilton, Canada, Sept. 7. J. W. ROSEBRUGH, M.D.

N.B.—*A Case of Spina Bifida.*—At the Congress of German Surgeons, held in Berlin in April last, Professor Langenbeck presented a boy, *twelve years of age*, who, when an infant, presented a spina bifida tumour in the lower part of the back. The tumour, which was about as large as the fist, was treated by puncture and the injection of iodine. At the present time the only mark of the affection is a small cicatricial depression; the bones have developed, and now close the spinal canal completely. J. W. R.

THE PENGE CASE.

[To the Editor of the Medical Times and Gazette.]

SIR,—Doubtless the Penge prisoners deserve to be hanged, but it seems to me that innocent persons would be in danger of suffering the same fate on similar evidence. The leading thread throughout the whole history of the unfortunate Mrs. Staunton—from the time of Mrs. Butterfield's attempt to make her daughter a lunatic, down to the post-mortem examination—is brain disease. Is it conceivable that a woman with a healthy brain would allow herself to be shut up and slowly starved, without the means of ordinary decency, and with her child by her side undergoing the same fate? Would she not go and take food for herself, or would she not find means of escaping, or of revealing her condition to the tradespeople who came to the house? That over-trusted witness, Clara Brown, might have been asked further details about the starvation and confinement, but was not.

In these days of full and accurate newspaper reports it is surely competent for any medical person to form an opinion on a case without having been in court during the trial; and the judge's refusal to admit such independent testimony had an appearance of great harshness, more especially as a strong suspicion of the prisoners' guilt seems to have existed in the mind of the learned judge from the first.

That there was gross and possibly criminal neglect is clear; but the evidence of imprisonment and starvation seems to be insufficient; whilst the brain disease, of which there can be no doubt, furnishes a clue to the case from beginning to end.

I am, &c., EMERITUS.

MANCHESTER WORTHIES.

[To the Editor of the Medical Times and Gazette.]

SIR,—I find that I have wrongfully accused the *Medical Times and Gazette* of substituting the name Ward for Wood, in the report of Dr. Priestley's address at Manchester, so I humbly beg to withdraw my accusation, and to thank Dr. Lloyd Roberts for telling me of one more Manchester worthy—Mr. Ward, of whom I knew nothing. I am, &c., R. D.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, September 27:—

Boreham, Frank Squire, Lowestoft.
Lyddon, Richard, Folkestone.

The following gentlemen also on the same day passed their Primary Professional Examination:—

Clark, Thomas Furze, King's College.
Sturge, Henry Havelock, Guy's Hospital.
Whitworth, William, Guy's Hospital.

At the Preliminary Examination in Arts, held at the Hall of the Society on September 28 and 29, the number of candidates that presented themselves was 106, of whom two retired, thirty-four were rejected, and the following seventy passed and received certificates of proficiency in general education, viz.—in the First Class, in order of merit:—

1. Charles S. Evans; 2. R. D. Brinton and S. C. Townsend; 4. T. W. Bullock, H. Fickling, E. O. Newland, Reginald Rygate, and W. G. Tyrrell; 9. L. M. Anderson, H. Appleton, Edith Croft, J. Dowson, W. E. Driffield, Arabella M. Kenealy, J. F. Lea, J. Sinclair, and Ernest L. Wright.

In the Second Class, in alphabetical order, viz.:—

F. T. Bennett, T. Christie, J. H. Crouch, G. H. Darwin, D. J. Dixon, J. B. Dorrian, S. Ellis, G. A. C. Fletcher, E. Fraser, J. C. Garman, Mary Ann Handson, J. Hepburn, M. Henry, J. Hern, J. Hick, G. F. Hobson, W. Holdsworth, W. Jeffrey, E. J. Johnson, F. R. Johnston, C. H. Jones, J. W. Jones, R. Lee-Huzzey, A. W. Low, J. S. B. McBurney, H. M. Massey, H. R. Mead, J. D. Menzies, J. Miller, A. M. Moore, J. S. Murr, E. M. E. Munns, W. Murch, A. E. Nelham, F. Oldfield, F. H. Pike, G. F. Rhodes, H. E. Richardson, F. S. Rix, J. Royston, Adela H. Ryate, J. R. Rygate, D. G. Sandeman, H. L. Smith, H. Stott, F. M. Swallow, E. C. Thomas, W. R. Tytheridge, S. Whitten, R. H. Wilkinson, W. Wilson, T. C. Winn, and Richard S. Wright.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

LAMB, JOSEPH, M.R.C.S., L.S.A.—Medical Officer to the Post-office, Birkenhead.

BIRTHS.

CARR.—On September 30, at 6, Lee-terrace, Lee, S.E., the wife of W. Ward Carr, M.D., of a daughter.

COLEMAN.—On September 30, at Holly Lodge, Streatham, the wife of Alfred Coleman, F.R.C.S., of a daughter.

DE LA COUR.—On September 27, at 282, Camden-road, N.W., the wife of G. F. De la Cour, M.D., of a son.

DUKE.—On September 30, at Fernside, Sydenham-hill, the wife of Allen A. Duke, M.D., of twins—boy and girl.

GREENHOW.—On October 1, at Lillesworth, Esher, the wife of H. M. Greenhow, F.R.C.S., Surgeon-Major Bengal Army (retired), of a daughter.

HURLSTONE.—On September 29, at Richmond-gardens, West Brompton, the wife of M. de G. Hurlstone, M.R.C.S., of a daughter.

NICHOLSON.—On September 29, at 89, Camden-road, N.W., the wife of Emilius Rowley Nicholson, M.D., of a son.

RAVEN.—On September 28, at Barfield House, Broadstairs, the wife of Thos. F. Raven, L.R.C.P., of a son.

STOCKER.—On September 26, at Sanghall, near Chester, the wife of J. R. Stocker, M.B. Lond., M.R.C.P. Lond., of a son.

TEMPLE.—On August 14, at Gulmarg, Cashmere, the wife of Surgeon-Major Wm. Temple, M.B., V.C., A.M.D., of twin sons.

TUCK.—On October 2, at Seaford, Sussex, the wife of Buckmaster Joseph Tuck, M.R.C.S., of a daughter.

VISE.—On September 17, at Holbeach, the wife of Ambrose B. Vise, M.R.C.S. Eng., of a son.

MARRIAGES.

CAMPBELL—MILTON.—On September 29, at All Saints, Stoke Newington, William Campbell, L.R.C.S. Edin., of Wellington-square, Hastings, to Harriet M. A., only daughter of the late John Milton, of Doctors' Commons.

NICHOLLS—CROMPTON.—On September 6, at St. George's Church, Dominica, West Indies, Henry Alfred Alford Nicholls, M.D., to Marion, third surviving daughter of the late John Corney Crompton, Esq.

SMITH—CAMERON.—On October 2, at St. Jude's, Southsea, Henry R. Smith, L.R.C.P. Edin., of Dover House, Southsea, to Arabella Mary, only daughter of the late Major Donald Mint Cameron, 3rd Buffs and 94th Regiment.

SPRING—INGLIS.—On September 26, at St. Helier's, Jersey, Frederick William Mackenzie Spring, Captain R.A., to Ellen Harriet, elder daughter of Surgeon-General J. Gordon Inglis, C.B.

STURGE—BOVELL.—On September 27, at St. Saviour's Church, Paddington, William Allen Sturge, M.D., of 9, Wimpole-street, Cavendish-square, eldest son of William Sturge, of Tyndall's-park, Clifton, to Emily Bovell, M.D., daughter of the late John Roach Bovell, of Demerara.

WINTLE—RUMBLE.—On September 26, at St. Leonards, Streatham, Henry Wintle, M.B., of 12, Park-road-villas, Forest-hill, to Amy, second surviving daughter of Frederick Rumble, Esq., C.E., of Telford House, Balham.

DEATHS.

BOW, JOHN CAMPBELL, M.D., Deputy Surgeon-General, Meerut Circle, at 19, Queen's-crescent, Edinburgh, on September 29.

CLEAVER, LOUISA, wife of Henry A. Cleaver, M.R.C.S. Eng., at North-end, Croydon, on October 1, aged 62.

DICKINSON, WILLIAM, M.R.C.S. Eng., at 12, St. Leonard's-terrace, Chelsea, on September 29, in his 82nd year.

GILL, WILLIAM PERCY, only son of William Gill, L.R.C.P. Edin., at Somerset House, St. Philip's-road, Sheffield, on September 28, in his 7th year.

GRANT, MARY ANNE, wife of Surgeon-General J. M. Grant, M.D., at Park-street, London, on September 25, aged 59.

LUPTON, ALFRED WILLIAM, M.B., at Patani, Singapore, on September 18, 1876, aged 32.

PAXON, ESTHER AUGUSTA, wife of George Kirkham Paxon, M.R.C.S. Eng., at Dorking, on September 28, aged 57.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made and the day of election (as far as known) are stated in succession.

BERKHEMPSTEAD UNION.—Herts and Bucks District of Berkhempstead. Medical Officer. Candidates must be duly registered practitioners, and hold the certificate of proficiency in vaccination required by the Local Government Board. Applications, with recent testimonials, to Samuel Statton, Clerk, Hemel Hempstead, on or before October 15.

CASTLE WARD UNION, NORTHUMBERLAND.—Medical Officer. Applications, accompanied by testimonials of recent date, and evidence of qualifications and registration under the Medical Acts, to Thos. Arkle, Clerk to the Guardians, Highlaws, Morpeth, on or before October 13.

ROTHERHAM HOSPITAL.—Resident House-Surgeon. Candidates must be M.R.C.S. Eng., and Licentiates of the Society of Apothecaries or of the Royal College of Physicians, London, registered, and unmarried. Applications, with testimonials as to professional ability and moral character, to the Honorary Secretary, on or before October 15.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1871.

APPOINTMENTS.

Cardigan Union.—William Davis, M.R.C.S. and L.S.A. Lond., to the First District.

Carmarthen Union.—Thomas Hope Lewis, M.R.C.S. Eng., L.S.A. Lond., to the Carmarthen District and the Workhouse.

Cheadle Union.—Joseph Fitzgerald, L.R.C.S. Ire., L.K.& Q.C.P. Ire., and L.M., to the Ipstones District.

Chesterfield.—Alfred H. Allen, F.C.S., as Analyst for the Borough; salary by fees.

Drayton Union.—John Lyon, M.B. and M.C. Aber., to the Hodnet District.

Worksop Union.—Frederick Joseph Elsom, M.R.C.S. Eng., L.R.C.P. Edin., to the Cuckney District.

RESIGNATIONS.

Berkhempstead Union.—Mr. Thomas C. Lawson has resigned the Berkhempstead District; area 9835; population 6342; salary £65 per annum.

Brentford Union.—Mr. B. S. White has resigned the Ninth District; area 2240; population 8070; salary £90 per annum.

Manchester Township.—Mr. Walter Needham has resigned the office Assistant Medical Officer at the Workhouse Hospital; salary £190 annum.

Runcorn Union.—Mr. W. Carruthers has resigned the Halton Distr area 9807; population 3442; salary £40 per annum.

West Bromwich Union.—Mr. Benjamin S. Browne has resigned the W Bromwich South District; salary £85 per annum.

MORTALITY OF CHILDREN IN BERLIN.—This at present time has reached so fearful a height that it surpas that of all other large towns of Europe. The Berlin Pub Health Society has appointed a committee for the purpose investigating the calamity, its attention being especia directed to the connexion of this with the mode of feedi children.—*Wien. Med. Zeit.*, No. 32.

LOTION IN INTERTRIGO.—M. Delioux recommen from two to four parts of borate of soda to one hund of distilled water. After using the lotion a powder is to applied, consisting of subnitrate of bismuth two parts, star fourteen parts. If the oozing is considerable, the quantity bismuth may be increased, or oxide of zinc may be substitut for it. M. Delioux states that he has also employed this tre ment with success in some cases of acute eczema with mo or less abundant oozing.—*Union Méd.*, September 27.

THE RADICAL CURE OF BRONCHOCELE.—Prof. Oll described at the Havre meeting his mode of radical treatm of cysts of the thyroid. Bonnet used to make repeated a plications of Canquoin's paste, but this constituted a ve prolonged and horribly painful mode of procedure, a Prof. Ollier has modified it in the following manner:—I carefully dissects layer by layer until he reaches the walls the cyst, dissecting away the sterno-mastoid and fixing it the skin, when he finds it, as is often the case, spread over t tumour. Having thus exposed the wall of the cyst, he appl Canquoin's paste freely to it. The wall sphacelates and ope spontaneously without producing any hæmorrhage, and then passes a drainage-tube into the interior of the cyst, a washes it out frequently, in order to prevent the transform tion of organic matters and the septicæmia which mig result. By this procedure Prof. Ollier has obtained so very excellent results, and has only had one fatal issue.—*Ga des Hôp.*, September 25.

ENUCLEATION OF THE EYE.—Dr. Warlomont sur up a paper on this subject read at the Congress of Geneva follows:—1. The sympathetic accidents consequent on injuri of the eye are primary or secondary, the former occurri soon after the injury, and the latter after a more or less lo period—of months or years—after the patient has "doubl the Cape" of the early accidents consequent on the traumat action. 2. When an eye is *destroyed* by a traumatic cau and all hope is lost of the persistence or return of usef vision, an immense service is rendered to the patient by r moving the eye then and there by enucleation under anæsthetic He is thus spared the immediate consequences of the tra matism, as ophthalmitis, etc., and is restored at once, so say, to his occupation in an excellent condition for short receiving an artificial eye, which is then worn without inco venience. He is certainly preserved from consecutive acc dents. When there is reason to suppose that the wound globe contains a foreign body, the indication for enucleatio is still more pressing. 3. When an eye, lost from any cau (traumatic or other), or the stump which represents it, becom the seat of continuous or intermittent sensibility, or the sub ject of acute or chronic inflammation, or the asylum of foreign body, or of a crystalline that has become cretaceous- enucleation is indicated as a preventive means, even when a sympathetic manifestation is absent. 4. Enucleation of a lo eye, even if completely painless, is still indicated if, as possible even under these conditions, the second eye becom the seat of symptoms attributable to sympathy.—*Gazet Hebd.*, September 28.

ANÆSTHETICS DURING LABOUR.—M. Piachaud, Geneva, read a report at the Congress held in that city, which he strongly advocated the use of chloroform in natur labour. The precept is generally delivered, he observed, administer it only during the period of expulsion; but i certain cases of extreme nervousness (*neurosité*) and agitatio it is advantageous not to wait for complete dilatation befo employing it. It is also indicated when labour is suspende or retarded by suffering induced by anterior diseases, or whic may arise during its course; and also in cases in whic

ular or partial contractions occasion internal and almost inuous suffering without furthering the progress of the ur. Chloroform, he adds, should never be given without consent of the woman and her family. Prof. Courty, of tpellier, observed that the French school had shown too t timidity in the obstetrical employment of chloroform, thus left lying-in women exposed to numerous accidents. Dubois rejected chloroform in general, but admitted its loyment when the pains were so abnormal as to call for r sedative means or surgical intervention. Since that the question has not advanced a step in France. Prof. ty feels himself authorised by the results of his own tice to strongly advise the use of chloroform in labour. not indicated in cases that are quite normal, but only n the pains are too severe and irregular, or when the nts demand its employment. A semi-narcosis suffices to er the pains quite supportable. It diminishes perineal tance, so that all the force of the uterus is usefully loyed, and the duration of labour is diminished by nearly half. Uterine inertia is of much rarer occurrence—so chloroform has the advantage of chloral and ergot united. *zette Hebd.*, September 28.

OMPOSITION AND QUALITY OF THE METROPOLITAN ERS IN SEPTEMBER.—The following are the returns (by Dr. mott Tidy) of the Society of Medical Officers of Health:—

nes of Water ompanies.	Total Solid Matter per Gallon.	Oxygen required by Organic Matter, etc.	Nitrogen: As Nitrates, etc.	Ammonia.		Hardness. (Clarke's Scale).	
				Saline.	Organic.	Before Boiling.	After Boiling.
ames Water ompanies.	Grs.	Grs.	Grs.	Grs.	Grs.	Degs.	Degs.
d Junction .	20·80	0·000	0·090	0·001	0·009	13·7	3·3
Middlesex .	17·30	0·048	0·111	0·000	0·009	12·6	3·0
wark and uxhall . .	19·70	0·110	0·118	0·002	0·010	13·2	3·3
ea . .	21·00	0·092	0·105	0·001	0·009	14·3	3·3

e.—The amount of oxygen required to oxidise the organic matter, es, etc., is determined by a standard solution of permanganate of h acting for three hours; and in the case of the metropolitan waters uantity of organic matter is about eight times the amount of oxygen red by it.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

ffenburg.—Please send copy of thesis referred to.

rer.—We hope to publish next week the list of the successful candidates the Preliminary Examination of the Royal College of Surgeons.

. L., Pilstlin, Bavaria.—The lectures in question derive their name m the circumstance that there was founded at the College of Surgeons, honour of John Hunter and in perpetuation of his memory, a Hunterian" Professorship of Pathology and Surgery. This profesship is generally held for two years by the same person, who delivers h year a course of six lectures upon some surgical subject selected himself. No translation of the lectures could be published without permission of the author; but this would probably not be difficult obtain.

. S.—Under the head of "Secret Service" money, in the time of orge I., between the dates March 25, 1721, and March 25, 1725, we ice the following instructive items, in a list of "gifts, rewards, nties, and extraordinaries, of divers natures":—"To Dr. James uglas for his performance and publishing his anatomical observans, £500." (Douglas was a London practitioner of some fame, and n in Scotland in 1675.) "To Dr. Thomas Renton, for making known art, skill, and mystery in curing of ruptures, etc., £5000." "To Charles itland, surgeon, for inoculating Prince Frederick for small-pox, 00." "To Gideon Harvey, Doctor in Physic, Physician at the Tower, visiting the State prisoners, £300." (Harvey was appointed to the wer about 1689, and is said to have been physician there for fifty years).

Lancashire.—Professor Huxley's remark in regard to the proposal to a university charter for Owens College, was—"A university is, in judgment, a corporation which has charge of the interests of owledge as such, and the business of which is to represent knowledge the requirements of its members, to increase knowledge by their investigations, to diffuse knowledge by their teaching."

Cyrus.—Dutchmen, though great drinkers, are not drunkards. Much beyond the point where the average Englishman begins to feel decidedly the worse for liquor, the Dutchman is only imbibing medicinally. If he took the pledge, he would have to change his habits and abandon his favourite enjoyments.

P. H. P. S.—The "Association of German Natural Philosophers and Physicians" is the oldest of its kind. It was founded in 1822, and became the predecessor, therefore, by several years of the British Association, a similar institution.

L. C. P.—Voltaire scornfully called the air "a blue and white heap of exhalations." Of Nature he observed, "She is most wrongly named, for she is in reality all art, and not nature at all."

Students.—Dr. Paris's maxim to his patients was—that they might eat anything they liked, provided they were *regular* in their hours of feeding.

A Pupil.—For Italian medical research the *Gazeta Medica di Roma* is a well-known and excellent journal.

A Sanitary Inspector.—The total amount of accommodation secured by the London School Board for sites of schools up to March 24 last was for 172,914 children.

Max.—1. No. 2. Pliny relates that the coffin in use among the Romans was generally of stone. In some cases it was made of a certain stone from a district in Troas, which had, or was believed to have, the peculiar faculty of destroying all the body, the teeth excepted, in forty days. Hence the name "sarcophagus" (see Plin. H. N. ii. 98, xxxvi. 27). This stone was probably a species of limestone.

Paterfamilias.—Service in the Indian Medical Department may be said to have two branches—as an army official in medical charge of a native regiment and as a civil official in medical charge of first-class civil stations. These lead up to the higher appointments of Inspector-General and Deputy Inspector-General. Besides these regular appointments there are many other special appointments, such as Principalships of Medical Colleges, Superintendentships of Gaols, Lunatic Asylums, etc. Except in the case of officers holding special staff appointments, private practice is not forbidden, and in many civil stations this adds very substantially to the income of the doctor.

Prison Science.—A most useful book is "Prisons and Reformatories at Home and Abroad," being the *Transactions of the International Penitentiary Congress*, London, 1872. It is a perfect compendium of the prison systems of every country in Europe, of the United States, and of other nations.

An Old Subscriber.—You will find a record of the circumstance mentioned published exclusively in the *Medical Times*, vol. xviii. There is a complete copy from the commencement in the Library of the College of Surgeons.

L.S.A.—At the Arts Examination, which was brought to a close last week at the Hall, there were some female candidates.

Art Student.—The lectures at the Royal Academy, on Anatomy, are delivered at Burlington House about Christmas. The following distinguished members of our profession have occupied the chair:—The first was Dr. William Hunter, who held the appointment from 1768 until his death in 1783, when he was succeeded by Mr. John Sheldon, who also held it until his death in 1808. Sir Anthony Carlisle, who succeeded him, resigned in 1824, when Mr. Joseph Henry Green received the appointment; he resigned in 1851, and was succeeded by Mr. Richard Partridge; and, after his death, the present distinguished occupant of the chair—Mr. John Marshall—was elected.

Archæologist.—Drs. Akinside, Arbuthnot, and Sydenham were buried in St. James's, Piccadilly; Oliver Goldsmith in the Temple Church; Cheselden at Chelsea; Hunter at St. Martin's-in-the-Fields, afterwards reinterred in Westminster Abbey.

A Provincial Surgeon.—The registration at the College of Surgeons will not terminate until the 15th inst.

Mr. Williams, Islington.—The person named has no right to place "M.D." after his name because he holds the "L.K. & Q.C.P. Ire."; only graduates in medicine of a university can do this.

A Student, St. Bartholomew's.—Sir Trevor Lawrence, M.P., who took the chair at your annual dinner, is the only son of the late Sir William Lawrence. He received his education at St. Bartholomew's, and was admitted a Member of the College of Surgeons in 1853, soon after which he entered her Majesty's Indian Army.

A Lecturer.—The operation for popliteal aneurism was first performed by John Hunter in 1785, and the preparation deposited a few years ago in the Museum of the College of Surgeons.

GERMAN SURGEONS AND THE WAR IN THE EAST.

Nine army surgeons left Berlin on the 28th ult., for Bucharest, to take charge of the great hospital erected in the capital by the Roumanian Government. They have received indefinite leave of absence. The dispute as to whether those gentlemen were ordered, or departed of their own free will to the seat of war, is not yet settled.

River Pollution.

The Mayor reported to the meeting of the Town Council of Dorchester that Mr. Floyer, M.P., had objected to any further outfall of town sewage into the river Frome, and that a Government Inspector was coming down to examine the drainage system of the district.

COMMUNICATIONS have been received from—

Mr. Timothy Holmes, London; Mr. John Chatto, London; Dr. Thos. Barlow, London; Dr. W. R. Macdonald, Ayr; Mr. Francis Mason, London; Mr. B. R. Wheatley, London; Dr. Robert Smith, Sheffield; The Secretary of the Clinical Society of London; Dr. R. Druitt, London; Mr. G. J. S. Causden, Rhyl; Mr. Hensman, London; Mr. John Slatter, Radcliffe Infirmary; S., March; Mr. J. D. Campbell, London; The President of Guy's Hospital, London; Mr. Blyth, London; The Principal of the Veterinary College, London; Dr. Bate, London; Mr. Nunneley, Leeds; Mr. De Watteville, London; Mr. R. B. Carter, London; Dr. J. W. Moore, Dublin; Mr. W. W. Wagstaffe, London; Dr. Meymott Tidy, London; Mr. T. Nelson Hardy, London; Dr. Spencer Cobbold, London; Dr. Banham, Sheffield—Mr. Farrington, Diss; Messrs. Calvert and Co., Manchester; The Registrar of the Apothecaries' Hall, London; Dr. J. Williams, London.

BOOKS AND PAMPHLETS RECEIVED—

Medical Reports for the Half-Year ended March 31, 1877, forwarded by the Surgeons to the Customs at the Treaty Ports in China—Charles Bell Taylor, M.D., Clinical Lectures on Diseases of the Eye: Lecture III., Squint—Cassell's History of India, part 22—Rickman J. Godlee, M.S., F.R.C.S., Atlas of Human Anatomy, part 1.

PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Berliner Klinische Wochenschrift—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Gazette Hebdomadaire—Le Progrès Médical—Bulletin de l'Académie de Médecine—Pharmaceutical Journal—Wiener Medizinische Wochenschrift—Medical Examiner—The Louisville Medical News—Boston Medical and Surgical Journal—Nature—Philadelphia Medical Times—Iron—Cincinnati Clinic—Dairyman—Night and Day—Morningside Mirror—Chicago Medical Journal and Examiner—Home Chronicler—La Province Médicale—Sunday at Home—Leisure Hour—Medical Temperance Journal—Hardwicke's Science Gossip—Gazeta Medica da Bahia—British and Foreign Medico-Chirurgical Review—Guy's Hospital Gazette—Obstetrical Journal of Great Britain and Ireland—Monthly Homœopathic Review—Toronto Sanitary Journal—Veterinarian—Edinburgh Medical Journal—Students' Journal and Hospital Gazette—Archives Générales de Médecine—Union Médicale et Scientifique du Nord-Est—Analyst.

APPOINTMENTS FOR THE WEEK.

October 6. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 1½ p.m.

8. *Monday*.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

9. *Tuesday*.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

Royal Medical and Chirurgical Society, 8½ p.m. Dr. A. E. Sansom, "On a Case of Noma in which Moving Bodies were observed in the Blood during Life." Mr. Furneaux Jordan, "On Two Peculiar Varieties of Hydrocele of the Cord."

10. *Wednesday*.

Operations at University College, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 1½ p.m.

11. *Thursday*.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing-cross, 2 p.m.; St. Thomas's (ophthalmic operations), 4 p.m.

12. *Friday*.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1½ p.m.; Guy's, 1½ p.m.

Clinical Society, 8½ p.m. Mr. Bryant, "Cases to illustrate the behaviour of the Carbolised Catgut Ligature upon Human Arteries." Dr. Henry Thompson, "A Case of Hysterical Anæsthesia in a Male." Dr. G. H. Evans, "Some recent Cases of Paracentesis Thoracis." Mr. Lawson (for Dr. Aikman), "A Case of Injury to the Lower Portion of the Spinal Cord, followed by Wasting and Contraction of the Muscles of the Lower Extremities."

At the Royal Observatory, Greenwich, the mean reading of the baro last week was 30·03 in. The lowest reading was 29·74 in. on S morning, and the highest 30·23 in. on Thursday morning.

* The figures for the English and Scottish towns are the nu enumerated in April, 1871, raised to the middle of 1877 by the ad of six years and a quarter's increase, calculated on the rate which vailed between 1861 and 1871. The population of Dublin is tak stationary at the number enumerated in April, 1871.

ORIGINAL LECTURES.

INTRODUCTION TO A

COURSE OF CLINICAL SURGICAL LECTURES

DELIVERED AT ST. GEORGE'S HOSPITAL.

By TIMOTHY HOLMES, M.A., F.R.C.S. Eng.,
Surgeon to, and Lecturer on Surgery at, St. George's Hospital; Surgeon to the Hospital for Sick Children, etc.

GENTLEMEN,—In appearing before you to commence a course of clinical lectures, I think it desirable on the present occasion to do what I should regard as superfluous generally—viz., to tell you very briefly what objects I propose to myself in these lectures, and how I conceive such courses of lectures are related to the general subject of clinical instruction in surgery. I say that this seems to me necessary on the present occasion especially, since you must have lately seen our whole system of clinical instruction in London spoken of in terms which, if they were susceptible of polite or candid interpretation, were undeniably extremely in want of such an interpretation, for at first sight they read like an absolute, and indeed arrogant, denunciation of the method of surgical instruction pursued in the very schools in which the lecturer had himself received his own surgical tuition. But on that specially personal aspect of the matter I will not waste more words. Rude epithets seem to me much out of place between those who profess to be colleagues in the pursuit of the same science. The accusation of one's brethren is not a graceful occupation, and it derives no added grace from an admixture of self-laudation. I will only say that if our clinical teaching is deficient in reality, it is less our fault than our misfortune. We spend our best thoughts upon it, and our best energies as far as the time at your disposal and at ours allows. We have inherited at this Hospital, and elsewhere in London, the traditions of some of the most famous clinical teachers that the world has as yet seen; and if we have degenerated from our predecessors, it has been in power, not in zeal. But it is possible that I, in company with some other London surgeons, take a different view of the objects, and therefore of the necessary methods, of clinical teaching from those which the critic to whom I allude—Professor Lister—would adopt. If so, a difference in our proceedings is inevitable. I am not prepared, however, to abandon my practice without better ground than has yet been shown for doing so.

What, then, is the chief object of clinical teaching? I reply, to instruct the student in the elements of every-day diagnosis, so to familiarise him with the aspect, and the physical characters, and the symptoms of the commonest diseases, as to give him a good groundwork on which he can start for himself in after-life. Now, this can no more be given by lectures or by demonstrations in a crowded theatre than a knowledge of practical anatomy can. As the student of practical anatomy learns not a tenth part in the lecture-room of what he acquires in the dissecting-room, so the student of clinical surgery acquires not a tenth part so much in clinical lectures as he does in the wards of the hospital. The elements of diagnosis—that familiarity with the cases which will make you to tell a hernia from a hydrocele, for instance, with certainty and rapidity—must be acquired by feeling, touching, and examining carefully for yourselves, and with your own hands and eyes, a sufficient number of patients in the wards and out-patient room. Hence, as it seems to me, the radical vice of the system upheld by Mr. Lister, of having a single professor of clinical surgery—a great luminary who is to drag along in his orbit a galaxy of students, who derive certainly a sort of reflected light from having been his satellites, but who, if I am not much mistaken, do not learn much of the elements of diagnosis in a method of instruction almost exclusively demonstrational, and in which the demonstrations are shared by too many to be of much practical utility. It is, indeed, not very much that can be imparted by demonstration in any circumstances. Still, the two or three students who stand close enough to an operation really to follow its successive steps, or the few who can be admitted to verify for themselves the salient features of a well-marked case, may carry away useful information about it, and obtain hints which they do not afterwards forget. But a man on a back bench, who can hardly see the patient's body, far less verify his symptoms, must content himself (be he ever so attentive and intelligent) with jotting down a few of the precepts of the lecturer—which, after all, he could as easily have looked out in a book. Even in a school so small as this, it appears to me that our four surgeons and two assistant-surgeons are too few, though all are, I believe, zealous in that real clinical teaching which consists in admitting the students who accompany them to ascertain and verify for themselves the salient points in the diagnosis of the most practically important (*i.e.*, the most familiar) cases. I would add to these six the two house-surgeons, whose accident-practice in the early morning is a most important and rich field for the diagnosis of those every-day accidents which you will all of you be expected to be familiar with on the first day that you begin to practise for yourselves. What melancholy, what ludicrous, what disastrous mistakes has not every experienced surgeon seen from a neglect of this primary maxim in clinical instruction!—that the great object of the student during his hospital career should be to acquire a knowledge of the first rudiments of diagnosis. Everybody could tell you of dislocated shoulders and hips left unreduced, of herniæ opened by mistake for abscesses, and iliac and psoas abscesses mistaken for herniæ, and all kinds of disgraceful and criminal errors which a very little rudimentary skill in diagnosis would have made impossible. I am not conjuring up imaginary circumstances. I refer mentally to cases which I have myself seen, and in which, by the culpable negligence or ignorance of the surgeon, mischief was caused, which in many instances inflicted lifelong mutilation on the patient, and in all might have been the ground for legal punishment to the medical practitioner. This diagnostic precision, like all other acquirements, is largely the result of habit. When you come to meet other practitioners in consultation, you will, I think, be ready to admit the fact that many of them hardly ever make a precise diagnosis in cases which admit of any doubt whatever. They have not been trained to do so, and they are glad to take refuge in the haze of some ambiguous expression, instead of definitely stating to themselves the possibilities of the diagnosis, excluding the rest, and fixing upon one as the correct solution. I do not mean to assert that the course of surgery pursued at this or any other hospital is long enough to make the student an accomplished diagnostician; but I say that the elements of diagnosis, and especially the method and habit of forming a diagnosis, can be acquired, and that this acquirement should be the first and main object of every clinical course, and that any hospital system is woefully incomplete which does not make use of the services of every one of the members of its staff in the work of clinical tuition; for even at the smallest schools the number of students is usually larger than can be efficiently instructed, and where it is not so, it is an undoubted benefit to the student to be brought into contact with various minds, and be familiar with various ways of looking at the same class of cases.

Clinical tuition in therapeutics is, to my mind, an inferior object of our hospital system, though I do not deny its very great importance. I say expressly of "our hospital system," because we must never forget how extremely limited the time is, and that all our pupils are at the very commencement of their studies. In foreign countries there may be professors who address audiences composed of expert practitioners; but we, in this city, are speaking to students who know sometimes absolutely nothing, and never more than the mere rudiments, of surgery, and whose period of study is limited to two years. What possibility is there of indoctrinating such an audience in the therapeutic controversies of the day? and what profit in spending time in such an attempt which is already too short for the all-important object I have above stated? There are, indeed, great principles of surgical treatment which are incontestable, following as they do logically from the diagnosis; and there are traditions of each school which may fairly enough be laid down before its students. Nor do I think it is time wasted if the clinical surgeon turns aside sometimes from his main object, as a teacher of diagnosis, to set forth and defend those methods of treatment which he has adopted, or possibly originated. But I hold the therapeutical part of the clinical tuition as being inferior, both in importance and value, to the diagnostic; and in both parts I think it is of the greatest importance that the whole staff of the hospital should co-operate, and that the instruction should take place in the wards of the hospital over the bed of the patient, where the student can realise and verify for himself the points brought under his notice.

If this be so, what is the function of formal courses of lectures like these? They bear, in my view, somewhat the same relation to the surgical instruction as anatomical lectures do to the instruction of the dissecting-room, but are almost more necessary for the completeness of the surgical than those are for the anatomical course. Since there is much in

surgery that can hardly be described in text-books,—we meet in practice with many apt illustrations of disputed or neglected points in diagnosis and therapeutics,—and the surgeon can hardly employ an hour more usefully than in bringing such matters before the larger audience of all the students of the hospital, as well as the smaller class which accompanies him on his visit,—elaborated and completed by reference to other cases in his own experience and that of others, more than the familiar intercourse of the wards will allow. And I need hardly say that, holding the views I do about clinical instruction, I should regard it as a distinct loss to the school if any one of the surgeons alone was appointed to perform this or any other part of it. The students benefit by hearing the various topics which occasion brings up treated by various persons, and the patients benefit by the greater interest which the surgeon naturally feels in his cases when he has to make them the subject of special study. Any hospital in which a single member of the staff is appointed clinical professor appears to me to be in danger of sacrificing a good deal of its available resources, and of obscuring the more important bedside work by the undue exaltation of the work of the lecture-room; in fact, of putting the professor's demonstrations in place of the student's work.

These, however, are only my individual views, coloured, no doubt, by the habits and traditions of the school in which I have been brought up. I know that many excellent schools of clinical medicine and surgery in London and elsewhere have adopted the method of appointing special clinical professors. I no more wish to speak disrespectfully of their practice, than I expect to hear them do so of ours. I only wished in these few introductory remarks to protest—though, I hope, without any anger—against the statement that clinical surgical instruction in London is a sham. At this school we do all we can to make it a reality; and, if it were not so, we should indeed have strangely departed from the traditions of St. George's. We follow the method of teaching which we have inherited from our great predecessors, because it appears to us to give the students the best opportunities for real work, and the greatest available amount of practical instruction.

THE PRESENT POSSIBILITIES OF SANITARY LEGISLATION.(a)

By ROBERT BRUDENELL CARTER, F.R.C.S.,
Ophthalmic Surgeon to St. George's Hospital.

Mr. President,—I have selected as the subject of my discourse this morning "The Present Possibilities of Sanitary Legislation"; or, in other words, the inquiry what amendments of the law, in the interests of public health, are practicable in the existing state of enlightenment and of opinion. It is universally admitted that no law can be useful which does not command the willing assent of the majority of those who live under its provisions; and I think it is also admitted that legislation, especially when it has regard to questions upon which knowledge is increasing, and is becoming every year more widely diffused, may with propriety be a little in advance of prevailing practice, so that it may to some extent exert an educational influence. A legislature has to ask, in such a case, first, how far it must go in order to fulfil a plain duty; and next, how much farther it may venture without fear of frustrating its own endeavours by an excess of zeal. We shall perhaps find it more easy to reply to both these questions if we begin at the beginning, and if we briefly consider why it is that laws in the interests of public health are required at all, and what purposes they are intended to fulfil.

If we enclose a warm-blooded living animal—a human being or any other—in a case impervious to air, the inmate will soon perish of suffocation, because he has rendered the air enclosed with him irrespirable, or incapable of sustaining life. If the case were so arranged as to allow a partial renewal of the contained air, the inmate would none the less perish after a time, poisoned by the excretions of his own body. The rate of poisoning, and in some degree also the symptoms, would depend upon the size of the case and upon the amount to which the air was renewed, but the process would always be essentially the same. If the case contained two or more animals instead of one only, they would exert a reciprocally injurious influence upon one another, and each would hasten the deaths of his fellow-prisoners. In order to render it possible for them to live in the supposed confinement, air must be admitted freely, and the case must be cleansed at stated periods. In these few facts we have at once the basis of all sanitary science, and the explanation of the need for sanitary legislation.

The state of the members of a crowded community bears a very close analogy to that of several animals imprisoned in a cage with an insufficient air-supply and with inadequate provision for the removal of nuisances. The latter element of the supposed condition may be seen under two chief forms: one, in which the nuisances remain about the dwellings of those who have produced them; another, in which the nuisances are carried a little way from these dwellings, to some other place where their noxious influence is exerted upon persons who are innocent of having produced them. In either case, the noxious influence displays itself in the production of symptoms of poisoning, which are differentiated by various known and probably by some unknown conditions, and which are called, or are said to constitute, different contagious or communicable diseases. Among the known causes of variation, I may mention the different proportions in which the symptoms may be due to deficient air-supply or to the influences of filth, together with the different degrees of individual resisting power which may be produced by inherited strength or weakness, good or bad living, and the like. Among conditions the operation of which is unknown, although their activity may be surmised, I may mention various telluric or atmospheric influences, and various methods of the propagation or diffusion of the poison.

In former times, the experiment of compulsory overcrowding and of the imperfect removal of nuisances was systematically tried in English prisons; and the results obtained were of a twofold nature. In the first place, the prisoners so treated became the subjects of pestilential disease, which was described under different names, as "black death" and so forth, by successive contemporary chroniclers, but which was probably always what we now know as typhus fever. In the next place, not only did the prisoners suffer, but they also revenged themselves in a terrible manner. The disease engendered by the conditions under which they were placed was not restrained within limits imposed by those conditions, but diffused its poison from the persons and from the clothing of those who were first affected, and was even carried long distances by the intermediation of people and of things. Prisoners who themselves escaped fever, but who were brought into courts of law from the dens in which it prevailed, brought with them, in their garments or in the emanations from their bodies, the means of conveying it to others, by the process which we now call contagion or infection. Judges, counsel, jurymen, spectators, all fell victims; and at the famous Black Assize at Oxford, held on the 4th, 5th, and 6th days of July, in the year 1577, it is recorded by Holinshed that "when one Rowland Jenkes was being arraigned for his seditious toong, there arose amongst the people present such a dampe that almost all were smouldered. The jurors died presently; shortly after died Sir Robert Bell, Lord Chief Baron, with twelve others whose names are given. There died in the town of Oxford 300 persons, and there sickened there, but died in other places, 200 and odd more from the 6th of July to the 12th of August." The plague, which in the following century almost depopulated London, was indebted for its power of mischief, if not for its existence, to the filthy houses of our ancestors, in which the removal of nuisances was systematically neglected, and where the floors were strewn with rushes, placed in successive layers over the refuse of all kinds which was suffered to rot below. The glorious history of the British Navy is shamefully chequered by the records of the pestilences which from time to time have been originated or cultivated on board our ships; and it is only comparatively recently that the health of the inmates of public buildings and institutions has in any case been duly cared for. To this care, if we believe only a portion of what is said, the War Office still remains a striking and instructive exception.

In times within living memory, the apparent origination of sickness by insanitary conditions has become a less familiar phenomenon than its propagation under circumstances favourable to its increase. We have now constantly amongst us seven principal types of communicable disease, classified by the Registrar-General under the names of small-pox, measles, scarlet fever, diphtheria, hooping-cough, fever, and diarrhœa. These seven destroy in England and Wales often more, and never less, than sixty thousand lives every year; and it is known that some of them, it is with much reason surmised that all, are produced or propagated by means of filth; that is, they are results of

(a) An address delivered before the Sanitary Institute of Great Britain, at the Leamington meeting, on October 5, 1877.

imperfect nuisance-removal, or, in other words, of that self-poisoning or reciprocal poisoning process which would occur in the cage or case imagined at the beginning of my address, and which occurred in mediæval gaols. These results, however, are modified by various circumstances which have tended to mitigate the intensity of the poison; and therefore, regarded from an experimental aspect, they seem less conclusive than such histories as that of the Black Hole at Calcutta, or the Black Assize at Oxford. Moreover, the diseases in question, apart altogether from their first origin, have now acquired, or at least possess, a power and method of self-propagation which have caused them to be called zymotic. No one is able to say that the process of fermentation and the process of contagion-increase are identical, and it is even possible that there may be important differences between them; but there is certainly enough resemblance to justify the use of the word "zymotic" as a reminder of the way in which a morbid poison may be multiplied in the human body, so long as we do not become enslaved by the word, nor suffer it to restrain the freedom of our thoughts.

The phenomena resembling zymosis, with which we are abundantly familiar, are that some small portion of the poison generated by a disease, say the matter of small-pox, is introduced into a susceptible human body, and that it gives rise there to symptoms of illness which issue in the formation of a great deal more material similar to itself, and capable of communicating the same disease to others. We find that nearly every zymotic, or, to use the better phrase of Dr. Budd, which expresses a fact instead of a hypothesis, every self-propagating malady, attacks its one especial part of the organism, and discharges its poison by its own especial channel. For this reason, among others, it has been assumed by some that the poison is to be regarded as consisting of seeds or germs, necessarily reproducing their own kind; and we have heard much talk about these germs, and about germicide remedies, as if the existence of germs were a fact, instead of only a convenient assumption, like that which is conveyed by the word "zymotic" itself. It is perfectly conceivable that the poison may not consist of germs at all, but that it may be dead matter, acting by means of chemical affinities; and it is an inconvenience incidental to the use of the word "germ," that it tends to impose a hypothesis upon us for a truth. People often talk about germs as if they were known to exist, as if they could be seen and felt; whereas, in fact, we have no certainty even of their existence. This want of certainty does not matter much as far as scientific men are concerned, because they are not likely to be misled by what South felicitously called, "the terrible imposture and force of words"; but it matters greatly with regard to some of those to whom the Legislature has committed the care of the public health in districts or localities, because it may lead them to fancy that they know something, to fancy themselves less ignorant than they are, and thus to undertake responsibilities, and to pursue conduct, from which wiser or better instructed persons would shrink with something like dismay.

The ordinary traceability of zymotic disease to infection from a pre-existing case of the same kind, and the uniformity with which the chief zymotic diseases retain their peculiar or distinctive characters, have led to the further inferences that these diseases, as we now know them, are the results of distinct varieties of poison, that they have ceased to originate spontaneously, and that they always depend upon infection. It is held by some, however—and by some whose opinions are entitled to weight,—that the evidence is against all of these suppositions; that different types of disease may originate from a common cause; and that the epidemic maladies with which we are familiar may be generated anew under certain combinations of circumstances. Dr. Budd and his followers hold very strongly that every case, say of typhoid, whatever may have been the origin of typhoid fever in the first instance, must now be the offspring of a pre-existing case, as strictly as a child must be the offspring of its parents; and this is manifestly the view to which the habitual use of the word "germs" would lead. On the other hand, there have been many instances of typhoid and of analogous diseases in which no source of contagion could be discovered. Not very long ago, for example, there was a single case of cholera in the gaol at Agra—a case which terminated fatally within four hours, and was of the most malignant type. The disease was not known to be existing in the vicinity; the man who was the subject of it had been a prisoner for more than two years, and the daily routine of his gaol-life had not been departed from in any discoverable way. There were a great many prisoners in the gaol—speaking from memory, I think over 2000,—but there was no second case of cholera. If we take the reverse of the picture, we find many instances in which the origin of what at first seemed to be spontaneous typhoid has been traced to its parent case as soon as the investigation has been undertaken by a person of sufficient skill and knowledge; and no more notable example of this could be quoted than Dr. Buchanan's discovery of the channel through which typhoid poison found entrance to Caius College. The question thus raised is not merely a speculative one, but it is of the highest practical importance to all who seek the preservation of the public health. It is manifest, if the period of the new generation of any disease has passed away, if every case of it must now be the outcome of a pre-existing case, that the entire extinction of such a disease is at least theoretically practicable. We should only have to destroy all the newly-formed poison for a certain number of weeks or months, and the malady would disappear, only to be reintroduced, if ever, by importations from foreign countries, against which it should not be insuperably difficult to guard. On the other hand, if it be true that the zymotic diseases constantly spring up afresh, that they arise out of certain combinations of favourable conditions, and especially if favourable conditions which are essentially the same may give rise to different forms of disease under circumstances of accidental or trivial variation, then the work of sanitary reformers, although by no means hopeless, is almost inconceivably more difficult and more arduous. Which of these views may be true, we are at present wholly uncertain; and we must not suffer ourselves to imagine that certainty can be attained by the simple process of talking about germs. It can only be attained by the patient investigation of competent observers—that is to say, of men who are possessed of all the knowledge necessary to perceive the nature of the facts which come before them, and who seek for truth without reference to preconceived opinions. I think it must be universally admitted that the question is of great practical importance. We do not want to follow some philosophers in their disputes over the necessarily insoluble problem of spontaneous generation, over the question which Froude put so happily, "Which came first, the bird or the egg?"—but we do want to know whether, as a matter of practical fact, a case of typhoid fever necessarily presumes a pre-existing case and a channel of contagion, or only a pre-existing combination of physical conditions. The great difficulty of answering this question arises from the extraordinary complexity of the conditions favourable to the diffusion of disease which we have allowed to spring up around us. We cannot say that typhoid has arisen spontaneously, unless we are able to exclude every possible channel through which its poison could have been introduced from without. Such channels are at present innumerable; and one thing which we ought to seek from the law is their gradual closure. As soon as it is certain that the poison of typhoid commonly reaches us by some particular inlet, that inlet should be made secure against it for the future; and so, in time, by the mere process of stopping inlets or of guarding them, we should arrive, by a method of exclusion, at certainties which are at present unattainable. A few years ago I lived near some people with whom I had no acquaintance, who had young children, and these children were accompanied in their walks by a very pretty, gentle, playful dog, which we knew well by sight. One day this dog found its way into my garden, where it joined my children in their play, and, as we supposed, gave them all scarlet fever. The children to whom it belonged, as we discovered afterwards, were all down with the disease, and the dog had come straight from their beds to us. So, when scarlet fever appears, and we want to trace it to its origin, we have first to consider that it may have been conveyed in some such unsuspected manner as this, by a stray dog, by a beggar, by a tradesman's messenger, in a public conveyance, in a place of amusement, or by casual contact in the street. It may have been put into the letter-box by the postman, or delivered with the clean linen by the laundress. As long as all these possibilities exist, we can be sure of nothing; not even that the disease has actually found admission through the particular channel which we chiefly suspect. In my own case, for example, I suspected my neighbour's dog; but it could not be said that I had a tittle of evidence either against the dog or against its owners. In like manner, any research into the means of the diffusion of cholera is hopeless in India, where the possible channels of diffusion are countless; and first became practicable in this country, where circumstances afforded a greater simplicity of data.

Now, one of the things which I think we may ask from the law, even in the present state of knowledge, is adequate assistance in closing or guarding some of the channels, such as soil-

pipes and water-courses, through which the diseases most familiar to us are daily distributed.

