PRINCIPAL CONTENTS.

ENCYCLOPÆDIA BRITANNICA.

G

G represents the sound of Gamma, the third letter of the Greek alphabet; but in the Latin alphabet, and in the alphabets derived from the Latin (including our own), it holds the place which Z held in the different Greek alphabets. The history of this remarkable change is well known. It has been already stated (see letter C) that in the 5th century before our era, the distinction between the *k*-sound and the *g*-sound became lost at Rome: apparently the surviving sound was *g*; but, at all events, the symbol K went out of use, being retained only in a few familiar abbreviations, and C (which was the Latinized form of the Greek Γ) remained. Thus in the column of Duillius we find C representing the original surd in *castreis*, *cepet*, &c., but the sonant in *macistratos*, *leciones*, *ceset* (*i.e.*, *gessit*), &c. When, in the 3d century, the two sounds were again distinguished, two symbols were again required; but the K was not taken again to represent the surd; C, the old symbol for the sonant, was put to that use. A new symbol was therefore necessary for the sonant *g*-sound, and it was found by modifying C into G. This G should then have replaced C as the third letter of the alphabet, where it would have stood, as before, between B and D, the sonants of the labial and dental classes respectively. But this was not done. The symbol C was left in its old place with its new value of *k*. The new symbol G was set in the seventh place of the alphabet, which had been vacated by Z, the representative of a sound not used by the Romans of that day. G is found for the first time in the inscription on the tomb of Scipio Barbatus. Its invention is attributed to Spurius Carvilius.

There can be no doubt that the sound of G in Latin, as of Γ in Greek, was always the sonant guttural—which we hear in *gate*, &c. It was not the sonant palatal, which it represents in *gem* or *gin*. This sound began to supplant it about the 6th century of our era, but only when it preceded *e* or *i*—the two vowels which require a position of the tongue nearer to the palatal than to the guttural consonants. We find this change of sound in French and in Italian. In the Latin part of our vocabulary there is naturally the same weakening; whereas, in words of English origin, the original guttural is generally preserved, even before *e* or *i*, as in *get* and *give*. Sometimes it has been weakened at the end of a word, as in *bridge* and *ridge*, which were originally *brigg* and *rigg*, and are still so in the north of England.

It is noteworthy how a *g*-sound made its appearance in French at the beginning of words which originally began with the *w*-sound. An example is *guerre*, a borrowed word from the Teutonic; we see it in Old High German as *werra*, a quarrel. The Gauls apparently found a difficulty in producing the initial German sound, and (there being no difference in the position of the back of the mouth for *g* and *w*, except that the passage between the back-palate and the tongue is entirely closed for *g*, but left slightly open for *w*) they did not keep the *w* pure, but sounded a *g* before it by unintentionally closing the oral passage for a moment. The same thing is seen in *guérir*, which corresponds to Gothic *varjan*; in *garant*, which we have in English *warrant*; *garnir* corresponds to Anglo-Saxon *warnian*. In a few instances the word so modified seems to have been originally Latin, as *gaîne*, a sheath, the Latin *vagina*.

This French change has led to a curious result in England. Many words were introduced by the Normans into England in their French form, which were already existent there in their Teutonic form. Thus we have such pairs as *wile* and *guile*, *wise* and *guise*, *warranty* and *guarantee*, *wager* and *gage*, and many others. It is strange that in so many cases each of the pair of words should have remained in use, and with so little change of meaning.

GABELENTZ, Hans Conon von der (1807–1874), a distinguished linguist and ethnologist, born at Altenburg, October 13, 1807, was the only son of Hans Karl Leopold von der Gabelentz, chancellor and privy-councillor of the duchy of Altenburg. From 1821 to 1825 he attended the gymnasium of his native town, where he had Matthiæ (the eminent Grecist) for teacher, and Hermann Brockhaus and Julius Löbe for schoolfellows. Here, in addition to ordinary school-work, he carried on the private study of Arabic and Chinese; and the latter language continued especially to engage his attention during his undergraduate course, from 1825 to 1828, at the universities of Leipsic and Göttingen. In 1830 he entered the public service of the duchy of Altenburg, where he attained to the rank of privy-councillor in 1843. Four years later he was chosen to fill the post of "landmarschall" in the grand-duchy of Weimar, and in 1848 he attended the Frankfort parliament, and represented the Saxon duchies on the commission for drafting an imperial constitution for Germany. In November of the same year he became president of the Altenburg ministry, but he resigned office in the following August. From 1851 to 1868 he was president of the second chamber of the duchy of Altenburg; but in the latter year he withdrew entirely from public life, that he might give undivided attention to his learned researches. He died on his estate of Lemnitz, in Saxe-Weimar, on the 3d of September 1874. In the course of his life he is said to have learned no fewer than eighty languages, thirty of which he spoke with fluency and elegance. But he was less remarkable for his power of acquisition than for the higher talent which enabled him to turn his knowledge to the genuine advancement of linguistic science. Immediately after quitting the university, he followed up his Chinese researches by a study of the Finno-Tataric languages, which resulted in the publication of his *Élémens de la Grammaire Mandchoue* in 1832. In 1837 he became one of the promoters, and a joint-editor, of the *Zeitschrift für die Kunde des Morgenlandes*, and through this medium he gave to the world his *Versuch einer mordwinischen Grammatik* and other valuable contributions. His *Grundzüge der syrjänischen Grammatik* appeared in 1841. In conjunction with his old school friend, Julius Löbe, the Germanist, he brought out a complete edition, with translation, glossary, and grammar, of Ulfilas's Gothic version of the Bible (Leipsic, 1843–46); and from 1847 he began to contribute to the *Zeitschrift der deutschen morgenländischen Gesellschaft* the fruits of his researches into the languages of the Suahilis, the Samoyeds, the Hazaras, the Aimaks, the Formosans, and other widely-separated tribes. The *Beiträge zur Sprachenkunde* (Leipsic, 1852) contain Dyak, Dakota, and Kiriri grammars; to these were added in 1857 a *Grammatik u. Wörterbuch der Kassiasprache*, and in 1860 a treatise in universal grammar (*Ueber das Passivum*). In 1864 he edited the Manchou translations of the Chinese Sse-shu, Shu-king, and Shi-king, along with a dictionary; and in 1873 he completed the work which constitutes his most important contribution to philology, *Die melanesischen Sprachen nach ihrem grammatischen Bau und ihrer Verwandschaft unter sich und mit den malaiisch-polynesischen Sprachen untersucht* (Leipsic, 1860–73). It treats of the language of the Fiji Islands, New Hebrides, Loyalty Islands, New Caledonia, &c., and shows their radical affinity with the Polynesian class. He also contributed most of the linguistic articles in Pierer's *Conversations-Lexicon*.

GABII, an old, and at one time important, city of Latium, on the Via Prænestina, or road to Præneste, between 12 and 13 miles E. of Rome. Long before the foundation of Rome, Gabii appears to have been one of the largest of the Latin cities; and, according to an old tradition noticed by Dionysius and Plutarch, Romulus and Remus were educated there. During the greater part of the regal period of Rome Gabii maintained its ground, and it only fell into the hands of Tarquin the Proud through a stratagem contrived by his son Sextus, who was afterwards slain by the inhabitants, when, on the expulsion of his family from Rome, he sought refuge in the town. After this period Gabii always appears in history as the ally or dependent of its more powerful neighbour, and it gradually fell into such a state of decay as to become a proverb of desolation—*Gabiis desertior*. The fame of its cold sulphurous waters gave new life to the place in the reign of Tiberius; and the emperor Hadrian, one of whose favourite residences was not far distant, at Tivoli, appears to have been a very liberal patron, building a town-house (*Curia Ælia Augusta*) and an aqueduct. After the 3d century Gabii practically disappears from history, though its "bishops" continue to be mentioned in ecclesiastical documents till the close of the 9th. The principal relic of the ancient city is a ruined temple (probably of Juno) on a hill now crowned by the ruins of the mediæval fortress of Castiglione. It is a hexastyle structure of uncertain date, uniting the characteristics of Greek and Italian architecture; but the fragments of the pillars are not sufficient to show whether it belonged to the Ionic or the Corinthian order. Its length is about 48 English feet. Since 1792, when explorations were commenced by the Prince Borghese, a large number of minor antiquities have been discovered at Gabii, and the sites of the forum and a theatre have been ascertained. The statues and busts are especially numerous and interesting; besides the deities Venus, Diana, Nemesis, &c., they comprise Marcus Agrippa, Tiberius, Germanicus, Caligula, Claudius, Nero, Trajan and Plotina, Hadrian and Sabina, Aurelius Antoninus, L. Septimius Severus, Septimius Geta, Gordianus Pius, &c. The inscriptions relate mainly to local and municipal matters. In the neighbourhood of Gabii were valuable and extensive quarries of an excellent building stone, known as the *lapis Gabinus*, which was largely used by the Romans. It was a hard and compact variety of volcanic tufa, and closely resembled the *lapis Albanus*, to which, however, it was superior. The name of *cinctus Gabinus* was given by the Romans to a peculiar method of girding the toga, with one end thrown over the head and the other fastened round the waist, which was employed by the founder of a new town, or by the consul when he "declared war in the name of the Roman people, or devoted himself to death for his country."

See Ciampini, *Monumenta Vetera* (which contains a plan and elevation of the temple); Gallatti, *Gabii antica città di Sabina scoperta*, 1757; Fea, *Lettere sopra la scoperta delle rovine della città di Gabio*, 1792; Visconti, *Monumenti Gabini della villa Pinciana*, Rome, 1797, new edition, Milan, 1835; Gell, *Rome and its vicinity*; Nibby, *Contorni di Roma*; and Canina, *Storia e topographia di Roma antica*. An interesting comparison of the temple of Juno with the similar building at Aricia was contributed by Abeken to the *Annali dell. instit. di corr. arch.*, Rome, 1841.

GABLER, GEORG ANDREAS (1786–1853), a German philosophical writer of the school of Hegel, was born at Altdorf, in Bavaria, where his father was professor, on the 30th of July 1786. In 1804, when his father was translated to Jena, he accompanied him to that university, where he completed his studies in philosophy and law, and became one of the most enthusiastic of the hearers and disciples of Hegel. After holding successive educational appointments at Weimar, Nuremberg, and Ansbach, he, in 1817, became one of the masters in the gymnasium at Baireuth. In 1821 he was appointed rector, and in 1830 general superintendent of schools. In 1827 he brought out the first volume of a *Lehrbuch der philosophischen Propädeutik als Einleitung zur Wissenschaft*, in which his design was to give a popular exposition of the Hegelian philosophy, which he himself regarded as fitted to give "absolute satisfaction to the faculties of thinking and knowing." In 1835 he succeeded Hegel in the Berlin chair. His other works were a treatise *De veræ philosophiæ erga religionem Christianam pietate* (1836), and *Die Hegel'sche Philosophie*, a defence of the Hegelian philosophy against Trendelenburg, which was published in 1843. He died at Teplitz, September 13, 1853.

GABLER, JOHANN PHILIPP (1753–1826), a learned Protestant theologian of the school of Griesbach and Eichhorn, was born at Frankfort-on-the-Main, June 4, 1753. He had already acquired an extensive acquaintance with the ancient languages and their literatures, as well as with the philosophy of Wolf and the theology of Baumgarten, when, in his nineteenth year, he entered the university of Jena as a divinity student. In 1776 he was on the point of abandoning theological pursuits, when the arrival of Griesbach inspired him with new ardour. After having been successively repeteut in Göttingen and teacher in the public schools of Dortmuud (Westphalia) and Altdorf (Bavaria), he was, in 1793, appointed second professor of theology in the university of the last-named city, whence he was translated to a chair in Jena in 1804. At Altdorf he published (1791–93) a new edition, with introduction and notes, of Eichhorn's *Urgeschichte*; this was followed, two years afterwards, by a supplement entitled *Neuer Versuch über die mosaische Schöpfungsgeschichte.* He was also the author of several original works which were characterized by much critical acumen, and which had considerable influence on the course of German thought on theological and biblical questions. From 1798 to 1811 he was editor of the *Theologisches Journal*, first conjointly with Hänlein, Ammon, and Paulus, and afterwards unassisted. He died at Jena, February 17, 1826.

GABLONZ, the chief town of a circle in Bohemia, is situated in a hilly country on the river Neisse, about 6½ miles S.E. of Reichenberg. It possesses a Catholic and a Protestant church, a city school, a hospital, and a fine new town-house. Its principal industry is the manufacture of glass, the export of which reaches an annual value of over 6 million guilders. It has also net and cloth factories. The population in 1869 was 6752.

GABOON RIVER, or Rio de Gabão, called Olo' Mpongwe by the Mpongwe natives, and Aboka by the Fan, is, in reality, not a river but an estuary on the west coast of Africa. It lies immediately north of the equator, disemboguing in 0° 21′ 25″ N. lat. and 9° 21′ 23″ W. long. At the entrance, between Cape Joinville, or Santa Clara, on the N., and Cape Pangara, or Sandy Point, on the S., it has a width of about 18 English miles. It maintains a breadth of about 7 miles for a distance of 40 miles inland, when it contracts into what is known more correctly as the Rio Olambo, which is not more than 2 or 3 miles from bank to bank. Two rivers, the Nkomo or Como and the Mbokwa or Bokoe, discharge into the upper portion of the Rio Olambo, both taking their rise in the country of the Sierra dal Crystal. The former, which far exceeds the other in the length of its course, has its head waters, according to M. Genoyer (1862), in that part of the range which is known to the natives as Anenguenpala, or the "Water-jug." Mr Winwood Reade reached the rapids in 1862, and Mr R. B. N. Walker, one of the traders in the Gaboon, has ascended for about 30 miles up the river, which had still 2 fathoms of water. Captain Burton, who in 1870 sailed up the Mbokwa as far as Tippet Town or Mayyan, a little way beyond the confluence of the Londo, found it there "some 50 feet broad," with a tidal rise of nearly 7 feet. There are a great number of other streams that fall into the Gaboon, but only two are worthy of special mention,—the Remboa, which, rising like the Nkomo and Mbokwa in the Sierra dal Crystal, enters the estuary at its south-east corner, and the Eko or Cohit, which is the largest of the right hand affluents. Though the whole estuary is studded with islands, reefs, and shoals, none of the islands are of great extent except Coniquet, or King's Isle, at the mouth of the Cohit, and Embeneh, or Parrot Island, in the middle of the channel.

The four principal tribes in the country of the Gaboon are the Mpongwa, the Fan, the Bakalai, and the Boulous. The first of these tribes, usually called *Gabons* or *Gabonese* by French writers, is distributed along both banks of the "river," occupying the villages of Kringer, Quaben, Louis, Libreville, and Glass on the right side, and those of George Town and Denis on the left. According to Captain Burton, they are now one of the most civilized of African tribes, displaying a keen interest in trade, and great ease and urbanity of manner. There are three grades or quasi-castes among them—1st, those of pure blood, who rejoice in the title of Ongwá Ntye or "sons of the soil"; 2d, the children of freemen by slaves; and, 3d, the slaves themselves. Marriage is by purchase, and polygamy is the rule, but the women hold a position of considerable social influence, and maintain a secret society of their own. The men are excellent makers of canoes, and, within the present generation, they have learned to build boats of considerable size after the European model. From childhood both sexes are habitual smokers of tobacco or hemp—the tobacco being imported from America, although it might be readily cultivated in the country. A baptismal rite, almost identical with the Christian ceremony, is administered to the new-born child. The language of the Mpongwa has been reduced to writing by the American missionaries. As early as 1847 they published a grammar and vocabulary at New York; and in 1859 the American Bible Society brought out a Mpongwa translation of the books of Proverbs, Genesis, part of Exodus, and the Acts. The language belongs to the same family as the Sechwana, the Zulu, &c., and is characterized, says Captain Burton, by inflexion, by systematic prefixes, a complex alliteration, and the almost unparalleled flexibility of the verb, which can be modified in several hundred different ways. M. Catteloup describes it as "riche, criard, imagé, et compliqué." It has been adopted by the Pahouins, the Bakalai, and the Boulous as a kind of commercial *lingua franca*, and bids fair to become the dominant language of the coast, if it does not give way before English or French, which have both become familiar in a corrupted form to a large number of the maritime population.

The Fan, whose name appears under the various forms of Fanwe, Panwe, Phaouin, and Paouen, are new comers to the Gaboon district, having, it is said, appeared there for the first time in 1842. They are described as of mean height, chocolate complexion, and remarkably regular features. Their reputation as cannibals is evidently well founded; but they seem to partake of human flesh rather as a ceremonial observance than as an ordinary means of nourishment, and both Winwood Reade and Captain Burton speak in favourable terms of their general characteristics. They are skilful workers in iron, and manufacture cross-bows which discharge poisoned darts 40 or 50 yards. Tattooing is practised by both sexes, and the women often stain the whole body red or yellow. The tribe has come very little into contact with Europeans, but it is moving towards the coast, and will probably before long be the dominant race in the Gaboon.

The Gaboon was early visited by the Portuguese explorers, and it became one of the chief seats of the slave trade. It was not, however, till well on in the present century that Europeans made any more permanent settlement than was absolutely necessary for the maintenance of their commerce. In 1839 Captain Bouet of the "Malouine" obtained for France the right of residence on the left bank, and in 1842 he secured better positions at Louis and Quaben on the right bank. The chief establishment, called Le Plateau, at Libreville, was founded in 1845, and gradually acquired considerable importance. In 1867 the troops numbered about 1000, and the civil population about 5000, while the official reports about the same date claimed for the whole colony an area of 8000 square miles, and a population of 186,000. A large building with arcades at Libreville served as Government house, and there were pretty extensive warehouses, a hospital, and a small dockyard, as well as gardens, and a nursery for coffee plants and fruit trees. At some little distance off a convent was founded in 1844 by Mgr. Bessieux. In consequence of the war with Germany the colony was practically abandoned in 1871, and the establishment at Libreville is now maintained only as a coaling depôt. There are numerous English trading ports along the shores of the estuary, as at Glass Town and Olemi; and even when the French influence was at its greatest almost the whole commerce of the Gaboon was in English hands. The chief articles of export are ivory and beeswax; to which may be added caoutchouc, ebony, and camwood. Mission stations are maintained by French, English, American, German, and Portuguese societies.

See Bowditch, *Mission from Cape Coast Castle to Ashantee*, &c., 1819; E. Bouet-Willaumez, *Descr. nautiques des côtes de l'Afrique Occidentale*, 1846; Pigeard "Rapport addressé a M. Montagnies de la Roque," in *Annales maritimes*, 1847; J. L. Wilson, *Western Africa*, 1858; Winwood Reade, *Savage Africa*, 1863; *Annales des Voyages*, 1868; Du Chaillu, *Journey to Ashangoland*, 1867; "Notice d'une Carte," in *Bull. de la soc. géog.* 1869; Catteloup, in *Revue maritime et coloniale*, 1874; Burton, *Two Trips to Gorilla Land*, 1876; Coello's map in *Boletin de la soc. geogr. de Madrid*, 1878.

GABRIEL (גַּבְרִיאֵל *i.e.*, man of God, Γαβριήλ) is the name of the heavenly messenger (see Angel) who was sent to Daniel to explain the vision of the ram and the he-goat, and to communicate the prediction of the Seventy Weeks (Dan. viii. 16; ix. 21). He was also employed to announce the birth of John the Baptist to Zechariah, and that of the Messiah to the Virgin Mary (Luke i. 19, 26). Both Jewish and Christian writers generally speak of him as an archangel—a habit which is readily accounted for when Luke i. 19 is compared with Rev. viii. 2, and also with Tobit xii. 15. In the apocryphal *Book of Enoch* (c. ix.) he is spoken of as one of "the four great archangels," Michael, Uriel, and Suriel or Raphael being the other three. His name frequently occurs in the Jewish literature of the later post-Biblical period. Thus, according to the Chaldee paraphrase of Pseudo-Jonathan, the man who showed the way to Joseph (Gen. xxxvii. 15) was no other than Gabriel in human form; and in Deut. xxxiv. 6 it is affirmed that he, along with Michael, Uriel, Jophiel, Jephephiah, and the Metatron, buried the body of Moses. In the Targum on 2 Chr. xxxii. 21 he is named as the angel who destroyed the host of Sennacherib; and in similar writings of a still later period he is spoken of as the spirit who presides over fire, thunder, the ripening of the fruits of the earth, and similar processes. In the Koran great prominence is given to his function as the medium of divine revelation, and, according to the Mahometan interpreters, he it is who is referred to by the appellations "Holy Spirit" and "Spirit of Truth." He is specially commemorated in the calendars of the Greek, Coptic, and Armenian churches.

GAD (גָּד) in Hebrew and Chaldee means "luck"; hence, in the Phœnician and Babylonian cultus, the god of luck, who is mentioned in Isa. lxv. 11 (where for "that troop" should be read "Gad"), and whose name appears in several names of places, such as Baal-Gad (Josh. xi. 17, xii. 7); possibly also in Dibon-Gad, Migdol-Gad, and Nahal-Gad. Gad was the name given by Leah, the wife of Jacob, to the patriarch's seventh son, the first-born of Zilpah, her maid; see Gen. xxx. 11, where the Hebrew K'tib is בְּגָד, and the K'ri בָּא גָד. The former is adopted by the LXX., and rightly rendered ἐν τύχῃ (Vulgate *feliciter*); the latter reading is adopted in the Targums and Peshito, which translate "luck is come," and by the Samaritan and Ven., which interpret the expression as meaning "a troop (or army) is come." This last rendering has doubtless been influenced by Gen. xlix. 19, where the name is played on as if it were גְּדוּד, "a plundering troop"; "Gad, a plundering troop shall plunder him, but he shall plunder at their heels." Of the personal history of Gad nothing is related. According to Gen. xlvi. 16, he had seven sons when he went down to Egypt along with Jacob; and in Num. xxvi. 15 these appear as seven families, one of the names, however, being changed (Ozni for Ezbon). At the Exodus the tribe numbered 45,650 fighting men (Num. i. 25); but they declined to 40,500 during the forty years' wandering in the wilderness (Num. xxvi. 18). During the subsequent period the fortunes of this tribe were very closely connected with those of the tribe of Reuben. At the division of the country a portion in the trans-Jordanic territory was, at their special request, allotted to them by Moses (Num. xxxii. 33), and this arrangement was carried out by Joshua; but considerable difficulty arises when the attempt is made to define the precise limits of the district thus assigned. It is certain that Gad never extended further west than the Jordan; but in different passages we find its northern, eastern, and southern boundaries stretched as far as to the Sea of Galilee, Salkah in the desert, and the river Arnon respectively. In the book of Numbers (xxxii. 34) the cities of Gad appear to lie chiefly to the south of Heshbon; in Joshua xiii. 24–28 they lie almost wholly to the north; while other texts present discrepancies that are not easily reconciled with either passage. That Gad, at one time at least, held territory as far south as Pisgah and Nebo would follow from Deut. xxxiii. 21, if the rendering of the Targums, revived by Ewald and Diestel, were to be accepted—"and he looked out the first part for himself, because there was the portion of the buried lawgiver;" it is certain, however, that, at a late period, this tribe was localized chiefly in Gilead, in the district which now goes by the name of Jebel Jilad. Possibly some cities were common to both Reuben and Gad, and perhaps others more than once changed hands. Both tribes were pastoral and warlike; but the latter seems to have excelled in bravery and force of character, and indeed there are indications that the tribe of Reuben had been absorbed, or become extinct, at a somewhat early date. David's men of Gad (1 Chr. xii. 8) are famous, and Jephthah and Elijah seem to have belonged to that tribe. It followed Jeroboam in the great revolt against the house of David; and a genealogy, as at the time of Jeroboam II., is given in 1 Chr. v. 11–16, where the names are in every case different from those in Numbers. The tribe was "carried into captivity" by Tiglath Pileser in the 8th century B.C. (1 Chr. v. 26; comp. 2 Kings xv. 29), and at this point it wholly disappears from history.

GAD is also the name of a "prophet" or "seer," who was probably a pupil of Samuel at Naioth, and a companion of David, to whom he early attached himself. It is not known to which tribe he belonged. He is first mentioned in 1 Sam. xxii. 5 as having joined David while he was "in the hold;" and he afterwards became a member of his regal court, where he seems to have held an official position, being occasionally designated as "the king's seer." He assisted in organizing the musical service of the "house of of God" (2 Chr. xxix. 25), and also wrote a "book of the acts of David," which is referred to in 1 Chr. xxix. 29.

GADÂMES, GHADÂMES, or RHADÂMES, the chief town of an oasis of the same name, in that part of the Sahara which belongs to the regency of Tripoli, not far from the frontier of Algeria. According to Dr Rohlfs, the last form of the word more correctly represents the Arabic pronunciation; but the other forms are more usual in European books. The whole oasis is surrounded by a dilapidated wall varying in height from 12 to 20 feet, and it requires about an hour and a half to make the circuit of the enclosure at an ordinary walking space. In the town proper the streets are narrow and tortuous, and they are usually covered in overhead to keep out the heat. Its public buildings comprise six mosques and seven schools; and it is worthy of note that all the inhabitants can read and write, and that those who cannot pay for their children are allowed to send them to school free of charge. The Gadamsi merchants have been known for centuries as keen and adventurous traders, and their commercial establishments are to be found in many of the more important cities of northern and central Africa, such as Kano, Katsema, Timbuctoo. Gadames itself is the centre of a large number of caravan routes, and it is calculated that, on an average, about 30,000 laden camels enter its markets every year. At the time of Richardson's visit in 1845 the total population was estimated at 3000, of whom about 500 were slaves and strangers, and upwards of 1200 children; but it now amounts in round numbers to 7000 or even 10,000. The natives are mainly of Berber descent, although their blood has from generation to generation been mingled with that of Negro slaves from various parts of Africa. It is evident, from the remains that are still extant, that the oasis of Gadames was formerly inhabited by people whose architecture was of Roman origin; and it is not unlikely that the Romans themselves may have been attracted to the spot by the presence of the warm springs which still rise in the heart of the town, and spread fertility in the surrounding gardens. An identification has been made with Cydamus, a town mentioned by Pliny. See Largeau in *Bull. de la soc. géogr. de Paris*, 1877.

GADARA, an ancient city of Syria, in the Decapolis, about 6 miles S.E. of the Sea of Galilee, on the banks of the Hieromax. The site, now called Um Keis, is marked by extensive ruins, which are quite in keeping with the statements of Josephus and Polybius that Gadara was the capital of Peræa, and one of the most strongly fortified places in the country. The walls can still be traced in a circuit of about 2 miles; one of the principal streets—a *via recta*, or straight street—has evidently been bordered on both sides by colonnades; and two theatres are the most noticeable of the ruined edifices. The cliffs round the town are full of tombs excavated in the limestone rock, and by a curious irony of fate these chambers of the dead are the only places where a living inhabitant of Gadara is to be found. According to Josephus, Gadara was a Greek city, and it appears at least not improbable that it was a foreign settlement. The name does not occur in the Scriptures; but in the New Testament, the phrase "the country of the Gadarenes" is used more than once, and there is no reason to doubt that the vicinity of the town was the scene of the healing of the demoniacs by the Saviour, recorded in Matt. viii., Mark v., and Luke viii. Josephus informs us that Gadara was captured by Antiochus in 218 B.C., and, about 20 years afterwards, stood a ten months' siege by Alexander Jannæus. It was twice taken by Vespasian, though, on the first occasion, the Jewish inhabitants offered a stout resistance. At a later period it recovered from the injuries he inflicted, and was one of the most beautiful and flourishing cities of Syria; and it was not till after the Mahometan conquest that it fell again into decay. Its archæon or prefecture is mentioned in the Midrash Rabba (*circa* 278) and other Jewish writings. According to Dr O. Blau the town was also known as the Arabian Antioch. To the literary student it is interesting as the birthplace of Meleager the anthologist.

GADDI. Four painters of the early Florentine school—father, son, and two grandsons—bore this name.

1. GADDO GADDI (1239 to about 1312) was, according to Vasari, an intimate friend of Cimabue, and afterwards of Giotto. He was a painter and mosaist, is said to have executed the great mosaic inside the portal of the cathedral of Florence, representing the coronation of the Virgin, and may with more certainty be credited with the mosaics inside the portico of the basilica of S. Maria Maggiore, Rome, relating to the legend of the foundation of that church; their date is probably 1308. In the original cathedral of St Peter in Rome, he also executed the mosaics of the choir, and those of the front, representing on a colossal scale God the Father, with many other figures; likewise an altarpiece in the church of S. Maria Novella, Florence; these works no longer exist. It is ordinarily held that no picture (as distinct from mosaics) by Gaddo Gaddi is now extant. Messrs Crowe & Cavalcaselle, however, consider that the mosaics of S. Maria Maggiore bear so strong a resemblance in style to four of the frescos in the upper church of Assisi, representing incidents in the life of St Francis (frescos 2, 3, 4, and especially 5, which shows Francis stripping himself, and protected by the bishop), that those frescos likewise may, with considerable confidence, be ascribed to Gaddi. Some other extant mosaics are attributed to him, but without full authentication. This artist laid the foundation of a very large fortune, which continued increasing, and placed his progeny in a highly distinguished worldly position.

2. TADDEO GADDI (about 1300–1366, or later), son of Gaddo, was born in Florence, and became one of Giotto's most industrious assistants for a period (as usually stated) of 24 years. This can hardly be other than an exaggeration; it is probable that he began painting on his own account towards 1330, when Giotto went to Naples. Taddeo also traded as a merchant, and had a branch establishment in Venice. He was a painter, mosaist, and architect. He executed in fresco, in the Baroncelli (now Giugni) chapel, in the Florentine church of S. Croce, the Virgin and Child between Four Prophets, on the funeral monument at the entrance, and on the walls various incidents in the legend of the Virgin, from the Expulsion of Joachim from the Temple up to the Nativity. In the subject of the Presentation of the Virgin in the Temple are the two heads traditionally accepted as portraits of Gaddo Gaddi and Andrea Tafi; they cannot, at any rate, be portraits of those artists from the life. On the ceiling of the same chapel are the Eight Virtues. In the museum of Berlin is an altarpiece by Taddeo, the Virgin and Child and some other subjects, dated 1334; in the Naples Gallery, a triptych, dated 1336, of the Virgin enthroned along with Four Saints, the Baptism of Jesus, and his Deposition from the Cross; in the sacristy of S. Pietro a Megognano, near Poggibonsi, an altarpiece dated 1355, the Virgin and Child enthroned amid Angels. A series of paintings, partly from the life of S. Francis, which Taddeo executed for the presses in S. Croce, are now divided between the Florentine Academy and the Berlin Museum; the compositions are taken from or founded on Giotto, to whom, indeed, the Berlin authorities have ascribed their examples. Taddeo also painted some frescos still extant in Pisa, besides many in S. Croce and other Florentine buildings, which have perished. He deservedly ranks as one of the most eminent successors of Giotto; it may be said that he continued working up the material furnished by that great painter, with comparatively feeble inspiration of his own. His figures are vehement in action, long and slender in form; his execution rapid and somewhat conventional. To Taddeo are generally ascribed the celebrated frescos—those of the ceiling and left or western wall—in the Cappella degli Spagnuoli, in the church of S. Maria Novella, Florence; this is, however, open to considerable doubt, although it may perhaps be conceded that the designs for the ceiling were furnished by Taddeo. Dubious also are the three pictures ascribed to him in the London National Gallery. As a mosaist, he has left some work in the baptistery of Florence. As an architect, he supplied in 1336 the plans for the present Ponte Vecchio, and those for the original (not the present) Ponte S. Trinita; in 1337 he was engaged on the church of Orsan-Michele; and he carried on after Giotto's death the work of the unrivalled Campanile.

3. AGNOLO GADDI, born in Florence, was the son of Taddeo; the date of his birth has been given as 1326, but possibly 1350 is nearer the mark. He was a painter and mosaist, trained by his father, and a merchant as well; in middle age he settled down to commercial life in Venice, and he added greatly to the family wealth. He died in October 1396. His paintings show much early promise, hardly sustained as he advanced in life. One of the earliest, at S. Jacopo tra' Fossi, Florence, represents the Resurrection of Lazarus. Another probably youthful performance is the series of frescos of the Pieve di Prato—legends of the Virgin and of her Sacred Girdle, bestowed upon St Thomas, and brought to Prato in the 11th century by Michele dei Dagomari; the Marriage of Mary is one of the best of this series, the later compositions in which have suffered much by renewals. In S. Croce he painted, in eight frescos, the legend of the Cross, beginning with the Archangel Michael giving Seth a branch from the tree of knowledge, and ending with the Emperor Heraclius carrying the Cross as he enters Jerusalem; in this picture is a portrait of the painter himself. Agnolo composed his subjects better than Taddeo; he had more dignity and individuality in the figures, and was a clear and bold colourist; the general effect is laudably decorative, but the drawing is poor, and the works show best from a distance. Various other productions of this master exist, and many have perished. Cennino Cennini, the author of the celebrated treatise on painting, was one of his pupils.

4. GIOVANNI GADDI, brother of Agnolo, was also a painter of promise. He died young. (W. M. R.)

GADIATCH, a town of Russia, at the head of a district in the government of Poltava, situated on the elevated banks of the Grun and the Psel, 73 miles N.N.W. of Poltava, in 50° 22′ N. lat. and 34° 0′ E. long. It is a plain wood-built town, with four Greek churches and two synagogues, deriving its main importance from its four annual fairs, one of which, lasting for three weeks, was, up to 1857, held at the Hermitage of the Transfiguration (*Skeet Preobrazhenski*). In 1860 the population was 7263, 1213 of the number being Jews. According to W. Struve's *Calendar* for 1878, it was 8425. Gadiatch was the place where the assembly was convoked by the hetman Vigofski in 1658, for the publication of the treaty contracted between the Ukrainians and the Poles. During the hetmanate it had fortifications of which traces are still extant, ranked as a garrison town, and was the residence of the hetman. At first it was included in the military district of Luben, but after 1650 in the district to which it gave its name. Along with 13 large villages it was bestowed by the empress Elizabeth on Count Razumofski, but it was afterwards purchased from him by the empress Catharine II. In 1771 the town and district were incorporated with the province of Kieff, and in 1802 they obtained their present position in the government of Poltowa.

GADWALL, a word of obscure origin,[1] the common English name of the Duck, called by Linnæus *Anas strepera*, but considered by many modern ornithologists to require removal from the genus *Anas* to that of *Chaulelasmus* or *Ctenorhynchus*, of either of which it is not only the typical but the sole species. Its geographical distribution is almost identical with that of the common Wild Duck or Mallard (see DUCK, vol. vii. p. 505), since it is found over the greater part of the Northern Hemisphere; but, save in India, where it is said to be perhaps the most plentiful species of Duck during the cold weather, it is hardly anywhere so numerous, and both in the eastern parts of the United States and in the British Islands it is rather rare than otherwise. Its habits also, so far as they have been observed, greatly resemble those of the Wild Duck; but its appearance on the water is very different, its small head, flat back, elongated form, and elevated stern rendering it recognizable by the fowler even at such a distance as hinders him from seeing its very distinct plumage. In coloration the two sexes agree much more than is the case with any of the European Freshwater Ducks (*Anatinæ*)—one only, the *Anas marmorata*, excepted; but on closer inspection the drake exhibits a delicate ash-coloured breast, and upper wing-coverts of a deep chestnut, which are wholly wanting in his soberly clad partner. She, however, has, in common with him, some of the secondary quills of a pure white, presenting a patch of that colour which forms one of the most readily-perceived distinctive characters of the species. The Gadwall is a bird of some interest, since it is one of the few that have been induced, by the protection afforded them in certain localities, to resume the indigenous position they once filled, but had, through the draining and reclaiming of marshy lands, long since abandoned. In regard to the present species, this fact is due to the efforts of the late Mr Andrew Fountaine, on whose property, in West Norfolk and its immediate neighbourhood, the Gadwall has now, for nearly thirty years, annually bred in constantly increasing numbers, so that it may again be accounted, in the fullest sense of the word, an inhabitant of England; and, as it has been always esteemed one of the best of wild fowl for the table, the satisfactory result of its encouragement by this gentleman is not to be despised. (A. N.)

[1] Webster gives the etymology *gad well*=go about well. Dr R. G. Latham suggests that it is taken from the syllables *quedul*, of the Latin *querquedula*, a Teal. The spelling "Gadwall" seems to be first found in Willughby in 1676, and has been generally adopted by later writers; but Merrett, in 1667, has "Gaddel" (*Pinax Rerum naturalium Britannicarum*, p. 180), saying that it was so called by bird dealers. The synonym "Gray," given by Willughby and Ray, is doubtless derived from the general colour of the species, and has its analogue in the Icelandic *Gráönd*, applied almost indifferently, or with some distinguishing epithet, to the female of any of the Freshwater Ducks, and especially to both sexes of the present, in which, as stated in the text, there is comparatively little difference of plumage in Drake and Duck.

GAELIC LANGUAGE AND LITERATURE. Until recently there was doubt as to the family of languages to which the Gaelic belonged; indeed, with many scholars the impression existed that it belonged to the Semitic branch, and that its relations must all be traced among some one or other of its varieties. This view arose very much from the neglect with which the language had been treated by scientific men. Comparative philology is itself a modern subject of study. Naturally, in its progress, the more prominent languages came first, while the more obscure were passed over as of comparatively subordinate importance. The study is one so comprehensive, and requiring so large an amount of acquirement of various kinds, that it is no real reproach to modern scholarship that the study of such languages as the latter should have been postponed in favour of that of languages more generally known. Their turn, however, gradually came, and no one can complain now that they have not received the attention of very competent scholars. It is doubtful whether a higher class of scholarship has been nurtured anywhere than in the study of the Celtic languages, as exhibited by such men as Zeuss, Dieffenbach, Ebel, Whitley Stokes, the Chevalier Nigra, Henri Gaidoz, and others who have devoted their strength to their exposition. The result has been the complete establishment of the fact that this class of languages belongs to the Indo-European or Aryan stock, and is closely related to the classical branch of those tongues.

The first who brought real scholarship to bear upon the question of the family to which the Celtic dialects belonged was Dr Cowles Pritchard. His *Eastern Origin of the Celtic Nations* is a work of the highest value, distinguished by its erudition, and the sound judgment it displays. He was one of the most remarkable men whom Britain has produced in the field of comparative philology. No doubt it is with the Welsh he chiefly dealt, but, in discussing such questions as he had to deal with, it mattered little which of the Celtic tongues was made use of. Many writers followed Dr Pritchard, and there is now, as has been said, no question about the Aryan source of the Celtic languages. It is not that the words are to a large extent analogous, but the grammatical structure and the idioms correspond to such an extent that the question is put beyond a doubt; while, with the exception of a few common vocables, there is little that is analogous between the Celtic and the Semitic languages.

The territory once occupied by the Celtic race is a question of much interest. Now they are confined within well-known limits. On the European continent they occupy that part of France usually called Brittany, the most westerly portion of the country terminating in Cape Finisterre. They occupied this territory so early as the days of Julius Cæsar, although it has been said that they were emigrants from Britain at a later period. The topographical terms given by Cæsar in describing the Roman invasion all indicate that the language of the natives of Brittany used then, and for a long time before, was as much Celtic as it is now. Opposite to Brittany lies British Cornwall, a region with a Celtic tongue until about 100 years ago. The two Cornwalls—one in Britain and the other in France—terminated, one on each side, the territory occupied by the Celt. The dialects spoken in these stood in the closest relationship. To the north of this lies the greatest of all the modern se-tions of the Cimbrian Celts. Wales, occupied by about a million inhabitants, is nearly Celtic, and uses the ancient tongue of Wales, Cumbria, and Strathclyde. Across the sea from Wales lies the Isle of Man, where the Gaelic branch of the Celtic held sway, and does to some extent still. In Ireland the Gaelic also prevailed, and is still spoken by about a million people. And lastly, in the Scottish Highlands about 300,000 people still use, less or more, the old Gaelic tongue of Scotland. Thus Brittany, Wales, Man, western Ireland, and the Scottish Highlands are now the territory of the Celtic languages. That they once occupied a wider sphere is beyond a doubt. There are traces of the tongue, in one form or other, to be found all along southern Europe. Topography is a valuable source of evidence, and one that will be made to serve purposes it has never served as yet; and it furnishes us—in Italy, France, Switzerland, Spain, and Portugal—with relics which, like animal fossils dug from the depths of the earth, speak unmistakably of what formerly existed there. How far the Gaelic form of Celtic speech prevailed it is difficult to say, or whether it existed alongside of the Cimbric on the continent of Europe. But the name Gallia is significant as applied to France; and it is a suggestive fact that, to this day, the Bretons call France Gaul, as distinguished from their own country, and in like manner call the French language Gallic, as distinguished from the Breton. In Scotland the Gaelic and Cimbric races long dwelt together, distinct and yet nearly related. When they separated, either as to race or language, is not easily settled. There are indications on the Continent which rather throw doubt on the idea maintained by some writers that the divergence took place after the settlement of the race in Britain, and farther inquiry as to these indications is essential ere a satisfactory conclusion can be reached. But within the historic period the two races existed side by side in Scotland, the Cimbric occupying the region called Strathclyde, with their separate government and laws, and the Gael at least occupying the Dalriadic kingdom of Argyll. The people called by the Romans Picts occupied the north and east of Scotland. That these were the same people with the Dalriadic Scots is somewhat questionable. That they were closely related to them is beyond doubt, but that they had linguistic and other peculiarities is manifest. Their topography proves it, being different from that of either Ireland or Argyll, and, so far as the historic relations of both are concerned, they indicate a state of chronic war. For centuries there were mutual raids of Scots on Picts, and Picts on Scots, until finally, under Kenneth MacAlpine, king of Dalriada, the Picts were overcome in the year 843, and they and the Scots became united under one monarchy. The tradition is that the Picts were annihilated,—meaning, in all likelihood, their power,—and there arose one great united kingdom. The united people are the ancestors of the present Scottish Highlanders, and the Gaelic language has come down from them to us, influenced as to structure by the dialect spoken and written by the victors.

The Gaelic language, as now in use in Scotland, resembles closely in its structure both the Irish and the Manx. They form one family, and yet it has its own distinctive features. Irish scholars maintain that it is a modern and corrupt offshoot of the Irish, and account in this way for these peculiarities. They say, for example, that the absence of the present tense in the Gaelic verb is a mere instance of decay, and proves the modern character of the dialect. But the Welsh is no modern and corrupt form of Irish, but an ancient distinct tongue, so far back as history carries us. And yet it wants the present tense, indicating that this peculiarity is distinctive of some of the Celtic tongues, and that what is cited as a proof of recency may in reality be a proof of priority. The present tense may be called an Irish addition made to the verb in the process of culture. At the same time it must be allowed that there is a difficulty in proving from any literary remains existing that the present Scottish form of the language is of great antiquity. All the literary relics that have come down to us are written in what is usually called the Irish dialect. The present tense is in universal use, as well by Scottish as by Irish writers. This arose from the identity of the Irish and Scottish churches. The dialect in which all theological treatises were written was one, and this dialect extended from the clergy to bards, and sennachies, and medical men. There is not a page of Gaelic written in any other dialect before the middle of last century. But as in other countries there was both a spoken and a written dialect in use, so in both Scotland and Ireland there appears to have been a dialect in use among the people as their common speech, and another used by their scholars,—the former varying according to locality, and the latter being identical throughout. Some of the features that distinguish the Gaelic language, partly in common with the other Celtic tongues, and partly not, are the following:—

1. The aspiration of consonants. This is accomplished by the change of *m* into *v*, of *b* into *v*, of *d* into *y*, of *g* into a broad *y*, of *p* into *f*, and *s* and *t* into *h*. As appearing in the initial articulations this presents a peculiar difficulty to the learner of Gaelic. He has been accustomed, in learning other tongues, to observe the changes required by inflexion, and other requirements of correct grammatical structure. But he has not been familiar with changes in the initial letters of words. In English these letters never undergo any change; but in Gaelic he meets with such changes at once. He finds *mac*, a son, becoming in certain circumstances *vac*, and he is ready to doubt whether both forms belong to the same word. To make the difficulty as little formidable as possible to the reader, the authors of the Gaelic orthography fell upon the method of using the letter *h*, which, though hardly a letter in Gaelic, and never used to begin a word, is now used more than any other letter. The Irish use a dot. The use of the *h* serves to preserve to the reader the original form of the word. Hence *mac* becomes by aspiration, or *adoucissement* as the French call it, *mhac*, pronounced *vac*. These initial changes of certain consonants are made for the purpose of euphony, to which Gaelic makes large sacrifices, and also for the purpose of distinguishing gender. An aspiration converts the feminine into the masculine, and, *vice versa*. *An ceann* is the head, masculine, *a' chos* the foot, feminine. So *a chos* is his foot, *a cos* is her foot; *a cheann* is his head, *a ceann* is her head, the pronoun undergoing no change, although its gender is indicated by the change. There are other purposes served by aspiration of considerable importance. The Gaelic learner makes a large acquisition when he masters the principles of aspiration, and inquirers into the characters of the language will cease to blame the frequency with which *h* appears in Gaelic writing when they come to see how important a purpose it serves.

2. Another peculiarity of the Gaelic language is to be found, as already said, in the want of a present tense in the verb. The verb "to do" is *dean*, the theme of the verb being in the imperative mood. There is no tense expressing simply I do, the form in use being I am doing, *tha mi a' deanamh*. The Irish say *deanaim*, I do, but that is not the Scottish form of the expression. In this Gaelic is not only at one with several of the Celtic branches, but with some of the Semitic tongues. And it has this further in common with these last, that the future is used to express present time. This occurs frequently in the Gaelic version of the Bible, where we have *an ti a chreideas anns a' Mhac*, he that will believe in the Son, for he that believeth. And yet occasionally a true present tense appears in Gaelic:—*an cluinn thu sin?* Do you hear that? *cluinnidh*, I do hear it; *am faic thu sin?* Do you see that? *chi*, I do see it. In those cases and some others there is no doubt a distinct present tense. The cases are, however, few, and occur in peculiar circumstances.

3. Another feature peculiar to Gaelic is that there is no real infinitive in the verb. The infinitive in use is a noun which may appear either in the form of a participle or an infinitive, according to the effect of the preceding preposition. I am going to strike, *tha mi 'dol do bhualadh*, I am going to striking; I am striking, *tha mi a' bualadh*, I am at striking,—the preposition *do*, to, in the one case giving the noun the force of an infinitive, and the preposition *ag* or *a'*, at, giving the same noun the force of a participle. The Gaelic infinitive is thus identical with the Latin gerund, and is one of the points where the classical and the Celtic tongues meet and touch.

In the article CELTIC LITERATURE reference is made to some of those cases in which the Irish dialect of the

Celtic differs from some of the others. It is unnecessary here to go over the same ground again. What is distinctive of the Irish is, for the most part, distinctive of the Scottish Gaelic. The Gaelic retains the hard or *k* sound of *c*. There is not an instance of a purely Gaelic word in which the *c* is pronounced soft. There are dialects of Gaelic, however, in which the *c* becomes aspirated in the middle or at the end of a word. Thus *mac*, a son, is pronounced *machd*; *peacadh*, sin, is pronounced *peachdadh*. This peculiarity does not exist in the counties of Sutherland and Caithness, where the hard sound of *c* is retained. The Scottish Gaelic, in like manner, in common with Sanskrit, Latin, German, and Slavonian, retains the sibilant *s*, where other dialects have discarded it. Many words beginning in Gaelic with *s* have *h* as the initial letter in Welsh. It is worthy of observation, however, that, in the aspirated form of the *s* used in inflexion or as indicative of gender, the *s* assumes the sound of *h* in Gaelic. In like manner, words in Gaelic, as in Irish, can end in *s*, *r*, and *n*. The instances of these are numerous. So also does the Gaelic, like Irish, retain a harder form of the articulation than the British, but not to the same extent; for *huvel*, low, in Irish *humal*, is in Gaelic *umhal*, approaching in this, as in many other cases, nearer to the British form. So the Gaelic preserves letters where the British loses them, but not to the same extent as the Irish. For when the Irish has *tech*, a house, and the British *ti*, the Gaelic has both *teach* and *tigh*, and for the most part uses the latter. In addition to this, the Gaelic, like the Irish, has preserved the declension of its noun, which cannot be said of the British. Four of the cases are in constant use, the nominative, the genitive, the dative, and the vocative in both numbers, the dative plural alone having almost disappeared from common speech. In the singular number these cases are distinctly marked—*cos*, a foot, gen. *coise*, dat. *cois*, voc. *a chos*. Wherever the language is well spoken these cases are in daily use, and are lost only when the language is far on in the process of decay.