It cannot be said that in preferring such a request we are asking the Legislature to interpose in a small matter, or to take upon itself duties unworthy of an Imperial assemblage. One of my first lessons in politics was to read in the writings of Lord Macaulay that the business of a government is to protect the lives and property of the governed; and both the lives and property of the English people suffer terribly from the state of things which we now permit to exist amongst us. Three years ago, in an address to the Medical Society of London, I made an attempt to express the amount of this suffering in figures. I found that the seven so-called zymotic diseases had caused in twenty-five years the loss of two millions and a half of lives in England and Wales, out of a total mortality of eleven millions, or one death in every 4·48. By adding another half-million for another five years we shall arrive at a zymotic mortality of three millions, nearly equal to the population of London, in the course of a single generation. I multiplied the average annual mortality by six, so as to obtain a very low estimate of the average annual sickness; and I divided the resulting number into adult males, adult females, and children, according to the census proportions of the three classes. Dr. Buchanan was good enough to furnish me with estimates of the duration of each form of sickness. He set the duration of typhus and of relapsing fever at five weeks, that of typhoid at six weeks, that of febricula at three weeks, and that of scarlet fever at four weeks, reckoning from the first appearance of the symptoms to the time when the duties of life may be resumed. From his data I obtained an average duration of four weeks and a half. I estimated the lost earnings or productiveness of each male adult at £1 per week, and the cost of nursing, maintenance, and medical attendance at the same amount, making a total of £9 an illness. In the case of adult females, I estimated cost and loss at £6 an illness; and in the case of children, cost alone at £1 an illness. These estimates mount up to a total of more than two millions and a half sterling, to represent what would be the total annual cost and loss occasioned by the zymotic diseases in England and Wales, if they fell upon the wage-earning classes alone. The greater cost and loss of their incidence upon the better classes cannot be estimated from any data known to me. The illness of the Prince of Wales disturbed the whole current of English society; and the value of such a life as that of the Prince Consort, or the value of some of the lives which were destroyed by the milk typhoid in Marylebone, transcends my powers of expression. The money cost, whatever it may be, falls partly, of course, upon the relatives of the sick, partly upon the members of clubs and benefit societies, partly upon the savings of the sufferers, and partly, and very largely, upon the poor-rate. The 100,000 premature interments must cost at least two pounds each; and they raise our money total to more than two millions and three-quarters (£2,796,402) yearly. Besides the mortality, and the cost of sickness, we must also take cognisance of the loss to the community which is occasioned by imperfect recoveries. It is my lot, at two hospitals, to see a large number of children suffering from eye-disease; and my inquiries about the origin or duration of the malady are constantly followed by the reply, "Ever since he had the scarlet fever," or "Ever since he had the measles." In the Irish census return for 1871 it is stated that out of 6347 blind persons living in that country, 526 had lost their sight from small-pox, 31 from measles, 34 from scarlet fever, and 99 from fever, or 690 in all; so that more than one-tenth of the existing blindness was due to zymotic diseases. Typhoid fever, scarlet fever, small-pox, and measles, all entail upon some of their victims an indefinite period of broken health or of impaired usefulness, of which Bright's disease after scarlet fever, or a consumptive tendency after typhoid, or blindness produced by small-pox, may be cited as extreme, though very common, examples. In cases of a less marked kind, these maladies often leave a protracted feebleness which may be communicated to offspring. The miscarriage of pregnant women is common in typhus, still more common in relapsing fever, and occurs occasionally in all zymotic diseases, whence it seems reasonable to suppose that unborn children may habitually be more or less injured in such cases. If the several evils which I have described were to fall, for the first time, upon a community paying due heed to sanitary regulations, scarcely any sacrifice would be thought too great for the sake of removing them. It is only the deadening influence of habit which enables so many among ourselves to regard them with comparative indifference.

It would be too much to say, of course, that all zymotic disease could be prevented by proper legislation and by adequate care; and no such statement could in any case be made until our uncertainty about the possibility of its originating anew is removed; but past experience is distinctly in favour of the proposition. We know that the improvement of the public health of England, coincidently with improved nuisance-removal, has been very remarkable; and this not only if we compare the plague period with the present day, but even in our own time. In the sixth volume of Mr. Simon's masterly Reports, there is one by Dr. Buchanan on the changes produced in certain towns by works for promoting public health. Time does not allow me to repeat Dr. Buchanan's statement in detail; but I may mention that at Macclesfield a death-rate of 33 per 1000 was in a few years replaced by a death-rate of 26, which implies a saving of 250 lives annually; and that the inhabitants of four streets, who received £158 5s. 6d. from the poor-rate in 1848, received only £25 4s. 9d. in 1855. You all know the old scholastic definition of the relation which a cause bears to its effect: "Præsens facit, mutata mutat, sublata tollit,"—and the relations of insanitary conditions to disease afford a manifest fulfilment of the first two clauses of this definition. When our forefathers lived in filth unspeakable, the country was ravaged by pestilences of greater severity than we can now easily realise—*præsens facit*. As we have become somewhat more cleanly, our epidemics have become of changed character and of less severity—*mutata mutat*. If we could become cleanly altogether, I for one have little doubt that we should realise the final clause also—*sublata tollit*,—and that we should banish epidemics altogether from the land.

It is by these preliminary considerations that I am led to what seems to me to be the proper answer to the question, What can the Legislature now do for us, consistently with the present state of public opinion and intelligence, which may lead, in due time, to a more complete recognition of the value of public health, and of the necessity for taking, in the public interest, such measures as may tend to its preservation. It is obvious that the nature of the answer must depend upon the nature of the impediments which stand in the way of complete and effectual reform. These impediments, as it seems to me, depend chiefly upon four causes—(1st) upon the manner in which legislation is made subservient to the interests of party, without sufficient reference to the needs or to the welfare of the State; (2nd) upon the degree in which local government is impeded by centralisation; (3rd) upon the real or apparent inequalities in the incidence of the local taxation from which the cost of sanitary reforms must be defrayed; and (4th) upon the existence of an apathy which is the result of almost inconceivable ignorance, largely tempered by superstition. These four causes are so intermingled in their operation, that although they may be separately stated, they can hardly be separately considered; and it is unnecessary to point out that the last of them—the apathy engendered by ignorance and superstition—is practically that which permits the existence of the others. If the inhabitants of this country were once to realise that the 10,000 annually recurring deaths, say from typhoid fever, are not due to any occult or supernatural causes, but are simply so many murders, resembling, in everything but the element of individual criminality, the starving to death of children in baby-farms, or the wanton destruction of life by any other description of neglect, the indignation which would be aroused would make short work of imaginary obstacles to reform. As long as the ignorance and the superstition remain, all that can be done is to regard insanitary abuses as giants to be circumvented—not as pigmies to be overthrown,—and to avail ourselves of every opportunity for endeavouring to spread abroad knowledge. In respect of this endeavour, and without any present infringement of the liberty of every free-born Briton to diffuse contagion where he pleases, the law might be so modified as to render assistance of the greatest possible value.

The first step towards such assistance would be, I think, to provide for the registration of every case of self-propagating disease which came under the notice, in his official capacity, of any public practitioner; any surgeon, that is, to a parish, district, a gaol, or a workhouse. I should like to see far more than this—that is, a complete registration of all the self-propagating disease of the country. I should like to see it made a matter of statutory obligation upon every medical practitioner to report to the sanitary authority of his district, in the person of its appointed officer, every case of contagious illness to which he was called. We must not, however, aim at too much at once; and the benefits which would arise from the registration of self-propagating disease among public patients would soon lead to its registration among private patients also

When a fire breaks out in a densely populated quarter, we do not try to conceal the fact, but we give an alarm, and we do all in our power to restrain the spreading of the flames. When a contagious disease breaks out in the same locality, we treat it, as long as may be, as if the facts were matters of confidential medical knowledge, not to be divulged beyond the houses in which they occur. The result is that we leave open many doors for the diffusion of infection—doors which should have been closed with the most jealous care—and we prepare the way for a tenfold greater degree of alarm than the truth would justify, as soon as the inevitable time comes at which some distorted and exaggerated version of it creeps out. The use which should at once be made of the registration of infectious illness among public patients should be that the central health officer of the country, under whatever title known, or to whatever department of Government affiliated, should immediately, upon the appearance of any such malady in a place where it had broken out afresh, send down an inspector to ascertain how the disease had been introduced, and by what channels it was being diffused. Permit me to say explicitly that by an inspector I do not mean a barrister, nor an engineer, nor a surveyor, nor a person who does not know scarlet fever from measles, nor one whose report, from very stress of ignorance, would be certain to contain as many blunders as words, but that I mean a physician, thoroughly trained in the difficult art of sanitary inquiry, and thoroughly conversant with every branch of the subject to which his attention would be directed. Especially he must be conversant with the natural history and possible variations of the disease under consideration, with all its known channels of diffusion, whether of an ordinary or of an exceptional character; and with all the circumstances capable of modifying its period of incubation, that is, of latency after infection has been received. If anyone would desire to know the amount of medical learning, and the qualities of mind, which are necessary for a successful sanitary inspector, he may find them shadowed forth in the chain of reasoning by which Dr. Buchanan determined that the cases of typhoid fever in Caius College were not due to the cause to which they had been attributed, and by which he traced them to their actual source of origin. As an illustration of how needful it is to leave no element in such a question out of sight, I may remind you that, when Prince Albert Victor of Wales sickened with typhoid, it was at once announced, on what seemed to be authority, that he must have contracted the disease at Sandringham, and a very circumstantial story was told of the how and the when. A simple comparison of dates showed that this story had no foundation in fact, and that the infection must have been received at Marlborough House. Passing on from this digression, I will suppose that, by a proper system of registration, the central sanitary authority is made aware of every outbreak of disease as soon as it occurs, and that he straightway sends down an inspector, not to interfere with local authorities, but simply to find out and to declare the truth. The report of this inspector, after having been approved by his chief, should be made public in the place where the facts occurred. It should be communicated to the local authorities, and then, of course, it would be published in the local papers. It should be part of the inquiry to bring the cost of sickness into prominence; and every week some board of guardians or other health authority would receive a document tracing out the history of events in which their parishes had been concerned. The general tone of such reports would be, say with regard to typhoid fever, that some passing tramp had poisoned the contents of Farmer Jones's cesspool, that the cesspool leaked into the adjoining brook, that the water of the brook was drunk by the inhabitants of the neighbouring village, that there had been so many cases, so many deaths of adults, so many of children, so much expense for temporary relief, so much for the maintenance of widows or orphans left permanently chargeable, and a total cost which might be capitalised, and estimated, let us say at £1500. All this would have been saved if Farmer Jones's cesspool had not leaked into the brook, and it might have been prevented from leaking, say for £5. What I would have, therefore, is that every occurrence of an epidemic should come without delay under the cognisance of the central authority, who should not override the local authorities, but should send down an inspector, again and again if necessary, for the sole purpose of observing the facts, and of writing them down in simple language. When the epidemic had ceased, the local authorities would be presented with an impartial account of their stewardship. They, or their constituents, would be made to see the cost of this piece of ignorant parsimony, or the consequences of that instance of presumptuous rashness. I think it would be wise for the central authority to confine its activity, for a time at least, to the one disease of typhoid fever, partly because this alone would provide work enough for a considerable staff, and partly because it is known to be frequently diffused through two very simple agencies—by sewer-gas in towns, and by polluted water in all places. It is hopeless to talk to the average vestry or board-of-guardian mind about sewer-gas or polluted water as abstract agencies. You must tell them about the leakage from Farmer Jones's cesspool, which they have seen and can realise, or about the escape of sewer-gas into the house of this or that neighbour. You must put aside misery, and must keep, with steady persistence, to the question of expense. You must show them, again and again, how much money their respective parishes have paid for having the fever, and at how small a cost they might have been saved from having it. Every report which put such facts as these into plain words, and forced them upon the attention of people living in the places where they happened, would furnish seeds of thought, which would germinate surely, even if slowly. A time would come in which there would be a growing public opinion in favour of ventilating sewers and of protecting drinking-water from pollution; and hence a readiness to submit to any legislative enactments which were manifestly necessary for the attainment of these ends. At present, although the medical inspectors of the Local Government Board pay visits of inquiry and make reports, these reports do little more than swell a mass of evidence which sanitary reformers highly value, but of which they have enough. The inquiries are conducted under circumstances highly detrimental to their usefulness. The department does not hear of the prevalence of the disease until it writes itself down in the quarterly returns of mortality, or until it reaches alarming dimensions; and, in either case, the difficulties of investigation are enormously increased. The facts of the beginning of the epidemic have been driven out of memory by subsequent ones; or the first patients, whose histories it would be most desirable to trace out, have died, or have gone away. The first cause, no bigger than a grain of mustard-seed, is obscured and lost sight of among subsequent occurrences, and the public interest in the whole question has perhaps begun to flag with the subsidence of fear and with the diminution of sickness. In order that such inquiries may be useful, or, more properly, in order that they may be useful in the greatest possible degree, they must be instituted concurrently with the events to which they relate; and they must be instituted not only with regard to epidemics of exceptional prevalence or fatality, but with regard to all occurring illnesses of a certain kind. The important fact, scientifically speaking, would be the presence of fever in a given district; and the subject for inquiry would be how it came there, and then, if it were to spread, through what channels or means of communication. Whether the fever attacked two persons or two hundred would be a very serious question in one sense, but a matter of comparative indifference in another; and it would be highly probable that groups of three or four cases in a locality, by the simplicity of the data which they would furnish, would afford the means of clearing up some of the most obscure points in the natural history of disease. If public opinion were sufficiently enlightened to insist upon the ventilation of soil-pipes and the protection of drinking-water, the two ordinary channels for the diffusion of typhoid would be closed. We should then come fairly face to face with the questions whether there are other channels of diffusion, now concealed from us by the universal presence of the common ones, and whether there are instances in which the disease originates *de novo* from certain combinations of conditions. I therefore ask it of the Legislature, as our most urgent present requirement, that infectious disease occurring among public patients should be registered, that the attention of the central medical officer of health should be directed to this register, and that the occurrence of self-propagating disease should be made the subject of regular official investigation and report. By the fulfilment of this requirement I should expect the eyes of householders to be opened to the true nature of events which are constantly taking place at their doors; and hence the growth of a public opinion which would ultimately demand reforms by which the chief of the existing facilities for the diffusion of disease would be taken away, and the problems incidental to the investigation of its modes of origin or of propagation would be so far simplified. In this suggestion I think there is nothing to which, on the score of the liberty of every Englishman to do that which is right in his own eyes, exception could be fairly taken.

In the meantime, while registration and investigation were doing their appointed work, there are yet other directions in

which present progress might be made. In the first place, politicians should, I think, turn their attention without delay to the question of the incidence of rating; not to trifle with it, not to allay discontent by a tiny bribe from the consolidated fund, but to revise and rearrange a system which the nation has long since outgrown. Real sanitary reform, whatever its nature, and whatever prospects of future saving it may hold out, must cost money, and this money must be obtained from rates. I do not know, for I have never studied the question, whether the apparent injustice and inequality of rating are real, or only apparent, being corrected by some compensating influence; but I do know this, that vast numbers of people who see and feel the inequalities neither see nor feel the compensations, if such there be, and that these people would oppose any increased expenditure from rates, however desirable in itself, merely because they are dissatisfied with the way in which rates are levied. The next direction in which legislation would be immediately practicable would be in a great extension of the powers of local self-government. We are supposed to have local government; but what we have is little better than an imitation of it, and not a very good one. Our so-called local authorities are so tied and bound in the chains of centralisation that we often can only obtain somewhat inferior persons to hold offices which entail considerable trouble, and which confer no real authority. A board of guardians, for example, is elected by the votes of the ratepayers; but a board of guardians has no more control over the expenditure of the funds which it is supposed to administer than if its members were so many automata. A board of guardians cannot give an extra shilling a week to a workhouse porter, or an extra half-pint of beer to an inmate, cannot engage a servant or dismiss one, not so much as a "probationary wardswoman," without the sanction of the Local Government Board; and the supposed reason for this is the necessity of protecting the ratepayer against the extravagance of his own nominees. Would he not be much better protected, in the long run, if he had to protect himself; and if he were therefore forced to be careful about the abilities and the characters of the men for whom his votes were recorded? Under the present system boards of guardians are often elected by a party vote, without any reference to their capabilities, and in municipal boroughs they are largely composed of persons who cannot aspire to be town-councillors, but whose services to their party are rewarded by this minor degree of promotion, which gives them a claim to have their speeches reported in the local papers. Again, would it not be much better if corporations and other local authorities were empowered to pass any by-laws, not in contravention of the laws of the kingdom, which their local circumstances might render desirable? Why should not our great towns, for example, be at liberty to act as pioneers in the way of social or sanitary legislation, by bringing the opinions of a majority of the inhabitants to the test of practice in the shape of local enactments. Why should not the corporation of Birmingham be allowed to control the local liquor traffic in its own way, and to control it without any appeal to the Imperial Legislature on a question which is of local and not of Imperial concern. At present, we find Parliament constantly unable to accomplish the work which it commences, and this, to some extent at least, because so much of every session is consumed over matters which might be perfectly well settled by local bodies. I feel sure that a gradual emancipation of such bodies is the direction in which our steps must tend; and that either we or our near posterity must see local government a reality. The result of making it so would be that communities which elected incapable men would smart for their mistake and would learn not to repeat it; and communities which elected capable men would be able to bring measures of improvement, sanitary or social, to practical tests which would guide other communities with regard to them. The blunders of any locality would furnish warnings to be avoided, and its successes would furnish examples to be followed. The lessons of caution which would be taught by the results of municipal elections, would lead inevitably to increased care in the exercise of the Parliamentary franchise. In health matters, of which alone I must speak, we should almost certainly see the towns which are known as health-resorts eager to take the lead in endeavours to diminish local mortality; and, if they succeeded, they would also diminish local charges. Their success in this direction would not fail to obtain for them, before long, the sincere homage of imitation.

I had intended, sir, before concluding this discourse, to say a few words about that unclean idol of Party Politics, which has been so great an obstacle in the way of sanitary reform, and before whose shrine, therefore, the lives of the people of England have been offered up. But the hour warns me that I must not longer trespass upon your indulgence; and this part of the question is one upon which I feel so warmly, that if I were to express my feelings I might unwittingly give offence, and might thus perhaps even hinder the advancement of the cause which I have at heart. I will be content to utter the wish that, if such a transformation is possible, some professional politician of the day may undergo development into a statesman, and may thus become able to perceive the opportunity for the highest statesmanship, which would invite him to enter upon a comparatively untrodden career. I am certain that any man of adequate culture and adequate capacity, who would devote himself to this great subject with a determination to understand it, and with a determination to rouse his fellow-countrymen from their present indifference with regard to it, might, by the patient and well-directed Parliamentary labour even of only a few years, write his name upon the pages of history as that of the greatest benefactor of his kind. In the meanwhile, sir, we here are like passing travellers, who throw single pebbles upon the cairn, which at last, by innumerable contributions, will attain monumental magnitude. Our present business may seem trivial; it may produce no immediate or perceptible results. None the less, however, will it be seed which cannot fail hereafter to yield a harvest; and in proportion as our work is earnest and truthful, so far will it hasten the advent of the time to which we must look forward with hope and confidence, when Englishmen and Englishwomen will no longer every year be poisoned by thousands, by accumulations of filth against which individuals are powerless, and which we, as a nation, are too indolent or too ignorant to remove.

ABSTRACT OF AN INTRODUCTORY ADDRESS

DELIVERED AT THE ROYAL FREE HOSPITAL, TO THE STUDENTS OF THE CLINICAL DEPARTMENT OF THE LONDON SCHOOL OF MEDICINE FOR WOMEN,

By JOHN COCKLE, M.D., F.R.C.P.,
Physician to the Royal Free Hospital.

The Lecturer commenced by observing that no embarrassment need be felt in addressing them, inasmuch as they had an undoubted right to determine upon the profession they would adopt; and he could only wish them success in their choice. Fears had been entertained that, from the very nature of the pursuit, their physical powers would prove insufficient, and their natural refinement would be blunted; but such fears as respects the latter might be regarded as entirely groundless. The tendency of the study, if conscientiously carried out, was clearly to elevate, and not to degrade the mind. On the other hand, it was idle to dispute their intellectual capacity for the study. They could triumphantly answer the contrary allegation by pointing to the honours gained by their leaders in universities of repute. Let such examples be their stimulus to profit by such instruction as this Hospital was capable of affording.

In their own College they learnt from able teachers all that was sound in theory; here was the place of applied science. They would be no longer passive, but active agents, with, for the time, incessant demand upon eyes, ears, and hands. But clinical study required, in common with other arts, a method; and on the method adopted their success or failure would in great part depend. What, in the lecturer's opinion, formed valid method was next pointed out. This achieved, they would be in a position successfully to commence *observation* in disease—to become clinical observers. But to succeed required a straightforward mental vision for the facts revealed to observation, untainted by any preconceived theory. The facts observed were to be well assorted and classified, in order that they might be generalised, and the law that they obeyed finally determined.

This reasoned Observation was the only safe and sure way to clinical success, for, unlike the kindred sciences, they were debarred experiment in the rigid sense.

The great advances in physico-chemical procedure were pointed out, and the vast advances of recent experimental knowledge as regards the development of zymotic disease. The historic filiation of the science was briefly sketched, to prove how much of present knowledge was foreshadowed in the past. This was more especially true as regarded the

physiology and pathology of the nervous system, and one or two illustrative examples were given.

The Address closed with remarks on the ethical side of a medical mission.

ORIGINAL COMMUNICATIONS.

A CASE OF PULMONARY EMBOLISM,

WITH NOTES BEARING GENERALLY ON THE SUBJECT OF EMBOLI.(a)

By W. ROBERT SMITH, M.B.,

Honorary Medical Officer to the Hospital for Sick Children, Sheffield.

In connexion with the notes of the case which I am shortly to read, I have thought that perhaps a brief review of the subject of embolism might not be out of place; and although I have no original views to advance on this most important disease—important alike to the physician, surgeon, and accoucheur—and have consequently hesitated in bringing the subject before you, yet I do feel that if by discussion any new light can be thrown upon the pathology or treatment of a disease which is unfortunately so frequently attended with the worst results, our meeting this evening will not be devoid either of interest or profit.

The existence of the morbid condition which has been designated embolism was, to a certain extent, known at a very early period in the history of our art, and has over and over again been established by well-authenticated cases and carefully made post-mortem examinations. Thus, a connexion between gangrene of a limb and plugging of the main artery, between apoplexy or sudden asphyxia and hyperinosis of the blood or the so-called polypi of the heart, has long been recognised and looked upon as cause and effect. Yet it is to Virchow, as all know, that science is indebted for having first placed, by his many admirable researches, the theory of emboli upon a firm foundation. But before his time embolism did not pass unnoticed. Even Galen states ("De Loco Adfecto," iv., page 295) that he often met with cases of sudden death in persons labouring from cardiac affections; in such he suggested as the cause the sudden obliteration of the pulmonary arteries by bodies which were subsequently called cardiac polypi. But later on the importance of embolism was more fully recognised; for Vesalius, in the sixteenth century, relates ("De Gangrena et Sphacelo," c. 4, page 775) a case of an enormous polypus in the left cardiac ventricle, weighing two pounds, and which gave to the heart the size and form of the gravid uterus. At the same time, he states that with the growth of this mass gangrene of the extremities is often combined; and that slight irregularity of the pulse is the only sign by which this condition is revealed. In short, the whole doctrine of emboli, by which I mean the plugging of vessels by foreign bodies, was first based upon the theories suggested by the supposed spontaneous formation of the so-called polypi within the vascular system. From this time much was written and said about embolism, but still no great advance seems to have been made upon the teaching of the older writers; for we find Cruveilhier, notably with many others, advocating that if any plug was found in the vascular system it was to be considered as a local product, the result of inflammation or some other process—the some other process, however, never being very distinctly defined; and thus a new variety of arteritis was taught, consisting essentially in the formation of a coagulum, the co-existence of inflamed arterial walls being considered altogether beside the point. In 1828, Alibert reported a case ("Recherches sur une Occlusion peu comme des Vaisseaux Artériels considérée comme Cause de Gangrène") of gangrene of the extremities, and obstruction to the circulation in the left arm, and distinctly showed the resemblance of the coagula which existed here to that of certain fibrinous formations in the left cardiac auricle. Immediately after this, Victor François published a work, in which sudden arterial obstruction was taught to be caused by foreign plugs, the result of a more or less distant arteritis, and which had been carried along by the circulating fluid. These views, however, made but little headway, for Tiedemann, in his work on the "Constriction and Closing of Arteries in Disease," published in 1843, mentions that coagulations, which, like stoppers, block up the arterial canals, may be either processes of the fibrinous layers of aneurismal sacs extending more or less into the arteries; or simple depositions of fibrine upon the sharp points of earthy concretions projecting through the inner arterial coat into the canal. Here there is evidently no thought of embolism. Four years after the publication of this book, a case manifestly depending upon emboli was published in the *Gazette Médicale de Paris*, page 672, by Pioch. A patient, labouring under hypertrophy of the heart and valvular induration, had several sudden arterial obstructions occurring in the brachial, vertebral, and right and left femoral vessels. Gangrene followed in the extremities, but no post-mortem was allowed; about this time also (but I forget where) another case was published, where obstruction in several main trunks existed subsequent to rheumatism, and accompanying endocarditis, but there was no gangrene. In the same year, Professor Virchow, of Berlin, first published a paper on Arteritis, in the *Archiv für Physiologische Anatomie*, in which he questioned many of the generally received views, and clearly showed that those products which had been taught to be the result of inflammation were of embolic origin. Virchow also taught that when a clot existed in the pulmonary artery long before death, and when, subsequent to this obstruction, changes took place in the parenchyma, such obstructions have always arisen in a part of the circulation anterior to the pulmonary arteries, either in the right side of the heart or systemic veins; he supported this view by a series of experiments introducing animal substances, etc., and produced (if you will allow me to quote his own words from page 15 of his work) "violent pneumonias, commencing with inflammatory hyperæmia, and causing the rapid deposition in the pulmonary vesicles of fibrinous exudations, which either underwent purulent metamorphosis or became gangrenous. With the advance of these changes, pleurisy was soon developed at the periphery, at first producing fibrinous, coagulable, and viscid exudations over the affected portion of the lung, but rapidly and as it progressed toward the other side of the chest, accompanied with enormous increase of hyperæmia, extravasations in the parenchyma of the pleura, and large watery hæmorrhagic exudations, with preponderating tendency to ichorous metamorphosis in its cavity. At the affected part of the lung the pleura became gangrenous, and finally gave way, and pneumothorax set in. The whole series of phenomena was developed in not quite five days."

Shortly after this another work of great interest to the surgeon was published—viz., "Investigations on Inflammations of the Arteries in general." Physiologists had long taught that the inner coat of arteries had no bloodvessels: How then could an exudation be produced through it? Was this to be looked upon as the result of a local inflammation? or was it the local manifestation only of a generally morbid blood condition? or was it, in the third place, a solid body, which, by some means or other, had entered the circulation, and got carried on with the stream until it entered a vessel too small to allow of its passage? Arteritis certainly could not exist in the deposit of an exudation upon a free surface; abscesses had been found between the inner and middle coats of arteries, without any corresponding production in the arterial cavity; in many cases gangrene of the limbs was found co-existent with plugging of the main arterial branch. Now, in such cases was the obstruction primary, and the inflammation of the vessel a secondary matter caused by the irritating properties of the embolon? or was the relation reversed? or, in the third place, were the obstruction and inflammation the joint effects of a cause separate and distinct? According to Virchow, the inner coats of arteries are not permeable to inflammatory exudations from the vasa vasorum of such vessels, this exudation being capable of coagulation; but this is found either between the outer and middle coats, or between the middle and inner ones; and this latter must give way before pus can be deposited in the arterial cavity. Sometimes coagula are found in an inflamed vessel when they are caused by a deposition of fibrine upon a roughened arterial wall, or upon some projection through such wall, the result of imperfect nutrition. In some cases the coagulum adheres only to one wall of the vessel, with the effect of narrowing the tube. This is not true embolism, although such a condition may give rise to embolic obstruction. Embolism may be defined as the existence of a clot in an artery without simultaneous lesion of its walls, this clot having been carried with the circulating stream from some distant spot as far as it would go, the arrest always taking place in vessels of a suddenly constricted calibre, too small to allow the solid body to pass. Such are briefly the views set forth in Virchow's work on Arteritis.

Since his time many able observers have written upon the subject, but their works are for the most part all based upon Virchow's theses, and are confirmatory of his observations.

(a) Read before the Sheffield Medical Society.

Time will not allow of reference to these, but I would remind you of Dr. Kirkes' conclusions from a careful study of the whole subject—viz., (1) that fibrous concretions did separate from the heart during life; (2) that these were arrested in certain peripheric organs, where they caused obstruction and structural changes; and (3) that by simple admixture with the blood they might give rise to pyæmia or other blood-poisoning conditions. That part of his observations is most interesting where he explains the petechial spots with which we are all familiar as very frequently occurring in endocarditis and pyæmia, on the skin, mucous membranes, and even on the peritoneum, as being caused by capillary embolisms. Since this paper appeared in the *Lancet* of June, 1852, we have learnt to attribute many sudden attacks of hemiplegia to embolic causes; and those researches are very interesting upon brain-softening as the result of embolism, where the anæmia of the brain is clearly shown to be the cause of the softening. And yet this term "anæmia" is a bad one, for very soon the collateral vessels enlarge and give way; extravasation then takes place, giving rise to a uniform red appearance, and that condition which we know as "hæmorrhagic infarct," and red softening. It is only when the circulation is very slightly interfered with, or when it is materially affected (as, *e.g.*, by plugging of the middle cerebral), that we get white softening. Here we see that brain-softening as the result of embolism, unlike senile gangrene, is not caused by a mere deficiency of blood, but is owing to serous effusion, the consequence of hyperæmia and stasis, the remote cause being the embolus. These hæmorrhagic infarcts are now also well known to exist in the lungs, liver, kidneys, and spleen, and present subjects of the deepest interest to the pathologist.

The most frequent source of emboli is undoubtedly venous thrombi, this giving rise to it in many ways: the thrombns may become softened and disintegrated, the fragments being carried into the circulation; or the blood-clot may not for some reason or other, fill the vessel—the blood passing over it in this condition is very liable to carry away portions, or the whole, into the general circulation; or, thirdly (and this perhaps is the most frequent way), the conical clot, which extends in a ruptured vessel as far as the first branch, is very prone to have its apex broken off by the onward rush of blood, which is always stronger at this place, owing to the obstruction forming a point which the blood can wash round, and which momentarily impedes its progress. If the embolus is found in the veins, it may pass through the right side of the heart and become impacted in the lungs; but if small enough it may traverse the pulmonary capillaries, pulmonary veins, and left heart, and cause obstruction in the renal or splenic capillaries. The pathological results of such obstruction are most interesting. First there is complete perversion of function, followed sooner or later (according to the more or less rapid formation of the collateral circulation) by a zone of intense hyperæmia around the area of tissue from which the blood-supply has been removed. Very soon, if the circulation be not re-established, the embolic area becomes distended with blood, owing to extravasation from the over-distended capillaries, the blood regurgitating from the veins. The subsequent changes depend upon the character of the embolus: if this be small, and not infective, then the mass softens, the blood changes from red to brown or yellow, and the whole contracts and becomes shrivelled, but is always surrounded by a zone of hyperæmic tissue; but if the embolus is caused by a softening and disintegration of the thrombus (say, *e.g.*, after an amputation, and when the stump looks unhealthy), then the embolus is associated with the infective properties of putrefaction and suppuration, and a number of metastatic abscesses appear in various organs as the result of impaction, and that condition which the surgeon most dreads—viz., pyæmia—exists. The point is not yet settled, I believe, whether true pus can cause capillary embolism, but there can hardly be a doubt, one would think, that if pus cells existed in such quantities as to occlude any capillary vessel, the pathological results with which we are all familiar as supervening upon embolism would follow. There is a point of much value practically in connexion with this surgical view of the subject, worthy of note. I believe it was first suggested by Professor Burrow. He states that the frequent bandaging of limbs after amputation is the cause of many unfavourable results; the veins are compressed by this application, and after a few days, when the bandage is removed, the venous walls of course become relaxed, and the coagula no longer fill the vessels, and are liable to be washed away by the passage of the blood over them. Embolism, and not pyæmia, is really the cause of death in such cases. I well remember a case which occurred whilst I was house-surgeon, which no doubt was owing to this cause. A healthy man had his thigh amputated after a severe crush of the leg implicating the knee-joint, and a bandage was applied round the stump to control the excessive spasm of the muscles. All went on well for some time—the wound looked healthy, and the man's general condition was good; but he subsequently had one or two severe rigors and died, and after his death several abscesses were found in his lungs. This case was registered as death from pyæmia, but I believe it was entirely of an embolic origin, caused by the removal of the bandage, and consequent relaxed venous walls. This supposition, I know, some will take exception to. Still, considering the man was placed under the best hygienic conditions, that the most scrupulous care was taken as to cleanliness and the dressing of the wound—the antiseptic treatment being adopted,—and the absence of any unhealthy appearance of the stump, I think my impression not altogether an erroneous one.

To the accoucheur the frequent and sudden fatal results of embolism after parturition are too well known and cannot fail to make the subject interesting. His patient may be bright and cheerful, and he may be congratulating himself upon the very favourable progress of the case, when all at once he is summoned only to find her a corpse. The following case will illustrate this:—

On the morning of February 24, about 6 a.m., I was called to attend a woman, aged twenty-four years, in her second confinement; for some months she had suffered severe pain in the abdomen and back, accompanied during the preceding week with much nausea and vomiting. As far as I could learn, she had been very injudicious during her pregnancy, carrying heavy weights, and generally busying herself too much about household duties. Even the night her labour commenced she had carried a heavy child of two years up a flight of stairs. I found Mrs. W. suffering severely from sharp acute pains, not of a bearing-down character, which were very irregular in their recurrence, but for the most part frequent. She had also constant vomiting. Her countenance was anxious; pulse fair volume, 82 per minute; skin cool and moist. Before I could make an examination, unfortunately, the membranes broke, and the liquor amnii escaped in large quantities, soaking the mattress, and dripping on to the floor beneath. This fact first awoke my suspicions that all was not right. Upon making a vaginal examination these were confirmed, for I found the right hand presenting, the child lying in the right oblique diameter, with its back to the mother's abdomen. The mother, however, was very sensitive, and it was with great difficulty I could satisfactorily make a diagnosis as to the child's position. I saw that any attempt to turn without administering chloroform would be entirely futile, so, in spite of the serious sickness from which the patient was suffering, I used this anæsthetic; then, introducing the left hand, I grasped the left foot, and completed the operation of version, afterwards delivering the child in the way usually adopted in breech cases. The placenta followed in due course, and the uterus became firmly contracted. Matters, however, did not go on so smoothly with the child: for fifteen minutes artificial respiration had to be kept up before it evinced any signs of life, then by vigorously slapping the buttocks it began to cry lustily.

Twelve hours after I found Mrs. W. feeling very comfortable. She had not been sick, but had felt great nausea. Complained a little of after-pains; skin cool and moist; pulse 110. Had passed water, and the discharge was not excessive. Milk was ordered to be given in small quantities frequently, and ice was allowed.

February 25.—Has slept fairly well; expresses herself as feeling better, and complains less of after-pain; has had no recurrence of the vomiting, but still feels much nausea. Temperature 101·4°; pulse 120, good volume. Has no abdominal tenderness; lochial discharge plentiful. The patient was ordered still to persevere with the milk and ice, and a small quantity of sago or arrowroot was likewise allowed, perfect rest in the horizontal position was enjoined, and the temperature and ventilation of the room were carefully attended to.

26th.—Has slept well; countenance cheerful; feels much better; tongue clean and moist; complains less of the nausea; bowels moved gently this morning; appetite good, the patient asking for a more substantial diet; discharge plentiful and healthy; milk abundant. Temperature 100·6°; pulse 96. The same treatment was persevered with, beef-tea and sago-pudding being ordered in addition.

From this date the patient progressed very favourably until March 1, when I found her by no means so cheerful. She had had a slight rigor the night before, which came on after

her removal to another bed, which had been done without my knowledge; had slept badly, and complained of great pain in her breasts, which were found to be swollen and hard; tongue furred, with a dryish white fur on dorsum; bowels not moved the day before. Temperature 103·2°; pulse 126, irregular and jerky; lochial discharge abundant; no abdominal tenderness; patient's countenance was anxious, and she expressed herself as feeling very ill and depressed. Milk diet was ordered, a gentle aperient given, a simple effervescing draught ordered three times a day, and hot flannels were applied to the breasts.

March 2.—Has slept well, and feels better this morning; tongue less furred; bowels moved freely twice; has taken her nourishment better. Temperature 102·4°; pulse 120, irregular and rather jerky.

3rd.—Much better; slept well; tongue clean; is more cheerful; temperature 102°; pulse 120, still distinctly irregular. At 5 p.m. I was summoned to see the patient at once, as she was much worse; upon visiting her two hours afterwards, when the message reached me, I found her dead. As far as I could learn from the husband, who was present, it appears she had raised herself in bed to use the bed-pan, and felt suddenly so ill that she laid down again, and died within a quarter of an hour with all the signs of asphyxia. The face was pale, the eyes were open, pupils widely dilated, the muscular system rigid, and hands firmly clenched.

Autopsy, twenty-four hours after Death.—Rigid mortis present; body well nourished. Upon opening the chest, the left lung was found collapsed, although the right was by no means over-distended. Heart: Pericardium contained a small quantity of serum; right cavities and large veins distended with dark fluid blood; left chambers empty. Trachea congested, and the left bronchus contained a little frothy fluid. Lungs: Right normal; hypostatic congestion at base. Left—upon tracing the branches of the pulmonary artery into its substance, at the site of the bifurcation of one of the main branches, an embolism, composed of clot, was found firmly wedged; it was about three-quarters of an inch in length, and rather larger round than a piece of slate-pencil. The lung-tissue was congested about the site of the embolus, but there was no distinct infarct. Uterus firm, five inches in length, and seven-eighths of an inch in thickness; no signs of inflammation present.

The embolon in this case I believe to have been detached from the uterine sinuses at the time my patient walked from one bed to the other. If this hypothesis is correct, the embolus was probably detained in the heart by the relaxed tendinous cords which are so abundant in the right ventricle, and thus gave rise to the high temperature, and quick, jerky pulse. At any rate, I think it is clear that, if this were the case, treatment, to be of service, should then have been adopted, but unfortunately at this stage there is a marked absence of symptoms sufficiently reliable to insure a satisfactory diagnosis. I believe the rigors which my patient had were owing to the sudden appearance of a clot in her circulation, and not, as I then believed, to the swelling and tenderness of the breasts: yet why should this not have been the cause? or how is it possible to diagnose with certainty a condition of so much danger to the patient? The only symptoms I could not explain were the continued high temperature and quick pulse after the mammary trouble had subsided. I know some will urge that the embolus might have been separated directly at the time of death, but I think the absence of all inflammation of the veins and uterus goes far to negative this idea. It is with the view of learning something as to the treatment and diagnosis of such cases, from those who have had far more experience than myself, that I have ventured to trouble you, at, I fear, some length, with this subject to-night.

THE CORONER'S COURT IN ENGLAND.(a)

By FRED. W. LOWNDES, M.R.C.S. Eng.

I MAY safely assert that there are very few gentlemen present who have not at some time or other been brought in contact with the coroner's court, to act in their professional capacity, either in giving evidence as to the cause of death of some one whom they may have previously attended, or been called to see after death; to give the details of a post-mortem examination made by the coroner's order; or—and this is of no less importance—to give such written or verbal information as shall have precluded the necessity for holding any inquest at all. Many gentlemen, moreover, are present, who are, from the offices they hold, and other circumstances, very frequently required to perform some of these duties; and their appearance in the coroner's court occurs with sufficient frequency to enable them to form an opinion as to the merits and demerits of this ancient tribunal. In inviting, therefore, your attention to the subject, I am not bringing forward a matter of mere curiosity nor one of public rather than medical interest; but one of very practical importance, which concerns some of us very greatly, and may be said to penetrate every part of the vast field of medical practice. It is very evident that we shall soon see considerable changes made in this ancient (I think I may say), antiquated legal institution, and the materials at our disposal for considering what they should be are very abundant. Newspapers, both lay and medical, have devoted a considerable portion of their space to show what in the opinion of the writers, is required to make the coroner's court all that it should be; and at the recent meeting of the Association for the Promotion of Social Science, a gentleman learned in the law had his say. Let us now examine the subject from a medical point of view, with especial reference to the three points I have given in the notice of this paper.

And firstly, as regards the providing a more satisfactory inquiry into all doubtful and suspicious deaths. Let us first see what the present mode of inquiry is. We may conveniently separate all deaths, as they come before us as medical practitioners, into three divisions—viz., (1) those where no inquest is required, (2) those where an inquest is imperative, and (3) doubtful cases.

The *first* of these is soon disposed of. It comprises that very large class of cases where a patient is attended by a duly qualified medical practitioner, who visits up to the time of death, and gives a certificate of its cause. An immense amount of most valuable information is furnished to the authorities (by this means) gratuitously by the profession, while an enormous power is wielded by the medical profession—a power which we must all allow to be, on the whole, most fairly exercised.

The *second* division also requires only a very few words, comprising as it does those cases—unhappily very numerous in this and other large towns—where death results from violence, accidental, homicidal, or suicidal, from criminal neglect, poison, or in such other ways as to make it obviously a case where an inquest will be held as a matter of course. In most of these cases we are not even asked for a certificate of death, the police taking up the matter and giving the necessary information to the coroner.

The *third* division requires more consideration from us, including as it does all those numerous cases where the death is sudden or the cause of it doubtful, rendering an inquiry into all the surrounding circumstances necessary. These are among the most anxious and least satisfactory cases with which we can have to deal, and I ask your earnest attention to this, as much difference of opinion prevails among us as to the rule we should adopt. For instance, we are called (we will suppose) to a person whom we find on arrival to be dying or dead. There are no marks of violence, neither is there any evidence of unfair play, but every external appearance that the death is a natural one, though the exact cause cannot be ascertained without a post-mortem examination. Now, one gentleman called to such a case would give a certificate on his own responsibility; a second would refer the friends of the deceased to the registrar of the district; a third to the police; a fourth to the coroner; a fifth would communicate directly with the coroner; while a sixth would prefer to wash his hands of the whole affair, refusing to give a certificate or any information whatever. The desirability of some more uniform practice must be obvious, whatever changes may occur in the constitution of the coroner's court, or even should there be no change at all. Let us now take a glance at the law on the subject so far as it affects this question. The office of coroner is, as you all know, a very ancient one—so ancient that its origin is lost in obscurity. And eight years ago our worthy coroner (Mr. Aspinall), with that ready wit for which he is so well known, remarked somewhat prophetically, "that it was a very *ancient* office, and he trusted that it was *equally enduring*." One of the ancient duties of coroner (that of hearing and determining felonies) was abrogated by Magna Charta, and the statute on which coroners act to this day is the statute "*De officio coronatoris*," passed in the reign of Edward I., six

(a) A paper read before the Liverpool Medical Institution, November 16, 1876, entitled "The Coroner's Court in England, and the means by which it may be rendered more effectual in providing—(1) a more satisfactory inquiry into all doubtful and suspicious deaths; (2) the more efficient performance of all medico-legal autopsies; (3) a field for the practical study of forensic medicine in our medical schools."

centuries ago. It provides that "The coroner upon information shall go to the place where any be *slain, or suddenly dead*, or wounded"; the remainder, given in rather wearisome phraseology, I may briefly state, enacts that a searching inquiry shall be made by the coroner and jury into all the circumstances, and any found guilty of having caused the death may be committed for trial at the assizes. You will thus see that the coroner is invested with very great discretionary power, the word "slain" being taken to include death by acts of omission as well as commission, and the right to inquire into any sudden death being accorded to him. This would seem from very early times to have been a cause of much dispute, there being on the one hand a very natural dislike to the privacy of domestic life being thus rudely invaded; on the other hand, a dislike equally strong on the part of the coroner to have his rights and privileges set aside. And it may relieve what I fear is rather a dry paper if I quote a passage from "The Brothers of Birchington" in the "Ingoldsby Legends." The good Prior of the Monastery had been found in the paddock "stone dead," and we read that—

"They sent for the mayor
And the doctor—a pair
Of grave men, who began to discuss the affair;
When in bounced the coroner, foaming with fury,
Because, as he said, 'twas pooh-poohing his jury."

Now, of course, the six centuries which have passed since the reign of Edward I. have brought great changes into the manner of holding inquests. Thus, the coroner and jury were directed that "all wounds ought to be viewed, the length, breadth, and deepness; and with what weapons, and in what part of the body the wound or hurt is; and how many be culpable, and how many wounds there be, and who gave the wound." This was done by the coroner and jury seated round the body. Hence the term, "sitting upon the body." To quote again, but for the last time, our friend "Ingoldsby," in the "Lay of St. Gengulphus" we read:—

"The coroner sat on the body that night,
And the jury agreed—not a doubt could they harbour—
That the chin of the corpse, the sole thing brought to light,
Had been recently shaved by a very bad barber."

We are brought face to face with what I believe to be the great objection to an inquest—the jury, *alias* the twelve good men and true. The object of an inquest now is essentially to ascertain the cause of death; and this is, of necessity, furnished by the medical evidence, if there be any. In other words, the jury simply repeat by their verdict what one—or at most two—gentlemen have told them. But there are a large proportion of cases, especially in towns such as this, where the cause of death is obvious without medical evidence. Surely in the case of a body taken out of the river, in a very decomposed state, it does not require thirteen men to tell us that it was a case of "Found drowned"; or, in another case, to tell us that the deceased was accidentally burned, accidentally scalded, etc. Such conclusions might be arrived at in a much less cumbrous way. There is a remarkable family likeness (as it seems to me) between the coroner's jury and that provided by two other ancient statutes to determine a purely medical question, viz., that of pregnancy. The first was that when a woman, after the death of her husband, to whom she had been only recently married, declared herself pregnant, the statute "*De ventre inspiciendo*" enacted that she should be examined by the sheriff, assisted by twelve matrons and twelve respectable men. The second is: when a woman pleads pregnancy in bar of execution, and twelve matrons of those who may happen to be in court are sworn to try whether she be "quick with child, of a quick child, or not." Medical evidence has enabled the Court to dispense with the sheriff and his twenty-four assistants, and with the jury of matrons. Might it not also dispense with the coroner's jury? This has been frequently suggested by most people who have handled this subject; and I think, as medical practitioners, we must agree that the abolition of the coroner's jury would simplify inquiries into the cause of death, without in any way impairing their efficiency. Coroners complain—and, perhaps, with reason—of the various and uncertain ways in which information of deaths reaches them. Sometimes it is received from a constable or beadle, whose sharpness is stimulated by a fee per inquest; sometimes from a registrar, who has received no certificate of death, or one which he cannot register; sometimes from a medical practitioner, who declines to certify as to its cause. Members of our profession complain—and perhaps with equal reason—of the uncertainty and capriciousness with which the discretionary powers of the coroners are exercised. I would refer you here to a paper published by me in the *Medical Times and Gazette*, June 28, 1873, page 683, in which I have detailed eighteen cases of sudden death occurring in different parts of the country, involving the practice of several coroners and several practitioners, which illustrates very forcibly what I have said. But it is so obvious that these irregularities must occur till a more uniform system be adopted, that nothing more need be said.

The changes I would suggest are briefly these:—

1. That the jury should be dispensed with.
2. That the coroner should be a member of the legal profession assisted by a medical assessor.
3. That every uncertified death should be referred to the coroner.
4. That he should have power to examine witnesses on oath when conducting preliminary inquiries.
5. That the body of the deceased should be identified on oath in the presence of the coroner by two or more witnesses.
6. That medical practitioners should be furnished with printed forms, to be filled up in cases of sudden death, or when the cause cannot be certified, and forwarded to the coroner.

These changes would assimilate our law very closely to that of Scotland, where all uncertified and violent deaths are referred to the public prosecutor or procurator-fiscal, who holds preliminary and subsequent inquiries, directing the police, the medical examiners, and completing the case for the trial. Gentlemen are present who will be able to tell us how complete and satisfactory the system is.

(To be continued.)

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

CASES OF THROAT DISEASE.

MIDDLESEX HOSPITAL.

Case 1.—*Pharyngeal Diphtheria—Vomiting and Fatal Syncope on the Fifteenth Day.*

(Under the care of Dr. EVANS.)

[Reported by Dr. FINLAY, Medical Registrar.]

M. B., aged eight years and a half, admitted on August 22. Family history good. Child has had good health before present illness.

August 18.—Complained of headache; no shivering; bowels confined.

21st.—Complained of pain in neck behind angles of jaw, where there was some swelling. Said her throat did not feel sore.

22nd.—On admission, temperature 100°; pulse 116; urine 1027, acid, no albumen. Patient is a fair-complexioned, well-nourished child. Glands below mastoid on left side enlarged. Has frontal headache. Tongue coated in centre with yellowish fur, red at tips and edges. Temperature in the evening 100·4°; pulse 116. Headache has disappeared.

23rd.—Temperature normal; pulse 104. Complains of pain in swallowing. Pain referred to glands behind jaw on left side. Throat examined: found somewhat swollen and congested. Uvula and adjacent parts of fauces found covered by a grey, tough membrane, partly separated from uvula. Throat bleeds readily. Temperature at 9 p.m. 98·6°.

24th.—9 a.m.: Temperature 99°; pulse 100. No pain, except in neck and throat when she swallows. Throat less swollen. Left side of uvula cleaner; some grey membrane on the right side. Evening temperature 97·7°; pulse 96.

25th.—Temperature in morning 98·2°; pulse 92. The glands along the sterno-mastoids are less swollen; throat less sore; and the membrane is now distributed over both tonsils and uvula in patches only. Temperature in evening 97·6°.

26th.—Pulse 84; temperature 98°. Throat is cleaner; no longer any pain in swallowing. Evening temperature 98°.

27th.—Has vomited twice after taking the medicine (tinct. ferri perchlor. and glycerine, spirits of chloroform). Urine 1020, acid, albumen one-twentieth. (This continued till September 1, when the albumen disappeared.)

Improved in general condition until the morning of September 2. Then for the first time it was noted that the child's

pulse was very feeble, and that she had become rather suddenly pale and dusky, with cold extremities. Vomited twice; tongue rather brown; has no cough nor any embarrassment in breathing. At 2 p.m. vomited again without obvious cause, and died suddenly in ten minutes.

Post-mortem Examination, twenty-four hours after Death.—Weather dull, damp, and cold. Rigidity moderate; body fairly nourished, surface pale. Thorax, etc.: The right pleura contained a few ounces of clear straw-coloured fluid; excepting this, and that all the chambers of the heart were much distended by dark-coloured clot, there was no abnormal appearance. The substance of the organs appeared natural. There were no appearances anywhere of diphtheritic membrane, the tonsils, uvula, epiglottis, etc., seeming perfectly healthy, and the trachea containing only a little frothy mucus. Abdomen: The peritoneal cavity contained a few ounces of clear pale fluid similar to that present in the right pleural sac. The substance of all the organs appeared natural, being, however, considerably engorged with blood. No urine was found in the bladder, so that a test for albumen could not be made.

Note.—In the common form of diphtheritic paralysis, a month to six weeks after the clearing off of the pharyngeal false membrane (which may have been slight in amount), the patient begins to talk like a child with cleft palate, fluids return through his nose, he loses his accommodation, squints a little, and perhaps manifests some unsteadiness in his gait. The prognosis in such cases is almost always good. But the case here recorded comes under another group, in which the prognosis is almost as certainly bad. In Sir William Jenner's matchless little volume on Diphtheria this group of cases is described in the chapter on disordered innervation. The vomiting and the infrequency and feebleness of the pulse point, as Sir William Jenner notes, to some altered function of the vagus. The important features are that this condition may come on quite suddenly whilst the patient is convalescing, and when other symptoms seem favourable; that it supervenes earlier than the common form above described—generally, in fact, within three weeks—and that stimulants appear to be quite ineffectual. The pathology of diphtheritic paralysis has yet to be worked out. Is it, after the fashion of some cases of so-called reflex paraplegia, a neuritis creeping up from the soft palate to the medulla, thence setting up changes by continuity, which are specialised either in the nuclei of the vagus or other cranial nerves, or in some part of the spinal cord?

Addendum.—We have received from Dr. Gwynne, of the Sheffield Dispensary and Hospital, brief notes of a case resembling the above, which case was attended by Dr. Gwynne as an out-patient at her own home:—

E. F., a fairly healthy female child, was seen first on April 26. She had well-marked diphtheritic patches on both tonsils and on the soft palate. She had a fair pulse; was able to swallow well; was dressed, and could sit up on the sofa. After a few days the throat got quite well. Appetite was fitful, and pulse varied a great deal in frequency, and became on the 30th very feeble. Still she was dressed every day, and was able to walk about the room.

May 1.—There were some very slight patches of membrane again to be seen on the tonsils. Glycerine of carbolic acid was applied, as had been done before, with obvious advantage; and next day the patches had disappeared, and no fresh patches had formed elsewhere. The child continued pale and feeble, walked in a tottering way, and pulse was very weak. Otherwise nothing noticeable.

May 3.—Whilst being held over a chamber utensil, which she said she wished to use, the child suddenly became pale; and when Dr. Gwynne saw her the pulse was barely perceptible, and she died immediately, apparently from syncope.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

Case 2.—Tubercular Ulceration of Fauces.

(Under the care of Dr. GEE.)

[For the notes of this case we are indebted to Dr. Garlick, Registrar.]

Alice B., aged seven years, admitted February 20. Parents both strong; no history of phthisis on either side. Two other children alive and healthy; one died teething. The child had been deserted recently by her mother, and evidently much neglected; was in a state of dirt and destitution. The only account obtainable was that five weeks ago the child had lumps in the neck, but made no complaint of the throat; that she had been wasting much, coughing for the last week, and made a noise in her throat at night as if she would be choked. Appetite bad. Bowels natural.

February 21.—Child looks extremely pale and ill; very thin; body and limbs much emaciated. Is dull; answering questions slowly, and with a thick voice. She coughs frequently, bringing into her mouth a thick, very yellow, sickly-smelling muco-pus, which also hangs about the fauces, obscuring the parts. Lymphatic glands on both sides of jaw much swollen. Fauces and back of pharynx eroded. A muco-purulent discharge from the nostrils. Last night some fluid returned by the nose. She swallows solids better than liquids. Chest is small; normal resonance and inspiration all over, but there are diffused all over, but especially on the left side, subcrepitant râles. Abdomen is retracted. Spleen a finger's breadth below rib-margin. Liver not enlarged. Urine, no albumen.

22nd.—Has marked hectic.

March 5.—Fever continues. Child now very depressed. Ulceration of fauces has extended; uvula almost gone. Now the whole of right front is quite dull on percussion, and respiration is covered by abundant sharp râles. Similar râles over left front. Posteriorly, impairment of resonance, with bronchial breathing at both apices. Urine contains a trace of albumen.

10th.—Marked and rapid wasting; now almost a skeleton; very pale and weak; continually febrile. Takes little but liquids, and these return frequently by the nose. Lies on the right side, and is constantly bringing up, with the slightest cough, abundant sulphur-yellow expectoration. A good deal of dyspnœa; respirations 60 in the minute. Chest râles over right front now replaced by strong tracheal respiration; dulness absolute; sharp clicks at both apices; no diarrhœa.

11th.—Died rather suddenly at 3 p.m.

Post-mortem, twenty-four hours after Death.—Rigor mortis present. Body much emaciated. Marked thickening of soft palate—almost double the normal; edge of palate and almost whole of uvula completely and sharply eaten away; mucous membrane on under surface of soft palate, and for some distance, smoothly and superficially ulcerated; edges of ulcers sharply cut, and not thickened. Tonsils small; no evidence of ulceration. Back of tongue deeply ulcerated; edge of epiglottis eaten away; also the arytænoid cartilages partially. Whole interior of larynx presents a finely flocculent appearance, due to adherent small sloughs, the different parts being, however, distinguishable. Superficial small ulcers below to the cricoid cartilage, the size of a poppy-seed. Glands to the right of trachea enlarged, the size of a sparrow's egg; that in the bifurcation not enlarged. Right lung adherent firmly almost throughout; a small trabeculated cavity at the apex; the whole lung presents a densely packed mass of opaque yellowish tubercles from apex to base, the lung between being consolidated by a grey and granular infiltration in the front, and congested in the rest. Left lung also closely packed throughout with tubercles; no cavity. Pericardium and heart natural. Liver twenty-four ounces, much congested. No tubercles; and none found in the kidneys or spleen. The mesenteric glands are enlarged and caseous; and there are numerous tubercular intestinal ulcers with tubercle on the peritoneal surface leading up to the enlarged glands.

Note.—Three other cases of tubercular ulceration of the fauces have been recorded by Dr. Gee, two of them in vol. vii., and one in vol. xi. of the *St. Bartholomew's Hospital Reports*. Two of these are reported in detail, and give a tolerably complete picture, clinically and pathologically, of this disease. Amongst salient features are the slow eroding character of the ulceration (quite different from the "quick melting down of lupiform angina"); the copious formation of muco-pus; the extreme enlargement of the lymphatic glands of the neck (not found as an accompaniment of syphilitic disease of the fauces, and of itself strongly suggestive of tuberculosis); the marked dysphagia which in this, as in two of the other cases, led to frequent regurgitation of fluids through the nose; and finally, the accompanying general tuberculosis.

Mr. Wood, surgeon, of Kirkby Moorside, who has for ten years been Deputy Coroner for the North Riding of Yorkshire, was last week elected Coroner for the district, in the room of the late Mr. J. Ness, who died suddenly at Plymouth during the recent meeting there of the British Association.

THE SANITARY CONGRESS.

Congresses, conferences, and meetings of a scientific (or would-be scientific) character, multiply at such a rate nowadays, that it would be simply impossible to record, however briefly, the proceedings of all of them, even if we believed that it would be profitable to do so. We do not know whether any hypothesis or theory has been put forward to account for this rapid production and spread of these institutes and assemblings: but perhaps we may be permitted to suggest the question whether the glandular theory or the germ theory can afford any explanation of the matter; or are any of these congresses purely fortuitous? Be that as it may, however, we cannot allow the late Congress of the Sanitary Institute of Great Britain to pass without a few words on the chief addresses delivered during it. It will be remembered that the Institute held its first public meeting at the Royal Institution, London, in July last, under the presidency of the Duke of Northumberland, when Dr. Richardson, the chairman of its Council, delivered an address, which we noticed at the time. Last week it held a Congress, presided over by Dr. Richardson, at Leamington; and this meeting is the first of a number of similar ones meant to be held in other places in future years. Dr. Richardson again opened—we believe we ought to say "inaugurated"—the proceedings by an Address on the Glandular Origin of Communicable Diseases. He entirely disbelieves in the germ theory of disease; and made use of the present occasion to review the theory which he brought forward ten years ago, in Leamington, on the occasion of a congress being held there to discuss the subject of the disposal of sewage, and which his subsequent experience and reflection have, he says, only tended to confirm. He holds, we believe (for we have seen only an abstract of his address), that a patient suffering from communicable disease is for the time being a poison-producing animal; the substance or material by which each communicable disease is produced, and spread, being an organic poison, or septine, which is the result of disturbed glandular action, and the patient being temporarily in a condition analogous to that of a poisonous or venom-producing snake. He has noted that the number of the distinctly communicable diseases is closely related with the number of the secretions in the healthy body: "the poison of hydrophobia is from the salivary secretion; of diphtheria from the mucous glands of the throat; of scarlet fever, he believed, from the lymphatic glandular secretion; of glanders, from the mucous secretion of the nasal surface; of typhoid, from mucous glands of the intestinal surface; and so on. In some instances the blood itself is infected, and the corpuscular matter becomes the seat of the catalytic change." And the matter or particle which sets up the poisonous action, instead of being a living germ, is matter actually dead; its power for evil depending upon its being dead. By this, then, also is explained the fact that under certain influences affecting glandular action the poisons may arise directly through nervous impression without the necessary intervention of an infecting particle. In many epidemics it is common, Dr. Richardson says, to see a number of examples of the prevailing disease, the origin of which is traceable only to fear or anxiety. "My theory," he continues, "explains fully the reason of this. It indicates that an extreme nervous impression acts on the glandular nervous supply, paralyses the glandular function, and thereupon produces the same phenomena as are produced in other instances by the action of a specific poison. The theory in this manner accounts for the origin of an epidemic disease from an impression made on the nervous system without the direct contact of poisonous matter, as well as for the after-propagation of the disease by distribution of poisonous particles, when that is communicated from an infected to a healthy person. It accounts equally for the production of disease and of a poisonous glandular product under conditions of starvation and cold, by which the nervous tension is reduced. Again, it accounts for the production of disease and of a poisonous glandular secretion under special atmospherical conditions in which the activity of the atmospheric oxygen is reduced in sustaining power." By it we can also account for the distinct "heredity" of some of these diseases. The impression of disease made on a nervous centre is transmissible, and thus a tendency to typhoid fever, to diphtheria, to scarlet fever, is transmissible; and as this tendency or susceptibility is, for a time at any rate, worn out by one attack, the glandular function being modified, we have in this an explanation of the protection afforded, sometimes for a lifetime, against future attacks of the same disease. The germ hypothesis—Dr. Richardson will not allow that *it* deserves to be called a theory—of disease fails altogether of proof; and, if true, how can anyone escape fertilisation, and how can any infected person ever recover?—while everything is explained by the glandular theory, and recovery is only one of the natural terminations of the glandular derangement! We must not suggest, we suppose, that such a subject is best or only fitted, at present, to be treated scientifically, and before a scientific audience, for the germ theory is made by eminent professors a subject for popular discourses. Dr. Richardson's subject was skilfully and ingeniously placed before his hearers; and, as is always the case when he is the lecturer, the address was highly applauded.

The second address which we shall mention was one from Dr. George Wilson, Medical Officer of Health for Mid-Warwickshire, on "The Past History and Future Prospects of Sanitary Science." He described the "insanitary" mode of living of our forefathers, and spoke of the results in the terrible diseases which from time to time made such havoc in the land. He traced the rise of better conditions of life from the introduction of soap and soda, and the adoption of cleanliness of the person and in the houses, and pointed out how diseases that before were constantly raging, gradually disappeared; and he showed how the death-rate for England and Wales had

improved. The death-rate in Lincoln, for instance, had been lowered from 80 per 1000 in the seventeenth century to 50 per 1000 in the last century, and to 24 per 1000 in the present day—and might, and ought to, be made lower still. "If," he said, "the death-rate of the whole country were reduced to the low average death-rate of a town like Leamington, 17 per 1000—and such reduction was quite within the possibilities of sanitary science—then, the Registrar-General's returns proved, there would be an annual saving of 115,000 human lives in England and Wales." And the hope of saving any number of these lives, and of mitigating to some extent the enormous amount of needless suffering which they represented, was surely, he urged, enough, and more than enough, to fire the ambition of everyone who believed in human progress. The paper was a very able, instructive, and encouraging one.

The last of the Congress subjects to which we shall now, at any rate, allude is the speech delivered by Mr. Brudenell Carter. This was an eloquent address on the "Present Possibilities of Sanitary Legislation." Greatly as we admire it, however, we need not speak at length about it here, for, as we are happily enabled to publish it *in extenso*, it speaks for itself elsewhere in our columns. Mr. Carter's theme was, to quote his own development of the title of his address, the inquiry, "What amendments of the law, in the interests of public health, are practicable in the existing state of enlightenment and of opinion?" and he asserted that it is universally admitted that "no law can be useful which does not command the willing assent of the majority of those who live under its provisions." We have more than once had occasion to point this out, but we must say that, if universally admitted, it is not always remembered or acted on. Mr. Carter also said he thinks (and we agree with him) "that it is also admitted that legislation, especially when it has regard to questions upon which knowledge is increasing, and is becoming every year more widely diffused, might with propriety be a little in advance of prevailing practice, so that it might, to some extent, exert an educational influence." He then shortly considered why it is that laws in the interests of public health are required at all, and what purpose they are intended to fulfil. Having explained this with happy clearness and brevity, he illustrated his teaching by a description of the ravages committed by gaol-fever, the plague, and other preventable diseases which have destroyed or still do destroy, yearly, tens of thousands of lives in England and Wales. In speaking of these filth diseases, Mr. Carter justified the use, for the present at any rate, of the word "zymotic"; and, referring to "the talk about 'germs' and 'germicide remedies,' as if the existence of germs were a fact instead of only a convenient hypothesis," and noting that "an inconvenience incidental to the use of the word 'germ' is that it tends to impose a hypothesis upon us for a truth," he pointed out that the want of certainty here does not matter to men of science, because they "are not likely to be misled by what South felicitously called 'the terrible imposture and force of words';" but that it did matter greatly to some to whom the care of the public health in districts and localities is committed, "because they were led to fancy that they knew something when they did not, and to think themselves less ignorant than they really were; and thus to undertake responsibilities and to pursue conduct from which wiser or better instructed persons would shrink with something like dismay." He then dealt with the question whether these diseases, as they are now known, always arise only from infection, and are the results of distinct varieties of poison, or are different types of disease having a common cause, and originating sometimes *de novo* under certain combinations of circumstances; and pointed out that it is a question of the greatest importance to know whether, as a matter of practical fact, a case of typhoid, for instance, "necessarily presupposes a pre-existing case in a channel of contagion, or only a pre-existing combination of physical conditions." And this knowledge can only be obtained by the patient investigation of competent observers, for "disease may be conveyed in some such unsuspected manner as this—by a stray dog, by a beggar, by a tradesman's messenger, in a public conveyance, in a place of amusement, or by casual contact in the street. The postman may have put it in a letter-box, or it may have been delivered with clean linen by the laundress." Then he considered the various ways in which the Legislature or the local government may and ought now to protect and help and teach the public; and the way and the degree in which they fail. It may be said that in his indictment against them he certainly does not aught extenuate, but then as certainly he does not set down aught in malice. His admirable speech concludes with a few eloquent sentences on the fame and honour that would be won by any politician and statesman, of adequate culture and adequate capacity, who would, during a few years of patient and well-directed Parliamentary labour, ceasing to give to party what is meant for mankind, devote himself to the great subject of public health; and finally, alluding to the work of the Congress, the orator said—"Our present business may seem trivial; it may produce no immediate or perceptible results. None the less, however, will it be seed which cannot fail hereafter to yield a harvest; and in proportion as our work is earnest and truthful, so far will it hasten the advent of the time to which we must look forward with hope and confidence, when Englishmen and Englishwomen will no longer every year be poisoned by thousands, by accumulations of filth against which individuals are powerless, and which we, as a nation, are too indolent or too ignorant to remove."

VACCINATION STATISTICS.

To the vast majority of educated persons, and certainly to our readers, any serious discussion of the question, "Does vaccination afford any protection against small-pox?" would seem a most idle and futile misuse of time; and we have not any intention of wasting time and space in that way. But there appeared, not long ago, in the *Journal of the Institute of Actuaries, and Assurance Magazine*, and has since been republished in a separate form, a paper having for its title that question; and the paper merits notice in our pages for two or three reasons. It is written by Mr. T. B. Sprague, a well-known actuary, and a vice-president of the Institute of Actuaries; it points out what is, in the writer's opinion, a serious fault in many of our vaccination statistics; and it supplies a very forcible argument in favour of revaccination. It is curious to observe that Mr. Sprague, with the instinct of a keen man of business, has contrived to make the publication of his paper serve a double purpose. He is "a spelling reformer," and, holding that it is of primary importance that the public should gradually "becom familiarized with the idea that a spelling reform is possibl," he has had his paper printed in accordance with his views of what spelling ought to be. And as this is the only object mentioned in the brief preface to his paper it might almost be considered his chief one. We are, however, only concerned with the other purpose of it. He says (and we once more adopt in quoting from his paper the mode of spelling that he favours), "I had supposed until lately that the statistics compiled by different persons at varios times, and publisht in medical works, prove beyond all reasonabl dout that vaccination affords an almost certain and complete protection from smalpox. It appears, however, that in certain quarters the efficacy of vaccination is now altogether denied. Vaccination is denounst as in all cases useless, and in many positively injurios, becaus it introduces an animal poison into the system, which often produces very serios ilness. Such is the view taken by the National Anti-Compulsory Vaccination

Leag, som of(a) whoze publications hav recently been brot under my notis. . . . From the nature of the case, statistics on the subject must be furnisht by members of the medical profession, and the actuary can hav litl or nothing to do with the preparation of them. He may, however, usefully examin such statistics when givn to the world, and state, without being considerd presumptuos, what conclusion may in his opinion be fairly drawn from them." And that was the task which Mr. Sprague set himself: examining statistics both for and against vaccination. On the side of vaccination he took Dr. William Robertson's Seventh Annual Report on the Vaccination of Children born in Scotland during 1870; and the statistics contained in Dr. Thorburn's "very readabl litl work" on vaccination, and applied to the examination and criticism of them all the trained skill of an actuary expert. We have not space to enter into the statistics, and in addressing medical men it is not necessary to do so, Dr. Thorburn's pamphlet being well known; but Mr. Sprague arrives at the conclusion that they "can leave no reasonable doubt as to the reality of the protection afforded by vaccination," and he says also that Dr. Thorburn's pamphlet deals with a number of other questions bearing on the efficacy of vaccination, besides the statistical one, "in a most interesting and satisfactory manner." He objects, however, that in none of the statistics contained in the papers he had examined, with the exception of one short table which he took from Dr. Robertson's Report for 1874, was any information given as to the ages of the persons attacked with small-pox.

The statistics prepared by an opponent of vaccination were next examined. They are contained in a report by Dr. L. J. Keller, Chief Medical Officer of the Imperial Austrian State Railway Company, on the sickness from small-pox among the employees of the Company in the year 1873. It appears that the Company has always in its employ about 37,000 men, forming, with the addition of wives and children, pensioners, and others, a population of near 60,000 persons. Eighty medical men are engaged by the Compauy, the employees, and their wives and children, and are required to keep exact records of all the cases of sickness that occur, and to send monthly and yearly statistical reports to the directors; and all these medical men are under the supervision of the Chief Medical Officer. Dr. Keller, in the report mentioned, examines into all the cases of small-pox which had occurred during the year 1873 among the population under the care of the Medical Officers of the Company, and considers that he has proved that vaccination is utterly useless. His report was, very naturally, translated and published by the Anti-Vaccination League, and it came into Mr. Sprague's hands. Finding, however, that Dr. Keller's principal statistical tables had been omitted, he obtained, through Mrs. Mary C. Hume-Rothery, a copy of the report in the original German, and examined for himself the statistics, and the conclusions drawn from them. The results are sufficiently striking to command attention. There occurred altogether, in the year 1873, among the population concerned—viz., from 55,000 to 60,000 persons—2054 cases of small-pox. Of these the "vaccinated" numbered 1337, of whom 219, or 16·38 per cent., died; the "unvaccinated" were 596, of whom 148, or 24·83 per cent., died; the "revaccinated," were 46, of whom 7, or 15·22 per cent., died; 11 had small-pox previously, and of these 2, or 18·18 per cent., died; and 64 were classed "doubtful," of whom 9, or 14·06 per cent., died. The first thing to strike our readers will probably be that vaccination affords at any rate very nearly as much protection as a previous attack of small-pox does; and the next, that the statistics do not show in what degree, if any, vaccination gives protection against an attack of small-pox, but only the degree in which, supposing the tables to be trustworthy, it protects against, or lessens, the mortality of small-pox among those whom it does attack: a point of immense importance when such statistics are employed to answer the question, "Does vaccination afford any protection against small-pox?" Mr. Sprague, as we shall see further on, notices this. In all Dr. Keller's tables, the ages of the persons attacked are given, and he finds that "the mortality is heaviest in the first two years of life, then gradually diminishes, reaches its minimum between fifteen and twenty, and from that point increases gradually and with great rapidity at advanced ages. *This is just the law which human mortality in general follows.*" We cannot give all Dr. Keller's tables, nor all the conclusions he draws from them, but Mr. Sprague considers that, assuming his statistics to be entirely trustworthy (which he sees no reason to doubt), two points are clearly established by them. First, "that small-pox statistics in which no account is taken of the age are of little value, if any, and are often positively misleading." This he shows by the following figures, taken (or deduced) from a table of Dr. Keller's relating to the years 1872 and 1873 combined:—

	Vaccinated.			Unvaccinated.		
	Number of cases.	Deaths.	Mortality per cent.	Number of cases.	Deaths.	Mortality per cent.
Under 2 . . .	89	49	55·06	278	118	42·44
Over 2 . . .	1,570	210	13·37	515	66	12·82
Total . . .	1,659	259	15·61	793	184	23·30

"Here," says Mr. Sprague, "the rate of mortality among the vaccinated, taken as a whole, is very much less than that among the unvaccinated; but when we divide the cases into those under and above two years of age, we find that in each class the mortality of the vaccinated is greater than that of the unvaccinated. If, therefore, the age were not taken into account, the figures relating to the vaccinated and the unvaccinated of all ages would lead us to an erroneous conclusion." Secondly, Mr. Sprague concludes "that the mortality among persons attacked with small-pox depends almost entirely on the age, and is very little, if at all, affected by the fact of their having been vaccinated or having had a previous attack of small-pox. In other words, the rate of mortality among the vaccinated persons who were attacked was quite as heavy as that among the unvaccinated."

In considering the value of these conclusions it is to be observed that Dr. Keller does not appear to take any note of the number or the character of the vaccination marks on the persons classed as "vaccinated,"—and these points are, we know, of the highest importance as affects both the degree of protection afforded by vaccination against small-pox, and the degree in which it alters the fatality of the disease when this occurs; and further, that Mr. Sprague views the matter purely as a statistician. He apparently supposes that but few children escape vaccination, and that it is only or chiefly the "sickly children" that are left unvaccinated; and we know but too well that this is not the case. But he sees that Dr. Keller's statistics certainly do not justify the conclusion that vaccination is of no use. "In order to determine this," he says, "we require further information beyond that furnished by Dr. Keller's tables—namely, as to comparative numbers of the vaccinated and the unvaccinated among the population of from 55,000 to 60,000, upon whom his observations were made." He draws, moreover, one other conclusion from Dr. Keller's statistics, and it is a very noteworthy and important one. Looking at one of the tables, he finds a remarkably steady and rapid increase in the ratio of the number of vaccinated persons attacked by small-pox to that of unvaccinated; and this, he observes, is an indication of "a gradual wearing out with lapse of time of the protection

(a) It is remarkable that in the early pages of the pamphlet Mr. Sprague spells "of" in the usual way, while in his preface and about the latter half of the pamphlet it is spelt with a "v"—*ov*. His reforms are mild, but are they needed? Do we not recognise words by the ear rather than by the eye?

afforded by vaccination. The rapid increase of the ratio between the ages of fifteen and twenty appears to indicate that between those ages vaccinated persons become much more susceptible to the infection of small-pox, and that it is, therefore, highly desirable that they should be revaccinated." Mr. Sprague, in conclusion, expresses a hope that his description of the statistics put forward by the opponents of vaccination may be useful to its defenders, by drawing their attention to certain points on which further information is desirable; and he considers that as vaccination has now for many years been compulsory, and the registrars are able to calculate with very considerable accuracy the number of children which escape the provisions of the law, and grow up unvaccinated, persons having the necessary ability, spare time at command, and familiarity with the returns, might draw various important conclusions from them.

The outcome of the discussion is, not to throw the shadow of a doubt even on the entire reasonableness of our trust in vaccination as a protection against attacks of small-pox, but to warn us to make our vaccination statistics more minutely full and perfect, and to furnish an additional and powerful argument in support of regular and systematic revaccination. For this the profession owe thanks to Mr. Sprague, though we may have a "reasonable" fear that extracts from his paper may possibly be used for a purpose he probably never thought of, and certainly never intended.

CLINICAL TEACHING.

Our hospitals are once again thronged with students, come to listen to the clinical instructions of the surgeons and physicians in their several wards. On the thoroughness and soundness of the instruction here given will depend very materially the future success of the student, not only at his examinations, but also in his further career as a practitioner. Holding these views very strongly, we may be permitted to revert to an old subject—the clinical teaching in the various London hospitals,—and criticise or commend, as occasion and opportunity occur. Taken as a whole, our clinical teaching, as compared with that given in Germany or France, is decidedly poor. There is certainly no lack of material; and the men who have risen to be surgeons and physicians to the London hospitals are in no way inferior to the corresponding officers of the foreign schools. We must seek in another direction, then, for the difference in the teaching powers here and elsewhere exhibited. We believe it is mainly to be found in the mode of education. The art of public speaking, of expressing oneself tersely and to the point, is seldom, if ever, a natural gift, any more than is the power of condensing the salient points of a case into a running commentary, which shall not only be interesting, but precise and exhaustive. This power and art is cultivated from the very earliest date on the Continent, and especially in France. Again, the aspirants to what we call house-surgeoncies and house-physiciancies—all of which posts are decided by public *concours*—must show evidences of original work and original ideas in order to be successful; and any hope of further successful competitions for hospital and university appointments depends absolutely on aptitude for ward or laboratory work, backed up by patient and laborious original research. Even the ordinary degree in medicine is not conferred until after a thesis on some subject has been publicly sustained before the assembled magnates of the university. Of course some (perhaps many) of these theses, as such, are not worth the paper on which they are printed, but this does not in any serious degree detract from the general educational value which the practice of thinking and writing undoubtedly possesses.

It is, perhaps, not generally known that French house-surgeons are not allowed to take their degree until after their house-surgeoncy has expired. They must have passed all the necessary examinations, but they are ineligible for office if they have graduated. The utility of this rule is self-evident, for the long period during which these gentlemen hold office gives them ample opportunity for working out some subject, while the necessity of sustaining a thesis for their degree gives them a definite object for which to strive. As we have before said, all appointments in the French Faculties are open to, and only given away after, a public *concours;* and as the younger men all know this and constantly keep it in mind, they are ever on the look-out for some suitable subject to discuss, and for material and cases to support their views.

With such objects constantly in view (for men do not rise by mere seniority), the French *agrégés* and professors enter their wards and go their rounds. Thus, long before they have arrived at the teaching stage of their career, they have been engaged in original work, they have exercised themselves in the art of *observing*, of *recording*, and of *making the most of* their cases, so that by the time they attain to the rank of our assistant-surgeons and physicians, and have a *service* of their own, they are probably men who have been weeded and thinned out as much by the hardships of competition as by the principle that the fittest only survive. We must further remember that all this work has been done under the immediate eye and superintendence of men trained in a similar manner to themselves—trained in a school which can claim such men as Bretonneau, Dupuytren, Velpeau, Trousseau, and a host of others, as pupils first, and professors afterwards.

There is another factor too, of not less importance than the preliminary training—it is the *necessity* of giving some *definite clinical teaching*. This is a most important part of the curriculum, and each morning's visit is consecrated to the study of at least one subject in either medicine or surgery. It is far better for the student to have one hour of systematic teaching over one or two well-chosen cases, than to spend the greater part of an afternoon in listlessly following a physician or surgeon from bed to bed, and being compelled to listen to remarks which, as a second year's man, he would not understand, and which, as a third or fourth year's man, would be of little use to him from an examination point of view. The mode of imparting this instruction varies. In some of these hospitals the students collect round the bedside, and the physician asks one of them to examine the case; the student is then cross-questioned; finally, the physician sums up the case, perhaps gives an imaginary typical case, and contrasts with it the one under observation. In other hospitals, two or three of the senior men are set to examine each a case, the physician going from one to the other to see that each man makes his examination *systematically*. Then they all retire to a distant part of the ward, where physician and student may each speak plainly without offending the ear of a sensitive patient; the student is publicly cross-questioned on his case, and his faults, both of omission and commission, are then pointed out. In large schools, such as Berlin or Vienna, where the number of students is very great, this is done in a suitable theatre, and then all can both hear and see with ease and satisfaction to themselves, and with little or no annoyance and irritation to the patients in the ward.

Almost unconsciously we contrast this *systematic* and *regular daily* clinical instruction of Continental universities with the spasmodic, irregular, disjointed, and often unprofitable remarks which many of our English physicians and surgeons, as a mere matter of habit, call clinical teaching. Not a few go their bi-weekly rounds without even attempting this much; they fall into the too common error of imagining that these "everyday" cases are not really worth speaking of, and only when some rare case, as uncommon as it is incurable, comes before them, can they get up sufficient energy to give a

clinical lecture. This is much to be regretted, for it is exactly the common, everyday cases—acute dyspepsia, chronic bronchitis, phthisis, heart and kidney disease, or, again, fractures of all kinds, ulcers, hip disease, spine disease, common skin eruptions—that the large mass of students will be called upon to treat, and it is in this class of diseases where so much yet remains to be done.

There is another feature, too, of foreign clinical teaching of which we would speak. It is the obligation which is imposed on the younger members of the staff to do their share of regular work; and indeed not the least interesting part of clinical work and public clinical instruction is done by men who are, as yet, young and untrammelled by the cares of private practice, and whose time and thoughts are consequently the more at the disposal of the school to which they belong. A sufficient remuneration too is offered, so that the worry of "making both ends meet" is reduced to a minimum. We do not say that all the younger men give clinical instruction equal to that of the most distinguished clinical teachers; but we maintain that there is teaching and teaching; and he is not a less useful member of a school who tells students how to bandage a wound or set a fracture, than the fine physician who will diagnose a case to a hair's breadth, but forgets to say what is to be done for the patient. Neither would we advocate a wholesale importation of foreign customs into our own schools. Least of all would we advocate the system of writing theses for the ordinary qualification to practise medicine or surgery. We believe, however, that some such regulation might be usefully imposed on all candidates for the higher qualifications of the Colleges of Physicians and Surgeons; and certainly it ought to be obligatory on all candidates for the staff appointments of our hospitals and schools. As the regulations at present stand, no one is eligible for the higher examinations in either medicine or surgery who has not held the office of house-physician or house-surgeon; and this period, if properly utilised under the eye of a clever clinician, would allow ample scope for original observation and original work. To such as aspire still higher, these habits of thinking for oneself would be of great service in after-life, while the power of suitably expressing one's ideas developes as one's ideas become more definite and less diffuse. Let only those be appointed teachers who have themselves been well and *systematically* taught, for the power of imparting knowledge depends less on the amount which is stored up than on the manner in which it is arranged. It should never be forgotten that clinical instruction, to be of real service, must be something more than a mere recital of one's own ideas and practice; it must be a *résumé*, a contrasted parallel, of what is done in the same science in all countries.

THE WEEK.

TOPICS OF THE DAY.

The first permanent hospital for non-pauper cases of infectious and contagious diseases founded by any Metropolitan District Board of Works, with the exception of the Cottage Hospital buildings at Lewisham, was inaugurated last week at Plaistow by the Poplar District Board of Works. Since the passing of the Sanitary Act of 1866, this Board has provided two disinfecting houses with all the necessary apparatus; two ambulances for the conveyance of infected patients to hospitals; and a mortuary for the reception of infected corpses, when their remaining in a room would endanger the health of survivors. For some time the Metropolitan Asylums Board had assisted the several districts by receiving patients needing removal from their homes; but in January last the Local Government Board gave notice that this arrangement could not be continued, and the present building has been the result, and will afford a much-needed means of isolation in cases of outbreaks of cholera, fever, or small-pox in the neighbourhood. The site of the hospital is a freehold plot of ground near the Barking-road, 190 feet long, and 170 feet broad; the buildings consist of two pavilions, each of a couple of storeys, together with the necessary offices. Each of the pavilions is designed to accommodate thirty-six patients, and there is ample space between the two for a recreation-ground for the use of convalescents. The cost of the land and of the buildings is estimated at about £14,000. It is to be hoped that the example set by Poplar in this matter will speedily be followed by other metropolitan districts.

The services of Mr. Rawlinson, C.B., C.E., the Local Government Board Inspector, seem in great request in enforcing the provisions of the Rivers' Pollution Prevention Act of last year. An inquiry has just been instituted as to the condition of the Avon in Wilts, the flow of sewage into which from the city of Salisbury has led to a threat of legal proceedings by a neighbouring landowner. The river Frome, in Dorset, is the next which will occupy the attention of the inspector. From these early indications of commencing action, it is clear that the Act, even in the mutilated condition in which it was finally passed, may be of much service to the country.

It seems probable that an earnest effort will be made to meet and do away with the prejudices against water-cresses which exists in many quarters, on account of the contamination to which they are exposed through the pollutions common to the rivers, brooks, and water-cress beds in which they are generally grown. At a recent meeting of the Royal Horticultural Society, Mr. Shirley Hibberd, of Stoke Newington, presented a dozen pans of water-cresses, grown in the manner he has practised and recommended for some time. One of the advantages of his system is that the plants are under complete control to be placed in the sun or shade, or during winter in heated plant-houses, and can at all times be supplied with pure water. The pans in which they are grown measure from fifteen inches to twenty inches across, and from six inches to nine inches deep, the smaller size being described as most convenient. The pans are filled with rich loamy soil, intermixed with lumps of chalk or old mortar, and then very small cuttings are inserted. These soon become strong plants, and in from fifteen to twenty days they may be gathered from, the cresses being tender and delicate in flavour, and of the most beautiful appearance. The twelve pans shown had been regularly gathered from for the table for a period of six weeks, and the fresh appearance of the plants indicated that they might be cut from for another six weeks without being exhausted.

It is stated, in reference to the movement for establishing Home Hospitals for the well-to-do, that nearly £5000, or one-fourth of the guarantee fund which the Provisional Committee have fixed as a sufficient sum to warrant them in opening a Home Hospital as an experiment, has already been obtained, but that the Committee will delay for the present the issue of any general statement to the public. Thus far the money has been obtained with practically no outlay whatever; and there seems a good prospect that the whole sum requisite will, ere long, be available for practically testing the scheme.

The results of a first attempt to construct a Scottish life-table out of the materials afforded by the census enumeration of 1871, and by the registered deaths of that year, have just been made public by the Registrar-General for Scotland in his "detailed report" on the year 1873. The delay in preparing this information would certainly seem to have been excessive. Much difficulty is caused by the practice adopted by many persons at the census, of not disclosing their exact age; and it is only after grouping enumerated ages into quinquennial periods, and making various assumptions, that an approximation to the truth can be obtained. Dr. W. Robertson, who presents the tables, explains carefully the course which

had to be taken. The death-rate in Scotland in 1871 was higher than that of England in 1841; and hence it is not unnatural to find that this approximate Scottish life-table gives to the expectation of life, at most ages, values somewhat lower than Dr. Farr assigns in his first English life-table, based on the census of 1841. The expectation of life in Scotland is stated at its highest—namely, 49·10 years for persons aged four years; after nineteen it never again reaches forty years; after thirty-four it never reaches thirty years; after fifty it is less than twenty; after sixty-seven, less than ten; and after eighty, less than five years. In Scotland, in 1871, the lowest death-rate was of persons between ten and fifteen years old—viz., one in 172·71; but it was as high as one in 6·69 for infants in their first year of life—a rate which it never again attained in any quinquennial period until that which includes persons who are from eighty to eighty-five years old.

A severe outbreak of scarlet fever is reported to have taken place at Stafford, where it is raging in all parts of the town. The local authorities, assisted by the medical officers of the district, are taking active steps for arresting the progress of the epidemic.

In giving an account of the quality of the water-supply on the Yorkshire, Cumberland, and Lancashire coasts, the *Sanitary Record* finds that at Bridlington the supply would be a satisfactory one if it were properly filtered—a process which it evidently needs, in order to remove a large quantity of foreign matter and vegetable impurities held in suspension. The watering-place of Filey gets but a bad character for its water; it is found to be badly filtered, of third-rate quality, and generally unsatisfactory. Some water from a private well in an hotel at Filey, stated to be used for washing purposes only, is said to be of a dirty yellow colour, while the taste and smell resemble those of a sample of stagnant sewage. The sooner the use of this well is abandoned altogether, the better it will be for those who may visit the hotel. It is satisfactory to learn that Scarborough has a constant supply of good water, and that the same may also be said of Whitby.

A curious instance of the evils attributable to the overflow of rivers has been brought to notice by M. Duplessis at a meeting of the Academy of Sciences in Paris. It is well known that serious damage is frequently done to lands by the overflow of rivers containing polluted matter; and large tracts of land have been destroyed in this way by floods in the mining and manufacturing districts of South Wales, and the Northern and Midland counties. Instances have also occurred where diseases have been communicated both to human beings and to animals by water brought down from infected districts. A still more remarkable case of the transmission of disease has been observed in the South of France, and is commented on by M. Duplessis. A field of rye, which had previously produced a crop of vetches, was observed to be partially affected with "smut." As vetches are known not to suffer from the disease, and as only part of the field was attacked, its origin was doubtful. It was eventually discovered, however, that some fields at a distance further up the river—the Loire—had been affected, and that the river in overflowing had covered that portion of the crop which was now found to be diseased. There could be no doubt, therefore, that the floods had been the means of communicating the disease to the flooded portion of the lower ground.

An "Infirmary Manager" in Edinburgh has addressed the following letter to the *Times*:—"Will you permit me, through your columns, to draw attention to the unreasonable delay of the Home Secretary in filling up the chair of Clinical Surgery at Edinburgh, which was vacated by Professor Lister some months ago? Not to mention the cruelty of keeping at least five candidates in suspense during all this time, I may state that the clinical lectures should commence on November 1, and the new Professor will have certain arrangements to make before entering upon his duties. He is enabled to give his *clinique*, by the managers of the Royal Infirmary of Edinburgh allotting him wards in the surgical hospital. The adjustment of these wards—as there are other four surgeons whose interests require to be considered—will take some time, and yet the Home Secretary still defers his decision, though it is now only about three weeks to the commencement of the winter session, with even a larger number of medical students already entered than at the corresponding period of last year." We should imagine that Mr. Cross can hardly be aware of the necessity for prompt action in this matter, or the delay complained of would scarcely have been allowed to occur.

QUEEN'S UNIVERSITY IN IRELAND: ADMISSION OF WOMEN.

The annual meeting of Convocation was held on Friday, the 5th inst., in the Privy Council Chamber, Dublin Castle, Sir Dominic Corrigan, Bart., M.D., Vice-Chancellor of the University, presided. Mr. J. Wilson, Clerk of Convocation, read the report of the Annual Committee. The adoption of the report was moved by Sir Robert Kane, seconded by Mr. A. M. Porter, Q.C., and carried. The most important business of the meeting was the discussion of the following notice of motion, which had been put on the paper by Dr. H. MacNaughton Jones, of Cork, viz.:—"That inasmuch as the Senate of the Queen's University in Ireland have granted to women the privilege of being admitted to degrees in medicine, this Convocation is of opinion that no obstacle should be placed in the way of women availing themselves of that privilege, through the action of the Council of any of the Queen's Colleges in refusing to permit them to attend such lectures in the Colleges as are necessary to qualify them for admission to these degrees." In the absence of Dr. Jones, the resolution was moved by Dr. Thornley Stoker (who thought that a discussion on the subject was perhaps desirable), and seconded by Dr. McDonald, *pro formâ*. After considerable discussion, Dr. Stoker, in reply to the Chairman, stated his willingness to withdraw the motion unconditionally, and leave was given to do so. The Annual Committee for the ensuing year having been elected, Professor Yonge moved a vote of thanks to the Vice-Chancellor of the University for presiding. He only expressed the sincere hope of all present when he said that they trusted Sir Dominic would be spared to occupy the chair for many years to come. The vote was passed with acclamation, and Sir Dominic having replied, the proceedings terminated.

VICARIOUS CHARITY.

The front sheet of the *Times* newspaper of Wednesday last was almost half-filled with acknowledgments, from various London charities, of bequests which they had received from the trustees and executors of the late James Graham, Esq., of Regent's-park, who left the residue of his estate, about £170,000, to be distributed among public charities, at their absolute discretion. It is indeed a matter of almost national congratulation to think of the numberless charities which are voluntarily carried on and supported by private munificence. In no other country in the world do such institutions exist to the same extent as in England. Among the bequests we notice that the London Hospital receives the largest legacy (£2500); and seeing its large size, its position in one of the poorest districts of London, and that it depends for support almost entirely on public subscriptions, no one will grudge this Hospital its good fortune. There are twelve legacies of £2000 each, and thirty-four of £1000, besides a very long list of £500 and £250 legacies. The executors of this will—D. R. Porter, Esq., Captain A. F. Stewart, and J. T. A. Patrick, Esq.—are to be congratulated very sincerely on the manner in which they have discharged their onerous, and not altogether easy, task. In a very large majority of cases the awards are made with great judgment

We trust that the funds will be as carefully expended by those into whose hands they have fallen. We take this opportunity, on behalf of the London medical charities, of publicly thanking the executors of the late Mr. Graham for the great care and labour which they have devoted to the carrying out of the trust imposed on them.

THE FLESH OF CATTLE AFFECTED WITH EPIDEMIC PLEURO-PNEUMONIA.

The Dublin Sanitary Association has drawn up a report on this important subject, in which the following conclusions are put forward:—"1. That epidemic pleuro-pneumonia of oxen is a specific contagious fever, and therefore affects the whole system of the animal, including its flesh and milk. 2. That the flesh of animals affected with the disease, except in the earliest stages, is known to present unhealthy appearances. 3. That the flesh is especially prone to become putrid, and therefore dangerous as an article of food. 4. That it is not known with certainty at what stage of the disease the flesh first shows signs of infection. 5. That there is no evidence of a scientific character to prove that the flesh of oxen affected with the disease has not produced injurious effects. 6. That there is some evidence to show that the flesh when eaten has produced injurious results. 7. That the proposal to sell the flesh at a reduced price, and to make it less prone to putrefaction by careful bleeding, is, if carried out, calculated seriously to endanger the health of the consumers, especially the poor, and to leave a loophole for the sale of all kinds of diseased flesh." The Association is therefore of opinion that the flesh of animals which have suffered from pleuro-pneumonia in any stage should not, under any circumstances, be permitted to be sold for human food.

THE METROPOLITAN ASYLUMS BOARD.

At a numerously attended meeting of the managers of the Metropolitan Asylums Board, held last week, a report was presented from the General Purposes Committee, which stated, in reference to the decrease of small-pox in the metropolitan district, that, having regard to the existing pressure for accommodation for female imbeciles chargeable to the metropolitan parishes and unions, it would be desirable to utilise one of the Asylum hospitals for this class of patients, but only so long as such hospital may not be required for the reception of persons suffering from any contagious or infectious diseases for which the managers are called upon to provide accommodation. Mr. Galsworthy moved the adoption of the report. The returns as to small-pox, showing the number of cases remaining in most of the hospitals up to date, gave the following results:—At Homerton, 40; Stockwell, 86; Hampstead, 43; and Fulham, 21. For the fortnight ending Friday, October 5—admitted, 60; died, 15; discharged, 59; total, 146. Total for the preceding fortnight—admitted, 67; died, 12; discharged, 101; remaining under treatment, 160. The report was received, and after some routine business the Board adjourned.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

The annual meeting of this Society was held in the library of the Newcastle-on-Tyne Infirmary, on Thursday, September 27; Mr. G. B. Morgan, President, in the chair. The Committee presented a very satisfactory report, and stated that "during the session 1876-77 nineteen papers were read, fifty pathological specimens were exhibited, and fifteen patients were introduced at the meetings. The total number of members now is 161." The following is the list of officers for the ensuing session:—*President:* Mr. G. B. Morgan, Sunderland; *Vice-Presidents:* Dr. Luke Armstrong, Newcastle; Mr. S. W. Broadbent, South Hetton; Dr. Barnup, Newcastle; Mr. Hawthorn, Newcastle. *Secretary:* Mr. Byrom Bramwell, Newcastle. *Committee:* Mr. H. E. Armstrong, Newcastle; Dr. Arnison, Newcastle; Mr. Carr, Newcastle; Dr. Denham, South Shields; Dr. Eastwood, Dinsdale; Dr. Frain, South Shields; Dr. Hume, Newcastle; Dr. Page, Newcastle; Dr. Philipson, Newcastle.

THE CHAIR OF ANATOMY IN GALWAY.

Last week we were able to announce the transfer of Dr. Cleland from the Chair of Anatomy in the Queen's University, Galway, to that in the University of Glasgow. We have now to announce that already a candidate apparently made for the vacant chair appears, in the person of the present Demonstrator of Anatomy in the University of Edinburgh, Dr. J. Cunningham. This gentleman is the author of many scientific papers on anatomical subjects, and moreover—what is much more to the point—he has had five years' practical training in lecturing and teaching under the superintendence of Professor Turner.

THE MEDICAL SOCIETY OF LONDON.

The 105th session of the Medical Society of London will open on Monday next, the 15th inst., with a short address by the President, Dr. George Buchanan, after which Dr. P. M. Braidwood, of Birkenhead, will read an epitome of his Fothergillian Essay on Pyæmia, for which the gold medal of the Society was awarded. Numerous specimens prepared by the author during his recent researches will be shown under microscopes; and a case containing portions of viscera showing secondary abscesses will be exhibited.

THE SANITARY STATE OF THE BELFAST FACTORY DISTRICT.

A pamphlet published recently by Mr. C. D. Purdon, M.B., F.R.C.S.I., Certifying Surgeon for the Belfast District, on the sanitary state of the Belfast Factory District during ten years from 1864 to 1873 inclusive, is well worth attention. Mr. Purdon has dealt with the subject exhaustively under most of its various aspects, and he has, to corroborate his statements and conclusions, compiled a series of tables which cannot but prove valuable to all persons interested in the subject. It would be impossible in the limited space at our disposal to follow Mr. Purdon in the various inquiries he has instituted and the knowledge he has consequently acquired on this subject; but the suggestions which his experience dictates for decreasing the excessive mortality that occurs amongst the mill-workers, from various causes, are as follows:—1. That no half-timers be employed in unhealthy processes; and that those that are employed should be at least fifteen years of age, healthy, and well developed. 2. That no one under eighteen should get a card, or obtain two looms. 3. A thorough system of ventilation should be effected in the rooms in which the preparing is carried on. 4. Inspection of children and young persons employed should be instituted at stated intervals to see if health is injured by the employment, and those found to be suffering from incipient disease or severity of work should be compelled to cease work in that department, and that there should be a fresh medical examination at each engagement. 5. That they should be examined to see that they have been efficiently vaccinated. The wearing of the "Baker respirator" to be compulsory. Temperature to be kept at 70°, by ventilation. The schools of the half-timers to be well looked after. 6. Soup kitchens to be established, where the worker could obtain, at a small cost, good and wholesome food. These suggestions certainly deserve consideration, but taken as a whole, they involve a development of "parental government," and an amount of interference with the "liberty of the subject," that would make them, we suspect, simply impracticable, at least at present. We do not think that even "Home Rule" could make them law, or enforce them if they were made law.

FROM ABROAD.

Treatment of Scarlatina and its Complications.

From an account of a discussion at the New York Academy of Medicine, on the Treatment of Scarlatina and its Complications, which appears in the *New York Medical Record* (August 4), we make the following extracts:—

Dr. Lewis Smith first directed attention to the *nervous complications*, which are accompanied by a rapid pulse, marked elevation of temperature, and occasionally eclampsia. They may arise from either active congestion of the cerebro-spinal axis, or from the direct influence of the specific poison upon the nervous system. The earlier and milder eclampsia is not usually serious, but the later and protracted eclampsia is exceedingly grave. It has been said, indeed, that eclampsia in scarlatina always proves fatal, except when it occurs before or at the commencement of the eruption; but Dr. Smith believes that, by the combined use of the bromides and chloral, cases at the later stage have been saved. By far the larger portion, however, perish. In the *throat complications*, the inflammation which commences in the absorbents and lymphatics along the side of the neck, and extends to the connective tissue, is dangerous in proportion to the swelling and induration produced. It arises from the absorbents taking up the poisonous material on the mucous surface, and is less frequently met with since the practice has prevailed (during the last five or six years) of disinfecting the fauces as a part of the treatment of scarlatina. The diminished mortality which has been observed of late may, however, be due to a change of type, which so often occurs in scarlatina, rather than to improved treatment. This throat complication, cervical cellulitis, etc., may produce death in three ways—by exhaustion, consequent on ulceration, suppuration, or sloughing; by inducing œdema of the larynx; and more frequently, by retarding the flow of blood from the brain through pressure on the jugular veins, thus giving rise to congestion of the cranial sinuses, veins, and capillaries of the brain and membranes, and perhaps to a transudation of serum. Some of the cases formerly thought to have proved fatal from the scarlatina poison, have done so owing to this pressure on the jugulars. *Diphtheria* has been frequently seen as a complication of scarlatina in New York, as it may in any locality where the two diseases had prevailed. "Scarlet fever invited diphtheria, but diphtheria did not return the compliment." Diphtheritic poison may remain in a room for two months, and then give rise to the disease, and the scarlatina poison may retain its power for three months. *Nephritis* is usually regarded as a sequel to scarlatina, but Dr. Smith is disposed to consider it as a complication, and one of earlier occurrence than is usually supposed. If the urine were examined at each visit, it would be found that albumen was present before the eruption had faded away.