Difference between Gaelic and Irish.—The differences between the Gaelic and the Irish are considerable, and, though Irish writers maintain the contrary, are not to be taken as indications of the modern origin of the former. Without entering on that question, we find a marked distinction in the use by the Irish of what is called eclipsis,—that is, the use of other and softer articulations to eclipse the harder in the beginning of a word, in some cases, as, for instance, in the genitive plural of nouns. The object aimed at would seem to be euphony, and in seeking this object the Irish and the Scottish ear did not altogether correspond. In Irish, the law as given by O'Donovan is that *m* eclipses *b*, as *ar m-bo*, our cow; *g* eclipses *c*, as *ar g-ceart*, our right; *n* eclipses *d*, *bh* eclipses *f*, *n* eclipses *g*, *b* eclipses *p*, *d* eclipses *t*, *t* eclipses *s*. This system of eclipsing runs through the nouns and verbs. It is unknown in Gaelic, if we except the eclipsing of *s* by *t*, as *an t-sùil*, the eye, *an t-slat*, the rod, and certain words which, in some districts of the Highlands, suffer eclipse. In Skye the expression for the number of men is *àireamh nan n-daoine*, the *n* eclipsing the *d*. Other instances may be found along the west coast of Scotland. But eclipsis is, for the most part, distinctive of the Irish dialect. The Gaelic is further marked by a greater tendency to aspiration than the Irish. The sentence *cionnas ta tu*? how art thou? in Irish, is in Gaelic *cionnus tha thu*? the verb and the pronoun being both aspirated. Other differences might be referred to, but one is prominent, the difference of accent or emphasis. The tendency of the Irish is to emphasize the final syllable, that of the Gaelic to emphasize the penultimate. Thus *salàch*, dirty, in Irish, is in Gaelic *salăch*; *Oisìn*, Ossian, is in Gaelic *Oisiăn*. This makes a striking difference in the spoken tongues, and occasions one of the main difficulties Irish and Scottish Celts have in understanding each other's speech.

Advantages and Defects of Gaelic.—The Gaelic language, as now existing, has its advantages and its corresponding defects. It is admirably adapted for the purposes of the poet. In descriptive poetry few languages excel it. There are some pieces of ancient, authentic, Ossianic poetry existing that are equal in power and beauty to the compositions of any age or country. Such are the description of Cuchullin's chariot and horses, and the description of the swords of the Ossianic heroes. The same is true of more modern poetic compositions. Macintyre of Glenorchy's *Beinn Douran* and *Coire Cheathaich* are fine specimens of descriptive poetry—poetical in conception throughout, couched in the choicest language, and with rhythm of unfailing accuracy. The same may be said of Macdonald's *Oran an t-samhraidh*, or Ode to Summer, which is a remarkable specimen of what the Gaelic is capable of when used for the description of nature. Other lyrical compositions are also of a high order of merit. Love-songs and boat-songs abound, and are in many cases full of life and force; and the numerous songs expressive of clan affections and animosities display the same characteristics. No language is more capable of expressing both love and hate, and there seems to have been ample scope for both in the past history of the Highland clans. Within certain limits the Gaelic is the language of poetry, extending from the epic of the Ossianic bards down to the lyric or less aspiring efforts of lesser bards.

The language is also admirably fitted for the communication of religious knowledge. It is in its structure metaphorical and emotional, and renders with wonderful precision and effect the statements of Scripture. The saying attributed to one of the dukes of Argyll is well known, that if addressing his sovereign he would choose English, if addressing the lady of his affections he would choose French, but if he was addressing his God he would choose Gaelic. Few of those whose calling it is to teach religious truth, and who know how to handle the language with effect, have failed to feel and own that it is incomparable for conveying the knowledge of the truth with power. Perhaps no preachers have surpassed the Welsh in real eloquence, and yet some of the Gaelic preachers have not been behind them. The language has served a great purpose in the Highlands in connexion with the religious life of the people.

The defects of the language are to be found chiefly in the departments of philosophy, science, and art. There it has either to be rejected or to be supplied from foreign sources. Indeed in this field it seems to have deteriorated during the course of several centuries. There are MSS. of the 14th and 15th centuries in existence, in which terms are employed in connexion with discussions in philosophy, theology, and medicine that could not now be understood. The philosophy of Aristotle is well rendered, as are also the theology of the fathers and the medical disquisitions of the Arabic writers on medicine. But when modern science and philosophy, and even theology in some of its departments, have to be dealt with, the lack of terms renders the task a difficult one. It is here that, in the progress of education, the difficulty of preserving the language lies. The effect of this want is traceable in common speech, when English words have of necessity to be used in connexion with objects of everyday use. Steamer, train, boiler, engine, railway, quay, &c., have just to be introduced from the Saxon, and presented with a little of the Gaelic tone in them to suit the Celtic ear. Some writers and speakers do try to invent Gaelic terms to represent all these and similar objects, but popular usage rejects them and prefers the foreign words.

Gaelic Literature.—The literature of the Scottish Highlands may be divided into several branches. The following outline comprehends more perhaps than is usually included under that term; in particular, it appears necessary to give here some account of topographical and personal names.

Mythology.—We have first the mythology of the race. Little of this now exists, and it is difficult to piece the scattered fragments together. We find the mythology of the older faith or faiths interwoven in some cases with the mythology of the Northmen. The mythology of the East appears at some points, and we have giants, fairies, and witches, some of them firmly believed in to the present day. Adamnan, in his life of Columba, refers to the magi who were in the palace of the Pictish king whom the missionary sought to convert. Who these were, and what was their creed, is not clearly stated, but all we read of that early faith, and all that tradition brings down to us, would seem to indicate that their worship was a form of sun worship. The words applied to the cardinal points of the compass convey this impression, the fear shown in many ways of going against the course of the sun, and certain festivals in which fire was and is used, would seem to confirm it. The bodies of the dead are in some cases carried sunwise round certain objects on their way to the burial ground; in fact, words and practices crop up in several parts of the country serving to show that the sun was worshipped. *Rath*, a circle, is used in Gaelic to express good fortune:—*cha-n'eil rath air*, there is no circle on him,—he is not fortunate,—referring, no doubt, to the course of the sun. There was a Gaelic mythology connected with the Fingalian heroes. Whether they themselves were mythical or not is debated, but there was a mythology connected with them. Fingal had a sword that never required to be used twice; the Vulcan of the race could cross a glen with a stride; Manannan, son of Lir, from whom the Isle of Man is named, could clothe himself in a fog, and so hide himself from his enemy. The story of Diarmad and the boar and the story of Fraoch and the beast are mythological, the former being the Celtic story of Achilles, and the latter the Celtic version of the Garden of the Hesperides. Then there were giants called *Na Fiantaichean*, men of colossal mould. *Dun Fhian*, the giant's castle, is a common topographical term. Here is the description (with English translation) of one of these heroes:—

"Tamhull mòr, mac sheann Tamhuil,
Cha ruigeadh a' mhuir mhòr a ruinnse,
Cha thàradh e mach, 's cha thàradh e steach,
'Us 'n uair a bhitheadh e 's a bheul fodha,
Bhitheadh a dhruim a' sgriobadh an athar."

Great Taval, son of old Taval,
The great sea wouldn't reach his middle;
He couldn't get out and he couldn't get in;
And when he lay down on his face,
His back would be scratching the sky.

Some of these tales of the giants attribute to them a great age. There is one tale in which five generations in succession are said to exist at the same time, and the youngest of them a very aged man. The traditional tales taken down by Mr J. F. Campbell, from oral tradition in the Highlands are full of mythology. Animals in these play an important part, and are endowed with remarkable powers. How far this mythology is original, or is borrowed from the East, is an interesting question. In some of the Western Isles, the Scandinavian god Odin enters into the popular mythology, a relic, no doubt, of the Norse occupation of the territory. Fairies, or the *daoine sìthe* or *sìthichean*, fill an important place in the mythology of the Highlands. The name of these imaginary beings is derived from their supposed habits. *Sìth* is a common name in Gaelic for a hill of a peculiar form. As a diminutive it is *sìthean*, the word used for green hillocks, which abound throughout the Highlands. These hills are supposed to be the abodes of fairies, who, in consequence, are called *daoine sìthe*, or the men of the hillocks. *Sìth*, peace, has no part in forming the designation, although often said to have. These beings were the very opposite of peaceful in the popular belief. It is impossible here to give an account of the common belief in the Highlands regarding fairies, but there is a great deal of popular literature taken up with descriptions of it, and with stories regarding these mischievous and meddling beings. They were fond of carrying away young children, and substituting young fairies in their place, to the grief and harassment of the mother. Nor did they confine their assaults to children, but sometimes carried men and women to their underground abodes, where they passed through extraordinary scenes. The Rev. Robert Kirke of Balquhidder wrote an account of the fairies which awakened their anger, and they spirited him away to fairyland. He was able to appear in the room at the baptism of a child born after his removal, when it was arranged that for his deliverance a knife was to be thrown over his head at a certain moment. The hour came, but through some infatuation the party entrusted with the duty failed in the performance. Mr Kirke was not delivered, and is believed to be in fairyland to this day. Similar stories are without number, and show how widely extended the belief in fairies was.

Witchcraft had a large place in the popular beliefs, and has not lost it altogether at the present day. It was supposed possible for a person endowed with this power to inflict great damage upon an adversary. Milk could be abstracted from the cows of a neighbour and brought to swell the produce of the party abstracting it. This belief has been the source of much animosity and strife among neighbours down to the present time. Clay bodies stuck over with pins could be formed representing an adversary, and could be laid in a stream, and as the clay wasted, the body of the man represented pined until he died. This afforded ample room for the exhibition of party or personal hatred, and is not altogether unknown now. The literature of witchcraft is of considerable extent, and consists in tales and forms of exorcism which are very various, and some of them very curious. The forms are all in rhyme, and do not display much of the genius of poetry; they are usually made up of appeals to saints and apostles, with the occasional introduction of the Virgin Mary. Several of these have been handed down by tradition, and are scattered through various works devoted to Highland lore. Near the valley of the Spey there recently lived a noted wizard, who possessed a charmed bridle which exercised a most powerful influence over all forms of bewitchment. A clergyman, not far from the residence of this man, was on one occasion much disturbed by the state of his cows, which had suddenly ceased to give milk. The neighbours assured the minister that it was witchcraft, and that he ought to send for the man with the charmed bridle, which, very much against his will, he was induced to do. The wizard came, and was told by the clergyman that he had no faith in his witchcraft, but he should very much like to have his counsel as a man of skill. The so-called wizard, understanding with whom he had to deal, at once laid aside all pretension to superhuman power, and asked the minister where his cows usually fed, saying that they would go and take a look at the grass. They did so, when the wizard pointed out a plant, then in flower, which he said was, in that condition, most injurious to cows yielding milk. He advised the minister to keep the cows away from that piece of pasture for a fortnight. This was done, and the cows recovered. The wizard got his fee and a promise that nothing should be said to affect the public confidence in his power. This is the kind of witchcraft that has existed all along, and which has cost many poor helpless creatures their lives at the stake.

Topography.—In dealing with the literature of the Highlands we cannot overlook the topography of the country. It is to be regretted that in Scotland we have no such MS. remains, containing topographical terms with their origin, as are to be found in Ireland, nor have we any work on the subject of topography possessed of the slightest authority. But we have numerous ancient charters containing names of places, and we have what are called the *retours*, connected with the succession to property throughout the country, and these contain extensive lists with the spelling adopted for the names at different periods. These names belong to different languages. There is apparently an original language, if not more than one, which is now lost. Without this assumption there is no accounting for many of the names applied to natural objects. Then there is the old Norse and the Anglo-Saxon, the one using *wick* for a bay, as in Caithness, and the other for a town, as in Roxburghshire; then there is the British, as in the old Strathclyde territory, and the Gaelic. The Gaelic, in its topographical distribution, does not occupy the same field with that occupied by it as a spoken tongue. The spoken language and the topography of Galloway are quite at variance; so with Lewis and others of the Western Isles. The spoken language of Galloway is Scottish, the topography is almost wholly Gaelic. The spoken language of Lewis, Harris, Skye, &c., is Gaelic, the topography is almost wholly old Norse. But one thing is manifest, that Gaelic names are distributed over the whole surface of Scotland, although not in equal proportions. These names contain a history, could it be evolved. They speak of races distinct and successive, although their testimony as to dates is difficult to read. The county names of Scotland in Gaelic are suggestive:—

Shetland	*Sialluinn.*	Fife	*Fiu.*
Orkney	*Arcaibh.*	Stirling	*Sruileadh.*
Caithness	*Gallthaobh.*	Galloway	*Gallthaobh.*
Sutherland	*Cataobh.*	Dumfries	*Dunphris.*
Ross	*Ros.*	Lanark	*Lanerch.*
Cromarty	*Crombadh.*	Argyll	*Araghael.*
Inverness	*Inbhearnaoise.*	Dumbarton	*Dunbhreatuinn.*
Nairn	*Inbhearnarunn.*	Bute	*Boite.*
Moray	*Morthaobh.*	Linlithgow	*Lanneuthaich.*
Banff	*Banabh.*	Lothian, M. & E.	*Loudaidh.*
Aberdeen	*Abaircadhain.*	Renfrew	*Renfrcudh.*
Kincardine	*Cinnechardainn.*	Ayr	*Siorramacha Adhar.*
Forfar	*Farfair.*	Kirkcudbright	*Cillechuibeirt.*
Perth	*Peart.*		

This list does not include Peebles (which is probably Celtic), Selkirk, Roxburgh, and Berwick, as there are no Gaelic terms for them, but in the other cases it will be seen to what an extent the county names are really Gaelic. The same is true of names of parishes, which are, to a large extent, Gaelic both in the north and in the south.

It is to be observed that the Gaelic topography of Scotland differs widely from that of Ireland. The Irish *sliabh*, for a mountain, rarely occurs in Scotland, where the word in use chiefly is *beinn*. It does occur, but the instances are few, while the Scottish *ben* is as rare in Ireland. *Baile*, a township, is sufficiently frequent in Scotland, but not so much so as the Irish *bally*. The word *strath*, for a great valley, occurs but rarely in Ireland; in Scotland it abounds over the whole kingdom. The *abers* and *pits* and *invers* of Scotland are rare in Ireland, or altogether unknown, while there is little resemblance in the names of rivers. These two systems of topography may have originated with the same people, but in one of the sections there were influences manifestly at work which were unknown in the other. Even in the Dalriadic kingdom of Argyll there are features which indicate a marked distinction between the topography and that of Ireland. The study of this subject is full of interest, and is capable of producing important results both linguistic and historical. The field is as yet unoccupied, and affords much to encourage the judicious and painstaking student.

Names of Persons.—The literature of the Highlands may be held further to include the names of persons as well as those of places. Indeed some of the older MSS. are filled with pedigrees, sometimes of kings, sometimes of lesser persons. Many of these ascend up to Noah, and even to Adam, showing at least that they date since the conversion of the Gael to Christianity. There are several interesting genealogical lists in the volume of transactions published by the Iona Club, and there are MSS. in the Advocates' Library, Edinburgh, which contain several lists of a similar kind. The descent of family representatives is in these traced up to the original source, which in many cases is found among the ancient Scottish kings. The preparing and continuing of these pedigrees was one of the duties of the ancient bards and sennachies, who transmitted their knowledge of family history from generation to generation. It may be believed that these officials would have a measure of bias in favour of their own patrons, and this may have, in some cases, influenced their accounts of family history; but, upon the whole, there seems to be a large amount of truth in what they have transmitted to us, back to a certain date. The rest is pure fiction. A specimen may be given, extracted from the genealogy of the family of Argyll.

Genelach mac Cailin Gillespic mac Cailin anann mac Gillespic mac Donch anagha mac Cailin mac Gillespic ruoidh mac Cailin oig mac Neill mac Cailin moir mac Gillespic mac Dubgaill, &c., and so on through King Arthur up to Seth, the son of Adam, the son of God. In English this is—The genealogy of Mac Cailin: Gillespick, son of Colin, son of Gillespick, son of Duncan the fortunate, son of Colin, son of Gillespick the red, son of Colin the young, son of Neil, son of Colin the great, son of Gillespick, son of Dougal, &c. So far the genealogy corresponds nearly with the usual genealogies of the family historians of the house of Argyll. Similar pedigrees are furnished of most of the Highland clans.

The names of persons among the Gaelic races are for the most part patronymic.

The first name in its earlier form is usually descriptive, as *Donnghal*, *Dubhghal*, *Donnachadh*, *Gillespuig*,—Donald, Dougal, Duncan, Gillespick,—the brown man, the black man, the brown-faced man, the servant of the bishop; often it is taken from the Scriptures, as *Eoin* John, *Scumas* James, *Tomas* or *Tabhas* Thomas, *Peadar* Peter, &c.; some of the names come from the Norse, as *Torcuil* Torquil, *Tormaid* Norman, *Aulaidh* Olave, *Leod* Leod, and some are borrowed from the Normans, as *Uilleam* William, *Eanraic* Henry, &c. The surnames are for the most part patronymics, as *Eoin Mac Neill*, John the son of Neil; and in case there should be another John M'Neil, another step is introduced, as *Eoin Mac Neill mhic Dhomhnaill*, and perhaps a third until the person is thoroughly identified. Sometimes there is a reduplication of the sonship, as *Mac Mhic Alasdair*, *Mac Mhic Ailein*, the son of the son of Alexander or Allan, names of important Highland chiefs. In other cases the surname is descriptive, as *Dubh* black, *Eoin dubh* Black John, *Beag* little, *Mor* big *Buidh* yellow, *Crom* bent, *Ruadh* red, &c., whence many well known English names are derived. A large number of Highland names and surnames are ecclesiastical, as those derived from St John, St Columba, St Cattan, St Bridget, and others, and thus become helps to historical inquiry. One thing is somewhat remarkable, that there is not an *O'*, in accordance with Irish nomenclature, among the Scottish Celts. The old O'Duinn of Argyle is lost, and the patronymic of the Celt is marked by the uniform use of *mac*, representing a son, as *O'* does a grandson. The age of fixed family names seems no older than the age of charters. Previous to that patronymics universally prevailed, but when charters were taken fixed names were essential to their value.

Proverbs.—From names of persons we may pass to proverbs as a part, and a very curious part, of Gaelic literature. Few languages so abound in proverbs, and proverbs of a very clever and popular caste. A Highlander seldom gives expression to an important sentiment without backing it with a proverb, and these give force and pungency to what he says. A collection of these proverbs was made, in the year 1819, by the Rev. Donald Mackintosh, and, to form some idea of the number of them, it is only necessary to observe that, under the letter "I" alone, they reach the number of 382 in the first edition of the book. A large number of these proverbial sayings escaped the notice of Mr Mackintosh, and additions were made in the second edition, while some of the very best are not recorded even yet. Proverbial sayings in English are represented by sayings of a different kind in Gaelic, having the same meaning. "There is many a slip between the cup and the lip" is represented by *Is le duine an ni a shluigeas e, ach cha leis an ni a chagaineas e*, "What a man swallows is his own, but not what he chews." "It never rains but it pours" is represented by *An uair a theid a' chailleach 'n a ruith, theid i 'n a deann-ruith*, "When the old woman takes to running, she runs with a will." "Sour grapes"—*Mionnan a' bhaird ris a' chaisteal, cha téid mi fhéin do'n chaisteal bhreun, cha teid, cha leig iad ann mi*, "The bard's oath to the castle, 'I wont go to the vile castle; no, they won't let me in.'" The Gaelic proverbs are full of interest, and add much to the power of either speech or writing when skilfully used.

Sgeulachdan, or Tales of Fiction.—These at one time abounded in the Highlands, and had much in common with the tales collected and published by Grimm and Dasent, from the German and the Norse. Until lately, these tales were entirely oral, and were little known beyond certain portions of the West Highlands. Recently they have been collected, translated, and edited, with peculiar care and skill, by Mr J. F. Campbell, in four 8vo volumes. This is a real addition to Gaelic literature, and Mr Campbell has laid every friend of that literature under obligation. One real service it has done in preserving for us admirable specimens of the most idiomatic and popular forms of the Gaelic language. We have it there as used by the tellers of popular tales among the people for generations. Whence many of these tales have come it is hard to say, but tales have been collected in the small islands south of Barra, where the people seldom tread the soil of even their main island, containing ideas and forms of thought which never could have originated there, and the preservation of which, in such a locality, is a remarkable fact. Are they relics of a higher civilization existing in ages long gone by? It is remarkable that the Thomas the Rhymer of Lowland tradition is well known in the traditions of the Highlands, and that stories of him related on the borders in broad Scotch are related in the Highlands in Gaelic as tales of great antiquity.

Clan History.—A portion of the literature of the Gaelic Celt consists of clan history. The clan system does not seem to be very ancient. In all probability it dates from the period when the Gaelic kingdom of Scotland ceased to exist. It has been already said to date from the era of charters. But the two eras are pretty nearly identical. Down to the reign of Malcolm III. the Gaelic kingdom appears to have been to a large extent homogeneous. There were no elements in it but what were Celtic, as it never really embraced within it the Scandinavian sections. Then the land was governed by its *maormors* and *toiseachs*, men who represented the central governing power. It would seem that when, in the reign of David I., the kingdom became largely Anglo-Saxon and Anglo-Norman, the Gaelic people became estranged from their native kings, and gathered themselves in sections under the sway of their own chiefs; and hence came chiefs and clans, instead of a king and his subjects forming a united nation. The change was a serious one for the Gaelic people, as they never became again what they had been before. Clan names appear at an early period, and in some form or other must have existed before the time of the Saxonized kings; but not one of the great clans of Highland history—the Macdonalds, the Macleans, the Campbells, the Macleods, the Mackenzies, the Mackintoshes, or others—appears at all. In the book of Deer, supposed to be of the 11th or 12th century, the names of two clans—the clan Morgan and the clan Canan—appear; but it is very questionable whether these represent any clan existing now, although clan Morgan is said to be the old name of the Mackays of Strathnaver. But the names in that interesting record are for the most part purely patronymic, and do not indicate any connexion with existing clans. The fact is that, till very recently, the clan name was confined to the chief, as records of old deeds and processes at law serve to show.

The Gaelic historical literature of one kind or another is of considerable extent, and consists of relics, written and traditional, of the old sennachies or family historians. In certain sections of the country the local traditions are full of the stories of old feuds, and, though not to be implicitly relied on, contain usually an element of truth. In Sutherland the feuds of the Sutherlands and the Mackays, in Lewis those of the Mackenzies and Macleods, in Skye the feuds of the M'Leods and the Macdonalds, in eastern Inverness-shire those of the Mackintoshes and Cummings, in Lochaber those of the Mackintoshes and the Camerons, in Perthshire those of the Campbells and the Macgregors, and others in other quarters are largely related. Native accounts of the clans were sometimes committed to writing, a specimen of which appears in the transactions of the Iona Club. For a good deal of what is historical regarding the Highlands, recourse must be had to the Irish Annals, which occasionally refer to events occurring in Scotland.

MS. Literature.—The written Gaelic literature was at its earlier period so mixed up with that of Ireland that it is not easy in every instance to distinguish them. The early church of both countries was one, and the early literature was the offspring of the early church. The very first notices we have of the church, whether among the mission institutes of Ireland or in Iona, indicate the existence and extensive cultivation of a native literature. The transcription or translation of portions of the Scriptures is shown to have been one of the frequent exercises of the early missionaries, and they all learned to write the same dialect and make use of the same letters. Many of the MSS. written in Iona may be credited to Ireland, and *vice versa*; and writings found in Continental libraries may be presumed to have been the work of Scottish as truly as of Irish writers. The early treatises, and glosses upon Latin treatises, on theological and other subjects still existing in the early Gaelic dialect are numerous, and have afforded materials for the acute and masterly criticism of Zeuss, De Nigra, Stokes, and others; and these are accompanied by treatises on grammar, history, medicine, astrology, metaphysics, poetry, and similar subjects, which are of much interest. Most of these remains are found in the collections in Trinity College, Dublin, and in the library of the Irish Royal Academy; but there are numerous remains in the Edinburgh Advocates' Library, which prove at least that there were in Scotland persons who valued and collected this literature. There can be no doubt that there were many contributors to it as well.

The earliest specimen of Gaelic writing, which can be pronounced to be Scottish beyond any question, is the *Book of Deer*, said already to be a work of the 11th or 12th century. The book itself consists of portions of the New Testament written in Latin. The Gaelic portion consists of historical references, with notices of grants of land bestowed on the old monastery of Deer, in Aberdeenshire. These references and notices are, for the most part, written on the margin. They show that, at the time the book was written, the Gaelic language was used, both for speaking and writing, in the district around Deer, where it is now unknown except in the topography. There is not a shade of difference between the language of the *Book of Deer* and the language of the Irish writings of the same age. The following specimen of the notices of grants of land may be interesting:—*Donchad mac mec bead mec híded dorat achad madchor docrist acus drostan acusdocholuimcille insóre gobrád malechí acuscómgell acusgille crist mac fingúni innáienasi intestes*, &c. "Duncan, son of MacBeth, son of Idid, gave Achad Madchor to Christ, and to Drostan, and to Columcille, in freedom for ever; Malechi, and Comgall, and Gilchrist, son of Fingon, witnesses in proof of it." The notice of grants continue in similar form, being records kept within the monastery of what had been given. The *Book of Deer* is a work of much interest to the Gaelic scholar, and his best thanks are due to the Spalding Club and the late Dr John Stuart for the excellent volume they have published, containing all that is interesting in the original, with a full and learned account of it.

Of the period immediately after the *Book of Deer* there are several MS. remains of Scottish Gaelic writing in existence. There is the Glenmasan MS. in the Edinburgh Advocates' Library, inscribed with the date 1238, and containing several interesting fragments. Here we find the famous lay of Deirdre or Darthula, connected with the story of the sons of Usnoth. The whole character of this MS. is identical with that of the Irish MSS., and yet it is manifestly a Scottish work. There are lives of saints preserved; one of these, in the Advocates' Library, is the life of St Findchua. Mr Skene, in his *Chronicles of the Picts and Scots*, gives transcripts of several important MSS., as the Duan Albanach, or poetical accounts of the Scottish kings, recited by the royal bard at the coronation of Malcolm Kenmore. This was copied from an Irish MS., but is manifestly a Scottish composition. The bards of both Ireland and Scotland often crossed the Irish Channel, and their works were well known on both sides of it.

The 14th and 15th centuries were a period of revival of literature over the whole continent of Europe, and the Celts of Great Britain and Ireland felt the impulse. This was a period of much writing both in Ireland and in Scotland. The remains that exist are of a varied kind, and are numerous, especially those of the 15th century. Of this century is the only Gaelic charter that we possess, which is printed, with a translation, in the *National Records of Scotland*. Of this age also are numerous medical MSS. Some of these belonged to the famous family of Beatons, hereditary physicians to the Lords of the Isles, and contain accounts of such remedies as were believed at the time to have efficacy in the cure of disease. Others are metaphysical treatises, while others deal with what were looked upon as the great and important mysteries of astrology. Of this period also are most of the written genealogies that remain. The remarkable thing is the extent to which the Gaelic language bears the marks of cultivation at the time. In both medicine and metaphysics words are found to express the most abstract ideas, which could not be understood by the modern Highlander. As has already been said, some of these writings are translations from Arabic writers, as Averroes, Avicenna, Iacobus de Forlivio, and others. The state of learning at the time in the Highlands was not behind that in the rest of the kingdom. The clergy and the physicians, and even the bards, were possessed of real learning, and have left evidence of it.

The 16th century was the period of two important additions to Gaelic literature. The first of these was what is called "The Dean of Lismore's book," a collection of poetical pieces, and an obituary, chiefly of the M'Gregor chiefs, made about the year 1512. The work has recently been transcribed, translated, and edited, with notes by the Rev. Dr M'Lauchlan, and an introduction and additional notes by Mr W. F. Skene. The work is one which has helped to settle several interesting questions connected with Gaelic literature. It makes clear that, down to the period of the dean of Lismore of 1512, there was much in common between the Celtic scholars and bards of Ireland and those of Scotland, while the latter were striking out a course for themselves, in laying aside the Irish letter and orthography, and in using the Saxon letter and an orthography almost purely phonetic. The dean of Lismore's book is a substantial addition to the literature of the Gael. The same century furnished us with another important addition in the translation of the prayer-book usually called "John Knox's Liturgy" into Gaelic, by John Carswell, the bishop of the Isles. This is the first Gaelic book that ever was printed, and bears the date of 1567. There was till very recently only one complete copy of this work in existence, that in the library of the duke of Argyll; but now the book has been reprinted, edited by Dr M'Lauchlan, who has given an English translation, and such notices of the life of Carswell as very scanty materials would permit. This book is printed in the Roman letter. The publication of Carswell's Gaelic prayer-book would seem to indicate that at the time of its publication the Highlanders could read Gaelic, and that they were familiar with the dialect then in use among scholars both in Scotland and Ireland.

Of the 17th century not many remains exist. Calvin's *Catechism* was published about the beginning of the century, probably translated by Carswell, and published long after his death. A copy is now hardly to be found. But two important contributions were made towards the close of the century. The one of these was the metrical translation of the Gaelic Psalms, executed both by the synod of Argyll and the Rev. Robert Kirke of Balquhidder; and the other was an edition, in the Roman letter, of Bedell's Irish Bible for the use of the Highlanders of Scotland. The first fifty of the psalms by the synod were published in 1659, and the whole psalter was completed in 1694. Kirke published his version in 1684. Both are highly creditable performances, and Kirke is entitled to special commendation, inasmuch as the Gaelic language was acquired by him after he was settled in the Highlands. Kirke's version of the Irish Bible for the use of the Highlanders was published in 1690. The New Testament is that of O'Donnell. This work is accompanied by a glossary including the words in the Irish Bible not generally in use in the Highlands. The book was for a time used in Highland churches, but the Irish Bible, in the Irish letter, was well known and read in the Highlands—both in churches and in families.

The 18th century was productive of large additions to Gaelic literature, partly due to an awakening of religious life, partly to the Jacobite rising, and partly to the progress of literary culture. In the beginning of the century Lhuyd produced his *Vocabulary*, accompanied by a few interesting Gaelic compositions from the Highlands. About the same time, the synod of Argyll executed a translation of the Confession of Faith and Larger and Shorter Catechisms. These were published in 1725. M'Donald's *Vocabulary* appeared in the year 1741. It is the first attempt at anything like a vocabulary of the Gaelic. It is of little value except as being the first book in which the orthography approached to that of the modern Gaelic. During this century several famous Gaelic bards flourished. M'Donald, the author of the *Vocabulary*, filled the country with Jacobite and other songs. The former are of a violent character, indicating keen partisanship with the exiled Stuarts. M'Intyre of Glenorchy, commonly called Duncan Ban, flourished about the same period, and, though he was a Jacobite at first, this appeared less in his compositions than in M'Donald's. His hunting and other descriptive songs are admirable. M'Kay or Calder, usually called Rob Donn, the Reay bard, flourished about the same time, and has left numerous admirable pieces of Gaelic poetry. Others were also successful composers, such as William Ross of Gairloch, and the religious poet of the Highlands, Dougal Buchanan. And towards the close of the century was published Gillies's *Collection of Gaelic Poetry*, one of the best collections we possess, containing, as it does, many authentic pieces of Ossianic poetry taken down when the old clan system was still in force in the Highlands to a larger extent than now. But the 18th century was distinguished by two works of special interest, in different departments. The first of these was the Gaelic translation of the Bible, and the second was Macpherson's *Ossian*. The former was executed chiefly by the Rev. James Stewart, of Killin, and his son the Rev. Dr John Stewart, of Luss,—two eminent scholars, who had all the soundness of judgment necessary for such a work. This translation of the Bible has been most popular in the Highlands and throughout the British colonies where the Gaelic is still spoken. The Gaelic learner cannot do better at the outset than master the Gaelic Bible. Macpherson's *Ossian* appeared about the same time, but not in Gaelic. It appeared first in English dress. This was the only mode of making the general public acquainted with it. Macpherson's first small volume of fragments appeared altogether in English; it would have been well if both the original and the translation had been published simultaneously. The only part of the Gaelic that was published before 1818 was what is called a "Specimen of the Original of Temora," given with the other poems in English in 1762. The opinions with regard to the authenticity of Macpherson's *Ossian* are as various as ever, and yet considerable progress has been made in the discovery of truth, which all parties are prepared to acknowledge. It has been established that poems ascribed to Ossian have been known and written down in the Highlands for 300 years, that many of them have been handed down by tradition, that these were fragments referring to certain important events in the history of the Gaelic race, and that there was nothing to make it improbable that such poems as those translated by Macpherson could have existed. Further, it is clear that the Highlanders at once, whether they knew the pieces or not as given by Macpherson, recognized them as in a style familiar to them, and as relating to persons and events with which they were familiar. That Macpherson found materials for his work in the Highlands is beyond a doubt, and it seems quite as manifest that he used very considerable liberties with them in order to serve his object of producing a great Gaelic epic poem or poems. In 1818 the full Gaelic version was printed, long after the death of James Macpherson. *The Poems of Ossian*, as collected, and translated, and edited by Macpherson, are a valuable and interesting addition to Gaelic literature, and enter largely into the history of the modern literature of Europe. The Saxon may have his doubts about Ossian, and may have little scruple or delicacy in stating them, but the Gael knows more about Ossian than he does about Milton, and is more familiar with his heroes than with those of Homer.

The 19th century has seen many large contributions to the literature of the Gaelic Celt. It has shared in the general progress of learning, and with this it has risen in the estimation of the scholars of Europe. Grammars and dictionaries have been compiled; magazines of various kinds have been started and carried on for a time with much vigour; collections, such as Mackenzie's *Beauties of Gaelic Poetry*, have been made; and such provisions have been laid up for the future as to secure an ample supply of materials for the scholars of a coming age. That appears to be the special work laid upon the scholars of the present time. They have to collect materials and commit them to writing, and to describe the peculiarities that are distinctive of a living language, for the use of those who hereafter can only study it as existing in books, where emphasis, and tone, and accent are altogether unknown, and where the comments and expositions of living men, familiar with the language and the literature from their childhood, are altogether awanting. For that the Gaelic language is in a state of decay is manifest to the most ordinary observer. And the decay is twofold, being both within and without. Within, the vocabulary is waning, and English words are coming into use. Gaelic idioms are in like manner disappearing, and English idioms replacing them; while from without, under the influence of education, immigration, steamboats, railways, and other modern devices, English is rapidly finding its way into the land, and pushing the ancient tongue out of it. When this process is completed, a change will befall the people too, for there is no doubt that there is a close relation between the character of a language and the character of the people who use it; so that, when the Gaelic disappears, many of the features distinctive of the Highland character will disappear along with it. In some respects this will be cause of regret; in others perhaps it will not.

At the close of the article CELTIC LITERATURE a list is given of the existing MS. remains of Gaelic literature. It may interest readers and aid students of Gaelic to furnish here a list of some of the more important printed books in the language. They are as follows:—

Fragments in *Report of Highland Society on Ossian*; Fragments in *Chronicles of Picts and Scots*; *The Book of Deer*; *The Book of the Dean of Lismore*; Carsewell's Prayer Book; Bedell's and O'Donell's Bible; The Gaelic Psalter, various editions; The Confession of Faith, and Catechisms; Lhuyd's *Vocabulary*; M'Donald's *Vocabulary*; *Ossian's Poems*; Smith's *Sean Dana*; Gillies's *Collection of Poems*; Macdonald's *Poems*; M'Intyre's *Poems*; Rob Donn's *Poems*; Dougal Buchanan's *Hymns*; M'Callum's *Collection of Poetry*; The Gaelic Bible; Stewart's *Collection of Poems*; Turner's *Collection of Poems*; *Sacred Poetry of the North*, edited by Rose; *The Beauties of Gaelic Poetry*, M'Kenzie; Grant's *Hymns*; M'Intosh's *Gaelic Proverbs*; Stewart's *Gaelic Grammar*; Munro's *Gaelic Grammar*; Highland Society's *Gaelic Dictionary*; Armstrong's *Gaelic Dictionary*; M'Alpin's *Gaelic Dictionary*; *Highland Tales*, collected and edited by J. F. Campbell; *Leabhar na Feinn*, by J. F. Campbell; *An Duanaire*, by D. C. M'Pherson; *An Teachdaire Gaelach*, by Rev. Dr M'Leod; *An Fhianis*, by Rev. Dr Mackay; *An Gaidheal*, a magazine; numerous translations from the English, chiefly religious works; Connell's *Astronomy*; M'Kenzie's *History of Scotland*; besides many others. (T. M'L.)

GAETA, at one time the "Gibraltar of Italy," a strongly-fortified seaport town in the province of Caserta, at the extremity of a peninsula forming the N.W. boundary of the Gulf of Gaeta, with a station on the railway 40 miles N.W. of Naples. The citadel occupies the heights of the peninsula, and the town stretches below in a long thin line. To the east lies the harbour, one of the safest on the whole coast, with a depth of about 15 feet. The principal buildings are the cathedral, the churches, the conventual buildings (of which the most noteworthy are those of the Franciscans and the Benedictines), the hospital, and the foundling asylum. In the cathedral, which was founded or partially built by Barbarossa, are several objects of historical interest:—the body of St Erasmus (the St Ermo or Elmo, whose "fires" are familiar to the Mediterranean sailor); the standard presented by Pope Pius V. to Don John of Austria, the hero of the battle of Lepanto; and a baptismal font from the ruins of Formiæ, which had formerly been an altar to Bacchus, and still bears the Greek inscription Σαλπίων Ἀθηναῖος ἐποίησε. Among the larger remains of Roman Gaeta are a temple and an aqueduct; and the circular *Torre d'Orlando*, which crowns the height above the citadel, is, in reality, the sepulchre of L. Munatius Plancus, as is distinctly proved by a well-preserved inscription. The suburbs of Gaeta, called Castellona, Mola di Gaeta, and Del Borgo, are larger than the town itself, and form a separate commune under the name of Formia (see FORMIA). The population of the town in 1871 was 7193, and of the commune, which includes Anatola, 18,385.

Gaeta is identified with Caieta, a town of great antiquity, about whose origin and name very different accounts are offered by the various Greek and Roman writers. Virgil makes it the burial-place of Caieta the nurse of Æneas, while Strabo connects the name with a Laconian word signifying a cavern. In Cicero's time the harbour of Caieta was a *portus celeberrimus et plenissimus navium*, and it was afterwards greatly improved by Antoninus Pius. As a town, the Roman Caieta does not appear to have attained to any great development or importance. On the fall of the Western empire it became a republic, or free town, under the Byzantine government, and it was also the residence of the imperial prætor for Sicily. A considerable increase of its population and power resulted from the destruction of the neighbouring town of Formiæ by the Arabs, in 850. In the 9th century Pope John VIII. bestowed the fief on Pandolf, count of Capua; but in 877 Duke Docibilis called in the assistance of the Arabs against the Capuans, and in the course of the 11th century we find the people of Gaeta exercising their rights for the election of their dukes. At a later period the fief became an apanage of the princes of the successive dynasties of Naples. The capture of the town by Pedro, brother of the king of Aragon, in 1435, was followed by the erection of the fortress to which so much of its subsequent importance was due. Ferdinand the Catholic and Charles V. both added to the strength of its defences. In 1707 the citadel was taken by storm by the Austrian general, Daun, after a three months' siege; and in 1734 it was forced to capitulate, after a five months' siege, by the allied army under Charles, afterwards king of Naples. In 1806 it was brilliantly defended against the French, under Masséna, by Prince Louis of Hessen-Philippsthal, who was, however, severely wounded and obliged to leave the fortress to its fate. Pope Pius IX. found an asylum in the governor's palace at Gaeta in 1848, and remained there till September 1849. In 1861 it afforded a last point of defence for Francis II. of Naples, who capitulated to the Piedmontese on 13th February. Gaeta has given the name of Gaetani to a famous Italian family, about whose original connexion with the town there are, however, various accounts; and Antonio di Gaeta, one of the great Benedictine missionaries to Africa in the 17th century, bears the mark of his origin.

See Rosetto, *Breve descrizione delle cose più notabili di Gaeta*, reprinted by Antonio Bulifone, at Naples, in 1690; "Geschichte von Gaeta," in *Oester. milit. Zeitschrift*, 1823.

GÆTULIA, or the land of the Gætuli, an ancient district of somewhat uncertain limits in northern Africa. It may be roughly said to have been bounded on the N. by Mauretania and Numidia, E. by the country of the Garamantes, S. by the basin of the Niger, and W. by the Atlantic; but the frontiers must have been of a very uncertain and shifting character. The Gætulians, who, according to a tradition mentioned by Sallust, were one of the two great aboriginal races of northern Africa, appear to have retreated inland before the encroachments of the Numidians and Mauretanians, but continued to make incursions over a wide stretch of country. Ethnographically, they were quite distinct from the negro races, and indeed probably belonged to the great Berber race, which still forms so important an element in the population of North Africa. Their southern tribes having mingled with negro tribes, acquired the distinctive title of Melano-Gætuli or Black Gætulians. A warlike, roving people, they bestowed great attention on the rearing of horses, and, according to Strabo, had 100,000 foals in the course of a year. They were clad in skins, lived on flesh and the milk of their cows, mares, and camels, and took almost no advantage of the valuable productions of their country. It was not till the Jugurthine war that they became familiar to the Romans; but afterwards their name occurs with great frequency in Latin poetical literature, and, indeed, the adjective Gætulian became little more than a synecdoche for African. Allusions are more particularly made to Gætulian purple, which was obtained from the murex of the African coast. In the Jugurthine war some of the Gætulian tribes assisted the Numidian king with a contingent of horse; but during the civil war Cæsar found among them very serviceable allies in his contest with Juba. Augustus, having made Numidia a Roman province, affected to assign a portion of the Gætulian territory to Juba as a compensation; but the Gætulians rose in revolt and massacred the Roman residents, and it was not till a severe defeat had been inflicted on them by Cossius Lentulus that they consented to recognize their gratuitous sovereign. By his victory Lentulus acquired the title of Gætulicus. Ibn Said in the middle of the 13th century, Ibn Khaldun at the end of the 14th, Leo Africanus in the beginning of the 16th, and Marmol about sixty years later, are all quoted by M. Vivien de St Martin in his *Le Nord de l'Afrique*, 1863, as mentioning a mountainous country called Gozulé, Gutzula, or Guézula in the south of Morocco. He is disposed further to identify the Gætulians with the Godâla, who, according to Ibn Said, occupied the maritime portion of the great desert, and are referred to by other Arabian geographers as the Djoddala; and it is even possible, he thinks, that their name survives in that of the Ghedala between Cape Blanco and the Lower Senegal on the one hand, and that of the Beni Guechtula in the Algerian province of Bougie on the other.

GAGE, THOMAS (1721–1787), governor of Massachusetts, second son of the first Viscount Gage, was born in England in 1720. He entered the army at an early age, became lieutenant-colonel of the 44th regiment of foot in 1750, was made major-general and governor of Montreal in 1761, and in 1763 succeeded Amherst in the command of the British forces in America. In 1774 he was appointed governor of Massachusetts, and in that capacity was entrusted with carrying into effect the Boston Port Act. In this political crisis, by his hesitancy in adopting measures against the leaders of the insurrectionary party, and contenting himself with fortifying Boston, he enabled the Americans to mature their plans in comparative security. The battle at Lexington, in which a detachment sent by him, on the 18th April 1775, to destroy the cannon and ammunition at Concord was defeated, inaugurated the American revolutionary war. On the 12th June he proclaimed martial law, and proscribed Samuel Adams and John Hancock, offering pardon to all the other rebels who should return to their allegiance; but the result of these measures was at once to exasperate and encourage the Americans. Although Gage gained the nominal victory of Bunker's Hill (June 17), he was unable to raise the siege of Boston; and being shortly afterwards superseded by General Howe, he sailed for England. He died in 1787.

GAGERN, HANS CHRISTOPH ERNST, BARON VON (1766–1852), a German statesman and political writer, was born at Kleinniederheim, near Worms, January 25, 1766. After completing his studies at the universities of Leipsic and Göttingen, he entered the service of the prince of Orange-Nassau, whom in 1791 he represented at the imperial diet. He was afterwards appointed ambassador to Paris, where he remained till the decree of Napoleon, forbidding all persons born on the left side of the Rhine to serve any other power than France, compelled him to resign his office. He then retired to Vienna, and in 1812 he endeavoured to promote insurrection against Napoleon in Tyrol. On the failure of this attempt he left Austria and joined the headquarters of the Prussian army. When the prince of Orange became king of the Netherlands, Baron Gagern was appointed his prime minister, and in 1815 he represented him at the congress of Vienna, and succeeded in obtaining for the Netherlands a considerable aggrandisement of territory. From 1816 to 1818 he continued to be Netherland ambassador at the German diet, where, while endeavouring to promote German unity, he also advocated the adoption of measures which should secure the independence of the individual states. In 1820 he retired with a pension to his estate of Hornau, in Hesse-Darmstadt; but, as a member of the first chamber of the states of the grand duchy, he continued to take an active share in the promotion of measures for the welfare of his country. He retired from public life in 1848, and died at Hornau, 22d October 1852. Three of the sons of Baron Gagern have attained considerable eminence—one as a soldier, and two, who are still living (1879), as politicians.

His principal works are—*Die Resultate der Sittengeschichte*, 6 vols., 1808–1822; *Die Nationalgeschichte der Deutschen*, Vienna, 1812; 2d ed. in 2 vols., Frankfort, 1825–26; *Mein Antheil an der Politik*, 4 vols., Stuttgart, 1823–33; *Kritik des Völkerrechts*, Leipsic, 1840; and *Civilisation*, Leipsic, 1847.

GAILLAC, the capital of an arrondissement in the department of Tarn, France, is situated on the right bank of the Tarn, 12 miles W. of Albi. It possesses two churches of the 13th century, a communal college, a hospital, a theatre, and a military prison. Its industries include the manufacture of wine casks, leather, brandy, bricks, and various kinds of coarse cloth; and it has a considerable trade in corn, vegetables, dried plums, and wine, the white and red wines of the arrondissement having a high reputation. Gaillac was in existence in the 7th century. It was captured by the English in 1280, and its archives were taken to London. Even at that time it was famed for its wines, which, under the name of *Vin du Coq*, were exported to England and Holland. The population in 1876 was 6099.

GAILLARD, Gabriel Henri (1726–1806), a French historian, was born at Ostel, Picardy, in 1726. He was educated for the bar, but after finishing his studies adopted the literary profession, ultimately devoting his chief attention to history. In 1801 he was chosen a member of the French Academy, and he was also one of the original members of the Institute. For forty years he was the intimate friend of the minister Malesherbes. He died at St Firmin, near Chantilly, 13th February 1806. Gaillard is painstaking and impartial in his statement of facts, and his style is correct and elegant, but the unity of his narrative is somewhat destroyed by digressions, and by his method of treating war, politics, civil administration, and ecclesiastical affairs under separate heads.

His most important work is his *Histoire de la rivalité de la France et de l'Angleterre*, in 11 vols., 1771–1777; and among his other works may be mentioned *Essai de rhétorique française, à l'usage des jeunes demoiselles*, 1745, often reprinted, and in 1822 with a life of the author; *Histoire de Marie de Bourgogne*, 1757; *Histoire de François I.*, 7 vols 1776–1779; *Histoire des grandes querelles entre Charles V. et François I.*, 2 vols., 1777; *Histoire de Charlemagne*, 2 vols., 1782; *Histoire de la rivalité de la France et de l'Espagne*, 8 vols., 1801; *Dictionnaire historique*, 6 vols., 1789–1804, making part of the *Encyclopédie méthodique*; and *Mélanges littéraires*, containing *éloges* on Charles V., Henry IV., Descartes, Corneille, La Fontaine, Malesherbes, and others.

GAINSBOROUGH, a market-town and port of Lincolnshire, is situated on the right bank of the Trent, 21 miles above its junction with the estuary of the Humber, and 16 miles N.W. of Lincoln. It consists chiefly of one long well-paved street running parallel to the river, which is here crossed by a fine stone bridge of three arches. The parish church, a fine building in the Grecian style, was rebuilt in 1748, with the exception of the old tower, which belongs to the 12th century. Holy Trinity church, built in 1843, has annexed to it an ecclesiastical district taken out of the old parish of Gainsborough. The old hall, supposed to have been partly built by John of Gaunt, is a curious oak-timber framed building, forming three sides of a quadrangle, and having a tower 78 feet high. It has been restored, and part of it converted into a corn exchange and assembly rooms. Gainsborough possesses a grammar school (founded in 1589 by a charter of Queen Elizabeth) and other schools, a town-hall, a county court-house, a literary institute, a temperance hall, a savings-bank, and a provident dispensary. Ship-building is carried on, and there are manufactories of linseed cake, ropes, malt, and tobacco, with breweries and iron and brass foundries. Vessels of 200 tons burden can come up to the town. The population in 1871 was 7564, and since that date has been rapidly increasing.

GAINSBOROUGH, Thomas (1727–1788), a painter famous for the truth and elegance of his portraits, and for the simple beauty of his landscapes, was born at Sudbury, Suffolk, in the year 1727. His father, who carried on the business of a woollen crape-maker in that town, was of a respectable character and family, and was noted for his skill in fencing; his mother excelled in flower-painting, and encouraged her son in the use of the pencil. There were nine children of the marriage. At ten years old, Gainsborough had sketched every fine tree and picturesque cottage near Sudbury, and at fifteen, having filled his task-books with caricatures of his schoolmaster, forged his father's handwriting to get a holiday, and sketched the portrait of a man whom he had detected in the act of robbing his father's orchard, he was allowed to follow the bent of his genius in London, under such advantages as Hayman, the historical painter, and the academy in St Martin's Lane, could afford. Three years of study in the metropolis were succeeded by two years of idleness in the country. Here he fell in love with Margaret Burr, a young lady of many charms, including an annuity of £200, married her after a short courtship, and, at the age of twenty, became a householder in Ipswich, his rent being £6 a year. The annuity was reported to come from Margaret's real (not her putative) father, who was one of the exiled Stuart princes, or else the duke of Bedford. At Ipswich, Gainsborough tells us, he was "chiefly in the face-way," though his sitters were not so numerous as to prevent him from often rambling with his friend Joshua Kirby (president of the Society of Artists) on the banks of the Orwell, from painting many landscapes with an attention to details which his later works never exhibited, or from joining a musical club, and entertaining himself and his fellow-townsmen by giving concerts. But as he advanced in years he became ambitious of advancing in reputation. Bath was then the general resort of wealth and fashion, and to that city, towards the close of the year 1759, he removed with his wife and two daughters, the only issue of their marriage. His studio in the circus was soon thronged with visitors; he gradually raised his price for a half-length portrait from 5 to 40 guineas, and for a whole-length from 8 to 100 guineas. Among his sitters at this period were the authors Sterne and Richardson, and the actors Quin, Henderson, and Garrick. Meanwhile he contributed both portraits and landscapes to the annual exhibitions in London. He indulged his taste for music by learning to play the viol-di-gamba, the harp, the hautboy, the violoncello. His house harboured Italian, German, French, and English musicians. He haunted the green-room of Palmer's theatre, and painted gratuitously the portraits of many of the actors. He gave away his sketches and landscapes to any one who had taste or assurance enough to ask for them; and, in the summer of 1774, having already attained a position of great prosperity, he took his departure for the metropolis, and fixed his residence at Schomberg House, Pall Mall, a noble mansion still standing, for which the artist paid £300 a year.

Gainsborough had not been many months in London ere he received a summons to the palace, and to the end of his career he divided with West the favour of the court, and with Reynolds the favour of the town. Sheridan, Burke, Clive, Blackstone, Hurd, were among the number of those who sat to him. But in London as in Bath his landscapes were exhibited, were commended, won the good opinion of Walpole the fastidious and Wolcot the surly, and were year after year returned to him, "till they stood," says Sir William Beechey, "ranged in long lines from his hall to his painting-room." Gainsborough was a member of the Royal Academy, but in 1784, being dissatisfied with the position assigned on the exhibition-walls to his portrait of the three princesses, he withdrew that and his other pictures, and he never afterwards exhibited there. In February 1788, while witnessing the trial of Warren Hastings, he felt an extraordinary chill at the back of his neck; this was the beginning of a cancer (or, as some say, a malignant wen) which proved fatal on 2d August of the same year.

Gainsborough was tall, fair, and handsome, generous, impulsive to the point of capriciousness, easily irritated, not of bookish likings. The property which he left at his death was not large. One of his daughters, Mary, had married contrary to his wishes, and was subject to fits of mental aberration.

Gainsborough and Reynolds rank side by side as the greatest portrait painters of the English school. It is difficult to say which stands the higher of the two, although Reynolds may claim to have worked with a nearer approach to even and demonstrable excellence. In grace, spirit, and lightness of insight and of touch, Gainsborough is peculiarly eminent. His handling was slight for the most part, and somewhat arbitrary, but in a high degree masterly; and his landscapes and rustic compositions are not less gifted than his portraits. Among his finest works are the likenesses of Lady Ligonier, the duchess of Devonshire, Master Buttall (the Blue Boy), Mrs Sheridan and Mrs Tickell, Orpin the parish-clerk (National Gallery), the Hon. Mrs Graham (Scottish National Gallery), his own portrait (Royal Academy), Mrs Siddons (National Gallery); also the Cottage Door, the Market Cart, the Return from Harvest, the Woodman and his Dog in a Storm (destroyed by fire), and Waggon and Horses passing a Brook (National Gallery). He made a vast number of drawings and sketches.

In 1788 Philip Thicknesse, lieut.-governor of Landguard Fort, who had been active in promoting Gainsborough's fortunes at starting, but was not on good terms with him when he left Bath, gave to the world *A Sketch of the Life and Paintings of Thomas Gainsborough*; in 1829 Allan Cunningham published a memoir of him in his *Lives of the Painters*; and in 1856 there appeared *A Life of Thomas Gainsborough, R.A.*, by G. W. Fulcher.

GAISSIN, Gaicyn, or Haiscin, a town of Russia, at the head of a district in Podolia, 178 miles E. of Kamenetz Podolski or Podolian Kamenetz, in 48° 39′ N. lat. and 29° 23′ E. long., near the river Sop, a tributary of the Bug. With few exceptions, the houses are built of wood, and the inhabitants are mainly supported by agriculture. Among the public buildings are an orthodox church, a synagogue and four Jewish chapels, and a town hospital. In 1860 the population was 10,106, of whom 1863 were Jews. In the *St Petersburg Calendar* for 1878 the total is given as 9417. Gaissin dates from about 1600: in one of the Acts of 1615 it is stated that Heyszyn or Gaissin was founded with royal privilege by the ban Swierski about 15 years before. In 1659 King John Casimir of Poland bestowed it on Maximus Buliga the Zaporogian chief. It obtained Magdeburg rights in 1744 or 1745; and in 1796, after the incorporation of Podolia with Russia, it was made a district town.

GAIUS, a celebrated Roman jurist. Of his personal history very little is known. It is impossible to discover even his full name, Gaius or Caius being merely a personal name (prænomen) very common in Rome. From internal evidence in his works it may be gathered that he flourished in the reigns of the emperors Hadrian, Antoninus Pius, Marcus Aurelius, and Commodus. His works were thus composed between the years 130 and 180, at the time when the Roman empire was most prosperous, and its government the best. Most probably Gaius lived in some provincial town, and hence we find no contemporary notices of his life or works. After his death, however, his writings were recognized as of great authority, and the emperor Valentinian named him, along with Papinian, Ulpian, Modestin, and Paulus, as one of the five jurists whose opinions were to be followed by judicial officers in deciding cases. The works of these jurists accordingly became most important sources of Roman law.

Besides the *Institutes*, which are a complete exposition of the elements of Roman law, Gaius was the author of a treatise on the *Edicts of the Magistrates*, of *Commentaries on the Twelve Tables*, and on the important *Lex Papia Poppæa*, and several other works. His interest in the antiquities of Roman law is apparent, and for this reason his work is most valuable to the historian of early institutions. In the disputes between the two schools of Roman jurists he generally attached himself to that of the Sabinians, who were said to be followers of Ateius Capito, of whose life we have some account in the *Annals* of Tacitus, and to advocate a strict adherence as far as possible to ancient rules, and to resist innovation. Many quotations from the works of Gaius occur in the *Digest* of Justinian, and so acquired a permanent place in the system of Roman law; while a comparison of the *Institutes* of Justinian with those of Gaius shows that the whole method and arrangement of the later work were copied from that of the earlier, and very numerous passages are word for word the same. Probably, for the greater part of the period of three centuries which elapsed between Gaius and Justinian, the *Institutes* of the former had been the familiar text-book of all students of Roman law.

Unfortunately the work was lost to modern scholars, until, in 1816, a manuscript was discovered by Niebuhr at Verona, in which certain of the works of St Jerome were written over some earlier writings, which proved to be the lost work of Gaius. The greater part of the palimpsest has, however, been deciphered by various German scholars, and the text is now fairly complete.

This discovery has thrown a flood of light on portions of the history of Roman law which had previously been most obscure. Much of the historical information given by Gaius is wanting in the compilations of Justinian, and, in particular, the account of the ancient forms of procedure in actions. In these forms can be traced "survivals" from the most primitive times, which provide the science of comparative law with valuable illustrations, which may explain the strange forms of legal procedure found in other early systems. Another circumstance which renders the work of Gaius more interesting to the historical student than that of Justinian, is that Gaius lived at a time when actions were tried by the system of formulæ, or formal directions given by the prætor before whom the case first came, to the judex to whom he referred it. Without a knowledge of the terms of these formulæ it is impossible to solve the most interesting question in the history of Roman law, and show how the rigid rules peculiar to the ancient law of Rome were modified by what has been called the equitable jurisdiction of the prætors, and made applicable to new conditions, and brought into harmony with the notions and the needs of a more developed society. It is clear from evidence of Gaius that this result was obtained, not by an independent set of courts administering, as in England until recently, a system different from that of the ordinary courts, but by the manipulation of the formulæ. In the time of Justinian the work was complete, and the formulary system had disappeared.

The *Institutes* of Gaius are divided into four books—the first treating of persons and the differences of the status they may occupy in the eye of the law; the second of things, and the modes in which rights over them may be acquired, including the law relating to wills; the third of intestate succession and of obligations; the fourth of actions and their forms.

There are several carefully prepared editions of the *Institutes*; the first was that of Göschen, published in 1820. During the next fifty years more than twenty new editions appeared. A list of these, and of the various treatises on Gaius, is given in the preface to Böcking's edition. The most complete English edition is that of Mr Poste, which includes beside the text an English translation and copious commentary. A comparison of the early forms of actions mentioned by Gaius with those used by other primitive societies will be found in Sir H. Maine's *Early Institutions*, cap. 9. For further information see M. Glasson, *Étude sur Gaius et sur le jus respondendi.*

GALABAT, GALLABAT, or METEMME, a town in the frontier district of Egypt and Abyssinia, near one of the western sub-tributaries of the Atbara, about 100 miles W. of Gondar, in 13° N. lat. and 36° E. long. Most of the houses are built in the Abyssinian style, with conical roofs of grass, and the place would be of little importance if it were not the staple market for the exportation of Abyssinian produce across the Egyptian frontier. Beeswax, coffee, cotton, and hides are the principal articles of legitimate trade; but as recently at least as 1873 the traffic in slaves was quite as important a department of its commerce. The town and district form a small ethnographical island, being peopled by a colony of Tokrooris from Darfur, who, finding the spot a convenient resting-place for their fellow-pilgrims on their way to Mecca and back, obtained permission from the king of Abyssinia to make a permanent settlement. They are an industrious race, and grow a considerable quantity of cotton. When Sir Samuel Baker was at Galabat in 1862, the sheikh refused to recognize the authority of the viceroy of Egypt; but when De Cosson passed through in 1873, the Egyptians had a camp, with a strong stone wall, on the top of a hill commanding the town, and acted as masters of the place. The population of the town and district, which have an area of about 40 square miles, is estimated at 20,000. Galabat is the proper name, and Metemme is really the native word for a capital.

GALANGAL, formerly written "galingale," and sometimes "garingal," *rhizoma galangæ* (Arabian, *Kholinjan*;[1] German, *Galgantwurzel*; French, *Racine de Galanga*), is an aromatic stimulant drug. Lesser galangal root, *radix galangæ minoris*, the ordinary galangal of commerce, is the dried rhizome of *Alpinia officinarum*, Hance, a plant of the natural order *Zingiberaceæ*, growing in the Chinese island of Hainan, where it is cultivated, and probably also in the woods of the southern provinces of China. The plant is regarded by Dr Hance as closely allied to, but as perfectly distinct from, the *Alpinia calcarata* of Roscoe, the rhizome of which is sold in the bazaars of some parts of India as a sort of galangal. Its stems attain a length of about 4 feet, and its leaves are slender, lanceolate, and light green, and have a hot taste; the flowers are ebracteate, white with red veins, and in simple racemes; the roots form dense masses, sometimes more than a foot in diameter; and the rhizomes grow horizontally, and are ¾ inch or less in thickness. The drug occurs in short, cylindrical, or somewhat tuberous, often forked pieces, which have a fibrous structure, and externally are reddish-brown and marked with fine longitutional striations, and with transverse rings showing the points of attachment of scales or leaves, and internally are of a light-brown, becoming darker at the centre. It has a warm, aromatic taste, resembling that of mingled ginger and pepper. On analysis it yields, among other constitutents, much starch, an essential oil of the composition $C_{10}H_{16},H_2O$ (Vogel), and a crystalline body, *kämpferid* (Brandes). Greater or Java galangal, *radix galangæ majoris* (French, *Galanga de l'Inde*), the rhizome of *Alpinia Galanga*, Willd., is a drug rarely now imported into Europe. It is mentioned by Marco Polo (ed. Yule, ii. p. 217) and Garcias da Horta as a product of Java, and the latter distinguishes it from the Chinese or lesser galangal, from which it is known by its larger size, orange-brown exterior, and feebler and less aromatic odour. The seed-capsules of *Alpinia Galanga* are believed to be what are termed "galanga cardamoms," which have the properties of cardamoms and ginger combined, and in China are used for various medicinal purposes. (See Hanbury, *Science Papers*, pp. 107–9, and 252, 253, 1876; and F. P. Smith, *op. cit.*) Galangal seems to have been unknown to the ancient Greeks and Romans, and to have been first introduced into Europe by Arabian physicians. It is mentioned in the writings of Ibn Khurdádbah, an Arabian geographer who flourished in the latter half of the 9th century, and "gallengar" (galingale or galangal) is one of the ingredients in an Anglo-Saxon receipt for a "wen salve" (see O. Cockayne, *Saxon Leechdoms*, vol. iii. p. 13). In the Middle Ages, as at present in Livonia, Esthonia, and central Russia, galangal was in esteem in Europe both as a medicine and a spice, and in China it is still employed as a therapeutic agent. Its chief consumption is in Russia, where it is used as a cattle-medicine, and as a flavouring for liqueurs. By the Tartars it is taken with tea (see Hanbury, *op. cit.*, p. 374). The exports of galangal from Shanghai, in China, amounted in 1869 to 370,000 ℔, value £3046, 16s. 9d. Chinese or lesser galangal was in past times commonly known as "Cyperus Babylonicus," from its resemblance to the tubers of plants of the genus *Cyperus*, which apparently served as a substitute for it[2] (*cf.* Fuchs, *Op. Didactica*, pars ii. p. 28, 1604, fol.; and Avicenna, ed. Plempii, lib. ii. p. 297, 1658, fol.). Gerarde (*The Herball*, p. 28, 1597) terms the species *Cyperus longus* "English galingale."

Soc.*, Botany, vol. xiii., 1873, p. 1; Flückiger and Hanbury, *Pharmacographia*, 1874, and the above quoted *Science Papers* of the latter author, pp. 370–375; Bentley and Trimen, *Medicinal Plants*, pt. xxxi., tab. 271; and *Histoire des Drogues*, vol. ii., 7th ed., 1876.

GALAPAGOS ISLANDS, an archipelago of five larger and ten smaller islands, situated in the Pacific Ocean exactly under the equator, about 500 or 600 miles W. of Ecuador. They were discovered about the beginning of the 16th century by the Spaniards, who gave them their present name from the numerous *galápago* or giant tortoises they found there. The larger members of the group, several of them attaining an elevation of 3000 to 4000 feet, are Albemarle (75 miles long and 15 broad), Narborough, Indefatigable, Chatham, and James Islands. The total area is estimated at 2250 square miles.

The extraordinary number of craters, a few of them still active, "in size from mere spiracles to huge caldrons several miles in circumference," to be found throughout the islands, gives evidence that the archipelago has been the result of volcanic action. It stands in very deep water, and Mr Darwin thinks that it has never been nearer to the mainland than it is now, nor have its members been at any time closer together. None of the islands are inhabited, with the exception of Charles, Chatham, and Albemarle, which, since 1829, have been used by the Government of Ecuador

[1] Apparently derived from the Chinese *Kau-liang-Kiang*, *i.e.*, Kau-liang ginger, the term applied by the Chinese to galangal, after the prefecture Kau-chau fu in Canton province, formerly called Kau-liang (see F. Porter Smith. *Contrib. to the Materia Medica . . . of China*, p. 9, 1871).

[2] Alexander Neckam, an English author (1157–1217), says of "cyperus," in his poem *De Laudibus Divinæ Sapientiæ* (see Wright's edition of his works, p. 478, London, 1863) —

"Hydropicus laudat cyperum, vulnus, stomachusque,
Humor siccandus. calculus, atque lien."

as a penal settlement for political offenders, who find an easy subsistence on the bananas, Indian corn, and sweet potatoes which readily grow in the black fertile mud of the higher parts, and on the large herds, now become wild, of cattle, swine, and goats. The principal settlement, founded by General Vilamil in 1832, is situated in Charles Island, and bears the name of La Floreana, in honour of Floris, the president of Ecuador. At one time it contained 200 or 300 inhabitants; but when the United States steamer "Hassler" visited the Galapagos in 1871, there were little more than a dozen. In 1872 about 2000 cattle had perished in the island. The archipelago was formerly a frequent resort of vessels in quest of turtle; and it is still visited by parties from Guayaquil in quest of a species of moss, which is sent to the English market under the name of *orchilla*.

Though the islands are under the equator, the climate is not intensely hot, as it is tempered by cold currents from the Antarctic Sea, which, having followed the barren coast of Peru as far as Cape Blanco, bear off to the N.W. towards and through the Galapagos. Very little rain falls, except during the short season from November to January. The clouds indeed hang low, and the nights are misty, but this benefits those districts only which attain a height of over 800 or 1000 feet and enter the moist upper air; so that there alone, and chiefly on the side from which the winds oftenest blow, is there anything like a luxuriant vegetation. The low grounds are entirely parched and rocky, presenting merely a few thickets of Peruvian cactus and stunted shrubs, and a shore as uninviting as it well can be.

The greatest interest attaches to the study of all the oceanic islands, for the elucidation of the origin and development of their fauna and flora has an important bearing on the question of the genesis of species. The Galapagos archipelago possesses in this respect a rare advantage from its isolated situation, and from the fact that its history has never been interfered with by any aborigines of the human race, and that it is only very lately that the operation of man or of animals introduced by his means have disturbed, and that to a very limited extent only, the indigenous life. Many of the more remarkable animal and vegetable forms are confined to one islet of the group, and are represented on the others by allied but different species. Of the indigenous gigantic tortoises there are five species at present known, each of which is an inhabitant of a different island, and it is believed that many others have become extinct. There are two species, one terrestrial, the other marine, of a peculiar genus of lizard. Nearly all the land birds are peculiar to the archipelago, and of these more than half belong to peculiar genera. The flora of the Galapagos is most remarkable; it differs by upwards of one half of its species from that of the rest of the globe. Both the fauna and flora indicate affinity with the South American continent; and the peculiarities of their distribution can be explained only by the supposition that species were transported to the islands by some accident at very rare and remote intervals, and have become changed through natural selection under the new conditions to which they have been exposed. That there should be so few species common to the different islands is accounted for by their separation from each other by deep channels scoured by rapid currents, the direction of which, and of the winds, rarely violent in this region, does not favour inter-migration. Many of the islands are yet but imperfectly known.

Soc.*, part ix., 1876, p. 447; Sir J. D. Hooker, "On the Vegetation of the Gal. Arch.," *Trans. Lin. Soc.*, vol. xx. p. 235; Dr A. Günther, "Description of the living and extinct races of Gigantic Tortoises of the Galapagos Islands," *Phil. Trans.*, vol. clxv. p. 251; A. R. Wallace, *Geographical Distribution of Animals*; Villavicencio, *Geografia de la Rep. del Ecuador*, 1858.

GALASHIELS, a parliamentary burgh and manufacturing town of Scotland, built on both sides of the river Gala, about a mile above its confluence with the Tweed, and 33 miles south of Edinburgh. It is situated partly in Roxburghshire and partly in Selkirkshire, but for all judicial purposes it is held, by special Act of Parliament passed in 1867, as entirely within the county of Selkirk. The "forest-steading of Galashiels" is first mentioned in history shortly after the beginning of the 15th century, when it was the occasional residence of the Douglases, who at that time held the office of keeper of Ettrick forest. In 1599 it was erected into a burgh of barony, when it contained 400 inhabitants. For the next 200 years Galashiels remained a mere village, as the population in 1778 had only grown to 600. At that time, however, we find its inhabitants engaged—though in a limited way—in those manufactures by which it has since so greatly prospered. There were 30 looms and 3 waulk (or fulling) mills; and the cloth manufactured was a coarse woollen texture which sold at from 1s. 6d. to 2s. a yard. In 1790 the quantity of wool used annually was 2916 stones, and the value of goods manufactured was about £1000. In the same year the first factory was erected, and advantage taken of the Gala water as a motive power; and from this time forward the woollen trade in Galashiels underwent steady progress, until, in 1879, the town contains about 20 factories with 100 sets of carding engines, using annually 220,000 stones of wool, and producing goods to the value of £750,000.

The wool chiefly used is imported from Australia and the Cape of Good Hope. The manufacture was at one time of a more diversified character than now, and embraced tweeds, shawls, tartans, &c., but it is now almost exclusively devoted to the production of tweeds. The Galashiels manufacturers have long been united in a corporation called by their name, which was instituted in 1777, and of which the minutes during the whole intervening period are still preserved. In addition to its woollen trade Galashiels has also a large skinnery, capable of manufacturing into leather 35,000 skins per week. In recent years the external aspect of the town has been very much improved by the erection of several handsome public buildings, and the introduction of a better style of architecture for shops and dwelling-houses. It was made a parliamentary burgh in 1868, and unites with Hawick and Selkirk in returning a member to parliament. Municipally, it is governed by a provost, four bailies, and ten councillors. In 1876 an Act was passed for the extension of the burgh and the introduction (since effected) of a water supply. As significant of the rapid growth of Galashiels it may be mentioned that, while in 1851 the population was only 5921, in 1871 it was 9678, and that of the extended burgh is now estimated to be nearly 15,000; while the annual assessable rental, which in 1864 was £21,000, is now £49,000.

GALATIA, afterwards called also GALLO-GRÆCIA, in ancient geography, an inland division of Asia Minor, bounded on the N. by Bithynia and Paphlagonia, E. by Pontus, S. by Cappadocia and Lycaonia, W. by Phrygia. These boundaries, however, varied at different periods in the history of Galatia. The river Halys flowed in a northerly direction through the centre of the province, the eastern half of which was watered by tributaries of that stream, while the Sangarius and its affluents traversed the western half.

Galatia originally formed a part of the extensive province of Phrygia; after its separation it was occupied by three Gallic tribes, who still continued distinct in the time of Strabo—the Trocmi, who dwelt in the east, the Tectosages in the centre, and the Tolistobogii in the west. Each of these tribes was subdivided into four parts, and these were ruled over each by a tetrarch of its own. The power of the tetrarchs was limited by a senate of 300, before which also all capital cases were tried. Minor offences came under the cognizance of the tetrarchs and special judges appointed by them. The three tribes all spoke the same tongue; and though in course of time they became Hellenized, their original language was still in use among them as late as the time of Jerome.

The physical characters of Galatia are in great measure similar to those of the adjoining provinces of Phrygia and Lycaonia, the whole region being an elevated plateau or table-land, no part of which is less than 2000 feet above the sea, while the greater part exceeds 3000 feet in elevation. The southern portion, towards Lycaonia, is the most level, and is an almost perfect plain, passing gradually into the expanse of salt desert which occupies the frontier lands of the two provinces. The rest of the country consists for the most part of vast undulating downs, affording excellent pasture for sheep and goats, and capable of producing good crops of corn, though at present in great part uncultivated, and almost wholly devoid of wood. Towards the frontiers of Bithynia it becomes more broken, and is intersected by numerous valleys, as well as by several detached ranges of hills, none of them, however, attaining to any considerable height or importance. The lofty range of the Ala-dagh (6000–7000 feet), though frequently termed the Galatian Olympus, is not properly included within the limits of the province, but forms in part the natural boundary which separates it from Bithynia. From its elevated position, the climate of Galatia is naturally one of considerable extremes of heat and cold; and while the summers are burning hot, the winters at Angora are more severe than at Paris, and the snow often lies on the ground for a month together.

The only towns of importance in Galatia were Tavium, the capital of the Trocmi, a small town which speedily fell into decay; Ancyra, the capital of the Tectosages, which under the Romans became the capital of the country, and has ever since retained its importance as one of the principal cities of Asia Minor (see ANGORA); and Pessinus, the chief town of the Tolistobogii, where a splendid temple was consecrated to Agdistis, the mother of the gods, the divinity who was worshipped at Rome under the title of Rhea or Cybele.

Galatia took its name from a body of Gauls who invaded Asia Minor about the year 277 B.C. They had formed part of the army which invaded Greece under Brennus, but having quarrelled with that commander, had left his standard, and marching into Thrace under generals of their own choice, advanced to Byzantium, whence they were invited by Nicomedes, king of Bithynia, to cross into Asia, and help him in his struggle against his brother Zipætes. After performing the required services, they turned their arms against their employer, and ravaged the western half of Asia Minor. Their success allured other hordes of their countrymen, who readily took service with the Asiatic kings in their wars against each other. No Oriental prince was found able to check them, until Attalus, king of Pergamus, defeated them in a great battle, 239 B.C., and compelled them to settle in that part of the country which after them was called Galatia. They still remained independent, however, and proved a formidable foe to the Romans in their wars with Antiochus. It was found necessary to direct a special army against them, under Cn. Manlius, and the result of the campaign (189 B.C.) was their complete subjugation to the power of Rome. Galatia was not at this time reduced to a Roman province, but the Gauls were still allowed to retain their own government under their tetrarchs. This system, however, gradually gave way, and the whole country passed under the authority of one ruler. The first of these sole tetrarchs was Deiotarus, a contemporary of Cicero and Cæsar, who, in return for the assistance which he gave the Romans in their wars against Mithridates, was rewarded with a part of Pontus and Armenia Minor, and was styled king by the senate. It was afterwards united with Lycaonia, Isauria, and several adjoining districts, under a king named Amyntas, at whose death, in 25 B.C., Galatia became a Roman province. Theodosius the Great subdivided it for purposes of government into Galatia Prima, of which Ancyra was the capital, and Galatia Secunda, with Pessinus for its chief town.

The antiquities of Galatia have in recent times been made the subject of special investigation by a French commission composed of MM. Perrot, Guillaume, and Delbet, and the result of their labours published in 2 vols. fol., Paris, 1872; but with the exception of those of Angora, they are not of much general interest.

GALATIANS, EPISTLE TO THE. *Origin.*—Although "Galatia," as a united kingdom under Amyntas, included Pisidia, as well as portions of Lycaonia and Pamphylia, and when constituted a Roman province was further enlarged so that it extended from Taurus to the Euxine (Ptol., v. 1), it may with safety be taken for granted that the name is never used in the New Testament except in its older colloquial sense as equivalent to "Gallogræcia" or "Eastern Gaul" (Γαλλία ἡ ἑῴα, Appian, *De Bell. Civ.*, ii. 49), the country of those Galli (Γλῆτες, Γαλάται, Κέλται) whose migrations and final territorial limits have already been indicated in the preceding article.[1] On this assumption, the history of the formation of the Christian "churches of Galatia" is very obscure. It is obvious enough, from the epistle itself, that they had been planted by Paul; but when, or under what circumstances, we are nowhere explicitly informed. In the Acts of the Apostles we read that, accompanied by Silas, he set out on what is generally known as his second missionary journey soon after the council of Jerusalem, which may be dated approximately as having occurred about the year 52 A.D.[2] After having traversed "Syria" and "Cilicia," strengthening the churches, they "passed through Phrygia and the region of Galatia (τὴν Γαλατικὴν χώραν), being forbidden of the Holy Ghost to preach the word in Asia; and after they were come to Mysia, they assayed to go into Bithynia, but the Spirit of Jesus suffered them not."[3] The language here employed, even if, as Wieseler argues, it implies that preaching was engaged in, can hardly be said to suggest of itself that churches had been formed on the route, but rather appears to hint at a forced and rapid march. Acts xviii. 23, however, indicates that "disciples" at least had been made, and it is well known that in the narrative of the Acts many important passages in the eventful public life of the apostle have been passed with even less explicit allusion. Combining then the meagre facts which that narrative in this instance affords with inferences derived from incidental expressions made use of in the epistle itself, we conjecture the apostle to have been detained by ill-health (see Gal. iv. 13, "because of bodily weakness"), probably in the western district of Galatia (that of the Tolistobogii), though not at the capital Pessinus itself, but nearer the borders of Asia and Mysia; and there, in the προσευχαί or synagogues, to have addressed his message to Jews,[4] proselytes, and as many of the native

[1] See Strabo, xii. p. 566 (where the words are τὴν νῦν Γαλατίαν καὶ Γαλλογραικίαν λεγομένην); and compare Pliny (*H. N.*, v. 25), who continues to distinguish Lycaonia from Galatia. The later historian Memnon also incidentally mentions that the Galatæ had taken possession of τὴν νῦν Γαλατίαν καλουμένην. Renan (*Saint Paul*, p. 48) and, latterly, Hausrath (*NTliche Zeitgeschichte*, ii. 258), however, uphold the theory that Paul when he uses the word Galatia intends the Roman province, and that by the Galatians we are to understand chiefly the Christians of Antioch, Iconium, Derbe, and Lystra. Their arguments are drawn from the ordinary *usus loquendi* of Paul (by Asia, Macedonia, Achaia he invariably means the provinces bearing these names); from the analogy of 1 Pet. i. 1, where all the districts mentioned happen to be "provinces"; from such considerations as the inaccessibility of Galatia proper; from inferences based on Acts xviii. 23, Gal. ii. 5, and other texts; and from the admittedly perplexing fact that unless the churches of Derbe, Lystra, &c., be regarded as Galatian, we are left in ignorance of the names, localities, and histories of the churches addressed. But, as has been seen, the ancient *usus loquendi* appears on the whole to have disregarded the Roman division of provinces in this case at least; moreover, Iconium was never a part of the Roman Galatia; and in any case there would have been an inappropriateness in addressing Lycaonians and Pisidians by a title so rich in ethnological and historical suggestion as that of "Galatians" is.

[2] The full consideration of the chronology of this period of sacred history must be postponed to the article PAUL.

[3] So Acts xvi. 6, 7, according to the oldest texts. See Lachmann, Tischendorf, Tregelles.

[4] For the fact of the prevalence of Jews in Galatia reference may be made to the Monumentum Ancyranum (Joseph., *Ant.*, xvi. 6. 2: *cf.* xii. 3, 4): compare 1 Pet. i. 1.

pagan population as could be induced to hear. The Galatians, although in their intercourse with one another they still continued to make use of their ancient dialect, were quite able to understand the then almost universally diffused Greek;[1] and some of them, both Jews and Gentiles,[2] almost immediately began to receive Paul's doctrine with favour and even with enthusiasm (Gal. iv. 14). How long this visit continued we are not told; but most of the chronological evidence goes to show that it cannot have lasted more than six months, and that it probably came to an end within a much shorter interval. Resuming the journey by Mysia and the Troad, Paul and his companion proceeded to "Macedonia" and "Achaia," spending in the latter province at least eighteen months, and finding no opportunity of revisiting Galatia for a space of at least three years. During this interval several causes must have been quietly but constantly working with a tendency to alienate the Galatian converts from the new "gospel of the uncircumcision" (εὐαγγέλιον τῆς ἀκροβυστίας, ii. 7), and induce them to that conformity with certain parts of Jewish ceremonial which was even at that time described by the word "Judaizing" (ἰουδαΐζειν, Gal. ii. 14). Even among those whose leanings were towards the spiritual religion of the Old Testament, Jewish habits of thinking and feeling could never fail to assert themselves with considerable strength; and there were also elements peculiar to the old pagan religion of the district which were fitted to predispose even the heathen mind towards that ceremonialism and "making a fair show in the flesh" (εὐπροσωπῆσαι ἐν σαρκί) which the apostle deprecated.[3] How or when these tendencies had first begun to manifest themselves in the way of deliberate rebellion against the teachings which Paul had left behind him, can only be a matter of pure conjecture; but it would appear that, even if the revolt had been originated by Palestinian Jews, it had at least been fomented by other agitators who were Gentiles by birth (v. 12; vi. 13); nor does it seem improbable that they had begun their work very soon after the time of the apostle's first visit. The second visit, mentioned in Acts xviii. 23, which must have taken place about 55 A.D., and have occupied very little time, appears to have been on the whole a pleasant one; the apostle was still received with due respect (iv. 12, 18), and may well have left Galatia with the impression that the disciples had been "strengthened" by him, and that they "were running well" (v. 7). But shortly after his departure tidings reached him that, though the influence of the Judaizers had for the time been neutralized by his presence, it had begun to reassert itself with greater force than ever almost immediately after he had gone, and that his disciples had been so "bewitched" that, after "having begun in the spirit," they were now endeavouring to be "made perfect by the flesh." He also learned that the reactionary doctrines had been supported by a suggestion that he himself was no teacher of independent authority, but merely a subordinate, and that a treacherous one, of the original apostles and pillars of the church, whose "gospel" was emphatically "of the circumcision." Immediately on receipt of this intelligence, he wrote the present epistle.

Contents.—It consists of three parts, in which the personal, the doctrinal, and the practical elements respectively predominate. (1.) After an expression of surprise at the instability displayed by his Galatian converts, the author proceeds to establish the divineness of his message by an historical proof of the wholly divine character of his commission to be its messenger. He urges that he had received his apostleship directly from God; and that, far from proceeding from men, it had been tardily, and so far reluctantly, acknowledged by them only after it had become an altogether patent and undeniable fact. His first visit to Jerusalem had been three years after his conversion. If it had not resulted in his recognition as on a footing of equality with the apostles, it at least had not led to his taking any position of subordination; while on his second visit to Jerusalem he had met the apostles and deliberated with them on terms of undisputed parity. On the third occasion of his coming into contact with an apostolic person so distinguished as Peter, he had openly withstood him and vanquished him in argument, thereby even establishing a superiority. (2.) He proceeds to state and defend the doctrine of justification by faith in the crucified Christ. After alluding to it as a truth already established in their Christian consciousness (iii. 1–5), he proceeds to show that the same truth had been embedded in the whole Old Testament revelation, and was capable of being deduced from the entire course of the past history of the church. The religion of Abraham had been a religion of faith, and his justification had not been a justification by works (iii. 6–18). The law which came later is misunderstood if it be regarded as superseding the promise which had been the foundation of the religion of the patriarch. Its relation to the promise was manifestly of a subordinate and temporary kind. To regard it as having been otherwise would be as absurd as to suppose that a Hagar and an Ishmael could ever have taken that place in the family which belonged of inalienable right to Sarah and to Isaac (iii. 19—iv. 31). (3.) He exhorts to a continuance in the life of faith which is also the life of freedom, and warns against any relapse under the yoke of Judaism (v. 1–12). He explains that Christian freedom is a freedom conditioned by morality (v. 13—vi. 10), and concludes with a recapitulation and the benediction.

Genuineness, Date, and Place.—The genuineness of this epistle has never been disputed. The external evidence is remarkably clear and continuous, while the internal has been such as to satisfy even the most negative school of modern criticism.[4] Its autographic character, also, is inferred by many, including Hilgenfeld, Holzmann, and other moderns, from the expression used in vi. 11; but it is at least possible that the word ἔγραψα may refer only to vi. 11–18. The question as to its date has given occasion for considerable diversity of opinion. It has been seen that the apostle wrote immediately after he had heard of the change that had come over the Galatian churches, and that this change occurred "soon" (ταχέως) after his second visit. These facts favour a date not much later than 55 A.D. Further, a comparison of the epistle to the Galatians with those to the Romans and Corinthians results, on the whole, in favour of the opinion that it was the earliest of the four, or at all events not much later than the latest, in other words, not later than 59 A.D. It is probably idle to attempt to fix the date much more precisely. The reference in 1 Cor. xvi. 1, which may mean either that friendly relations with the Galatians had been until then uninterrupted, or that they had been already restored, have determined the critics, according to the interpretation adopted, in placing it either early in the Ephesian sojourn or late in the Corinthian. The majority of the moderns is in favour of the former date (55–57 A.D.), but the latter still continues

[1] See Jerome's often-quoted *Prol. in Epist. Gal.*, "Galatos, excepto sermone Græco quod omnis oriens loquitur, propriam linguam eandem habere quam Treviros." Philologists have hardly any doubt of the essentially Celtic character of this dialect; though many German theologians still maintain it to have been Teutonic. See Lightfoot (*Galatians*), and Grimm in the *Studien u. Kritiken* for 1876.

[2] That there were any Jews among Paul's converts here has sometimes been doubted, but unreasonably. See Gal. iii. 23, 25; iv. 3. It seems probable, however, that the Gentiles were in the majority.

[3] Galatia, and particularly Pessinus, was famed for its worship of Cybele. See Livy, xxxviii. 18; Strabo, xii. p. 567.

[4] The only dissenting voice has been that of Bauer (1851).

to find supporters. Reference has already been made to the theory of Renan and Hausrath, which leads them to assign this epistle to the period of the second missionary journey. Apart from the considerations which have been indicated in a preceding note, this view is open to the objection that it raises new and gratuitous difficulties in connexion with the history and chronology of the Acts; it has accordingly met with comparatively little acceptance. According to some older writers, such as Michaelis, Koppe, Borger, the supposed absence of any reference to the council of Jerusalem implies a very early date; English readers, on the other hand, are familiar with the statement derived from some of the later Greek MSS., and supported by the Syriac and Arabic versions, as well as by the weighty authority of Eusebius, Jerome, and Theodoret, that the epistle was "written from Rome." This view has been advocated in modern times also by C. Schrader; but the general verdict will probably continue to be, as it has for some time been, adverse to a theory which would group this among the letters of the captivity rather than among those of an earlier period.

On the relation of Galatians to the book of the Acts of the Apostles, see vol. i. pp. 124, 125.

Literature.—For an interesting and detailed account of the patristic commentaries on this epistle reference may be made to an excursus by Bishop Lightfoot (*Saint Paul's Epistle to the Galatians*, 1865, 2d ed. 1874). Those belonging to the Reformation period are sufficiently well known, particularly Luther's, Calvin's, and Beza's. Of modern English commentaries the most exhaustive is that of Dr Lightfoot, already referred to; but those of Ellicott (1854), Jowett (1855), and Alford (1857) are also of great value. In Germany one of the latest is that of Wieseler (*Commentar über den Galaterbrief*, 1859); and among those who preceded him in this field, Winer (*Pauli ad Galatas Epistola lat. versa et perpetua annotatione illustrata*, 1829, 4th ed. 1859), Usteri (*Comm. ü. d. Galaterbrief*, 1833), Rückert (1833), Olshausen (1840), De Wette (1845, 3d ed. 1864), Meyer (1851, 5th ed. 1870), Hilgenfeld (1852), and Ewald (*Die Sendschreiben des Apostels Paulus übersetzt und erklärt*, 1857) are all worthy of particular mention. Windischmann's *Commentar* (1843) is an able and learned exposition from the Roman Catholic point of view. See also Holsten (*Inhalt u. Gedankengang des Br. a. d. Galater*, 1859), Hofmann (*Die heilige Schrift Neuen Testaments zusammenhängend ausgelegt*, 1863), Brandes (*D. Ap. P. Sendschreiben a. d. Galater*, 1869), Sanday (in vol. iii. of the *Speaker's Commentary*), and Venn (*On the Epistle to the Galatians*, 1878). Much help in the interpretation of the epistle is to be derived from the various works on the apostle Paul and the apostolic period of church history; also from those on New Testament Introduction, such as Hilgenfeld's (*Einl.*, 1875) and Bleek's (*Einl.*, 1875). (J. S. BL.)

GALATINA, a town of Italy, in the province and circondario of Lecce, on the road from Otranto to Taranto. It still preserves its ancient walls and towers, and possesses an interesting Franciscan church and monastery (St Catharine's), founded in the 14th century by Raimondo Orsini del Balzo, prince of Taranto. The frescos with which the church is richly decorated are of no small historical value. For a long time the inhabitants were attached to the Greek Church. In 1871 they numbered 7873.

GALATZ, or GALACZ, a town and port of Roumania, principality of Moldavia, chief town of the district of Covurlin, on the left bank of the Danube (there 2000 feet wide), between the mouths of the Pruth and Sereth, about 85 miles from the Sulina mouth of the Danube, and 130 miles N.E. of Bucharest, with which it is connected by rail, lat. 45° 26′ 12″ N., long. 28° 3′ E. Galatz is said to have got its name from a colony of the same Galatians who invaded Asia Minor in 278 B.C., though this seems doubtful. The town stands on a level plateau, and consists of two portions, an old and a new. The former, which is nearest to the river, is irregularly and badly built, with crooked streets paved with wood, some of them being regular sewers. This part of the town is liable to be flooded, and, as in the greater part of Roumania, the sanitary conditions are bad. The new town, which has rapidly extended during the past few years, is built on the rising ground towards the north-west. It is partly paved, is much more open and comfortable than the old town, and contains most of the public buildings, consulates, &c. Galatz is now to a considerable extent lighted with gas, and some time ago a regular system of water-works was commenced to supply the town with purified and filtered water. There are several Roman Catholic and Greek churches, educational institutions, a hospital, a quarantine building, &c. In the church of St Mary is the tomb of Mazeppa, said, however, to have been rifled of its contents by the Russians. Galatz is the seat of the international commission instituted by the treaty of Paris, 1856, to insure the free navigation of the mouths of the Danube; and by the treaty of Berlin, 1878, Roumania is to be represented on this commission, which exercises its duties as far as Galatz independently of all territorial rights. Galatz has been a favourite place for crossing the Danube with military expeditions since the time of the Roman emperors, though during the war of 1877–78 the Russians did not adopt it except for parties of reconnaissance. There are very few strictly Roumanian industries carried on at Galatz. There are several flour-mills, saw-mills, and breweries, extensive cooperage works, and soap and candle manufactories to a small extent; light wines are also made. Galatz is an important free port, and shares with Ibraila most of the trade of the lower Danube. The navigation of the Sulina mouth of the river has so improved that steamers of 850 tons can sail up to Galatz. There are French, Austrian, Russian, and British steamboat companies that carry on a regular trade with Galatz, and attempts have been made by the municipality to construct solid stone wharfs. For the traffic generally much inconvenience is felt from want of adequate quay and warehouse accommodation; but now that Roumania is an independent state, improvements may be made in this and other directions. A considerable proportion of ships unload at Sulina and send their cargoes up to Galatz in lighters. The river is generally frozen over for a few weeks during winter.

The staple article of export from Galatz is grain of various kinds, of which large quantities are grown in all the districts situated on the Danube. In 1876 281 sailing ships, 157 steamers, and 873 lighters, of an aggregate tonnage of 258,391 tons, cleared from the port of Galatz. The lighters had a total of 102,564 tons, while of the remainder 13 sailing ships and 70 steamers of 49,779 tons were British. In the same year the principal articles of export were—wheat, 313,673 qrs.; maize, 423,775 qrs.; barley, 160,443 qrs.; oats, 421,457 qrs.; rye, 167,840 qrs.; flour, 391,657 cwt.; fir planks, 766,869; besides considerable quantities of linseed, rape seed, beans, and small quantities of millet, wool, hides, cheese, and dried prunes. Of wheat 8000 qrs. went to Britain and 19,549 to Holland; maize, 71,500 qrs. to Britain, 21,000 to Malta; rye, 58,485 qrs. to Holland; barley, 37,347 qrs. to Britain. The total value of exports from Galatz in 1876 was £1,215,621, being a considerable increase over 1875. There does not seem to be any return of exports by rail, though Galatz is now connected with the general European railway system. The imports for 1876 were valued roughly at £1,750,000, among which manufactured goods figured at £354,000; sugar, £117,000; coal, £112,000; iron, £80,000; caviare, £66,000; oil, £65,000; rice, £58,000; coffee, £32,000; leather, £28,000; sacking, £29,000; soap, £26,000. Galatz is to cease to be a free port on 13th January 1880, after which import duties will be imposed. Constant steam communication is maintained between Galatz and Constantinople, and regular lines of steamers sail from London, Liverpool, and Hull. There is a British consulate at Galatz. The population in 1873 was estimated at 80,000; if this is correct, it has more than doubled itself in ten years; it was only 8000 in 1835.

GALBA, SERVIUS SULPICIUS (3 B.C.–69 A.D.), a Roman emperor. He came of a noble family, being sixth in direct descent from the great orator of the same name, though unconnected either by birth or adoption with the line of the first six Cæsars. He owed his elevation to the growing power of the prætorians and the discontent of the provincials, weary of Nero's rule, and beginning to assert their independence. As Tacitus justly remarks, the death of Nero divulged that secret of the empire, that emperors could be made elsewhere than at Rome. From the little we know of his earlier years he appears as a young man of remarkable gifts and even fascination—a strange contrast to his weak and unlovable old age. His biographer, Suetonius, relates that both Augustus and Tiberius prophesied to him his future rise. The story is improbable, though in part borne out by Tacitus, and rests on the authority of a credulous gossip, who inserts an omen or a prodigy at every turn of his hero's fortunes; but it helps to show, what we learn from other sources, that while still a youth he was regarded as one who was capable of great things. He resisted the solicitations of the empress Agrippina, and refused the rich legacy of Livia Augusta. Rising through the various grades of office to the consulship in 33 A.D., he acquired a high and well-merited reputation both as a general and an administrator in the provinces of Gaul, of Africa, and of Spain, which he successively held. For the first half of Nero's reign he lived in retirement, till, in 61, the emperor bestowed on him the province of Hispania Tarraconensis.