Dr. W. H. Thompson, adverting to the general treatment of scarlatina and its complications, stated that several years ago, when he had charge of a large number of these patients, he tried three different modes of treatment, milk diet being given in all the cases. These were—1. To do nothing beyond giving milk, with or without lime-water, and some placebo for its moral effect. 2. To use carbonate of ammonia freely. 3. To adopt the chlorine treatment, consisting in the use of chlorate of potash and dilute muriatic acid. The result was a general preference of the chlorine treatment, the carbonate of ammonia being used with noted benefit also in exceptional cases. Thus, in some cases, there is marked tension of the pulse, this being within the first two or three hours as high as in Bright's disease or in gout. Such tension is characteristic of scarlatina among the eruptive fevers, and is sufficient in itself to excite suspicion of the disease. When this tension is markedly developed, there is a greater liability to hæmorrhage in the skin and in the viscera, and perhaps in the serous membranes, and even in the substance of the heart. There is then a tendency to the production of minute emboli and thromboses, and it is possible that ammonia may prevent hyperinosis of the blood, with especial tendency to deposit of fibrin. But the chlorine treatment had much the advantage in the general statistics of the cases treated. Eighty grains of the chlorate of potash and two drachms of dilute muriatic acid were given, diluted with a quart of water, every twenty-four hours. Of late years, however, Dr. Thompson has preferred bromine as being a more powerful antiseptic; and since he has used these remedies internally as well as externally, he has, like Dr. Smith, met with far fewer throat complications. To two ounces of a saturated solution of bromide of potassium he adds very slowly, and frequently shaking it, one ounce of bromine. When this is dissolved, water is added so as to make a four-ounce mixture. Of this solution one drachm is added to one ounce of water, and a teaspoonful is given in a tablespoonful of sweetened water, as required, the solution being kept in a dark place. As a local application, equal parts of the solution and of glycerine are used, or in bad cases the solution alone. Occasional purges of calomel and jalap may be given, until the action of which the antiseptics may be suspended. When the disease sets in suddenly, rapidly affecting the cerebrum, and raising the temperature to perhaps 104°, 105°, or 106° Fahr., or even more, the douche of iced water to the head (the child being wrapped in blankets) is strongly recommended until the pulse loses its tension. The steady use of cold water in this manner whenever high tension is present will be followed by good results in any stage of the disease. When the temperature reaches 104°, the cold wet pack (not the cold bath) is recommended, and is never followed by any harm. Wring from a wet sheet the water at the ordinary temperature, wrap the child in it, and over that lay one wrung out of iced water. The prompt manner in which the symptoms improve shows the wet-pack to be one of the great therapeutic resources in this class of cases. There is a tendency to parenchymatous degeneration of internal organs in connexion with a high temperature in scarlet fever, more marked than in typhoid fever. There is a greater tendency to blueness of the surface in a case of scarlet fever with a temperature of 105°, than in a case of typhoid with a temperature of 108° or 110°. Grave symptoms, however, associated with a high temperature are to be regarded with more favour than the same symptoms without high temperature, for, as a rule, such cases take a more favourable turn.

Dr. Thompson recommends that from the very commencement of the disease the body should be oiled over three times a day. The reason for this is that it is the most effectual means of relieving the itching of the skin, and the excessive restlessness which is due to the irritation of the peripheral nerves caused by the heat of the skin. This is relieved more rapidly by oiling than by sponging with tepid water. Oiling, too, is truly antipyretic, reducing the temperature. Another reason for its use is found in the close sympathy found existing between the skin and the kidneys. In scarlatina there are two periods at which albumen is found in the urine. It is found in the febrile stage, when it is of no more significance than when found in pneumonia. But subsequently albuminuria is found invariably present at the end of the second week—perhaps not reaching its maximum until the fourth week—which indicates congestion of the kidney; and oiling of the surface is one of the best means of relieving that engorgement, the renal disturbance being mainly due to the condition of the skin. The oiling keeps the glands of the skin in an active condition, and promotes diaphoresis.

With reference to the nephritic complication, no case is to be despaired of in its acute stage, for recoveries from apparently the most desperate circumstances (as in cases in which urine has continued suppressed for seven and nine days) have taken place. The measures to be adopted are oiling the skin, the hot-water pack, dry cupping, counter-irritation by means of spoons heated in hot water and applied momentarily over the kidneys, the free use of the infusion of digitalis, etc., after diaphoresis, large injections of warm water. The injections are preferable to purgatives, because the action of the warm water favours the discharge of water from the bladder. A quart may be perhaps used as many as six times a day, and passing the urine may come only with the last injection. The infusion of digitalis should be given to children in very nearly as large doses as are required for adults.

Dr. Noyes, speaking of the ocular and aural complications in scarlet fever, observed that these may occur early or late, but usually do so late, especially with reference to the eye. The eye and ear by far most frequently become affected by extension of the inflammation of the skin to their mucous membranes; but they may become also affected by blood-poisoning. There is nothing peculiar in the pathological processes of the inflammation by extension, but the organs are of a very delicate character, and their power of resistance is greatly impaired in consequence of the general conditions of the system, the inflammation proving more destructive in consequence of the unfavourable condition of the health. There is no special treatment called for beyond sustaining

nutrition, and the doing all that is possible to "antidote" the poison and facilitate the action of local remedies. Severe local applications to the eye are out of place, and where nitrate of silver is used it must not exceed five grains to the ounce, and usually not two grains. As a rule, simple astringents, as alum, etc., should be employed, zinc and copper being rejected. The cornea must be especially watched, and a local anodyne, formed of two grains of sulphate of atropia to the ounce, may be used, from one to three drops being dropped into the eye three times a day. When there is photophobia there should be a moderate exclusion of light. Inflammation of the ear more commonly produces disastrous consequences, giving rise to external or internal otitis, according to where the inflammation spreads from. When the membrana tympani appears sodden and swollen, and acute inflammation is going on in the tympanum, it is preferable to make an artificial aperture rather than allow one to result from ulceration. If there is any tenderness in the mastoid region, leeches should be resorted to; and if the tenderness continues marked, an incision should be made. When suppurative action occurs in the middle ear, the pus should be thoroughly evacuated; and for this, inflation by Politzer's bag is sometimes necessary. In children this inflation is very easy, all that is necessary being to place the tube of the bag in the nostril, shut the nose over it, have the mouth closed, and then simply blow, no water or swallowing being necessary. The secretions can thus be driven out better than by a syringe. When the secretions are removed by the simple douche, very warm water (99° or a little higher) should be employed. For syringing, a syringe of not less than two ounces, having a long slender nozzle protected by a small bit of indiarubber, should be used, and copious streams of water employed. When the eye is affected from blood-poisoning there is neuro-retinitis, due to the Bright's disease incident to scarlatina. The prognosis is usually good, sight being partially recovered, and sometimes completely. It commonly occurs without any very marked symptoms; and there is no condition of the ear analogous to this affection of the eye. Dr. Noyes, while noting the value of anointing the skin, suggested the use of borax and glycerine; borax being a powerful solvent of the epidermis, might assist the skin in resuming its functions. The proportion might be one ounce of borax to from one to two ounces of glycerine. With respect to borax, Dr. Thompson remarked that there was a use for it which would be of value. Desquamation occurs last about the roots of the nails, and the scales that fall off have the power of communicating the disease. The strong antiseptic powers of borax might be here rendered available by having the lotion recommended applied to the hands and feet, in order to assist desquamation and destroy the poison existing in the epidermic scales.

Death of Professor Dr. Karl Ritter von Heine.—This distinguished surgeon has just died, in the thirty-ninth year of his age, of diphtheria, while on a visit to his father at Canstatt. Strange to say, it was from the same disease that his former teacher, Prof. C. O. Weber, was carried off at Heidelberg, and whose post he temporarily supplied. So also the most considerable publication which he has left is a treatise on Diphtheria contained in Billroth and Pitha's *Lehrbuch der Chirurgie*. After holding the post of Extraordinary Professor of Surgery at Heidelberg, Prof. Heine was appointed Ordinary Professor at Innsbrück, where he remained for four years, until "called" in 1873 to Prague. —*Wien. Med. Zeit.*, September 18.

West Kent Medico-Chirurgical Society.—The first meeting of the twenty-second session was held on Friday, October 5, at the Royal Kent Dispensary, Greenwich-road, Dr. Creed, President, in the chair. The following members were elected officers for the session 1877-78:—*President:* W. Johnson Smith, F.R.C.S.E. *Vice-Presidents:* John Prior Purvis, M.R.C.S.E.; Arthur Roper, M.R.C.S.E. *Council:* John Anderson, M.D.; Hughes G. Cable, M.R.C.S.E.; Thos. Creed, M.D.; Ralph Gooding, B.A., M.D.; H. W. Jackson, M.R.C.S.E.; William Lockhart, F.R.C.S.E.; Frederick Moon, M.B. *Treasurer:* Prior Purvis, M.D. *Secretary:* Harry K. Hitchcock, M.D. *Librarian:* J. B. Saundry, L.R.C.P., M.R.C.S.E. Mr. W. Johnson Smith, F.R.C.S.E., then took the presidential chair, vacated by Dr. Creed, and proceeded to deliver a very interesting and practical inaugural address, chiefly treating of pyæmia and typhoid fever.

REVIEWS.

Cyclopædia of the Practice of Medicine. Edited by Dr. H. von Ziemssen, Professor of Clinical Medicine in Munich, Bavaria. Vol. XII. Diseases of the Brain and its Membranes. Translated by Henry A. Swanzy, M.D., of Dublin; Charles Emerson, of Concord; E. H. Bradford, M.D., Eldridge G. Cutler, M.D., Robert I. Edes, M.D., James J. Putnam, M.D., F. C. Shattuck, M.D., and S. G. Webber, M.D., of Boston; and Louis Velder, M.D., of Elmira. London: Sampson, Low, and Co. 1877.

In none of the volumes of his Cyclopædia which have at present appeared has Professor Ziemssen shown better judgment in his selection of authors than in the one before us. He has chosen men distinguished in their special lines, but who are at the same time representatives of the younger schools of thought in relation to cerebral disease, and who are able to bring the most recent experimental knowledge to bear on the elucidation of the subjects allotted to them for description. The names of Nothnagel, Heubner, and Hitzig are well known to English readers as those of first-rate original observers; and though we are less familiar with those of Obernier and Huguenin, the articles which they have contributed to this volume stamp them at once as men of great promise.

To the pen of Professor Nothnagel, of Jena, we owe the articles on Anæmia, Hyperæmia, Hæmorrhage, Thrombosis and Embolism of the Brain, which occupy about one-fourth of the work. Of these, that on cerebral hæmorrhage is naturally the most interesting and important, and we shall confine our brief remarks on Professor Nothnagel's contributions to it. In speaking of etiology, he lays great stress on "diseases of the cerebral vessels, especially the arteries, as by far the most important predisposing cause of cerebral hæmorrhage." He agrees with those authors who have described "miliary" aneurisms as the seat of rupture, and concludes that "atheromatous degeneration does not of itself (*i.e.*, apart from such aneurisms) directly lead to rupture, and that consequently the existence of rigidity of the peripheral arteries is of no diagnostic significance." That simple increase of the blood pressure in the cerebral arteries or veins, *without* disease of their walls, rarely causes cerebral hæmorrhage, is, he believes, on the one hand, clearly proved by the statistics of apoplexy occurring in conjunction with Bright's disease, in nearly every instance of which atheroma was present; and on the other by the fact that in whooping-cough, parturition, and epilepsy, all of which are associated with increase in venous pressure, cerebral hæmorrhage is scarcely ever met with.

The following remarks deserve attention at the present time, coming as they do from one of the leaders of cerebral experimentation:—"In view of the structural differences between the brain of man and that of animals, which for certain regions is not inconsiderable, the conclusions drawn from physiological experiments are only to be applied within very narrow limits to pathological cases. *We regard it as very important in the present state of our knowledge to use great caution in adopting the results obtained from experiments on animals as a guide in the localisation of circumscribed diseases of the brain.* (The italics are our own.) At the same time, as may be said in passing, we regard it as still less admissible to draw conclusions from the effects of disease as to the normal physiological functions of the injured parts, or on the same grounds to attempt to throw discredit upon the significance of carefully conducted experiments."

Under the head of "Symptomatology," Professor Nothnagel expresses his concurrence in the opinion of those who maintain that lesions of the optic thalamus alone do not give rise to motor paralysis, and he regards it also as demonstrated that lesions in the interior of the thalamus cause no disturbance of the *sensibility*. As far as the possibility of localising hæmorrhagic lesions is concerned, he believes that this can only be done for (1) the pons; (2) the cerebral peduncle; (3) the nucleus lenticularis of the corpus striatum; (4) the crura cerebelli; and (5), if anæsthesia be the only or prominent symptom, certain parts in the immediate neighbourhood of the optic thalamus.

In discussing the treatment of cerebral hæmorrhage, Professor Nothnagel has some excellent remarks on venesection, which he regards as indicated "if cerebral pressure, already considerable, has begun to cause paralysis of the vagus centre (as

indicated by a rapid pulse), and the respiratory centre (as indicated by the presence of Cheyne-Stokes' respiration)." He thinks that, *faute de mieux*, we should not neglect to apply the old-established remedies in apoplexy, even though they lack a scientific basis; but, taken as a whole, his estimate of the value of *any* remedy for apoplexy or its sequelæ is not a high one, and though he gives electricity its full share of credit, it does not amount to very much after all.

Obernier's article on Cerebral Tumours is a very valuable one, especially from a diagnostic point of view; and his tables of special groups of symptoms, arranged (*a*) according to their course, (*b*) according to the nature of the neoplasm, and (*c*) according to its situation, will be of the greatest service to the careful practitioner. Under the third head, detailed typical illustrative cases of tumours situated close to the convexity, tumours of the cerebellum, etc., are given. In reviewing the general symptoms of tumour, Dr. Obernier expresses his opinion that the occurrence of psychical disturbances is the rule rather than the exception, and he describes the different kinds of mental alteration which are here met with. Under Disturbances of Motion reference is made to the discoveries of Hitzig, Fritsch, and Ferrier, and the following explanation is given of the recovery of the functions supposed to be innervated by the so-called "cortical centres" after their extirpation:—"It would seem that in these centres it is a question of certain associations of motor paths for impulses arising in the grey matter, whose function, in case of their destruction, may be undertaken in some degree by other conducting-paths which have remained intact."

As the subject of Cerebral and Spinal Syphilis has so recently undergone discussion in this country, and Heubner's researches have been so often referred to, we shall not do more than recommend to our readers a careful perusal of his article on this subject, not only because of its intrinsic excellence, but because while "the syphilitic affections of the nervous system are among the gravest of the maladies which *lues* is capable of producing," it is "only in the very earliest stages of the affection that a complete recovery can reasonably be expected." Hence the special need for accurate and intimate knowledge of the disease in question.

Acute and Chronic Inflammations of the Brain and its Membranes have been entrusted to Professor Huguenin, of Zürich, and he has admirably fulfilled his trust. The article on Meningitis Tuberculosa is very carefully written. Caseous infection (Buhl) is the theory of its origin adopted by the author, though he confesses that "it is still entirely unknown which ingredient of the softened mass works as the infectious agent." The statement that, while tubercles in the choroid are not uncommonly present in general miliary tuberculosis, they are, strangely enough, very seldom found in tuberculosis of the pia mater alone, is one not to be found in the ordinary text-books, and deserves to be noted. A still more interesting observation at the present time, as bearing on the late Penge Trial, is that of the case (Huguenin's own) reported at page 518, in which *miliary tubercles were developed in the pia mater of a girl of sixteen without a single symptom during life leading to a suspicion of their existence.* In the treatment of tubercular meningitis, Professor Huguenin justly lays the greatest stress on *prophylaxis*, but, even after the disease has developed, he urges that various measures should be tried, and does not limit himself, as (if we remember rightly) the writer on the same subject in "Reynolds's System of Medicine" does, to fixing the upper and lower eyelids together with plaster, to prevent ulceration of the cornea.

There is a good account of that curious disease, Simple Basilar Meningitis, and also, *inter alia*, of Chronic Abscess of the Brain. In the latter connexion the author remarks, as Obernier has also done with regard to cerebral growths, that the implication of the psychical processes by abscess has not been by any means sufficiently investigated. "A number of patients," he says, "show sufficient intelligence in the hospital to make them appear as if normal, but, on account of weakness of their intelligence, they have become incapable of pursuing their former occupation." He also observes that abscesses develope unnoticed in positions in which, according to accepted physiological laws, they ought to produce all kinds of sensory and motor lesions. After this it reads almost like satire to find that the only positive indication for trephining is, that the lesion shall undoubtedly be an abscess of the brain, whose "location is known beyond a doubt."

Professor Hitzig only has the comparatively small section on Hypertrophy and Atrophy of the Brain allotted to him. His article on Progressive General Paralysis of the Insane is, however, one of the best in the book, and though he expressly states that "it makes no pretensions to being considered a complete monograph," it is none the less useful and interesting. The pathological anatomy is clearly and concisely done, and under "Symptomatology" the "*development by stages*" which the disease undergoes, and "which inspires a certain anxiety in the family friends, but which they are disposed to explain in any other than the right way," is pointed to as the social danger to be feared from paralytics. "They often destroy . . . the very substance of their families, because . . . they have lost every idea of the worth of money, and the significance of their own personality." The practical hint under the head of "Diagnosis," that "a patient who clearly states events in the distant past, and leaves enormous gaps in those of the last few days, is not likely to be anything else than a paralytic," is worth remembering.

The matter of this volume is certainly equal to that in any other volume of the series which we have noticed; we only wish the translation did the author's language more justice. Some extraordinary phrases, which may be good American, but are not good English, are scattered throughout the work, and indicate a want of special aptitude for their task on the part of several of the translators. "The focus makes pressure" (*i.e.*, presses), page 168, and "mistaking for uræmia has taken place," page 570, are not elegant sentences; and the following, which, in the absence of the original German, we have not as yet comprehended, seems to reflect very little credit on whoever allowed it to appear in print:—"But if we enter upon a psychological analysis of that which from all time has made men celebrated, and which will none the less serve as the future measure for human greatness, it is evident that it implies nothing for which organs are needed which shall vary much from the average human organs."

The Cottage Hospital: its Origin, Progress, Management, and Work. By Henry C. Burdett, Secretary to the Seamen's Hospital Society (late *Dreadnought*), Greenwich, etc. London: J. and A. Churchill. 1877. Pp. 272.

There is not the slightest need nowadays to explain the *raison d'être* of, or to defend, cottage hospitals. Since the first was established by Mr. Albert Napper some twenty years ago, the institution of them has spread throughout the country, and the system has fully justified itself. Mr. Burdett has taken great trouble to find out how many of these hospitals now exist, and how many others have been established and since discontinued, and he gives a list of about 170. But about ten of these have been closed, for various reasons; and some are "not true cottage hospitals." So that the number about which he has been able to learn anything must be reduced to some 140; though he states that "it is probable that there at the present time something like 200 cottage hospitals in the United Kingdom." A good work on the organisation and management of institutions so popular and of such recognised utility cannot fail to be of value; and such a work Mr. Burdett's book, on the whole, is. The best mode of giving a general idea of its scope, and fulness of detail, will, probably, be to point out the subjects of the several chapters into which the book is divided. Chapter I. is introductory, and gives, among other things, "Examples of Growth from Cottage to General Hospitals"; examines into the causes of the failures that have occurred in some cottage hospitals; reviews the growth of the movement; and examines into the financial aspect of the question. Chapter II. treats of the Medical Department. Chapter III. is on "Cottage Hospital Construction and Sanitary Arrangements"; and Chapter IV. on "Nursing Arrangements, Domestic Supervision, and General Management." Chapter V. is devoted to "A more Detailed Account of certain Cottage Hospitals, with Plans of the Buildings, Elevations, etc." Chapter VI. treats of "Peculiarities and Special Features in the Working of Cottage Hospitals"; and Chapter VII. is on "Cottage Hospital Appliances and Fittings." The last chapter, Chapter VIII., is suggestive, treating of "Midwifery in Cottage Hospitals." We much question the advisability of this, and Mr. Burdett admits that "if these cases are admitted into cottage hospitals, it must be either into one built especially, and kept entirely for that purpose, or into a part of the building set apart for such cases, with a separate nurse or attendant." Added to the book is an appendix, on "Hospitalism in Cottage Hospital Practice, in relation to Sir James Simpson's Theory." We take leave to

think that this appendix is a mistake, and is out of place in this book. Mr. Burdett states that "the accuracy of Sir James Simpson's statistics of the results of amputations in country and private practice have been seriously impugned by Callender, Holmes, and other authorities, chiefly on the ground of the impossibility of proving the reliability of the sources from which they were derived." We should say that this was not by any means the chief ground of objection to them, and that much more fatal objections were raised on the ground that they gave no information as to differences in the vitality—state of health, powers of resistance, etc.—of the patients, or as to conditions of injury or disease, and so on; and we do not see that Mr. Burdett's statistics are fuller on these points, or more valuable, than Sir James Simpson's, though we do not in the least impugn their accuracy as mere figures. Mr. Burdett himself, indeed, gives us full reason for thinking that no statistics of the mortality or death-rates of cottage hospitals, that can be considered of any real value in attempting to judge of their healthiness, can yet be obtained, for he says, "over and over again a patient is put down as suffering from an 'accident,' or from 'rheumatism,' etc.; several instances of 'internal diseases' and 'spinal complaints' occur, whilst 'run over,' 'railway accidents,' 'injured,' 'bad cough,' and such like, are terms frequently used, without further explanation or details."

But the book contains a vast amount of practical information, and may on that ground be strongly recommended to all who may wish to found, or may have to manage, a cottage hospital. They will find, we think, advice, founded on experience, on pretty well every subject that they are likely to be called upon to deal with.

GENERAL CORRESPONDENCE.

HOSPITAL MORTALITY.

Letter from Mr. Lawson Tait.

[To the Editor of the Medical Times and Gazette.]

Sir,—I regret that I must object to the following sentence which occurs at the end of the notice of my book in the *Medical Times and Gazette* of September 29:—

"We do not think that Mr. Tait's communications always were quite as courteous as they might have been, and we have reason to know that this fact explains the difficulties he met with on more than one occasion."

It seems to me that this is a personal charge which no anonymous reviewer is entitled to make without a perfectly explicit statement of the grounds upon which he makes it. The same circular was sent to all the hospitals, and I have heard no complaints of any discourtesy in the wording of it. If I have been guilty of discourtesy, it must have been in correspondence arising out of the circular, and all that I have carefully kept. I must, therefore, ask your reviewer to specify the instances to which he alludes. If I have been guilty of a want of courtesy, I shall gladly make the fullest apology; but if the charge cannot be sustained, then I must ask you to withdraw the sentence I have quoted.

I am, &c., Lawson Tait.

[The observation was founded on an actual incident which may have escaped Mr. Tait's memory. Beyond this it is not necessary to go to justify the writer.—Ed. *Med. Times and Gaz.*]

"THE TREATMENT OF SPINA BIFIDA."—REPLY TO DR. ROSEBRUGH.

Letter from Dr. James Morton.

[To the Editor of the Medical Times and Gazette.]

Sir,—In your issue of to-day (October 6), a letter appears on the above subject, questioning my claim to the employment of a new method. The information possessed by the writer is such as might lead him to do so, but he might have inquired further. That the use of iodine is not new, surely no one needs to informed; but the novelty consists in the solvent used, and the precautions requisite to prevent injury to nerve-structure and the escape of the spinal fluid.

It may be right to inform Dr. Rosebrugh that the first of my cases was treated in 1871, and published in the April of the following year in the *British Medical Journal;* and others have followed in succession at various dates, one appearing in the *Lancet* in December last. Those treated by others have been published by them in different periodicals, but no one, either here or elsewhere, has claimed to be the originator of what I still venture to call "the new method," regarding which I have had congratulations from a number of the most eminent surgeons, who cannot be supposed to be ignorant of the modes of treatment previously followed. It is not known that anyone in Glasgow has treated a case by this method; and this is partly due to the fact that my professional brethren have most courteously sent me such cases to treat, thus enabling me to test the new mode of procedure. At the time of the Congress in Berlin, I observed the notice of Professor Langenbeck's case, and rejoiced to see it, as it strengthens the position of those who now try to cure such cases, in place of leaving them to die. Allow me, in conclusion, and for the sake of brevity, to refer Dr. Rosebrugh to the medical journals, or to my small volume, where he "may ascertain how far Dr. Morton is entitled to credit as the originator of this procedure." I trust that he may indeed prove to be "a Daniel come to judgment." I do not pretend to account for the mistakes of Canadian editors. I am, &c., James Morton.

199, Bath-street, Glasgow, October 6.

THE PENGE CASE.

Letter from Dr. James Turle.

[To the Editor of the Medical Times and Gazette.]

Sir,—The medical evidence was absolutely the *only* evidence given at the trial of the crime for which the four prisoners at Maidstone have been condemned to death—viz., *the intentional starving to death of Harriet Staunton.* It is, therefore, the imperative duty of the mass of the medical profession to point out to the Home Secretary the essential fact that the symptoms and post-mortem appearances proved by the medical witnesses for the prosecution are antagonistic to the theory of the prosecution, instead of supporting it. I write hurriedly, to urge that all our medical brethren should lose no time in writing either to Dr. Bristowe, of 11, Old Burlington-street, or to Dr. Greenfield, of 93, Wimpole-street, giving authority for their names to be appended to an address to the Home Secretary, embodying a declaration to the above effect.

Our philanthropic profession—I use the attribute in no sentimental sense, but as an essential one—should not sanction one day longer than can be helped the condemnation, much less the penal execution, of even *one* individual who has been found guilty on erroneous medical conclusions.

I am, &c.,

North Finchley, N., October 4. James Turle.

CORRIGENDUM.

Letter from Dr. Charles H. Blackley.

[To the Editor of the Medical Times and Gazette.]

Sir,—In your issue of to-day, in the article on "The Nerve Theory of Hay-Fever," there is a mistake in the spelling of my name. On page 386 you say, "If Helmholtz and Tyndall and Bulkeley," etc. This last name should be spelled "Blackley." Will you have the kindness to correct this mistake in your next issue, and oblige Yours, &c., Chas. H. Blackley.

Arnside House, Stretford-road, Manchester, Oct. 6.

Teaching-Power of the University of Vienna.—For this ensuing session there will be not less than 53 Professors, 46 Privat-docenten, and 12 Assistants. There are in the General Hospital 15 clinics, 4 dissecting-rooms, 6 institutes, two museums, and a library.—*Wien. Med. Zeit.*, September 18.

Electro-Puncture in Hydrocele.—Dr. Macario, of Nice, relates two cases in which he perfomed this, inserting one needle at the base and the other at the apex of the tumour. In the first case the needles were immediately withdrawn in consequence of the pain caused; but in a few hours all the liquid had been absorbed, and had not been reproduced at the end of several years. In the second case the same rapid absorption followed the application of the needles for about a minute; but in a few months the hydrocele reappeared, and this second time did not yield to electro-puncture.—*Gaz. Med. Ital.*, September 8

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, OCTOBER 9.

CHARLES WEST, M.D., President, in the Chair.

TWO PECULIAR VARIETIES OF HYDROCELE OF THE CORD.

MR. FURNEAUX JORDAN read a paper describing two peculiar varieties of hydrocele of the cord. After enumerating the different varieties of hydroceles in the scrotum, and their various combinations, the author referred to the origin of hydroceles of the cord, to which he limited his remarks. He considered them due to an imperfect obliteration of the peritoneal prolongation which took place along the cord from the internal inguinal ring to a point a little above the testis. This obliteration begins at two points—the ring, and near the testis—and, if incomplete, fluid may collect in the unobliterated space, forming a spherical enlargement, which is movable from the testis. Transparency is present, but is distinguished with difficulty unless in the lithotomy position. The disease is most frequent in early life, and is called "encysted hydrocele of the cord," probably to distinguish it from the so-called "diffused" variety. Of the two peculiar varieties now referred to, the first is a so-called encysted hydrocele of the cord, connected with the abdominal cavity by a long fine tube; the second, an encysted hydrocele of the cord, with a fine tubular prolongation upwards, which ceases near the external ring, not communicating with the abdomen. The point of interest in the first case is the communication of the hydrocele with the abdominal cavity by means of a fine tube of unobliterated serous membrane; in the second, the existence of a tubular prolongation running upwards, but ending in a blind extremity outside the inguinal ring. In the first case a truss was applied; in the latter case acupuncture was resorted to, and proved successful after two or three repetitions. The globular collection of fluid, with the upward neck-like prolongation, suggests for it the name of "water-bottle hydrocele of the cord."

Mr. RIVINGTON thought that the main question was that of name. Two distinct conditions were described—one where the canal communicated with the peritoneum, the other where it did not. The latter might be described as encysted; the former was usually congenital, and this distinguishing title might be applied to it.

Mr. HOLMES considered that the cases would have been more interesting had they been accompanied by actual anatomical proof. Nevertheless it was easy to admit the existence of such openings from the cord into the peritoneum. They actually existed in the case of Sir Astley Cooper. No doubt they also existed in many of Mr. Birkett's cases of hernia occurring suddenly in adults. The second case was a mere accidental modification of the former, where from some cause closure had resulted.

Mr. CROFT had now under his care a child about five years old, who was apparently the subject of the former variety described by Mr. Jordan. The fluid could be sent back, but only very slowly. He had tried a truss, but this had failed to obliterate the swelling.

Mr. OSBORNE suggested that the opening might result from external dilating force; but

Mr. WILLETT thought, rather, that the opening had never closed. This was easily conceivable. The shape would naturally be due to the surroundings of the sacs—they were hardly cysts.

Dr. JOHN HARLEY mentioned the case of a gentleman who had a soft tumour in this situation, which gave rise to some mental annoyance. Was there any connexion between such cases and those just described?

Mr. HULKE said he had made many post-mortem inquiries into the frequency of the occurrence of these congenital canals. They were very frequent. The wonder was that fluid did not occur oftener. The obliteration was usually greatest above and below.

In reply, Mr. JORDAN said all kinds might be congenital. Here there was no hernia, and no truss had been worn. The truss was applied to relieve pain. The fluid might have been mechanically removed, and iodine introduced by a thread. Dr. J. Harley's case was probably one of fatty tumour.

CASE OF NOMA IN WHICH MOVING BODIES WERE OBSERVED IN THE BLOOD DURING LIFE.

Dr. A. E. SANSOM read a paper on a case as above. The author said that the history of the case shows that noma must be added to the list of diseases in which bacterioid particles in active movement are present in the blood and in the fluids. These moving particles have many special characters, and have been probably hitherto undescribed. It is proved also that the fluids in the disease possess the faculty of virulent infectiveness. Dr. Sansom desired to express his obligation to Mr. G. Needham, late House-Surgeon of the North-Eastern Hospital for Children, for the painstaking manner in which he recorded the observations in the case. The patient, Alice C., aged four years and a quarter, was admitted into the North-Eastern Hospital for Children, under the care of Dr. Sansom and Mr. Tay, on February 12, 1876. Her disease commenced a fortnight before admission, with pain in the left cheek; she had had no other disorder. Very great prostration occurred and increased till admission, when she was found anæmic and drowsy, but not emaciated. The left cheek was indurated, and the surrounding tissues were œdematous. Sloughing rapidly took place, the check became perforated, and the inferior maxillary bone necrosed. Copious hæmorrhage ensued on the third day after admission; on the same day broncho-pneumonia set in, and the following day general œdema. The child died on the eighth day after admission. The post-mortem examination revealed very extensive necrosis of the tissues surrounding the left cheek and left side of the tongue, complete sloughing of the temporal muscle, and necrosis of both superior and inferior maxillæ. The bases of both lungs were in a condition of consolidation from broncho-pneumonia. The organs generally showed no morbid sign other than extreme anæmia. A microscopical examination of the blood was first made on the third day after the child's admission. The white elements were in excess; their protoplasm seemed unusually granular, and many of them existed in fragmentary condition. Examined by a high power (Nos. 7 and 8 Hartnack), a large number of small, highly refractile bodies were seen in active movement. These resembled minute colourless crystals; their motion was usually rectilineal, and sometimes in opposition to a current. Two or three attached to a red blood-corpuscle were distinctly observed to move the latter. The movements were quite dissimilar to others (evidently Brownian) observed in the same field. Reagents acted upon them variously: whilst weak solutions of carbolic acid and of quinine caused the particles to come to rest, weak solutions of potash and of sulphuric acid appeared to stimulate the movements. The number of these mobile bodies varied greatly at different times. After hæmorrhage and fall of temperature they were greatly reduced in number; again when temperature had risen to 103° Fahr. they were in great abundance. When they were numerous they tended to form groups resembling zooglœa. In size they were about one-twentieth part of an ordinary red blood-corpuscle. Shortly before the fatal issue, ordinary bacteria were observed in addition to the translucent bodies. The red blood-corpuscles presented great variations in size. Translucent bodies, exactly resembling those observed in the blood, were found in the urine examined immediately after it had been voided, and a large number were seen in the fæces. The discharges from the wound also manifested them in abundance, intermixed with the usual organisms accompanying putrefaction. Investigations concerning the infective characters of the blood and the secretions were commenced on the second day after the fatal issue, the fluids used for inoculation having been preserved in sealed capillary tubes. A healthy mouse inoculated with a minute quantity of blood from the right auricle died on the day following the inoculation, and on examination showed evidences of peritonitis, the exudation containing a large number of mobile translucent bodies, exactly resembling those present in the blood of the child. A like inoculation was also performed on a guinea-pig, which died five days after the operation. The signs observed were those of intense cellulitis of the abdominal wall about the site of inoculation, and peritonitis. The blood, especially that which was obtained from the vena cava and from the right cavities of the heart, was found to contain a vast number of the special translucent bodies. Inoculation of the fluids from the seat of the noma was practised upon a mouse. The animal died the following morning, but none of the characteristic bodies were found in the blood. In the case of a cat also inoculated with a minute portion of fluid obtained

from the diseased part of the cheek of the child, though intense peritonitis occurred, there was a complete absence of the mobile translucent bodies from the blood. It would appear, therefore, that whilst inoculation of the fluids derived from the diseased tissue (with the decomposing matters which they necessarily contained) induced peritonitis without discoverable alteration of the blood; inoculation of the diseased blood produced septicæmia, with the manifestation of the characteristic motile particles observed in the original disease.

Dr. John Harley thought there was no doubt but that noma was occasioned by the bloodvessels being filled with clot, probably originating in a pneumonic lung. The small bodies described might have originated in broken-down blood-clots. Such destruction of parts and breaking down of blood-clots was often seen in typhus and typhoid. The small bodies greatly resembled crystals of oxalate of lime. The distinct cross more especially indicated their inorganic character.

Mr. Hulke could not accept Dr. J. Harley's views as to noma—viz., that it was due to arterial thrombosis, and that again to embolism connected with pneumonia. True gangrene might result from such plugging, but noma was much more rapid in its course. No doubt there was plugging in noma, but was the pneumonia antecedent or subsequent to this?

Mr. Godlee inquired in what respect the moving bodies discovered were different from bacteria. Were they essential to the disease, or were they accidental? It was often possible to find organisms in the blood of infants suffering from acute disease; he had, however, examined the blood in a case of noma, and found nothing.

The President could not allow Dr. J. Harley's doctrines as to the relationship between pneumonia and noma to pass unnoticed. In all fatal cases of noma he thought there was pneumonia, but this was consequent upon, and not antecedent to, the disease. Pneumonia was very common in children; noma was rare. Besides, noma almost invariably affected the face, especially in the vicinity of the mouth; it was not casually diffused over the body, as would be the case were it dependent on embolism from pneumonia.

In reply, Dr. Sansom said he had studiously made his paper a statement of fact. Dr. J. Harley took it for granted that there was pneumonia before the noma: in this case there was no pneumonia when the child was first seen, nor for some time after. In another case of noma which he had examined there were no organisms visible. There was no evidence of their origin in broken-down clots. The bodies themselves were strikingly like crystals, and like no known forms of bacteria, yet they moved freely. Perhaps they were surrounded by a transparent protoplasm.

Salicylic Acid in Hay-Fever.—At the Lower Rhine Medical Society, Prof. Binz, after relating the success which has attended Helmholtz's recommendation of treating this apparently parasitic disease by quinine, stated that some recent trials had shown that probably salicylic acid will also prove an efficacious remedy, and relates a case in which a solution of one part to 1000 parts of water thrown up into the nares cut short the disease.—*Deutsche Med. Woch.*, September 22.

Sanitary Neglect.—A gross case of contemptuous disregard of all sanitary laws was heard last week before Mr. D'Eyncourt at the Westminster Police-court. The owner of the premises, 10, Symons-street, Chelsea, was summoned to show cause why an order should not be made on him requiring him to do away with certain existing nuisances at the house in question. The sanitary inspector of the parish said that the defendant had notice on the 6th of last month to abate the nuisance—viz., that the drains were untrapped, and water of a fetid character percolated the foundations. That notice had been totally disregarded, and the present summons had been taken out, to which the defendant did not now appear. The house consisted of six rooms, occupied by no less than six families, numbering twenty-three souls; the ground of the yard was rotten, and the soil from the neglected draius, which had been opened a week before, and had not been closed, was lying about the yard. The basement was in a filthy state, so much so that Dr. Barclay, the Medical Officer of Health, was of opinion that epidemic disorders would be spread. The parish had already taken proceedings for the overcrowding of the premises. Mr. D'Eyncourt made the nccessary order for the work to be done within seven days, and the cost of the proceedings to be paid by the defendant.

MEDICAL NEWS.

Royal College of Surgeons of England.—At t recent half-yearly examination in Arts, etc., for the diplom of Fellow and Member of this institution, 374 candidates pr sented themselves—viz., 107 for the first-named distincti and 267 for the Membership. The following gentlemen pass for the Fellowship, viz.:—

Edward Armitage, Charles Atkin, J. H. R. Bond, C. L. S. Branson, H. Birch, G. N. Caley, G. A. Carpenter, J. T. Chevers, William Coates, E. Colville, E. T. Collins, M. L. B. Coombs, John Coveney, A. B. Cottell, S. Crick, E. H. Crisp, C. F. Cuthbert, J. M. Davidson, E. S. S. Davis, Wal Dendy, H. W. Dodd, D. P. Edwards, H. J. Fletcher, George Fox, G. H. Fuller, F. H. Furnivall, H. E. Garrett, F. C. Gibbs, Arthur Goulston, C. Guy, Alexander Hamilton, D. P. Harris, Francis Heath, G. T. Hockin, Holcroft, J. G. Holmes, H. C. Howard, T. J. Hudson, J. S. Hunt, G. Hunter, William Huntington, S. F. C. Hart, Ho Kai, A. W. D. Leal E. W. Livesey, A. G. S. Mahomed, J. H. Mawson, J. F. Molineux, T. Morse, J. T. J. Morrison, C. A. Morton, H. R. Mosse, Thomas Mudge, C. Muriel, C. S. Murray, H. C. Nance, C. D. Nuttall, J. M. Owen, F. C. Payn C. L. Pinniger, W. R. Pollock, J. L. Poynder, H. Rayner, J. J. Reynol W. B. Roué, W. H. Sharpies, Frederick Stroyan, J. E. Square, H. B. Ta D. D. Thomas, A. H. Thompson, J. B. Tiernay, R. C. D. Traies, E. Trevor, F. S. Turner, T. H. Waller, F. P. Wightwick, C. Williams, a J. W. Winterburn.

The following gentlemen passed the preliminary examin tion for the Membership of the College, viz.:—

W. P. Allen, William Alpin, G. A. Ambler, E. Apthorp, J. J. Y. Babe H. A. W. Batten, Alfred Bastin, William Bird, A. F. Blagg, J. S. Bolto Philip Boobbyer, Josiah Blomfield, W. F. Boycott, W. A. R. Welsfor J. A. Williams, J. H. H. Williams, A. G. Wildey, Neville Wood, H. Woolbert, W. H. Wright, A. D. Willcocks, and J. J. G. Whittindale.

For the Fellowship seventy-seven were successful; twenty having failed to reach the required standard for that distinc tion, obtained sufficient marks for the Membership; and te were rejected. For the Membership there were 267 candidate of which number 179 were successful; the remainder—viz eighty-eight—were rejected. These gentlemen can at onc commence their hospital studies, either in this metropolis, or a recognised schools in the provinces.

Apothecaries' Hall.—The following gentleme passed their examination in the Science and Practice Medicine, and received certificates to practise, on Thursday October 4:—

Chicken, Rupert Cecil, Nottingham.
Vickerstaff, William Harry, Macclesfield.
Walsh, William Arthur Stephenson, Worcester.

The following gentleman also on the same day passed hi Primary Professional Examination:—

Brown, Percy, London Hospital.

BIRTH.

Clouston.—On September 30, at Pemberton House, Hay, Breconshir the wife of C. S. Clouston, M.B., of a daughter.

MARRIAGES.

GES—SPURGEON.—On October 4, at the Congregational Chapel, Havant, oaquin Pages, Esq , of Sabadell, Spain, to Aline Louise, only daughter f the Rev. S. Spurgeon, M.R.C.P., Principal of the Manor House 'ollegiate School, Havant.

CHARDS—WILSON.—On October 4, at All Saints', Bromsgrove, J. Peeke Richards, Medical Superintendent of the Middlesex County Asylum, Hanwell, to Harriott, younger daughter of John Wilson, Esq., of Greenwich.

DEATHS.

AMMER, SAMUEL RICHARD, M.R.C.S., L.S.A., late of Canonbury, slington, at Calne, Wilts, on September 29, in his 53rd year.

IPE, JOHN COPELAND, M.R.C.S. Eng., late Surgeon-Major 36th Regt., t 37, Morehampton-road, Dublin, on October 3.

WSON, HENRY, M.D., Assistant-Physician to, and Lecturer on Physiology t, St. Mary's Hospital, on October 4, in his 37th year.

RVES, REBECOA, wife of William Laidlaw Purves, M.D., at 7, Hanover-treet, Hanover-square, W., on October 4, in her 33rd year.

BERTSON, ADAM, M.D., Staff Surgeon Royal Navy, third son of the late Robert Robertson, merchant and manufacturer, of Dunfermline, at Aden, f sunstroke, on August 1, aged 39.

M, CHARLES, M.D., late of Ripon, Yorkshire, at Torquay, on October 8, n his 79th year.

VACANCIES.

the following list the nature of the office vacant, the qualifications re-uired in the Candidate, the person to whom application should be made nd the day of election (as far as known) are stated in succession.

RKHEMPSTEAD UNION.—Herts and Bucks District of Berkhempstead. Medical Officer. Candidates must be duly registered practitioners, and old the certificate of proficiency in vaccination required by the Local Government Board. Applications, with recent testimonials, to Samuel Statton, Clerk, Hemel Hempstead, on or before October 15.

STLE WARD UNION, NORTHUMBERLAND.—Medical Officer. Applications, ccompanied by testimonials of recent date, and evidence of qualifica-ions and registration under the Medical Acts, to Thos. Arkle, Clerk to he Guardians, Highlaws, Morpeth, on or before October 13.

THERHAM HOSPITAL.—Resident House-Surgeon. Candidates must be M.R.C.S. Eng., and Licentiates of the Society of Apothecaries or of the Royal College of Physicians, London, registered, and unmarried. Appli-ations, with testimonials as to professional ability and moral character, o the Honorary Secretary, on or before October 15.

ESTMINSTER HOSPITAL, BROAD SANCTUARY.—House-Physician. Candi-lates must be registered under the Medical Registration Act, 1858, and roduce testimonials as to moral character, and a certificate that they ave served the office of Clinical Clerk for not less than six months in ome recognised hospital. Applications to the Secretary not later than October 16.

UNION AND PAROCHIAL MEDICAL SERVICE.

* The area of each district is stated in acres. The population is nputed according to the census of 1871.

RESIGNATIONS.

Keynshan Union.—Mr. John Lodge has resigned the Keynsham District; a 10,002; population 4716; salary £53 per annum.

Launceston Union.—Mr. William Brown has resigned the Fifth District: a 8880; population 2422; salary £12 per annum.

APPOINTMENTS.

Beverley Union.—Thomas John Thompson, L.R.C.P. Edin., L.R.C.S. Ire., the First District.

Southwell Union.—Henry P. Long, M.R.C.S. Eng., to the Farnsfield strict.

NAVAL MEDICAL SUPPLEMENTAL FUND.—At the uarterly meeting of the Directors of the Naval Medical Com-ssionate Fund, held on the 9th inst., Dr. J. W. Johnston, spector-General, in the chair, the sum of £85 was distributed ong the various claimants.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—The follow-g gentlemen have been elected:—Mr. R. H. S. Spicer, to e Scholarship in Natural Science; Mr. J. B. F. Eminson, to e Exhibition in Natural Science; and Mr. F. H. Butler, to e Extra Scholarship in Natural Science.

PRESERVATION OF LEECHES.—This, although of less nsequence than formerly, when they were so much employed, ay yet be sometimes desirable, and it is said in the *Union édicale* to be effectually accomplished by the addition of thirty ops per litre of a 3 per cent. solution of salicylic acid.

PRIZES.—The subject for the Jacksonian Prize of the llege of Surgeons for the present year is "The Disease of e Lymphatic System known as Hodgkin's Disease or ymphadenoma," the essays for which must be sent in on or fore Monday, December 31. The subject of this prize for 78 is, "Glaucoma, its Causes, Symptoms, Pathology, and eatment." The Collegial-Triennial Prize of fifty guineas, of the John Hunter Medal of that value, is, "The Anatomy d Physiology of Third, Fourth, and Sixth Nerves, as illus-ated by observation and experiment in health, and by refer-ce to the effects of injury and disease." The essays for is prize must be sent in on or before December 31, 1879.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

J.R.—Try Kimpton, High Holborn.

Dr. A. Leslie Mease.—We do not find that any distinct history of vivisection has ever been published; or any defence or condemnation of vivisection "on scientific and moral grounds," as a separate work. A very able and interesting pamphlet, entitled "The Vivisection Question properly Discussed," published by Dr. L. Hermann, Professor of Physiology in the University of Zürich, was translated and edited by Dr. Archibald Dickson, and published by Williams and Norgate, Henrietta-street, Covent-garden, London, 1877. But you will probably find the very thing you want, on both sides of the question, in the Report of the Royal Commission on Vivisection, published by Eyre and Spottiswoode, printers to her Majesty.

S. Doddington, Cambs.—You will do best to write to Mr. Alfred Haviland, Northampton.

A Teetotaler.—The justices at the late licensing session for Manchester expressed a hope that the Legislature would confer upon them the same discretion in granting or withholding retail licences for consumption off the premises as they now possess in all other cases.

A Nervous Traveller.—The apparent immunity from accidents on the Russian railways may be accounted for by the fact that the speed of locomotives is limited by law to twenty miles an hour.

M.D., Glasgow.—Dr. Pritchard of your city was executed for murder on July 28, 1865. See the *Medical Times* of that time.

A Demonstrator.—Try the effects of Rimmel's Vaporisers. They were used for some time at the summer examinations on anatomy at the College of Surgeons.

M.D., Royal Navy.—Mr. Robert McCormick, F.R.C.S. Eng., Surgeon and Naturalist to the Parry and Ross expeditions, is living. He was admitted a Member of the College of Surgeons so long ago as December, 1822, and therefore is about seventy-six or seventy-seven, presuming him to have been of the required age when admitted a Member.

An Old Subscriber.—The lectures of the distinguished surgeon were published at the time, with his permission and corrections, exclusively in this journal. See Pettigrew's "Medical Portrait Gallery."

Mr. Williams.—We will endeavour to obtain the information for you in a week or two, but we have ascertained that in the collegiate year 1846-47 only seven members were admitted to the Fellowship by *examination*; in 1856-57, sixteen; in 1866-67, twenty; and in 1876-77, twenty-four.

An Anxious Parent.—Dr. Carpenter, in his evidence before the "English Public Schools Commission," lays great stress upon the importance of enabling children to begin the study of physical and natural science at an early age. He maintains that "the training of the observing faculties by attention to the phenomena of nature, both in physical and in natural science, seems to him to be the natural application of time at the age of, say, from eight to twelve.

A Factory Hand.—It is surely impossible to deny that the Factory Acts have accomplished a large amount of good. They have fulfilled to a very considerable extent the objects of their original institution, shortened the habitual hours of labour, rescued children from oppressive toil, and conferred many comforts and benefits morally and physically which operatives did not formerly enjoy.