The first years of his rule were marked by rigorous discipline and strict justice, which sometimes degenerated into cruelty. We are told how he nailed the hand of a cheating money-changer to his bench, and how, when a guardian who had murdered his ward appealed to his Roman citizenship, he allowed him the honour of a higher gallows. It is true that during the later period of his administration he was indolent and apathetic, whether it was that he sought to elude the jealousy of Nero, or, as is more probable, felt the growing infirmities of age. Yet his career, taken as a whole, shows the justice of the common judgment, as reported by Tacitus, that all would have pronounced him fit for empire had he not been emperor indeed. In the spring of 68 Galba was holding an assembly at New Carthage when the news reached him of the insurrection in Gaul. The appeal of Vindex urging him to assume the championship of the oppressed human race placed Galba in an awkward dilemma, and his decision was prompted not so much by ambition as by fear of Nero, whom he knew to be plotting his death. The fall and suicide of Vindex renewed his hesitation, when the news that Nymphidius Sabinus, the prefect of the prætorians, had declared in his favour, and by large promises in his name carried the troops with him, revived his spirits. Before, he had only dared to call himself the minister of the senate and Roman people; he now assumed the title of Cæsar, and marched straight for Rome.

At first he was welcomed by the senate and the party of order, but he was never popular with the soldiers or the people, and he soon forfeited the regard even of his few supporters. He was ruined by his virtues no less than by his vices. To the prætorians who claimed their promised largess he replied that he chose his soldiers and would not buy them. The mob was disgusted at the moroseness and niggardliness of a prince who hated all display, and rewarded a popular singer with a paltry present of five denarii. But the respectable classes had graver causes of discontent. They soon found that the government was wholly in the hands of three favourites—two of them officers, and one a freedman who had followed Galba from Spain. Thus the worst abuses of the last reign were revived, without any of its brilliance and gaiety.

Galba was first made aware of the general discontent by an outbreak among the legions of Germany. He sought to avert the rising storm by an act which, if better timed and performed in a more popular way, might have saved him. He adopted as his coadjutor and successor Piso Frugi Licinianus, a man in every way worthy of the honour. The speech in which he announced to Piso his election has a genuine ring, and convinces us that his choice was wise and patriotic; but by the populace it was attributed solely to fear, and the prætorians were indignant at it because unaccompanied with the usual donative. When the elements of a revolution are all in train a leader is not far to seek. Salvius Otho, a disappointed candidate for the office of Piso, entered into communication with the discontented prætorians, and was by them adopted as their emperor. Two soldiers from the ranks undertook to transfer the empire of Rome, and actually transferred it. Galba, on his way to meet the rebels, was met by a troop of cavalry and butchered near the Lacus Curtius. A common slave severed the bald head from the body, and thrusting it inside his toga presented the bloody offering to Otho. Thus perished, unwept and unpitied, a man who, had he died a proconsul instead of an emperor, would have left as fair a fame as any Roman of the first century.

GALBANUM (Hebrew, *Chelbenah*; Greek, χαλβάνη), a gum-resin, believed to be the product of *Ferula galbaniflua*, Boiss. et. Buhse, and *F. rubricaulis*, Boiss., indigenous to Persia, and perhaps also of other umbelliferous plants. From the stems of these it is said to exude as a milk-white juice, which is rendered yellow by exposure to light and air. It occurs usually in hard or soft, irregular, more or less translucent and shining lumps, composed of agglutinated drops or tears, or occasionally in separate tears, and is of a light-brown, yellowish, or greenish-yellow colour, and has a disagreeable bitter taste, a peculiar, somewhat musky odour, and a specific gravity of 1·212. Exposed to cold, it becomes brittle, and may be reduced to powder (Pereira). To separate the vegetable and other impurities commonly present in it, galbanum is melted at 100° C., and strained. On analysis 100 parts yield about 65 of resin soluble in ether and alkaline liquids, 20 to 25 of gum, and about 7 of volatile oil. The last furnishes a colourless crystallizable substance, *umbelliferone*, $C_9H_6O_3$, which may be recognized by its formation of a blue colour with ammonia, destroyed by acids. Galbanum oil has been shown by J. Kachler (see *Journ. Chem. Soc.*; xxiv., 1871, p. 258) to contain a colourless limpid oil, boiling at 160° to 165° C., and a blue oil, of boiling point 240° to 250° C., varying in quantity with the temperature of distillation, which is isomeric with oil of turpentine, and identical with the oil of *Matricaria Chamomilla*, L. Galbanum is one of the oldest of drugs. In Exodus xxx. 34 it is mentioned as a sweet spice, to be used in the making of a perfume for the tabernacle. Hippocrates employed it in medicine, and Pliny (*Nat. Hist.*, xxiv. 13) ascribes to it extraordinary curative powers, concluding his account of it with the assertion that "the very touch of it mixed with oil of spondylium is sufficient to kill a serpent." By Arabian and Persian authors it was termed *barzud*, the plants producing it being known as *kinneh* and *nafeel* (Royle, *Man. of Mat. Med.*). Avicenna extols the drug for its emmenagogue, diuretic, and various other virtues, and as an antidote "for all poisons." In Chinese writings galbanum, *O-yü*, is not met with as a distinct drug (F. Porter Smith). It is now administered for its antispasmodic, expectorant, and stimulant properties. As an antispasmodic it is considered inferior to asafœtida, but superior to ammoniacum, which, however, is more efficacious as an expectorant in asthma. Galbanum (German, *Mutterharz*) has been supposed to have a stimulating effect upon the uterus, and has been given, combined with salts of iron, in amenorrhœa, and also is recommended in hysteria and neuralgia accompanied by uterine affections. It is an ingredient in the *pilula asafœtidæ composita* of pharmacy, and in a plaster, *emplastrum galbani*, which has been found serviceable in cases of indolent tumours and chronic arthritic swellings. Galbanum is imported to some extent from the Levant, but chiefly from India, through Bombay

See Waring, *Manual of Practical Therapeutics*, 3d ed., 1871, p. 311; Flückiger and Hanbury, *Pharmacographia*, p. 285, 1874; Bentley and Trimen, *Medicinal Plants*, No. 128.

GALE, Theophilus (1628–1678), a distinguished divine, was born in 1628 at King's Teignmouth, in Devonshire, of which place his father was vicar. In 1647 he was entered at Magdalen College, Oxford, where he took his B.A. degree in 1649, and M.A. in 1652. In 1650 he was made fellow and tutor of his college. He remained five years at Oxford, discharging actively the duties of tutor, and was then appointed to a church at Winchester. After the restoration he refused to submit to the Act of Uniformity, and was ejected from his parish. In 1662 he accepted the post of tutor to the sons of Lord Wharton, whom he accompanied to the college of Caen, in Normandy. He returned to England in 1665 and spent some years in literary work. The latter portion of his life he passed in London as assistant to the Rev. John Rowe, a dissenting minister, who had charge of an important church in Holborn. Gale succeeded Rowe in 1677, and died in the following year.

His principal work, *The Court of the Gentiles*, which appeared in parts in 1669, 1671, and 1676, is a strange storehouse of miscellaneous philosophical learning. It resembles the *Intellectual System* of Cudworth, though very inferior to that work both in general construction and in fundamental idea. Gale's endeavour is to prove that the whole philosophy of the Gentiles is a distorted or mangled reproduction of Biblical truths. Just as Cudworth referred the Democritean doctrine of atoms to Moses as the original author, so Gale tries to show that the various systems of Greek thought may be traced back to Biblical sources. Like most of the learned works of the 17th century, the *Court of the Gentiles* is chaotic and unsystematic, while its erudition is rendered almost valueless by the complete absence of any critical discrimination. The other writings of Gale are—*The Idea of Jansenism*, 1669; *Theophilus, or a Discourse of the Saint's Amity with God in Christ*, 1671; *Anatomy of Infidelity*, 1672; *Idea Theologiæ*, 1673; *Philosophia Generalis*, 1676.

GALE, Thomas (1636–1702), an eminent classical scholar, was born at Scruton, Yorkshire, in 1636. He was educated at Westminster School and at Trinity College, Cambridge, of which he became a fellow. In 1666 he was appointed regius professor of Greek, in 1672 head-master of St Paul's School, in 1676 a fellow of the Royal Society, and also prebendary of St Paul's, and in 1697 dean of York. He died at York in 1702. Gale published a collection of *Opuscula Mythologica, Ethica, et Physica*, and editions of several Greek and Latin authors, but his fame rests chiefly on his collection of old works bearing on early English history, entitled *Historiæ Anglicanæ Scriptores* and *Historiæ Britannicæ, Saxonicæ, Anglo-Danicæ, Scriptores XV*. He is the author of the inscription on the London Monument in which the Roman Catholics are accused of having originated the great fire.

GALEN, Christoph Bernhard van (1600–1678), prince-bishop of Münster, was descended from a noble family in Westphalia, and was born 15th October 1600. After attending the Jesuit college at Münster, and the universities of Cologne, Mainz, Louvain, and Bordeaux, he was engaged in several diplomatic missions. Subsequently he became colonel in the army of the elector Ferdinand of Bavaria, and took part in campaigns against the French and Swiss. On the death of Ferdinand he was chosen prince-bishop of Münster, but scarcely had he succeeded in restoring the internal prosperity of his territories, and freeing them from foreign invaders, when an insurrection arose in the city which he was unable completely to subdue till 1661. In 1664 he was chosen, along with the margrave Frederick of Baden, joint administrator of military affairs of the Rhenish alliance in its war against the Turks. After the peace that followed the victory of St Gotthard, he concluded an alliance with Charles II. of England against the Netherlands; but through the intervention of Louis XIV. an arrangement was made in 1666 by which the king of the Netherlands vacated all the territories of Galen, with the exception of the town of Borkelo. In 1672, in conjunction with France, Galen renewed hostilities against the Netherlands, but in the same year suffered a severe defeat at Coevorden, and although, along with the French general Turenne, he afterwards obtained several successes, he concluded a peace in 1674, by which he resigned all the advantages he had gained. In the following year he entered into an alliance with the king of Denmark and the elector of Brandenburg against Charles XI. of Sweden, and in 1676 captured Stade, the capital of the duchy of Bremen, after which he took possession of that duchy and of several places in the duchy of Verden. Subsequently he became involved in a war with East Friesland, and only consented to evacuate that territory on payment of a large sum of money. He died at Ahaus, 19th September 1678.

The *Vie de Christophe Bernard de Galen, évêque de Münster*, was published at Rouen in 1679; J. Ab. Alpen's *De vita et rebus gestis Ch. Bern. de Galen* appeared at Koesfeld in 2 vols. in 1694, an abridgment of this work at Münster in 1790, and a more extended abridgment at Ulm in 1804; and Tucking's *Geschichte des Stifts Münster unter Galen* was published at Münster in 1865.

GALEN, or Galenus, Claudius, called Gallien by Chaucer and other writers of the Middle Ages, the most celebrated of ancient medical writers, was born at Pergamus, in Mysia, about 130 A.D. His father Nicon, from whom he received his early education, is described as remarkable both for excellence of natural disposition, and for mental culture; his mother, on the other hand, appears to have been a second Xanthippe. In 146 Galen commenced the study of medicine, and in about his twentieth year he left Pergamus for Smyrna, in order to place himself under the instruction of the anatomist and physician Pelops, and of the peripatetic philosopher Albinus. He subsequently visited other cities, and in 158 returned from Alexandria to Pergamus. In 164 he went for the first time to Rome. There he healed Eudemus, a celebrated peripatetic philosopher, and other persons of distinction; and ere long, by his learning and unparalleled success as a physician, earned for himself the titles of "Paradoxologus," the wonder-speaker, and "Paradoxopœus," the wonder-worker, thereby incurring the jealousy and envy of his fellow-practitioners. Leaving Rome in 168, he repaired to his native city, whence he was soon sent for to Aquileia, in Venetia, by the emperors Lucius Verus and Marcus Aurelius. In 170 he returned to Rome with the latter, who, on departing thence to conduct the war on the Danube, having with difficulty been persuaded to dispense with his personal attendance, appointed him medical guardian of his son Commodus. In Rome Galen remained for some years, greatly extending his reputation as a physician, and writing some of his most important treatises. It would appear that he eventually betook himself to Pergamus, after spending some time at the island of Lemnos, where he learned the method of preparing a certain popular medicine, the "terra lemnia" or "sigillata." Whether he ever revisited Rome is uncertain, as also are the time and place of his death. According to Suidas, he died at the age of seventy, or in the year 200, in the reign of Septimius Severus. If, however, we are to trust the testimony of Abul-faraj, one of his Arabian biographers, his decease took place in Sicily, when he was in his eightieth year. Galen was one of the most versatile and accomplished writers of his age. He composed, it is said, nearly 500 treatises on various subjects, including logic, ethics, and grammar. Of the published works attributed to him 83 are recognized as genuine, 19 are of doubtful authenticity, 45 are confessedly spurious, 19 are fragments, and 15 are notes on the writings of Hippocrates.

Galen, who in his youth was carefully trained in the Stoic philosophy, was an unusually prolific writer on logic. Of the numerous commentaries and original treatises, a catalogue of which is given in his work *De Propriis Libris*, one only has come down to us, the treatise on Fallacies *in dictione* (*περὶ τῶν κατὰ τὴν λέξιν σοφισμάτων*). Many points of logical theory, however, are discussed in his medical and scientific writings. His name is perhaps best known in the history of logic in connexion with the fourth syllogistic figure, the first distinct statement of which was ascribed to him by Averroes. There is no evidence from Galen's own works that he did make this addition to the doctrines of syllogism, and the remarkable passage quoted by M. Minas from a Greek commentator on the *Analytics*, referring the fourth figure to Galen, clearly shows that the addition did not, as generally supposed, rest on a new principle, but was merely an amplification or alteration of the indirect moods of the first figure already noted by Theophrastus and the earlier Peripatetics.

In 1844 M. Minoides Minas published a work, avowedly from a MS. with the superscription *Galenus*, entitled Γαληνοῦ Εἰσαγωγὴ Διαλεκτική. Of this work, which contains no direct intimation of a fourth figure, and which in general exhibits an astonishing mixture of the Aristotelian and Stoic logic, Prantl speaks with the bitterest contempt. He shows demonstratively that it cannot be regarded as a writing of Galen's, and ascribes it to some one or other of the later Greek logicians. A full summary of its contents will be found in the 1st vol. of the *Geschichte der Logik* (591–610), and a notice of the logical theories of the true Galen in the same work, pp. 559–577.

There have been numerous issues of the whole or parts of Galen's works, among the editors or illustrators of which may be mentioned Jo. Bapt. Opizo, N. Leonicenus, L. Fuchs, A. Lacuna, Ant. Musa Brassavolus, Aug. Gadaldinus, Conrad Gesner, Sylvius, Cornarius, Joannes Montanus, Joannes Caius, Thomas Linacre, Theodore Goulston, Caspar Hoffman, René Chartier, Haller, and Kühn. Of Latin translations Choulant mentions one in the 15th and twenty-two in the following century. The Greek text was edited at Venice, in 1525, 5 vols. fol.; at Basel, in 1538, 5 vols. fol.; at Paris, with Latin version by René Chartier, in 1639, and in 1679, 13 vols. fol.; and at Leipsic, in 1821–33, by C. G. Kühn, considered to be the best, 20 vols. 8vo. An epitome in English of the works of Hippocrates and Galen, by J. R. Coxe, was published at Philadelphia in 1846.

Further details as to the life and an account of the anatomical knowledge of Galen will be found in the art. ANATOMY, vol. i. pp. 802–804. See also René Chartier's Life, in his edition of Galen's works; N. F. J. Eloy, *Dictionnaire Historique de la Médecine*, s. v. "Galien," tom. i., 1778; F. GALENA, a city of the United States, the capital of Jo Daviess county, Illinois, is situated on the Fever or Galena river, 6 miles above its junction with the Mississippi, and on the northern division of the Illinois Central Railroad, 180 miles W.N.W. of Chicago. The city winds around the base of rocky limestone bluffs, which spring rather abruptly from the river on both sides, and the streets rise above one another, and are connected by flights of steps. It is the commercial depôt of an extensive and fertile district, but owes its prosperity chiefly to the species of lead from which it takes its name, and the mines of which surround it in all directions, underlying, more or less densely, an area of over 1,500,000 acres. In these mines copper is also found in combination with the galena. In the earlier years the produce of the mines found its way by water to St Louis, but in 1829 the first load, 3000 ℔, was conveyed overland to Chicago. In 1846 the yield reached its highest point of 50,000,000 ℔; in 1852 it was 40,000,000; and in 1877 only 3,300,000. This diminution is due to the absence of the expensive appliances necessary for deep mining. Meanwhile zinc ore has been discovered, of which 12,000,000 ℔ were mined in 1877. The lumber produce is also considerable, averaging 7,000,000 feet annually. The principal buildings are the German-English normal school, the high school, and the building in which are included the custom-house and post-office. Galena has an iron-foundry, flour-mills, woollen mills, saw and planing mills, besides furnaces and manufactories for lead, zinc, copper, and furniture. Mining commenced in 1820, and in 1822 the United States began to grant leases of the mineral lands. The first street was laid out in 1826; village government was legalised in 1837, and a city charter granted in 1839. Population in 1850, 6004; in 1860, 8196; and in 1870, 7019, of whom 2473 were foreigners.

GALESBURG, a city of the United States, the capital of Knox county, Illinois, is situated at the junction of the Burlington and Peoria branches of the Chicago, Burlington, and Quincy Railroad, 163 miles W.S.W. of Chicago, and is the centre of a farming district of great fertility. It has several extensive manufactories of agricultural implements, besides carriages and waggons, and also contains the machine-shops and car-works of the railroad company. It is the seat of two colleges, Knox College (Congregational), founded in 1841, and Lombard University (Universalist), founded in 1852, to both of which female students are admitted. Population in 1860, 4953; and in 1870, 10,158, of whom 3136 were foreigners.

GALIANI, FERDINANDO (1728–1787), one of the most celebrated, if not one of the soundest, political economists of Italy, was born at Chieti on the 2d of December 1728. For his early education and opportunities of advancement in life he was less indebted to his parents than to his uncle, Monsignor Celestino Galiani. By his care, and at his expense, Galiani received the best education which Naples and Rome could then furnish, becoming qualified for an ecclesiastical career at a time when a clever abbé might hope to fill with profit and reputation important offices in the state as well as in the church. Galiani gave early promise of distinction as an economist, and even more as a wit. At the age of twenty-two he had produced two works by which his name became widely known far beyond the bounds of his own Naples. His taste for economic studies had been developed in the society of such men as Genovesi and Intieri, and prompted the composition of his *Trattato della Moneta*, in which many aspects of the question of exchange are set forth, always with a special reference to the state of confusion then presented by the whole monetary system of the Neapolitan Government. Galiani's fame as a humorist dated from the appearance of the *Raccolta in Morte del Boia*, a work as popular in Italian literary circles during the last century as the *Rejected Addresses* and *Bon Gaultier Ballads* have been in our own. In this volume Galiani parodied with exquisite felicity, in a series of discourses on the death of the public hangman, the style of the most pompous and pedantic Neapolitan writers of the day. Galiani's political knowledge and social qualities now pointed him out to the discriminating eye of Charles III., and his liberal minister Tanucci, as one eminently fitted to serve the Government as a diplomatist in France. He was therefore attached in the character of secretary to the Neapolitan embassy at Paris. Thither he repaired in 1759, at a time when a change in the relations between the courts of Paris and Vienna was about to exercise an influence on the course of the Seven Years' War, when the different Bourbon courts were engaged in a common action against the Jesuits, and when economic science held a foremost place in the speculations of the most eminent French writers. Galiani is chiefly remembered by posterity by the part which he took in these economic discussions. His *Dialogues sur les blés*, though published after his return to Naples, produced on its appearance a great impression, and has again and again furnished to future controversialists arguments more specious than solid against the liberty of exporting corn. The criticism of Voltaire, that Galiani's volume united the wisdom of Plato and the wit of Molière, will not be accepted as a decisive judgment on the merits of the treatise; but it may be viewed as a tolerably fair test of the regard in which it was held by Galiani's contemporaries. Galiani returned to Naples after a ten years' residence in Paris, where his reputation as a wit had long surpassed that of an economist or a statesman. Until his death at Naples, on October 30, 1787, he kept up with his old Parisian friends a correspondence, of which the tone on his side can only be compared to the wailing and howling sent forth by Ovid during his banishment to the shores of the Euxine. Absence from Paris was with him the synonym of social and literary death.

To the common editions of Galiani which are found in great public libraries must be added the essay recently published at Naples, *L'Abate Galiani*, by Alberto Marghieri, 1878, and the copious extracts from his correspondence with Tanucci, likewise published very recently in the new series of Viesseux's *L'Archivio Storico*, Florence, 1878.

GALICIA, in German *Galizien*, and in Polish *Halicz*, a crown-land of Austria which comprises the old kingdoms of Galicia and Lodomeria, the duchies of Auschwitz and Zator, and the grand-duchy of Cracow. Towards the N. and E. it has an extensive and irregular frontier conterminous with the Russian empire; in the S.W. it meets the Hungarian territory along the ridge of the Carpathian Mountains; its western borders, which are of small extent, touch both Austrian and Prussian Silesia; and in the S. it is bounded by the province of Bukowina, which was separated from it in 1849. As its area is 30,299 square miles, or more than 10,000 square miles greater than that of Bohemia, it is the largest of all the crown-lands of Austria. The population in 1869 was 5,418,016, which showed an increase since 1857 of 785,150. Of the whole 2,660,518 were males, and 2,757,498 females. The density was greatest in the circles of Biala, Tarnow, and Cracow, and least in the circle of Radworna. In 1876 the total was 6,000,326.

About a third of the whole area of Galicia is occupied by the Carpathians, and the greater proportion of the remainder consists of the terraces by which the mountain system gradually sinks down to the great eastern plains of Russia. Only a very small district near the Vistula can properly be described as lowland. The two most prominent summits of the Galician Carpathians are the Babia Gora or Women's Mountain, 5648 feet above the level of the sea, and the Waxmundska, 7189. Of the famous massif of the Tatra, hardly a fourth is within the Galician boundaries.

By its rivers Galicia belongs partly to the basin of the Baltic and partly to the basin of the Black Sea. The Dunajec, the San, and the Premsza, tributaries of the Vistula, are the navigable streams of the western region; and the Dniester, which is the principal river of the east, is navigable as far as Czartoria. There are few lakes in the country except mountain tarns; but considerable morasses exist about the Upper Dniester, the Vistula, and the San, and the ponds or dams in the Podolian valleys are estimated to cover an area of 208 square miles. Of the 35 mineral springs which can be counted in Galicia, the most frequented are Konopowka, south of Tarnopol, and Lubian and Sklo, west of Lemberg. The last is a good example of the intermittent class. The Galician climate is exceedingly severe, the range of temperature being nearly 145°. In July and August the mean temperature is 66° or 67° Fahr.; in March it is 32° or 33°. Winter is long, and the snowfall, which oftens begins in the early part of October, is very abundant. At Cracow the annual precipitation is about 23 inches, and at Lemberg about 28. Rather more than 6 per cent. of the surface of Galicia is unproductive. Forests occupy upwards of 4 million acres, but they are so badly managed that in some districts straw has to be used as fuel; 1,550,128 acres are devoted to pasture, 8,486,358 are under tillage, and 3,007,024 are under gardens and meadows. Barley, oats, and rye, are the prevailing cereals; but wheat, maize, and leguminous plants are also cultivated, and hemp, flax, tobacco, and hops are of considerable importance. In 1873 the whole crop of cereals amounted to 9,878,563 bushels; and there were 2,016,326 bushels of pulse, and 65,581,331 bushels of potatoes. In 1869 the number of horses in the crown-land was 695,610; of asses and mules, about 2000; of cattle, 2,070,572; sheep, 966,763; goats, 35,825; and swine, 734,572. The stocks of bees were upwards of 257,490, and the yearly produce of honey and wax is about 18,300 and 7166 cwt. respectively. In West Galicia there are mines of coal, ironstone, and zinc ore; and in Eastern Galicia a certain quantity of lignite is obtained. The iron ore is poor, containing only 10 or 11 per cent. of metal; and in 1873 the out-put did not exceed 108,546 cwt. Salt is procured both from mines and from salt-springs in sufficient abundance to make it an article of export to Russia. The great factory at Kalusz for the making of potash was closed in 1875, the company having failed; and the exploitation of the rich petroleum springs of East Galicia languishes for lack of capital. Cracow is the centre of the iron manufacture, but it is of comparatively small development. Tile works are very numerous; stoneware is produced in a few establishments; and the glass works number about 15. In 1874 there were 237 breweries, 598 distilleries, and 3746 mills,—no fewer than 3524 of the mills being driven by water and 172 by wind. Cigars are manufactured at Monasteryska and Winniki, Cracow, Jupielnica, and Zablotow. The textile industries are for the most part very slightly developed, but the linen trade employs 11,255 looms. Railway traffic is rapidly increasing. There is a large transit trade down the river Dniester to Russia by means of light boats built at Zuravero, Halicz, Marianpol, &c., which are usually broken up for firewood when they reach Odessa; and all the navigable streams, both north and south, are used for the transport of wood from the forests. Large quantities of Galician timber thus find their way to Dantzic, Stettin, Hamburg, and Berlin. The country is divided into the eight districts of Lemberg, Zloczow, Tarnopol, Stanislawow, Sambor, Przemysl, Tarnow, and Cracow, which altogether comprise 74 administrative circles. There are in all 83 towns, 230 market villages, and 11,000 hamlets, the most populous places being Lemberg, 87,109; Cracow, 49,835; Tarnow, 21,779; Tarnopol, 20,087; Brody, 18,890; Kolomiya, 17,679; Drohibiez, 16,888; Przemysl, 15,185; Stanislau, 14,479; Sambor, 11,749, Jaroslau, 11,166; Rzesznow, 10,090; and Sniatyn, 10,305. The chief town is Lemberg, which is the seat of the royal imperial lieutenancy or K. K. Statthalterei. According to the laws of 1861 the diet of Galicia consists of the three archbishops (those of the Roman Catholic, the Greek Catholic, and Armenian Catholic Churches), the three Roman Catholic bishops, the rectors of the universities of Lemberg and Cracow, 44 representatives of the larger landowners, 4 representatives of the capital, 3 representatives of the chambers of trade and industry, 16 from the towns and industrial centres, and 74 from the rural communes. Sixty-three members are sent to the imperial diet, of whom 20 represent the landowners, 13 the towns, 27 the rural communes, and 3 the chambers of trade, &c. The two principal nationalities in Galicia are the Poles and the Ruthenians—the former predominating in the west and the latter in the east. The Poles who inhabit the Carpathians are distinguished as Goralians (from gor, a mountain), and those of the lower regions as Mazures and Cracoviaks. The Ruthenian highlanders bear the name of Huzulians.

Galicia (or Halicz) took its rise along with the neighbouring principality of Lodomeria (or Vladimir) in the course of the 12th century—the seat of the ruling dynasty being Halicz or Halitch, a town in the present district of Stanislawow at the confluence of the Lukev with the Dniester. Disputes between the Galician and Lodomerian houses led to the interference of the king of Hungary, Bela III., who in 1190 assumed the title of *Rex Galatiæ*, and appointed his son Andreas lieutenant of the kingdom. Polish assistance, however, enabled Vladimir the former possessor to expel Andreas, and in 1198 Roman, prince of Lodomeria, made himself master of Galicia also. On his death in 1205 the struggle between Poland and Hungary for supremacy in the country was resumed; but in 1215 it was arranged that Daniel, son of Roman, should be invested with Lodomeria, and Koloman, son of the Hungarian king, with Galicia. Koloman, however, was expelled by Mstislaff of Novgorod; and in his turn Andreas, Mstislaff's nominee, was expelled by Daniel of Lodomeria, a powerful prince, who by a flexible policy succeeded in maintaining his position. Though in 1235 he had recognized the overlordship of Hungary, yet, when he found himself hard pressed by the Mongolian general Batu, he called in the assistance of Innocent IV. and accepted the crown of Galicia from the hands of a papal legate; and again, when Innocent disappointed his expectation, he returned to his former connexion with the Greek Church. On the extinction of his line in 1340 Casimir III. of Poland incorporated Galicia and Lemberg; on Casimir's death in 1377 Louis the Great of Hungary, in accordance with previous treaties, became king of Poland, Galicia, and Lodomeria; and in 1382, by the marriage of Louis's daughter with Ladislaus II., Galicia, which he had regarded as part of his Hungarian rather than of his Polish possessions, became definitively assigned to Poland. On the first partition of Poland, in 1772, the kingdom of Galicia and Lodomeria came to Austria, and to this was added the district of New or West Galicia in 1795; but at the peace of Vienna in 1809 West Galicia and Cracow were surrendered to the grand-duchy of Warsaw, and in 1810 part of East Galicia, including Tarnopol, was made over to Russia. This latter portion was recovered by Austria at the peace of Paris, and the former came back on the suppression of the independence of Cracow in 1846. Within the short period since 1860 great advances have been made in many ways in the development of the natural resources of the country and in the education of the people; and the general prosperity of the kingdom is evidenced by the rapid growth of several of its larger towns.

See Lill de Lilienbach, "Description du bassin de la Galicie et de la Podolie," in *Mémoires de la société géologique de France*, tome I., mém. iv., 1833-34; Schmedes, *Geogr.-statist. Uebersicht Galiziens*, Lemberg, 1869; Lipp, *Verkehrs- und Handelsverhältnisse Galiziens*, Prague, 1870; Zehlicke, "Die polit. und socialen Zustände Galiziens," in *Unsere Zeit*, 1870; "Die Ruthener in Galizien," in *Die Globus*, 1870; Pilat, *Statist. Mittheil. über die Verhältnisse Galiziens*, Lemberg, 1874; *Ortsrepertorium des Königreichs Galizien und Lodomerien* (official), Vienna, 1874; Zelicke, "Die deutschen Kolonien in Galizien," in *Im Neuen Reich*, 1876; Kelb in *Jahrbericht der K. Geol. Reichs-Anstalt*, 1876; "Culturfortschritte in Galizien," in *Das Ausland*, 1876. Remarkable sketches of Galician life have been given by Sacher-Masoch, whose works are well known in France and Germany. A rich literature on the subject exists in Polish.

GALICIA (Gallæcia or Callæcia, Καλλαικία, Καλαικία), an ancient kingdom, countship, or province in the N.W. angle of Spain, now divided into the provinces of Coruña, Lugo, Orense, and Pontevedra, lies between 41° 51′ and 43° 47′ N. lat., 6° 50′ and 9° 16′ W. long., and is bounded on the N. and W. by the Bay of Biscay and the Atlantic, on the S. by the Portuguese provinces of Entre Douro e Minho and Traz os Montes, and on the E. by Leon and the Asturias. The greatest length is about 125 miles, greatest breadth 115 miles; area, 11,222 square miles; population (1867), 1,937,792. Galicia is traversed from E. to W. by a continuation of the great Pyrenean and Cantabrian chain; and its surface is further broken by two spurs from that system, which, running in a south-westerly direction, enclose the basin of the Miño. The average elevation of the province is considerable, and the maximum height (6593 feet) is reached in the Peña Trevinca on the east border of Orense. The principal river is the Miño (Portuguese, *Minho*; Latin *Minius*; so named, it is said, from the minium or vermilion found in its bed), which, rising near Mondoñedo, within 20 miles of the northern coast, after a course of 170 miles in a south and south-west direction, enters the Atlantic near the port of La Guardia. It is navigable by small vessels on the lower part of its course. Of the numerous affluents of the Miño, the most important are—on the left the Sil, which rises among the lofty mountains between Leon and Asturias, and on the right the Tea, which rises on the eastern flank of Monte Fano. Among other rivers having a westerly direction may be mentioned the Tambre, the Ulla, and the Lerez or Ler, which fall into the Atlantic by estuaries or *rias* called respectively Ria Muros y Noya, Ria Arosa, and Ria Pontevedra. The rivers of the northern versant, such as the Eume, the Juvia, and the Mero, are, like those of the Asturias, for the most part short, rapid, and subject to violent floods. The coast-line of Galicia, extending to about 240 miles, is everywhere bold and deeply indented, presenting a large number of secure harbours, in this respect forming a marked contrast to the neighbouring province. The Eo, which bounds Galicia on the east, has a deep estuary, the Rivadeo, which offers a safe and commodious anchorage in 3 fathoms water at ebb-tide. Further to the west is Vivero Bay, 1 mile wide and 3 in length, affording good anchorage throughout, with from 6 to 8 fathoms of water. The Ria del Varquero y Vares is of a similar character; while the harbour of Ferrol (see FERROL) ranks among the best in Europe. On the opposite side of Betanzos Bay (the μέγας λιμήν or Portus Magnus of the ancients) is the great port of Coruña (see CORUNNA). The principal port on the western coast of Galicia is that formed by the deep and sheltered bay of Vigo, which is navigable for vessels of 500 tons to a distance of 16 miles from the ocean; but there are also good roadsteads at Corcubion under Cape Finisterre, at Marin, and at Carril. The climate of the Galician coast is mild and equable, but the interior, owing to the great elevation (the town of Lugo is upwards of 1900 feet above the sea level), has a wide range of temperature. The rainfall is exceptionally large, and snow lies on some of the loftier elevations for a considerable portion of the year. The soil is on the whole fertile, and the produce very varied. A considerable quantity of timber is grown on the high lands, and the rich valley pastures support large herds of cattle, while the abundance of oak and chestnut favours the rearing of swine. In the lowland districts good crops of maize, wheat, barley, oats, and rye, as well as of turnips and potatoes, are obtained. The fruit also is of excellent quality and in great variety, although the culture of the vine is limited to some of the warmer valleys in the southern districts. The dehesas or moorlands abound in game, and fish are plentiful in all the streams. The mineral resources of the province, which are considerable, were known to some extent to the ancients. Strabo speaks of its gold and tin, and Pliny mentions the gemma Gallaica. Mines of lead, tin, copper, and iron pyrites continue to be wrought, though under considerable disadvantages, and chiefly by foreign capitalists. Galicia is also remarkable for the number of its sulphur and other warm springs, the most important of which are those at Lugo and those from which Orense is said to take its name (Aquæ urentes).

Ethnologically the Galicians (Gallegos) are allied to the Portuguese, whom they resemble in dialect, in appearance, and in habits more than the other inhabitants of the peninsula. The men are well known all over Spain, and also in Portugal, as hardy, honest, and industrious, but for the most part somewhat unskilled, labourers; indeed the word Gallego has come to be almost a synonym in Madrid for a "hewer of wood and drawer of water." Agriculture engages the greater part of the resident population, both male and female; other industries are little developed, and the fisheries are not extensive. There are a few linen and cotton factories in the larger towns. The principal exports are live cattle, preserved meats, eggs, bones, mineral ore, fish oil, salt fish (especially sardines), chestnuts and other nuts, grain (especially maize), and potatoes. The first-mentioned item is the most considerable; the exports to England from Coruña alone having mounted in 1875 to 17,000 head, at an average value of £15. The chief imports are coal, iron, tobacco, and manufactured goods. Apart from the few carreteras reales or royal roads, which are, as elsewhere in the Peninsula, unexceptionable, the means of internal communication in Galicia are decidedly defective. The only railways are those betwixt Lugo and Coruña (61 miles), and betwixt Santiago and Carril (24½ miles). Another line, from Vigo to Orense, has been in course of construction for some time, and it is also proposed to connect Lugo with Astorga. Galicia has 10 cities and 115 towns. The capital is Santiago, which is also an archbishopric, with a population of 29,000. Lugo, Tuy, Mondoñedo, Orense, are also episcopal sees. The largest city is Coruña, the seat of the audiencia (population about 40,000). The others are Ferrol, Vigo, Betanzos, and Pontevedra.

Gallæcia, the country of the Callaici or Gallaici, seems to have been very imperfectly known to the earlier geographers. According to Eratosthenes the entire population of the peninsula were at one time called Galatæ. The region properly called by their name, bounded on the S. by the Douro and on the E. by the Navia, was first entered by the Roman legions under Decius Junius Brutus in 137–6 B.C. (Livy, lv., lvi., *Epit.*); but the final subjugation cannot be placed earlier than the time of Augustus. Under the Antonines, possibly even under Hadrian, Gallæcia and Asturia were erected into a separate Provincia Cæsaris, having been regarded previously as merely a portion of Lusitania. On the partition of Spain, which followed the successful invasions of the Suevians, Alans, and Vandals, Gallæcia fell to the lot of the first-named (411 A.D.). After an independent subsistence of nearly 200 years, the Suevian kingdom was annexed to the Visigothic dominions under Leovigild in 590. In 713 it was occupied by the Moors, who in turn were driven out of it about the year 734 by Alphonso I. of Asturias and his brother Froela. During the 9th and 10th centuries it was the subject of dispute between more than one count of Galicia and the suzerain, and its coasts were repeatedly ravaged by the Norsemen. When Ferdinand I. divided his kingdom among his sons in 1063, Galicia was the portion allotted to Garcia, the youngest of the three. Ten years afterwards it was forcibly reannexed by Garcia's brother Alphonso, and thenceforward it remained an integral part of the kingdom of Castile or of Leon. The honorary title of count of Galicia has frequently been borne by younger sons of the Spanish sovereign. In the patriotic struggles of 1808 the junta of Galicia took an important part. For administrative purposes the ancient province has since 1833 been divided into four, namely, Coruña, Lugo, Orense, and Pontevedra.

GALILEE (Γαλιλαία, גָּלִיל), the most northerly of the three provinces into which Palestine was at the Roman period divided, was bounded on the E. by the Jordan, on the S. by Samaria, on the W. by the Mediterranean, on the N.W. by Phœnicia, and on the N. by the Leontes, the extreme length being about 60 miles, the extreme breadth 30, and the area 1000 square miles. The Galilee thus defined, however, though doubtless the Galilee of Herod's tetrarchy and of later centuries, was hardly that of ordinary parlance at the beginning of the Christian era. Josephus himself, while substantially giving these boundaries (*B. J.*, iii. 3, 1, and elsewhere), yet incidentally in one place speaks of Upper Galilee as constituting the whole of Galilee proper (*Ant.* xx. 6, 1), and elsewhere in giving Xaloth (Iksâl) and Dabaratta (Debûrieh) as boundary towns, seems to exclude from Galilee the plain of Esdraelon. In the early period of the history of Israel, the word גָּלִיל or גְּלִילָה, meaning a circle, was hardly a proper name at all, but was applied to several districts with considerable generality. Thus in Josh. xiii. 2 and Joel iv. 4 reference is made to the "borders" or "coasts" (Geliloth) of the Philistines. In Josh. xxii. 10, 11, however, the "Geliloth" of Jordan means the plain of Jordan referred to in Ezekiel xlvii. 8 as "the eastern Gelilah" (compare Josh. xviii. 7); while in Josh. xx. 7, xxi. 32, hag-Galil denotes the north portion of the territory of Naphtali westward of Merom, where Kadesh, one of the six cities of refuge, lay. Here were situated the twenty "worthless" cities which Solomon gave to Hiram (1 Kings ix. 11; 2 Chr. viii. 2); and here, notwithstanding the conquests made successively by Joshua, several of the judges, David, and Solomon, the population seems to have retained a prevailingly ethnic character; for even in Isaiah's time "the land of Zebulun and the land of Naphtali" is called "Galilee of the Gentiles" (Isa. ix. 1). After the deportation by Tiglath Pileser (2 Kings xv. 29), in which it is to be presumed that chiefly Israelites were carried away, this ethnic character would most probably be intensified and extended rather than diminished either in area or in amount; and already in the time of the Maccabees, accordingly, we find the word apparently used in a considerably wider sense than in earlier times (1 Macc. v. 14, 15, x. 30; *cf.* Tob. i. 2). The later extension of the designation cannot be more particularly traced, but we know with considerable exactness what the limits were at the time of the Talmudists. The southern boundary was defined by the towns of Bethshean (Beisân), Ginæa (Jenîn), Caphar Utheni (Kefr Adân), and by the ridge of Carmel; on the east the Jordan formed the limit; while on the west and north the line ran from Carmel to Accho (Akka), and thence ascended eastwards by a great valley just south of Achzib (ez Zîb) extending 8 miles, past Kabartha (el Kâbry), Gathin (J'athûn), and Beth Zanita (Zucinîta), to Gelila (Jelîl), where it turned north near M'alia, probably the Melloth which Josephus notices as on his boundary (*B. J.*, iii. 3, 1). From Melloth it ran 12 miles north to Kania and Aiya (probably Kânah and 'Aiya), and then appears to have run east along a high ridge by Berii and Tirii (Beriâs and Tîreh), and thence, after a course of 5 miles, it trended north-east by Tifni (Tibnîn), Sifneta (Safed el Battîkh), Ailshitha ('Atshîth), and Aulam (Almôn), arriving thus at the deep gorge of the Leontes. Turning east it passed Migdol Kherub (el Khurbeh) and the "hollow of Ayun" (Merj 'Ayûn), past Takra (unknown) to Tortalga ("the snowy mountain," or Hermon), and to Kisrîn and the bounds of Iitir—that is, to Cæsarea Philippi (now Bânias), and thus to beyond Jordan. The boundary between Upper and Lower Galilee was natural, being marked on the east by the town of Caphar Hananya (Kefr 'Anân), situated at the foot of the high ridge which formed the actual line; Bersobe, on the same boundary (Josephus, *B. J.*, iii. 3, 1), is not as yet known.

Lower Galilee.—The whole of Galilee presents country more or less disturbed by volcanic action. In the lower division the hills are all tilted up towards the east, and broad streams of lava have flowed over the plateau above the sea of Galilee. In this district the highest hills are only about 1800 feet above the sea. The ridge of Nazareth rises north of the great plain of Esdraelon, and north of this again is the fertile basin of the Buttauf, separated from the sea-coast plains by low hills. East of the Buttauf extends the basaltic plateau called el Ahma ("the inaccessible"), rising 1700 feet above the sea of Galilee. North of the Buttauf is a confused hill country, the spurs falling towards a broad valley which lies at the foot of the mountains of Upper Galilee. This broad valley, running westwards to the coast, is the old boundary of Zebulun—the valley of Jiphthah-el (Josh. xix. 14). The great plain of Esdraelon is of triangular form, bounded by Gilboa on the east and by the ridge which runs to Carmel on the west. It is 14 miles long from Jenîn to the Nazareth hills, and has a mean measurement of 9 miles east and west. It rises 200 feet above the sea, the hills on both sides being some 1500 feet higher. The whole drainage is collected by the Kishon, which runs through a narrow gorge at the north-west corner of the plain, descending beside the ridge of Carmel to the sea. The broad valley of Jezreel on the east, descending towards the Jordan valley, forms the gate by which Palestine is entered from beyond Jordan. Mount Tabor stands isolated in the plain at the north-east corner, and rather further south the conical hill called Neby Duhy rises between Tabor and Gilboa. The whole of Lower Galilee is well watered. The Kishon is fed by springs from near Tabor and from a copious stream from the west side of the plain of Esdraelon. North-west of Nazareth is Wâdy el Melek, an open valley full of springs. The river Belus, just south of Acre, rising in the sea-coast marshes, drains the whole valley of Jiphthah-el. On the east the broad valley of Jezreel is full of magnificent springs, many of which are thermal. The plains of Esdraelon, and the Buttauf, and the plateau of el Ahma, are all remarkable for the rich basaltic soil which covers them, in which corn, cotton, maize, sesame, tobacco, millet, and various kinds of vegetable are grown, while indigo and sugar-cane were cultivated in former times. The Nazareth hills and Gilboa are bare and white, but west of Nazareth is a fine oak wood, and another thick wood spreads over the northern slopes of Tabor. The hills west of the great plain are partly of bare white chalk, partly covered with dense thickets. The mountains north of the Buttauf are rugged and covered with scrub, except near the villages, where fine olive groves exist. The principal places of importance in Lower Galilee are Nazareth (10,000 inhabitants), Sepphoris (now Seffûrieh), a large village standing above the Buttauf on the spurs of the southern hills, and Jenîn (En Gannim), a flourishing village, with a palm garden (3000 inhabitants). The ancient capital, Jezreel (Zerin), is now a miserable village on a precipitous spur of Gilboa; north of this are the small mud hamlets, Solam (Shunem), Endûr (Endor), Nein (Nain); on the west side of the plain is the ruin of Lejjûn (the Legio of the 4th century, which was then a place of importance). In the hills north of the Buttauf is Jefât, situated on a steep hill-top, and representing the Jotapata defended by Josephus. Kefr Kenna, now a flourishing Christian village at the foot of the Nazareth hills, south of the Buttauf, represents the probable site of Cana of Galilee, and the ruin Kâna, on the north side of the same plain, represents the site pointed out to the pilgrims of the 12th and 13th centuries.

Upper Galilee.—The mountains are tilted up towards the sea of Galilee, and the drainage of the district is towards the north-west. On the south the rocky range of Jebel Jermûk rises to 4000 feet above the sea; on the east a narrow ridge 2800 feet high forms the watershed, with steep eastern slopes falling towards Jordan. Immediately west of the watershed are two small plateaus, covered with basaltic debris, near el Jish and Kades. On the west are rugged mountains with deep intricate valleys. The main drains of the country are—first, Wâdy el 'Ayûn, rising north of Jebel Jermûk, and running north-west as an open valley, and secondly, Wâdy el Ahjâr, a rugged precipitous gorge running north to join the Leontes. The district is well provided with springs throughout, and the valleys are full of water in the spring time. Though rocky and difficult, Upper Galilee is not barren, the soil of the plateaus is rich, and the vine flourishes in the higher hills, especially in the neighbourhood of Kefr Birim. The principal town is Safed, perched on a white mountain 2700 feet above the sea. It has a population of about 9000, including Jews, Christians, and Moslems. It is one of the four sacred cities in Palestine revered by the Jews, to which nationality the majority of the inhabitants belong. Among the smaller towns we may notice Meirûn, near Safed, a place also much revered by the Jews as containing the tombs of Hillel, Shammai, and Simon bar Jochai. A yearly festival of most curious character is here celebrated in honour of these rabbis. The site of Hazor, one of the chief towns of Galilee in Bible times, has also been lately recovered. It was situated, according to Josephus, above the Lake Semechonitis (Bahr el Hûleh), and the name Hudîreh, identical with the Hebrew Hazor, has been found by the survey party in 1877 applying to a mountain and plain, near an ancient ruin, in the required position. The little village of Kades represents the once important town of Kadesh Naphtali (Josh. xix. 37). The ruins are here extensive and interesting, but belong apparently to the Greek period.

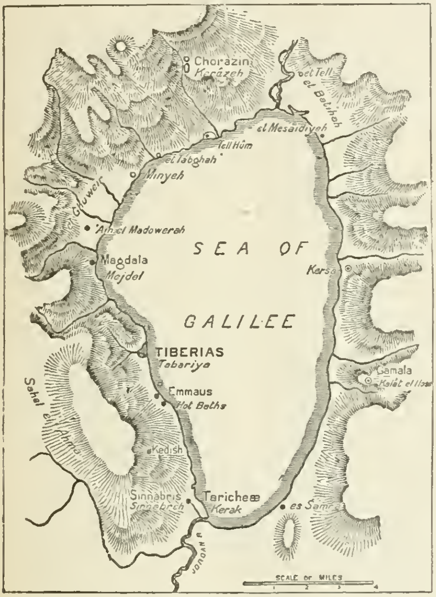
The population of Galilee is mixed. In Lower Galilee the peasants are principally Moslem, with a sprinkling of Greek Christians round Nazareth, which is a Christian town. In Upper Galilee, however, there is a mixture of Jews and Maronites, Druses and Moslems (natives or Algerine settlers), while the slopes above the Jordan are inhabited by wandering Arabs. The Jews are engaged in trade, and the Christians, Druses, and Moslems in agriculture; and the Arabs are an entirely pastoral people.

The principal products of the country are corn, wine, oil, and soap (from the olives), with every species of pulse and gourd.

The antiquities of Galilee include cromlechs and rude stone monuments, rock-cut tombs, and wine-presses, with numerous remains of Byzantine monasteries and fine churches of the time of the crusades. There are also remains of Greek architecture in various places, but the most interesting buildings are the ancient synagogues. These have not been found in other parts of Palestine, but in Galilee eleven examples are now known. They are rectangular, with the door to the south, and three rows of columns forming four aisles east and west. The architecture is a peculiar and debased imitation of classic style, attributed by architects to the 2d century of our era. The builder of the examples at Kefr Birim, el Jish, and Meirûn is known to have been the famous Simeon bar Jochai, who lived about 150 A.D., and built 24 synagogues in Galilee. The similarity of style renders it probable that the other examples at Tell Hûm, Kerâzeh, Nebartein, Umm el 'Amed, and Sufsâf were also his work. Both at el Jish and at Kefr Birim there are two synagogues, large and small. At Irbid, above Tiberias, is another synagogue of rather different character, which is said to have been built by Rabbi Nitai. Traces of synagogues have also been found on Carmel, and at Tireh, west of Nazareth. It is curious to find the representation of various animals in relief on the lintels of these buildings. Hebrew inscriptions also occur, and the carved work of the cornices and capitals is very rich. These synagogues were erected at a time when the Galilean Jews were flourishing under the Roman empire, and when Tiberias was the central seat of Jewish learning and of the Sanhedrin.

In the 12th century Galilee was the outpost of the Christian kingdom of Jerusalem, and its borders were strongly protected by fortresses, the magnificent remains of which still crown the most important strategical points. Toron (now Tibnîn) was built in 1104, the first fortress erected by the crusaders, and standing on the summit of the mountains of Upper Galilee. Beauvoir (Kaukab, built in 1182) stood on a precipice above Jordan south-west of the Sea of Galilee, and guarded the advance by the valley of Jezreel; and about the same time Château Neuf (Hunîn) was erected above the Hûleh lake. Belfort (esh Shukîf), on the north bank of the Leontes, the finest and most important, dates somewhat earlier; and Montfort (Kalat el Kurn) stood on a narrow spur north-east of Acre, completing the chain of frontier fortresses. The town of Bânias, with its castle, formed also a strong outpost against Damascus, and was the scene, in common with the other strongholds, of many desperate encounters between Moslems and Christians. Lower Galilee was the last remaining portion of the Holy Land held by the Christians. In 1250 the knights of the Teutonic order owned lands extending round Acre as far east as the Sea of Galilee, and including Safed. These possessions were lost in 1291, on the fall of Acre. (C. R. C.)

GALILEE, The Sea of, with its surrounding shores, deserves a more special description than that given of the rest of the district, as being the part of Palestine which most interests modern students and travellers. The lake was also called the Sea of Chinnereth or Chinneroth, and the Lake of Gennesaret or Tiberias; and by Pliny it is said to have been once called Lake of Tarichea. In form it is pear-



Sea of Galilee.

shaped, 12½ English miles in length, and 7½ at its greatest width. The level is now known to be 682·5 feet below the Mediterranean. The water is fresh and clear, and large shoals of fish abound in it. The formation of the lake basin occurred later than the Chalk period, and was due to a subsidence of the strata, which appears to have been sudden and violent, and probably accompanied by extensive volcanic eruptions from three centres east, west, and north of the lake. The district has always been liable to volcanic disturbance and to earthquakes. In 1837 Safed and Tiberias were destroyed by earthquake, and the temperature of the hot springs round the lake was then observed to rise considerably for a time.

The Sea of Galilee is best seen from the top of the western precipices, and presents a desolate appearance. On the north the hills rise gradually from the shore, which is fringed with oleander bushes and indented with small bays. The ground is here covered with black basalt. On the west the plateau of el Ahma terminates in precipices 1700 feet above the lake, and over these the black rocky tops called "the Horns of Hattîn" are conspicuous objects. On the south is a broad valley through which the Jordan flows. On the east are furrowed and rugged slopes, rising to the great plateau of the Jaulân (Gaulonitis). The Jordan enters the lake through a narrow gorge between lower hills. A marshy plain, 2½ miles long and 1½ broad, called el Batîhah, exists immediately east of the Jordan inlet. There is also on the west side of the lake a small plain called el Ghuweir, formed by the junction of three large valleys. It measures 3¼ miles along the shore, and is 1 mile wide. This plain, naturally fertile, but now almost uncultivated, is recognized to be the plain of Gennesareth, described by Josephus (*B. J.*, iii. 10, 8). The shores of the lake are of fine shingle. On the east the hills approach in one place within 40 feet of the water, but there is generally a width of about ¾ of a mile from the hills to the beach On the west the flat ground at the foot of the hills has an average width of about 200 yards. A few scattered palms dot the western shores, and a palm grove is to be found near Kefr Hârib on the south-east. Thermal springs are found on each side of the lake, with an average temperature of about 80° Fahr. The hot baths south of Tiberias include seven springs, the largest of which has a temperature of 137° Fahr. The plain of Gennesareth, with its environs, is the best watered part of the lake-basin. North of this plain are the five springs of et Tâbghah, the largest of which was enclosed about a century ago by Aly, son of Dhahr el 'Amr, in an octagonal reservoir, and the water led off by an aqueduct 52 feet above the lake. The Tâbghah springs, though abundant, are warm and brackish. At the north end of the plain is 'Ain et Tîneh ("spring of the fig-tree"), also a brackish spring with a good stream; south of the plain is 'Ain el Bârdeh ("the cold spring"), which is sweet, but scarcely lower in temperature than the others. The most important spring remains still to be noticed, namely, 'Ain el Madâwerah ("the round spring"), situated 1 mile from the south end of the plain and half a mile from the shore. The water rises in a circular well 32 feet in diameter, and is clear and sweet, with a temperature of 73° Fahr. The bottom is of loose sand, and the fish called coracinus by Josephus (*B. J.*, iii. 10, 8) is here found in abundance. Dr Tristram was the first explorer to identify this fish, and points out that it could not exist in the other springs. We are thus able to identify the "round spring" with the fountain of Capharnaum, which, according to Josephus, watered the plain of Gennesareth.

The principal sites of interest round the lake may be enumerated from north to west and from south to east. Kerâzeh, the undoubted site of Chorazin, stands on a rocky spur 900 feet above the lake, 2 miles north of the shore. Foundations and scattered stones cover the slopes and the flat valley below. On the west is a rugged gorge. In the middle of the ruins are the remains of a synagogue of richly ornamental style built of black basalt. A small spring occurs on the north. Tell Hûm is an important ruin on the shore south of the last mentioned site. The remains consist of foundations and scattered stones (which in spring are concealed by gigantic thistles) extending about half a mile along the shore. The foundations of a fine synagogue, measuring 75 feet by 57, and built in white limestone, have been excavated. A conspicuous building has been erected close to the water, from the fragments of the Tell Hûm synagogue. Since the 4th century Tell Hûm has been pointed out by all the Christian writers as the site of Capernaum, but the fatal objections to such an identification are—(1) the great distance from the fountain of Capharnaum, and (2) the fact that Jewish tradition preserves another site. The ruins at Tell Hûm are not of necessity as old as the time of Christ. The name Hûm means "black," and is probably connected with the surrounding black basalt. The place seems to be mentioned in the Talmud under the titles Caphar Ahim and Caphar Tanhumin (see Neubauer's *Geog. Tal.*, p. 220). Minyeh is a ruined site at the north end of the plain of Gennesareth, 2½ miles from the last, and close to the shore. There are extensive ruins on flat ground, consisting of mounds and foundations, with traces of a wall once surrounding the site. Masonry of well-dressed stones has also been here discovered in course of excavation. Near the ruins are remains of an old khân, which appears to have been built in the Middle Ages; and above this a curious hillock, with an artificial rock-platform, called el 'Oreimeh, "the little knoll." Immediately to the north-east a precipice projects to the lake, and the aqueduct from the Tâbghah spring is led to an ancient rock-cut channel, which seems to have been once intended for a road in the face of the cliff. In the 17th century Quaresmius speaks of this place, Minyeh, as the site of Capernaum. In the 14th Isaac Chelo was apparently shown the same site as containing the tomb of Nahum, and as being the "city of the Minai." The "Minai," or "sorcerers," are mentioned in the Talmud, and by this title the Jews stigmatized the early Christians; and these "Minai" are called in one passage of the Talmud "sons of Capernaum." There is thus a close connexion between this Minyeh—named from the Minai—and the town of Capernaum. The position of the site is also suitable for that of Capernaum, being in the plain of Gennesareth, two miles from the "round spring," or fountain of Capharnaum. No other site of any importance exists in the plain of Gennesareth. See CAPERNAUM.

South of the plain of Gennesareth is the undisputed site of the New Testament town of Magdala. A few lotus trees and some rock-cut tombs are here found beside a miserable mud hamlet on the hill slope, with a modern tomb-house or *kubbeh*. Passing beneath rugged cliffs a recess in the hills is next reached, where stands Tabarîya, the ancient Tiberias or Rakkath, containing 3000 inhabitants, more than half of whom are Jews. The walls, flanked with round towers, and now partly destroyed by the earthquake of 1837, were built by Dhahr el 'Amr, as was the serai or court-house. The two mosques, now partly ruinous, were erected by his sons. There are remains of a crusading church, and the tomb of the celebrated Maimonides is shown in the town, while Rabbi Akiba and Rabbi Meir lie buried outside. The ruins of the ancient city, including granite columns and traces of a sea-wall with towers, stretch southwards a mile beyond the modern town. An aqueduct in the cliff once brought water a distance of 9 miles from the south.

Kerak, at the south end of the lake, is an important site on a peninsula surrounded by the water of the lake, by the Jordan, and by a broad water ditch, while on the north-west a narrow neck of land remains. The plateau thus enclosed is partly artificial, and banked up 50 or 60 feet above the water. A ruined citadel remains on the north-west, and on the east was a bridge over the Jordan; broken pottery and fragments of sculptured stone strew the site. The ruin of Kerak answers to the description given by Josephus of the city of Tarichеæ, which lay 30 stadia from Tiberias, the hot baths being between the two cities. Taricheæ was situated, as is Kerak, on the shore below the cliffs, and partly surrounded by water, while before the city was a plain (the Ghôr). Pliny further informs us that Taricheæ was at the south end of the Sea of Galilee. Sinnabreh, a ruin on a spur of the hills close to the last-mentioned site, is undoubtedly the ancient Sinnabris, where Vespasian (Joseph., *B. J.*, iii. 9, 7) fixed his camp, advancing from Scythopolis (Beisân) on Taricheæ and Tiberias. Sinnabris was 30 stadia from Tiberias, or about the distance of the ruin now existing.

The eastern shores of the Sea of Galilee have been less fully explored than the western, and the sites are not so perfectly recovered. The town of Hippos, one of the cities of Decapolis, was situated 30 stadia from Tiberias, and 60 stadia from Gadara (Umm Keis). It is conjectured that the town Susitha, mentioned in the Talmud, is the same place, and the name Susyeh seems to have existed east of the Sea of Galilee at a late period. Susitha from "sus," meaning "horse," is, etymologically at least, suggestive of the Greek "hippos." The site is at present unknown. Kalat el Hosn ("castle of the stronghold") is a ruin on a rocky spur opposite Tiberias. Two large ruined buildings remain, with traces of an old street and fallen columns and capitals. A strong wall once surrounded the town; a narrow neck of land exists on the east where the rock has been scarped. Rugged valleys enclose the site on the north and south; broken sarcophagi and rock-cut tombs are found beneath the ruin. This site answers to the description Josephus gives of Gamala, an important fortress besieged by Vespasian (*Bell. Jud.*, iv. 1, 1). Gersa, an insignificant ruin north of the last, is thought to represent the Gerasa or Gergesa of the 4th century, situated east of the lake; and the projecting spur of hill south of this ruin is conjectured to be the place where the swine "ran violently down a steep place" (Matt. viii. 32). The site of Bethsaida Julias, east of Jordan, is also unknown. It has been supposed (and the theory is supported by even so important an authority as Reland) that two separate places named Bethsaida are mentioned in the New Testament. The grounds for this conclusion are, however, very insufficient; and only one Bethsaida is mentioned by Josephus. It was near the Jordan inlet, on the east side of the river, and under its later Greek name of Julias, it is mentioned, with Hippos, by Pliny. The site usually pointed out is the ruin of et Tell, north of the Batîhah plain; the remains are, however, modern and insignificant. Just south of the same plain is a ruined village called Mes'aidîyeh, the name of which approaches Bethsaida in sound but not in meaning. This is the site pointed out by Vandevelde, and it is possible that the course of Jordan has shifted westwards, and that the old mouth is marked by the two creeks running into the shore on the east, in which case the site of Mes'aidîyeh might be accepted as the Bethsaida of the gospels, which appears to have been east of Jordan.

Literature.—The most important works on the subject of Galilee and the Sea of Galilee are the following:—Robinson's *Biblical Researches*; Stanley's *Sinai and Palestine*; Tristram's *Land of Israel*; Warren and Wilson's *Recovery of Jerusalem*; Conder's *Tent Work in Palestine*; and the *Memoirs of the Survey of Palestine* (sheets 1–6, 8, 9). (C. R. C.)

GALILEO. Galileo Galilei (1564–1642), one of the earliest and greatest of experimental philosophers, was born at Pisa, February 18, 1564. His father, Vincenzo, was an impoverished descendant of a noble Florentine house, which had exchanged the surname of Bonajuti for that of Galilei, on the election, in 1343, of one of its members, Galileo de' Bonajuti, to the college of the twelve Buonuomini. The family, which was fifteen times represented in the signoria, and in 1445 gave a gonfalonier to Florence, flourished with the republic and declined with its fall. Vincenzo Galilei was a man of better parts than fortune. He was a competent mathematician, wrote with considerable ability on the theory and practice of music, and was especially distinguished amongst his contemporaries for the grace and skill of his performance upon the lute. By his wife, Giulia de' Ammannati of Pistoja, he had two sons, Galileo and Michelangiolo, and two daughters, Virginia and Livia. From his earliest childhood Galileo was remarkable for intellectual aptitude, as well as for mechanical invention. His favourite pastime was the construction of toy-machines, not the less original and ingenious that their successful working was usually much hindered by the scarcity of suitable materials. His application to literary studies was equally conspicuous. In the monastery of Vallombrosa, near Florence, where his education was principally conducted, he not only made himself acquainted with the best Latin authors, but acquired a fair command of the Greek tongue, thus laying the foundation of the brilliant and elegant style for which his writings were afterwards distinguished. From one of the monks he also received instruction in logic, according to the system then in vogue; but the futilities of the science revolted, while its subtleties failed to interest his understanding, and he was soon permitted to abandon a study so distasteful to him. A document published by M. Selmi in 1864 proves that he was at this time so far attracted towards a religious life as to have joined the novitiate of the order; but his father, who had other designs for him, seized the opportunity of an attack of ophthalmia to withdraw him permanently from the care of the monks. Having had personal experience of the unremunerative character both of music and of mathematics, he desired that his son should apply himself to the more profitable study of medicine, and, not without some straining of his slender resources, placed him, before he had completed his eighteenth year, at the university of Pisa. He accordingly matriculated, November 5, 1581, and immediately entered upon attendance at the lectures of the celebrated physician and botanist, Andrea Cesalpino.

The natural gifts of the young student, not less multifarious than those of an earlier Tuscan prodigy, Leonardo da Vinci, seemed at this time equally ready to develop in any direction towards which choice or hazard might incline them. In musical skill and invention he already vied with the best professors of the art in Italy; his personal taste would have led him to choose painting as his profession, and one of the most eminent artists of his day, Lodovico Cigoli, owned that to his judgment and counsel he was mainly indebted for the success of his works; his wit and eloquence gave promise that he would one day add to the literary glories of his country; while his mathematical and mechanical genius only awaited a suitable opportunity for full display and development. In 1583, while watching the vibrations of the great bronze lamp still to be seen swinging from the roof of the cathedral of Pisa, he observed that, whatever the range of its oscillations, they were invariably executed in equal times. The experimental verification of this fact led him to the important discovery of the isochronism of the pendulum. He at first applied the new principle to pulse-measurement, and more than fifty years later turned it to account in the construction of an astronomical clock. Up to this time he was entirely ignorant of mathematics, his father having carefully held him aloof from a study which he rightly apprehended would lead to his total alienation from that of medicine. Accident, however, frustrated this purpose. A lesson in geometry, given by Ostilio Ricci to the pages of the grand-ducal court, then temporarily resident at Pisa, chanced to have Galileo for an unseen listener; his attention was riveted, his dormant genius was roused, and he threw all his energies into the new pursuit thus unexpectedly presented to him. With Ricci's assistance, he rapidly mastered the elements of the science, and eventually extorted his father's reluctant permission to exchange Hippocrates and Galen for Euclid and Archimedes. In 1586 he was withdrawn from the university, through lack of means, before he had taken a degree, and returned to Florence, where his family habitually resided. We next hear of him as lecturing before the Florentine Academy on the site and dimensions of Dante's *Inferno*; and he shortly afterwards published an essay descriptive of his invention of the hydrostatical balance, which rapidly made his name known throughout Italy. His first patron was the Marchese Guidubaldo del Monte of Pesaro, a man eminent for his scientific attainments, as well as influential by his family connexions. At his request he wrote, in 1588, a treatise on the centre of gravity in solids, which obtained for him, together with the title of "the Archimedes of his time," the honourable though not lucrative post of mathematical lecturer at the Pisan university. During the ensuing two years (1589–91) he carried on that remarkable series of experiments, by which he established the first principles of dynamical science, and by which he earned for himself the undying hostility of the bigoted Aristotelians of that day. From the leaning tower of Pisa he afforded to all the professors and students of the university ocular demonstration of the falsehood of the Peripatetic dictum that heavy bodies fall with velocities proportional to their weights, and with unanswerable logic demolished all the time-honoured maxims of the schools regarding the motion of projectiles, and elemental weight or levity. But while he convinced, he failed to conciliate his adversaries. The keen sarcasm of his polished rhetoric was not calculated to soothe the susceptibilities of men already smarting under the deprivation of their most cherished illusions. He seems, in addition, to have compromised his position with the grand-ducal family by the imprudent candour with which he condemned a machine for clearing the port of Leghorn, invented by Giovanni de' Medici, an illegitimate son of Cosmo I. Princely favour being withdrawn, private rancour was free to show itself. He was publicly hissed at his lecture, and found it prudent to resign his professorship and withdraw to Florence in 1591. Through the death of his father in July of that year family cares and responsibilities devolved upon him as eldest son, and thus his nomination to the chair of mathematics at the university of Padua, secured by the influence of the Marchese Guidubaldo with the Venetian senate, was welcome, as affording a relief from pecuniary embarrassment, no less than as opening a field for scientific distinction.

His residence at Padua, which extended over a period of eighteen years, from 1592 to 1610, was a course of uninterrupted prosperity. His appointment was three times renewed, on each occasion with expressions of the highest esteem on the part of the governing body, and his yearly salary was progressively raised from 180 to 1000 florins. His lectures were attended by persons of the highest distinction from all parts of Europe, and such was the charm of his demonstrations that a hall capable of containing 2000 people had eventually to be assigned for the accommodation of the overflowing audiences which they attracted. His ingenious invention of the proportional compasses—an instrument still used in geometrical drawing—dates from 1597; and about the same time he constructed the first thermometer, consisting of a bulb and tube filled with air and water, and terminating in a vessel of water. In this instrument, the results of varying atmospheric pressure were not distinguishable from the expansive and contractive effects of heat and cold, and it became an efficient measure of temperature only when Rinieri, in 1646, introduced the improvement of hermetically sealing the liquid in glass. The substitution, in 1670, of mercury for water completed the modern thermometer.

Galileo seems, at an early period of his life, to have adopted the Copernican theory of the solar system, and was deterred from avowing his opinions—as is proved by his letter to Kepler of August 4, 1597—by the fear of ridicule rather than of persecution. The appearance, in September 1604, of a new star in the constellation Serpentarius, afforded him indeed an opportunity, of which he eagerly availed himself, for making an onslaught upon the Aristotelian axiom of the incorruptibility of the heavens; but he continued to conform his public teachings in the main to Ptolemaic principles, until the discovery of a novel and potent implement of research placed at his command startling and hitherto unsuspected evidence as to the constitution and mutual relations of the heavenly bodies. Galileo was not the original inventor of the telescope.[1] That

[1] The word *telescope*, from τῆλε, far, σκοπέω, to view, was invented by Demiscianus, an eminent Greek scholar, at the request of Prince Cesi, president of the Lyncean Academy. It was used by Galileo as early as 1612, but was not introduced into English until much later. In 1655 the word *telescope* was inserted in Bagwell's *Mysteries of Astronomy*, as a term requiring explanation, *trunk* or *cylinder* being commonly used instead.

honour must be assigned to Hans Lippershey, an obscure optician of Middleburg, who, on the 21st of October 1608, offered to the states of Holland three instruments by which the apparent size of remote objects was increased. But here his glory ends, and that of Galileo begins. The rumour of the new invention, which reached Venice in April or May 1609, was sufficient to set the Italian philosopher on the track; and after one night's profound meditation on the principles of refraction, he succeeded in producing a telescope of threefold magnifying power. Upon this first attempt he rapidly improved, until he attained to a power of thirty-two, and his instruments, of which he manufactured hundreds with his own hands, were soon in request in every part of Europe. Two lenses only—a plano-convex and a plano-concave—were needed for the composition of each, and this simple principle is that still employed in the construction of opera-glasses. Galileo's direction of his new instrument to the heavens formed an era in the history of astronomy. Discoveries followed upon it with astounding rapidity and in bewildering variety. The *Sidereus Nuncius*, published at Venice in the early part of 1610, contained the first-fruits of the new mode of investigation, which were sufficient to startle and surprise the learned on both sides of the Alps. The mountainous configuration of the moon's surface was there first described, and the so-called "phosphorescence" of the dark portion of our satellite attributed to its true cause—namely, illumination by sun-light reflected from the earth.[1] All the time-worn fables and conjectures regarding the composition of the Milky Way were at once dissipated by the simple statement that to the eye, reinforced by the telescope, it appeared as a congeries of lesser stars, while the great nebulæ were equally declared to be resolvable into similar elements. But the discovery which was at once perceived to be most important in itself, and most revolutionary in its effects, was that of Jupiter's satellites, first seen by Galileo January 7, 1610, and by him named *Sidera Medicea*, in honour of the grand-duke of Tuscany, Cosmo II., who had been his pupil, and was about to become his employer. An illustration is, with the general run of mankind, more powerful to convince than an argument; and the cogency of the visible plea for the Copernican theory offered by the miniature system, then for the first time disclosed to view, was recognizable in the triumph of its advocates, as well as in the increased acrimony of its opponents.

In September 1610 Galileo finally abandoned Padua for Florence. His researches with the telescope had been rewarded by the Venetian senate with the appointment for life to his professorship, at an unprecedentedly high salary. His discovery of the "Medicean Stars" was acknowledged by his nomination (July 12, 1610) as philosopher and mathematician extraordinary to the grand-duke of Tuscany. The emoluments of this office, which involved no duties save that of continuing his scientific labours, were fixed at 1000 scudi; and it was the desire of increased leisure, rather than the promptings of local patriotism, which induced him to accept an offer, the first suggestion of which had indeed come from himself. Before the close of 1610 the memorable cycle of discoveries begun in the previous year was completed by the observation of the ansated or, as it appeared to Galileo, triple form of Saturn (the ring-formation was first recognized by Huygens in 1655), of the phases of Venus, and of the spots upon the sun. Although his priority in several of these discoveries has been contested, inquiry has in each case proved favourable to his claims. In the spring of 1611 he visited Rome, and exhibited in the gardens of the Quirinal Palace the telescopic wonders of the heavens to the most eminent personages at the pontifical court. Encouraged by the flattering reception accorded to him, he ventured, in his *Letters on the Solar Spots*, printed at Rome in 1613, to take up a more decided position towards that doctrine on the establishment of which, as he avowed in a letter to Belisario Vinta, secretary to the grand-duke, "all his life and being henceforward depended." Even in the time of Copernicus some well-meaning persons had suspected a discrepancy between the new view of the solar system and certain passages of Scripture—a suspicion strengthened by the anti-Christian inferences drawn from it by Giordano Bruno; but the question was never formally debated until Galileo's brilliant discoveries, enhanced by his formidable dialectic and enthusiastic zeal, irresistibly challenged for it the attention of the authorities. Although he earnestly deprecated the raising of the theological issue, and desired nothing better than permission to pursue unmolested his physical demonstrations, it must be admitted that, the discussion once set on foot, he threw himself into it with characteristic impetuosity, and thus helped to precipitate a decision which it was his ardent wish to avert. In December 1613 a Benedictine monk named Benedetto Castelli, at that time professor of mathematics at the university of Pisa, wrote to inform Galileo of a recent discussion at the grand-ducal table, in which he had been called upon to defend the Copernican doctrine against theological objections. This task Castelli, who was a steady friend and disciple of the Tuscan astronomer, seems to have discharged with moderation and success. Galileo's answer, written, as he said himself, *currente calamo*, was an exposition of a formal theory as to the relations of physical science to Holy Writ, still further developed in an elaborate apology addressed by him in the following year (1614) to Christina of Lorraine, dowager grand-duchess of Tuscany. Not satisfied with explaining adverse texts, he met his opponents with unwise audacity on their own ground, and endeavoured to produce scriptural confirmation of a system which to the ignorant many seemed an incredible paradox, and to the scientific few was a beautiful but daring innovation. The rising agitation on the subject which, originating probably with the sincere upholders of the integrity of Scripture, was fomented for their own purposes by the rabid Aristotelians of the schools, was heightened rather than allayed by these manifestoes, and on the fourth Sunday of the following Advent found a voice in the pulpit of Santa Maria Novella. Padre Caccini's denunciation of the new astronomy was indeed disavowed and strongly condemned by his superiors; nevertheless, on the 5th of February 1615, another Dominican monk named Lorini laid Galileo's letter to Castelli before the Inquisition.

Cardinal Robert Bellarmine was at that time by far the most influential member of the Sacred College. He was a man of vast learning and upright piety, but, although personally friendly to Galileo, there is no doubt that he saw in his scientific teachings a danger to religion. The year 1615 seems, however, to have been a period of suspense. Galileo received, as the result of a conference between Cardinals Bellarmine and Del Monte, a semi-official warning to avoid theology, and limit himself to physical reasoning. "Write freely," he was told by Monsignor Dini, "but keep outside the sacristy." Unfortunately, he had already committed himself to dangerous ground. In December he repaired personally to Rome, full of confidence that the weight of his arguments and the vivacity of his eloquence could not fail to convert the entire pontifical court to his views. He was cordially received, and eagerly listened to, but his imprudent ardour served but to injure his cause. On the 24th of February 1616 the consulting theologians of the Holy Office characterized the two propositions—that the sun

[1] Leonardo da Vinci, more than a hundred years earlier, had come to the same conclusion.

is immovable in the centre of the world, and that the earth has a diurnal motion of rotation—the first as "absurd in philosophy, and formally heretical, because expressly contrary to Holy Scripture," and the second as "open to the same censure in philosophy, and at least erroneous as to faith." Two days later Galileo was, by command of the pope (Paul V.), summoned to the palace of Cardinal Bellarmine, and there officially admonished not thenceforward to "hold, teach, or defend" the condemned doctrine. This injunction he promised to obey. On the 5th of March the Congregation of the Index issued a decree reiterating, with the omission of the word "heretical," the censure of the theologians, suspending, *usque corrigatur*, the great work of Copernicus, *De Revolutionibus orbium cœlestium*, and absolutely prohibiting a treatise by a Carmelite monk named Foscarini, which treated the same subject from a theological point of view. At the same time it was given to be understood that the new theory of the solar system might be held *ex hypothesi*, and the trivial verbal alterations introduced into the Polish astronomer's book in 1620, when the work of revision was completed by Cardinal Gaetani, confirmed this interpretation. This edict, it is essential to observe, of which the responsibility rests with a disciplinary congregation in no sense representing the church, was never confirmed by the pope, and was virtually repealed in 1757 under Benedict XIV.

Galileo returned to Florence three months later, not ill-pleased, as his letters testify, with the result of his visit to Rome. He brought with him, for the refutation of calumnious reports circulated by his enemies, a written certificate from Cardinal Bellarmine, to the effect that no abjuration had been required of or penance imposed upon him. During a prolonged audience, he had received from the pope assurances of private esteem and personal protection; and he trusted to his dialectical ingenuity to find the means of presenting his scientific convictions under the transparent veil of an hypothesis. Although a sincere Catholic, he seems to have laid but little stress on the secret admonition of the Holy Office, which his sanguine temperament encouraged him gradually to dismiss from his mind. He preserved no written memorandum of its terms, and it was represented to him, according to his own deposition in 1633, solely by Cardinal Bellarmine's certificate, in which, for obvious reasons, it was glossed over rather than expressly recorded. For seven years, however, during which he led a life of studious retirement in the Villa Segni at Bellosguardo, near Florence, he maintained an almost unbroken silence. At the end of that time he appeared in public with his *Saggiatore*, a polemical treatise written in reply to the *Libra Astronomica* of Padre Grassi (under the pseudonym of Lotario Sarsi), the Jesuit astronomer of the Collegio Romano. The subject in debate was the nature of comets, the conspicuous appearance of three of which bodies in the year 1618 furnished the occasion of the controversy. Galileo's views, although erroneous, since he held comets to be mere atmospheric emanations reflecting sunlight after the evanescent fashion of a halo or a rainbow, were expressed with such triumphant vigour, and embellished with such telling sarcasms, that his opponent did not venture upon a reply. The *Saggiatore* was printed at Rome in October 1623, by the Academy of the Lincei, of which Galileo was a member, with a dedication to the new pope, Urban VIII., and notwithstanding some passages containing a covert defence of Copernican opinions, was received with acclamation by the ecclesiastical, no less than by the scientific authorities. Everything seemed now to promise a close of unbroken prosperity to Galileo's career. Maffeo Barberini, his warmest friend and admirer in the Sacred College, was, by the election of August 8, 1623, seated on the pontifical throne; and the marked distinction with which he was received on his visit of congratulation to Rome in 1624 encouraged him to hope for the realization of his utmost wishes. He received every mark of private favour. The pope admitted him to six long audiences in the course of two months, wrote an enthusiastic letter to the grand-duke praising the great astronomer, not only for his distinguished learning, but also for his exemplary piety, and granted a pension to his son Vincenzo, which was afterwards transferred to himself, and paid, with some irregularities, to the end of his life. But on the subject of the decree of 1616, the revocation of which Galileo had hoped to obtain through his personal influence, he found him inexorable. Nevertheless, the sanguine philosopher trusted, not without reason, that it would at least be interpreted in a liberal spirit, and his friends encouraged his imprudent confidence by eagerly retailing to him every papal utterance which it was possible to construe in a favourable sense. To Cardinal Hohenzollern Urban was reported to have said that the theory of the earth's motion had not been and could not be condemned as heretical, but only as rash; and in 1630 the learned Dominican monk Campanella wrote to Galileo that the pope had expressed to him in conversation his disapproval of the prohibitory decree. Thus, in the full anticipation of added renown, and without any misgiving as to ulterior consequences, Galileo set himself, on his return to Florence, to complete his famous but ill-starred work, the *Dialogo dei due Massimi Sistemi del Mondo.* Finished in 1630, it was not until January 1632 that it emerged from the presses of Landini at Florence. The book was orginally intended to appear in Rome, but unexpected obstacles interposed. The Lyncean Academy collapsed with the death of Prince Federigo Cesi, its founder and president; an outbreak of plague impeded communication between the various Italian cities; and the *imprimatur* was finally extorted, rather than accorded, under the pressure of private friendship and powerful interest. A tumult of applause from every part of Europe followed its publication; and it would be difficult to find in any language a book in which animation and elegance of style are so happily combined with strength and clearness of scientific exposition. Three interlocutors, named respectively Salviati, Sagredo, and Simplicio, take part in the four dialogues of which the work is composed. The first-named expounds the views of the author; the second is an eager and intelligent listener; the third represents a well-meaning but obtuse Peripatetic, whom the others treat at times with undisguised contempt. Salviati and Sagredo took their names from two of Galileo's early friends, the former a learned Florentine, the latter a distinguished Venetian gentleman; Simplicio ostensibly derived his from the Cilician commentator of Aristotle, but the choice was doubtless instigated by a sarcastic regard to the double meaning of the word. There were not wanting those who insinuated that Galileo intended to depict the pope himself in the guise of the simpleton of the party; this charge, however, was not only preposterous in itself, but wholly unsupported by intrinsic evidence, and Urban was far too sagacious to give any permanent credit to it.

It was at once evident that the whole tenor of this remarkable work was in flagrant contradiction with the edict passed sixteen years before its publication, as well as with the author's personal pledge of conformity to it. The ironical submission with which it opened, and the assumed indetermination with which it closed, were hardly intended to mask the vigorous assertion of Copernican principles which formed its substance. It is a singular circumstance, however, that the argument upon which Galileo mainly relied as furnishing a physical demonstration of the truth of the new theory rested on a misconception. The ebb and flow of the tides, he asserted, were a visible effect of the terrestrial double movement, since they resulted from the inequality of the absolute velocities through space of the various parts of the earth's surface, produced by the motion of rotation. To this notion, which took its rise in a confusion of thought, he attached capital importance, and he treated with scorn Kepler's suggestion that a certain occult attraction of the moon was in some way concerned in the phenomenon. The theological censures which the book did not fail to incur were not slow in making themselves felt. Towards the end of August the sale was prohibited; on the 1st of October the author was cited to Rome by the Inquisition. He pleaded his age, now close upon seventy years, his infirm health, and the obstacles to travel caused by quarantine regulations; but the pope was sternly indignant at what he held to be his ingratitude and insubordination, and no excuse was admitted. At length, on the 13th of February 1633, he arrived at the residence of Niccolini, the Tuscan ambassador to the pontifical court, and there abode in deep dejection for two months. From the 12th to the 30th of April he was detained in the palace of the Inquisition, where he occupied the apartments of the fiscal, and was treated with unexampled indulgence. On the 30th he was restored to the hospitality of Niccolini, his warm and generous partisan. The accusation against him was that he had written in contravention of the decree of 1616, and in defiance of the command of the Holy Office communicated to him by Cardinal Bellarmine; and his defence consisted mainly in a disavowal of his opinions, and an appeal to his good intentions. On the 21st of June he was finally examined under menace of torture; but he continued to maintain his assertion that, after its condemnation by the Congregation of the Index, he had never held the Copernican theory. Since the publication of the documents relating to this memorable trial, there can no longer be any doubt, not only that the threat of torture was not carried into execution, but that it was never intended that it should be. On the 22d of June, in the church of Santa Maria sopra Minerva, Galileo read his recantation, and received his sentence. He was condemned, as "vehemently suspected of heresy," to incarceration at the pleasure of the tribunal, and by way of penance was enjoined to recite once a week for three years the seven penitential psalms. This sentence was signed by seven cardinals, but did not receive the customary papal ratification. The legend according to which Galileo, rising from his knees after repeating the formula of abjuration, stamped on the ground, and exclaimed, "*E pur si muove!*" is, as may readily be supposed, entirely apocryphal. The earliest ascertained authority for it is the seventh edition of an *Historical Dictionary*, published at Caen in 1789. It seems probable that Galileo remained in the custody of the Inquisition from the 21st to the 24th of June, on which day he was relegated to the Villa Medici on the Trinità de' Monti. Thence, on the 6th of July, he was permitted to depart for Siena, where he spent several months in the house of the archbishop, Ascanio Piccolomini, one of his numerous and trusty friends. It was not until December that his earnest desire of returning to Florence was realized, and there, in the Villa Martellini at Arcetri, he spent the remaining eight years of his life in the strict retirement which was the prescribed condition of his comparative freedom.

Domestic afflictions combined with numerous and painful infirmities to embitter his old age. His sister-in-law and her whole family, who came to live with him on his return from Rome, perished shortly afterwards of the plague; and on the 1st of April 1634 died, to the inexpressible grief of her father, his eldest and best-beloved daughter, a nun in the convent of San Matteo at Arcetri. Galileo was never married, but by a Venetian woman named Marina Gamba he had three children—a son who married and left descendants, and two daughters who took the veil at an early age. Notwithstanding this stain on the morality of his early life, which was in some degree compensated by the regularity of his subsequent conduct, Galileo's general character was one which commanded the respect of all who approached him. His prodigious mental activity continued undiminished to the last, nor were his latter years the least profitable to science of his long and eventful career. In 1636 he completed his *Dialoghi delle Nuove Scienze*, in which he recapitulated the results of his early experiments and mature meditations on the principles of mechanics. This, in many respects his most valuable work, was printed by the Elzevirs at Leyden in 1638, and excited admiration equally universal and more lasting than that accorded to his astronomical treatises. His last telescopic discovery—that of the moon's diurnal and monthly librations—was made in 1637, only a few months before his eyes were for ever closed in hopeless blindness. It was in this condition that Milton found him when he visited him at Arcetri in 1638. But the fire of his genius was not even yet extinct. He continued his scientific correspondence with unbroken interest and undiminished logical acumen; he thought out the application of the pendulum to the regulation of clock-work, which Huygens successfully realized seventeen years later; and he was engaged in dictating to his disciples Viviani and Torricelli, his latest ideas on the theory of impact when he was seized with the slow fever which in two months brought him to the grave. On the 8th January 1642 he closed his long life of triumph and humiliation, and the coincidence of the day of his birth with that of Michelangelo's death was paralleled by the coincidence of the year of his death with that of the birth of Isaac Newton.

The direct services which Galileo rendered to astronomy are virtually summed up in his telescopic discoveries. To the theoretical perfection of the science he contributed little or nothing. He pointed out indeed that the so-called "third motion," introduced by Copernicus to account for the constant parallelism of the earth's axis, was a superfluous complication. But he substituted the equally unnecessary hypothesis of a magnetic attraction, and failed to perceive that the phenomenon to be explained was, in relation to absolute space, not a movement, but the absence of movement. The circumstance, however, which most seriously detracts from his scientific reputation is his neglect of the discoveries made during his life-time by the greatest of his contemporaries. Kepler's first and second laws were published in 1609, and his third ten years later. By these momentous inductions the geometrical theory of the solar system was perfected, and a hitherto unimagined symmetry was perceived to regulate the mutual relations of its members. But by Galileo they were passed over in silence. In his *Dialogo dei Massimi Sistemi*, printed not less than thirteen years after the last of the three laws had been given to the world, the epicycles by which Copernicus, adhering to the ancient postulate of uniform circular motion, had endeavoured to reduce to theory the irregularities of the planetary movements were neither expressly adopted nor expressly rejected; and, after exhausting all the apologies offered, the conclusion seems inevitable that this grave defection from the cause of progress had no other motive than the reluctance of the Florentine astronomer to accept discoveries which he had not originated,—this not through vulgar jealousy, of which he was incapable, but through a certain unconscious intellectual egotism, not always unknown to the greatest minds. His name, however, is justly associated with that vast extension of the bounds of the visible universe which has rendered modern astronomy the most sublime of sciences, and his telescopic observations are not less remarkable for the sagacity which directed, than for the inspiration which prompted them. With the sure instinct of genius, he seized the characteristic features of the phenomena presented to his attention, and his inferences, except when distorted by polemical exigencies, have been strikingly confirmed by modern investigations. Of his two capital errors, regarding respectively the theory of the tides and the nature of comets, the first was insidiously recommended to him by his passionate desire to find a physical confirmation of the earth's double motion; the second was adopted for the purpose of rebutting an anti-Copernican argument founded on the planetary analogies of those erratic subjects of the sun. Within two years of their first discovery, he had constructed approximately accurate tables of the revolutions of Jupiter's satellites, and he proposed their frequent eclipses as a means of determining longitudes, not only on land, but at sea. This method, on which he laid great stress, and for the facilitation of which he invented a binocular glass, and devised some skilful mechanical contrivances, was offered by him in 1616 to the Spanish Government, and afterwards to that of Tuscany, but in each case unsuccessfully; and the close of his life was occupied with prolonged but fruitless negotiations on the same subject with the states-general of Holland. The idea, though ingenious, has been found of little practical utility at sea, where the method founded on the observed distance of the moon from a known star is that usually employed.

A series of careful observations made him acquainted with the principal appearances revealed by modern instruments in the solar spots. He pointed out that they were limited to a certain defined zone on the sun's surface; he noted the *faculæ* with which they are associated, the penumbra by which they are bordered, their slight proper motions, and their rapid changes of form. He inferred from the regularity of their general movements the rotation of the sun on its axis in a period of little less than a month (the actual period is 25d. 7h. 48m.); and he grounded on the varying nature of the paths apparently traversed by them a plausible, though inconclusive, argument in favour of the earth's annual revolution. Twice in the year, he observed, they seem to travel across the solar disk in straight lines; at other times, in curves. These appearances he referred with great acuteness to the slight inclination of the sun's axis of rotation to the plane of the ecliptic. Thus, when the earth finds herself in the plane of the sun's equator, which occurs at two opposite points of her orbit, the spots, travelling in circles parallel with that plane, necessarily appear to describe right lines; but when the earth is above or below the equatorial level, the paths of the spots open out into curves turned downwards or upwards, according to the direction in which they are seen. The explanation, however, of this phenomenon is equally consistent with the geocentric as with the heliocentric theory of the solar system. The idea of a universal force of gravitation seems to have hovered around the borders of this great man's mind, without ever fully entering it. He perceived the analogy between the power which holds the moon in the neighbourhood of the earth, and compels Jupiter's satellites to circulate round their primary, and the attraction exercised by the earth on bodies at its surface;[1] but he failed to conceive the combination of central force with initial velocity, and was disposed to connect the revolutions of the planets with the axial rotation of the sun. This notion, it is plain, tended rather towards Descartes's theory of vortices than towards Newton's theory of gravitation. More valid instances of the anticipation of modern discoveries may be found in his prevision that a small annual parallax would eventually be found for some of the fixed stars, and that extra-Saturnian planets would at some future time be ascertained to exist, and in his conviction that light travels with a measurable although, in relation to terrestrial distances, infinite velocity.

The invention of the miscroscope, attributed to Galileo by his first biographer, Vincenzo Viviani, does not in truth belong to him. Such an instrument was made as early as 1590 by Zacharias Jansen of Middleburg; and although Galileo discovered, in 1610, a means of adapting his telescope to the examination of minute objects, he did not become acquainted with the compound microscope until 1624, when he saw one of Drebbel's instruments in Rome, and, with characteristic ingenuity, immediately introduced some material improvements into its construction.

The most substantial, if not the most brilliant part of his work consisted undoubtedly in his contributions towards the establishment of mechanics as a science. Some valuable but isolated facts and theorems were previously discovered and proved, but it was he who first clearly grasped the idea of force as a mechanical agent, and extended to the external world the conception of the invariability of the relation between cause and effect. From the time of Archimedes there had existed a science of equilibrium, but the science of motion began to exist with Galileo. It is not too much to say that the final triumph of the Copernican system was due in larger measure to his labours in this department than to his direct arguments in its favour. The problem of the heavens is essentially a mechanical one; and without the mechanical conceptions of the dependence of motion upon force which Galileo familiarized to men's minds, that problem might have remained a sealed book even to the intelligence of Newton. The interdependence of motion and force was not indeed formulated into definite laws by Galileo, but his writings on dynamics are everywhere suggestive of those laws, and his solutions of dynamical problems involve their recognition. The extraordinary advances made by him in this branch of knowledge were owing to his happy method of applying mathematical analysis to physical problems. As a pure mathematician he was, it is true, surpassed in profundity by more than one among his pupils and contemporaries; and in the wider imaginative grasp of abstract geometrical principles he cannot be compared with Fermat, Descartes, or Pascal, to say nothing of Newton or Leibnitz. Still, even in the region of pure mathematics, his powerful and original mind left notable traces of its working. He studied the properties of the cycloid, and attempted the problem of its quadrature earlier than Mersenne; and in the "infinitesimals," which he was one of the first to introduce into geometrical demonstrations, was contained the fruitful germ of the differential calculus. But the method which was peculiarly his, and which still forms the open road to discoveries in natural science, consisted in the combination of experiment with calculation—in the transformation of the concrete into the abstract, and the assiduous comparison of results. The first fruits of the new system of investigation was his determination of the laws of falling bodies. Conceiving that the simplest principle is the most likely to be true, he assumed as a postulate that bodies falling freely towards the earth descend with a uniformly accelerated motion, and deduced thence the principal mathematical consequences, as that the velocities acquired are in the direct, and the spaces traversed in the duplicate ratio of the times, counted from the beginning of motion; finally, he proved,

[1] The passage is sufficiently remarkable to deserve quotation in the original:—"Le parti della Terra hanno tal propensione al centro di essa, che quando ella cangiasse luogo, le dette parti, benchè lontane dal globo nel tempo delle mutazioni di esso, lo seguirebbero per tutto; esempio di ciò sia il seguito perpetuo delle Medicee, ancorché separate continuamente da Giove. L'istesso si deve dire della Luna, obbligata a seguir la Terra."—*Diologo dei Massimi Sistemi*, Giornata terza, p. 351 of Albèri's edition.

by observing the times of descent of bodies falling down long inclined planes, that the postulated law was the true law. Even here, he was obliged to take for granted that the velocities acquired in descending from the same height along planes of every inclination are equal; and it was not until shortly before his death that he found the mathematical demonstration of this not very obvious principle.

The first law of motion—that which expresses the principle of inertia—is virtually contained in the idea of uniformly accelerated velocity. The recognition of the second—that of the independence of different motions—must be added to form the true theory of projectiles. This was done by Galileo. Up to his time it was universally held in the schools that the motion of a body must cease with the impulse communicated to it, but for the "reaction of the medium" which helps it forward. Galileo showed, on the contrary, that the nature of motion once impressed is to continue indefinitely in a uniform direction, and that the effect of the medium is a retarding, not an impelling one. Another commonly received axiom was that no body could be affected by more than one movement at one time, and it was thus supposed that a cannon ball, or other projectile, moves forward in a right line until its first impulse is exhausted, when it falls vertically to the ground. In the fourth of Galileo's dialogues on mechanics, he demonstrated that the path described by a projectile, being the result of the combination of a uniform transverse motion with a uniformly accelerated vertical motion, must, apart from the resistance of the air, be a parabola. The establishment of the principle of the composition of motions formed a conclusive answer to the most formidable of the arguments used against the rotation of the earth, and we find it accordingly triumphantly brought forward by Galileo in the second of his dialogues on the systems of the world. It was urged by anti-Copernicans that a body flung upwards or cast downwards would, if the earth were in motion, be left behind by the rapid translation of the point from which it started; Galileo, however, proved that the reception of a fresh impulse in no way interfered with the movement already impressed, and that the rotation of the earth was insensible, because shared equally by all bodies at its surface. His theory of the inclined plane, combined with his satisfactory definition of "momentum," led him towards the third law of motion. We find Newton's theorem, that "action and reaction are equal and opposite," stated with approximate precision in his treatise *Della Scienza Meccanica*, which contains the substance of lectures delivered during his professorship at Padua; and the same principle is involved in the axiom enunciated in the third of his mechanical dialogues, that "the propensity to fall of a body is equal to the least resistance which suffices to support it." The problems of percussion, however, did not receive a definitive solution until after his death.