A Subscriber.—There have been three famines in India between 1866 and 1877. In the Orissa famine, in 1866, according to official returns, a million and a half of people died. In Bengal, in 1874, a yet greater loss was prevented only by the vigilance of the Government.

A REPRISAL.

At the Sheffield County Court, a milkman, who had been fined 2*l.* and costs for selling adulterated milk, recovered the amount from the dealer who had supplied him, the milk having been seized in the condition in which the plaintiff had bought it.

RIVER POLLUTION IN ITALY.

The Italian Minister of Public Works is occupied on a sanitary scheme of some importance. It is reported to have under examination various schemes for deflecting the course of the Brenta, and other streams, from the lagoons, where their deposits, owing to Austrian neglect, have been for years swamping the estuary, and tainting the air of Chioggia and of Venice itself.

STATISTICS.

A Frenchman calls statistics "the science of natural, social, and political facts, expressed in numerical terms." A German, that "history is statistics in movement; statistics are history at rest." A Scotchman describes them as "the means of determining and augmenting the sum of happiness which a nation enjoys." A fourth, of unknown origin, asserts that they are "the science which shows us how to deduce the succession of social facts from analogous numerical terms." Napoleon bestowed upon statistics the denomination of "the budget of things," and proclaimed that they are "the art of making the inventory of a country." Goethe said of them that "if figures do not govern the world, at all events they show us how it is governed." It is further said that "statistics ameliorate the condition of humanity by pointing out its sufferings in numbers."

INFECTION.

Under the Sanitary Acts, the Vestries and District Board of Works have ample power to provide small-pox hospitals, and to cause the removal thither of small-pox patients who cannot remain in their homes without danger to others. In establishing the Metropolitan Small-pox Hospitals, under Mr. Gathorne Hardy's Act of 1871, the object of the Legislature was to decrease the number of centres of infection.

COMMUNICATIONS have been received from—

Mr. GEO. NORRIS, London; Mr. JAS. TURLE, Finchley; THE REGISTRAR OF APOTHECARIES' HALL, London; Mr. RYMER JONES, London; Mr. A. L. MEADE, Cavan; Mr. LAWSON TAIT, Birmingham; Mr. KATER, Reading; Mr. BYROM BRAMWELL, Newcastle-on-Tyne; Prof. MORTON, Glasgow; Mr. J. DONOVAN, Cork; Dr. H. A. HITCHCOCK, Lewisham; Dr. J. W. MOORE, Dublin; THE EDITOR OF THE "FAMILY HERALD"; THE SECRETARY OF THE PATHOLOGICAL SOCIETY; Dr. BLACKLEY, Manchester; Mr. J. W. GROVES, London; Messrs. WRIGHT, LAYMAN, and UMNEY, London; Mr. J. GIBSON BOWLES, London; Dr. COCKLE, London; THE SECRETARY OF THE HARVEIAN SOCIETY; THE SECRETARY OF THE NAVAL MEDICAL SUPPLEMENTAL FUND; Dr. ELLERTON, Middlesborough; THE LIBRARIAN OF CHARING-CROSS HOSPITAL; Dr. T. BARLOW, London; Dr. WM. ROBERT SMITH, Sheffield; Mr. JOHN CHATTO, London; Mr. B. WHEATLEY, London; Mr. F. W. LOWNDES, Liverpool; Dr. EDWARD R. SPARKS, Camberwell; Mr. R. BRUDENELL CARTER, London; Mr. T. M. STONE, London.

BOOKS AND PAMPHLETS RECEIVED—

Robert Liveing, A. M. and M.D. Cantab., Notes on the Treatment of Skin Diseases—C. D. Purdon, M.B., F.R.C.S.I., The Sanitary State of the Belfast Factory District during Ten Years (1864 to 1873 inclusive) under various aspects—Lewis A. Sayre, M.D., Spinal Disease and Spinal Curvature—Robert Bentley, F.L.S., and Henry Trimen, M.B., F.L.S., Medicinal Plants, part 25—Francis Mason, F.R.C.S., On Hare-Lip and Cleft Palate—Dr. Terber's Model Diagram of the Organs in the Thorax and Upper Part of the Abdomen—Edward A. Aveling, D.Sc., F.L.S., Physiological Tables for the Use of Students—Society of Medical Officers of Health Annual Report.

PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Berliner Klinische Wochenschrift—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Gazette Hebdomadaire—Le Progrès Médical—Bulletin de l'Académie de Médecine—Pharmaceutical Journal—Wiener Medizinische Wochenschrift—Medical Examiner—The Louisville Medical News—Boston Medical and Surgical Journal—Nature—Philadelphia Medical Times—Iron—Cincinnati Clinic—Night and Day—Morningside Mirror—Chicago Medical Journal and Examiner—Home Chronicler—La Province Médicale—Monthly Letter of the English Anti-Tobacco Society—American Practitioner—New York Druggists' Advertiser—Anti-Compulsory Vaccination Reporter—Practitioner.

APPOINTMENTS FOR THE WEEK.

October 13. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 1½ p.m.

15. *Monday.*

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

MEDICAL SOCIETY OF LONDON, 8½ p.m. A Short Address by the President, Dr. George Buchanan. Dr. P. M. Braidwood (of Birkenhead), "On Pyæmia" (epitome of Fothergillian Essay).

16. *Tuesday.*

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

PATHOLOGICAL SOCIETY, 8½ p.m. Dr. Wickham Legg—1. Aneurism of the Left Ventricle of the Heart; 2. Aneurism of the Anterior Communicating Artery of the Brain; 3. Free Balls of Fibrin in the Left Auricle, Mitral Stenosis; 4. Complete Obliteration of the Aorta. Dr. P. Irvine—1. Destructive Pneumonia from Pressure on Bronchus; 2. Two Cases of Abdominal Aneurism. Mr. Christopher Heath—Conclusion of Case of Cystine Calculi. Dr. Barlow—Aneurism of the Anterior Cerebral Artery. And other Specimens.

17. *Wednesday.*

Operations at University College, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex. 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 1½ p.m.

18. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing-cross, 2 p.m.; St. Thomas's (ophthalmic operations), 4 p.m.

HARVEIAN SOCIETY, 8 p.m. Dr. William Squire, "On Cases of Acute Pneumonia in Children."

19. *Friday.*

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1½ p.m.; Guy's, 1½ p.m.

MEDICAL MICROSCOPICAL SOCIETY, 8 p.m. Meeting.

VITAL STATISTICS OF LONDON.

Week ending Saturday, October 6, 1877.

BIRTHS.

Births of Boys, 1253; Girls, 1167; Total, 2420.

At the Royal Observatory, Greenwich, the mean reading of the barome last week was 30·08 in. The lowest reading was 29·83 in. on Tues evening, and the highest 30·45 in. at the end of the week.

* The figures for the English and Scottish towns are the numb enumerated in April, 1871, raised to the middle of 1877 by the addit of six years and a quarter's increase, calculated on the rate which p vailed between 1861 and 1871. The population of Dublin is taken stationary at the number enumerated in April, 1871.

ORIGINAL LECTURES.

CLINICAL LECTURE ON A CASE OF PROGRESSIVE PERNICIOUS ANÆMIA CURED BY ARSENIC.

By BYROM BRAMWELL, M.D.,

hysician and Pathologist to the Newcastle-on-Tyne Infirmary, Lecturer on Clinical Medicine and Pathology in the University of Durham College of Medicine at Newcastle-on-Tyne.

Lecture II.

ENTLEMEN,—In my last lecture I described to you a typical ase of that interesting affection which has been called liopathic, or progressive pernicious anæmia.

The disease may be described as follows:—A profound næmia, which is associated with marked changes in the icroscopical characters of the blood, and (in most cases) with ne presence of retinal hæmorrhages. The patient is generally ell covered with fat, the skin is smooth and soft, the face oks slightly swollen, and is of a pale yellow or yellowish-reen colour. All the symptoms of profound anæmia are resent—viz., extreme pallor of the mucous membranes, great ebility, tendency to fainting, dyspnœa and palpitation on xertion, buzzing in the ears, headache, subcutaneous œdema, c.; loud blowing murmurs are heard over the heart and reat vessels; there is a venous hum in the neck; the pulse very soft and compressible. Attacks of vomiting and diar-nœa are frequent; irregular elevations in temperature, tran-ent paralyses, hæmorrhages from the mucous membranes, ccasionally occur. The causes of the disease are at present nknown. The disease is said to occur more frequently in omen than in men. In the majority of cases the termination in death, the end being ushered in by profuse diarrhœa, oma, or delirium.

And this brings us to the *post-mortem appearances*. In order o illustrate this part of the subject, I will read to you the post-ortem record of my first fatal case. The patient, a man aged hirty-four, was admitted on June 10, 1875, and died on June 25. The post-mortem was made four hours after death. The body as warm. The skin was of a pale yellow colour. The feet nd legs were slightly œdematous. The abdominal parietes nd the body generally contained a fair amount of fat. The ericardium contained a few ounces of clear yellow serum. n the anterior aspect of the left ventricle, just over the posi-on of the tricuspid orifice, there was a large milk-spot; another naller one was situated on the anterior surface of the apex. n the anterior aspect of the left ventricle, an inch above the pex, was an extravasation of blood the size of a threepenny-iece. The cavities of the organ were almost empty, the only ontents being a small quantity of thin fluid blood. (There was he same bloodless condition of all the organs.)

The cavities of the heart were dilated; the muscular sub-ance was very soft and friable; the interior of the left entricle was dotted over with small yellowish spots. On icroscopical examination, well-marked fatty degeneration of he muscular fibre was seen. The posterior segment of the itral valve contained a small calcareous deposit, and was mewhat shrunken; the heart weighed 13½ ozs.

The interior of the ascending portion of the aortic arch was otted here and there with spots of fatty degeneration.

The left lung was pale, and absolutely bloodless; it weighed ½ ozs. The right lung was adherent at the apex; it weighed lb. 4½ ozs. There was a commencing consolidation of the pper lobe. On section of this part of the organ, a considerable uantity of red frothy serum escaped.

The liver weighed 4 lbs. 0½ oz., and was pale and fatty.

The spleen weighed 9½ ozs.; it was of a uniform dark purple olour; its structure was normal.

The kidneys were surrounded with fat. The left weighed ozs.; the right 5½ ozs. The cortical substance was markedly ale. On microscopical examination, the renal epithelium as seen to be in places fatty.

The thyroid gland was the size of a hen's egg; it weighed ½ ozs.; both lobes were enlarged. On section, it was found be in places of a pale yellow colour and gelatinous; in other arts it was dark purple; in the lower part of the left lobe here was a calcareous mass.

The stomach, in the neighbourhood of the pylorus, was udded with small round projections. These projections ere arranged in rows. On microscopical examination, they ere found to consist of round lymphoid cells.

The mucous membrane of the intestines seemed softened. The various coats were separated very easily one from the other.

The other parts of the body were normal. These appearances may be summed up as—fatty degeneration of the heart, liver, and kidneys; a bloodless condition of the body; commencing pneumonia of the upper lobe of the left lung; enlargement of the thyroid and of the spleen; a mammillated appearance of the stomach; and an atrophied condition of the intestine.

The pneumonia only came on during the last few hours of life, and had nothing therefore to do with the essential pathology of the disease. The enlargement of the thyroid is interesting, but probably not of great importance. It did not occur in any other case which I have seen described.

The enlargement of the spleen has been previously noted, but is not essential. It was not present in any of Professor Quincke's fatal cases. The mammillated appearance of the stomach has not, so far as I know, been previously noted. It has, however, been found in cases of Addison's disease. Dr. Greenhow speaks of it as follows ("Croonian Lectures," page 28):—

"In many cases, also, including one of Dr. Addison's cases, reported on by Dr. Hodgkin, the mucous membrane of the stomach, especially towards the pylorus, has presented a mammillated appearance, and the mucous surface has not unfrequently been covered with thick tenacious mucus. Careful microscopical examination of the mucous membrane of stomach in two different cases, by Dr. Coupland and Mr. Schäfer, have shown that the mammillations are caused by numerous overgrowths of lymphoid tissue around and between the gastric tubules. Some of the mammillations presented small depressions in their centres, which were ascertained by Mr. Schäfer to be due to a breaking down and opening into the surface of the summit of the patches."

There remain the bloodless condition of the body, and the fatty degeneration of the heart, liver, and kidneys. These appearances have been repeatedly observed.

The marrow of the bones was not examined. This is unfortunate, for Professor Pepper, of the University of Pennsylvania, has described certain abnormal appearances in the marrow, and on these appearances has propounded a theory as to the cause of the disease. He thinks progressive pernicious anæmia "is merely the medullary form of pseudoleukæmia."

Dr. Bradbury and some other observers who have examined the marrow have not detected anything abnormal.

Professor Pepper's views are therefore still uncertain.

So much, then, for the pathological appearances, which, it must be confessed, are not satisfactory. We now pass on to the diagnosis.

Profound anæmia is a very common condition. It is met with—1st. *In all cases where there is great loss of blood, lymph, or any of the secretions or excretions.* This form of anæmia is called by Professor H. Lebert "spoliative" (*Medical Record*, July, 1876, page 289). It is readily distinguished from the idiopathic form by the fact that there is an obvious cause for the anæmia, and that recovery follows the removal of that cause. The diagnosis is aided, too, by the microscopical condition of the blood and the absence of retinal hæmorrhages. Professor Eichhorst believes that progressive pernicious anæmia can be surely distinguished by a microscopical examination of the blood. I agree with him in thinking the microscopical characters of the blood to be of great diagnostic value; but the following case seems to show that if the anæmia and its cause are of sufficiently long duration, the same alterations of the red corpuscles may be assumed:—

M. M., aged twenty-two, married, was admitted under my care on August 12, 1875, suffering from most profuse menorrhagia. She had been ill since the birth of her first child, which took place eight months previously. She was profoundly anæmic. On microscopical examination the blood appeared perfectly normal. She was discharged very much better in September.

On August 31, 1876, she was re-admitted, and stated that the loss of blood had commenced immediately after her discharge from hospital last year, and had continued almost uninterruptedly until the present time. On microscopical examination of the blood it was seen that the red corpuscles did not form rouleaux; many of them were misshapen, and some of them were apparently nucleated, and smaller than natural. These changes were much less marked than in any of my cases of progressive pernicious anæmia, but still they were the same in kind.

2nd. *In cases where there is insufficient nourishment* (the "inanitive" form of Lebert) the diagnosis is of course easy. These cases get well with proper feeding.

3rd. *In cases of chlorosis.* This condition is very common in females between the age of fourteen and twenty-four. Indeed, according to Niemeyer, "obstinate chlorosis attacks all young girls without exception in whom the menses have appeared in the twelfth and thirteenth year, and before the development of the breasts and pubes" ("Text-Book of Practical Medicine," vol. ii., page 743). The appearance of patients suffering from the two affections (chlorosis and progressive pernicious anæmia) is the same. The symptoms, too, are almost identical. Professor Eichhorst thinks we have a sure diagnostic in the microscopical characters of the blood. I am unable to speak personally on this point, nor can I tell you the diagnostic value of the retinal hæmorrhages. The two affections are, however, distinct, as shown by the facts (1) that chlorosis "never endangers life excepting through its complications, particularly the very common one of chronic ulcer of the stomach" (Niemeyer's "Text-Book of Medicine," page 747); (2) that iron is of the greatest benefit in chlorosis, but in progressive pernicious anæmia it is useless—indeed, so far as my observation goes, it seems to do harm.

4th. *In cases of malignant disease.* A typical example of this condition is seen in the patient P., who lies in the Bishop's ward, slowly dying from cancer of the stomach. In a recent lecture I fully went into his case. It is unnecessary, therefore, to recapitulate. The case is at once distinguished from progressive pernicious anæmia by the abdominal tumour, the characteristic vomit, the appearance of cachexia, and the great emaciation. There are no hæmorrhages on the retina, and the blood is fairly normal. The red corpuscles are more adhesive than in health, but normal in size and shape. The white corpuscles are natural, and there is a large amount of fine colourless granular matter. In this case the anæmia is partly caused by the imperfect assimilation of the food, partly by the profound alteration of nutrition which is seen in cases of malignant disease.

5th. *In cases of chronic Bright's disease.*—In my first lecture we considered this subject (chronic Bright's disease). I then described to you three chief varieties which are distinct clinically and pathologically. In the first form the kidney is large and white; in the second, small and granular; in the third, waxy.

You will remember that I told you that in some cases of the small granular kidney the patient is anæmic, the face bloated and somewhat sallow-coloured, the urine copious and containing little or no albumen, the tube-casts few and difficult to find, the dropsy slight or absent. The patient in such cases frequently suffers from vomiting and palpitation. Vision may be imperfect, the result of albuminous retinitis.

In this description you will see a considerable resemblance to progressive pernicious anæmia. You will perceive it all the more when I tell you—and I should have mentioned this point in describing the symptoms—that in some cases of progressive pernicious anæmia the urine may contain, for a time, a small quantity of albumen.

The two affections are, however, readily distinguished (1) by the microscopical characters of the blood; (2) by the state of arterial tension. In chronic Bright's disease, especially in the variety in which the kidney is small and granular, the arterial tension is high. (We considered this point fully in relation to the cardiac hypertrophy which is found in these cases.) In progressive pernicious anæmia the tension is low. In the tension of the pulse, then, you have, I believe, a sure diagnostic.

6th. *In cases of chronic poisoning by lead and copper.* The diagnosis in such cases is readily arrived at by the previous history and the symptoms.

7th. *In cases of Addison's disease.* In both the affections (Addison's disease and progressive pernicious anæmia) there is a profound and apparently causeless anæmia, unattended by loss of fat, and associated with great debility, fainting, vomiting, and diarrhœa.

The points of dissimilarity are—

1. *The colour of the skin.* In progressive pernicious anæmia the skin is of a pale yellow or yellowish-green colour; in Addison's disease it is brown, like walnut-juice. It must, however, here be noted that in some cases of Addison's disease—*i.e.*, those in which the affection runs a rapid course—the discoloration of the skin may be undeveloped. Again, in other cases the discoloration is only seen in certain parts—viz., the face, neck, hands, axillæ, genital organs, and about the umbilicus.

2. *The microscopical characters of the blood.* "In uncomplicated cases of Addison's disease," says Dr. Grecnhow, "so far as I have been able to ascertain, the composition of the blood does not undergo any important alteration. In all my later cases the blood has been examined microscopically with virtually negative results."

3. *The retinal hæmorrhages.* These are very characteristic of progressive anæmia, but are not, so far as I know, seen in Addison's disease.

4. The dyspnœa, palpitation, and hæmic murmurs are much more marked in progressive anæmia than in Addison's disease.

Then there is of course, too, the pathological distinction—Addison's disease depending upon one and only one morbid condition of the supra-renal capsules, a lesion which is closely allied to tubercle, and has therefore been called the quasi-tubercular change.

Some of you will, no doubt, remember a case of Addison's disease which was in my wards for a long time. In order that you may be able to compare the two affections, I will read the notes:—

Case of Addison's Disease.—J. B., aged forty-one, married, a puddler, was admitted under my care on March 30, 1876, complaining of general weakness and of pain in the abdomen. He had been ill and off work for six months. Previous to that date he had enjoyed exceptionally good health. He had not had syphilis, and had been steady. His illness commenced with weakness, and a pain in the left hypochondriac region. He knows no cause for the attack. One of his sisters died of consumption. His condition on admission was as follows:—He was a tall dark-haired man; the conjunctivæ were very white and pearly, the mucous membranes anæmic; he was somewhat thin and emaciated (he had been very badly off for some weeks); the skin of the face, neck, hands, axillæ, nipples, and genital organs was of a dirty-brown colour; on the neck, face, and hands small white patches were interspersed here and there on the brown discoloured parts. The discolorations on the face, neck, hands, and axillæ were strikingly symmetrical, as you will see by the photograph which I now hand round to you. There were no stains on the buccal mucous membrane. The patient was exceedingly feeble; he several times fainted on getting out of bed or after having been at stool. He felt sick, but did not vomit. He complained of pain and tenderness on pressure in the left hypochondriac and right lumbar regions. The tongue was tremulous; it could not be kept protruded unless grasped between the teeth. The papillæ were prominent and red. The gait was peculiar: he took very short steps; the head was turned to the right side; the right shoulder slightly raised; the hands kept close in to the groins. The fundus oculi was normal. The blood was fairly normal; the white corpuscles were few; some of the red corpuscles slightly misshapen. The heart was exceedingly weak, but normal. The other organs were normal. The patient had several sharp attacks of diarrhœa while in hospital, but eventually improved considerably, and gained flesh. He discharged himself on July 13, and, unfortunately, has not been heard of since.

8th. *In leucocythæmia.* I show you here the spleen of a patient who suffered from this affection, and who died on Tuesday last. You remember how profoundly anæmic he was. It was impossible, however, to confound his condition with progressive pernicious anæmia. The great size of the spleen (it measured twelve inches in length, and weighed five pounds thirteen ounces and a half), and the enormous increase of the white corpuscles of the blood, at once showed the nature of the case.

9th. *Hodgkin's disease.* Another affection closely allied to leucocythæmia, and attended by marked anæmia, is Hodgkin's disease. It consists in profound anæmia, associated with painless enlargement of the lymphatic glands. Nearly all the lymphatics in the body may be enlarged. The enlarged glands have no tendency to soften or to suppurate. I will shortly detail to you the history of a case:—

Case of Hodgkin's Disease.—W. W., aged twenty-nine, a moulder, married, was admitted under my care on September 7, 1876, complaining of swelling of the glands of the neck, emaciation, and debility. His illness commenced three months previously with pain in the abdomen. Before that time he was a fairly healthy man. He had twice before suffered from glandular swellings in the neck. He had not had syphilis. The family history was good. On admission his condition was as follows:—He was thin and emaciated. The expression of countenance was remarkable. The glands at each side of the angle of the jaw were much enlarged; the face thin; the skin dry and of an earthy-brown colour. The cervical, axillary, inguinal, and abdominal glands were all enlarged, hard, and painless. There was no appearance of softening nor inflammation. The gums and mouth were red and dry. He complained of great thirst. The liver dulness measured five inches. The splenic dulness was slightly increased. The heart's action was very

eble. The blood contained a considerable quantity of fine anular matter; the white corpuscles were, if anything, ightly in excess; the red globules were normal. The fundus uli was normal. The urine contained a trace of albumen, but casts (the albumen disappeared the day after his admission). n September 15 the face and eyelids were swollen. On the th he was much worse, complaining of severe pain and nderness on the slightest pressure over the upper part of e abdomen. On the 21st, at 1.15 a.m., he died. The st-mortem examination was made thirteen hours after ath. There was recent inflammation of the peritoneum, left eura, and pericardium. The lungs and heart were healthy. he heart weighed seven ounces. The liver weighed five unds three ounces, and was waxy. The spleen weighed six nces, and was a good example of the "sago" spleen. There ere two or three small ulcers at the lower end of the ileum. he mesenteric and retro-peritoneal glands were much enlarged. he inguinal, axillary, cervical, and maxillary lymphatics were l greatly enlarged, and tough on section; none of them were ftened nor caseous.

The anæmia of Hodgkin's disease, then, is distinguished om progressive pernicious anæmia by the peculiar enlargeent of the lymphatic glands, by the marked emaciation, by e absence of characteristic changes in the blood, and by the sence of retinal hæmorrhages.

10th. *Typhoid fever.* If a case of progressive pernicious æmia is seen during one of the attacks of irregular fever, may perhaps be mistaken for typhoid. The distinction is be made by the previous history of the case, the condition of e blood and retinæ, and, above all, by the irregular course of e fever.

11th. *Organic cardiac affections* may also be simulated, espeally when a well-marked mitral murmur is present. Dr. eorge W. Balfour thinks the regurgitation in such cases is e to a relaxed and dilated condition of the left ventricle. have no doubt that this explanation is correct; and in proof it I may remind you of the fact that the cardiac muscle is und soft and flaccid after death, the cavities often dilated. e systolic murmurs at the base are due to the spanæmic conion of the blood.

The diagnosis in these cases must be based on the presence hæmic murmurs at the aorta and pulmonary artery, the nous hum in the neck, the marked anæmia, the absence of ng symptoms (cough, bronchitis), and the fact that the patient s not suffered from acute rheumatism.

It is interesting, in connexion with this subject, to note the t that in the patient I have brought before you there is w no cardiac lesion. The case is, in fact, a good example curable mitral regurgitation. In Dr. Balfour's "Clinical ctures on Diseases of the Heart and Aorta" you will find a st interesting chapter on this subject.

Treatment.—I have little to tell you with regard to the atment of progressive pernicious anæmia. Many cases, in te of everything which can be done, end fatally. Iron, ich is so beneficial in other forms of anæmia, especially in orosis, not only does no good, but, so far as my observation es, is harmful. Alcohol, too, seemed in my cases injurious. inine is useless. Phosphorus cured a case reported by Dr. oadbent (*Practitioner*), but has since been tried in vain. senic was of signal benefit in the case I have related; leed, I firmly believe that D. owes his life to the drug. fore its administration he steadily got worse; after he gan to take it he as steadily got well. In my two other es which recovered, arsenic was also administered.

I was induced to prescribe the drug from its known efficacy a blood tonic, and from the remarkably good effect which lows its administration in some forms of cardiac disease, re especially in dilatation and fatty degeneration—conditions which were probably present in this case.

I would not, however, have you suppose that we have in enic a specific for the disease. It is always dangerous and scientific to draw conclusions from individual cases. Until, n, the drug has been extensively tried by other observers, utility must remain *sub judice*.

If progressive pernicious anæmia be a condition which is the ult of various morbid processes, the same drug may not always efficacious. This may explain the failure of arsenic t has been noted in some cases in which it has already been ministered.

I must not conclude without telling you that in some cases nsfusion of blood has been performed. In no case, however, has a fatal result been prevented. This may, perhaps, be to the fact that the operation was not performed until a y late stage of the disease.

ORIGINAL COMMUNICATIONS.

THE CORONER'S COURT IN ENGLAND.(a)

By FRED. W. LOWNDES, M.R.C.S. Eng.

(*Concluded from page* 412.)

2. We now come to a very interesting part of this subject—how the more efficient performance of all medico-legal autopsies may be provided. Mr. Herschell, Q.C., in his recent paper already alluded to has given us an excellent opportunity of "seeing ourselves as others see us." Let us give due attention to what he says, in the hope that it will "from many a hindrance free us and foolish notion." He says, "Almost invariably the medical practitioner who happens to be nearest is sent for. He examines the body, gives evidence of its condition, the position and character of the wounds if there be any, and to him is very frequently entrusted the duty of making the post-mortem examination. How long it is since death took place; whether the wounds could or could not be self-inflicted; what was the probable weapon or other cause of death;—for all these and many other most material facts you have to place reliance almost exclusively upon the evidence of this expert. What guarantee have you that he will be the person best fitted to lead you to a right conclusion in these matters? It is as likely as not that such investigations have never occupied his attention since he was a student, and that even then he was but ill qualified to conduct them. Even supposing there was a time when he was capable of forming an opinion on such matters, it is only too likely that during years exclusively occupied with the treatment of ordinary human diseases, his knowledge and skill in this special department have become rusty and unavailable. I believe I shall have the concurrence of the highest medical authorities when I say that the investigations to which I have referred require special training, skill, and experience, and that it would be quite false to suppose that you are likely to find them in every practitioner to whom chance may direct your steps."

There is a *tu quoque* argument which suggests itself in a very tempting manner, but as it is an objectionable mode of answering anyone who has a strong case, I pass it by. But I must remark that Mr. Herschell has ignored the Medical Witnesses Act, which binds the coroner to summon the medical attendant of the deceased at his death or during his last illness; or, failing such, any legally qualified practitioner in actual practice in or near the place where the death happened. The circumstances under which these cases generally occur seem also to have been overlooked altogether by the learned gentleman, for in cases of wounding, poisoning, strangulation, etc., the nearest doctor must, for obvious reasons, be sent for, and who is so competent as he to answer many of the above questions put by Mr. Herschell? I may go further, and say that he is the only competent person to answer some of them. But I think we are all agreed that the whole and sole responsibility of making a post-mortem examination, and giving evidence before the coroner, the magistrate, and the judge, ought not to devolve upon him; and, to a certain extent, this contingency is provided for. The majority of jurors at an inquest may, if they are not satisfied with the medical evidence, call for the evidence of such other medical witnesses as they may desire. Again, any gentleman who, being the nearest practitioner, has been called in to a case involving an inquest and a post-mortem examination, may, if he wish, request the coroner to give the order for this latter to another gentleman, he himself assisting or not as he prefers. But there can be no doubt that these duties do require "special training, skill, and experience," and that their performance by gentlemen experienced in pathological anatomy is greatly to be desired. And, as not only is experience in pathology required, but also some knowledge of medical jurisprudence, the concentrated attention of some gentleman selected for his knowledge of these subjects on all the numerous cases of this nature occurring in this large town would add greatly to our knowledge of the different departments of forensic medicine. In Scotland the medical attendant of the deceased

(a) A paper read before the Liverpool Medical Institution, November 16, 1876, entitled "The Coroner's Court in England, and the means by which it may be rendered more effectual in providing—(1) a more satisfactory inquiry into all doubtful and suspicious deaths; (2) the more efficient performance of all medico-legal autopsies; (3) a field for the practical study of forensic medicine in our medical schools."

or the practitioner summoned to see the body, is always one of the medical inspectors who examine the body. But in all cases involving a criminal charge, the police surgeon, who, from the office he holds, has had considerable experience in such cases, is appointed by the procurator-fiscal to be present and assist in the examination. His duties are (1) to see that the examination be as complete and searching as possible; (2) that everything tending to exculpate the prisoner should be fully and frankly stated; and (3) that the report should be drawn up in due form. Dr. Littlejohn, of Edinburgh, from whose admirable papers in the *Edinburgh Medical and Surgical Journal* I have derived much of the information I have given, is entrusted with most of the medico-legal cases in and around Edinburgh, and is also Lecturer on Medical Jurisprudence, in which he is able to instruct students very practically. Gentlemen are present who will be able to confirm this.

It has fallen to me to make many autopsies for five different coroners in town and country. I have always endeavoured to obtain the assistance of some gentleman older and more experienced than myself, and I have to express my thanks to many gentlemen present for their kind assistance. But such assistance should be not voluntary, but properly remunerated; and should Mr. Cross bring in a Bill for reforming the coroner's court, I trust that his attention will be called to the subject of fees, which are at present wholly inadequate to secure the services of experienced and skilled pathologists.

There are three matters of detail on which I should like to say a few words; and the first is as to note-taking, which is believed by many to be prohibited in courts of law. This is not so; notes are allowed to be taken for the purpose of refreshing the memory, provided they be made at the time of the examination, and that the original memoranda are preserved. Secondly, as to the preservation of viscera for analysis. It is not always easy to procure suitable vessels for this purpose. The smaller of the two jars you see on the table is easily procured, and Dr. Campbell Brown has informed me that it is perfectly suitable for the purpose. The larger one is from Mr. Syme's establishment, and he can furnish them for 2s. each. Attention to such details as these, simple though they are, is so important that no apology is necessary for mentioning them. Thirdly, most of the cases containing instruments made for post-mortem examinations are far from complete, containing things that are not wanted, while what is most required is often absent. The one I show you was made for me some years ago, and I have submitted it to a gentleman present who is frequently making autopsies. He will, I think, tell you that it at least contains all that is required, and you will see that it is fairly portable.

3. We now come to the last, though not least important, part of our subject—the means by which the Coroners' Court may be made available for the practical study of forensic medicine in our medical schools. It has long been admitted that anatomy can only be learned in the dissecting-room; chemistry in the laboratory; medicine, surgery, and obstetrics by clinical study; pathology in the post-mortem room. Now, it is also insisted that physiology must be learned in a practical manner in the physiological laboratory; and that one in our medical school is the object of great admiration to every medical visitor whom I have taken into it. In a word, every department of medicine should be taught and learned "practically." Why should forensic medicine be any exception to the rule? It is true that the cases admitted into hospital do not furnish a large quota of medico-legal cases, though some very interesting ones are seen. But within a distance of very little over a mile from the Royal Infirmary is a place which affords a field for the practical study of forensic medicine, little inferior to the Morgue of Paris, where world-renowned medical jurists, Orfila, Devergie, and others, acquired their reputation. I refer to the Dead-house, Prince's Dock, where cases of death from drowning, burning, suffocation, exposure to cold, infanticide, may be seen in almost every variety. Of the architectural appearances of the present and former dead-houses, both external and internal, the less I say the better, but I am glad to be able to say on good authority that it is intended by the authorities to erect a suitable building where post-mortem examinations may be made with facilities and comforts which do not now exist. Now, without encroaching upon other gentlemen's province, the students of the Royal Infirmary School of Medicine might have many opportunities afforded which they do not now possess. During the summer session the Lecturer on Forensic Medicine might, I am sure, easily obtain permission of the authorities to visit this pla and show the external appearances of death from the vari causes I have indicated as to be met with there. Aga many gentlemen present would be very glad of the assista of one or even two students in making a post-mortem exa nation, and especially those whose obstetric and other du render it desirable to avoid such work. And many a m interesting case, which, for want of time and assistance, is n lost to the profession, might then be fully and accurat detailed.

In conclusion, gentlemen, I fear that in some of the fo going remarks I have been less serious than so grave a subj and so serious an audience required. My apology must that, by a strange contradiction, it is one of the peculiarit of the coroner's court in this country, that it never can discussed without exciting ridicule. The memorable sc from *Hamlet* is familiar to us all, when the first grave-digg puts forth as an argal, "He that is not guilty of his o death shortens not his own life"; and when this very s evident proposition is challenged by his comrade's questi "But is this law?" the answer is emphatic, "Ay, marry is' crowner's quest law!" Ever since then, crowner's quest l has been a standing jest, till recent cases, especially the l inquest at Balham, have awakened the English public to fact that there is a tragical as well as a comical side to picture. A young man is cut off in the heyday of his life poison, and an inquiry is requisite to see if it be a case suicide, or as insidious and foul a murder as was ever per trated. Two inquiries are held—the first a solemn farce; second a public scandal and national disgrace. Much was doubt due to the circumstances of the case, but much a arose from the system. We are promised a change, and m hope that it will be better, since it cannot very w be worse. Many of you will remember how the late James Simpson used to try and picture the future; a in his last Graduation Address he looked forward to the d "when physicians shall melt down all calculi, necrosed bo etc., chemically, and not remove them by surgical operatio when the bleeding in amputations and other wounds shall stemmed, not by septic ligatures, nor stupid needles, but the simple application of hæmostatic gases or washes; . . when man shall have invented means of calling down rain will; when he shall travel from continent to continent by su marine railways, or by flying and ballooning through the a and when, to venture on only one illustration more, tireso Graduation Addresses shall no longer require to be written old professors, nor listened to by young physicians." Lo before that day I trust that the patient, much-enduring me bers of this Institution shall no longer be bored by tireso papers from another member of a fault-finding, over-refor ing disposition, and that we shall soon cease to hear of t strange contradictions, the inconclusive verdicts, the deplora waste of scientific material, involved in that ancient institut "the coroner's court."

ABSCESS IN THE LEFT FRONTAL LOBE O THE BRAIN.

DISTENSION OF THE LATERAL VENTRICLE—A PERSISTENT STAT OF IMPERCEPTION.

By JAMES RUSSELL, M.D., F.R.C.P.,
Physician to the Birmingham General Hospital.

Dr. Hughlings-Jackson has remarked that the term imbecili as ordinarily used, may cover defects as special as those co tained in the term "loss of speech"; so it is with the wo "unconsciousness." To say that the subject of the followi case was semi-conscious would constitute an insufficient accou of his condition. He retained automatic consciousness, co nected with the activity of a lower centre, but had lost the time that form of consciousness which is developed in t highest centre, and consists in an intelligent perception impressions made upon his senses. It was interesting to wat the steps by which the patient emerged from this state of i perception, and renewed intelligent relations with the ou world. His speechlessness, absolute as it was, most probab depended upon absence of ideas, not upon inability to call words, as in ordinary forms of loss of speech connected wi right hemiplegia. Speech returned as evidence of intellige consciousness when sudden death terminated the process.

The mental condition of the patient gained increased inter

from its being associated with distension of the left lateral ventricle, and especially with such marked distension of the posterior horn of that cavity, and with pressure consequently exerted upon the surrounding cerebral tissue, especially of the occipital lobe; the relation of the condition to certain speculations of Hughlings-Jackson, Charcot, and Bastian requiring no comment. The position of the abscess, as regards the corpus striatum, probably explains the hemiplegia through the operation of pressure upon the motor centre. It would be refining too much to connect the deviation of the eyes, noticed before death, with the situation of the abscess close to the ocular motor centre in the posterior part of the first and second frontal convolutions. The cause of the ventricular effusion did not appear; the effusion itself had been removed before death, the removal doubtless coinciding with the restoration of consciousness.

G. D., aged 42. His wife was not aware of the presence of any symptom of cerebral disease, except a single fit two years ago. He was suddenly seized with an epileptic fit whilst at work, and was sent home. He returned to his occupation next day, but about noon again fell into a fit, and again on reaching home. From that time, through the next thirty-six hours, he suffered from a constant succession of fits, in which his wife positively affirms that the right side only was engaged. One side of the face was drawn, but it was not clear which. The right hand was clenched. He remained unconscious after the cessation of the fits until the period of his admission, six days afterwards.

He then presented the ordinary form of right hemiplegia, so far as the motor functions were concerned. His mental condition was one of mere automatic consciousness, sufficiently manifest, but at first of a very low grade; and he gradually emerged from this state to one of intelligent perception, by slow but well-marked gradations. His urine was first retained, then was passed unconsciously, as were his stools. He lay without uttering a sound as if asleep, his left arm under his head, occasionally opening his eyes in a drowsy manner, his gaze, if directed to the bystander, perfectly expressionless. He was gentle, unreceptive of any command, and without the least indication that he was conscious of our presence. Roused by sharp pinching of his leg, he tardily twisted his face into an expression of discomfort, and after some time used his left foot to push away my hand, but never moved his left hand for that purpose, reminding one of the condition of the decapitated frog when acid was placed on the skin.

In a week's time he could be induced to make an attempt, with very partial success, to protrude his tongue. At that time he is described as lying on his side, with bedclothes drawn tightly over his head, rubbing his eyes when they were removed, and yawning as if awakened. When pinched sharply there was the same painful expression, but now he used his hand to remove the offending object, though he did not utter a sound. Nor did he direct his eyes towards me when I spoke; but on the nurse addressing him, with whose voice he was more familiar, he looked sleepily at her. She succeeded in inducing him to raise his hand, at her direction, and she has got him to make an affirmation in this way when asked if he wanted more to eat; moreover, his signs of discomfort are sufficiently indicative to enable her to prevent his wetting the bed. On my leaving him he drew the clothes again over his head.

At the end of the second week his eyes were directed towards me, and had a more intelligent expression, though his countenance showed no change when I spoke to him. He followed moving objects with his eyes. It was still very difficult to make him put out his tongue. Two days afterwards he turned his head to me as I came up, and not only raised his hand when directed, but one or the other finger according to command. For eighteen days he was perfectly speechless, but then he said "Yes" and "No," though not correctly. On this day, too, he burst into tears on seeing his wife. Two days afterwards he asked for the *pôt*, and in reply to an inquiry where he was, said, "In the hospital"; but a week later he was quite intelligent, though he still sometimes blundered in using "Yes" and "No."

The temperature taken for the first eight days was perfectly normal. His urine was free from albumen. His bowels were costive. The sphincter ani was relaxed. Pupils were natural. The sounds of the heart were healthy. The optic discs were healthy, Mr. Priestley Smith confirming my own observation ten days before the patient's death.

On the thirtieth day of his residence in hospital he was seized quite suddenly with shivering and vomiting. He was found by Dr. Bindley breathing heavily, with contracted pupils, the eyes oscillating; the axillary temperature 104·8°; pulse 106; respirations 24. In an hour and a half the temperature had reached 106·2° in the right, and 105° in the left axilla. He died two hours after the seizure, the eyes being turned upwards and to the right. The temperature in the rectum three hours after death was 107·2°.

On post-mortem examination, the vessels and membranes of the brain were found perfectly healthy. The surface of the brain was very dry, and the convolutions, especially of the left hemisphere, were much flattened. The convolutions, especially the occipital and frontal, were carefully examined in the fresh state; they were universally anæmic to a great degree, but, with the exception of the left superior frontal, were healthy in structure. The greater part of the left upper frontal convolution was destroyed by an abscess, which lay within the frontal lobe. When the brain had been hardened in spirit, the difference in bulk—apparent enough in the fresh state—between the frontal lobes of the two sides was very striking; the one on the left side was much bulged out, and advanced in front of its fellow. The abscess commenced in the first frontal convolution, close to the surface, and in the adjacent white matter, three-eighths of an inch behind the anterior extremity of the hemisphere; it extended backwards for two inches, tending inwards, and partially engaging the second frontal convolution. It just overlapped the corpus striatum to the extent of a third of an inch, lying upon the nucleus caudatus, but not extending into its tissue. It came into such immediate contiguity with the anterior horn of the ventricle as to create a suspicion of its having opened into that cavity; but the ventricles had been examined before removal of the brain from the skull, and no fluid was found within them, nor did any communication disclose itself. The abscess was lined by a firm membrane. No evidence of surrounding softening existed in the hardened brain in the anterior part, but behind the abscess and around its posterior extremity evidence of softening was very apparent. The tissue of the corpus striatum merely differed from that of the opposite side in the fact that the separation of the two nuclei by the commencement of the internal capsule was more confused. The left lateral ventricle had been subjected to considerable distension. It was much dilated, but the evidence of the distending process was most striking in the case of the posterior horn of the cavity, which, in the vertical section by which the examination was conducted, presented a wide gaping mouth admitting a large finger, and presenting a striking contrast with the horn of the opposite side. Unfortunately, we omitted to note the condition of the lining membrane of the ventricle, and I have further to admit that the source of the abscess was insufficiently searched for. All the other organs were healthy.

Royal College of Surgeons.—The number of gentlemen admitted Fellows of the College by examination in the corresponding years of the following decades is interesting—viz., from July, 1846, to 1847 there were fourteen; July, 1856, to 1857, seventeen; July, 1866, to 1867, twenty-three; July, 1876, to 1877, twenty-seven. The largest number ever examined occurred in the collegiate years 1844-45 and 1849-50, when it amounted to thirty-nine in each year. The smallest number was in 1855-56—viz., six.

Effects of Alcoholism on Mental Diseases.—M. Magnan, of the St. Anne Asylum, Paris, terminates a paper read at the Geneva Congress with these conclusions:—1. Alcoholism present different characters, according to the nature of the drinks which have been abused. 2. Alcohol of itself does not give rise to epilepsy; and when this occurs, it depends upon a predisposition in the subject, or upon some other substance than alcohol. The epileptiform attacks in chronic alcoholism do not depend upon the drink taken, but upon the organic lesions which have been already produced in the nervous centres. 3. Special characteristics enable us to distinguish three forms of delirium tremens—the one symptomatic of an injury or of an intercurrent affection; the second, spontaneous, apyretic, and benign; and the third, spontaneous, febrile, and grave. 4. Alcoholism may lead directly to general paralysis, certain terminal lesions of chronic alcoholism not differing from the lesions of general paralysis. 5. Alcoholic insanity is distinct from all other forms of insanity; but it may complicate and mask them, hasten their appearance, and accelerate their progress, and may become the point of departure of a partial delirium, with a tendency to systematisation and chronicity.—*Gaz. Méd.*, October 13.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

SOUTH LONDON OPHTHALMIC HOSPITAL.

CASES OF TOBACCO AMBLYOPIA (AMAUROSIS).

(Under the care of Mr. NETTLESHIP.)

THE following short series of cases is offered with but little comment in illustration of the well-defined group of symptoms which occur when the optic nerves suffer in chronic tobacco-poisoning. Oculists are far from agreed either upon the share attributable to tobacco in causing damage to sight, or on the visible changes in the eyes which it produces. Mr. Nettleship thinks that this want of unanimity may be traced partly to the undue frequency with which complete blindness and advanced atrophy of the optic discs have been spoken of, especially in some of the earlier publications, as due to tobacco-smoking. Another cause, undoubtedly, is the difficulty of assigning to each of several possible agencies their proper share in this malady—a difficulty which serves not only to strengthen a commendable caution, but to shelter a certain amount of slovenly observation. Even in some of our latest English text-books, we find only a most inadequate notice of the influence of tobacco upon sight; and this chiefly, as Mr. Nettleship believes, because the writers have had in their thoughts only advanced cases of atrophy. It is to be kept constantly in mind (as has been pointed out by Mr. Hutchinson) that the disease is, at any rate nowadays, but seldom allowed to run on to its natural ending, and that, even when unchecked, its tendency is, in a large number of cases, to come to a standstill considerably short of such extreme results. The present is not the place in which to discuss the reasons for asserting that tobacco is the *essential* cause of the symptoms in most of the well-known cases of symmetrical progressive amblyopia occurring solely in men, and in which more or less complete recovery takes place. That the symptoms are arrested, and sight restored, in degree varying with the previous severity and duration of the case, when tobacco is wholly and in great degree given up, and that cases agreeing in all respects with these are scarcely ever met with in persons who do not smoke, are the two most important positive pieces of evidence. The objection that this form of disease is not met with in countries such as Egypt and Turkey, where tobacco is more largely used than in the North and West of Europe, will have weight only when several obvious sources of fallacy have been carefully set aside, particularly as to the kind of tobacco used, and the manner of using it. The influence of sex is one of those which it is most difficult to estimate, and the effect of alcohol is another. The much greater liability of men to locomotor ataxy and to general paralysis of the insane (two diseases in which amaurosis is apt to occur), as also to the rare disease in which amaurosis with atrophy of discs is hereditary, may show some special aptitude for slow disease of the optic nerves in males; but this, if true, does not make it less likely that tobacco is the sole exciting cause of the disease illustrated in the following cases. Mr. Nettleship concurs in the general opinion that alcohol, and especially spirits, when taken largely enough to cause either chronic dyspepsia or the nervous symptoms of chronic alcoholism, is an important predisposing cause of tobacco amblyopia, as are prolonged anxiety, and perhaps sexual excess; but he has seen no evidences that these same influences can produce any such result either in men who do not smoke or in women.

Case 1.—*Severe Amblyopia, with Slight but Definite Changes in Discs, Six Months—Central Scotoma (?)—Patient a Heavy Smoker and Liberal Drinker—Perfect Recovery—Tobacco absolutely relinquished.*

Benjamin I., a big, robust signalman, of fifty-one, came under care at the South London Ophthalmic Hospital on April 2, 1873, complaining that his sight had been failing for six months. The failure had been gradual, and had been first apparent by artificial light. There had been no failure of appetite nor any disturbance of sleep, but he considered that he had lately been getting nervous. His vision was with the right barely 18 Jäger, and no letters of 200 Snellen at twenty feet; left, barely 16 Jäger and $\frac{20}{200}$. This slight difference was not of any material importance in aiding the diagnosis. Sight was not improved by any glasses. There was no colour-blindness, and he was still able, he said, to distinguish the colours of his signal-lights. He could see best in a dul light (central scotoma), but there were no marked variation in sight. The ophthalmoscopic appearances were identical i each eye; the yellow-spot third of each optic disc slightly but decidedly, paler than the remaining two-thirds, whic seemed (the patient's pupils not being dilated) redder than i health, being, indeed, not much less red than the surroundin choroid. The other parts of the fundus were healthy. H had been a smoker thirty-five years, and for the last seve years had smoked an ounce of shag tobacco daily. Formerl he had been a heavy drinker, and was still in the habit o taking from three to five glasses of brandy-and-water daily There was no history of bad sight in his family, except tha his mother's vision failed her in old age. He was ordered te minims of tincture of nux vomica thrice daily, to abstai entirely from the use of tobacco, and to drink somewhat less He remained under care for ten months, taking the medicin regularly.

In January, 1874 (nine months after admission), he had no improved to any very striking extent, vision being then 16 Jäge and $\frac{20}{50}$ imperfectly.

He ceased attendance and medicine in February, 1874, bu came to see Mr. Nettleship at request in April, 1875, when i was found that he could see $\frac{20}{30}$ and 10 Jäger without his glasses while with them he could read 1 Jäger ("brilliant") easily. H considered his sight as good as it had been before the failur began. He said that at the time when he ceased taking th medicine his sight had not fully recovered; that at first i went back a little, so that he thought he should have to atten again, but that it soon improved once more, and progressed t complete recovery. He said that he had never either smoke or chewed once since tobacco was forbidden at his first attend ance. He still takes "a little brandy." He is no longe "nervous."

This case is particularly interesting as showing the probabl negative effect of the treatment used, since nearly half of th patient's improvement occurred after he had left off all treat ment. The perfect recovery of sight with total abstinenc from tobacco is a result which Mr. Nettleship believes is th rule in cases which come under care in an early stage. Many o the patients who do not improve will be found, on investigatio to be still smoking more or less.

Case 2.—*Amblyopia in a Heavy Smoker, Temperate in Alcohol—Onset Slow and Degree Slight—Anxiety as a possible Exciting Cause—Recovery of nearly Perfect Sight in Four Month after ceasing to Smoke.*

Wm. W., aged fifty-three, mason, admitted November, 187 Had been anxious and troubled for the last fifteen month owing to his wife's death, but did not consider that his healt had failed. Habitually smoking half an ounce of shag a day drinks beer very moderately, and seldom touches spirits. Sigh failing slightly for twelve months, the defect being most ap parent in a bright light (? central scotoma). With his glasse he could, however, still read the newspaper; but his distan vision (unaided by glasses) was only 40 Snellen at fifteen fee There was no hypermetropia. Optic discs definitely pale a their temporal portion; no other changes.