His services were no less conspicuous in the statical than in the kinetical division of mechanics. He gave the first direct and entirely satisfactory demonstration of equilibrium on an inclined plane, reducing it to the lever by a sound and ingenious train of reasoning; while, by establishing the theory of "virtual velocities," he laid down the fundamental principle which, in the opinion of Lagrange, contains the general expression of the laws of equilibrium. He studied with attention the still obscure subject of molecular cohesion, and little has been added to what he ascertained on the question of transverse strains and the strength of beams, brought by him for the first time within the scope of mechanical theory. In his *Discorso intorno alle cose che stanno su l'acqua*, published in 1612, he used the principle of virtual velocities to demonstrate the more important theorems of hydrostatics, deducing from it the equilibrium of fluid in a siphon, and proved against the Aristotelians that the floating of solid bodies in a liquid depends not upon their form, but upon their specific gravities, relative to such liquid.

In order to form an adequate estimate of the stride made by Galileo in natural philosophy, it would be necessary to enumerate the confused and erroneous opinions prevailing on all such subjects in his time. His best eulogium, it has been truly said, consists in the fallacies which he exposed. The scholastic distinctions between corruptible and incorruptible substances, between absolute gravity and absolute levity, between natural and violent motions, if they did not wholly disappear from scientific phraseology, ceased thenceforward to hold the place of honour in the controversies of the learned. Discarding these obscure and misleading notions, Galileo taught that gravity and levity are relative terms, and that all bodies are heavy, even those which, like the air, are invisible; that motion is the result of force, instantaneous or continuous; that weight is a continuous force, attracting towards the centre of the earth; that, in a vacuum, all bodies would fall with equal velocities; that the "inertia of matter" implies the continuance of motion, as well as the permanence of rest; and that the substance of the heavenly bodies is equally "corruptible" with that of the earth. These simple elementary ideas were eminently capable of development and investigation, and were not only true, but the prelude to further truth; while those they superseded defied inquiry by their vagueness, and baffled it with their obscurity. Galileo was a man born in due time. He was superior to his contemporaries, but not isolated amongst them. He represented and intensified a growing tendency of the age in which he lived. It was beginning to be suspected that from Aristotle an appeal lay to nature, and some were found who no longer treated the *ipse dixit* of the Stagirite as the final authority in matters of science. A vigorous but ineffectual warfare had already been waged against the blind traditions of the schools by Ramus and Telesius, by Patricius and Campanella, and the revolution which Galileo completed had been prepared by his predecessors. Nevertheless, the task which he so effectually accomplished demanded the highest and rarest quality of genius. He struck out for himself the happy middle path between the *a priori* and the empirical systems, and exemplified with brilliant success the method by which experimental science has wrested from nature so many of her secrets. His mind was an eminently practical one. He concerned himself above all with what fell within the range of exact inquiry, and left to others the larger but less fruitful speculations which can never be brought to the direct test of experiment. Thus, while far-reaching but hasty generalizations have had their day and been forgotten, his work has proved permanent, because he made sure of its foundations. His keen intuition of truth, his vigour and yet sobriety of argument, his fertility of illustration and acuteness of sarcasm, made him irresistible to his antagonists; and the evanescent triumphs of successful controversy have been succeeded by the lasting applause of posterity.

The first complete edition of Galileo's writings was published at Florence (1842–1856), in 15 8vo vols., by the Società Editrice Fiorentina, under the able supervision of Signor Eugenio Albèri. Besides the works already enumerated, it contains the hitherto inedited *Sermones de Motu Gravium*, composed at Pisa between 1589 and 1591; his letters to his friends, with many of their replies, as well as several of the essays of his scientific opponents; his private comments on the *Orlando Furioso*, of which he was an enthusiastic admirer, and on the *Gerusalemme Liberata*, of which he was an equally persistent depreciator; some stanzas and sonnets of no great merit, together with the sketch of a comedy; finally, a reprint of Viviani's *Life*, with valuable notes and corrections. The original documents from the archives of the Inquisition, relating to the events of 1616 and 1633, recovered from Paris in 1846 by the efforts of Count Rossi, and now in the Vatican Library, were to a limited extent made public by Monsignor Marino-Marini in 1850, and more unreservedly by M. Henri de l'Épinois, in an essay entitled "Galilée, son Procès, sa Condemnation," published in 1867 in the *Revue des Questions Historiques.* He was followed by M. Karl von Gebler, who, in an able and exhaustive but somewhat prejudiced work, *Galileo Galilei und die Römische Curie* (Stuttgart, 1876), sought to impeach the authenticity of a document of prime importance in the trial of 1633. He has, however, been victoriously answered by Signor Domenico Berti, in *Il Processo originale di Galileo Galilei* (Rome, 1876), and by M. de l'Épinois, with *Les Pièces du Procès de Galilée* (Rome, Paris, 1877). The touching letters of Galileo's eldest daughter, Sister Maria Celeste, to her father were printed in 1864 by Professor Carlo Arduini, in a publication entitled *La Primogenita di Galileo Galilei.* See also M. Th. Henri Martin's excellent biography, *Galilée, les Droits de la Science et la Méthode des Sciences Physiques*, Paris, 1868; and the anonymous *Private Life of Galileo*, London, 1870. (A. M. C.)

GALITCH, or Halicz, a town of Russia, at the head of a district in the government of Kostroma, 80 miles N.E. of Kostroma, in 57° 15′ N. lat. and 42° 56′ E. long., on the low south-eastern shore of Galitch Lake. Among its public buildings are a hospital, a poorhouse opened in 1855, about 15 churches, and a convent of the third class. The chief occupation of the inhabitants is the manufacture of leather and gloves; and the fisheries of the lake yield about 30,000 rubles per annum, and give employment to about 400 fishermen, whose rights are secured by ancient charters. At the annual fair a considerable trade is done in woollen and cotton goods, earthenware, and miscellaneous articles. In 1860 the population was 6536; but in the *St Petersburg Calendar* for 1878 it is given at 5620.

GALL, Franz Joseph (1758–1828), anatomist, physiologist, and founder of phrenology, was born at Tiefenbrunn near Pforzheim, Baden, on the 9th of March 1758. After completing the usual literary course at Baden and Bruchsal, he began the study of medicine under Hermann at Strasburg, whence, attracted by the names of Van Swieten and Stoll, he removed to Vienna in 1781. Having received his diploma, he began to practise as a physician there in 1785; but his energies were mainly devoted to the scientific investigation of problems which, even from boyhood, had been occupying his attention. At a comparatively early period he had formed a generalization which he believed to be a sound one, that in the human subject at least a powerful memory is invariably associated with prominent eyes; and further observation had enabled him, as he thought, also to define the external characteristics indicative of special talents for painting, music, and the mechanical arts. Following out these researches, he gradually reached the strong personal conviction, not only that the talents and dispositions of men are dependent upon the functions of the brain, but also that they may be inferred with perfect exactitude and precision from the external appearances of the skull. Gall's first appearance as an author was made in 1791, when he published the first two chapters of a (never completed) work entitled *Philosophisch-medicinische Untersuchungen über Natur u. Kunst im kranken u. gesunden Zustande des Menschen.* The first public notice of his inquiries in cranioscopy, however, was in the form of a familiar letter addressed to a friend, which appeared in Wieland's *Deutscher Mercur* in 1798; but two years before this Gall had commenced giving private courses of phrenological lectures in Vienna, where his doctrines soon attracted general attention, and met with increasing success until, in 1802, they were interdicted by the Government on the ground that they were dangerous to religion. This step on the part of the authorities had the effect of greatly stimulating public curiosity and increasing Gall's celebrity. In March 1805 he finally left Vienna, in company with his friend and associate Spurzheim, and made a tour through Germany, in the course of which he lectured in Berlin, Dresden, Magdeburg, and several of the university towns. These expositions, which he knew how to make popular and attractive, were much resorted to by the public, and excited considerable controversy in the scientific world. He had almost reached the zenith of his fame when, in 1807, he repaired to Paris and established himself there as a medical practitioner, at the same time continuing his activity as a lecturer and writer. In 1808 appeared his *Introduction au cours de physiologie du cerveau*, which was followed in 1809 by the *Recherches sur le système nerveux en général, et sur celui du cerveau en particulier* (originally laid before the Institute of France in March 1808), and in 1810 by the first instalment of the *Anatomie et Physiologie du système nerveux en général, et du cerveau en particulier, avec des observations sur la possibilité de reconnaître plusiers dispositions intellectuelles et morales de l'homme et des animaux par la configuration de leurs têtes.* The *Recherches*, and the first two volumes of the *Anatomie*, bear the conjoint names of Gall and Spurzheim. The latter work was completed in 1819, and appeared in a second edition of six 8vo volumes shortly afterwards (1822–25). In 1811 he replied to a charge of Spinozism or atheism, which had been strongly urged against him in certain quarters, by a treatise entitled *Des dispositions innées de l'âme et de l'esprit*, which he afterwards incorporated with his greater work. In 1819 he became a naturalized French subject, but his efforts two years afterwards to obtain admission to the Academy of Sciences, although supported by Geoffroy St Hilaire, were unsuccessful. In 1823 he visited London with the intention of giving a series of phrenological lectures, but was disappointed of the reception he had anticipated, and speedily abandoned his plans. He continued to lecture and practise in Paris until the beginning of 1828, when he was disabled by an apoplectic seizure. His death took place at Montrouge near Paris, on the 22d of August 1828. The *Anatomie* has been translated into English by Lewis (Boston, U.S., 1835).

GALLAND, Antoine (1646–1715), Orientalist and archæologist, the first European translator of the *Arabian Nights*, was born in 1646 at Rollot, in the department of Somme. The completion of his school education at Noyon was followed by a brief apprenticeship to a trade, from which, however, he soon escaped, to pursue his linguistic studies at Paris. After having been employed for some time in making a catalogue of the Oriental manuscripts at the Sorbonne, he was, in 1670, attached to the French embassy at Constantinople; and in 1673 he also accompanied his chief (De Nointel) to Syria and the Levant, where he availed himself of the opportunity to copy a great number of inscriptions, and also to sketch, in some cases even to remove, historical monuments. After a brief visit to France, where his collection of antiquities attracted some attention, Galland returned to the Levant in 1676; and in 1679 he undertook a third voyage, being commissioned by the French East India Company to collect for the cabinet of Colbert; on the expiry of this commission he was instructed by the Government to continue his researches, and had the title of "antiquary to the king" conferred upon him. During his prolonged residences abroad he acquired a thorough knowledge of the Arabic, Turkish, and Persian languages and literatures, which, on his final return to France, enabled him to render valuable assistance to Thevenot, the keeper of the royal library, and to D'Herbelot. After their deaths he lived for some time at Caen under the roof of Foucault the intendant, himself no mean archæologist; and there he began the publication (1704–17) of *Les Mille et Une Nuits*, a translation which excited immense interest during the time of its appearance, and which is still the standard French translation (last edition 1872). In 1701 Galland had been admitted into the Academy of Inscriptions, and in 1709 he was appointed to the chair of Arabic in the Collége de France. He continued to discharge the duties of this post until his death, which took place February 17, 1715.

Besides a number of meritorious archæological works, especially in the department of numismatics, he also published a compilation from the Arabic, Persian, and Turkish, entitled *Paroles remarquables, bons mots et maximes des Orientaux* (1694), and a translation from an Arabic manuscript, *De l'origine et du progrès du Caffé* (1699). The former of these works appeared in an English translation in 1795. His *Contes et Fables Indiennes de Bidpaï et de Lokman* was published after his death (1724). Among his numerous unpublished manuscripts are said to be included a translation of the Koran and a Turkish dictionary.

GALLARATE, a flourishing town of Italy, the head of a circle in the province of Milan, situated on the railway 23 miles N.W. of Milan at the junction of the line running N. to Varese. It has a technical school, and carries on the manufacture of cotton and linen. In the Middle Ages it is mentioned as Galaratum and Glareatum, and especially in the 10th century it appears to have been a strongly fortified and important place. Population in 1871, 7576.

GALLAS, or more correctly GALLA, a powerful race of eastern Africa, scattered over the wide region which extends for about 1000 miles from the interior of Abyssinia to the neighbourhood of the river Sabacki, in 3° 12′ of S. latitude. Almost nothing has been definitely ascertained about the early homes and migrations of the race; but it appears to have occupied the southern portion of its present territory for nearly four centuries at least. According to Ludolf and Bruce, the Galla invaders first crossed the Abyssinian frontiers in the year 1537. The Gallas of Gojam (a district along the northern side of the river Abai) tell how their savage forefathers came from the south-east from a country on the other side of a bahr (lake or river), and the Yedju and Raia Galla also point towards the east and commemorate the passage of a bahr. Among the southern Gallas tradition appears to be mainly concerned with the expulsion of the race from the country now occupied by the Somali. It is usually maintained that the Gallas are ethnographically of Semitic affinity, and find their nearest kinsmen in the Somali, the Dankali, and the Abyssinians; but M. Lejean is of opinion that they rather belong to the Aryan race, and this is so far supported by their physiological characteristics. One thing is certain, that they have nothing in common with the negro type; the "musculation" of the arms, thighs, and calves is altogether different, and they have none of the fetor developed by the negro skin; their frame is large and powerful, their complexion a very dark brown, their brow broad and lofty, their eyes deep-sunk and lively, and their features not unfrequently of a regular and finely-shaped description. Of the Semitic affinity of the language their is no question, and according to the usual classification it belongs to the same Semitico-Hamitic group as the Somali, the Saho, and the Dankali.[1]

The Gallas are for the most part still in the nomadic and pastoral stage; though, as we advance northwards into Abyssinia, we find them more and more assimilated to the settled and agricultural inhabitants of that kingdom. Among the southern tribes it is said that about 7 or 8 head of cattle are kept for every man, woman, and child; and among the northern tribes, as neither man nor woman ever thinks of going any distance on foot, the number of horses is very large. The ordinary food consists of flesh, blood, milk, butter, and honey, the last being considered of so much importance by the southern Gallas that a rude system of bee-keeping is in vogue, and the husband who fails to furnish his wife with a sufficient supply of honey may be excluded from all conjugal rights. This last fact is one of those which indicate the comparatively high position occupied by the Galla women, who, moreover, have the right, but rarely granted in a savage state of society, of refusing an unacceptable offer of marriage. In the south monogamy is the rule, but in the north the number of a man's wives is limited only by his wishes and his wealth. Each tribe has its own heiitch or sultan, who enjoys the strange privilege of being the only merchant for his people, but in all public concerns must take the advice of the fathers of families assembled in council. The greater proportion of the tribes are still pagan, worshipping a supreme god Waka, and the subordinate god and goddess Oglia and Atilia, whose favour is secured by sacrifices of oxen and sheep. With a strange liberality of sentiment, they say that at a certain time of the year Waka leaves them and goes to attend to the wants of their enemies the Somali, whom also he has created. Some tribes, and notably the Wollo-Galla, have been converted to Mahometanism, and very bigoted adherents of the prophet they are. In the north a kind of superficial Christianization has taken place, to the extent at least that the people are familiar with the names of Maremma or Mary, Balawold or Jesus, Girgis or St George, &c.; but to all practical intents paganism is still in force. The serpent is a special object of worship, the northern Gallas believing that he is the author of the human race. A considerable number of the men find employment in the Abyssinian armies, and in comparison with their neighbours are brave and warlike. The total number of the Gallas was estimated by Krapf at from six to eight millions, and Plowden mentions individual tribes that could bring into the field 20,000 or 30,000 horse. Among the more important tribes in the south (the name in each instance being compounded with Galla) are the Ramatta, the Kukatta, the Baôle, the Aurova, the Wadjole, the Ilani, the Arrar, and the Kanigo Galla; the Borani, a very powerful tribe, may be considered to mark the division between north and south; and in the north we find the Amoro, the Jarso, the Toolama, the Wollo, the Ambassil, the Aijjo, and the Azobo Galla.

See Beke, "On the Origin of the Gallas," in *Trans. of Brit. Assoc.*, 1847; Krapf, *Travels . . . . in Eastern Africa*, 1860; D'Abbadie, *Douze Ans en Haute-Éthiopie*, 1868; Brenner, "Forschungen in Ost-Afrika," in Petermann's *Mittheilungen*, 1868; Plowden, *Travels in Abyssinia and the Galla Country*, 1868; and a paper by Louis Lande in *Revue des Deux Mondes*, 1878.

[1] The similarity to the Semitic was pointed out by Benfey in *Götting. Gelehrte Anzeigen*, 1846, in a review of Tutschek's lexicon and grammar (1844, 1845). Further details in regard to its vocabulary and structure will be found in Lottner's paper in the *Transactions of the Philological Society*, London, 1860-61, and in the *Novara Reise*, 1867. Krapf had published a grammar as early as 1840.

ALBERT GALLATIN.

ALBERT GALLATIN was born in Geneva, Switzerland, Jan. 29, 1761. His father, Jean Gallatin, was of an illustrious family and claimed descent from A. Atilius Callatinus, a Roman consul of the third century before Christ. This claim is not substantiated, as a period of fifteen hundred years lies between the Roman consul and the first authentic Gallatin who lived in Savoy in the thirteenth century. This Gallatin was at that time of aristocratic blood, with titles of nobility; so that the family must have been of considerable importance for at least a century before. In 1510 the family came to Geneva, identified themselves with John Calvin and a republican form of government, gave up their titles, and in large measure their fortunes, but they still held to the purity of their blood and were powerful factors in the social and political life of Switzerland. They were a numerous family and the little government did not afford employment for the talents of all of them, so they took service under different kings, won distinction, and lost their lives in gallant action; and became great civic potentates in foreign cities. Their personal friends were men whom accident or talent made famous, such as Voltaire and the Landgrave of Hesse.

Albert's father, Jean Gallatin, married Sophie Albertine Rolaz du Rosey, of Rolle, and died in 1765, when Albert was but four years of age. His mother followed in 1770, thus leaving the boy an orphan at the early age of nine, with an invalid sister five years older. At the time of his father's death one of his mother's intimate friends, Catherine Pictet, seeing the young widow overwhelmed with the care of her husband's business and of her sick daughter, took Albert into her own household. After his mother's death, he became virtually her own child, beside being the heir of his grandfather, Abraham Gallatin, and the favorite of a wealthy uncle, Alphonse Rolez, of Rolle. He had a right to expect a fortune from these three people and was popular and beloved by all his friends and relatives; his education was carefully supervised by his foster mother, Mlle. Pictet. At sixteen years of age he was sent to boarding-school and afterwards to an academy, graduating in 1779. No expense was spared in his education. His small property was so frugally managed that by the time he reached his majority his father's debts had all been paid from the income. About this time both his uncle and grandfather died insolvent, and Albert's patrimony was so small that he was thrown almost entirely on his own resources. Yet, from the distinction of his family, and the mental acquisitions he had gained in college, he was on the road to success and could easily have gained fame and fortune in the city of his birth. At the age of eighteen he was clear-minded, sober and practical. The first year after graduation he returned to Mlle. Pictet and occupied himself as tutor to her young nephew, Isaac Pictet. He often visited his grandmother, who urged him to enter the service of the Landgrave of Hesse, but a military life had but little attraction for him. During this year he visited Voltaire; and widened his acquaintance among the many learned and distinguished men who made Geneva their home. He breathed this balmy atmosphere of learning and was filled with ambitious dreams and at the same time with a noble discouragement. It seemed to the youth that where there was so much intellectual and moral worth in the market, distinction would be difficult to obtain. This, together with his loss of fortune and a quarrel with his grandmother on account of his refusal to "serve under a tyrant," as he termed the Landgrave of Hesse, made him resolve on a course of action, which lost a gladiator for the little arena of Geneva and gained Albert Gallatin for the larger political field which the young and growing government of the United States afforded.

He made silent preparations for his departure, and carrying with him such small resources as he could command, accompanied by his college friend Henri Serre, he departed from Geneva in the spring of 1780, leaving behind him the city of his ancestry, his influential friends, congenial society and prestige, and emigrated to America. He was but nineteen years of age when he thus took his fortunes in his own hands and cut himself off from the assistance of his grandmother and Mlle. Pictet. He regretted this step near the close of his life in spite of his wonderful successes, and said that he had advised only one man to emigrate, Jean Badollet, who afterwards joined him in America, and that he was sorry for having done so. He was proud, shy and reticent. He was moved by political ideals and filled with a spirit of adventure and leadership. For many years these traits of Albert Gallatin's character controlled his actions. They explain the apparent perversity with which he abandoned his friends and prospects. He departed secretly from fear that he would be restrained, should his plans become known. This was a weak and unworthy excuse, as he afterwards acknowledged, for although his friends opposed him they would gladly have furnished him with the necessary equipment for his journey to the New World, if he had only declared to them his intention to go. The two young men started with the small sum of 166 louis d'or. The cost of their passage reduced the little amount to about $400, all of which belonged to Gallatin. The friends in Geneva strove in every way to smooth the path to success for these young men, and wrote letters of introduction for them to influential people in America, but Gallatin disliked large cities, where his learning would have given him an immediate foothold, and disdaining all these helps struck out into the wooded wilderness of Maine. He had courage, endurance, hope and discipline of a high order, else he would have fallen back on the "cushion of circumstance," which was always held invitingly before him. He never used his letters of introduction. Mlle. Pictet wrote him long letters telling how she mourned his loss, but he was unwilling to tell her of his hardships and did not write to her for a whole year.

In 1781, after untold privations in the woods, and a failure in trade, he obtained a French class in Harvard College. But New England asceticism and the rigor of the climate were unfriendly to the Gallic youth. His life in Boston was unproductive and unsatisfactory, and he finally cut himself loose from it and plunged into the freer air of Pennsylvania and Virginia. Here he found his natural element. He engaged in land speculation and local politics, married a Miss Sophia Allegre and settled down in a country where it needed energy to live. Here he would have developed naturally into a provincial potentate and wealthy land owner on a large plantation, had his young wife not died a few months after marriage. To this sad event is probably due his subsequent career. He was driven into the excitement of politics by his grief and loneliness. Soon his rare origin and attainments brought him forward rapidly in a pioneer settlement. The times needed such men. Independence had been wrested from England, but the government had not yet been established. The constitution was before the States for adoption. Gallatin belonged to the anti-Federalist, the minority party, and was thus one of the men who helped draft some of the amendments to the constitution. He could not speak English plainly, and was hampered in debate, but the clear force of his reasoning, united with his grasp of the situation, at once brought him to the front in the legislature of Pennsylvania, and carried him to Congress. The impression he made on public men is to be explained only by his intellect and integrity, because he was not a man to whom many people ever became warmly attached. He was tall and strong, with a severe cast of countenance and cold manner, and disdained to conciliate any one. He soon became the leader of the Republican party in Pennsylvania. He came into collision with Alexander Hamilton at this time on account of the excise on spirits. This measure was the simplest way to meet the existing necessity for money in order to carry on the government. The tax was unpopular, as any tax was bound to be with a people who had just successfully resisted taxation, but Hamilton forced the excise, and subsequent events proved his wisdom in having done so Gallatin was one of the most powerful opponents of Hamilton's scheme, and, thus, while fighting on purely legal grounds, identified himself with a lawless element and was thus practically at war both with the Federalists and with his own constituents. His own force and integrity kept him erect and compelled the respectful attention of both parties throughout this trying period, when he stood the severest test to which a man in public life can be subjected. He received a singular proof of this confidence in him by being chosen to represent Pennsylvania in Congress by a vote of both parties. The Federalists being in a powerful majority annulled his election on the ground of his being the leader of the insurrectionists and retired him to private life. At the rise of the "whiskey rebellion" by the anti-Federalists he risked his life to face a mob of his own constituents and denounced them in unqualified terms, and by his prompt action turned this movement into a ridiculous affair. He had made a mistake in his estimate of the character of the population and hastened to oppose the rebellion. In history there will always be some doubts expressed as to Gallatin's part in the whole proceeding, and in the opinion of most people he must be held responsible for the first resistance to the government. But at the time he came out of the encounter with a spotless reputation,—the only western anti-Federalist who did so. Shortly afterwards he was again elected to the House of Representatives. His previous mistake in gauging his constituency seems to have been the only time in a long public career when he was not endowed with a keen faculty for feeling the public pulse. This quality was felt by all public men who came in contact with him, and had instant effect when he returned to Congress. He became the leader of the Republican party at once and held his place easily during the six years he remained in the House. There was no one else who compared with him in intellectual ability, foresight judgment, moderation or convincing speech, though many surpassed him in eloquence. He was always dignified and calm, never descending to personalities, but carrying his point by sheer force of reason. For opponents he had John Marshall, Griswold, Bayard, Harper, Dana and other distinguished men. He had besides to contend against an imperfect knowledge of English and bad pronunciation. His ultimatums were the result of hard study. He informed himself of the minutest details and depended upon his grasp of a subject more than his command of words. In his own party, as possible rivals for the foremost place, there were only Madison and Livingston; both great men, but not possessed of the qualities necessary for parliamentary leadership. He was never a radical Republican, but maintained an equilibrium between two parties on an individual platform. He often expressed views at variance with those of his party, so he affiliated with all men, on some points maintaining only his opposition to strong governments, when he identified himself with the Republicans.

He filled the position in Congress of financier for his party and succeeded in modifying the radical measures of Hamilton and improving the financial schemes of the government. His leadership laid him open to all the bitter personal attacks of the time, but he was never betrayed into retorts of the same kind, so that the assaults of his opponents lost their point. His was always the important speech of the opposition. His only mistakes were when he gave up his individual judgment in loyalty to his party. When the Republicans began to be deserted by their leaders in Pennsylvania, still steady, he stood alone, and then when quarrels split the opposition he carried the Republicans into power. When the country was in peril from the growing power, it was Gallatin and Jefferson who averted the calamity. The year 1801 was carried through without disaster, because these two men were at the helm. The "war party" was crushed.

When Jefferson came into power, Gallatin, and Madison with him, formed a triumvirate which ruled the United States for twelve years. Gallatin took the treasury portfolio at a time when Hamilton's brilliant policy needed modification. Debt was accumulating, and expenditures were greater than the country could bear. It took a wise mind and a firm hand to pilot the finances of the country into a safe port. Revenue must be increased, internal taxes must be reduced. The navy, however, demanded a greater sum for maintenance. Gallatin strove for freedom from debt and opposed war with the Barbary States. After six years' work with the debt nearly out of sight, foreign wars broke out and crippled Glalatin's plans. He fought the sympathy with Napoleon and urged peace with England at any cost. At this time, this opposer of strong governments became the champion of some of the most oppressive laws which have ever been framed, and failed in his efforts. He was not sustained by Jefferson, and though retaining his place in the cabinet under Madison, he had new difficulties to encounter. A strong faction had grown up against him in Congress, headed by Senator Smith, of Maryland. Every measure of Gallatin's was frustrated. The bank was defeated, the foreign policy overthrown and the legislative power of the government weakened. Bonaparte did the rest, and thus the war of 1812 with England was precipitated. At Gallatin's instance Robert Smith, brother of Senator Smith, was dismissed from the cabinet, and Gallatin was master of the situation. Then, for the only time in his life, this staunch Swiss weakened, and made such reports of the finances of the country as strengthened the war party. His object has been variously accounted for, but the fact remains that these false reports did incalculable harm and finished the work which ended in a three years' war with England. But he took the finances up with a strong hand after the beginning of the war, resigned from the treasury, and heading a commission, bombarded English diplomats and compelled peace. At the close of the war he went to Paris as American Minister to France, a position which he held for seven years. After having been one of the greatest financiers the country has seen, he became a diplomat second only to Franklin. In Paris he was surrounded by the most distinguished society of Europe, and did much to effect the stability of American commerce. In 1823 he returned to the United States, and after returning from a mission to England, on which he had been sent by John Quincy Adams, he retired to private life.

This versatile man then turned his attention to Indian ethnology, he being the first student of the subject who ever contributed any scientific knowledge to it. When more than eighty years old he appeared as an opposer of the annexation of Texas and of the war with Mexico.

Gallatin was an idealist in Civil Service. His thought was that employes of the government should be trained to the work and then have permanent positions, taking no part in politics. It was the opposite of the Jackson policy, which afterward carried everything before it. Jefferson was infected by the spoils system and failed to support Gallatin. Another idea of his was good management of the navy and in this also he was defeated. He held his place in the cabinet against all opposition of Jefferson to his policy and plans and bore the attacks of Duane and Leit without aid from his chief. Yet that Jefferson was able to defend him, was proved by his treatment of Burr and Randolph. Gallatin believed in simplicity of government, no debt, no taxes—and saw his plans again defeated by war. But, though all his theories failed, one after another his methods prevailed, and carried the party through a perilous period.

In religion Gallatin was a Calvinist of a severe type. He was austere, having no Gallic lightness of character.

He married a Sarah Nichelson for a second wife and left three children. In his home life he was tender and loving but never indulgent. He had the characteristics of the Scotch and of the Puritans. He was reticent, cool and tenacious, with severe morals. He stood unmoved amid storms of invectives.

Though he was not so great a man as Hamilton, he had sterling qualities which were needed by the times. He evinced cool judgement, rather than brilliancy, for the conduct of affairs.

He died in 1849, busy with private and public affairs to the last day of his life.

AUTHORITIES.—*The Life of Albert Gallatin*, by H. Adams; *Writings of Albert Gallatin*, by H. Adams; *Albert Gallatin*, by H. C. Lodge.

GALLE, or POINT DE GALLE, a town and port in the southern province of Ceylon, on the south-western coast, about 72 miles S. of Colombo, with which it is connected by a good carriage road. It was made a municipality in 1865, and divided into the five districts of the Fort, Callowelle, Galopiadde, Hirimbure, and Cumbalwalla. The fort, which is more than a mile in circumference, commands the whole harbour, but is commanded by a range of hills. Within its enclosure are not only several Government buildings, but an old church erected by the Dutch East India Company, a mosque, a Wesleyan chapel, a hospital, and a considerable number of houses occupied by Europeans. The old Dutch building known as the queen's house or governor's residence, which dated from the year 1687, was in such a dilapidated state that it was sold by Governor Gregory in 1873. Elsewhere there are few buildings of individual note, but the general style of domestic architecture is pleasant and comfortable, though not pretentious. One of the most delightful features of the place is the profusion of trees, even within the town, and along the edge of the shore—suriyas, palms, cocoa-nut trees and bread-fruit trees. The ramparts towards the sea furnish fine promenades. In the harbour deep water is found close to the shore, and the outer roads are spacious; but the south-west monsoon renders entrance difficult, and not unfrequently drives vessels from their moorings. Galle is an important point on the lines of communication between Calcutta and Australia, and between Suez and Singapore. The Peninsular and Oriental Steam Navigation Company, the *Messageries Maritimes*, and the British India Steam Navigation Company have agencies at the port. The trade is mainly in the productions of the surrounding country, of which in 1873 there was shipped 11,477 cwts.

of cocoa-nut oil, 10,083 cwts. of cinnamon, 23,377 cwts. of plumbago, and 22,932 cwts. of coir. Cotton goods are the principal import, 143,410 pieces being the amount for 1873. The inhabitants of Galle are of very mingled origin, comprising not only Singhalese European residents and Eurasian half-castes, who are locally denominated "Burghers," as being mainly the descendants of the old Dutch settlers, but also "Moors" or "Moormen" (that is, Arabians or semi-Arabians), Hindus, Parsees, people from the Coromandel coast, and Maldivians. The Moors are largely engaged as lapidaries and workers in tortoise-shell; and the urgency of the itinerant vendors is one of the inevitable plagues of the European visitor to the town. According to the returns of 1871, the total population of the municipality was 47,059, distributed in 8979 families, occupying 7496 houses, and consisting of 24,294 males and 22,765 females.

Galle, according to Sir J. E. Tennent, is the Tarshish of Solomon; but of this opinion there is no proof, even if it were certain that the Jewish fleets visited the island of Ceylon at all. The place is mentioned by none of the Greek or Latin geographers, unless the identification with Ptolemy's Avium Promontorium or Cape of Birds be a correct one. It is hardly mentioned in the native chronicles before 1267, and Ibn Batuta, in the middle of the 14th century, distinctly states that Kali,—that is, Galle,—was a *small* town. It was not till the period of Portuguese occupation that it rose to importance. When the Dutch succeeded the Portuguese they greatly strengthened the fortifications, which had been vigorously defended against their admiral, Kosten; and under their rule the place had the rank of a commandancy. In the marriage treaty of the infanta of Portugal with Charles II. of England it was agreed that if the Portuguese recovered Ceylon they were to hand over Galle to the English; but as the Portuguese did not recover Ceylon the town was left to fall into English hands at the conquest of the island in 1796. The name Galle is derived from the Singhalese *galla*, equivalent to rock; but the Portuguese and Dutch settlers, being better fighters than philologists, connected it with the Latin *gallus* a cock, and the image of a cock was carved as a symbol of the town in the front of the old Government house.

GALLIC ACID, trioxybenzoic acid, or dioxysalicylic acid, $C_7H_6O_5 + H_2O$ or $C_6H_2(OH)_3.CO(OH) + H_2O$, the *acidum gallicum* of pharmacy, is a substance discovered by Scheele, which exists as such in the leaves of the bearberry, in pomegranate root-bark, and in tea, in gall-nuts to the extent of about 3 per cent., and in other vegetable productions. It may be prepared by keeping moist and exposed to the air for from four to six weeks, at a temperature of 20° to 25° C., a paste of powdered gall-nuts and water, and removing from time to time the mould which forms on its surface; the paste is then boiled with water for twenty minutes to obtain a solution of the gallic acid; this is filtered through calico, and the deposit of acid it affords on cooling is drained by pressure between folds of bibulous paper, and purified by dissolving in boiling water, by recrystallization at about 27° C., and washing of the crystals with ice-cold water. The production of the acid appears to be due to the presence in the galls of a ferment. This is not contained in Chinese gall-nuts, which consequently require the addition of yeast or of common galls to determine the decomposition of their tannin necessary for the formation of gallic acid (see C. H. Viedt, *Dingler's Polyt. Journ.*, ccxvi., 1875, p. 454). Powdered gall-nuts, containing 43 per cent. of tannic acid, were found by M. Sacc to yield 50·4 per cent. of pure dry gallic acid (*Compt. Rend.*, lxxii., 1871, p. 766). Gallic acid is most readily obtained by boiling with weak solution of acids the tannin procured from oak-galls by means of alcohol and ether. The changes which take place in this, as in the first described mode of preparation, apparently consist in the splitting up of tannin, or gallo-tannic acid, which, according to some experiments, is a glucoside of tannic acid, of the formula $C_{34}H_{28}O_{22}$, to give with two molecules of water two molecules of digallic or tannic acid, $C_{14}H_{10}O_9$, and glucose, $C_6H_{12}O_6$. The former body, which may be represented as an etheric anhydride of gallic acid, $C_6H_2(OH)_2.CO(OH):O.CO.(OH)_3C_6H_2$, by the assimilation of a molecule of water is then converted into two molecules of gallic acid (see Armstrong, *Organic Chemistry*, p. 304, 1874). Gallic acid may be produced by heating an aqueous solution of diiodosalicylic acid with excess of alkaline carbonate, by acting on dibromosalicylic acid with moist silver oxide, and by other chemical methods. It crystallizes in white or pale fawn-coloured acicular prisms or silky needles, and is soluble in alcohol and ether, and in 100 parts of cold, and 3 of boiling water, is without odour, and has an astringent, acidulous taste, and an acid reaction. Dried at 100° C. it loses 9·5 per cent. of its weight of water; at about 200° C. it melts; and at 210 to 215° it is resolved into carbon dioxide and pyrogallol, $C_6H_3(OH)_3$. With ferric salts its solution gives a deep blue colour, and with ferrous salts, after exposure to the air, an insoluble, blue-black, ferroso-ferric gallate. Bases of the alkali metals give with it four series of salts; these are stable except in alkaline solutions, in which they absorb oxygen and turn brown. Solution of acid calcium carbonate becomes with gallic acid, on exposure to the air, of a dark blue colour. Unlike tannic acid, gallic acid does not precipitate albumen or salts of the alkaloids, or, except when mixed with gum, gelatin. Salts of gold and silver are reduced by it, slowly in cold, instantaneously in warm solutions, hence its employment in photography. With phosphorus oxychloride at 120° C. gallic acid yields tannic acid, and with concentrated sulphuric acid at 100°, *rufigallic acid*, $C_{14}H_8O_8$. Phosphorus perchloride, and also, after several hours, solution of arsenic acid near the boiling point (J. Löwe, quoted *Chem. News*, xix., 1869, p. 41), convert it into *ellagic acid*, $C_{14}H_8O_9 + H_2O$, a substance which occurs in gall-nuts, in the external membrane of the episperm of the walnut (T. L. Phipson, *Chem. News*, xx. p. 116), and probably many plants, and composes the "bezoar stones" found in the intestines of Persian wild goats. Gallic acid may be estimated, after removal of tannic acid by gelatin, by means of permanganate of potassium, with which it evolves carbon dioxide, and (F. Jean, *Compt. Rend.*, lxxxii., 1876, pp. 982–4), by means of iodine in the presence of an alkaline carbonate.

Gallic acid has been advantageously employed as an internal medicinal agent in scarlatinal albuminuria, in which its effect appears to be due to an astringent and tonic action on the inflamed capillaries of the kidneys;[1] in other forms of albuminuria;[2] in cases of chyluria, in which, as not causing nausea and headache, it is preferable to tannic acid;[3] and in pyrosis, diarrhœa, some forms of dysentery, and tabes and rickets, and atonic states of the alimentary canal and of the body generally. In checking the night-sweats of phthisis it has been found of especial service.[4] As a hæmostatic, when administered internally, it has proved of value in hæmatemesis, epistaxis, fungus hæmatodes,[5] menorrhagia,[6] and more particularly in hæmaturia. Gallic acid has been highly recommended in hæmoptysis,[7] in which, however, ergot, from its not occasioning griping and constipation, or interfering with a liberal use of milk, has been found a better remedy.[8] It may be given in considerable quantities without any evil consequences. The effects of too large a dose are to render

the pulse hard and wiry, and to produce pallor, a whizzing sound in the ears, dizziness, and faintness. Its administration in a case of Bright's disease described by Dr Bence Jones was followed by epilepsy (see *Med. Times*, 1853, ii. 495). As a topical styptic application, gallic is inferior to tannic acid.[1] With glycerin it is combined to form the pharmaceutical preparation *glycerinum acidi gallici.*

GALLIENUS, P. LICINIUS (218–268), Roman emperor, son of the emperor Valerian, was born about 218. From 253 to 260 he reigned conjointly with his father, and gave proof of both bravery and ability, especially in the defeat near Milan of 300,000 Alemanni, with a force of only 10,000 Romans. When, however, his father was defeated and taken prisoner by Sapor, king of Persia, in 260, Gallienus made no effort to obtain his release, or to withstand the incursions of the invaders who threatened the empire from all sides. He occupied part of his time in dabbling in literature, science, and various trifling arts, but gave himself up chiefly to excess and debauchery. His generals rebelled against him in almost every province of the empire, and this period of Roman history came to be called the reign of the thirty tyrants, although in reality the usurpers numbered only nineteen. Gallienus was killed at Milan in 268 while besieging Aureolus, who had been proclaimed emperor by the Illyrian legions.

GALLINULE. See MOORHEN.

GALLIO, JUNIUS ANNÆUS, proconsul or "deputy" of Achaia at the time of the apostle Paul's first visit to Corinth (53 A.D.), was the son of M. Annæus Seneca, a Roman eques and rhetorician, and was born at Cordova about the beginning of the Christian era. His mother's name was Helvia; and L. Annæus Seneca, the philosopher, and L. Annæus Mela, the geographer, were his full brothers, his own proper name being Marcus Annæus Novatus. After he had received a careful education from his father at Cordova, he went to Rome, where he attracted the notice of L. Junius Gallio, a rhetorician of some repute, who ultimately adopted him, thus conferring the name by which he is usually known. The terms on which he lived with his kindred and with the world are well illustrated in the epithet "dulcis" applied to him by Statius (*Silv.*, ii. 7, 32), and by Seneca (*Nat. Qu.*, 4 pref.—"nemo mortalium uni tam dulcis est quam hic omnibus"). It is probable that Gallio shared the misfortunes of his brother when the latter, having incurred the enmity of Messalina, was banished to Corsica; and that both returned together to Rome when Agrippina had selected Seneca to be tutor to Nero. Towards the close of the reign of Claudius, Gallio received the proconsulship of the newly constituted senatorial province of Achaia (Acts xviii. 12), but seems to have been compelled by ill health to resign the post within a few years (Pliny, *H. N.*, xxxi. 33; Seneca, *Ep.* civ.). In the fifth year of Nero we hear of him as having been again in Rome (Dio Cassius, lxi. 20, 21), and on the same authority we learn that he finally became one of the last victims of that emperor (lxii. 25). The statement of Jerome in the chronicle of Eusebius, that Junius Gallio "frater Senecæ, egregius declamator, propria se manu interfecit," appears to be founded on a confusion of names. Seneca's works, *De Ira* and *De Vita Beata*, are dedicated to Gallio, who himself appears to have written some treatises in natural history (Sen., *N. Q.*, v. 11). Compare Tacitus, *Ann.*, xv. 73; xvi. 17; Dio Cassius, lx. 35.

GALLIPOLI, the ancient Καλλίπολις, a seaport town of Turkey in Europe, in the province of Rumili and vilayet of Edirneh, at the north-east extremity of the Straits of Dardanelles, on a narrow peninsula 130 miles S.W. of Constantinople, and 90 miles due S. of Adrianople, in 40° 24′ N. lat. and 26° 40′ 30″ E. long. Nearly opposite is Lapsaki on the Asiatic side of the channel, which is here about 2 miles wide. The town of Gallipoli presents a miserable aspect; the streets are narrow, the houses mostly of wood and ill built, though there are a few better structures near the harbour, and the Anglo-French occupation of 1853–6 led to some improvements. The only noteworthy buildings are the large, crowded, and well-furnished bazaars, with leaden domes. There are several mosques, none of them remarkable, and many interesting Roman and Byzantine remains, especially a magazine of the emperor Justinian, a square castle and tower attributed to Bajazet I., and some tumuli on the south, said to be the tombs of the Thracian kings. The lighthouse, built on a cliff, has a fine appearance as seen from the Dardanelles. Gallipoli is the residence of a captain-pasha and the seat of a Greek bishop. It has two good harbours, and is the principal station for the Turkish fleet. From its position as the key of the Dardanelles, it was occupied by the allied French and English armies in 1854. Then the isthmus a few miles to the north of the town, between it and Boulair, was fortified with strong earthworks by English and French engineers mainly on the lines of the old works constructed in 1357, when the Turks first crossed over into Europe, nearly 100 years before they gained possession of Constantinople. These fortifications were renewed and enlarged in January 1878, on the Russians threatening to take possession of Constantinople. The peninsula thus isolated by the fortified positions has the Gulf of Saros on the N.W., and extends some 50 miles to the S.W. The guns of Gallipoli command the Dardanelles just before the strait joins the Sea of Marmora. The town itself is not very strongly fortified, the principal fortifications being further down the Dardanelles, where the passage is narrower. The district of Gallipoli is exceedingly fertile and well adapted for agriculture; a great variety of crops are raised, but, previous to the war of 1877–8, nearly all progress was stopped on account of the maladministration of the Turkish authorities. Nevertheless considerable quantities of the various cereals were exported, besides wine, oil, skins, cotton, sheep, &c., much of the trade being transit. The principal imports are manufactured goods, coal, sugar, coffee, rice, soap, iron. The line of railway between Adrianople and the Egean Sea has been prejudicial to the transit trade of Gallipoli, and several attempts have been made to obtain concessions for the construction of a railway that would connect this part with the Turkish railway system. There is little industry in Gallipoli, though previous to the war attempts had been made to extend and improve the manufacture of silk thread and silk goods, and some little business was done in the construction of coasting vessels. Steamers to and from Constantinople call regularly at Gallipoli. Widely different estimates have been given of the population of the town: it is probably somewhere about 25,000 or 30,000.

GALLIPOLI, an important seaport town of Italy, in the province of Lecce, and about 25 miles N.E. of the city of that name, beautifully situated on a rocky islet on the east shore of the Gulf of Taranto, and connected by a long stone bridge of twelve arches with the suburb of Lizza on the mainland. The town is well built and fortified, and has a castle erected by Charles I. of Anjou, a large cathedral, a gymnasium, and an episcopal seminary. It is chiefly noted for its extensive cisterns cut in the solid rock for containing the olive oil collected from all parts of Puglia; but it has besides a productive tunny fishery, and manufactures muslins, cotton stockings, and woollen goods. The harbour has been improved since 1855 by a new mole, but the entrance is still

[1] On the therapeutics of gallic acid see further R. Neale, "Clinical notes upon the use of gallic acid in various diseases," *Medical Times*, 1855, i. 458 *sq.*; and W. Bayes, "On Gallic Acid," *Association Medical Journal*, 1854, p. 506.

somewhat dangerous. In 1873 there entered 350 vessels with a total tonnage of 66,652 tons, 281 being Italian and 29 British. The principal exports are oil (of which 9628 tons were shipped in 1875), wine, oats, and cotton seed; and the imports, fish from Norway, manufactured goods from France, petroleum from the United States, staves from Austria, and wheat and barley from Greece and Turkey. The population of the town in 1871 was 7578, and of the commune 9951. Gallipoli preserves the name and almost certainly occupies the site of the ancient Callipolis, the "Beautiful City," founded, according to Dionysius, by a Spartan named Leucippus and a number of the citizens of Tarentum.

GALLIUM, so called in honour of France (Gallia), symbol Ga, atomic weight 69·9, a metal discovered, August 27, 1875, by M. Lecoq de Boisbaudran, in the spectroscopic examination of zinc-blende from Pierrefitte in the valley of Argeles, Hautes Pyrénées, and since found to exist in blende from several other localities, notably in that of the mines of Lüdrich and Apfel at Bensberg, on the Rhine, which contains nearly 16 milligrammes per kilogramme. Its density and approximate atomic weight, and other of its characters, were predicted by Mendeljeff, in accordance with his law that the properties of the elementary bodies, as also the constitution and properties of their combinations, are periodic functions of their atomic weights (see article CHEMISTRY, vol. v. p. 543, col. 2). Gallium may be prepared by a process the chief features of which are the treatment of the ore, which contains the metal in only very minute quantity, with zinc; the removal, from a hydrochloric acid solution of the gelatinous precipitate thereby produced, of various foreign metals by means of hydrogen sulphide; the fractionation of the residual liquid with sodium carbonate, gallium being thrown down before zinc by that reagent; the formation of a sulphate from the resultant precipitate; and, lastly, the electrolysis of a potash solution of the purified oxide obtained therefrom, the metal appearing on the negative platinum electrode. Solid gallium is greyish-white, of octahedral crystallization, and remarkably hard and resistant even at a temperature little below its melting point, and is but slightly malleable and flexible, though thin plates of it will bear bending several times without breaking. It melts when held in the fingers, its point of fusion being 30°·15 C. (86°·27 Fahr.). The liquid metal is of a silvery white colour, and adheres to glass, forming a mirror resembling that of mercury. It exhibits in a remarkable degree the phenomenon of superfusion, but when some degrees below its melting point crystallizes immediately if a small fragment of the solid metal attached to a platinum wire be inserted into it. At 24°·5 C. (76°·1 Fahr.) the specific gravity of the solid metal is 5·956, and of the liquid 6·069; the specific heat of the former between 12° and 23° C. is 0·079, giving atomic heat 5·52, and that of the latter between 119° and 106° C. is 0·0802 (Berthelot, *Compt. Rend.*, lxxxvi. 786–7). At a red heat in air gallium is not perceptibly volatilized. It is little affected by cold nitric acid, but dissolves readily in hydrochloric acid; with potash solution it liberates hydrogen. It furnishes a deliquescent and very soluble chloride, $GaCl_3$ or Ga_2Cl_6, a corresponding bromide and iodide, and an ammonio-gallic alum. Its oxide is more soluble in ammonia than is alumina. In basicity it holds a place intermediate between aluminium and indium. It is precipitated by alkaline carbonates and barium carbonate, but not by hydrogen sulphide and ammonium sulphide in the absence of zinc. Gallium affords two brilliant lines in the violet part of the spectrum.

Chim.*, ser. 4, xxvii. pp. 338–340—quoted in *Phil. Mag.*, 1878, p. 319, and *Journ. Chem. Soc.*, "Abstracts," 1878, pp. 556 and 837.

GALLOWAY, THOMAS (1796–1851), a Scottish mathematician, was born at Symington, in the upper ward of Lanarkshire, 26th February 1796. After receiving such education as the schools of his own and adjoining parishes could give, he entered in 1812 the university of Edinburgh, where he distinguished himself specially in mathematics. In 1823 he was appointed one of the teachers of mathematics at the military college of Sandhurst, and on the death of Sir John Leslie in 1832 he was an unsuccessful candidate for the vacant chair of natural philosophy in Edinburgh. In the following year he was appointed actuary to the Amicable Life Assurance Office, the oldest institution of that kind in London, and in this situation he remained till his death, November 1, 1851. Galloway was a voluminous though, for the most part, an anonymous writer, and took a leading part in the proceedings of the principal scientific societies of London. He contributed largely to the seventh edition of the *Encyclopædia Britannica*, and also wrote several scientific papers for the *Edinburgh* and *Foreign Quarterly Reviews*. His *Encyclopædia* article "Probability" was published separately.

GALLS. In animals galls occur mostly on or under the skin of living mammals and birds, and are produced by Acaridea, and by dipterous insects of the genus *Œstrus*. Signor Moriggia[1] has described and figured a horny excrescence, nearly 8 inches in length, from the back of the human hand, which was caused by *Acarus domesticus*. What are commonly known as galls are vegetable deformities or excrescences, due to parenchymatous hypertrophy, and, according to the definition of Lacaze-Duthiers, comprise "all abnormal vegetable productions developed on plants by the action of animals, more particularly by insects, whatever may be their form, bulk, or situation." For the larvæ of their makers the galls provide shelter and sustenance. The exciting cause of the hypertrophy, in the case of the typical galls, appears to be a minute quantity of some irritating fluid, or virus, secreted by the female insect, and deposited with her egg in the puncture made by her ovipositor in the cortical or foliaceous parts of plants. This virus causes the rapid enlargement and subdivision of the cells affected by it, so as to form the tissues of the gall. Oval or larval irritation also, without doubt, plays an important part in the formation of many galls. Though, as Lacaze-Duthiers remarks, a certain relation is necessary between the "stimulus" and the "supporter of the stimulus," as evidenced by the limitation in the majority of cases of each species of gall-insect to some one vegetable structure, still it must be the quality of the irritant of the tissues, rather than the specific peculiarities or the part of the plant affected, that principally determines the nature of the gall. Thus the characteristics of the currant-gall of *Spathegaster baccarum*, L., which occurs alike on the leaves and on the flower-stalks of the oak, are obviously due to the act of oviposition, and not to the functions of the parts producing it; the bright red galls of the saw-fly *Nematus gallicola* are found on four different species of willow, *Salix fragilis, S. alba, S. caprea*, and *S. cinerea*;[2] and the galls of a Cynipid, *Biorhiza aptera*, usually developed on the rootlets of the oak, have been procured also from the deodar.[3] Often the gall bears no visible resemblance to the structures out of which it is developed; commonly, however, outside the larval chamber, or gall proper, and giving to the gall its distinctive form, are to be detected certain more or less modified special organs of the plant. The gall of *Cecidomyia strobilina*, formed from willow-buds, is mainly a rosette of leaves the stalks of which have had their growth arrested. The small, smooth, seed-shaped gall of the

[3] *Entomologist*, vii. p. 47.

American *Cynips seminator*, Harris, according to Mr W. F. Bassett,[1] is the petiole, and its terminal tuft of woolly hairs the enormously developed pubescence of the young oak-leaf. The moss-like covering of the "bedeguars" of the wild rose, the galls of a Cynipid, *Rhodites rosæ*, represents leaves which have been developed with scarcely any parenchyma between their fibro-vascular bundles; and the "artichoke-galls" or "oak-strobile," produced by *Aphilothrix gemmæ*, L., which insect arrests the development of the acorn, consists of a cupule to which more or less modified leaf-scales are attached, with a peduncular, oviform, inner gall.[2] Mr E. Newman held the view that many oak-galls are pseudobalani, or false acorns: "to produce an acorn has been the intention of the oak, but the gall-fly has frustrated the attempt." Their formation from buds which normally would have yielded leaves and shoots is explained by Parfitt as the outcome of an effort at fructification induced by oviposition, such as has been found to result in several plants from injury by insect-agency or otherwise.[3] Galls vary remarkably in size and shape according to the species of their makers. The polythalamous gall of *Aphilothrix radicis*, found on the roots of old oak-trees, may attain the size of a man's fist; the galls of another Cynipid, *Andricus occultus*, Tschek,[4] which occurs on the male flowers of *Quercus sessiliflora*, is 2 millimetres, or barely a line, in length. Many galls are brightly coloured, as, for instance, the oak-leaf hairy galls of *Spathegaster tricolor*, which are of a crimson hue, more or less diffused according to exposure to light. The variety of forms of galls is very great. Some are like urns or cups; others lenticular. The "knoppern" galls of *Cynips polycera*, Gir., are cones having the broad, slightly convex, upper surface surrounded with a toothed ridge. Of the Ceylonese galls "some are as symmetrical as a composite flower when in bud, others smooth and spherical like a berry; some protected by long spines, others clothed with yellow wool formed of long cellular hairs, others with regularly tufted hairs."[5] The characters of galls are constant, and as a rule exceedingly diagnostic, even when, as in the case of ten different gall-gnats of an American willow, *Salix humilis*, it is difficult or impossible to tell the full-grown insects that produce them from one another. In degree of complexity of internal structure galls differ considerably. Some are monothalamous, and contain but one larva of the gall-maker, whilst others are many-celled, and numerously inhabited. The largest class are the unilocular, or simple, external galls, divided by Lacaze-Duthiers into those with and those without a superficial protective layer or rind, and composed of hard, or spongy, or cellular tissue. In a common gall-nut that authority distinguished seven constituent portions:—an epidermis; a subdermic cellular tissue; a spongy and a hard layer, composing the parenchyma proper; vessels which, without forming a complete investment, underlie the parenchyma; a hard protective layer; and lastly, within that, an alimentary central mass inhabited by the growing larva.[6]

Galls are formed by insects of several orders. Among the Hymenoptera are the gall-wasps (*Cynips* and its allies), which infect the various species of oak. They are small insects, having straight antennæ, and a compressed, usually very short abdomen, with the second, or second and third segments greatly developed, and the rest imbricated, and concealing the partially coiled ovipositor. The transformations from the larval state are completed within the gall, out of which the imago, or perfect insect, tunnels its way,—usually in autumn, though sometimes, as has been observed of some individuals of *Cynips Kollari*, after hibernation.

The phenomena of development in *Cynips* and associated genera present many features of interest. Not fewer than 12,000 living specimens of *C. Kollari*, Gir. (*C. lignicola*, Hart.), from Devonshire galls, were examined by the late Mr Frederick Smith,[7] of the British Museum, and proved to be all females, as also were the flies obtained in two successive years from some of these by breeding on isolated oak trees in the neighbourhood of London. The same observer detected among about 1200 flies of the gregarious species *Aphilothrix* (*Cynips*) *radicis* not a single male. In many thousands of Cynipids, representing 28 species, Hartig failed to discover any male. Von Schlectendal, on the other hand, between 24th April and 1st May 1871, from three galls of *Rhodites rosæ*, L., obtained in the previous year, bred only 2 females and 32 males. These males were of the normal coloration and shape; but some which appeared in the latter part of May, when the females were in larger numerical proportion, were varieties of three kinds, partly resembling the females in coloration.[8] Walsh[9] ascertained with respect to the galls of the American Black Oak, that their growth commences in May, and is completed in a few weeks, and that near the middle of June about a fourth of them yield both male and female fully developed gall-flies of the species *Cynips spongifica*, Osten-Sacken. In the remainder of the galls the larvæ do not attain their pupal condition till more than two months later, and the flies they produce, which appear about October, are all females. This autumnal brood has been experimentally ascertained to cause the generation of oak-apples in the following spring on trees not previously infected. Mr W. F. Bassett[10] considers that most, if not all, species of *Cynips* are double-brooded, and that one of the two broods consists of females only. "There are," he remarks, "so many one-gendered species, that we may reasonably suppose each to be the progenitor of the equally numerous double-gendered species, whose relationships have not yet been observed."

Among the commoner of the galls of the *Cynipidæ* are the "oak-apple" or "oak-sponge" of *Andricus terminalis*, Fab.; the "currant" or "berry galls" of *Spathegaster baccarum*, L., above mentioned; and the "oak-spangles" of *Neuroterus lenticularis*,[11] Oliv., generally reputed to be fungoid growths, until the discovery of their true nature by Mr Frederick Smith;[12] and the succulent "cherry-galls" of *Dryophanta scutellaris*, Oliv. The "marble" or "Devonshire woody galls" of oak-buds, which often destroy the leading shoots of young trees, are produced by *Cynips Kollari*,[13] already alluded to. They were first introduced into Devonshire about the year 1847, had become common near Birmingham by 1866, and two or three years later were observed in several parts of Scotland.[14] They contain about 17 per cent. of tannin.[15] On account of their regular form they have been used, threaded on wire, for making ornamental baskets. The large purplish Mecca or Bussorah galls,[16] produced on a species of oak by *Cynips insana*, Westw., have been regarded by many writers as the Dead Sea fruit, mad-apples (*mala insana*), or apples of Sodom (*poma sodomitica*), alluded to by Josephus and others, which, however, are stated by E. Robinson (*Bibl. Researches in Palestine*, vol. i. pp. 522–4, 3d ed., 1867) to be the singular fruit called by the Arabs *'Ösher*, produced by the *Asclepias gigantea* or *procera* of botanists. What in California are known as "flea seeds" are oak-galls made by a

species of *Cynips*; in August they become detached from the leaves that bear them, and are caused to jump by the spasmodic movements of the grub within the thin-walled gall-cavity.[1]

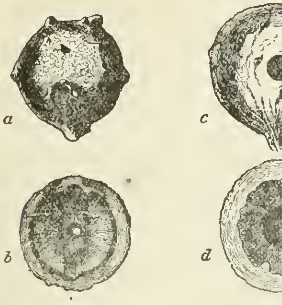

FIG. 1.—*a*, Aleppo "blue" gall; *b*, ditto in section, showing central cavity for grub; *c*, Aleppo "white" gall, perforated by insect; *d*, the same in section (natural size).

Common gall-nuts, nut-galls, or oak-galls, the Aleppo, Turkey, or Levant galls of commerce (German, *Galläpfel, Levantische Gallen*; French, *Noix de Galle*), are produced on *Quercus infectoria*, a variety of *Q. Lusitanica*, Webb, by *Cynips* (*Diplolepis*, Latr.) *tinctoria*, L., or *C. gallæ tinctoriæ*, Oliv. Aleppo galls (*gallæ halepenses*) are brittle, hard, spherical bodies, ⅗ – ⅘-inch in diameter, ridged and warty on the upper half, and light brown to dark greyish-yellow within. What are termed "blue," "black," or "green" galls contain the insect; the inferior "white" galls, which are lighter coloured, and not so compact, heavy, or astringent, are gathered after its escape (see fig. 1). Less valued are the galls of Tripoli (Taraplus or Tarabulus, whence the name "Tarablous galls"). The most esteemed Syrian galls, according to Pereira, are those of Mosul on the Tigris. Other varieties of nut-galls, besides the above mentioned, are employed in Europe for various purposes. Commercial gall-nuts have yielded on analysis from 26 (H. Davy) to 77 (Buchner) per cent. of tannin (see Vinen, *loc. cit.*), with gallic and ellagic acids, ligneous fibre, water, and minute quantities of proteids, chlorophyll, resin, free sugar, and, in the cells around the inner shelly chamber, calcium oxalate. Oak-galls are mentioned by Theophrastus, Dioscorides (i. 146), and other ancient writers, including Pliny (*Nat. Hist.*, xvi. 9, 10; xxiv. 5), according to whom they may be produced "in a single night." Their insect origin appears to have been entirely unsuspected until within comparatively recent times, though Pliny, indeed, makes the observation that a kind of gnat is produced in certain excrescences on oak leaves. Bacon describes oak-apples as "an exudation of plants joined with putrefaction." Pomet[2] thought that gall-nuts were the fruit of the oak, and a similar opinion obtains among the modern Chinese, who apply to them the term *Mu-shih-tsze*, or "fruits for the foodless."[3] Hippocrates administered gall-nuts for their astringent properties, and Pliny (*Nat. Hist.*, xxiv. 5) recommends them as a remedy in affections of the gums and uvula, ulcerations of the mouth, and some dozen more complaints. The drug has been used in the treatment of intermittent fevers,[4] but appears to be adapted only for their mildest phases.[5] In India it is given also in chronic diarrhœa, dysentery, gonorrhœa, and several other diseases.[6] In British pharmacy gall-nuts are used in the preparation of the two astringent ointments *unguentum gallæ* and *unguentum gallæ cum opio*, and of the *tinctura gallæ*, and also as a source of tannin and of gallic acid (*q.v.*). They have from very early times been resorted to as a means of staining the hair of a dark colour, and they are the base of the tattooing dye of the Somali women.[7] On the Continent they are employed in tanning. With respect to the technical application of gall-nuts, see further BLASTING, vol. iii. p. 808, DYEING, vol. vii. p. 579, and INK. In consequence of the increased consumption in dyeing of sumach, myrobalans, and new chemical substances, the British importations of gall-nuts have on the whole declined considerably.

The quantities and values of galls imported into the United Kingdom in 1877 were as follows:—From Germany, 1963 cwts., £7759; Turkey, 6420 cwts., £20,712; Egypt, 1702 cwts., £6244; China, 11,748 cwts., £32,715; British India (Bombay and Scinde), 2181 cwts., £2230; other countries, 2411 cwts., £7176; total, 26,425 cwts., of the value of £76,834, against 25.884 cwts., value £64,704, in 1876.

The gall-making Hymenoptera include, besides the *Cynipidæ* proper, certain species of the genus *Eurytoma* (*Isosoma*, Walsh) and family *Chalcididæ*, *e.g.*, *E. hordei*, the "joint-worm" of the United States, which produces galls on the stalks of wheat;[8] also various members of the family *Tenthredinidæ*, or saw-flies. The larvæ of the latter usually vacate their galls to spin their cocoons in the earth, or, as in the case of *Athalia abdominalis*, Klg., of the clematis, may emerge from their shelter to feed for some days on the leaves of the gall-bearing plant.

The dipterous gall-formers include the gall-midges, or gall-gnats (*Cecidomyidæ*), minute slender-bodied insects, with bodies usually covered with long hairs, and the wings folded over the back. Some of them build cocoons within their galls, others descend to the ground to become pupæ. The true willow-galls are the work either of these or of saw-flies. Their galls are to be met with on a great variety of plants of widely distinct genera, *e.g.*, the ash, maple, hornbeam, oak,[9] grape-vine,[10] alder, gooseberry, blackberry, pine, juniper, thistle, fennel, meadowsweet,[11] common cabbage, and cereals. In the northern United States, in May, "legions of these delicate minute flies fill the air at twilight, hovering over wheat-fields and shrubbery. A strong north-west wind, at such times, is of incalculable value to the farmer."[12] Other gall-making dipterous flies are members of the family *Trypetidæ*, which disfigure the seed-heads of plants, and of the family *Mycetophilidæ*, such as the species *Sciara tilicola*,[13] Löw, the cause of the oblong or rounded green and red galls of the young shoots and leaves of the lime.

Galls are formed also by hemipterous and homopterous insects of the families *Tingidæ*, *Psyllidæ*, *Coccidæ*, and *Aphidæ*. *Coccus pinicorticis* causes the growth of patches of white flocculent and downy matter on the smooth bark of young trees of the white pine in America.[14] The galls of examples of the last family are common objects on lime-leaves, and on the petioles of the poplar. An American Aphid of the genus *Pemphigus* produces black, ragged, leathery, and cup-shaped excrescences on the young branches of the hickory.

The Chinese galls of commerce (*Woo-pei-tsze*) are stated to be produced by *Aphis Chinensis*, Bell, on *Rhus semialata*, Murr. (*R. Bucki-amela*, Roxb.), an Anacardiaceous tree indigenous to N. India, China, and Japan. They are hollow, brittle, irregularly pyriform, tuberculated or branched vesicles, with thin walls, covered externally with a grey down, and internally with a white chalk-like matter, and insect-remains (see fig. 2). The escape of the insect takes place on the spontaneous bursting of the walls of the vesicle, probably when, after viviparous (thelytokous) reproduction for several generations, male winged insects are developed. The galls

are gathered before the frosts set in, and are exposed to steam to kill the insects.[1]

Chinese galls examined by Viedt[2] yielded 72 per cent. of tannin, and less mucilage than Aleppo galls. Several other varieties of galls are produced by Aphides on species of *Pistacia*.

M. J. Lichtenstein has established the fact that from the egg of the Aphis of Pistachio galls, *Anōplcura lentisci*, is hatched an apterous insect (the gall-founder), which gives birth to young Aphides (emigrants), and that these, having acquired wings, fly to the roots of certain grasses (*Bromus sterilis* and *Hordeum vulgare*), and by budding underground give rise to several generations of

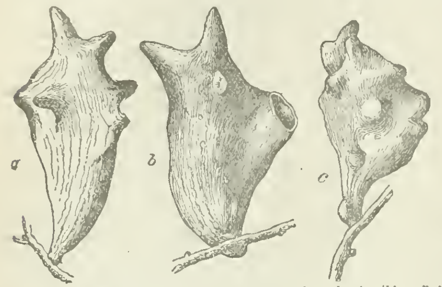

Fig. 2.—*a*, Chinese gall (half natural size); *b*, ditto, broken, showing thin-walled cavity; *c*, Japanese gall (natural size).

apterous insects, whence finally comes a winged brood (the pupifera). These last issuing from the ground fly to the Pistachio, and on it deposit their pupæ. From the pupæ, again, are developed sexual individuals, the females of which lay fecundated eggs productive of gall-founders, thus recommencing the biological cycle (see *Compt. Rend.*, Nov. 18, 1878, p. 782, quoted in *Ann. and Mag. Nat. Hist.*, 1879, p. 174).

Of other insects which have been recognized as gall-makers there are, among the Coleoptera, certain Curculionids (gall-weevils), and species of the exotic *Sayridæ* and *Lamiadæ*, and an American beetle, *Saperda inornata* (*Cerambycidæ*), which forms the pseudo-galls of *Salix longifolia* and *Populus angulata*, or cottonwood. Among the Lepidoptera are gall-forming species belonging to the *Tineidæ*, *Ægeriidæ*, *Tortricidæ*, and *Pterophoridæ*. The larva of a New Zealand moth, *Morova subfasciata*, Walk. (*Cacoëcia gallicolens*), of the family *Drepanulidæ*, causes the stem of a creeping plant, on the pith of which it apparently subsists, to swell up into a fusiform gall.[3]

Mite-galls, or *acarocecidia*, are abnormal growths of the leaves of plants, produced by microscopic Acaridea of the genus *Phytoptus* (gall-mites), and consist of little tufts of hairs, or of thickened portions of the leaves, usually most hypertrophied on the upper surface, so that the lower is drawn up into the interior, producing a bursiform cavity. Mite-galls occur on the sycamore, pear, plum, ash, alder, vine, mulberry, and many other plants; and formerly, *e.g.*, the gall known as *Erineum quercinum*, on the leaves of *Quercus Cerris*, were taken for cryptogamic structures. The lime-leaf "nail-galls" of *Phytoptus tiliæ* closely resemble the "trumpet-galls" formed on American vines by a species of *Cecidomyia*.[4] Certain minute Nematoid worms, as *Anguillula scandens*, which infests the ears of wheat, also give rise to galls.

Besides the larva of the gall-maker, or the householder, galls usually contain inquilines or lodgers, the larvæ of what are termed guest-flies or cuckoo-flies. Thus the galls of *Cynips* and its allies are inhabited by members of other cynipideous genera, as *Synergus*, *Amblynotus*, and *Synophrus*; and the pine-cone-like gall of *Salix strobiloides*, as Walsh has shown,[5] is made by a large species of *Cecidomyia*, which inhabits the heart of the mass, the numerous smaller cecidomyidous larvæ in its outer part being mere inquilines. In many instances the lodgers are not of the same order of insects as the gall-makers. Some saw-flies, for example, are inquilinous in the galls of gall-gnats, and some gall-gnats in the galls of saw-flies. Again, galls may afford harbour to insects which are not essentially gall-feeders, as in the case of the Curculio beetle *Conotrachelius nenuphar*, Hbst., of which one brood eats the fleshy part of the plum and peach, and another lives in the "black knot" of the plum-tree, regarded by Walsh as probably a true cecidomyidous gall. The same authority (*loc. cit.*, p. 550) mentions a willow-gall which provides no less than sixteen insects with food and protection; these are preyed upon by about eight others, so that altogether some twenty-four insects, representing eight orders, are dependent for their existence on what to the common observer appears to be nothing but "an unmeaning mass of leaves." Among the numerous insects parasitic on the inhabitants of galls are hymenopterous flies of the family *Proctotrypidæ*, and of the family *Chalcididæ*, *e.g.*, *Callimome regius*, the larva of which preys on the larvæ of both *Cynips glutinosa* and its lodger *Synergus facialis*. The oak-apple often contains the larvæ of *Braconidæ* and *Ichneumonidæ*, which Von Schlechtendal (*loc. sup. cit.*, p. 33) considers to be parasites not on the owner of the gall, *Andricus terminalis*, but on inquilinous *Tortricidæ*. Birds are to be included among the enemies of gall-insects. Oak-galls, for example, are broken open by the titmouse in order to obtain the grub within, and the "button-galls" of *Neuroterus numismatis*, Oliv., are eaten by pheasants.

GALLUPPI, Pasquale (1770–1846), a distinguished Italian philosopher, was born on 2d April 1770, at Tropea, in Calabria. He was of good family, and after completing his education at the academy of Tropea and the university of Naples he entered the public service, and was for many years employed in the office of the administration of finances. Altogether apart from academic influences he pursued his favourite studies, and it was not till he had reached the age

[5] *Proc. Entomol. Soc. Philadelphia*, iii., 1864, p. 549.

of sixty, and had become widely known by his writings on philosophy, that he was called to a chair in the university of Naples. This chair he held till his death in November 1846. Galluppi's first work was an essay on analysis and synthesis (*Sull' Analisa c sulla Sintesi*) published in 1807. This was followed by the important *Saggio filosofico sulla critica della conoscenza*, in 6 volumes, published from 1819 to 1832. In the *Lettere filosofiche sulle vicende della filosofia relativamente ai principii delle conoscenze humana, da Cartesio sino a Kant*, 1827, by which, through the translation into French (by M. Peisse, 1844), he is best known to foreigners, Galluppi traces his own philosophical development from the empiricism of the 18th century writers through the Kantian criticism to his final speculative view, one in many respects resembling the doctrines of the Scotch school as amended by Hamilton. His systematic work, *Elementi di filosofia* (4 vols. 1832), was long used as a text-book for instruction in the Italian colleges. Of other writings may be mentioned the *Lezioni di logica e di metafisica* (1832–3, 5 vols., 1842); the *Filosofia della Volonta* (3 vols., 1832–1842, incomplete); and the *Storia della Filosofia* (1842), of which only the first volume was published. Galluppi, though in many respects Kantian, can hardly be said to have taken up fully the speculative significance of the *Critique of Pure Reason*. He accepts the Kantian demonstration of the necessary unity of consciousness as the indispensable factor in knowledge, regards our knowledge of the ego as knowledge of substance, maintains that in external perception, or, as he puts it, in sensation, we are directly cognizant of the real thing, and holds that the existence of the unconditioned is given in knowledge as the necessary correlate of the conditioned, but rejects entirely the *a priori* element which is the distinguishing characteristic of the Kantian doctrine of cognition. All judgments, according to him, are ultimately identical—a relic of the empiricism of Condillac which is totally irreconcilable with the fundamental principles of his philosophy. On the other hand, Galluppi exaggerates the place and importance of the moral reason; with Kant he finds objective truth in the ideas of desert and duty, and admits that ethical judgments are *a priori*, without endeavouring to explain, in accordance with his theoretical views, how such judgments are at all possible.

A good view of Galluppi's place in Italian philosophy is given in Ferri, *Essai sur l'Histoire de la Phil. en Italie au XIXme Siècle*, vol. i., Paris, 1869. See also V. Botta, in Ueberweg's *History of Phil.* (Eng. transl., vol. ii., appendix ii.); Prof. Barzellotti, "Philosophy in Italy," in *Mind*, October 1878.

GALLUS, C. Cornelius, a Roman poet, orator, and politician, was born of humble parents at Forum Julii (Fréjus), in Gaul, about the year 66 B.C. At an early age he removed to Rome, where he was taught by the same master as Virgil and Varius. In political life he espoused the cause of Octavianus, and as a reward for his services was made prefect of Egypt. His conduct in this position afterwards brought him into disgrace with Augustus, and dreading the exposure of his arrogance, extortion, and cruelty, he put an end to his life by throwing himself on his sword, in the year 26 B.C. Gallus enjoyed a high reputation among his contemporaries as a man of intellect. He associated on terms of equality with Virgil, Ovid, Varius, Asinius Pollio, and others, and on account of his four books of elegies Ovid claimed for him the first place among the elegiac poets of Rome. His fame as an orator was hardly inferior to his renown as a poet; but as not a fragment of his composition has descended to our times, we have no means of judging the worth of his literary pretensions, and have to content ourselves with the somewhat partial estimate of his personal friends.

See Ch. C. Völker, *Commentatio de C. Galli Vita et Scriptis*, part i., Bonn, 1840; part ii., Elberfeld, 1844.

GALT, John (1779–1839), a Scottish novelist, was born at Irvine, in Ayrshire, on May 2, 1779. He received his early education at Irvine and Greenock, and read largely from one of the public libraries while serving as a clerk in a mercantile office. His first compositions appeared in the *Greenock Advertiser* and the *Scots Magazine*. In 1804 he went to settle in London, where he continued to work at a poem on the *Battle of Largs*, which was published anonymously. After unsuccessful attempts to succeed in business, Galt left for the Continent, and met Byron and Sir John Hobhouse at Gibraltar, with whom he had a tour in the Mediterranean. He remained abroad for three years, and then returned to London. His early works are the *Life and Administration of Wolsey*, *Voyages and Travels*, *Letters from the Levant*, the *Life of Benjamin West*, *Historical Pictures*, the *Wandering Jew*, and a volume of dramas; but he first showed his real power in *The Ayrshire Legatees*, which appeared in *Blackwood's Magazine* in 1820. This was followed in 1821 by his masterpiece—*The Annals of the Parish*; and, at short intervals, *Sir Andrew Wylie*, *The Entail*, *The Steam-Boat*, and *The Provost* were published. These are all in his happiest manner, and are unsurpassed as studies of Scottish character. His next works were *Ringan Gilhaize*, a story of the Covenanters; *The Spaewife*, which relates to the times of James I. of Scotland; *Rothelan*, a novel founded on the reign of Edward III.; *The Omen*, which was favourably criticized by Sir Walter Scott; and *The Last of the Lairds*, another picture of Scottish life. In 1826 he visited America for the second time, in connexion with the establishment of the Canada Company—an undertaking which involved him in great difficulties, and ultimately proved disastrous to his worldly prospects. It is pleasant to remember that, although Galt's connexion with Canada was unfortuate for himself, his youngest son, Sir Alexander Galt, has had a distinguished career there, and was, for some time, finance minister of the colony. In 1827 Galt founded Guelph in Upper Canada, passing on his way the township of Galt on the Grand River, named after him by the Hon. William Dixon. In 1829 he returned to England commercially a ruined man, and devoted himself with great ardour to literary pursuits, of which the first fruit was *Lawrie Todd*—one of his best novels. Then came *Southennan*, a tale of Scottish life in the times of Queen Mary. In 1830 he was appointed editor of the *Courier* newspaper—a post he soon relinquished. His untiring industry was seen in the publication, in rapid succession, of a *Life of Byron*, *Lives of the Players*, *Bogle Corbet*, *Stanley Buxton*, *The Member*, *The Radical*, *Eben Erskine*, *The Stolen Child*, his *Autobiography*, and a collection of tales entitled *Stories of the Study*. In 1834 appeared his *Literary Life and Miscellanies*, dedicated by permission to William IV., who sent the author a present of £200. As soon as this work was published Galt retired to Greenock, where he lingered on in bad health till his death on the 11th of April 1839.

Galt, like almost all voluminous writers, was exceedingly unequal. His masterpieces are *The Ayrshire Legatees*, *The Annals of the Parish*, *Sir Andrew Wylie*, *The Entail*, *The Provost*, and *Lawrie Todd*. *The Ayrshire Legatees* gives, in the form of a number of exceedingly diverting letters, the adventures of the Rev. Dr Pringle and his family in London. The letters are made the excuse for endless tea-parties and meetings of kirk session in the rural parish of Garnock. The *Annals of the Parish* are told by the Rev. Micah Balwhidder, Galt's finest character. This work is a splendid picture of the old-fashioned Scottish pastor and the life of a country parish; and, in rich humour, genuine pathos, and truth to nature, it is unsurpassed even by Scott. Like his other Scotch novels, it is a fine specimen of the homely graces of the Scottish dialect, and preserves much vigorous Doric phraseology fast passing out of use even in country districts. In this novel Mr Galt used, for the first time, the term "Utilitarian," which has since become so intimately associated with the doctrines of John Stuart Mill and his followers (see *Annals of the Parish*, chap. xxxv., and a note by Mr Mill in *Utilitarianism*, chap. ii.). In *Sir Andrew Wylie* the hero entered London as a poor lad, but achieved remarkable success by his shrewd business qualities. The character is somewhat exaggerated, but excessively amusing. *The Entail* was read thrice by Byron and Scott, and is the best of Galt's longer novels. Leddy Grippy is a wonderful creation, and was considered by Byron equal to any female character in literature since Shakespeare's time. *The Provost*, in which Provost Pawkie tells his own story, portrays inimitably the jobbery, bickerings, and selfseeking of municipal dignitaries in a quaint Scottish burgh. In *Lawrie Todd* Galt, by giving us the Scot in America, has accomplished a feat which Sir Walter never attempted. This novel exhibits more variety of style and a greater love of nature than his other books. The life of a settler is depicted with unerring pencil, and with an enthusiasm and imaginative power much more poetical than any of the author's professed poems.

Galt's humour is broader and more contagious than Scott's; and his pictures of the sleepy life of old Scottish towns are unrivalled in literature. He is generally called an imitator of Scott; but the *Annals of the Parish* existed in MS. before *Waverley* was published. As Galt is pre-eminently an illustrator of west-country Scottish life, his range may be said to be narrower than Scott's; but within it he is supreme. It would be difficult to overrate the immense services which Galt has rendered alike to the history of the manners and to the history of the language of the Scottish people.

For further information about Galt, see his *Autobiography*; *The Literary Life of John Galt*; and a biographical memoir by his friend the late Dr Moir of Musselburgh, prefixed to *The Annals of the Parish*. (T. GI.)

GALOIS, EVARISTE (1811–1832), an eminently original and profound French mathematician, born 26th October 1811, killed in a duel May 1832. A necrological notice by his friend M. Auguste Chevalier appeared in the *Revue Encyclopédique*, September 1832, p. 744; and his collected works are published, *Liouville*, t. xi. (1846), pp. 381–444, about fifty of these pages being occupied by researches on the resolubility of algebraic equations by radicals. But these researches, crowning as it were the previous labours of Lagrange, Gauss, and Abel, have in a signal manner advanced the theory, and it is not too much to say that they are the foundation of all that has since been done, or is doing, in the subject. The fundamental notion consists in the establishment of a group of permutations of the roots of an equation, such that every function of the roots invariable by the substitutions of the group is rationally known, and reciprocally that every rationally determinable function of the roots is invariable by the substitutions of the groups; some further explanation of the theorem, and in connexion with it an explanation of the notion of an adjoint radical, is given under EQUATION, No. 32. As part of the theory (but the investigation has a very high independent value as regards the Theory of Numbers, to which it properly belongs), Galois introduces the notion of the imaginary roots of an irreducible congruence of a degree superior to unity; *i.e.*, such a congruence, $F(x) \equiv 0$ (mod. a prime number p), has no integer root; but what is done is to introduce a quantity i subjected to the condition of verifying the congruence in question, $F(i) \equiv 1$ (mod. p), which quantity i is an imaginary of an entirely new kind, occupying in the theory of numbers a position analogous to that of $-\sqrt{-1}$ in algebra.

GALUPPI, BALDASSARRE (1706–1785), a musical composer, was born in 1706, in the island of Burano, near Venice. His father, a barber by profession, was a musical amateur, and prepared his son for the music school of Venice called Conservatorio degl' Incurabili, where the great Lotti became his master. His first opera, written at the age of sixteen, was a failure; but his comic opera named *Dorinda*, produced seven years later, was a great success, and laid the foundation of the youthful composer's fame. He was a prolific writer, and no less than seventy of his operas are enumerated, none of which, however, have kept the stage. Some of these were written for London, where Galuppi resided between 1741 and 1744, but his masterpiece in tragic opera was produced at St Petersburg in 1766. The composer had been induced by liberal offers to accept a position as imperial conductor of music, and to leave his native country for Russia, where he lived in high honour at the court of the czar, and is said to have in return done much for the progress of his art in Russia by introducing amongst other things Italian church-music. In 1768 he left Russia, and resumed his position as organist of the cathedral of St Mark at Venice, to which he had been appointed in 1762, and which had been kept open for him during his absence. He died in 1785, and left 50,000 lire to the poor of Venice. His best comic opera bears the title *Il mondo della luna*. The libraries of Dresden and Vienna preserve several of his operas in MS. At Vienna also some of his works of sacred music may be found. Others are in Paris and Rome.

GALVANI, LUIGI (1737–1798), an eminent Italian physiologist, after whom galvanism received its name, was born at Bologna, September 9, 1737. It was his wish in early life to enter the church, but by his parents he was educated for a medical career. At the university of Bologna, in which city he practised, he was in 1762 appointed public lecturer in anatomy, and soon gained repute as a skilled though not eloquent teacher, and, chiefly from his researches on the organs of hearing and genito-urinary tract of birds, as a comparative anatomist. His celebrated theory of animal electricity he enunciated in a treatise, "De viribus electricitatis in motu musculari commentarius," published in the 8th volume of the memoirs of the Institute of Sciences at Bologna in 1791, and separately at Modena in the following year, and elsewhere subsequently. The statement has frequently been repeated that, in 1786, Galvani had skinned some frogs to make broth for his wife, who was in delicate health; that the leg of one of these, on being accidentally touched by a scalpel which had lain near an electrical machine, was thrown into violent convulsions; and that it was thus that his attention was first directed to the relations of animal functions to electricity. From documents in the possession of the Institute of Bologna, however, it appears that twenty years previous to the publication of his *Commentary* Galvani was already engaged in investigations as to the action of electricity upon the muscles of frogs. The observation that the suspension of certain of these animals on an iron railing by copper hooks caused twitching in the muscles of their legs led him to the invention of his metallic arc, the first experiment with which is described in the third part of the *Commentary*, wherein it is registered September 20, 1786. The arc he constructed of two different metals, which, placed in contact the one with a nerve and the other with a muscle of a frog, caused contraction of the latter. In Galvani's view the motions of the muscle were the result of the union, by means of the metallic arc, of its exterior or negative electrical charge with positive electricity which proceeded along the nerve from its inner substance. Volta, on the other hand, attributed them solely to the effect of electricity having its source in the junction of the two dissimilar metals of the arc, and regarded the nerve and muscle simply as conductors. Galvani in one of his memoirs recorded the observation that muscular contractions may be caused in a prepared frog merely by bending back the legs and bringing them into contact with the lumbar nerves, as also when a nerve is touched at two different points with a morsel of muscle taken from a living frog, phenomena not satisfactorily explicable on the theories of Volta; but after the death of the Bologna professor very little was heard of animal electricity till, in 1827, the study of the subject was resumed by Nobili. On Galvani's refusal, from religious scruples, to take the oath of allegiance to the Cisalpine republic on its establishment, he was removed from his professorship. Deprived thus of the means of livelihood, he retired to the house of his brother Giacomo, where he soon fell into a feverish decline. The republican Government, in consideration of his great scientific fame, eventually, but too late, determined to reinstate him in his chair at the university of Bologna. He died December 4, 1798. A quarto edition of his works was published at Bologna in 1841–42, by the Academy of Sciences of the Institute of that city, under the title *Opere edite ed inedite del professore Luigi Galvani.*

GALVANISM. See ELECTRICITY and PHYSIOLOGY.

GALVANOMETER, an instrument used for indicating or measuring currents of electricity, wherein advantage is taken of the force exerted by such currents on movable magnets in their neighbourhood.[1] When a galvanometer is used for indicating merely, without measuring, it is sometimes called a galvanoscope. If we consider only such instruments as have come into actual use, this definition is strict enough for practical purposes. If we were to consider all the instruments that have been or might be made, some would come under the definition whose resemblance to the modern galvanometer would not at first sight be apparent. Such, for instance, is the electromagnetic balance of Becquerel,[2] which consists of two bar magnets hung from the scale pans of a delicate balance each in the axis of a cylindrical bobbin of wire—one being over, the other under its corresponding bobbin (see fig. 1). The north poles of both magnets hang

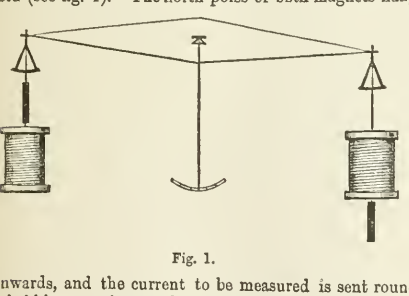

Fig. 1.

downwards, and the current to be measured is sent round the bobbin, so that each of the magnets is repelled. Weights are put into the left-hand scale until equilibrium in the original position is restored. The weight thus added is proportional to the current strength, so long as the induced magnetism of the magnets can be neglected. This instrument has fallen into disuse.

In a complete galvanometer of modern construction the following parts may occur:—(1) the coil or multiplier, (2) the needle or movable magnet or magnets, (3) the astatizing apparatus, (4) the deflecting or adjusting magnet, (5) the graduation or reading apparatus, (6) the damping apparatus, (7) accompanying the galvanometer, as a piece of auxiliary apparatus, we may also have a box of shunts. It would be easy to make a more minute enumeration of parts, but the above will serve our present purpose. On the other hand, it is not always that each of the above organs is represented separately; some may be wanting in certain cases, and the functions of two or more may be combined.

1. The multiplier or coil consists of a ring-shaped channel of elliptical, rectangular, or circular shape—usually the last, the cross section being in general rectangular. Into this is wound, as closely and regularly as possible, a quantity of silk-covered wire. The material chosen for the wire is usually copper, which should be as soft as possible in order to secure high conductivity. White silk is preferred for the insulating covering, on account of its freedom from iron, though this is for most purposes a needless refinement. Great care should be taken that the wire is dry when it is wound. It is usual, in order to secure and render permanent the insulation, to steep the whole coil in melted paraffin; after this has been done, there is little risk of loss of insulation, provided the layers have been carefully tested during the winding. The idea of the multiplier in sensitive galvanometers is to bring the greatest number of coils of wire within the least possible distances of the magnet. It is evident, therefore, that the insulating covering should be as thin as is consistent with good insulation; this consideration assumes great importance when coils of very fine wire have to be wound. After the wire has reached a certain fineness the proportion of space occupied by insulating matter is so great that further reduction of the section of the wire simply increases the resistance without enabling us to pack more turns into the same space. In general the section of the wire ought to be chosen with reference to the use which the galvanometer is intended to serve. The following ideal case will enable the reader to comprehend the principle which regulates the choice of multiplier under given circumstances. Suppose the dimensions of the channel, and the whole space which the wire is to fill, to be given, and the whole external resistance also given, then it may be shown that the section of the wire[3] ought to be chosen so that the resistance of the galvanometer shall be equal to the external resistance. The case contemplated here is that where we have a simple external circuit; many cases can be reduced to this at once, and we shall consider below a more complicated case of considerable practical importance. Theoretically the section of the wire ought to vary with the distance of the winding from the axis of the coil. The law is that the diameter of the wire in each layer ought to be proportional to the linear dimension of that layer. This is sometimes roughly carried out in practice by winding the outer layers of thicker wire than the inner.[4] The proper form of the longitudinal section of the coil depends on the use for which the instrument is destined, and will be more properly discussed when we describe particular instruments. In a certain class of galvanometers called differential, the wire on the coil is wound double, so that two currents can be sent through side by side in the same or in opposite directions.

2. The needle consists of a piece of magnetized steel,

[1] For another definition see the article ELECTROMETER.

[2] For a brief history of the construction of galvanometric apparatus see art. ELECTRICITY, vol. viii. p. 13.

[3] In this and all that follows the silk covering is either neglected or is supposed to vary in thickness as the diameter of the wire.

[4] The cross section of the coil is not a matter of indifference in sensitive galvanometers; but the question is hardly of sufficient importance to need discussion here. Information on the subject will be found in W. Weber's *Electrodynamische Maasbestimmungen*, Thl. ii.; H. Weber, *Pogg. Ann.*, 1869; Maxwell's *Electricity and Magnetism*, vol. ii. secs. 716 *sqq.*; Jenkin's *Electricity and Magnetism*, cap. xiii. sec. 9.

which should be as hard as possible. Watch-spring steel is sometimes used, and file steel is recommended by some authorities. The hardness is important for two reasons,—in the first place, to ensure that the permanent magnetism of the needle shall not alter. This is of small importance where permanent deflections are to be observed, provided we can be sure that the direction of the magnetic axis does not alter. In the second place the induced magnetism is less in hard than in soft steel, though not so much less as some writers would lead us to suppose. The best way of avoiding induced magnetism would be to make the needle spherical in form; the advantage thus gained, however, would in most cases be counterbalanced by other defects.

The form of the needle has been much varied by different constructors. In the earlier instruments they were made very long, and were suspended like compass needles by means of a jewelled cup playing on a steel point. We have heard on good authority that for some purposes, such as mounting tangent galvanometer needles, this method of suspension, if carefully carried out, really answers very well. By far the most usual mode of suspension, however, is by means of a raw silk fibre, or by a bundle of such fibres. Weber introduced the use of heavy magnets whose moment of inertia and time of oscillation were great. For many purposes such needles have great advantages—where, for instance, the time of oscillation, the logarithmic decrement, or the extent of swing of the needle has to be observed. Where, on the contrary, the galvanometer is to be used merely as an indicator, particularly in detecting transient currents, a light needle of small moment of inertia should be used. Continental constructors, no doubt unduly influenced by a reverence for Weber's methods, have failed to realize this; and we have seen few, if indeed any, instruments by them really well suited for measuring resistances with the Wheatstone's bridge. This principle has been carried farthest in the galvanometers of Sir William Thomson, in some of which the needle with all its appurtenances weighs little over a grain.

In some galvanometers (*e.g.*, certain telegraphic reading instruments) the needle is movable about a horizontal axis, and is weighted so as to be vertical in its undisturbed position. Owing to the friction at the points where the axis is supported, this method of suspension is useless for sensitive instruments.

3. When, as is usual, the galvanometer magnet is movable in a horizontal plane, the force which balances the electromagnetic force of the current in the multiplier is the horizontal component of the earth's magnetic force. Each of these forces is proportional to the magnetic moment of the galvanometer needle, and consequently the ratio of the forces, on which depends the magnitude of the deflexion of the needle, is independent of the magnetic moment of the needle. We cannot therefore increase the sensitiveness of the galvanometer by simply increasing the magnetic moment of the needle. The action of the earth can, however, be counteracted, and the needle rendered more or less *astatic* in one or other of two ways.

One way is to fix on the same axis of suspension two parallel magnets, whose magnetic moments are as nearly as possible equal, and which are turned opposite ways. The whole system is suspended so that one of the magnets swings inside the multiplier and the other over it, as in fig. 2. In more modern instruments, such as those constructed by Messrs Elliot Brothers, the multiplier consists of two equal coils placed one vertically over the other, each enclosing one of the magnets of the astatic system, as in fig. 3. Another method is to place a magnet, or a system of magnets, in the neighbourhood of the galvanometer, so as to counteract the earth's force. In general, one magnet will suffice, placed vertically under or over the galvanometer, in the magnetic meridian, its north pole of course pointing north. For convenience this magnet should be mounted on a vertical graduated rod, with a rough and a fine adjustment.

In adjusting the sensitiveness of the galvanometer, it will be useful to recollect that the couple tending to bring the needle back to its position of equilibrium varies directly as the square of the number of oscillations which the needle executes in a given time when no current is passing through the multiplier.[1] As the astatizing magnet is brought nearer and nearer to the galvanometer, the oscillations of the needle will be seen to become slower and slower, till at last the equilibrium becomes unstable, and the needle turns round through 180°; after which, on causing the magnet to approach still farther, the rapidity of oscillation increases. If the damping be very strong, and the mirror very light, an intermediate stage called the *aperiodic* state is passed through.

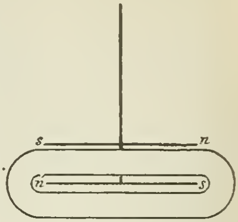

Fig. 2.

4. The normal position of the magnetic axis of the needle, when no current is passing, is parallel to the windings of the multiplier. It is particularly necessary that it should be in this position when the galvanometer is being used as a measuring instrument, and it is advisable in any case, since this is the position in which for a given current the electromagnetic action on the needle is greatest. The final adjustment might of course be made by moving the multiplier, but it is far more convenient to move the needle, a magnet being used for the purpose. Sometimes the astatizing magnet is used, but it is better to have a much weaker magnet for the fine adjustment, suspended like the astatizer on a vertical axis, having a vertical motion and a motion of rotation. It is better still to use a magnet placed with its axis in the axis of the multiplier, so that it can be slid backwards and forwards at pleasure. We have seen two such magnets placed side by side, with their north and south and their south and north poles together; this gives a differential adjustment which is very convenient. The main advantage of placing magnets in this way is that we can alter the direction of the lines of force with a minimum effect on the strength of the magnetic field.

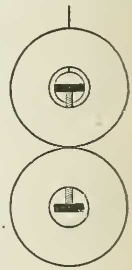

Fig. 3.