He left off smoking entirely. No improvement took plac for several months; but in March, 1876 (four months afte admission), he considered his sight better, reading (withou glasses) 8 Jäger, and nearly 20 Snellen at twenty feet, whil with + 11 glasses he almost read 1 Jäger ("brilliant"). H had quite left off smoking. He took only a little compoun tincture of lavender. Not seen him since April, 1876.

Case 3.—*Amblyopia, with Slight and not quite Symmetric Changes in the Discs, in a Man Smoking and Drinking Excess—Perfect Recovery under great Diminution of Tobac and more Moderate Use of Alcohol—Premature Senility.*

Geo. L., aged thirty-six, formerly a sailor, now a sorter i the Post-office, admitted in March, 1874, for recent failure o sight. Vision = 8 Jäger badly for a short time, and 20 Snellen at fifteen feet; not improved by any glasses. Opti discs—right slightly paler than left, and free from haze left somewhat dim at the margin, and redder than the right no other changes. Smoking half an ounce a day, and drink ing spirits freely. He attended only twice, and then becam a patient for twelve months under the care of Mr. Cowell a the Westminster Ophthalmic Hospital. He much diminishe his tobacco and drank less, and in about a year could se almost as well as ever.

April, 1877.—Patient comes at request. Is now smokin

om half an ounce to an ounce a week. He drinks, according his admission, Irish whisky to the extent of four to six unces a day, besides a pint of beer, but this is much less than e formerly took. Tongue furred, but not tremulous; appetite abitually bad; manner very excitable and irritable; is thin nd sallow, and looks ten years older than his years. Has lmost completely recovered his sight. Vision: Words of Jäger ("brilliant") and 30 Snellen at fifteen feet. Optic iscs show slight but definite pallor on their temporal sides, eing elsewhere healthy.

ase 4.—Amblyopia (Two Months) with Signs of Congestion or Slight Neuritis in an Intemperate Man who Smokes heavily—Perfect Recovery, Tobacco being almost given up, but Alcohol still taken in excess.

John G., aged forty-four, labourer, admitted September 25, 876. Sight failing steadily for two months. Lately had been eeping badly, but had had no other symptoms. Intemperate, nd smoking half an ounce a day. Married, and has four ildren. Vision: Makes out words of 14 or 12 Jäger and 200 nellen at twenty feet. Pupils active and of ordinary size. ptic discs rather too red; the left perhaps redder than the ght, and very slightly hazy, the haze extending into the tina. Retinal veins decidedly engorged, quite beaded in me cases. No other disease. Took nux vomica for five onths (till February, 1877), when he ceased attending.

May 7.—Attended at request. Vision = 1 Jäger slowly; etter with a low + glass; sees 20 Snellen at twenty feet. vidently still drinks heavily. Has very much diminished, ut not quite left off, smoking.

ase 5.—Amblyopia without Definite Changes in a Man Smoking largely and Drinking Spirits—Duration Three Months—Rapid Improvement after leaving off Tobacco.

Mr. H., aged fifty, an agent in the leather trade, smoking at ast half an ounce of birdseye daily, and drinking about ten r twelve ounces of gin daily, was sent to Mr. Nettleship by Ir. Starling, of Higham Ferrers, in April, 1876. His manner as nervous and rather fidgetty, but the tongue not tremulous. Ie had lately been under treatment for dyspeptic symptoms nd "biliousness," and had, on medical advice, left off beer, hich he had formerly taken, as well as gin. Appetite and eep good. Quantity of tobacco not increased of late. Sight ad been failing symmetrically for three months. Had had no ause for anxiety, and was quickly getting worse. Probable yphilis thirteen years ago. Vision alike in the two eyes; 14 äger barely, and 30 Snellen at ten feet. With his spectacles + 24) managed to read 10 Jäger for a short time. Optic iscs showed no definite changes—there was perhaps a slight ist over them and the surrounding retina. At extreme peri-hery of the fundus of each eye some patches of old choroidal isease.

Six weeks later, he having left off smoking, he had improved o much that with his glasses he read 6 Jäger easily, and ould make out No. 4. He was drinking less, but still took a ood deal.

ase 6.—Rapid Onset of Amblyopia, with Central Scotoma, in a Myopic Smoker and Spirit Drinker—Nervous Temperament—Intolerance of Tobacco—Recovery of nearly Perfect Vision.

C. W., aged forty-seven, a law-writer, came in November, 876, when his sight had been failing for four or five weeks. Ie was very nervous, and habitually drank spirits "to steady is hand." He would not admit that he consumed a large uantity of spirits, and said that he smoked only one ounce of obacco a week; he could not smoke more because it made im so nervous. Vision = 16 Jäger with each eye. Pupils mewhat sluggish. "The middle of each word is wanting." o other defect of field. Ophthalmoscopic examination showed high degree of myopia, with a crescent in each; media clear. o other changes.

He was told to leave off tobacco entirely, and some nux omica was prescribed. Two months later he had improved o much that he could make out 4 Jäger at 6 inches.

ase 7.—Gradually increasing Amblyopia (Six Months)—Slight but Definite Disc Changes—Patient a Smoker and Heavy Drinker, but not easily Intoxicated—Improvement.

H. A., aged forty-eight, a tanner, was admitted on April 19, 873, complaining that his sight had been failing gradually or about six months. The failure had been equal in the two yes. He had dark brown hair and grey irides. He considered imself in his usual good health, and had had no failure of ppetite. The pupils of ordinary size. Sight was equal in the two eyes. He could barely make out letters of 19 Jäger, and could not see 200 Snellen at twenty feet. The ophthalmoscopic inspection (after use of atropine) showed slight pallor of the yellow-spot third of each optic disc, the remaining portion being either healthy or perhaps slightly too red. There was no swelling of the discs, but there was slight notching of choroid on the yellow-spot side of the right disc, as if caused by some degree of former swelling of the nerve at this part. The retinal vessels and remainder of fundus healthy. No colour-blindness. He said that previous to the failure his sight had been excellent. He had been in the habit of smoking a quarter of a pound of shag weekly almost since boyhood, and he said that smoking more than usual never disagreed with him. He had been at sea, and was sometimes sea-sick. He was a heavy drinker, consuming from four to eight quarts of ale daily, and spirits also not unfrequently. He was a "strong-headed" man, and could take much liquor without being drunk.

He was ordered to leave off smoking entirely, and to diminish his drink; tincture of nux vomica in ten-minim doses thrice daily prescribed. He attended regularly till the middle of January, 1874 (*i.e.*, for nine months), at which time his sight had improved enough to enable him to see the time on the church clocks, which he could not do on admission (his own statements), and to read 16 Jäger with difficulty. He appears to have been satisfied with this amount of improvement, for he did not come again, and subsequent efforts to follow him up have not succeeded.

Case 8.—Slowly Progressive Amblyopia (Three Years) in a Smoker, arrested while still Smoking—Prolonged Anxiety as a Determining Cause—Great Defect of Sight, with Pallor of Optic Discs.

W. K., aged fifty, bootmaker, admitted in January, 1876, complaining that for three years past he had been unable to find suitable spectacles. The sight had failed gradually, but he believed that it had remained stationary for about the six months prior to admission. For thirty years had smoked about four ounces weekly ("shag" and "returns"), and has never found it disagree. Drinks three pints of beer a day; scarcely ever touches spirits. Not liable to sea-sickness; no indigestion. For some time before the sight began to fail had had much anxiety from the prolonged illness of his wife, which ended in her death nine months before his admission; did not admit, however, that his sleep was much interfered with. No failure of sexual desire. Vision, without glasses, each eye = 18 Jäger, and not 200 Snellen at twenty feet. Pupils active; the left rather larger than the right. Is using strong glasses (+ 5), but they are of little service. Optic discs definitely pale all over, but much more so on the yellow-spot side; retinal vessels natural. No other changes, unless a slight mistiness of the retina around the disc. He came only twice, and I have not been able to find him.

In this case it is to be noted as of much interest that, according to the patient's belief, the decrease of sight had stopped while he was still smoking his accustomed quantity; and that this occurred soon after his wife's death put an end to the anxiety which had troubled him during her three or four years' illness. He was a well-made, healthy-looking, robust man.

Case 9.—Progressive Failure of Sight (Ten Months) in a Heavy Smoker who also Drinks to excess—Other Symptoms referable to the Nervous System—Tobacco not given up—Sight deteriorating slightly while under care—Former Sexual Excesses—Discs Congested (?).

H. V., aged fifty, a baker, admitted in May, 1876. Sight failing steadily for ten or twelve months. Smokes half an ounce a day, and drinks a moderate quantity of stout, but denies taking spirits. Is nervous; for eighteen months has been liable to "curious feelings in the head," "pricking all over the top of the head," and to startings of his limbs during sleep, so that his arm sometimes hits him on the nose; he is also troubled by dreams, and he calls out in his sleep. Vision: Right, 16 Jäger barely, + 16 = 50 Snellen at twenty feet; left, 18 Jäger barely, and scarcely 200 Snellen at twenty feet, + 24 = 70 Snellen at 20 feet.

Ophthalmoscopic examination almost negative. The discs, perhaps, slightly too red, and surrounding retina showing a faint degree of haze; no other changes. To leave off tobacco, and take a bitter mixture. Married at seventeen, and in early life had indulged his sexual appetite very freely, but without causing any diminution of power. He left off smoking, but instead took to chewing about a quarter of an ounce a week, still taking his full quantity (about four pints) of beer. Five months after admission, sight decidedly worse; = only 20

Jäger, and not 200 Snellen at twenty feet. Nervous; appetite bad, and tongue furred and tremulous. Is probably drinking more than he admits; chews a little, as stated. Discs now decidedly pale and quite clear; the pallor greatest on the temporal side of each. To leave off tobacco entirely, and to drink less, especially at night.

A month later (November 7) sight was, if anything, rather better (19 Jäger, raised by + 9 to 14 Jäger). Has not been seen since.

Case 10.—*Amblyopia of Six Weeks' Duration in a Heavy Smoker—Note of Condition six months after Admission.*

John H., aged sixty-six, an ostler, admitted in November, 1876, complaining that for the last six weeks he had been unable to see so well as he used, the failure being alike in the two eyes, and unaccompanied by any pain or other symptoms. Vision equal to 16 Jäger; not improved by glasses. Smokes half an ounce a day. Notes of ophthalmoscopic examination are wanting.

April, 1877.—Writes that his sight is "no worse," but "about the same." As, however, he had never learned to read, and had no need for very good sight, he may have improved more than the above statement would indicate.

Case 11.—*Slowly Progressive Amblyopia (Eight Months) in a Man Smoking heavily and drinking Spirits freely—Tremor from Alcohol, but Health in all other respects considered Excellent—Appetite Unaltered—Slight Pallor of Discs, not quite Symmetrical.*

George P., aged fifty-two, a hatter, admitted in July, 1876. A robust, florid, sandy-haired man of large build; intelligent, but very excitable. Gradual failure of sight eight months, and still progressing. Has had no headache, and will not admit any symptom excepting the failure of sight. Smokes half an ounce of "black Cavendish" daily. For the last two years has lived in Glasgow and drunk whisky freely, and, in particular, has got into the habit of taking his dram before breakfast. His tongue is tremulous; he knows he is nervous, and attributes it to the whisky, not to the tobacco. Appetite has, however, never failed, and he has throughout been able to eat a hearty Scotch breakfast. Since returning to London (a few days before admission) he has taken less spirits, and is already less nervous than he has been. Married; sleeps well; is in excellent spirits. Vision (with his glasses) in each eye equals 16 Jäger and 200 Snellen at twenty feet without glasses. Pupils of normal size, and fairly active. Optic discs slightly pale all over, but more so on the yellow-spot side. After careful and repeated examination by two observers, it was thought certain that the right was paler than the left. No other changes. Remained under care only six weeks, and did not alter as to vision in that time.

Case 12.—*Amblyopia of Three Months' Duration in a Smoker—Central Scotoma—Discs Pale on Temporal Side.*

Wm. E., aged fifty-two, smith, a smoker, admitted July, 1875, complaining of failure of sight for three months, and in particular that "things looked black" (probably central scotoma). Sight did not vary on different days. Vision—right, letters of 18 Jäger and 50 Snellen barely at twenty feet; left, letters of 16 Jäger and 50 Snellen well at twenty feet. Pupils active. Tension normal. Slight hypermetropia, but sight not improved by glasses. Optic discs pale at the temporal portion; no other changes. The physiological cup very large in each, and in one eye spontaneous pulsation of the vein. Attended only once, and could not be traced.

Case 13.—*Amaurosis with very Pale Discs in a very Excessive Smoker who drinks but little.*

John W., aged fifty-two, varnish maker; nervous, and tongue tremulous; appetite bad. Both eyes failing alike for three to four months (? longer). Admitted in July, 1875. Vision of each eye = 20 Jäger; cannot see 200 Snellen at twenty feet. Glasses do not improve. Optic discs pale all over, the pallor being nearly uniform. Slight doubtful mistiness of surrounding retina. Retinal vessels normal, or perhaps slightly diminished. The appearances are those of an advanced tobacco amblyopia. Has smoked very heavily for thirty or forty years. Until six months ago he smoked three-quarters of a pound of shag a week, but (though he denies that it disagreed with him) about six months ago he reduced the quantity to three ounces. Has always been very moderate in his use of alcohol. Was once at sea, and not sea-sick. Attended only once, and could not be traced.

Case 14.—*Progressive Amaurosis, at first with very Slight Changes, afterwards with well-marked Atrophy of Discs, but with some Improvement of Sight—Patient an Intemperate, Unhealthy Man, Smoking largely, and not ceasing to Smoke for several months after Failure of Sight began—Final Ophthalmoscopic Changes not quite Symmetrical.*

James O., aged fifty-six, a bottle-nosed man of heavy aspect, looking half-asleep, and drinking heavily, admitted February 3, 1875, sight having failed for three months past. For the last thirty years he had smoked from a quarter to half an ounce a day. Vision: Cannot read 20 Jäger, nor see 200 Snellen at twenty feet. Slight doubtful pallor of optic discs at the temporal portion, and appearance of slight haze of surrounding retina, but this is perhaps due to some loss of transparency of the lenses.

Patient diminished smoking, and after a time quite left it off, and lessened his drink. For nearly four months he also took tincture of nux vomica. His sight was tested at intervals, and remained almost exactly the same. Thus, in August (about nine months after failure began) he could still not see 200 Snellen at twenty feet, but could make out 20 Jäger. In January, 1876 (fourteen months), he could make out letters of 19 Jäger, and was still, according to his statement, not smoking at all. At this date the discs were very pale, uniformly so all over, their edges clean and regular, and the retinal vessels not materially changed. Manner still nervous and hesitating, but health in other respects considered to be good.

April, 1877 (two years and a half after failure began).—Patient considers his sight a good deal better, but on trial it does not show much improvement. Reads 20 Jäger, but not 19; with his glasses can read 16. Discs about as at last note. The pallor is, however, rather more marked on the temporal side. In the right it has a greyish colour, and the arteries in this eye are notably diminished, being less than half the diameter of the veins, and bordered by white lines. In the left they are not diminished at all, and no white lines are visible, though the disc is not different in colour or appearance from the right. The haze of the lenses has increased, and accurate inspection of the region of the yellow spot is impossible, but so far as can be seen there is no disease there nor in any other part of the fundus excepting at the discs. The vitreous showed no disease. Pupils active, but rather large. Patient looks more healthy and less bloated, and is not nervous, though his drooping lids give him still a sleepy look. Smokes a pipe occasionally. Takes a little beer, but seldom any spirits. Subject to chronic articular rheumatism. No evidence of any disease of nervous system (particular inquiry having been made in this direction). He has never, to his knowledge, had any venereal disease. Still virile; has brought up a large family.

In this case the progressive opacity of the lenses has to some extent counteracted the improvement of vision.

The Medical Entrance Exhibitions at University College, of £30, £20, and £10 per annum, tenable for two years, have been respectively awarded to Mr. W. H. Evans, Mr. P. F. Moline, and Mr. F. de C. Skeete.

The Paris Faculty of Medicine.—The following is the programme of the courses of lectures to be delivered, each three times a week, during the session 1877-78, commencing November 5:—*Medical Physics.*—Prof. Gavarret: General physics, electricity, acoustics, meteorology, biological physics, and the phenomena of vision. *Medical Pathology.*—Prof. Jaccoud: On infectious diseases and on constitutional diseases. *Anatomy.*—Prof. Sappey: The apparatus of digestion, respiration, and generation. *General Pathology and Therapeutics.*—Prof. Chauffard: General pathology, continuation of the study of the common morbid elements, general therapeutics. *Medical Chemistry.*—Prof. Wurtz: Medical chemistry and biological chemistry, the chemical phenomena of digestion. *Surgical Pathology.*—Prof. Trélat: Hernia and diseases of the genito-urinary organs. *Operations and Apparatus.*—Prof. Léon le Fort: General operations; the therapeutics of diseases of the vessels, and of the bones and joints. *Histology.*—Assistant Prof. Cadiat, as substitute for Prof. Robin: The tissues and organic systems. *History of Medicine and Surgery.*—Prof. Parrot: History of some of the epidemic diseases, variola and vaccination, and rubeola. *Clinical Medicine* daily, by Profs. Sée, Laségue, Hardy, and Potain. *Clinic of Mental Diseases* daily, by Prof. Ball. *Clinical Surgery* daily, by Profs. Gosselin, Richet, Broca, and Verneuil. *Obstetrical Clinic* daily, by Prof. Depaul.

SATURDAY, OCTOBER 20, 1877.

THE PENGE INQUIRY.

We are not yet at the end of this painful, and from some points of view revolting case, but at all events it has passed beyond the region which specially concerns us. The calm voice of reason has been heard, and has silenced the voice of insensate prejudice and an overbearing moralism. The four convicts have been respited, and what should have been done by judge and jury has been done by the best Home Minister we have had for many a day.

In briefly recapitulating the ugly story which has given rise to such commotion, let us deal with bare and simple facts, and equally simple inferences. In the first place, we have a woman, no longer in the springtime of life, singularly unenticing in mind and body, but with some actual property and more in expectation, made love to, and ultimately married, by an auctioneer's clerk much younger than herself. The brother of this young man, also poor—for the two allowed their father to die in the hospital,—is an artist, and goes to reside in an out-of-the-way spot in Kent. Visits follow, and ultimately the auctioneer's clerk takes a farm not far from the painter's house, but instead of taking his wife there, he takes his sister-in-law, who passes as his wife. An agreement had been come to that the real wife was to live with the brother; and it is quite clear that, of necessity, this woman, never very strong in intellect, but disagreeable in many ways, had to be kept out of sight. By degrees, let us say, matters took another shape. The mental characteristics of this woman would not improve by the confinement and, possibly, ill-treatment; probably they would become more marked than before. Carelessness as to her bodily condition soon became callousness and indifference, and the minds of all the four convicts must have become still more disturbed when the condition of Alice Rhodes became manifest. That there might be a desire on the part of these four to get rid of Harriet Staunton, would have been perfectly natural; that this desire ever went further than carelessness and negligence there is no proof, for the evidence of the girl Clara Brown is not worth the paper it was written on; if it was true, she was one of the most guilty of them all. But let that pass. On a certain day the four got alarmed, scandal had to be avoided if possible, and the condition of Harriet Staunton had become alarming. What was to be done? The calling in of a medical practitioner in the country would have been sure to have given rise to talk and observation; this all of them desired to avoid. They were frightened at the extent and result of their own negligence; they determined to remove the dying woman. This was done, and they immediately sought medical aid; but it was too late—Harriet Staunton died. A certificate as to the cause of death had been granted—as valuable as the majority of such certificates so given are,—and the funeral would have taken place. Here intervenes a curious chapter of coincidences, which it is not our place to narrate; but in the end the fact that a certificate of the death of Harriet Staunton had been lodged with the Registrar reached the ears of her relations. This we understand was purely accidental; had the death been registered in any other name than that of Staunton, nothing could have been found out. This shows to our mind that, whilst wishing much, and doing little, no actual design or conspiracy had entered the minds of the culprits. If it had they would not have given real names.

Now comes the part of the story in which our professional brethren play a sorry part. We have a medical gentleman called in, doing what he could, leaving his patient in a dying condition, and going off to a concert. Calls for aid at his home are unattended to. A certificate of the cause of death is, however, given just as wanted, but is withdrawn, not because the pathological conditions required it, but because the writer had heard something from the relatives of the deceased. Blunder number one.

The coroner is written to, and orders an inquest to be conducted—by whom? The man who, on his showing, had made a gross mistake. Blunder number two.

The practitioner so appointed summons to his aid, not a man well skilled in post-mortem examinations—one who knows what is disease and what is not—but a band of brother practitioners who, without the slightest disparagement, may be said to be utterly unskilled in such matters. Blunder number three.

The post-mortem examination is made; the notes are taken anyhow, apparently registered in a book that is subsequently lost. The notes should have been duly taken step by step, and signed as matters of fact by each man present. Blunder number four.

The glorious privilege of blundering according to law here ceases to be the special prerogative of our professional brethren, if we except that extraordinary sitting when a certain number of those present at the post-mortem examination decided among themselves that Harriet Staunton had died of starvation, entirely overlooking the clinical facts and post-mortem conditions. We do not count this a blunder; it was an outcome of one of the others.

Next come the lawyers. Here in counting blunders we are fain to stop. On either side they seem to have been committed right and left. We shall pass at once to the trial. It is not often that a man, especially after a certain period of life, has the courage to say, "I was wrong." Yet such has been the case with Mr. Justice Hawkins. Neither is it always given to us to see in actual print the utter imbecility of a jury such as that which tried these four wretched people. With a fullness of faith, which is both wide and deep, in the stupidity of a select British jury (we expressly exclude Welsh and Sussex juries), it was a matter of surprise to us to find one of this famous jury writing to the newspapers and telling the public that, had the jury had time to sleep on it, they would have

returned a different verdict. This is shameful! Men met to judge of the guilt or innocence of four people, men and women where life and death are in the balance, to decide without that deliberation which is decent in the case of one accused of stealing sixpence! Had, as we hold, judge and jury done their duty, this most mischievous agitation would never have taken place; for it is most mischievous, and the effects of it are not likely soon to pass away. Putting morality or immorality out of sight altogether, it is quite plain that Harriet Staunton was ill-treated or improperly treated. It is not well that people guilty of criminal neglect—to call it by its slightest name—should become objects of popular sympathy. Yet such has been the result here. The verdict "Guilty of murder," and the inevitable sentence—death—sent a thrill of horror through the country. Had the verdict been "manslaughter," and the sentence as severe as the judge liked, provided it was duly graduated to each case, not a voice would have been raised, no sound would have been heard of the maladministration of justice. What has taken place we all know—the lives of the convicts are spared. The rest we may now safely leave in Mr. Cross's hands.

SCOTCH GROCERS' LICENCES.

As the attention of the medical profession has been drawn to the evils of the system of granting licences to grocers for the sale of intoxicating liquors, it is only fair to listen to what the parties concerned are able to advance in their own defence. The evidence submitted to the Commission on grocers' licences, which is now sitting, affords us the opportunity of showing that grocers not only have theories upon the subject, but that they can express them in striking language, and with perfect confidence. In the examination of the representative of an association of licensed grocers in Galashiels, the views of that association were tersely and humorously propounded by one who had been nearly thirty years "in the trade." This gentleman stated, to begin with, that the agitation against the licences under consideration had been initiated by licensed publicans, who hoped to benefit by the suppression of the system, and went on to say that the persecution of the grocers had not made much progress till the Edinburgh agent of the licensed victuallers made the wonderful discovery that it was only the liquor sold at the grocers' that made people drunk. When proceeding to say that the paid agent of the Permissive Bill Society had seriously adopted and promulgated this notion, the witness was told that there was no evidence to that effect; but the ready Scotchman at once replied that that was very likely, as all the evidence had been given on the other side! When questioned about the danger of selling small quantities of stimulants, and the advisability of grocers confining their sales to spirits in sealed bottles, he remarked, with some show of reason, that if it was an evil for a man to buy one glass of whisky, it must be a greater evil to make him buy a bottle, and expressed his fear that it would lead to great abuses were men compelled to buy more liquor than they wanted. The experience of the witness seems to have brought him into contact with people who, like the drouthy Highlander, think it unreasonable in anyone to expect that they could sleep "and whisky in the house." The Galashiels representative is anxious to protect the female customers of his clients from the charge of solitary drinking, and says that whisky is mostly sent for in the evening, which he thinks shows that the husbands of female purchasers are at home when it is consumed. Although this cannot be regarded as absolute proof, yet a knowledge of the Scotch character would lead one to think that if a woman's husband were not at home when she sent for whisky, he would certainly be at home as soon as he found out that she had done so. This representative grocer holds another opinion which is not altogether without foundation in fact. He believes that the more intelligent men become, the greater will be the consumption of liquor; and he propounds the wonderful theory that old whisky is a cure for drunkenness! How this pleasant method of cure is carried out, the newspaper report does not fully explain. Probably it consists in the consumer waiting patiently and abstemiously till the spirits and he have both reached a ripe old age. It cannot be that one glass of old whisky is supposed to counteract the effects of three or four glasses of the less mellow material, which "grips" the mouth, and which the witness describes by the expressive name of "Speil the wa'," or "Kill the carter" whisky. The American, who discovered that the best thing to remove the smell of whisky from the breath was a glass of rum, will be glad to hear of the great therapeutic value of old spirits in the treatment of drunkenness.

Notwithstanding this humorous merchant's defence of grocers' licences, there can be no doubt, on perusing the evidence laid before the Commission, that the system is liable to dangerous abuses. The Clerk of the Peace for the County of Edinburgh stated that cases had come under his official notice in which liquor obtained from grocers was entered as other articles to deceive those whose money was being spent. Only the previous Monday a case had occurred in which a woman stated that part of what was entered in her book as bread, butter, ham, etc., should have been whisky, which she and the merchant drank together.

A Scotch farmer when he first tasted spring rhubarb thought it would be a long time before it would be a substitute for potatoes; and the Scotch working-classes seem to have made up their minds that neither coffee nor Gladstone claret will take the place of whisky. The chairman said that the former was unpopular because the lower classes could not prepare it properly; and a witness affirmed that if Gladstone claret was not intoxicating it caused a craving for stronger drinks. To this remark the chairman gave a certain amount of countenance by stating that he knew a place in Glasgow where one could get a pie and a glass of claret for 8d., but a glass of brandy was an absolute and urgent necessity as a corrective. If the evidence placed before the Commission on Grocers' Licences is continued as it has been begun, it will develope into a blue-book replete not only with instruction, but with humour.

PHILANTHROPY IN WAR.

Our daily papers are once more brimming over with appeals to the benevolent in aid of the sick and wounded in war, and letters from private individuals, who, either as the result of accident or curiosity, are near and about the theatre of war, contain accounts of death and starvation which explain, even if they fail to justify, these appeals, and recommend them to the material sympathy of those who can afford to listen to them. After a most careful consideration of this subject, we cannot fail to see, however, that there are at least two sides to the unbounded "philanthropy in war" which this country has inaugurated within the last few years. However willingly we admit that suffering and sickness ought to be adequately relieved whenever and wherever we meet with it, we must, nevertheless, insist on the necessity of guarding most carefully against that arbitrary charity which would send help to one side alone. The moment it is conceded that a nation is to be helped to look after its wounded in war, we shall directly put a premium on the maladministration of the medical department of that nation's army. Of course the proper and adequate administration of what we may now call the "Red Cross Service" of a nation is no small matter in countries like Germany, France, Russia, or Turkey; and when nations deliberately set themselves to war they must adequately equip this medical department. We ask the question, Have the actual combatants done so? and we are obliged to answer it with an emphatic No. Under such cir-

cumstances, in sending medical help and stores, we are directly aiding and abetting the combatants, perhaps one more than another, while, as a nation, we are observing a so-called strict neutrality.

It is much to be regretted that there should be so many different funds in aid of either of the combatant armies. On looking over the daily papers, we find at least four separate subscription lists, and we should gather that three out of the four are intended for the Turkish side alone. We trust that those who go out to administer this kind of charity fully understand that they cannot claim the protection of the Geneva Convention. The National Aid Society, which did good work in the Franco-German war, and is, so far as we know, the only society acknowledged by the Convention, is now appealing for funds: and with what wretchedly poor results compared with its success formerly! Is this altered response from the British public an expression of want of confidence in those who administered the Society in 1870? We should fear it is. It is well known that a surplus of £70,000 remained over after the Franco-German war came to a close; this was invested in the names of trustees, and the interest which accrued from capital would no doubt go to greatly increase it. We ask—What has become of all this, and how is it that Colonel Loyd-Lindsay had again to appeal for help to send out a steamer to the Black Sea? Surely with such funds, and with a vessel placed at his disposal, we believe, by the Government, he need scarcely have applied for more money! We do not wonder that the response to his appeal was coldly received—for never did management of a charitable fund seem so utterly weak as in this case.

This money was subscribed for a definite purpose; why was it not utilised? The Franco-Prussian war came to an end truly, but its horrors continued to be felt for long after, and many of the wounded were utterly unable to do anything for months, and had therefore, we venture to believe, a claim on the funds which were subscribed for their benefit. Then, again, the Servian war broke out, and the Society, after a period of painful indecision, sent out a few surgeons just before the war came to a close. Judging from the telegraphic despatches of the war correspondents of the various daily papers, the whole expedition was characterised by the same want of method and of organisation as obtained during the Franco-German War. Those who are especially interested in this need only consult a telegraphic dispatch which appeared in the *Daily News* of September 13 of last year. We believe that the English hospital in Belgrade, which was started under the auspices of the National Society, was given up long before the wounded were all in a fit state to be discharged, and had it not been for the personal generosity of Dr. Attwood, its chief surgeon, many wounded would have had to die for want of the help which our National Aid Society would no longer bestow, although they were in possession of large sums of money, which had been subscribed for the "sick and wounded in war." All honour to Dr. Attwood! The Servian war came to a close, and we ask, What has the Society done since? Nothing, to the best of our knowledge. And that, too, although war had confidently been looked forward to all through the past winter. The want of organisation was so startling, even to this torpid Society, that at the close of the Franco-German War a list of questions was sent round to the members of the Society asking for information and opinions as to what ought to be done, so as to be ready for any future campaign. Now, although in many points there was great unanimity, not a single step was taken, and the outbreak of the Servian war found the National Aid Society as little organised and as unprepared as when it came into existence five years ago; and it is no better at this present moment. This want of activity and want of organisation have, indeed, at last aroused public attention, and a letter, powerfully signed, and headed by such men as the Duke of Westminster and Sir Henry Havelock, was, early in August, addressed to the Society, praying (1) That, with a view to prevent any misapprehension as to the impartiality of the operations of the Society, it is desirable that an equal number of ambulances should be sent direct on the one side to the Russian and Montenegrin armies, and on the other to the Turkish Army. (2.) That certain matters connected with the constitution of the Society and Council should be considered.

If we were ourselves to become involved in war, what would be the result of this inactivity? what account would the trustees be able to give of their stewardship? Would they be able to satisfy the nation if our own soldiers were dying on the battle-field for the want of help—which, to be of service, must be timely? Would they again be able to appeal to the country for funds and volunteer help; and, if they did appeal, would the country respond as it did in 1870, even though their help then was for the foreigner? We sincerely hope there will not be need for such appeal. But, at the same time, we do counsel the National Aid Society to be up and doing. We ask them, for the honour of our country, to throw off the mantle of idleness, and to set about a regular organisation of the volunteers, medical and otherwise, who would flock to their standard were an appeal but made. Let them take an example from Russia or Germany; organise and prepare fully equipped and drilled ambulance-trains, with wounded-bearers, nurses, etc.; and place themselves, as was intended, we believe, by the rules of the Geneva Convention, in alliance with the Army Medical Service. We know not how soon, or how suddenly, we may ourselves need their help; but when, if ever, that need does arise, it will be too late to begin to get ready to meet it.

THE WEEK.

TOPICS OF THE DAY.

It is very well known that not a few of our public buildings are, from a sanitary point of view, marked examples of what should not, rather than of what should be. Still, it is startling to read the following account of a metropolitan police-court:—Last week, Dr. Bateson, the Medical Officer of St. George's Vestry, Southwark, attended at the Southwark Police-court to support a summons obtained by the sanitary inspector, and before entering upon the case he complained of the filthy and unhealthy condition of the public entrance to the police-court. He stated that on passing the outer door he found a large room crowded by a number of rough-looking people, who pressed against a closed door leading to the ante-room of the court. He found the place in a terribly filthy condition. The effluvium was dreadful, and quite sufficient to breed typhus fever of the blackest kind. The people in the room were very dirty, and there was no officer to keep them in order. In fact, he and the sanitary inspector had the greatest difficulty in obtaining an entrance into the court. What he particularly wished to call attention to was the entrance-hall. There was no ventilator, nor anything to let off the filthy smells; there were two small windows, but they were kept closed on account of their overlooking the yard where the prisoners were brought in. He wondered that a malignant fever had not already broken out, and he was positive that unless the place was cleaned and properly ventilated, fever would be generated in the neighbourhood. Mr. Benson, in reply, said that the attention of himself and colleague had been called to the state of the entrance, and they had reported the circumstance to the Board of Works. He was obliged to Dr. Bateson for his remarks, and he trusted they would have the effect of removing the evil complained of.

A case of some interest to the profession was heard before Mr Justice Lopes, the Vacation Judge, last week, in which

Dr. March, practising at Wandsworth, sought for an injunction to restrain his assistant from attending patients in the neighbourhood. The agreement between the parties was determinable by a month's notice, and contained a provision that on the termination thereof the defendant "should not at any time practise the business or profession of a surgeon, or doctor of medicine, or apothecary, within three miles of the plaintiff's residence." On July 17 last the agreement was terminated by the plaintiff giving the defendant a month's pay in lieu of notice. Since that date it was alleged that the defendant had been going round to the plaintiff's patients stating that he was going to set up in business for himself within half a mile of the plaintiff, and further that he had actually attended some of these patients and given them medicines. The defendant, a Mr. Farraut, who is not a qualified medical practitioner, denied that he had acted as a surgeon or apothecary, and stated that he only intended to attend midwifery cases, which were outside the agreement. Mr. Justice Lopes was clearly of opinion that the plaintiff had proved sufficient to entitle him to an injunction.

It is stated that the Southern Committee of the Church of England Temperance Society have turned their attention to the production of a substitute for alcoholic liquors in the shape of a superior class of temperance drinks, and although they are unable officially to undertake the work, the result has been the creation of a "National Temperance Beverage Company (Limited),"—a small private company that has purchased "Larmuth's patents," and will shortly introduce these new beverages. This is following out some of the suggestions offered by Mr. Walter in his speech at Reading; but, although a step in the right direction, we fear that the beverages will have a hard time in opposition to the attractions of gin and beer.

A statement has been issued by the Metropolitan Asylums Board, illustrating the amount of work and responsibility thrown upon them by the recent epidemic of small-pox. The total number of small-pox patients received into the Asylum hospitals during the year ending the first week of October was 7333. Lambeth contributed the highest number—808; Hackney, 733; City of London, 90; Fulham, 73; Greenwich, 125; Holborn, 249; Lewisham, 31; Mile-end, 206; Poplar, 403; St. George's-in-the-East, 137; St. George's, Hanover-square, 157; Bloomsbury, 66; Camberwell, 386; Hampstead, 73; Shoreditch, 151; Chelsea, 148; Islington, 396; Kensington, 287; Bethnal-green, 260; Whitechapel, 169; Woolwich, 35; Strand, 38; Westminster, 56; Wandsworth and Clapham, 384; St. Saviour's, 556; St. Olave's, Bermondsey, 298; Marylebone, 270; Stepney, 219; St. Pancras, 381; and Paddington, 148. The return does not give the number of fatal cases.

A correspondent writing to the *Times* from Spain reports that for some months past small-pox has been ravaging several districts in the South-east of the Peninsula. Before and when it reached Calasparra—a small town of less than 1300 inhabitants,—the resident doctor did his best to convince the alcalde that vaccination ought to be encouraged. The alcalde, however, unfortunately "kept his mind open on the subject," and the doctor's advice was disregarded. From June to October, therefore, in a population of less than 1300, there had been between 400 and 500 cases, with 100 deaths, and of the few who could be persuaded to be vaccinated not one had died—one more argument, were any needed, of the protective influence of vaccination.

The further report of the water analyst of the *Sanitary Record* shows that the water-supply of Blackpool is not satisfactory; it was found to contain an excessive proportion of bacteria, and to be very imperfectly, if at all, filtered. Lytham, another favourite watering-place, is only supplied with a low second-rate sample of water. The large and rising town of Southport has a supply of good second-class water. New Brighton, on the other hand, is fortunate in possessing good and wholesome water. Coming to Wales, we find that Rhyl is supplied with bad second-class water, containing mud, decomposing vegetable matter, and having a decidedly unpleasant taste and smell. The public water-supply of Abergele is fairly satisfactory, but the water of a well used by some of the inhabitants is characterised as sewage only. It is the old story that the people drink this well-water because they think it nicer than the public supply. The water-supply of Llandudno, the most fashionable seaside resort in Wales, is not good at the present time, but arrangements are in progress which, it is to be hoped, will render it worthy of higher commendation.

The *Whitehall Review* states that it is the intention of the Home Office to make some reforms in the Metropolitan Police Force. This step is considered to be absolutely necessary in consequence of several cases that have lately happened of individuals being taken into custody upon charges of drunkenness, when they have been suffering from some illness which had the appearance of intoxication, but which, in reality, was nothing of the kind. It seems that the sergeants of the police force are at present too few in number; and that constables, who have no experience in the matter, and many of whom are new to London life, often exercise more zeal than discretion in locking up persons who ought to be submitted to the care of a doctor rather than to the custody of a police inspector. A thorough reform in the structure and size of the police-courts and the prisoners' cells, has also been determined upon. Improvements of this nature have long been called for, and the sooner they are begun and completed the better.

We are glad to hear that the War Office has at length decided to sanction the formation of a Volunteer Sick-Bearers' Association. The members of the Order of St. John of Jerusalem are according the new Association their valable aid. The members of the Association are providing themselves with the Kips cartouch (the invention of a Belgian), which contains, in a very handy form, lint, thread, pins, needles, and other requisites for attendance on the wounded. Application has also been made for the use, for purposes of ambulance practice, of the riding-schools at the Knightsbridge and the Albany Barracks.

A large and influential meeting was held at Bury last week for the purpose of bringing under the immediate attention of the principal inhabitants of that town, and of West Suffolk, the Suffolk County Medical Club. Sir E. Kerrison presided, and explained the aims that the promoters of the Club have in view, which, he said, were to make the labouring population of the county as independent as possible in case of sickness. The Duke of Grafton moved, with much willingness—"That the Suffolk County Medical Club, as proposed by the chairman, is deserving of the support of all classes throughout this county." Dr. W. A. Elliston, as a member of the medical staff of the East Suffolk Hospital, said the proposed Club would remove the stigma attaching to hospitals of giving gratuitous advice to those who could well afford to pay for it. This was a general grievance. Arrangements for the formation of the Club were submitted and agreed to, and the meeting ended with the usual formalities.

Another case under the recent Rivers' Pollution Act will be heard in the St. Albans County Court on the 26th inst. At a special meeting of the Town Council held last week, the clerk announced that the Corporation had been served with a summons, taken out by Mr. C. Woollam, of the Abbey Silk Mills, for allowing three sewers to drain into the river Ver. The Council immediately resolved itself into committee, and, after a long discussion, the Town Clerk was instructed to defend the action.

It is at length announced that Mr. Thomas Annandale, who was assistant to the late Professor Syme, has been appointed to the Chair of Clinical Surgery in Edinburgh University, vacant by the removal of Mr. Lister to King's College, London. From a paragraph which appears in the *Scotsman* it would also appear that Professor John H. Balfour, M.D., has resigned the Deanship of the Medical Faculty in the Edinburgh University.

At a recent meeting of the managers of the Edinburgh Royal Infirmary, Dr. Brakenridge was appointed an ordinary Physician to that Infirmary; and at the same time Dr. Angus Macdonald received the appointment of Extra Physician for Diseases of Women, rendered vacant by the resignation of Dr. Matthews Duncan. By the nomination of Dr. Brakenridge, the appointment of an Assistant-Physician to the Infirmary becomes vacant, the election for which has been fixed for Monday next.

THE COMPULSORY REGISTRATION OF INFECTIOUS DISEASES.

THE "Bolton Improvement Act," which was considered by a Committee of the House of Commons during the month of April this year, and received the Royal Assent on August 2, contains the following provisions for the compulsory registration of infectious diseases:—"Section 87. In order to secure that due notice be given to the Corporation of any inmate of any building used for human habitation who is suffering from small-pox, cholera, or any contagious or infectious fever, the following provisions shall have effect—that is to say: (1.) If any such inmate be suffering from any such disease, as aforesaid the occupier or person having the management or control of such building shall, as soon as he shall become aware of the existence in any such inmate of any such disease, forthwith give notice to the Corporation at the Town Hall of the existence in such inmate of such disease. (2.) If such inmate be not a member of the family of such occupier or person, the head of the family (resident in such building) to which such inmate belongs, or if there be no such head, then such inmate (unless prevented by reason of such disease or of youth) shall, on becoming aware of the existence in such inmate, or in his own person, as the case may be, of such disease, forthwith give notice thereof to such occupier or person. (3.) The Corporation shall provide, and supply gratuitously to every registered medical practitioner resident or practising in the borough, forms for the certificate or declaration by such medical practitioner of the particulars hereinafter mentioned in relation to such case, according to the form set forth in the Fifth Schedule to this Act. (4.) Every medical practitioner attending on or called in to visit such inmate shall, on becoming aware that such inmate is suffering from any such disease as aforesaid, forthwith fill up, sign, and send to the Corporation at the Town Hall a certificate or declaration stating, according to the forms prescribed and supplied to him by the Corporation, the name of such inmate, the situation of such building, and the name of such occupier or person, and the nature of the disease from which such inmate is suffering. (5.) The Corporation shall pay to every medical practitioner who shall, in pursuance of this section, duly make and give any such certificate or declaration, a fee of 2s. 6d. for each such certificate or declaration. And any person who shall offend against this enactment (unless ignorant thereof, the burden of the proof of which shall be on him) shall for every such offence be liable to a penalty not exceeding £10." It may be still a question whether or not the attending medical practitioner ought to be compelled to himself give information of the occurrence of every case of infectious disease among his private patients; but it is highly satisfactory that the importance of early information of the existence of every case of such disease is recognised by the Legislature; and that the principle that medical men shall be paid for giving such information has also been recognised. We learn on excellent authority that this section of the Bolton Improvement Act was put in force a month ago, and appears to be well received by the profession; and that the Medical Officer of Health for the Borough believes that the advantages to be gained from it will be even greater than had been anticipated.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

THE first monthly meeting of the Northumberland and Durham Medical Society was held in the library of the Newcastle-on-Tyne Infirmary, on Thursday, October 11; Mr. Morgan, President, in the chair. Mr. Embleton, in the name of the Society, congratulated Mr. Morgan on his re-election as President. Mr. H. E. Armstrong, Medical Officer of Health for Newcastle-on-Tyne, presented a report of the cases admitted to the Newcastle-on-Tyne Fever Hospital from March to September, and stated that the town had been unusually healthy during the past summer. Dr. Luke Armstrong showed a specimen of varicose veins excised from the leg of a female under antiseptic precautions; the patient had done well. Mr. J. D. Dixon showed a remarkable specimen of hypertrophied clitoris which he had excised from a woman aged twenty-two years. Dr. Byrom Bramwell showed a specimen of occluded abdominal aorta. The aorta was completely obstructed below the origin of the inferior mesenteric. An aneurism the size of a hen's egg was situated above the point of obstruction, and was almost completely filled with clot, the outermost layers of which were continuous with the clot in the obstructed part of the vessel. The patient from whom the specimen was removed was shown to the Society on December 14, 1876, as a case of abdominal aneurism, with occlusion of the aorta and establishment of the collateral circulation. The case is one of great interest, and will shortly be published in full. Mr. Byrom Bramwell also exhibited a very large infarctus of kidney; it was from the same patient as the occluded aorta previously shown. Dr. Embleton showed a photograph of varicose veins. Dr. Gibson detailed the history of a case of empyema cured by free incision and drainage, and also of a fatal case treated in the same manner. He strongly advocated a free incision wherever pus was present within the pleural cavity. Mr. Morgan showed a patient, a large portion of whose anterior chest-wall was removed by injury. The injury was a very severe one: the skin, muscle, etc., from the clavicle to the ninth rib were torn away, and the pleural cavity extensively opened. The case did well. Mr. Morgan read a paper entitled "External Urethrotomy." He advocated Mr. Coulson's operation as improved by Dr. Farley, of New York, and detailed the histories of two cases in which that operation had been followed by remarkable success. Dr. Newcombe read a paper entitled "Antiseptic Precautions in Midwifery Practice." The author pointed out the frequent occurrence of death from puerperal fever, and advocated greater cleanliness and stricter antiseptic precautions in the treatment of midwifery cases. He believed that many cases of milk fever are due to septic causes. Dr. Page read the history of a case of large lympho-sarcoma successfully removed from the neck of a child. The tumour was of large size and very rapid growth. The incision extended from the scalp to two inches beyond the clavicle in one direction, and across the neck for three inches in the other. Large drainage-tubes were inserted, the operation being performed strictly on Lister's method. In ten days the drainage-tubes were removed, and in fourteen days the child was out of bed. Dr. G. H. Philipson reported a case of ovarian cancer, and alluded to the conflicting statements which are found in books as to the frequency of primary cancer of the ovaries.

THE UNIVERSITY OF LONDON AND MEDICAL WOMEN.

AT a meeting of the Annual Committee of Convocation of the University of London, held on the 12th inst., it was resolved

to request the Senate to grant an audience to a deputation from the Committee on the subject of the proposed admission of women to degrees in medicine, and a sub-committee was appointed for the purpose of conferring with the Senate. The Senate met on Wednesday, the 17th inst., for the first time since the extraordinary meeting of Convocation in July, and we understand that they have consented to receive the deputation from Convocation at their next meeting. We confidently anticipate the happiest results from the action of the Senate in thus readily acceding to the request of the Lower House. Our readers must be familiar with the various stages and phases of the unfortunate difficulty in the University arising out of the women's question. They will remember that the point reached before the autumn recess was a purely constitutional one. This is the first fact that must be laid courteously but firmly before the Senate by the deputation from Convocation. We trust that the Senate may acknowledge that the admission of women to degrees in medicine would affect the very constitution of the University, and on that account could not in justice be accomplished without the consent of Convocation. Secondly, the Senate must be persuaded to forego availing themselves further of an Act which has been confessed by Russell Gurney himself to be misleading, and which, by carelessness in its language, would admit women graduating under it to a seat in Convocation. The Senate cannot well refuse to listen to these two arguments, urged by a powerful body like Convocation. Whatever some of the members of the Senate may think and say of Convocation, its influence both within and without the University is now very great. Convocation of the University of London includes such men as the Master of the Rolls, Mr. Stansfeld, Mr. Farrer Herschell, Sir William Jenner, Sir William Gull, Dr. Quain, Dr. Storrar, Mr. Hutton, Mr. Osler, and a host of names foremost in the Church, in Law, and in Medicine. The result will be watched with extraordinary interest by all members of the University of London, and by all who have University freedom sincerely at heart.

THE FAMINE IN INDIA.

The famine telegrams from India continue to be of a very cheering and reassuring character. A week's general rainfall throughout the drought-stricken provinces has changed the whole aspect of affairs; and it is considered that cultivation is now secured throughout the Punjaub, the North-West, Oude, the Central Provinces, Central India, and Behar. Some idea of the immense significance of this change of weather may be gained from the statement that it has been roughly estimated that the week's rain will save the Government four millions sterling. Favourable rains have fallen also in all the districts of Madras; agricultural operations are in full progress, and grain prices are falling. The distress is daily lessening, though, it must be remembered, it is still great. The total number on the relief works is reported as 587,228, showing a decrease since the last previous report of 41,031. The total number gratuitously relieved is 153,125, a decrease on the previous week of 72,466. In Mysore, also, the crops are flourishing, and prices falling; and the number of the gratuitously relieved is lessening. And it is anticipated that if the north-east monsoon is favourable, the famine pressure will be over in February. The importation of grain so far as Madras has been enormous, and the latest famine telegram in the *Times* speaks of the wonderful sight, in the Madras roads, of fifteen large steamers and more than twenty large ships, all discharging rice, while the beach for at least two miles was one gigantic warehouse of that grain, with stacks of bags fifteen feet high ranging all along the shore. The price of rice had naturally fallen in Madras 20 per cent.; but the difficulty, or rather the impossibility, of conveying this food in sufficient quantity and with sufficient rapidity into the famine-stricken districts in the interior remained the same; and therefore the distress in those parts cannot be relieved in anything like the same degree as at Madras itself. And one of the most, if not *the* most, important of the things to be considered in adopting measures for the future is the provision of facilities of carriage. The *Times'* correspondent, telegraphing from Simla, points to this when he says, "The present famine would not have occurred if the vast amount of rice in the different parts of India could have been carried to the famine districts." The Mansion House Indian Famine Fund amounts now to more than £380,000—a grand sum to have been contributed in about two months,—and a large amount is still received every day. But more aid still will be required, and the Lord Mayor, when expressing a hope that the contributions to the Fund may reach £500,000, did well to draw attention to the following statement in the *Times'* telegram from Simla:—"It may be well to warn the English public, though there is every prospect of the Madras Famine terminating by February, that infinite misery will still have to be endured, and the need of alleviation is as pressing as ever. It is most desirable that the flow of charity should not cease through a mistaken notion. Reports from Madras speak in the highest terms of the wise and provident distribution of the Famine Fund, of which no words can adequately measure the beneficial results."

MEDICAL STUDENTS.

The annual registration of gentlemen pursuing their studies in this metropolis has just been brought to a close, and from the report prepared at the College of Surgeons for Mr. Charles Hawkins, the Government Inspector of Anatomical Schools, it appears that the total number of entries is 1879, as follows:—

1. St. Bartholomew's	394,	including	149	new enties.
2. Guy's	338	„	112	„
3. University College	269	„	64	„
4. St. Thomas's	187	„	52	„
5. St. George's	128	„	35	„
6. The London	123	„	46	„
7. King's College.	115	„	40	„
8. Middlesex	112	„	35	„
9. St. Mary's	102	„	26	„
10. Charing-cross	82	„	29	„
11. Westminster	29	„	9	„

The above list includes also the separate registration of dental students. The various institutions are placed in numerical order of the gross number of students respectively pursuing their studies in them. The number of new entries, amounting to 597, is distributed in the following order:—1. St. Bartholomew's, 149, against 131 last year; 2. Guy's, 112, against 95; 3. University College, 64, against 79; 4. St. Thomas's, 52, against 43; 5. The London, 46, against 35; 6. King's College, 40, against 28; 7. The Middlesex, 35, against 38; 8. St. George's, 35, against 33; 9. Charing-cross, 29; 10. St. Mary's, 26; 11. Westminster, 9. Curiously enough, the three last-named hospitals register the same number this year as last. It will therefore be seen that there is a decrease in the following schools—viz., University College and Middlesex Hospitals—notwithstanding a large addition of dental students at the latter. In 1867 the gross number of students entered at the metropolitan schools amounted to 1125, and the new entries to 355.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.

At the annual meeting of the College, held on Thursday, the following office-bearers were elected for the ensuing year:—*President:* Patrick Heron Watson, M.D. *Secretary and Treasurer:* Joseph Bell. *Librarian:* David Wilson, M.D. *President's Council:* Andrew Wood, M.D.; James D. Gillespie M.D.; James Spence; William Walker; Henry D. Littlejohn, M.D.; John Smith, M.D.; *ex-officio*, Joseph Bell. *Examiners:*

Archibald Inglis, M.D.; Peter D. Handyside, M.D.; James D. Gillespie, M.D.; Henry D. Littlejohn, M.D.; Patrick H. Watson, M.D.; David Wilson, M.D.; John Smith, M.D.; Argyle Robertson, M.D.; Joseph Bell; John Duncan, M.D.; Robert J. B. Cunyngham, M.D.; Alexander G. Miller, M.D. *Assessors to Examiners:* William Brown; James Spence; William Walker; Jas. S. Combe, M.D. *Conservator of Museum:* Robert J. Blair Cunyngham, M.D. *Clerk:* Jas. Robertson.

QUEEN'S UNIVERSITY IN IRELAND.

The annual ceremony of the conferring of degrees on the students of the Queen's Colleges of Belfast, Cork, and Galway took place on the afternoon of Friday, October 12, in St. Patrick's Hall, Dublin Castle. His Grace the Duke of Leinster, Chancellor of the University, presided. The following is an extract from the annual report, which was read by the Chancellor:—"In the Faculty of Medicine 72 candidates have sought the degree of Doctor in Medicine, and of these 44 have satisfied the examiners. Out of 58 candidates for the degree of Master of Surgery, 35 have passed; and 25 out of 43 have been deemed qualified for the diploma in Midwifery. At the Second University Examination in Medicine, 115 candidates presented themselves, of whom 73 have satisfied the examiners; and 154 out of 198 candidates have been successful at the First University Examination in the same faculty. The Board report to the Senate the unusual excellence of 823, William Whitla. The Board report to the Senate J. W. Macnamara and William Macnamara for the excellence of their answering. The number of students attending lectures in the Faculty of Medicine during the past session was 527." On the same occasion the Peel Prizes in Composition (limited to the competition of undergraduates in medicine) were awarded as follows:—For the essay signed "Vis Medicatrix Naturæ," Alfred Henry Keogh, Galway. Proxime accessit, "Quid est in Somnis gelidæ nisi Mortis imago," Henry Tomkins, Belfast. Peel Exhibition, awarded at the First University Examination in Medicine—Robert Thomas M'Geagh, Belfast, first, £20 a year for two years.

THE METROPOLITAN WATER-SUPPLY FOR SEPTEMBER LAST.

The report of the Water Examiner on the metropolitan water-supply for the month of September last shows that the water drawn from the Thames by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies was much more polluted by organic matter during that month than in the preceding July and August. The water delivered by the Grand Junction Company was turbid, owing to inefficient filtration. The remaining Thames water was efficiently filtered, but that supplied by the Lambeth and Southwark Companies was distinguished by containing a large proportion of organic matter, some of which was of animal origin. The water from the Lea, supplied by the New River and East London Companies, was of much better quality, and was efficiently filtered before delivery. The water drawn from the deep wells by the Kent and Colne Valley Companies, and by the Tottenham Local Board of Health, was palatable, wholesome, and of most excellent quality for dietetic purposes. That portion of the Kent Company's supply obtained from their deep well at Crayford was slightly turbid, owing chiefly to the presence of minute particles of chalk. The water in the river Thames at Hampton, Molesey, Sunbury, and Ditton was fairly good during the month. The highest flood state of the river was recorded as nine inches above, and the lowest was at the summer level.

THE EFFECTS OF CLIMATE UPON HEALTH.

Among the many papers read at the recent Sanitary Congress at Leamington was a very interesting one by Surgeon-Major De Chaumont, on the Effects of Climate on Health. The conclusions at which he has arrived on the subject are—"1. That with proper hygienic precautions there is hardly a place on the earth where man may not enjoy good health, and that where this is not found possible it is from the existence of malaria. 2. That, admitting this much, there are, however, still differences existing which render residence in certain climates more desirable than in others, as most conducing to the fullest heath and vigour. 3. That the possibility of acclimatisation has been greatly exaggerated, but that there still remains a residuum of truth in the idea. 4. That there is still a certain importance to be attached to the climatic treatment of disease, although the particular factor or factors that produce the influence are still involved in much obscurity."

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

A full-sized marble statue of the late Dr. Robert J. Graves, one of the most distinguished ornaments of the medical profession in Ireland, is at present being placed on a pedestal in the Statue Hall of the College. Three other statues grace this beautiful apartment—those, namely, of Dr. Stokes (Graves's colleague at the Meath Hospital), the late Sir Henry Marsh, Bart., and Sir Dominic Corrigan, Bart. The statue of Graves is by Mr. Albert Bruce Joy, an Irishman resident in London, son of Dr. Bruce Joy, and a relative of the late Chief Baron Joy. It is an extremely successful work of art. It represents Dr. Graves in the act of commencing to lecture, and attired in an academical robe. His tall and manly figure, intellectual head, and handsome aquiline nose are faithfully portrayed. The attitude is easy, and the drapery very artistically carved. On the pedestal is the simple inscription, "Robert James Graves, M.D., President of the King and Queen's College of Physicians." Still more simple is the inscription, dictated by himself, which is engraved on his tomb in the cemetery of Mount Jerome, near Dublin—"Robert James Graves, son of Richard Graves, Professor of Divinity, who, after a protracted and painful disease, died in the love of God and in the faith of Jesus Christ."

CASE OF HYDROPHOBIA.

We have to record another case of hydrophobia. A farmer's boy in the village of Marston, near Oxford, was bitten in the thumb by a strange dog, at the latter end of June or the beginning of July. The wound was dressed at a chemist's shop, and healed in a week. The boy continued at work on the farm till October 4, when he complained of pain in his arm, and went home. In the evening it was observed that he could not swallow. He was taken to the Radcliffe Infirmary on the 6th, and died exhausted on the 9th inst. At an inquest held on the case, the Coroner (Mr. Hussey), in charging the jury, said that the number of dogs at large without a visible owner was a subject deserving serious consideration. He understood that in the London police district the police had the power, under a special Act of Parliament, to seize the stray dogs and to kill them. As a member of the Local Board he had made inquiry whether the Board, as the sanitary authority of the district, had any power to abate such an abominable nuisance; and he was informed that they had not. In addition to this unsatisfactory piece of information, he learned that a dog was entitled to have a bite of you before you had the right to knock him on the head.

THE EDINBURGH CHAIR OF CLINICAL SURGERY.

At the long last the Professor of Clinical Surgery in the University of Edinburgh has been appointed, and the choice of the Crown has fallen on Mr. Annandale. We have nothing to say against the appointment. Mr. Annandale is a good surgeon, and of sound experience. Of course the appointment will not please all—it would be strange if it did; but at all events it must be looked upon as fair. Certain of our contemporaries have ventured on strongly supporting one

candidate. We shrank from such a course when so many good men were in question. Personal feeling might have led us to adopt a similar course, but there are cases where this must be subordinated to more public considerations. We trust and believe that Mr. Annandale will worthily fill a chair so famous as that of Clinical Surgery in Edinburgh.

THE CHAIR OF ANATOMY AT QUEEN'S COLLEGE, GALWAY.

LAST week we announced the candidature of Dr. J. Cunningham for this vacant chair. There are also in the field three other gentlemen whose qualifications for the post are of a high order. One is Dr. Edward Wolfenden Collins, Surgeon to Jervis-street Hospital, Dublin, and Demonstrator of Anatomy in the School of Physic in Ireland (University of Dublin); the second is Dr. Anderson, Demonstrator of Anatomy in Queen's College, Belfast, and assistant to Professor Redfern of that College; and the third is Professor Pye, of Queen's College, Galway.

ASPIRATION IN PLEURITIC EFFUSION.

ELSEWHERE we publish an account of a brief discussion on the subject of aspiration in pleuritic effusion, before the Clinical Society. Most of the speakers seemed to be in favour of it; no one spoke strongly of its risks. Its needlessness and meddlesomeness in some cases were barely hinted at. It is a pity the Manchester discussion was not given to the world in full.

CLEOPATRA'S NEEDLE.

WE have much pleasure in recording the following, which has just been received from Lloyd's agent at Ferrol, in Spain, dated the 18th inst.:—"Steamer *Fitzmaurice*, from Middlesbro', for Valencia, recovered at sea Cleopatra's Needle, ninety miles north of Ferrol."

ISLINGTON MEDICAL SOCIETY.—The first meeting for the present session of this flourishing Society of medical practitioners will be held on the evening of the 23rd inst., when Mr. Keele, who has retired from the secretaryship, will be presented with an emblazoned address. Dr. Sansom will then open a discussion on anæsthetics.

THE HEALTH OF ST. MARYLEBONE PARISH.—In his report for the months of August and September last, Dr. John Whitmore, Medical Officer of Health for the parish of St. Marylebone, is able to record an exceedingly low rate of mortality for the district, very nearly 25 per cent. below the average annual death-rate of the parish for the last twenty years. This he considers is attributable to two causes—first, to the comparatively few deaths that occurred from zymotic diseases generally; and next, to the absence of sultry weather in August, owing to which the number of deaths from infantile diarrhœa were considerably decreased, and some other diseases also which are rendered more fatal by a high temperature. The last outbreak of small-pox in the parish, of any especial importance, occurred in Gray's-buildings, early in the month of August. Between the 1st and 8th of the month, twelve persons, nearly all children, were attacked in these buildings; ten of the cases were sent to the Hampstead Hospital, and two were treated in their own homes, one of the latter proving fatal. The disease was conveyed there by a woman suffering from the malady, and it spread, as infectious diseases invariably spread amongst the lowest and most ignorant classes, because nothing was done or attempted to prevent it. Since this outbreak there have been but very few fresh cases, and only one death from small-pox has been registered in the parish during the two months under notice. In all probability, Dr. Whitmore thinks, measles will be the next epidemic, and as there are no hospitals specially built for the reception and treatment of patients suffering from this disease, but little can be done to check its extension among the poor in crowded localities. Happily it is not so fatal as either small-pox or scarlet fever, but its fatality is greatly increased by being complicated with diseases of the respiratory organs, which are very likely to supervene by exposure to a low temperature. If, therefore, there should happen to be a severe winter, measles may become unusually fatal.

FROM ABROAD.

THE MEETING OF THE GERMAN NATURALISTS AND PHYSICIANS.—THE fiftieth and jubilee meeting of the Association of German Philosophers and Physicians, at Munich, this year, has been a success from the great number of members present, and the distinguished position in the world of science of many of these. Considerable dissatisfaction, however, prevailed at the determination which has been come to of abolishing the entertainments hitherto given by municipalities and governments, in order to render these meetings more strictly scientific. Many who looked forward to the jollification of a banquet, where they were brought much more intimately into communication than at the general and sectional meetings, do not admire the change at all. Something like an entertainment, termed a "Kellerfest," was got up at one of the great breweries, where at least there was no lack of beer to drink the toasts; but this had to be paid for at an increased price, as had other articles of food, and had to be partaken of amidst a crushing crowd of men, women, and children.

However, the meetings themselves seem to have gone off quite successfully. Geheimrath Prof. von Pettenköfer delivered the address of welcome, in which he reviewed the history of the Association, the prolific parent of such a vast tribe of associations and congresses. It was, he observed, to Ludwig Lorenz Oken that the establishment of this Association was due. Leading a most active life, both as a teacher and as a writer at Göttingen, Weimar, Jena, Basle, and Munich, he took a comprehensive view of the different branches of what was then called natural philosophy, and made many efforts to bring together in natural connexion that which was accidentally separated. Among these was his now famous journal "Isis," in which he first set forth his ideas concerning these assemblages. On his invitation, twenty men met at Leipzig in 1822, and founded the Association of German Naturalists and Physicians; and, under the political circumstances and the difficulty of intercourse of that time, even the modest number of twenty was regarded as a good beginning. The next meeting, at Halle, was attended by 34 members; the third, at Würzburg, by 36; the fourth, at Frankfort, by 110; the fifth, at Dresden, by 116; the sixth, at Munich, by 156; and the seventh, at Berlin, in 1828, by 464. The Association thus exhibited its viability, and the number increased with rapidity year by year, until at the last meeting at Hamburg it amounted to more than 2000. With these augmented numbers different arrangements and groupings were adopted. The first six meetings were conducted entirely in common, and it was at the seventh meeting, held at Berlin, that Alexander von Humboldt, who was president, created, besides the general meetings, seven sectional meetings. These have gradually increased in number, so that at the present meeting there are twenty-five—this increase being not only a sign of the increase in the numbers of members, but also a sign of the progress of science and the necessity of the division of labour. The Association calls itself a Society of Naturalists and Physicians, thereby unmistakably announcing that the science and practice of medicine is indissolubly united with the natural sciences and their development, and that the philosopher's stone, once dreamt of, conferring health, riches, and longevity, is only to be sought for in natural science. This day, in the fiftieth year of their union, natural science and medicine celebrate, so to say, their golden wedding.

Prof. Waldeyer, of Strasburg, delivered an interesting oration on "Carl Ernest von Baer and his Significance in Relation to the Natural Sciences"—this great Russian *savant* having died in his eighty-fourth year since the last meeting of the Association. In eloquent words he set forth the immense amount of work done by him in anatomy, zoology, palæontology, and other branches of natural science, and his claim to be regarded as the founder of modern embryology. As is usually the case at the general meetings of congresses, perhaps this part of the address, like that of Prof. Allen Thomson at the recent Glasgow meeting, went too much into detail for the comprehension of many of the auditory. The universality of knowledge, which (like Goethe and von Humboldt) von Baer attained, presents a picture of what

should be the aim of this Association. Year by year new special congresses spring into life, and in this much of its best power is drafted off. Surely it is not desirable that the separate branches of science should so isolate themselves as that at last they will scarcely comprehend each other; and if special congresses have become a necessity, yet men of science now, as heretofore, should lend their strength to this Association, so that the connexion of teachers and learners may be carried beyond the narrow limits of the university.

Other discourses were delivered by Prof. Haeckel, of Jena, "On the Present Condition of the Doctrine of Development in relation to the Sciences"; and by Prof. Virchow, "On the Freedom of Science in relation to Modern State-Life." A most liberal address was also delivered by the Grand Duke Karl Theodore of Bavaria, the honorary President of the meeting, in which he laid claim to participation in the honours done to science as being a doctor of medicine (and, we may add, as the author of a remarkable essay on the histology of the brain—the first instance, we suppose, of such a title having been conferred on one of royal blood.

The next place of meeting is to be Cassell.

Iodic Purpura.

In a paper contributed to the new journal, the *Révue Mensuelle*, for September, Prof. Fournier, of the St. Louis Hospital, observes that while among the numerous and various phenomena which may follow the ingestion of iodide of potassium, there are some which are of common occurrence and well known, there are others which have either escaped attention, or have only been imperfectly described. Among these may be ranged, he believes, a cutaneous affection, consisting in the production of small miliary, non-pruriginous, sanguineous spots, proceeding after the manner of purpura, and to which he proposes to give the name of iodic purpura, or petechial iodism. That the appearance of the exanthem and the taking the iodide are not a mere coincidence he concludes from the following observations:—1. In all the cases the purpura has appeared a very short time (from one to six days) after commencing the iodide. 2. In some of the patients the same purpuric eruption has been produced several times after each new administration of the iodide; and in three of these it occurred every time the medicine was used. Two cases are detailed in which this was the case three and four times. 3. In another case, in which the purpura was produced on three successive occasions, it was found in all these that whenever the dose was notably increased, a marked aggravation or additional production of the eruption ensued.

As to the characteristics of this eruption, in all the patients the well-known appearances of purpura, and the impossibility of effacing them by pressure with the finger, were distinctly present, the petechial colour due to extravasation being very obvious. The seat of the eruption, with one exception (when it was on the thorax, and that only), was in all the cases on the legs only, being always more confluent on their anterior than on their posterior part. It never descended to the foot or extended beyond the knee. This purpura seems to assume an eminently discrete form, few spots being usually observed, about a hundred of these on each limb constituting the maximum of confluence—fifty or sixty, or even less, being the number usually observed. On the successive appearances the purpuric spots are even yet fewer in number. This rarity of confluence, and the especial localisation of the exanthem about the anterior tibial region, impart to this variety of purpuric affection a somewhat peculiar physiognomy of its own. It is always a miliary purpura—that is, a petechial eruption of the smallest extent—resembling in size a millet-seed, the head of a pin, or at most, and that rarely, a grain of corn or a small lentil. The spots are usually of a regular rounded form, and less often oval or irregular in form and notched. The eruption never advances beyond this petechial and miliary condition. The spots are quite level with the skin, seemingly incorporated with the integument, the appearance of which they only modify by their bright colour. Like as in purpura vulgaris, these spots give rise to neither local nor constitutional disturbance, inducing neither heat, pain, nor pruritus. Thus there is a great chance of this eruption passing unperceived; and it is always by accident that the patients have observed its existence, while undressing, at the bath, etc., so that many cases have no doubt escaped the notice of patients and their attendants. The eruption comes on at an early period of the iodide treatment, and has completed its course in two or three days, at the end of which period it ceases to increase in confluence, even when the use of the medicine is continued. It remains for a certain time in the condition of purpurine petechiæ, after which the spots undergo the ordinary changes of colour observed in cutaneous hæmorrhages, finally disappearing at the end of two or three weeks. When, under the influence of a large dose of the iodide, a new purpuric outbreak is produced, the intruding eruption is easily distinguished from that which has preceded it by the bright purpurine colour of its spots, contrasting with the faded condition of the prior spots. It has a curious appearance, this intermixture in the same locality of petechiæ of different ages, with differences of colour corresponding to the periods of their appearance.

This purpura is certainly a rare accident, or rather phenomenon, for there are few remedies which are more employed than the iodide of potassium; and if iodic purpura were not almost an exceptional occurrence, it must have attracted the attention of observers. Professor Fournier, who, during the few years since he first became aware of its existence, has carefully sought for it, has not met with more than some fifteen cases. It would be premature, with so small a number of facts, to define the conditions which may act as predisposing or occasional causes of its production; but some etiological data may perhaps be derived from the cases already observed. *A priori* one would be inclined to believe that a predisposing and adjuvatory cause would be found either in the impoverished, anæmic, or debilitated condition of the patients, or in some of the graver forms of syphilis. This is far from being the case. All the subjects of the affection hitherto met with enjoyed either a flourishing or a medium condition of health; and although some of these seemed affected with a certain degree of "lymphatism," none could be said to suffer from anæmia or scrofula, and none had presented anterior hæmorrhagic proclivities. Any of these who were the subjects of syphilis exhibited only benign or medium forms of this; two-thirds of the cases being exempt from any specific manifestation of this disease at the time when the iodide, which in fact was only administered as a preventive, produced the purpuric eruption. Further, in a negative point of view, neither sex, age, occupation, nor external temperature seemed to have exerted any influence. Nor can the eruption be attributed to excess of dose, since most of these patients had not taken more than fifteen grains of the iodide when the eruption had manifested itself. Still, quantity is not a matter of indifference, for when a given dose has been followed by purpura, a kind of tolerance of the remedy seems to be established, and no further manifestation ensues. But let the dose be much increased—doubled, for example—and a new outbreak of purpura may be immediately produced, although this is less confluent and less important than that which preceded it. But it is probably the *individual predisposition* which predominates over all the etiology, for however unknown and impenetrable in their nature, the existence of idiosyncrasies in regard to the action of certain remedies and articles of diet is beyond doubt. Iodic purpura in its nature takes its place in the group of affections termed by M. Bazin *provoquées indirectes* or *pathogénétiques*. It is a medicinal eruption, which ranges nosologically with the roseola from copaiba, the erythema from belladonna, the exanthems from arsenic, the acne from iodine, etc.

Determined to be a Martyr.—On Saturday, a newsagent of Chesterfield, named Lawton, was brought up at the police-court for the twenty-fifth time for not having had his child vacciuated. He has several times been fined or sent to prison for similar disobedience; and on Saturday the magistrate again ordered that the child be vaccinated within fourteen days. Mr. Lawton once more declared he would not comply with the order.

Examinations for the Degree of M.B. and in Preventive Medicine and Public Health.—Examinations for the degree of Bachelor of Medicine will be holden at the University of Oxford early in December. Candidates are requested to forward their names to the Regius Professor of Medicine before November 24. Also, it is proposed to hold an examination in Preventive Medicine and Public Health in conformity with Statute XII., Titulus Sup. XIX., page 291, ed. 1877. The examination is open to all persons who have taken the degree of Bachelor of Medicine in the University of Oxford. Candidates are requested to send in their names to the Regius Professor of Medicine on or before November 10

REVIEWS.

An Atlas of Human Anatomy, illustrating most of the Ordinary Dissections, and many not usually practised by the Student; accompanied by an Explanatory Text. By Rickman John Godlee, M.S., F.R.C.S., Assistant-Surgeon to University College Hospital. Imperial 4to. London: J. and A. Churchill. 1877.

Messrs. Churchill, in publishing this volume, have added one more to their magnificent series of illustrated works by eminent authors; this last addition is as well chosen, both as to subject and author, as their previous volumes, and Mr. Godlee's Atlas will undoubtedly take a first place among illustrated works on anatomical dissections. The object of the author in bringing out this series of plates is to supply a full illustration of the anatomy of the human body in a portable form. It is also intended, by illustrating dissections not usually seen in the dissecting-room, to enable the student to understand the mutual relations of parts; and it is further hoped that, by making the dissections follow one after another, he may find assistance in working out for himself the steps by which particular organs and regions may be exposed. This summary of the author's preface speaks for itself, and clearly lays down what should be the object of every dissector, and points out how that object may most satisfactorily be obtained. Mr. Godlee is not only an able anatomist, but also an excellent and a successful teacher. Moreover, he is a clever artist, as the execution of these drawings sufficiently testifies. We are greatly pleased with the arrangement of the plates, and with the definite plan on which they are classed, for this will render them available for the physician or surgeon as much as for the student. In the accompanying text the author has fully described each plate, and has given a description of the manner in which the dissections were made. He has also made references to their medical and surgical bearings, so that the work, when completed, will really be a very comprehensive *exposé* of the subject. The Atlas commences, and we think rightly, with the dissection of the head and neck; the first part includes four plates, each with two figures. The parts are to appear at intervals of two months, until completed. We heartily recommend the work to the attention of all who wish to learn anatomy both practically and agreeably.

Hints on Insanity and Signing Certificates. By John Millar, L.R.C.P. Edin., Medical Superintendent, Bethnal House Asylum, London. Second Edition, enlarged. London: H. Renshaw, Strand. 1877. Pp. 142.

The first edition of Mr. Millar's little work was published so long ago as in 1861, and we must confess to a feeling of surprise that a second edition was not called for much sooner. The medical practitioner has, in general, but a very slight and imperfect knowledge of the various steps that have to be taken in order to place a person of unsound mind under legal restraint, and not much acquaintance with the different forms of insanity; and we are sure that he could not fail to find this book a very useful guide and aid. Mr. Millar gives first, very briefly, "a general view of insanity," dividing the cases into the two great classes of the "curable" and the "incurable," the former being "that in which the disorder may be considered as the result of functional derangement"; and the latter "that in which it is dependent upon organic change for its origin." The "curable" forms are—"acute mania," "ordinary mania," "melancholia," "recurrent mania," and "puerperal mania"; while "general paralysis," "epilepsy," "hallucinations," "masturbation," and "dipsomania" are called "incurable." We cannot say that we think the classification perfect, and Mr. Millar himself does not pretend that it is, as he mentions some cures of "incurable" cases; but it is a practically useful classification. The "hints" as to treatment, also, are generally good. Then follow notes on the responsibility of the insane, and on the prevention of insanity; and some general remarks on "visiting patients"; on "removal to asylums," its advantages and disadvantages; on the "class to be removed"; and on asylums. And then the form of admission of private patients to asylums is given, with minute and full directions on the filling up of the printed form, and examples of the errors of omission and of commission most frequently met with. This part of the book we look upon as particularly useful and instructive; and we recommend it to the careful study of medical practitioners. An Appendix is added, containing the "Instructions of the Commissioners in Lunacy with reference to Single Patients"; Notes on the Removal or Transference of Patients"; on "Chancery Patients"; and on "Wandering Lunatics"; Forms of Certificates for Admission into Private Asylums in Scotland and in Ireland—for, absurd and wrong as it may seem, the certificates differ in form in each division of the kingdom; and Lists of the Commissioners in Lunacy, of the Metropolitan and the Provincial Licensed Houses, of Lunatic Hospitals, and of the Lord Chancellor's Visitors in Lunacy. The little volume contains a large amount of very useful information.

La Province Médicale. Journal hebdomadaire de Médecine, de Chirurgie, et de Pharmacie. Bordeaux, 1877. (Première année.) Rédacteur-en-chef, G. Poinsot.

The Medical Provincial. A Weekly Journal of Medicine, Surgery, and Pharmacy. Bordeaux, 1877. (First year of publication. G. Poinsot, Chief Editor.

We have received several numbers of a new French medical paper, published at Bordeaux, and which appears to us to be edited with considerable ability. A high compliment is paid to British physicians by translations of the *verbatim* reports of clinical lectures by Dr. McCall Anderson, Dr. Hughlings-Jackson, and others, and also by detailed accounts of papers read at the Clinical and Pathological Societies of London. Among original works we notice a "Clinical Study on Osteo-Sarcoma of the Limbs," by the Editor; "Researches on the Lymphatics of the Mammary Glands and its Neighbourhood," by Professor Coyne, of Lille; and an article on "Detachment of the Retina, and its Treatment by a New Method," by Dr. Despagnet, chief assistant to Dr. Galezowski, of Paris. There are also some interesting reports of cases, and accounts of clinical and therapeutic novelties, extracted from a variety of French and foreign periodicals, as well as an extremely useful list of new works which deserve to be consulted on medical subjects. One feature, which is common to other French medical journals, such as the Paris *Progrès Médical*, is worthy of adoption in this country. We refer to the lists of new, or interesting cases, in the wards of the St. André Hospital at Bordeaux, which appear from time to time, and by which the medical men of the city have their attention called to examples of disease which they might otherwise never have an opportunity of seeing. As the beds are all numbered, and the wards all named, any case can easily be found at the hour of the visit of the *chef de service*. If similar lists of the cases in two or three of the large London hospitals were published each week, it would be a great boon to many busy practitioners. We welcome the appearance of the *Province Médicale*, and wish it success.

PROVINCIAL CORRESPONDENCE.

LIVERPOOL.

October 13.

The Medical Institution—Infectious Diseases Hospital at Birkenhead—Adulterated Cream—Whooping-Cough.

For a year or two past the increase in the number of members of the Liverpool Medical Institution has given rise to the belief that some modification of its premises would be necessary. In addition to a library, council, and several other rooms, it had two theatres, in the smaller of which (a most comfortable room) its ordinary meetings were held. So long as the number present did not exceeed fifty or sixty, no particular inconvenience was experienced from this. When, however, as has often been the case of late, seventy, eighty, or more attended, the heat and closeness of the room became very trying. It was resolved, therefore, at the close of last session to modify the larger theatre, which for several reasons was, without such modification, unsuitable for the meetings. the necessary change has been carried out at a cost of about £620, and the first public meeting held in it was that for the distribution of prizes to the successful students of the School of Medicine, on September 29, by Mr. Simon, when an introductory address was given by Mr. Rushton Parker, F.R.C.S., Lecturer on Surgery to the School.

Again, in the same room, on the 11th inst., Dr. Turnbull, the President, opened the session 1877-78 of the Institution

itself by an introductory address. Last year the same gentleman, on a similar occasion, chose Embolism as the subject of a singularly able address, which was subsequently published. This year he gave an interesting historical sketch of the rise and progress of the Institution. He remarked that it was about forty years ago that the late Dr. Rutter, the first president, gave an opening address in that place, but that the history of the Institution extended back for nearly a century, the first combined movement of the medical men of Liverpool for the advancement of professional knowledge having been made in 1779, on October 7 of which year twenty medical men united for the purpose of forming a medical library. The collection of books then made formed the nucleus of the present library. It had various local habitations, one after another being given up in consequence mainly of the demand for space for the erection of railways or other public works, owing to the rapid increase of the town, till at length, nearly fifty years ago, negotiations were entered into with the Corporation, which resulted in the erection of the present building. Soon after its completion an amalgamation was effected between the Library Committee and the Medical Society, which up to that time had been a separate body, meeting in a different place. The first meeting of the amalgamated institutions was held in the present structure in 1839. The early years of the united society were marked by many vicissitudes, and as its occasional want of success was thought to be in some measure owing to the existence and rival aims of yet a third society—the Pathological—a further union with this was effected in 1847, since which time the history of the Institution has been one of almost undeviating progress. In 1869, on the motion of Mr. Robert Hamilton, the scope of the Society was still further enlarged by the formation of a microscopical branch, which meets monthly and does good work. An able vindication of the claims of the microscope to have advanced practical medicine was then given, followed by an interesting sketch of the work of Dr. Roberts of Manchester, Dr. Burdon-Sanderson, and others, and a number of suggestive queries as to the possible antifermentative action of quinine, salicylic acid, arsenic, mercury, and other remedies.

In proof of the growth of the Institution, the number of members in 1856 (some years after the amalgamation of the three bodies) only amounted to 78; in 1866 it had risen to 117; in 1870, to 135; while at present it stands at 187.

A variety of suggestions were then offered as to the means best calculated still further to promote success, and among others that of the publication of an annual volume of proceedings. And lastly, in rapidly reviewing the work of the preceding session, special attention was drawn, firstly, to the fact that the prompt action of this Institution had had the effect of preventing such a change in the laws of the chief medical charity of the town as would have tended, in the opinion of the majority of the profession in Liverpool, to lower the status of its honorary officers, and hence, in time, of that of the officers of all other local medical charities; and, secondly, to meetings which had been held on the subject of gratuitous medical advice, with their outcome—the recommendation of provident dispensaries.

Great efforts have been made for a considerable time by Dr. Vacher, Medical Officer of Health for Birkenhead, to obtain for that town an infectious diseases hospital. There seems some probability of his wishes being at length fulfilled, as plans for such a building, to accommodate thirty-two patients, were passed by the guardians at their meeting on the 9th inst. Nothing now is required but the approval of the Local Government Board before the building can be commenced. It will cost £3500 without fittings.

A mixture of starch-paste, colouring matter, and new milk, so ingeniously effected as to give it the appearance of very rich cream, having been vended for that article by a Mr. R. Beardwood, an unappreciative customer caused his appearance before the Liverpool Stipendiary Magistrate on the 10th inst., who, while recognising Mr. Beardwood's originality and genius, felt compelled to mark his sense of the absence of other qualities, even more essential in a tradesman than they, by imposing a penalty of 20s. and costs.

Whooping-cough has prevailed in Liverpool for some time. During the week ending October 16 there were fifteen deaths from that disease, or ten above the average. The number of deaths from other zymotic diseases, however, was considerably below the average, and on the whole the health of the town is, as it has been during the whole of the past summer, fairly good. This week, however, the death-rate has risen.

GENERAL CORRESPONDENCE.

POISONING BY BICHROMATE OF POTASH.

LETTER FROM MR. METCALFE JOHNSON.

[To the Editor of the Medical Times and Gazette.]

SIR,—As the cases of poisoning by bichromate of potass have been hitherto somewhat rare, and the details of treatment and recovery both scanty and infrequent, I trust the following case may prove of some interest to your readers, not only as one of speedy recovery from dangerous symptoms, but as showing what dose may be dangerous and fatal if neglected:—

On the evening of a Saturday, after work was over, A. B. on going to bed thought to take a dose of medicine from a bottle which stood among others, one of which was a solution of bichromate of potass, which he used as a wood stain in his business of French polisher. After swallowing a wineglassful of this liquid, containing, as I afterwards ascertained by analysis (metrical), about two scruples of the salt, he felt a burning taste and sense of great heat and pain in the stomach. This at once showed him what was his mistake; on finding which he ran to my house (about two minutes' walk). I was from home. He went home, and swallowed the contents of three eggs, under some idea of an antidote. After this he returned to my house. I was still away, but after about twenty minutes had elapsed I arrived, and found him retching, vomiting slightly, and in very great agony of pain in the epigastrium. His skin was sweating profusely; pulse very rapid (about 120). Being a strong man he did not exhibit much fainting. I immediately administered a mustard emetic (a tablespoonful of mustard in powder in half a pint of warm water). This, with tepid water copiously swallowed, induced free vomiting, and I removed from the basin a piece of mucous membrane which would cover about an inch and a half of surface of the lining membrane of the stomach. This was one of many such shreds—perhaps half a dozen to a dozen,—with much other mucous fluid and a few drops of blood. A sense of pain and griping in the bowels was beginning to be felt. I applied a large liquid blister over the abdomen on either side, vesicating a surface (of about six or eight inches square) on either side.

I administered a large enema of about three to four pints of warm water, which brought away with it about half a pint of a sediment, consisting of the villi of the gastro-intestinal mucous membrane. I then inserted about a quarter of a grain of acetate of morphia by subcutaneous injection; and, visiting him once or twice in the night, found him next morning complaining of less pain, less vomiting, and no further action of the bowels. I ordered some ice for him to suck, and left instructions for a small quantity of tepid water-arrowroot to be administered occasionally, with the view to prevent the secretion of gastric juice acting injuriously on a perfectly empty stomach.

There is no need to describe in detail the recovery, which (excepting a slight threatening of general paralysis on the third day, which soon gave way) was uninterrupted, and requiring no treatment, save the use of liquid food and the abstinence from alcoholic drinks; and now, after the lapse of a few weeks, his stomach has resumed its tone, and his digestion is as good as ever—in fact, he seems to have sustained no permanent injury from the accident, which might without prompt measures very easily have proved speedily fatal.

Hoping you will find this slight sketch sufficiently interesting to your readers to give it a place in the pages of your journal,

I am, &c.,
METCALFE JOHNSON.

"BLOOD POISONING."

LETTER FROM MR. G. J. S. CAMDEN.

[To the Editor of the Medical Times and Gazette.]

SIR,—I unfortunately did not see and read the two letters in the *Times* of September 5, on poisoned arrows, until a few days since, from which it appears that, instead of mineral or vegetable poison being used, the arrows are simply dressed with putrid matter, obtained either from human or animal flesh; but *which* will not make the slightest difference, as death will generally ensue. If such is the case, from what I have done, it is easily curable. I once had a case (a lady) whose blood was thoroughly poisoned by absorption of putrid matter from a portion of highly putrid placenta, which had been

retained eighteen days; and only three or four more days would elapse before my patient would succumb, as the generality of cases sink before the expiration of twenty-two or twenty-three days. I fortunately thought I could, by saturating her system with hydrochloric acid, destroy the putridity. I accordingly gave her hydrochloric acid, eight drops in three tablespoonfuls of water, every four hours, drinking after each dose half a tumblerful of water; and I had the immense gratification to find that in twelve hours the room became tolerably sweet, which it had not been, nor could I keep it so, for days before; and within twenty-four hours the putrid part was thrown off blanched, the room was scentless, and my patient so far relieved that I felt no anxiety about her recovery. If the hydrochloric acid will act thus under such fearful conditions, how much more would it act on simple inoculation! I will add that I well remember hydrochloric acid being given by my late father, combined with decoction of bark, in typhus and typhoid fevers, in 1816-17, or 1817-18, with great success, and that those who had it in the earliest stages did the best. I have also given it myself, but much more freely. It would be well if Dr. E. G. Clarke's "Medicinæ Praxeans Compendium" was read more by the juniors of the profession—there is much to be gleaned from it; but unfortunately it is in Latin, an old work (two small volumes)—probably not to be had, as I had a difficulty to get one in 1824—first printed in 1800, June 4. There are many other disorders which, if treated in a similar way by other remedies, may be cured.

October 8.—I have just read a leading article in the *Times* of September 15, which referred to the sanitary state of the Turkish quarters, in the *Times*, September 13. It enables me to state that poisonous flies were not uncommon in England, as was stated in the *Times*, about July or August, 1865, from whose bite eight or ten persons died; but one case which came under my care was cured by one dose (twenty grains) of iodide of potash in a tumblerful of water on going to bed.

I am, &c., G. J. S. Camden.

REPORTS OF SOCIETIES.

THE CLINICAL SOCIETY OF LONDON.

Friday, October 12.

George W. Callender, F.R.S., President, in the Chair.

Cases illustrating the Behaviour of the Carbolised Catgut Ligature upon Human Arteries.

Mr. Bryant read a paper upon this subject. He said that the carbolised catgut, as made by the Apothecaries' Company, Virginia-street, Glasgow, had now been so freely employed since its introduction in 1869 by Professor Lister that the time had come when an estimate of its value might be arrived at. He, therefore, introduced the following cases supplied from his own practice, together with four preparations and drawings, in order to assist in solving the question. The first preparation was from a man in Guy's Hospital, who had had ruptured aneurism of the right common femoral artery, with ulcerative endocarditis. A catgut ligature was applied to the external iliac artery, but the man died of the heart affection fourteen hours subsequently. The inner and middle coats of the artery were then found completely divided by the ligature, and the external coat also divided in parts. Some clot existed above and below the ligature, and the catgut was intact. Preparation No. 2 was from a right common carotid artery, to which a ligature had been applied twelve days before death for supposed aortic and innominate aneurism, with the effect of relieving pain and other urgent symptoms. In this case the artery had been completely severed; there was clot above and below the point of separation, but it was not firmly adherent. The ligature had disappeared. Preparation No. 3 was that of a right subclavian artery ligatured with catgut thirteen days before death for ruptured traumatic axillary aneurism. The man had died from lung trouble; all the parts about the wound having gone on satisfactorily towards repair. After death, no suppuration was found about the wound; the artery and vein were normal, except that the former was ligatured. There was a firm clot in the vessel for half an inch above and the same distance below the ligature. All the coats of the artery had been divided and afterwards repaired. The knot of the ligature alone remained. Preparation No. 4 was from a right common femoral artery, ligatured nineteen days before death for elephantiasis Arabum of the leg. Death ensued from gangrene of the limb. Very little suppuration occurred at the wound. All the coats of the artery had been divided and repaired, and good clots existed above and below the ligature, the knot of which, with perhaps some of its loop, remained. In all these cases the inner and middle coats of the vessels had been probably divided at the time of operation, as would be done by any permanent ligature, the external coat afterwards by an ulcerative process, though in the first case this was partially accomplished in fourteen hours. Mr. Bryant stated that he had also ligatured ten other large arteries in their continuity with catgut, viz., five femoral, four external iliac, and one subclavian. One of these had died on the tenth day; in two, there was secondary hæmorrhage; and in the other cases an uninterrupted recovery, with little or no suppuration, ensued. In one of the femoral cases the wound healed by primary union, without one drop of pus. In no case was the antiseptic spray used. Rest, moderate pressure over the site of operation, and dry lint or water dressing were alone employed. In the single fatal case death ensued from pyæmia and cardiac disease. The inner and middle coats of the artery were there divided, and the outer coat ulcerated. Only the knot of the ligature remained. In the subclavian case, a little hæmorrhage took place on the fourth day, but was arrested by pressure, and the wound then healed. In one external iliac case, the wound, which had almost healed, bled on the twenty-ninth day, but pressure arrested the hæmorrhage, and all did well. These further cases led one also to conclude that the ligature at first divided the middle and inner coats, and then excited ulcerative action in the external coat. "If, therefore," said Mr. Bryant, "I cannot endorse what the distinguished introducer of the catgut ligature claimed for it in 1869, 'that by applying a ligature of animal tissue antiseptically upon an artery, whether tightly or gently, we virtually surround it with a ring of living tissue and strengthen the vessel where we obstruct it,' yet I may express my belief that, as the loop of the catgut ligature dissolves within an uncertain period, and there is not of necessity any sloughing or ulceration of the whole coats of the constricted artery, as must ensue where a more permanent material is employed, we have in the carbolised catgut the best ligature at our disposal."

Mr. Maunder said: It will be in the recollection of many that some years ago Mr. Lister advocated, by precept and practice, the use of carbolic silk for the ligature of an artery in continuity. Soon after the notification of this, I ligatured the common carotid with silk with antiseptic precautions. The wound quickly healed over the ligature, and I was delighted with the result. From silk, Mr. Lister progressed to catgut. It happens that I have tied nine arteries antiseptically, but only five with catgut, to which I shall confine my remarks; and I am bound to say that I was satisfied with the result. About three years ago I delivered some lectures at the Medical Society of London upon the Surgery of the Arteries; and on making inquiry concerning the use of catgut in the hands of other surgeons, I learned that several accidents of a most serious and fatal character had attended its use. I then stated "that the fate or behaviour of a given antiseptic catgut ligature, applied to the continuity of an artery, cannot be foretold." Since then other accidents of a serious character have reached my ears. It appears to me that if it is shown that certain casualties happen in connexion with the use of catgut, but which are not known when the time-honoured silk is employed, then the former ought to be discontinued. Serious consequences, such as solution, slipping of the knot, division of the coats of the artery in one instance, immunity from this in another, while death has followed from early hæmorrhage and embolism, have decided me—an enthusiast in its favour as I once was—never to use it again. It is obvious that no such accidents attend the use of silk.

Mr. Barwell said he had fortunately no post-mortem experience, but his views inclined towards those of Mr. Bryant. He had had five cases; all did well. The cutting through of the external coat was new to him. Greater force should not be employed than was necessary to occlude the artery or divide its internal coats. The ends of the ligature, moreover, should not be cut too close. Often the catgut ligatures spoiled by being kept too long in oil. With silk ligatures, however, there must be an opening right down to the artery, and from this cause he thought he had seen phlebitis arise. In a recent case of tying the subclavian and carotid the catgut ligatures did very well.

Mr. Sydney Jones asked what was the age of the patient just operated on. He also desired to know how long after the ligature of small vessels the ligatures were in being absorbed. He thought that in simple operations they tended to keep open or form troublesome sinuses.

Mr. Bryant said, in reply, that the age of the patient alluded to was twenty-nine, and that his arteries were perfectly healthy. He only spoke in this paper of arteries tied in their continuity. The ligatures, he thought, might exist for nineteen or twenty days. The gut ligature acted just like other ligatures, but then it was not necessary that the vessel should be actually sundered for its removal.

The President said that in each of the three Bartholomew's cases the ligature had been applied for aneurism. The ligature seemed to slip or yield, and pulsation returned in a few hours.

Recent Cases of Paracentesis Thoracis.

Dr. George H. Evans read notes of three cases of pleural effusion which had recently been under his care, in which he had performed paracentesis thoracis; and which cases seemed to illustrate some of the advantages of that operation:—1. A groom, aged twenty-three, was admitted into Middlesex Hospital on April 24, 1877. His previous health had been good. Three weeks before admission he had caught cold; sixteen days before admission he had felt pain in the right side of his chest, and had become short of breath. On admission his temperature was 101·6°; the respirations were 36. The right pleural sac was obviously full of fluid. On April 26, paracentesis was performed with Coxeter's aspirating syringe, and seventy-two ounces of clear serum were removed. He improved rapidly in health, and was discharged recovered on May 18. 2. A saddler, aged twenty-nine, was admitted on September 6, 1877. He had caught cold in November, 1876; was then in bed for four months, and had not since been fit for work. On admission his temperature was 98·2°; the respirations were 20. The right lung was healthy; the left pleural sac was full of fluid. On September 7 he was punctured with Coxeter's syringe (the syphon action only being used), and thirty-five ounces of rather cloudy serum were removed. Fat globules were found under the microscope in the fluid. He progressed rapidly to health, and was discharged convalescent on September 26. 3. A porter, aged thirty-two, of previous good health, was admitted on May 24, 1877. His illness had commenced in December, 1876, with pain in the left side. On admission, the left pleural sac was full of fluid, which had probably occupied it for some months. Temperature 98·6°; respirations 32. He was tapped on May 26, in the seventh interspace (Coxeter's aspirating syringe), but only fifteen ounces of serum were removed. On June 9 he was again tapped in the next interspace above, and fifty-five ounces of clear serum escaped. He then gradually improved in condition, and seemed to be doing well, when Dr. Evans ceased attending the hospital at the end of June. On July 24 he was discharged relieved, and made an out-patient. On Dr. Evans's return, the man was attending as an out-patient; and on August 15 his left chest was found to be fuller than before. Being readmitted on August 16, he was tapped on the 17th, and fifty-five ounces of serum were removed, with immediate improvement in the condition of his chest. He gradually improved in health and condition, with occasional suspicious signs at the upper part of the overworked right lung, which, however, had all disappeared, so that he was now convalescent, and rapidly gaining health and weight. Dr. Evans remarked that, having been for some years a strong advocate and admirer of the operation, he had been surprised to hear of and to read lately observations of much older and more experienced physicians rather in disfavour of the operation than otherwise. Of course, he must admit that, in many cases of effusion of serum into a pleural sac, the fluid disappeared without being artificially removed; but he believed that nobody would deny that this process involved usually a considerable amount of time, during which almost absolute rest was a necessary part of the treatment. Now, he could not see why one should not considerably shorten this interval by an operation of a very simple, and, as far as he had been able to ascertain, harmless description. He believed that the old doctrine, suggesting that the admission of air into the cavity during or after the operation would probably lead to the serous effusion becoming purulent, was now exploded. At all events, he had never seen nor heard of such a case, though he knew of certainly one and probably two cases in which the delay or neglect of paracentesis had been followed by a change from serum to pus, indicated in the one case, which he had followed throughout, by a rigor and afterwards a constant hectic temperature. As to the advantage of shortening the period during which fluid remained in the chest, one of the cases (No. 2) afforded an instance. The day before he was seen by Dr. Evans, he had, by the advice of his medical attendant, consulted an eminent hospital physician, whose advice was to the effect that he should rest at home for a month and then see him again, with the view of some action being taken in case the chest should be still occupied by fluid. Owing to the advice of a friend whom he met in the street, he came as an out-patient to the Middlesex Hospital, where, being admitted, he was at once tapped, and in three weeks afterwards sent out in good health.

Dr. Cayley said there were other reasons for speedy operation. One of these was the risk of tuberculosis, especially in children. In these cases he thought the uncompressed lung usually became affected—perhaps owing to the prolonged hyperæmia, the other being but little used.

Dr. C. T. Williams agreed with the practice of early tapping. Yet cases occurred to show that this was not necessary. Thus, in the case of a child twelve years old, whose pleura was full of fluid, he wanted to tap, but the parents refused. Gradually the child got better, and was now (five years after) quite well, and with no appearance of the old disease. He thought the compressed lung was most liable to tubercle.

Dr. Southey thought the question before the meeting was that of tapping whilst yet the fluid was serous; there could be no doubt of the rule when the fluid became purulent. Simple serous fluid was often very rapidly absorbed. As to the period for operation, he was guided by these rules: quick breathing, much displacement, fever, and diminution of urine. There was a risk in using too strong a vacuum, so he preferred the syphon method. With too great a vacuum blood might be effused.

Dr. James Pollock thought the operation was generally successful, but would wait a month to see the result of rest, quiet, etc. He preferred the syphon method. If there was too great delay the lung got fastened down. He thought the unaffected side was most apt to become tubercular.

Dr. Goodhart also thought the unaffected side was most apt to become tubercular, partly from hyperæmia, but partly, also, because the other was practically more at rest.

Mr. George Brown said that at the North-Eastern Hospital for Children the early operations did best.

Dr. Lees referred to a case where the fluid long remained serous, notwithstanding hectic symptoms.

Dr. Evans having replied, the meeting adjourned.

THE PATHOLOGICAL SOCIETY.

Tuesday, October 16.

Charles Murchison, M.D., LL.D., F.R.S., President, in the Chair.

New Volume of the Transactions.

The President laid on the table the volume of *Transactions* for the last session. It was in every respect worthy of the Society, and contained more plates than any of its predecessors. In a few words the President expressed his hope that the session just commenced might be as successful as the last.

Aneurism of the Heart.

Dr. Wickham Legg showed this specimen, which occurred in the left ventricle of a man of thirty-eight years. He had been a sailor, and served eighteen years in the navy. There was no history of syphilis. The aneurisms were in the form of bulgings, due to the growth in the cardiac wall of a firm white material, disposed in islets amongst the muscular fibres. The growth occurred in various places, very abundantly where the aneurisms were situated, but also at the attachment of the mitral valve and elsewhere. Microscopically examined, there were seen, at the edges of the growth, cells and nuclei embedded in a semi-fibrillar matrix. Towards the centre of the mass only dark granular material was found. These appearances, Dr. Legg said, were considered characteristic of syphilitic gumma. But there was no further evidence of syphilis in the body, and a clinical history of syphilis had not been obtained.

Dr. Stretch Dowse asked whether the cerebral capillaries had been examined microscopically, and whether atheroma was found in the aorta or in the arteries at the base of the brain.

Dr. Legg replied that the aorta was atheromatous, but not unusually so.

Cerebral Aneurism.

Dr. Wickham Legg also exhibited this specimen. A man of twenty was brought insensible to St. Bartholomew's Hospital, and soon died. It was reported that for some time previously he had been half-starved, and that the day before he had eaten a heavy meal of tea, new bread, and periwinkles, had become greatly excited and had danced, and finally had fallen down insensible. Post-mortem there was found extensive meningeal hæmorrhage. An aneurism occupied the anterior communicating artery, not larger than a millet-seed, and granular on the surface like a mulberry. Its cavity communicated with the lumen of the artery, and its wall was unruptured. The hæmorrhage had therefore some other source, but this could not be found. Only ten cases of unruptured aneurism of the anterior communicating artery had been recorded. There was no cardiac or renal disease in this case, and the body was remarkably free from atheromatous change.

Dr. Hare inquired whether the source of the hæmorrhage had been discovered; and

Dr. Legg replied in the negative.

The President remarked that in Dr. Peacock's collected cases of cerebral aneurism, embolism and syphilis had been found as important elements in the causation.

Dr. Thomas Barlow exhibited a specimen of aneurism of a branch of the anterior cerebral artery from a case of apoplexy. This was a specimen of the miliary aneurisms described first by Charcot and Bouchard. It was taken from the brain of a man of fifty-two, who had been a heavy drinker, and who was admitted into Charing-cross Hospital on account of dyspeptic symptoms. These symptoms (pain in left hypochondrium, vomiting, and wasting) were found post-mortem to depend on a scirrhus of the stomach. The only nervous signs presented by the patient were—a slight thickness in articulation, slight flattening of the left side of the face, and slight collapse of the left nostril. No history of previous hemiplegia could be obtained. On the third day after admission, without any warning, the patient had a general convulsion, which was slightly more pronounced on the left side, and which lasted ten minutes. After this he became comatose, his temperature rose to 100°, and he died within twenty-four hours. At the post-mortem there were found, in addition to the scirrhus of the stomach, granular cystic kidneys. Along the outer border of the right optic thalamus thero was an old narrow *plâque jaune*. There were no changes in the cortex. In the substance of the anterior lobe—viz., at the root of the right superior frontal convolution—there was a cerebral hæmorrhage about the size of a hazel-nut. In the centre of this was a small ruptured aneurism, of the size of a hemp-seed. It was composed of two parts—viz., a hard spherical nucleus, and an outer shaggy portion. It was situated on a minute vessel about half an inch long, a branch of the right anterior cerebral. On the proximal side of the aneurism, quite close to it, were found subsequently three minute dilatations, each not bigger than a pin's head, which must be regarded also as aneurismal. Another minute vessel opened into the aneurism before deseribed. All the vessels of the circle of Willis were extensively atheromatous, but the anterior cerebrals were not so in the ordinary sense. There was no source discoverable whence emboli could have been carried to this small branch of the anterior cerebral, and it seemed probable that the aneurisms had arisen from primary disease of the arterioles. Dr. Barlow believed that the discovery occasionally of small aneurisms in cerebral apoplexies ought strongly to suggest that in every case of cerebral apoplexy with granular kidney and hypertrophied left ventricle the local condition of the small vessels should be investigated before taking refuge in the hypothesis of increased arterial tension as a cause of the apoplexy.

Dr. Douglas Powell said that six years ago he had exhibited for Dr. Quain a specimen of a very similar kind from a girl of about twenty. A portion of the brain presented a group of minute aneurisms. Charcot spoke of the condition as occurring in quite young subjects.

Dr. Hilton Fagge said that there were certain difficulties in the way of Dr. Barlow's theory of the frequent connexion between miliary aneurism and apoplexy. Charcot and Bouchard found renal disease in very few of their cases of miliary aneurism, while contracted kidney is very common in cases of cerebral hæmorrhage. The account also given by these pathologists of the common situations of miliary aneurism, and of the other morbid states of the brain associated with it, did not agree with what is familiar to all in ordinary cerebral hæmorrhage. Miliary aneurisms were said to occur in numbers in some cases; and if they were so, it was not remarkable that one or more of them should be found in the centre of an extravasation of blood in the brain.

Dr. Greenfield said that he had seen several cases of cerebral hæmorrhage in which miliary aneurisms were found on the smaller vessels. In the last case of the kind that he had observed the hæmorrhage had proceeded, beyond all question, from an aneurism of a branch of the posterior cerebral artery. Therefore some cases of hæmorrhage were due to aneurism. On the other hand, he had failed to find aneurism in the usual seat of ordinary cerebral hæmorrhage; and this showed that there were other causes of cerebral hæmorrhage than aneurism. In cases of miliary aneurism Dr. Greenfield had found a peculiar condition of the cerebral vessels. It was not usually atheroma, but a condition in which the arteries were rigid, standing open when cut, and yet translucent—a kind of cirrhosis. This state had never been described by a special name. Much had been said about aneurism due to embolism. But there were many cases of embolism without aneurism, and in most cases of "aneurism from embolism" the condition of the clot was peculiar. Therefore they should hesitate to accept the conclusion that aneurism was in any large number of cases due to embolism.

Dr. Coupland suggested that the condition of cerebral vessels just described by Dr. Greenfield might be that called hyaline fibroid by Sir William Gull.

Dr. Greenfield replied that the specimens referred to would be submitted to the Committee upon the subject of the vessels in Bright's disease.

Dr. Goodhart said that Bouchard and Charcot had given a description of the state of the vessels associated with miliary aneurism closely resembling that of the hyaline-fibroid change of Gull and Sutton. With respect to the connexion between aneurism and embolism, he had, in drawing attention to it, never suggested that embolism was the only cause of aneurism; and he had pointed out that the clot in these cases was peculiar, and caused inflammatory changes in the wall. Dr. Goodhart showed a sketch of an aneurism due to embolism originating in ulcerative endocarditis.

The President said that when cerebral hæmorrhage occurred in kidney disease, a change was allowed to be present in the vessels not amounting to aneurism, though there might be aneurism in some cases. The age at which cerebral aneurism occurred was of much interest. No doubt a certain number of cases of apoplexy were due to rupture of aneurism, and in a large proportion in young subjects. Of eighty-six cases collected by Dr. Peacock, nine were quite young; and a case had come under Dr. Murchison's own observation in a patient of twenty-four. Therefore there was a strong presumption that cerebral apoplexy in young persons was due to aneurism.

Fibrinous Balls and Clot in Left Auricle in Mitral Stenosis.

Dr. Wickham Legg's third specimen was a heart in which three balls of fibrin were found in the left auricle, while the mitral opening was contracted. The patient, a man of twenty, died suddenly. The concretions of fibrin were large, spherical, and smooth, and presented no evidence of adhesion to the wall. One of them had found its way into the orifice and arrested the circulation. The concretions had undoubtedly resulted from the stenosis. A second specimen of the same kind was found in a woman who died slowly of mitral stenosis; the concretion exactly resembled a billiard-ball. Similar specimens were preserved in the museums of St. George's and St. Thomas's Hospitals.

The President said that there was also a specimen of the same kind in the Middlesex Hospital museum.

Dr. Hilton Fagge mentioned two cases of sudden death in mitral stenosis. In one of these an ordinary ante-mortem clot was found. In the other case a clot adherent to the valve had given way, and one portion of it had been folded over and driven into the orifice, which it blocked.

Dr. Ewart exhibited a specimen of ante-mortem clot filling the left auricle in mitral stenosis. A woman of thirty-seven had suffered from rheumatism at twenty-one and twenty-six, and for the last two years of her life from symptoms of chronic

disease of the heart. No clinical examination could be made. For months she had presented cyanosis, and this deepened greatly before death. Post-mortem both mitral and tricuspid openings were found to be contracted. The left auricle was filled by a clot, which was not solid until it had been put into alcohol. When pricked *in situ* it yielded a few drops of a grumous fluid. Nearly all the surface had been adherent to the endocardium; but two spaces were free from adhesions, and channels were found along which the blood had been transmitted from the mouths of the pulmonary veins. Even these had been plugged before death. The clot appeared to have commenced in the auricular appendage and grown thence.

(*To be continued.*)

NEW INVENTIONS AND IMPROVEMENTS.

UNGUENTUM PETROLEI.

The substance introduced by Messrs. Allen and Hanbury, of Plough-court, Lombard-street, E.C., into this country from America, under the name of "Unguentum Petrolei," is a hydrocarbon of the class of paraffins, as are cosmoline and vasiline, which it closely resembles. It is of about the consistence of good lard, has no smell, in colour reminds us somewhat of the old "unguentum citrinum," and possesses the same useful properties that vasiline does. It is bland and non-irritating; it keeps any length of time, apparently, without becoming rancid, and may be exposed to any kind of atmosphere without undergoing chemical change. It has long been, we understand, in use in America, where it enjoys a widespread popularity; and it will, we doubt not, come into extensive use here also, as a vehicle for making ointments, as a demulcent in various diseases of the skin, and as a lubricant. It is recommended "as an application to burns and scalds, inflamed and excoriated skin, chapped nipples, inflamed hæmorrhoids," etc., and as a dressing for wounds. It is said, also, to be much superior to lard for lubricating the finger and hand, the forceps, and the catheter, in obstetric practice; and for protecting surgical instruments, both steel and hard rubber, from rust and cracking—which, as it does not undergo oxidation, is in all probability quite true. And, as it is not acted on in any way by the secretions of the stomach and bowels, it will also, according to the importers, be found very serviceable for administration internally.

LIEBREICH'S SYRUP OF CHLORAL.

We need not dwell here on either the immense value of the hydrate of chloral as a nerve-sedative, or the importance of being able to feel sure when prescribing the drug that it will be obtained in a perfectly pure state. Unexpected inconveniences, and even serious danger, have sometimes resulted from its use; and Dr. Oscar Liebreich, Professor of Therapeutics in the University of Berlin, who introduced it into medicine, has, as is well known, insisted that it is of the highest importance that absolute purity should be obtained in the manufacture of the drug, and that all the solutions of it should be free from bye-products. In a valuable paper by him on Chloral, published in the *Practitioner* for June in the present year, he says, "I have good reason to believe that a large proportion of the chloral, both solid and liquid, which is at present employed in medicine is not trustworthy in respect to its purity. I am, moreover, well assured—and I wish to draw the attention of practitioners to this point—that many of the impurities of chloral, when it is not prepared with great strictness and tested with scrupulous accuracy, are of a kind seriously to detract from its uniformity of effect." And further on he adds, "The accidents which have occurred frequently in England are, I am satisfied, largely due to the impurities and uncertainty of the many preparations, and especially of many of the solutions in vogue." He tells us also that "there is no practical means by which the purity of chloral in solutions can be tested"; and that, according to the best authorities, a very large proportion of the solutions current in medical and pharmaceutical practice are of an impure, untrustworthy character, and therefore liable to produce dangerous results.

Messrs. Corbyn, Stacey, and Co., of High Holborn, London, have therefore met a very decided want in undertaking to supply a solution of chloral hydrate which shall be guaranteed as of the highest purity and efficiency, and of equal and standard excellence, being prepared under the immediate supervision and direction of Dr. Oscar Liebreich himself. Each tablespoonful of the syrup contains fifteen grains of chloral, and it is issued in bottles bearing Dr. Liebreich's signature. It will be known and should be ordered or prescribed under the title of "Syrupus Chloralis, Liebreich." Practitioners will unquestionably be glad to avail themselves of a preparation concerning the perfect purity of which there can be no doubt.

PATENT PRINTED PILLS.

Druggists and pharmaceutists have of late shown wonderful ingenuity in making medicine pleasant to the eye and not displeasing to the palate; and their attention has especially, and perhaps it may be said most successfully, been directed to improving the manufacture of pills. Almost any drug can now be exhibited in the pill-form, and pills or pilules may be had coated in various ways, so as to be tasteless and to look nice. But Messrs. Burgoyne, Burbidges, and Co., of Coleman-street, London, have gone a step further, and made each pill itself tell its composition and strength. Their "Printed Pills" are really a very ingenious invention. The pills are beautifully made; are tasteless, odourless, perfectly round and smooth, and quickly soluble; and, according to the description given by the makers, "they will keep for any length of time in any climate, and the coating is purely vegetable, and absolutely innocuous." Each sort of pill has a distinctive colour, so that they are almost attractive in appearance; and, moreover, each is stamped with its formula and dose in clear and distinct letters; as, "Pil. Al. c. Myrrhâ gr. v.," "Pil. Podophyl. gr. $\frac{1}{4}$," etc., according to order. We do not see what further improvement can be made, unless some druggist can bring out a "Self-administering Pill." Joking apart, however, the "Patent 'Star' Coated and Printed Pills" are a very striking and useful novelty. And it may be added, they are not dearer than other coated pills.

MEDICAL NEWS.

Queen's University in Ireland.—The following degrees in Medicine and Surgery, and diplomas in Midwifery, were conferred by his Grace the Duke of Leinster, Chancellor of the University, on October 12:—

Doctor in Medicine.—October, 1877.—First Honour Class: William Allen, Galway; James Clarke, Belfast; William Whitla, Belfast. Upper Pass Division: Gervase Robert Percy, Belfast; William John Sprott, Belfast. Lower Pass Division: Daniel Francis Barry, Cork; Patrick Maurice Carleton, Belfast; John Power Carmody, Cork; Thomas Reid Denham, Belfast; Robert E. Donovan, Cork; Isaac Chichester Dundee, B.A., Galway; Charles Frederick Knight, Cork; Joseph Stanislaus Lawlor, Galway; Robert Lindsay Love, B.A., Galway; Michael J. Lyden, Galway; John Wesley Megarry, Belfast; Thomas M. O'Brien, Galway; Patrick O'Connor, Galway; John O. G. Sandiford, Cork; James Stuart, Belfast; Garnett George Tatham, Galway; David Taylor, Belfast; Henry Tomkins, Belfast and Galway; Francis Henry Walmsley, Belfast; John Edward Walsh, Cork; Edward Alexander White, B.A., Belfast; James O'Brien Williams, Galway; John Wilson, B.A., Cork and Belfast; Thomas John Withers, Belfast. June, 1877.—Archibald R. H. Bland, Cork; William Henry Bracken, Belfast; George Henry Bull, Cork; William Corry, Belfast; Robert D. Donaldson, Cork; Hugh L. Donovan, Cork; J. J. Kent Fairclough, Belfast; Denis Harrington, Galway; Henry O'Neill, Belfast; William A. Quayle, Belfast; Robert H. Robinson, Belfast; Henry George Thompson, Galway and Cork; William Henry Thornhill, B.A., Cork; James Tidbury, Cork; Charles Workman, Belfast.

Master in Surgery.—October, 1877.—Denis Harrington, M.D., Galway; Henry O'Neill, M.D., Belfast; William Allen, Galway; Daniel Francis Barry, Cork; John Power Carmody, Cork; James Clarke, Belfast; Thomas Reid Denham, Belfast; Joseph Stanislaus Lawlor, Galway; Robert Lindsay Love, B.A., Galway; Michael J. Lyden, Galway; Thos. M. O'Brien, Galway; Patrick O'Connor, Galway; Gervase Robert Percy, Belfast; John O. G. Sandiford, Cork; William John Sprott, Belfast; James Stuart, Belfast; John Edward Walsh, Cork; Edward Alex. White, B.A., Belfast; James O'Brien Williams, Galway; Thomas John Withers, Belfast. June, 1877.—Dr. J. J. Adams, Belfast; David Bradley, M.D., Belfast; John Mulrennan, M.D., Cork; Archibald R. H. Bland, Cork; George Henry Bull, Cork; William Corry, Belfast; Robert D. Donaldson, Cork; Hugh L. Donovan, Cork; J. J. Kent Fairclough, Belfast; Wm. A. Quayle, Belfast; Robert H. Robinson, Belfast; Henry G. Thompson, Galway and Cork; Wm. H. Thornhill, B.A., Cork; James Tidbury, Cork; Charles Workman, Belfast.

Midwifery.—October, 1877.—Denis Harrington, M.D., Galway; Henry O'Neill, M.D., Belfast; Maurice J. O. Sullivan, M.D., Cork; William Allen, Galway; Daniel Francis Barry, Cork; Patrick Maurice Carleton, Belfast; James Clarke, Belfast; Thomas Reid Denham, Belfast; Robert E. Donovan, Cork; Charles Frederick Knight, Cork; John Wesley Megarry, Belfast; John O. G. Sandiford, Cork; William John Sprott, Belfast; James Stuart, Belfast; Edward Alex. White, B.A., Belfast; Thomas John Withers, Belfast. June, 1877.—Dr. J. J. Adams, Belfast; Archibald R. H. Bland, Cork; George Henry Bull, Cork; William Corry, Belfast; Hugh L. Donovan, Cork; William A. Quayle, Belfast; William H. Thornhill, B.A., Cork; James Tidbury, Cork; Charles Workman, Belfast.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At the ordinary monthly examination meetings of the College, held on Tuesday, Wednesday, and Thursday, October 9, 10, and 11, the following candidates were successful:

Previous Examination for the Licence to practise Medicine.

Butler, Frances Jane.

Final Examination for the Licence to practise Medicine.

Abbott, Charles Edward.
Canavan, Patrick.
Finegan, Lawrence Patrick Joseph.
Kehoe, Matthew Joseph.
McCann, Joseph George.
Mackey, Stephen William.
Macnamara, Rawdon, jun.
Miley, William Kildare.
Mitchell, Daniel.
Nicholson, Joseph John.
Owen, William Hall.
Pollard, Evelyn Richard Hugh.
Russell, Thomas O'Dwyer.
Smith, James.

For the Licence to practise Midwifery.

Abbott, Charles Edward.
Canavan, Patrick.
Finegan, Lawrence Patrick Joseph.
Kehoe, Matthew Joseph.
McCann, Joseph George.
Mackey, Stephen William.
Macnamara, Rawdon, jun.
Miley, William Kildare.
Mitchell, Daniel.
Nicholson, Joseph John.
Owen, William Hall.
Pollard, Evelyn Richard Hugh.
Russell, Thomas O'Dwyer.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

CRIPPS, W. HARRISON, F.R.C.S.—Assistant-Surgeon to the Royal Free Hospital, Gray's-inn-road.

STURGE, W. A., M.D. Lond., M.R.C.P.—Assistant-Physician to the Royal Free Hospital, Gray's-inn-road.

NAVAL, MILITARY, &c., APPOINTMENTS.

WAR OFFICE.—MEDICAL DEPARTMENT.—Surgeon-Major John Wickliffe Jones retires upon temporary half-pay; Surgeon Samuel Baptiste Gamble, M.D., resigns his commission; Deputy Surgeon-General James Pattison Walker, M.D., Bengal Establishment, to be granted the honorary rank of Surgeon-General on retirement.

BIRTHS.

BRAILEY.—On October 9, at 38, King's-road, Brownswood-park, N., the wife of Wm. Arthur Brailey, M.D., of a son.

HECTOR.—On August 28, at Wellington, New Zealand, the wife of James Hector, M.D., C.M.G., of a son.

HOPKINS.—On October 15, at Hovingham House, Highbury New-park, the wife of Alfred Boyd Hopkins, M.R.C.S. Eng., of a son.

LUPTON.—On October 2, at Stratford-on-Avon, the wife of Harry Lupton, L.R.C.P. Lond., of a daughter.

STOCKER.—On October 9, at Peckham House, Peckham, the wife of Alonzo H. Stocker, M.D., of a daughter.

MARRIAGES.

BAILY—BUCK.—On June 8, at Hindmarsh-square Church, Adelaide, South Australia, Frederic W. Baily, M.R.C.S., L.R.C.P., of The Parade, Kensington, Adelaide, to Helen, eldest daughter W. C. Buck, Esq., J.P., of Rosemont, Adelaide.

CULIMORE—HIRSCH.—On September 12, at St. Stephen's Church, Ootacamund, Daniel Henry Culimore, F.R.C.S.I., Surgeon Madras Army, to Emma Esther, third daughter of Jacob Francis Hirsch, of Oak Lodge, Kilburn.

HARRIS—CARR.—On October 9, at Christ Church, Cheltenham, Edwin P. Harris, Captain Suffolk Artillery Militia, younger son of the late C. P. Harris, Esq., of Newnham, Cambridge, to Maria Augusta, eldest daughter of J. K. Carr, M.D., Deputy Surgeon-General, retired.

HUMPHREYS—DUNCAN.—On October 11, at the parish church of Dagenham, Essex, Henry Humphreys, M.A., M.D., of Eccles, Assistant-Physician to the Hospital for Sick Children, Pendlebury, Manchester, to Louisa, youngest daughter of the late Edward Duncan, M.R.C.S., of Leadenhall-street.

LITTLE—SHAW.—On October 10, at Buglawton Church, Cheshire, David Little, M.D., of Manchester, to Marian, second daughter of Anthony Shaw, of Bank House, Congleton.

DEATHS.

BONNEY, FRANCIS AUGUSTUS BURDETT, L.R.C.S. Edin., L.S.A., at Elm House, Queen's Elm, Brompton, on October 13, in his 74th year.

BROWNE, JAMES HERBERT VALENTINE, son of James V. Browne, M.D., Surgeon to the Galway County Infirmary, at Prospect Hill, Galway, on October 7, in his 20th year.

DAVIES, FREDERICK, F.R.C.S., of 124, Gower-street, London, at Ryde, Isle of Wight, on October 7, aged 68.

JOHNSON, JAMES, M.R.C.S., at Grove Lodge, Fulham, on October 14, aged 65.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made and the day of election (as far as known) are stated in succession.

WORKSOP DISPENSARY.—Resident Surgeon. Candidates must be unmarried and doubly qualified. Applications, with testimonials, to J. Wilson Hamil, M.D., The Dispensary, Worksop, on or before October 27.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the censns of 1871.

RESIGNATIONS.

Castle Ward Union.—Mr. J. H. M. Gallwey has resigned the Pontelan District; area 19,839; population 2083; salary £20 per annum. Also the Workhouse; salary £30 per annum.

Drayton Union.—Mr. F. J. Sandford has resigned the Second District area 10,295; population 1485; salary £16 per annum. Also the Workhouse salary £25 per annum.

Drayton Union.—Mr. J. Stewart has resigned the Fifth District; area 11,201; population 2438; salary £21 per annum.

Southmolton Union.—Mr. F. F. Dickenson has resigned the Fourth District; area 25,887; population 2760; salary £50 7s. per annum. Mr Timothy Daly has resigned the Eighth District; area 10,638; population 1496; salary £20 per annum.

APPOINTMENTS.

Blandford Union.—James Bartlett, L.R.C.P. Edin., L.S.A. Lond., L.F.P.&S. Glasg., to the Holworth District.

Buckinghamshire.—James A. Wanklyn, M.D., as Analyst for the County until January 1, 1880.

Lincoln Union.—Joseph Goodall, M.R.C.S., L.R.C.P., and L.S.A. Lond., to the First District.

Llanfyllin Union.—Edward J. Edwards, M.B. Lond., L.S.A., L.R.C.S. Edin., to the Llanfyllin District and the Workhouse.

Merthyr Tydfil Union.—John Lewis William Ward, M.R.C.S. Eng., L.R.C.P. and L.M. Edin., to the Workhouse. Cornelius Biddle, M.R.C.S. Eng., and L.R.C.P. Lond., to the Town and Vaynor District.

Monmouth Union.—George O. Willis, L.R.C.S. Edin., L.R.C.P. Edin., to the Rockfield District.

St. Asaph Union.—Albert E. Lloyd, M.R.C.S. Eng., L.R.C.P. Edin., to the Rhuddlan District.

Shrewsbury.—James A. Wanklyn, M.D., as Analyst for the Borough.

Walsingham Union.—Robert Herbert Foot, M.B. and M.D. Univ. Dub., L.R.C.S. and L.M. Ire., to the Wells District.

THE Committee of Westminster Hospital are now able to announce that they have received half the amount (£12,000) required to defray the expenses of remodelling the building. Amongst the larger donations recently contributed are sums of £1000 from the residuary estate of the late Mr. James Graham, £500 from "A Friend to the Hospital," and £210 from the Corporation of the City of London. The improvements and alterations which have been in course of progress for the last few months are now so near completion that it is expected the Hospital will be ready to open for the reception of patients on the 23rd inst.

DR. WALTER FERGUS, of Marlborough, in writing to a contemporary, says:—"I was called to see a child five years old, who had been suddenly seized with symptoms of poisoning—sickness, diarrhœa, and great general depression. Nothing was found to account for this state of things, but, on examining a box of counters for the game of 'Go Bang,' one set of the counters was found to be bright green. The colour was easily removed, and had a very sour taste. The tests for arsenic showed the presence of that poison to a considerable extent, and as it is just possible that the child may have suffered from using and handling the counters, it may be well to give a word of warning."

DEATH OF SANITÄTSRATH DR. ALBRECHT ERLENMEYER.—This distinguished physician, so well known in the province of psychiatry, died (in his fifty-fifth year) last month at his residence at Bendorf, near Coblenz, where since 1849 he has had a large private asylum for mental and nervous diseases. He has just published the second edition of "Die luëtischen Psychisen" (Syphilitic Nervous Diseases), and was on the point of publishing the sixth edition of his "Wie sind Seelenstorüngen in ihrem Beginn zu behandeln?" (How are Mental Diseases to be Treated at their Commencement?)—a work that has been translated into every language in Europe except English.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

A Tutor, and A Successful Candidate.—You will find a list of those gentlemen who passed the Arts Examination at the College of Surgeons in the issue of this journal for last week.

M.D. Oxon.—It was founded by Dr. John Radcliffe; it was his successor, the equally celebrated Dr. Mead, who, according to Dr. Johnson, "basked in the broad sunshine of life more than almost any other man."

An Old Member.—If a fine skeleton, Professor Flower will no doubt accept it, but not as that of such a notorious criminal. The skeleton of Thurtell was presented to the museum by Mr. Percy Wormald on the death of his father.

DE LISLE ALLEN FUND.—AN APPEAL.

Since our last notice of this case, Dr. De Lisle Allen, who for more than two years was incapacitated from following his profession, has died in Bethlehem Hospital. An appeal is once more made to enable his widow and daughter to keep a home, and to put them in a position to earn a livelihood for themselves. Dr. W. B. Richardson, 12, Hinde-street, Manchester-square, is treasurer; and subscriptions will be received either by him or by the Union Bank of London, Argyle-place, Regent-street.

(Signed) J. E. ERICHSEN, F.R.C.S., F.R.S.
BENJAMIN W. RICHARDSON, M.D., F.R.S.
J. HUGHLINGS-JACKSON, M.D.
THOMAS SMITH, F.R.C.S.

A Manchester Teacher.—The return from the provincial schools is not yet made up.

Mr. T. Cawley, F.R.C.S. Edin.—Mr. Wadd, of facetious memory, states that when George II. went to Newmarket he made several doctors of physic. These, by way of joke, were called "Jockey Doctors." The qualification to which you allude is not registrable.

A Student, Bristol.—Having had two years at your school, you will, on coming to this metropolis to finish your studies, be considered a *first-year's student;* but full credit will be given to you for the time spent at Bristol. The return from the metropolitan schools will be found on another page. We cannot express any opinion on the matter; you can draw your own conclusions by referring to the "*pass and pluck*" report from the College of Surgeons. We believe the subject to which you allude was discussed at a meeting of the Council of the College on the 18th inst.

Aquæ.—The Chelsea Company have completed the construction of three out of the four new subsiding reservoirs at Molesey; and the Southwark and Vauxhall and Grand Junction Companies have acquired land for the construction of suitable storage reservoirs and other works at Hampton.

D. D. H.—Pinel, the great French physician, was appointed Physician to the Bicêtre in 1793, and entered on his great work of non-restraint treatment of the insane towards the end of that year. Holland has made great advance in her treatment of the insane. In 1837, Professor Van der Kolk succeeded in procuring the intervention of the Legislature. Commissioners were appointed, and laws passed for the regulation of existing asylums. In Germany, insanity had for a long period received much attention. The asylum of Lounenstein, near Dresden, was the first to adopt more humane modes of treatment. Austria is in advance of Prussia in the treatment of those afflicted with mental diseases. The new public asylums at Vienna and Prague are, in their construction and management, worthy of commendation.

Alcohol.—Yes, in New York the spirit trade was forbidden in 1837; but the result was that wine—so designated—was greatly more brandied, and the total consumption of spirits was not diminished.

Pharmacologist.—A return to the House of Commons, showing whether the guardians of provincial unions supplied cod-liver oil, quinine, and other expensive medicines, was a short time ago issued. Dr. Lush's return gives details for every union outside the metropolitan area, from which it appears that the majority of the unions do, in some form or other, provide costly medicines. Among 121 unions in widely different parts of the country, and of extensively different industrial circumstances, about one-sixth do not supply costly medicines. The medical officer, as part of his contract, affords that aid to the sick.

C. C.—The rank of Presidency Surgeon was conferred on Dr. Esdaile, a surgeon in Calcutta, by Lord Dalhousie—then Governor-General of India—"in acknowledgment of the services he had rendered to humanity." Dr. Esdaile performed numerous severe and tedious operations, without the infliction of pain, upon natives in whom he had induced the mesmeric sleep.

M. T. M.—Yes; the Cape of Good Hope University resolved to throw open, without reserve, degrees, honours, and pecuniary emoluments at their disposal, to candidates who desire to be examined in places beyond the bounds of the Cape Colony, upon the condition that the Government of the Colony or the State where such candidates reside contributed £200 annually to the funds of the University.

MEDICAL ADMINISTRATIVE POLITY, ET ALIA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I venture to put on paper some comments of the proceedings of the Medical Council which I have read in the *Medical Times and Gazette*, trusting to the *bonhommie* of the redaction (editorial body) for their insertion in the same journal.

What I want to make very clear is the incommensurable superiority of the Brazilian curriculum over the modest projects and requirements of the English Council. No one can matriculate in Brazil in the Faculties of Medicine without previous approval in separate examinations on the following subjects:—Portuguese, French, English, Latin, arithmetic and algebra, rhetoric, philosophy, history, and geography. After matriculation the student must follow a six years' course of academic study, being submitted to an annual examination; and when he fails in this he must repeat the year. At the end of the six years he must pass the examination of the year, and then a clinical examination, and finally must defend a printed thesis, and explain a certain number of aphorisms of Hippocrates; after which (and generally in the Rio de Janeiro Faculty in presence of the Emperor) he receives the doctor's gown, bands, cap, and and ring. This is the only medical qualification at present existing; but a want is felt of a second (less highly educated) class of practitioners, more apt to deal with the middle and lower classes, which are making their appearance in the Brazilian social organisation, the present physician class being the most convenient for the necessities of the landed proprietors and their slaves. Notwithstanding these rigorous exigencies as regards the home supply, the Brazilian Government admits to a pass examination and sustation of thesis all foreign medical and surgical qualified professionals, having only excluded bearers of Philadelphia diplomas. The majority of these foreign licentiates are decidedly inferior in illustration to the native physicians.

The Faculties have a *personnel* of a director, vice-director, secretary, eighteen *professores cathedratici*, and fifteen substitutes. The course of the first year comprises physics, chemistry and mineralogy, and descriptive anatomy; of the second, botany and zoology, organic chemistry, physiology, and descriptive anatomy; of the third, physiology, general and pathological anatomy, and general pathology; of the fourth, surgery, medicine, and obstetrics; of the fifth, medicine, regional anatomy, operative surgery, materia medica and therapeutics; of the sixth, hygiene and history of medicine, legal medicine, and pharmacy. Clinical surgery occupies the third and fourth years' students; clinical medicine those of the fifth and sixth years. The course is very complete, but I think it defective in not placing pharmacy in the third year, in not placing pathological anatomy in the sixth year, general pathology in the fourth, and in not separating materia medica from therapeutics. I trust that the present exposition may induce the Medical Council to make official inquiries, and, verifying its exactness, to place the Brazilian Faculties of Bahia and Rio de Janeiro on the same footing as to registration of qualification as that which must be accorded to the graduates of Paris, Montpelier, Vienna, Madrid, etc. It is not a little humiliating to compare English and even the Edinburgh curricula with this of the Brazils.

I regret the singular persistence of the Council and the concurrence of the University of Edinburgh and others in the (to me) incomprehensible violence of the forcible uniting of the professions of physician and surgeon. Both will lose by the innovation, which is opposed to the best traditions of medicine. This Conjoint Scheme I hold to be a pernicious levelling scheme, which will demoralise the corporations and the universities. It is a bad unitarian centralising idea, which will yield bitter fruits. I trust that Ireland and Scotland may, in the legitimate exercise of the little autonomy left them, reject any such project. The profession of pharmacy is here organised with a due regard to the public safety. Every pharmaceutist must have passed three years of practical service in a pharmacy, and afterwards a three years' course of lectures, with yearly examinations. The scholastic year in Brazil in all the Faculties and schools is of nine months' duration. The examinations are all public. The pass examinations of foreign medical men may be held in French, Latin, or Portuguese. The Physician of the Imperial Princess (actual Regent) is a viscount. A most distinguished physician of Rio is a grandee of the empire. Many physicians and eminent surgeons are barons. A distinguished physician of the province of Minas is also a viscount. These titles are not, however, hereditary. Brazil still offers a fair field for young physicians and surgeons of high attainments. What is indispensable is facility in acquiring languages. It is much to be regretted that some therapeutical society in Europe does not take measures to obtain from Brazil a collection of articles of the materia medica of the country, which is most rich in invaluable agents for encountering disease. The old Galenists would have turned the facilities of modern commerce to much better account. A neutral substance called Vixirino, from the name of a physician (Dr. Vixira), who was the chief instrument of popularising its properties, has been extracted from the Cinchona ferruginea, which abounds in the province of Minas Geraes and parts of San Paulo, and is proved a very effective substitute for quinine, and preferable to this when there is any gastric disturbance. I have employed it on a large scale—now as a tonic, now as an antiperiodic, now as a neurosthenic—with great success. I see that in Europe dog's milk has been preconised as an excellent remedy for rachitic children. Now, for the last two hundred years dog's milk has been used in the interior of Brazil for weakly and ill-nourished children. It is surprising what a number of fresh European discoveries are old news in the interior of this country. An interesting fact is the successful employment of the flesh of the rattlesnake as broth, and also stewed, in inveterate syphilis, and even in cases which have all the characters of cancer.

Some time ago I saw a dispute in the medical journals of London as to the reality of the existence of centenarians. Those who doubt the fact receive a weekly contradiction (even a more frequent one) in Brazil. Cases of longevity of 100 years are very common; of 110 are frequent; from that age to 120 are not uncommon; and even as high as 135 occur and are well authenticated. There is a village and district near San Paulo (city) called Santo Amaro, where the longevity was formerly great, and many old people are still to be found there. It is a mountainous, cold district. The cattle and horses are diminutive but powerful, and the people, who are laborious, moral, and hardy, often attain 120 years. Very long-livers were a number of inhabitants of the Azores brought here as colonists. I knew one who died aged 114 years, and several who exceeded 100. These cases occur in Africans, in Indians, in native whites, and even (as among these Azorians) among Europeans. I am &c.,

RICHARD GUMBLETON DAUNT, M.D. Edin.

Campinas, San Paulo, Brazil, September.

OPEN SPACES.

Mr. Cross's Enclosure Bill was brought in to defend the rights of the general population in waste lands, and to preserve open spaces for the recreation of the poorer classes. The Act is generally recognised as a compromise between the owners of the lands and those who oppose their enclosure. No enclosure, as a general rule, will be allowed within a certain distance of large towns; and when enclosures are effected, facilities are given for the protection of the rights of the poor commoners, and of the inhabitants of the neighbouring towns.

A HINT.

The Japanese are said to be most skilful operators and dissectors on account of their extreme delicacy of touch. This is chiefly attributable to their training in acquiring the Chinese written character, which is an essential feature in the education of every Japanese gentleman. The beauty and intricacy of this character, it is stated, are such that years of patient labour are required to master it.

Corrigendum.—In Mr. E. Marlett Boddy's paper on Neuralgia, in our issue of the 6th inst., at page 384, line 39, *for* "any amount of *sudorifics*," *read* "any amount of *soporifics*."

COMMUNICATIONS have been received from—

Dr. R. G. Daunt, Brazil; Dr. Llewelyn Thomas, London; Dr. Carter, Liverpool; Dr. R. Lawson, Banstead; Dr. Sparks, London; Mr. G. J. Cayden, Rhyl; Mr. Metcalfe Johnson, Lancaster; Mr. J. Ingpen, London; Dr. Greenfield, London; Dr. Lawrence Hamilton, London; Dr. J. W. Moore, Dublin; Mr. J. W. Bartleet, Edgbaston; Mr. W. Sargent, Bolton; The Secretary of University College; The Secretary of the Clinical Society; Mrs. Dinah de L. Allen, London; The Librarian of the Charing-cross Hospital; Dr. Gillespie, St. Thomas's Hospital; The Secretary of the London Hospital; The Secretary of the Leeds School of Medicine; Messrs. Pagny, Wallace, and Co, London; Dr. Byrom Bramwell, Newcastle-on-Tyne; Mr. W. E. Poole, London; Mr. John Chatto, London; Mr. Timothy Holmes, London; Mr. B. R. Wheatley, London; Dr. J. Mitchell Bruce, London; Dr. Thomas Barlow, London; Mr. T. M. Stone, London.

BOOKS AND PAMPHLETS RECEIVED—

APPOINTMENTS FOR THE WEEK.

October 20. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 1½ p.m.

22. *Monday*.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

Medical Society of London, 8½ p.m. Mr. J. Knowsley Thornton, "Removal of Fibroid Uterus and both Ovaries." Dr. C. Theodore Williams, "A Case of Persistent Pyrexia, during Phthisis, reduced by Diet." Dr. R. J. Lee, "Maternal Impressions."

23. *Tuesday*.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

Royal Medical and Chirurgical Society, 8½ p.m. Dr. William Miller Ord, "On the Œdema (Myxœdema) observed in the so-called Cretinoid Condition of Women."

24. *Wednesday*.

Operations at University College, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex. 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 1½ p.m.

25. *Thursday*.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing-cross, 2 p.m.; St. Thomas's (ophthalmic operations), 4 p.m.

26. *Friday*.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1½ p.m.; Guy's, 1½ p.m.

Clinical Society, 8½ p.m. Dr. Henry Thompson, "A Case of Hysteria, with Contraction of the Lower Limbs, Anæsthesia, and Ischæmia, in a Boy." Mr. Lawson (for Dr. Aikman), "A Case of Injury to the Lower Portion of the Spinal Cord, followed by Wasting and Contraction of the Muscles of the Lower Extremities." Mr. Bellamy, "A Case of Unusually Large Urethral Calculus." Dr. Dowse, "A Case of Cerebro-Spinal Lateral Sclerosis."

Quekett Microscopical Club, 8 p.m. Dr. James Edmunds, "On the Immersion Paraboloid."

VITAL STATISTICS OF LONDON.

Week ending Saturday, October 13, 1877.

BIRTHS.

Births of Boys, 1188; Girls, 1204; Total, 2392.
Average of 10 corresponding years 1867-76, 2213·1.

At the Royal Observatory, Greenwich, the mean reading of the barometer last week was 29·94 in. The highest reading was 30·45 in. at the beginning of the week, and the lowest 29·69 in. on Saturday morning.

* The figures for the English and Scottish towns are the number enumerated in April, 1871, raised to the middle of 1877 by the addition of six years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the number enumerated in April, 1871.

ORIGINAL LECTURES.

A CLINICAL LECTURE

ON DISLOCATION OF THE HIP INTO THE OBTURATOR FORAMEN.

By TIMOTHY HOLMES, M.A., F.R.C.S. Eng.,
Surgeon to, and Lecturer on Surgery at, St. George's Hospital.

GENTLEMEN,—The subject of our lecture to-day is a case of dislocation of the hip into the obturator foramen. I will first read the notes of the case. The patient was a young man, tall and very muscular, who was thrown from a carriage in Piccadilly on June 7, and brought at once to the Hospital, presenting the symptoms of dislocation of the hip into the thyroid foramen well marked. He was in great pain, but too much distressed and agitated to be able to describe exactly the seat and nature of that pain. The injured (right) limb looked much longer than the other, but accurate and repeated measurement, taken from the spine of the ilium to fixed points in the limb, on the two sides, showed that this was due entirely to twisting of the pelvis. Below the outer side of the buttock was a deep pit, at the bottom of which the trochanter was to be felt. The limb was abducted and everted to a moderate degree. On its inner side was a tense band, evidently formed by the adductor muscles (chiefly the adductor longus), to which region the pain and tenderness were chiefly referred. The head of the bone was not perceptible. He remembered that in his fall this leg was pointed outwards.

Chloroform was administered, and when the muscles were completely relaxed, attempts were made to reduce the dislocation by the method of flexion and inward rotation figured in Bigelow's work. The head of the bone did not, however, enter the acetabulum, though the position of the trochanter approached much more nearly to the normal. I then stood over the patient, and placed my foot on the horizontal ramus of the pubes, while the bystanders held the pelvis firm. The dislocation was then easily reduced by direct traction of the flexed thigh vertically upwards, along with slight to-and-fro or "wagging" movements, the head entering the acetabulum with a very perceptible snap.

A long splint was put on, and he was kept in bed for about twelve days. Beyond a little swelling and some tenderness of the part for a few days, there were no after-symptoms.

Dislocations of hip are rarely seen in hospital, especially at the present day, when the introduction of chloroform has rendered them easily reducible, so that it is less necessary to send them from their own homes. The great difference in the treatment of these injuries in old and recent times depends on the use of anæsthetics more than on any change in the theory of reduction. In these, as in all other dislocations, many methods of reduction will succeed, if only the head of the bone can be freely moved, for when it is once moved from its new position it will be pulled into its proper place by the elastic recoil of the muscles, which are mechanically on the stretch. This is still more the case when the patient is under anæsthesia, for then the recoil of these muscles is not opposed by any forcible or irregular action of their antagonists. Thus we see that many different methods of manipulation will succeed in reducing similar dislocations, even though some of the movements may be the very reverse of each other.

The most important change in surgical teaching on the pathology of dislocations is that the chief obstacle to reduction is now thought to reside, not in the muscles, but in the ligaments. We owe this change, no doubt, chiefly to the treatise of Bigelow, though there is nothing absolutely novel in his teaching—in fact, he himself is careful to observe that a portion of it is as old as Hippocrates. And those who have read the thoughtful and laborious treatise of Fabbri will be aware that he also showed that the obstacle to reduction in dislocations of the hip was not always or usually to be found in the muscles, though he attributes it to a different part of the ligamentous apparatus from that on which Bigelow has laid so much stress.

Still, no one is more conscious of the value of Bigelow's work than I am. If I dissent from any of his statements it is only in matters of less importance. The great cardinal fact which he has pointed out is, I think, indisputable; and it is, as he says, at the root of all successful treatment of this injury—viz., that the untorn portion of the capsule is the chief agent in fixing the head of the bone in its unnatural position, and that therefore this ligamentous band forms the chief agent in opposing the surgeon's efforts to replace the bone, especially when those efforts are not judiciously directed.

Now, much information on this subject may be obtained, as Fabbri has pointed out, by producing these dislocations in the dead subject; and he has given directions which are tolerably easy to follow for doing this. I have here specimens of each of the common forms of dislocation which I produced on the dead body in the post-mortem room some years since. All such manipulations require great force, and they may be, and very probably are, accompanied by more laceration of the articular capsule than takes place in accidents. However this may be, you will always find that in producing a dislocation of the hip on the dead body you tear away from the bone almost the whole capsule—except that very strong accessory part of it which is called by Bigelow the Y-ligament (but which is more accurately described in our books by the simple name of ilio-femoral), and a variable portion of the common capsular ligament near it. You will see that this is the case by inspecting these specimens.

The dislocation into the foramen ovale, which is the subject of these remarks, is usually produced in the living body (as it was in our patient) by a fall on the abducted limb. In the fall the foot gets fixed against the ground, and the falling weight of the body rotates the thigh so as to drive the head of the bone through the capsule inwards and backwards.

These movements are thus imitated in Fabbri's manipulation. He directs that the limb to be dislocated is first to be forcibly abducted till the capsule is heard to crack, and the head of the femur can be felt passing out of the joint on the inside of the thigh; then the knee is to be bent to a right angle, and the manipulator is to take the foot in one hand and the knee in the other, rotating the foot violently upwards and outwards, and the knee downwards and inwards, till a further cracking of the ligaments is felt, which Fabbri attributes to the tearing of the ligamentum teres; and now the head of the bone can be felt through the skin covering the tuber ischii. Finally, by extending the limb and turning the knee a little outwards, the head of the femur will be guided round the cotyloid cavity to the foramen ovale. This will be sufficient to indicate the method of production of the dislocation.

As for the anatomy, there can be no question that the internal portion of the capsule must be freely torn, and the ligamentum teres broken away. It seems probable, also, that the pectineus and some fibres of the adductor brevis, and possibly also the longus, are lacerated, and that the obturator nerve is put on the stretch and may also be lacerated. But it must be confessed that we have no accurate knowledge of the extent of the laceration in these cases, recent dissections of the accidental dislocation being, as far as I know, wanting.

The *symptoms* are always well marked. One of the main symptoms of all dislocations of the hip is the change in outline of the trochanteric region of the buttock. In the dislocations backwards and upwards (those which are classed in Sir Astley Cooper's nomenclature as "on the dorsum" and "into the sciatic notch") the trochanter is displaced outwards, and the buttock is broader, as is shown in Sir Astley Cooper's well-known pictures. In the forward or inward dislocations, on the contrary (those into the obturator foramen, and on to the pubes), the trochanter is displaced inwards, and the width of the buttock diminished. This symptom was strikingly marked in our patient, and is well shown in a sketch of him taken by Mr. Branson, one of my dressers. This alteration in the position of the trochanter forms one of the most prominent symptoms of the obturator dislocation, and I thought it well to bring it distinctly under your notice, since an unfortunate ambiguity in Sir Astley Cooper's language, which has been followed by later authors, has obscured this easy diagnostic point. In describing the dislocation on the dorsum, he says—"The trochanter is less prominent than that on the opposite side, for the neck of the bone and the trochanter are resting on the line of the surface of the dorsum ilii; on a comparison of the two hips the roundness of the dislocated side will be found to have disappeared." This description seems to me to be very obscure; but the plate which Sir Astley Cooper gives, and which has been copied by every author who has followed him, shows accurately what he means, and what may always be verified in this inquiry—viz., that the buttock is broader, but flatter, and the trochanter unnaturally near the spine of the ilium, whilst in the two anterior dislocations the trochanter is driven downwards, and lies at the bottom of a deep pit, being in the immediate neighbourhood of the acetabulum.

Another leading symptom is the length of the limb. In

many specimens of obturator dislocation this length may be absolutely increased, and sometimes very much so. Fabbri says that by accurate measurement he has been able to detect from one to two inches of lengthening, referring—I presume, to dislocations produced on the dead body. But this will vary with the precise position of the head of the bone. The nearer the head of the bone lies to the horizontal ramus of the pubes—*i.e.*, the further forward in the thyroid foramen it lies,—and the more nearly the dislocation approaches to the pubic, the less will be the lengthening, and the more at the same time will the limb be abducted and everted, as it is in that form of dislocation. In our patient, though the limb at first looked very much longer than the other, accurate measurement proved that this was not the case, but that the apparent lengthening depended on a twisting of the pelvis, no doubt instinctively adopted with the view of relaxing, as far as might be, the stretched muscles on the inner side of the thigh, as well as the psoas and iliacus. I think it highly probable that in many of the cases in which the limb has been said to be "lengthened," the lengthening, on accurate measurement, would have turned out to be apparent only, as in this instance.