5. The graduation or reading apparatus in the older instruments consisted of a pointer or index fixed to the magnet (very often it was the magnet itself), playing over a circular graduation centred as nearly as possible in the axis of rotation of the needle. The mirror method of reading which prevails in most modern instruments was originally suggested by Poggendorff, and carried out in practice by Gauss and Weber. A mirror is rigidly attached to the magnet, so that the reflecting face passes as nearly as possible through the vertical axis of rotation of the needle. The glass of the mirror should be very thin, otherwise a greater or less correction for its thickness will be necessary. In the *subjective* method of reading, a scale is fixed before the mirror, which is usually plane (it must be well made to

[1] This is not exactly true where there is damping: but the rule is sufficient for ordinary purposes.

be of any use), and the image of the scale is observed by means of a telescope fixed over or under the centre of the scale. The scale divisions are seen to pass the wires of the telescope, and if a circular scale be used, whose centre is in the axis of suspension of the mirror, the difference between the numbers on the cross wires in any two positions of the magnet is a measure of twice the deflection of the magnet. A correction is necessary when a straight scale is used. The reader who has occasion to use the method will find practical instructions, with tables of corrections, in Wiedemann's *Galvanismus*, Bd. ii. sec. 181 *sqq.*; Maxwell's *Electricity and Magnetism*, vol. ii. sec. 450 *sqq.* In the *objective* method, which is more usually practised in this country, the mirror is concave, and reflects the image of a fixed illuminated slit (often furnished with a vertical wire where greater accuracy is desired) upon a graduated scale. The readings are proportional to double the deflexion of the needle, or to the tangent of the double deflexion, according as the scale is circular or straight.

6. By damping is meant the decrease of the extent of the oscillations of the galvanometer needle arising from the dissipation of energy through the resistance of the air, the action of currents induced in neighbouring metallic circuits, the viscosity of the suspension fibre, and so on. There is always more or less damping owing to the first two causes, and possibly the third; but in many cases, where it is desirable that the oscillations should subside very quickly, the damping is purposely increased. In the older instruments the damping arrangement consisted of masses of copper surrounding the magnet. This is carried to the extreme in Wiedemann's tangent galvanometer, where the needle is ring-shaped, and swings in a ring-shaped cavity not much larger than itself, in the heart of a mass of copper. In the dead-beat galvanometers of Sir William Thomson the magnet with its attached mirror is enclosed in a flat cell, in which it can just move freely to the required extent. The damping, due to the pumping of the air backwards and forwards round the edges of the mirror, is so great that the needle swings off to its position of equilibrium, and remains there without oscillating at all. The same result is attained in Varley's construction by immersing the needle in a cell filled with liquid.

7. The box of shunts is simply a set of resistances; generally there are three,—$\frac{1}{9}$th, $\frac{1}{99}$th, and $\frac{1}{999}$th of the resistance of the multiplier When it is required to reduce the sensibility of the galvanometer, the terminals of one of these, say the $\frac{1}{99}$th, are connected with the terminals of the multiplier; we thus have a multiple arc in place of the galvanometer, and the current is divided between its branches in the ratio of their conductivities, so that one-hundredth[1] of the whole current flows through the galvanometer. By means of such a box as we have described, we can therefore send through the galvanometer the whole of any current, or the tenth, hundredth, or thousandth part. It must not be forgotten that the introduction of the shunt diminishes the whole resistance of the galvanometer circuit. In most cases, however, this is of little moment; where necessary, the alteration may be either compensated[2] or allowed for.

Sensitive Galvanometers.—In galvanometers of this class everything is disposed so as to bring the greatest possible number of turns of wire into the neighbourhood of the needle. The needle is therefore made as small and compact as possible, and the windings embrace it as closely as possible, the opening in the centre of the coil being reduced to a minimum. The astatic multiplier (fig. 4) is an instrument of this kind which was formerly much used. The coil is of flat, rectangular shape, with a narrow central opening just large enough to allow one of the magnets of the astatic system to swing freely. The other magnet swings over a graduated circle placed on the top of the coil, and serves also as an index. Sometimes a mirror and scale are substituted for the index and graduated circle. The sole on which the coil stands is movable on a fixed piece which can be levelled by means of three screws. A graduation is often furnished to measure the angle of rotation of the coil about a vertical axis; this is useful when the galvanometer has to be graduated or corrected for the torsion of the fibre.

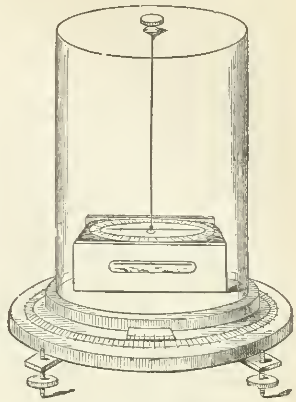

FIG. 4.—Astatic multiplier.

In the galvanometers of Sir William Thomson, which are the most sensitive hitherto constructed, the central opening of the coil is circular, being just large enough to allow free play to a small concave mirror a centimetre or so in diameter. Usually the coil is wound in two halves, which can be screwed together with a septum between them, in which is placed the arrangement for suspending the mirror and magnets. In dead-beat instruments the coil is often wound in a single piece, and the mirror is arranged in a cell,[3] glazed back and front, and fitted into a tube which slides into the core of the coil.

Fig. 5 represents a very convenient form of Thomson's

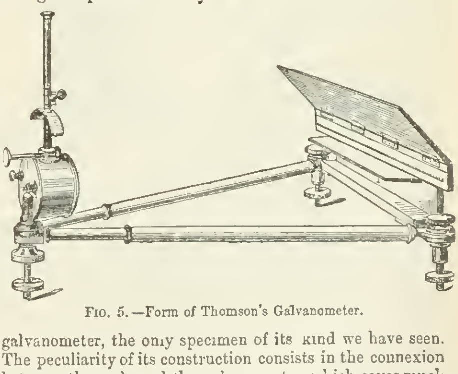

FIG. 5.—Form of Thomson's Galvanometer.

galvanometer, the only specimen of its kind we have seen. The peculiarity of its construction consists in the connexion between the scale and the galvanometer, which saves much trouble in adjusting the instrument. It was constructed by Elliot Brothers for the British Association Committee on Electrical Standards. Such a galvanometer as this, provided with a high and low resistance coil, would meet all the wants of most laboratories.

In another form called the marine galvanometer, the mirror is strung on a fibre stretched between two fixed points. In order to keep the needle from being influenced

[1] See art. ELECTRICITY, p. 43.

[2] *E.g.*, in above case by introducing into the galvanometer circuit $\frac{9}{10}$ths, $\frac{99}{100}$ths, $\frac{999}{1000}$ths, respectively of the resistance of the multiplier.

[3] This arrangement is that adopted by White of Glasgow in the galvanometers made by him after Sir Wm. Thomson's pattern.

by the rolling of the ship, its centre of gravity is carefully adjusted so as to be in the axis of suspension. The mirror is enclosed in a narrow cell which just allows it room to deflect to the required extent, and damps the oscillation so effectually that the instrument is "dead beat." In order to destroy the directive action of the earth, the inconvenience of which in a galvanometer for use on board ship is obvious, the case of this galvanometer is made of thick soft iron, which completely encloses the whole, leaving only a small window for the ingress and egress of the ray of light by means of which the motions of the mirror are read; a flat horse-shoe magnet placed on the top of the case still farther overpowers the earth's force and directs the mirror.

All these galvanometers may, of course, be wound double and used differentially. When this is the case, a small auxiliary compensating coil is often used to correct the inequality of the magnetic fields due to the two sets of windings. This auxiliary coil is usually mounted on a spindle in the axis of the main coil, and can be moved backwards and forwards till a current passing through it and one set of windings in one direction, and through the other set of windings in the other direction, does not sensibly deflect the mirror.

The astatic arrangement described above (p. 51, fig. 4) is often adopted. A galvanometer of this construction by Elliot Brothers is shown in fig. 6. It may be questioned, however, whether for ordinary purposes the additional sensibility thus gained compensates for the increased complexity and cost of the instrument.

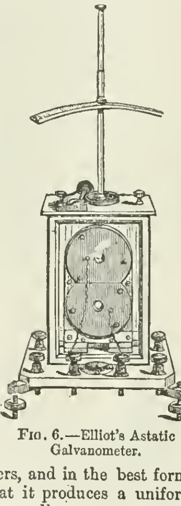

Fig. 6.—Elliot's Astatic Galvanometer.

Standard Galvanometers.—When galvanometers are intended for measuring currents, there must be some law connecting the indications of the needle with the strength of the current in the multiplier. It is therefore of great importance that slight variations in the position of the magnet should not introduce large or irregular (incalculable) variations into the indications of the instrument. Accordingly in standard instruments the windings are much farther removed from the magnet than in sensitive galvanometers, and in the best forms the multiplier is so disposed that it produces a uniform field of magnetic force around the needle.

The earliest forms of standard galvanometer were the tangent and sine compasses invented by Pouillet. The first of these consists simply of a single vertical coil of wire, with a magnet suspended at its centre, whose deflexion may be read in any of the various ways already described. If the length of the magnet be very small, the magnetic field in its neighbourhood may be regarded as uniform, and the electromagnetic couple will be proportional to $\cos\theta$, θ being the deflexion from the plane of the windings. If the windings be arranged so as to be in the magnetic meridian,[1] the couple due to the earth's action tending to bring the magnet back to its position of equilibrium will be proportional to $\sin\theta$, hence the current strength will be proportional to $\tan\theta$.

If the multiplier be movable about a vertical axis through angles which can be measured in any way, the instrument may be used as a sine compass. The current is applied and the multiplier turned round after the magnet until the axis of the latter is again parallel to the windings. The current strength is now clearly proportional to $\sin\theta$, where θ is the deflexion of the multiplier from the magnetic meridian. When the instrument is used in this way, the needle being always brought into the same position relative to the windings, the uniformity of the magnetic field is a matter of indifference, and there is no necessity for the needle to be short.

Gaugain attempted to improve the tangent galvanometer by suspending the magnet excentrically at a point in the axis of the coil distant from the centre by half the radius of the coil. This, however, is in reality the reverse of an improvement.[2]

A real advance, however, was made by Helmholtz, who placed two equal parallel and vertical coils, one on each side of the magnet, each at a distance from it equal to half the common radius. In fig. 19, at the end of his second volume, Maxwell gives a diagram of the lines of force due to two equal parallel circular circuits, from which it will be seen that the magnetic field at the centre of such an arrangement of currents is very approximately uniform. This approximation may be carried still farther by adding a third coil parallel to the two others, and equidistant from them. In some examples of Helmholtz's galvanometer the windings are arranged on a conical surface, so that the ratio of the radius of each to the distance of its plane from the centre of the magnet shall be 2 : 1. In reality this is unnecessary, provided the ratio of the depth and breadth of the usual rectangular channel be properly adjusted (see Maxwell, vol. ii. sec. 713). Fig. 7 represents a galvanometer of the kind described.

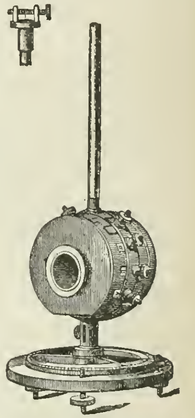

Fig. 7.—Galvanometer designed by Professor Maxwell.

The wire is wound in two parallel channels cut in a cylindrical block of hard wood, each an inch broad and an inch deep. The radius of the bottom of each channel is one inch, and the distance between them is half an inch. The cylindrical perforation in the core of the multiplier is $1\frac{3}{8}$ inch in diameter—large enough to allow the needle to swing freely without causing irregular air currents, &c. Into the ends of the core are screwed two caps containing a piece of plane parallel glass and a plano-convex lens respectively, the former for subjective, the latter for objective reading. By means of a slit and screw in the stem which supports the instrument, a horizontal bar can be fixed parallel to the axis of the multiplier. On this a deflecting magnet can be mounted, so that the galvanometer can be used as a magnetometer.

Reduction of Galvanometer Indications.—When the position of every layer of wire in the multiplier is known with sufficient accuracy, and the multiplier arranged so as to produce a sensibly uniform field, the electromagnetic action per unit of current can be calculated for every position of the magnet. In this case the galvanometer is an *absolute* instrument. When we possess one absolute instrument it is easy to evaluate the indications of any other in absolute measure by means of it; we have only to pass the same current through both galvanometers in series and compare the readings. The best way, however, to construct a standard galvanometer is to provide for uniformity of field in the core of the multiplier, and find the resultant electromagnetic force for unit current, or, as it is called, the constant of the instrument, by comparison with a pair of equal standard coils of large diameter (18 in. to 24 in.). These are arranged vertically on the same axis, the distance between them being equal to the mean radius, just as in Helmholtz's galvanometer. The galvanometer to be tested is placed symmetrically between the

[1] This can be done most easily by means of a mirror attached to the multiplier and adjusted so as to be parallel to the windings.

[2] See Maxwell, *Electricity and Magnetism*, vol. ii. secs. 712, 713.

standard coils, the centre of its multiplier being near the centre of the whole arrangement, and the axes of all the coils coincident. A multiple arc is then formed, one branch of which contains the coils and the other the galvanometer, so that the magnetic actions oppose each other. The resistances of the two branches are then adjusted till the galvanometer needle gives no indication when a current is sent through the multiple arc. The whole arrangement will be understood from fig. 8. If R and S be the resistances in the branches containing the galvanometer and coils respectively, then the constant of the galvanometer is to that of the coils as R : S; so that when the latter is calculated[1] the former is known.

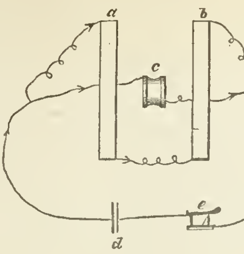

Fig. 8.

The constant of the galvanometer G being known, the value of a current producing a deflexion θ is given in absolute measure by

$$I=\frac{H}{G}\tan\theta,$$

H being the horizontal component of the earth's magnetic force.

In many cases it is necessary to correct for the torsion of the suspending fibre. The value of this correction is easily found by turning the multiplier[2] through 90° either way, and observing how far the needle follows it. The reader will find all necessary details in Maxwell, vol. ii., secs. 452, 742.

In all cases where great accuracy is required it is advisable to *graduate*, or, as it is sometimes said, to *calibrate* the galvanometer, that is, to compare the electromagnetic couple exerted by the multiplier when the needle is deflected through an angle θ with that when the needle is parallel to the windings. It is easy to see that this may be done by means of the arrangement described above for finding the constant of a galvanometer. If the object simply is to calibrate the galvanometer without reducing its indications to absolute measure, the standard coils may be replaced by a single coil of sufficient magnetic moment placed in the axis of the multiplier. Another method of calibration, which is simpler, and in some respects more satisfactory, although possibly more laborious, will be understood from fig. 9. The resistance a is equal to the

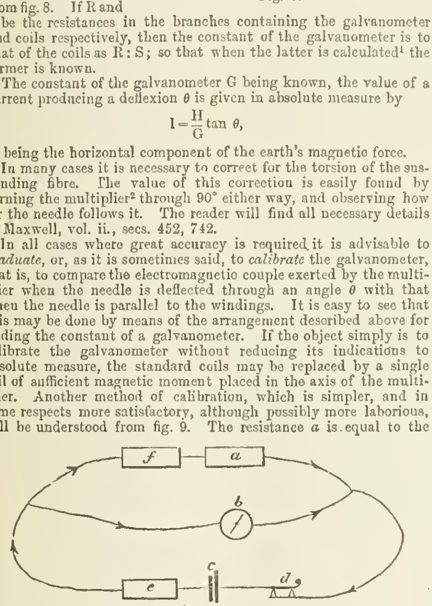

Fig. 9.

resistance of the galvanometer, and they can be rapidly interchanged. By adjusting f the ratio of the currents in the branches of the multiple arc may be varied as we please, and by varying e the current in one of the branches can always be brought to a standard strength, say that which produces unit deflexion of the galvanometer needle. We can thus, by repeatedly interchanging a and b, compare the deflexions produced by a series of currents whose strengths are given multiples of the standard strength. If the experimenter has two galvanometers at his disposal the interchanges may of course be avoided.

On the Use of the Galvanometer.—We may add a few remarks on the different uses to which a galvanometer may be put.

Detection of Currents.—One of the commonest of all the uses of a galvanometer is to indicate the currents sent through telegraph wires or cables. In the case of submarine cables, where the currents are often very feeble, dead-beat galvanometers of Thomson's or Varley's construction are used.

When a current is to be detected which produces a very small or quite insensible permanent deflexion, the following process, called the method of multiplication, is sometimes used. The period of oscillation of the needle is first found; then, the needle being at rest or only swinging through a very small arc, the current is applied through half the period of oscillation so as to urge the needle in the direction in which it is going, then intermitted for half a period, then applied again, and so on. If a current in the supposed direction really exist, the oscillations of the magnet will gradually increase, until the energy supplied by the intermittent action of the current is equal to that wasted by the damping of the needle.

It is obvious that this process is more effective the smaller the damping of the needle; it leads to no advantage whatever with a dead-beat instrument.

Resistance Measuring.—In comparing resistances, sensitive galvanometers of Sir William Thomson's construction[3] are by far the most convenient; the dead-beat arrangement is essential for rapid work.

If a differential galvanometer of given dimensions be used (see art. ELECTRICITY, p. 44), and if the resistance of the battery is negligible compared with the other resistances used, the wire with which it is wound should be chosen so that its resistance is one-third of the resistance to be measured.[4]

It is shown in the art. ELECTRICITY (p. 44) that, in arranging a Wheatstone's bridge to measure a given resistance, all the arms of the bridge and the battery and galvanometer should have equal resistances. As a rule, all these are not at our disposal. If the resistances of the arms and of the battery are given, and the resistance of the galvanometer (of given dimensions) is at our disposal, then the resistance of the galvanometer ought to be equal to that of the multiple arc which remains between the terminals of the galvanometer when the battery is disconnected from the bridge.[5] This may be deduced at once from the expression given in vol. viii. p. 44.

Again, the resistance to be measured and the battery and galvanometer resistance being given, we may inquire what is the best arrangement of the arms of the bridge.

Differentiating the expression given in vol. viii. p. 44 with respect to y and z, we get

$$BG-y^2z^2R^2=z\left\{y^2(R+G)R-G(R+B)\right\},$$
$$BG-y^2z^2R^2=y\left\{z^2(R+B)R-B(R+G)\right\};$$

the solution of which is obviously

$$y=\sqrt{\frac{G(R+B)}{R(R+G)}},\qquad z=\sqrt{\frac{B(R+G)}{R(R+B)}};$$

whence we have $S=\sqrt{RG\cdot\frac{R+B}{R+G}}$, $T=\sqrt{RB\cdot\frac{R+G}{R+B}}$, and $U=\sqrt{BG}$—determining the resistances of the disposable arms.

It appears that, when B and G are given, the resistance of the arm opposite to the resistance to be measured ought always to be the geometric mean between B and G.[6]

In a certain class of observations a needle with large moment of inertia is used. The methods in use are mostly due to Gauss and Weber. For an account of these methods the reader is referred to Maxwell, chap. xvi. He should also consult a paper by Du Bois Reymond in *Monatsber. d. Berl. Acad.*, 1869–70. (G. CH.)

GALVESTON.

GALVESTON, the largest and most extensively commercial city of the State of Texas, United States of America, is situated 340 miles west of the mouth of the South Pass of the Mississippi River, on Galveston Island, at the opening of the Bay of Galveston into the Gulf of Mexico. It is situated in latitude 29° 18′ north, and 94° 47′ west longitude. It is about two miles from the northeast corner of the island, which projection is known as Fort Point. It is a port of entry, and the principal seaport city of the State. Galveston is the county seat of Galveston county, of which the largest portion is on the main land, separated from the city and island by East and West Bays. The land is low and sandy and lies quite level. The island is long and narrow, extending parallel with the shore, in a northeasterly and southwesterly direction, for the distance of 28 miles, having an average width of about two miles.

Excellent opportunities are found for surf bathing on the beach, and for most beautiful drives during the periods of low tide. Bolivar Peninsula runs out from the main land to within two miles of Fort Point, and at the head of the peninsula is Bolivar Point lighthouse. The Galveston harbor is the best on the coast line of Texas. It has more than twelve and three-fourths feet of water over the bar at low tide. This bar stretches across the entrance to the bay and has been formed and maintained by the sand moved by the constant undertow of waves and currents.

Trinity River flows into the northern end of the bay, and San Jacinto River and Buffalo Bayou empty into it a little further south. The mean rise and fall of the tide is a little over one foot, but spring tides rise as high as three feet above

[1] See for such calculations Maxwell, vol. ii., chaps. xiv. and xv.

[2] Or the piece to which the fibre is attached, if it is not rigidly attached to the multiplier.

and fall two feet below the mean low-water mark. Under the influence of heavy winds and storms, the rise has been as high as nine feet.

The harbor at Galveston, having a depth at its entrance at the present time of nearly fourteen feet, is the best harbor on the entire gulf coast from the mouth of the Mississippi to the Rio Grande. It is also believed to be the one most susceptible of such improvements as would constitute a harbor of the first class. Its superiority to the other ports of Texas is clearly indicated by the coast survey charts and by the fact that the principal railroads of this State extend to Galveston or connect with railroads terminating at that point. The value of railroad properties in the State of Texas is about one hundred and sixty millions of dollars. This large expenditure of private capital in supplying means of internal transportation in Texas, expresses faith in the resources of this State, and emphasizes the importance of securing for it a first-class seaport. Such expenditure stands also as the strongest indorsement of any practical plan for the accomplishment of that object. The proposed improvement of the entrance to the port of Galveston would constitute a connecting link between this great system of internal transportation and the ocean, nature's great free highway of commerce. If the proposed depth of thirty feet at the entrance to the port of Galveston can be secured, that port would become the nearest and most accessible first-class seaport for the States of Texas, Kansas, New Mexico and Colorado, the Indian Territory and the Territory of Arizona, and parts of the States and Territories adjoining those just mentioned. The central portions of the State of Kansas are about equidistant from Chicago and Galveston. If the harbor of Galveston shall be so improved as to admit the entrance of vessels of the largest size, the various railroads connecting this city with Arkansas, Western Missouri, Western Iowa, Kansas, Nebraska, Colorado, and New Mexico, will become active competitors with the railroads extending east, not only with respect to trade with Europe, but also with respect to the trade between the area referred to and the chief Atlantic seaports.

The coast line of Texas from Sabine Pass to the Rio Grande, measures about 375 statute miles. In this distance there are four points which are now receiving the attention of the government with a view to harbor improvement, viz: Sabine Pass at the eastern extremity of the line; Brazos Santiago at the western extremity; Galveston, 65 miles from the eastern extremity, and Aransas Pass, 138 miles from the western extremity. The area of water in the Galveston harbor, 24 feet deep, is 1,304 acres, 30 feet deep, 463 acres, and a considerable acreage of 40 and 50 feet depth.

It is thus seen that the natural advantages which created Galveston and made her the principal port of the State still exist to maintain her pre-eminence.

The old south jetty has been built up to a height of five feet above mean low tide to a distance of 4,550 feet seaward, and connected with the shore by a wall of ordinary riprap 1,100 feet long, sloping gradually downward to the level of the ground, which is about six inches above mean low tide. The work of extending the jetty seaward was continued until July 17, 1888, when it was suspended for lack of funds. Additional funds having been provided in the River and Harbor act of August 11, 1888, work was resumed October 15, 1888, under a new contract, dated October 13, 1888. During the year a shore branch 8,464 feet long was constructed to connect the former work with the relatively high ground upon which Galveston is built. The object of this work is twofold, viz: to furnish a secure anchorage point for the south jetty, and also to improve the Galveston channel. The total length of the railway upon the crest of the jetty, including that built upon the trestle in advance of the stonework, is 17,375 feet. The level of mean low tide was five inches higher for the year 1888 than the level fixed for that plane in 1872.

The number of steam vessels entered at the port of Galveston for the year ending June 30th, 1887, was 250; number of sail vessels entered was 296. Total number of vessels 546. The tonnage of all vessels was 446,711 tons. The total value of their cargo was $27,903,000, and they carried 3,000 passengers. The number of steam vessels cleared was 256. The number of sail vessels cleared was 238. Total number of vessels, 494.

The tonnage of vessels cleared was 444,801 tons, valued at $73,874,701. The majority of vessels draw fifteen to twenty feet of water when fully loaded.

In addition to these there is a large number of small schooners, drawing five feet or less, engaged in the coasting trade.

The first settlement of Galveston was made in 1837. From 1817 to 1821 it had been the haunt of the famous pirate Lafitte, who was finally dislodged from the island in the latter year. The city is handsomely laid out upon ground which lies very even, elevated six or eight feet above the sea level. Its streets are straight, broad, and elegant; those running parallel with the bay are designated as avenues, and those at right angles simply as streets. The avenues are called by the letters of the alphabet, beginning on the bay front, and the streets are numbered First, Second, etc. The public building, containing the post-office and United States court house, stands at the crossing of 20th street and avenue "F." The avenues between this building and the bay are devoted to shipping and wholesale business, retail stores, shops, restaurants, hotels, banks and offices. Broadway, or avenue "J," is the most beautiful residence avenue of Galveston, and is considered the St. Charles of the city. Like some other southern cities, Galveston has been laid out upon a generous plan. Avenue "J" is 150 feet wide. An esplanade 36 feet in width runs through the middle, and its sidewalks are 16 feet wide on either side. The next street in point of width is Bath street, which is 120 feet wide. All the other streets are 80 feet wide and the avenues are 70 feet wide; all have sidewalks 16 feet in width. A shell road runs from the bay to the beach, which is called Fremont street. It is a favorite resort, as well as the beach, for driving. The streets are not paved, though the sidewalks in the center of the city are paved either with concrete or asphalt, or laid with brick or tile.

Galveston has a number of churches and schools of various kinds, an opera house and seven public halls. There are two libraries, two theaters, three market places and fourteen hotels of various grades. In the line of public buildings Galveston has a postoffice, custom house, and United States court house, a county court house, a county and city prison and a city hall. The churches number 15, and the schools, of all kinds, 30. It is also the see of the Bishop of the Roman Catholic Church for that diocese. Galveston has several foundries, flour and planing mills and machine shops. The wharves are good, and there are several ship-building yards, and cotton-presses. Papers, daily and weekly, as well as bi-weekly and tri-weekly, are published. There are two railroad bridges across West Bay—one two miles long—connecting the island with the main land, but no highway bridges have as yet been built. Cotton and cotton-seed oil form the great bulk of the foreign exports, which exceeded $17,000,000 in 1887. The foreign imports for the same year reached $1,765,612.

The following is a statement for 1878, 1879 and 1880 of the receipts from duties on imports and other sources, such as "tonnage tax," "hospital tax," etc.

From—	Imports.	Other Sources.
Jan. 1, 1878, to Dec. 31, 1878	$43,006 51	$23,035 97
Jan. 1, 1879, to Dec. 31, 1879	128,543 51	26,982 46
Jan. 1, 1880, to Feb. 13, 1880	24,196 65	2,433 15
Probable amount of collections during the year ending Dec. 31, 1880, approximated from invoices on hand and other reliable data		$250,000 00

The value of imports from foreign countries for the years 1877 and 1878 was $1,357,488 and $1,357,488 respectively. These imports consist mainly of coffee, woolen and cotton goods, and iron goods.

Galveston has railway communications with all parts of the country, and by lines of steamships with Liverpool, New York, New Orleans, and the ports of Texas as far as the Mexican boundary. These vessels engage to a large extent in direct trade with Great Britain and the continent of Europe, in the coffee trade with Rio Janeiro, and in the West Indies and Mexican trade. There are six cotton presses, with warehouses and yards occupying more than 40 acres of ground and storing more than 100,000 bales of cotton. There are ten miles of street railroads in the city; one savings bank and national banks with a capital of more than $800,000, and a paid up capital of $300,000. Galveston's taxable values were $21,000,000 in 1889 Galveston has not been visited by any epidemic disease since the yellow fever scourge of 1867. In other respects it is considered a most healthful city, possessing a delightful climate, and in every way is an inviting city to live in, affording abundant opportunities for business and pleasure.

The following table shows the rainfall, temperature and barometric pressure:

Year.	Rain Fall.	Highest Temperature.	Lowest Temperature.	Mean Temperature.	Mean Bar. Pressure.
1875	46.66 in.	98.5°	24°	69.6°	30.063 in.
1876	70.59	97°	40°	70.9°.	30.050 "
1877	42.99	96°	30°	68.7°	30.073 "
1878	67.47	97°	30°	70.2°	29.997 "

The population for 1850 was 4,177. In the next ten years it nearly doubled, so that the census for 1860 shows a population of 7,307; for 1870, 13,818; for 1880, 24,121.

Galveston is, without a doubt, destined to become one of the most important shipping ports of the United States. It is connected with the great railroad lines running into the interior and Northwest, and under proper management will afford a cheaper outlet for that great country than the overland railroad route. The great demand now is for improved harbor facilities. The people of Texas and Galveston recognize this demand, and at their earnest instigation the government is taking hold of the matter with vigor. An improved harbor is all that is required. Nature has done all that is possible to be done in furnishing shelter and protection and abundance of space. The competition that an excellent harbor would encourage, would build up still more rapidly this already fast growing city of our Southwest.

This competition would assert itself not only in the transportation of the products of the interior by way of Galveston, but also, and perhaps to a greater extent and more beneficially, in the regulating influence which it would exert over the rates charged by all the east and west railroads extending from Chicago to the Atlantic seaboard. The magnitude of the advantages which would be thus afforded to the commercial and industrial interests of the country, it is impossible accurately to compute or even approximately estimate, but the great importance of such advantages is clearly apparent. In view of the vast area of country, the commercial and industrial interests of which would be directly subserved by the proposed improvement in the harbor of Galveston, and by the fact that such improvement would also, through competition, directly benefit a very large proportion of the whole country, it appears proper to characterize that project as a work of great national importance.

About $1,500,000 were wasted by the government prior to the year 1886, in some tentative engineering experiments. The present plans and estimates were adopted in 1886, at which time Major O. H. Ernst was first assigned in charge of the work. Under his management the channel depth upon the outer bar was found to be 13¼ feet and that upon the inner bar 21 feet, both at mean low tide, which was in both cases an increase of 6 inches during the year 1888. The distance across the outer bar from 24 feet inside to 24 feet outside has diminished from 14,100 to 13,500 feet, a difference of 600 feet or about 4 per cent. The distance from 18 feet inside to 18 feet outside has diminished from 7,180 feet to 6,340 feet, a difference of 840 feet or nearly 12 per cent. The old mattress jetty, built previous to the year 1886, has continued to deteriorate. The average depth over the outer 5,000 feet of it was ten feet.

Of this work Captain Eads says: "A less channel than thirty feet should not be contemplated, inasmuch as cheap freights require vessels of deep draft, and there is no reason why such works should not be constructed at Galveston as would place her harbor within the reach of the largest carriers now contemplated. At least twenty feet could be relied on within two years after the work is begun, and about two or three feet each year thereafter until the thirty feet is obtained. The deepening would continue slowly under tidal action for several years thereafter, and I should expect it to reach at least thirty-five or possibly forty feet before a permanent regimen would be established through the channel. I have estimated the necessary works at Galveston to secure a permanent channel thirty feet deep at seven and three-quarters millions of dollars."

Why the government is directing its attention to Galveston and Galveston harbor instead of the other ports of Texas may be readily understood from the government estimates made in 1886. The channel depth over the bar at that time was:

Sabine Pass	8 feet
Galveston	12¾ feet
Aransas	8½ feet
Brazos Santiago	5 feet

—all measured at mean low tide. Foreign vessels which now visit the Texas coast draw about twenty feet, and to accommodate them there should not be less than twenty feet depth of channel over the bar. It can be obtained by suitable improvements at Sabine, Galveston, and Aransas, but not at Brazos Santiago. For safe anchorage, these vessels require about twenty-four feet in the harbor. The area of water twenty-four feet deep is, at

Sabine	100 acres
Galveston	1,304 acres
Aransas	60 acres

The improvements designed to furnish twenty feet depth over the bar at these places have been begun. To complete them there remains to be appropriated, for

Sabine	$2,379,000 00
Galveston	2,200,000 00
Aransas	1,471,000 00

Dividing these numbers by the number of acres of deep water, we find the cost per acre to reach the anchorage is, for

Sabine	$23,790 00
Galveston	1,687 11
Aransas	24,516 17

The depth of twenty feet over the bar, which is sufficient to answer the most immediate pressing needs of Texas, is not sufficient to admit many large commercial vessels and ships of war. To accommodate these an extension of the improvements at Galveston is contemplated, designed to give a depth of thirty feet at a cost of four millions additional to the amount mentioned above. No thirty-foot channel over the bar has been projected at either of the other places. The area of water thirty feet deep is, at

Sabine	63 acres
Galveston	463 acres
Aransas	19 acres

The vast country, that presents a front to the sea of three hundred and twenty-six miles, and of which Galveston is the only outlet that can be utilized for the accommodation of large vessels, as the certificates of experienced men who have been engaged in the coasting trade for years will evidence, demands from the general government some recognition of its importance to the commerce of the world. The resources of the State are but partially developed. Its population and productions are increasing with each succeeding year, and the time must inevitably come when Texas will assume grander proportions in all the essentials that can contribute to the prosperity of mankind. Its climate is salubrious and is blended with all the blessings and benefits that can be bestowed by fertile lands.

GALWAY, a maritime county in the province of Connaught, in the extreme west of Ireland, between 52° 54′ and 53° 43′ N. lat., and 7° 57′ and 10° 20′ W. long. It is bounded on the N. by Mayo and Roscommon; E. by Roscommon, King's County, and Tipperary; S. by Clare and the Bay of Galway; and W. by the Atlantic Ocean. The area comprises 2447 square miles. or 1,566,354 acres, of which 90,230 are under water.

Surface.—The county is naturally divided by Lough Corrib into two great divisions. The eastern, which comprehends all the county except the four western baronies, rests on a limestone base, and is, generally speaking, a level champaign country, but contains large quantities of wet bog. Its southern portion is partly a continuation of the Golden Vale of Limerick, so celebrated for its fertility, and partly occupied by the Slievebaughty Mountains. The northern portion of the division contains rich pasture and tillage ground, beautifully diversified with hill and dale. Some of the intermediate country is comparatively uncultivated, but forms excellent pasturage for sheep. The western division of the county has a substratum of granite, and is barren, rugged, and mountainous. It is divided into the three districts of Connemara, Jar-Connaught, and Joyce's Country; the name of Connemara is, however, often applied to the whole district. Its highest mountains are the grand and picturesque group of Binabola, or the Twelve Pins, which occupy a space of about 25 square miles, the highest elevation being about 2400 feet. Much of this district is a gently sloping plain, from 100 to 300 feet above sea-level. Joyce's Country, further north, is an elevated tract, with flat-topped hills of from 1300 to 2000 feet high, and deep narrow valleys lying between them.

Coast.—Galway enjoys the advantage of a very extended line of sea-coast, indented by numerous harbours, which, however, are rarely used except by a few coasting and fishing vessels. Commencing at the coast of Mayo in the north are the Killeries, two bays which separate the counties of Galway and Mayo. The first bay on the western coast capable of accommodating large ships is Ballynakill, sheltered by Freaghillaun or Heath Island. Next in succession is Cleggan Bay, having Inishboffin in its offing. Streamstown is a narrow inlet, within which are the inhabited islands of Omey, Turbot, and Inishturk. Ardbear harbour divides itself into two inlets, the northern terminated by the town of Clifden, with excellent anchorage opposite the castle; the southern inlet has also good anchorage within the bar, and has a good salmon-fishery. Mannin Bay, though large, is much exposed, and but little frequented by shipping. From Slyne Head the coast turns eastward to Roundstone Bay, which has its entrance protected by the islands of Inishnee and Inishlacken. Next in order is Birterbuy Bay, studded with islets and rocks, but deep and sheltered. Kilkerrin Bay, the largest on this coast, has a most productive kelp shore of nearly 100 miles; its mouth is but 8 miles broad. Between Gorumna Island and the mainland is Greatman's Bay, and close to it Costello Bay, the most eastern of those in Connemara. The whole of the coast from Greatman's Bay eastward is comprehended in the Bay of Galway, the entrance of which is protected by the three limestone islands of Aran—Inishmore (or Aranmore), Inishmann, and Inisheer.

Rivers.—The rivers are few, and, except the Shannon, are of small extent. The Suck, which forms the eastern boundary of the county, rises in Roscommon, and passing by Ballinasloe, unites with the Shannon at Shannon bridge. The Shannon, which rises at the foot of Cuilcagh in the county of Cavan, forms the south-eastern boundary of the county, and passing Shannon Harbour, Banagher, Meelick, and Portumna, swells into the great expanse of water called Lough Derg, which skirts the county as far as the village of Mount Shannon. The Claregalway flows southward through the centre of the county, and enters Lough Corrib some 4 miles above the town of Galway. The Ballynahinch, considered one of the best salmon-fishing rivers in Connaught, rises in the Twelve Pins, passes through Ballynahinch Lake, and after a short but rapid course falls into Birturbuy Bay.

Lakes.—The Lakes are numerous. Lough Corrib extends from Galway town northwards over 30,000 acres, with a coast of 50 miles in extent. It has now been made navigable to Lough Mask (which lies chiefly in Mayo county) and to the sea at Galway. The lake is studded with many islands, some of them thickly inhabited. Near it is Lough Ross, which receives a large supply of water from streams, but has no visible outlet. The district to the west of Lough Corrib contains in all about 130 lakes, about 25 of them more than a mile in length. Lough Rea, at the town of the same name, is more remarkable for scenic beauty than for extent. Besides these perennial lakes, there are several low tracts, called turloughs, which are covered with water during a great part of the year.

Geology and Minerals.—The boundary line between the limestone and granitic district is easily discernible by the diminution of the verdant hue which distinguishes the latter. The high road from Galway to Oughterard nearly marks the division. All the country to the north and east of this limit is limestone, all to the south and west granite, excepting some detached masses of primitive limestone between Oughterard and Clifden, and some scattered portions of other minerals, of great variety of appearance. The component rock of Binabola is quartz, in general distinctly stratified, or at least schistose. The position of its beds is various. Towards the western shore they are vertical, easily splitting by intervening mica plates, and affording good building stone. Limestone occurs in some places along the foot of these mountains. Round the base of this group are also gneiss and mica slate, with bands of hornblende and primitive mica. Along the north side of Lough Corrib to Ballynakill the mica slate and hornblende rise into mountains, and the limestone disappears. From Lough Mask to the Killeries is a transition country of greenstone and grauwacke slate covered by the Old Red Sandstone or conglomerate. The hill of Glan, on the shore of Lough Corrib, exhibits, in a small compass, all the formations which occur in the district. The western end is quartz, the north-eastern side mica slate; the middle is penetrated by beds of mica slate, containing hornblende and granular mica covered by thick beds of pyritous greenstone. On the south and east are granite and syenite, which runs under the sandstone conglomerate towards Oughterard, and this again passes under the flötz limestone, which, beyond Lough Corrib, occupies the greater part of Connaught and Leinster. Along the borders of the flötz limestone is a series of vast caverns, usually traversed by subterranean rivers. A fine gritstone, highly valued for making millstones, is raised near Dunmore. Crystalline sand, of a superior quality for scythe boards, occurs at Lough Coutra. Lead, zinc, copper, sulphur, and bismuth have been discovered in various parts of the western division of the county. Iron was raised at Woodford, and smelted until the timber was exhausted. The mountains of Slievebaughty, which separate Galway from Clare, are siliceous. In Connemara there is abundance of green variegated marble called serpentine; and a beautiful black marble, without spots or flaws, and susceptible of a high polish, is obtained near Oughterard. Mineral spas, mostly chalybeate, are abundant.

Climate and Agriculture.—The climate is mild and salubrious, but variable, and violent winds from the west are not uncommon. Frost or snow seldom remains long on the western coast, and cattle of every description continue unhoused during the winter. The eastern part of the county produces the best wheat. Oats are frequently sown after potatoes in moorish soils less adapted for wheat. The flat shores of the bays afford large supplies of seaweed for manure. Limestone, gravel, and marl are to be had in most other parts. When a sufficient quantity of manure for potatoes cannot be had, the usual practice is to pare and burn the surface. In many places on the sea-shore fine early potatoes are raised in deep sea-sand, manured with sea-weed, and the crop is succeeded by barley. Those parts of the eastern district less fitted for grain are employed in pasturage. Heathy sheep-walks occupy a very large tract between Monivea and Galway. An extensive range from Athenry, stretching to Galway Bay at Kinvarra, is also chiefly occupied by sheep.

The total area under crop in 1878 was 214,685 acres, as compared with 235,168 in 1853. The following tables show the acres under the principal crops, and also the numbers of the different domestic animals, during those years:—

	Wheat.	Oats.	Barley, Pease, &c.	Potatoes.	Turnips.	Other Green Crops.	Meadow and Clover.
1878	4,416	53,205	8,095	50,604	14,041	8,910	75,333
1853	16,817	83,840	15,751	46,134	18,788	10,764	45,780

	Horses.	Asses.	Cattle.	Sheep.	Pigs.	Goats.	Poultry.
1878	28,538	14,384	169,002	652,778	57,314	10,927	751,116
1853	25,916	13,714	139,497	466,430	41,403	16,632	410,199

According to the returns or 1875–6, the total value of land, exclusive of the town of Galway, was £437,686, 15s., and the average value per acre was 5s. 11¾d., as compared with 6s. 9d. for the province, and 13s. 3d. for the whole of Ireland. The county was divided among 1235 proprietors, of whom 332, or 27 per cent., held less than one acre. The following possessed more than 20 000 acres, viz:—Richard Berridge, 159,898; Marquis of Clanricarde, 49,025; Lord Dunsandle, 33,543; Allan Pollok, 29,366; Lord Clonbrock, 28,246; Sir Thomas J. Burke, 25,258; Earl of Clancarty, 23,896.

Manufactures.—Manufactures are not carried on beyond the demand caused by the domestic consumption of the people. Coarse friezes, flannels, and blankets are made in all parts, and sold largely in Galway and Loughrea. Connemara has been long celebrated for its hand-knit woollen stockings. Coarse linen, of a narrow breadth, called bandle linen, is also made for home consumption. A linen-weaving factory has been established at Oughterard. The manufacture of kelp, formerly a great source of profit on the western shores, is still carried on to some extent. Feathers and sea-fowls' eggs are brought in great quantities from the islands of Aran, the produce of the puffins and other sea-fowl that frequent the cliffs. Fishing affords occupation to many of the inhabitants, but from want of capital is not prosecuted with sufficient vigour. In 1877 the number of vessels engaged was 451, with 1104 men and 58 boys.

Population.—The county includes one parliamentary borough, Galway; and three townships, Ballinasloe (part of which is, however, in the county of Roscommon), 4159; Loughrea, 3072; and Tuam, 4223. The largest of the villages are Gort, 1773; Clifden, 1313; Athenry, 1194; Headford, 870; Oughterard, 861; and Eyrecourt, 747. The population in 1831 was 414,684; in 1851, 321,684; and in 1871, 248,458, of whom 122,496 were males and 125,962 females. In 1871 the number of Catholics was 239,902, and of Protestants 8556, of whom 7464 were Episcopalians and 615 Presbyterians. Of persons five years and upwards 173,361 were illiterate, a proportion of 56·9 per cent.; and 30,239 could speak Erse only, as compared with 41,572 in 1861. Emigration from this county has drafted off a very large number of its inhabitants. From the 1st of May 1851 to 31st December 1877 there were 104,691 emigrants, or an annual average of 3950.

Representation and Administration.—Two members of parliament are returned for the county, and two for Galway borough. There are in the county 35 petty-sessions districts, and part of another. Quarter-sessions are held at Ballinasloe, Clifden, Galway, Gort, Loughrea, Oughterard, Portumna, and Tuam. There are five poor-law unions wholly within the county, Galway, Loughrea, Mount Bellew, Portumna, and Tuam; nearly the whole of Clifden, Gort, and Oughterard; and parts of five others—Ballinasloe, Ballinrobe, Glennamaddy, Roscommon, and Scarriff. The county is within the Dublin military district, and there are barrack stations at Loughrea, Dunmore, Portumna, Galway, Gort, and Oughterard. It is divided into 18 baronies.

Antiquities.—Amongst these are the round towers of Ardrahan, Ballygaddy, Kilbannon, Kilmacduagh, Meelick, and Murrough. Raths are numerous, and several cromlechs are still to be seen in good preservation. The ruins of monastic buildings are also numerous. That of Knockmoy, about 6 miles from Tuam, said to have been founded in 1180 by Cathal O'Connor, was adorned with rude fresco paintings, still discernible, which were considered valuable as being the best authentic representations existing of ancient Irish costumes. Ancient castles and square towers of the Anglo-Norman settlers are frequently met with; some have been kept in repair, but the greater number are in ruins. The castle of Tuam, built in 1161 by Roderick O'Connor, king of Ireland, at the period of the English invasion, is said to have been the first building of this description of stone and mortar in Ireland. The remains of a round castle, a form of building very uncommon in the military architecture of the country, are to be seen between Gort and Kilmacduag.

GALWAY, the county town, and a parliamentary borough, is also a county in itself, with an exclusive jurisdiction extending two miles on every side except the south. It stands on the northern shore of the Bay of Galway, on both sides of the river Corrib, which connects Lough Corrib with the sea. The space within the walls formed an oval of about 3426 square perches. Some of the streets are very narrow, and contain several curious specimens of old buildings, chiefly in the antique Spanish style, being square, with a court in the centre, and a gateway opening into the street. The finest of these is the pile of buildings known as Lynch's Castle. During the last few years many large shops have been built in the principal streets, and several handsome residences have been erected in the suburbs. St Nicholas church is the most remarkable building in the town. It is cruciform, 152 feet long by 126 broad, with a steeple rising over the nave, and the side aisles separated from the centre by Gothic pillars. It contains several antique monuments. The exchange, near the church, consists of an open corridor, 90 feet long by 28 broad, with a front of arches supporting an upper story, in which are apartments for holding the local courts, and for other public purposes. St Augustine's church (Roman Catholic), an edifice in the First Pointed style, was erected in 1859. The county court-house is an elegant and commodious building; near it are the county and town prisons. The town also contains a county infirmary, a union workhouse, a fever hospital, three monasteries, five nunneries, and two barracks. A grammar-school is in the immediate neighbourhood of the town. Queens College, built of beautiful grey limestone, is an elegant and extensive quadrangular structure in the Tudor Gothic style. Near the college is a national school. The shipping trade of Galway has for some time been gradually increasing. In 1877 the number of British vessels that entered the port was 153, with a tonnage of 30,034; of foreign vessels 33, with a tonnage of 16,166. The number of British vessels that cleared was 136, with a tonnage of 29,827; of foreign vessels 27, with a tonnage of 13,225. The chief articles exported are agricultural produce, wool, and marble. There are a brewery, a distillery, a paper mill, a tannery, and several flour mills; and a company has recently been formed for the purpose of extracting iodine and marine salts from seaweed. The salmon fishery is of considerable value. Galway is divided into the old and new towns, and the maritime suburb of Claddagh, inhabited almost entirely by fishermen and their families, who have acquired or retained certain peculiar usages and habits of their own.

Little is known of the history of Galway until after the arrival of the English, at which time it was under the protection of O'Flaherty, who possessed the adjoining district to the west. On the extinction of the native dynasty of the O'Connors, the town fell into the hands of the De Burgos, the head of a branch of which, under the name of M'William Eighter, long governed it by magistrates of his own appointment. After it had been secured by walls, which began to be built in 1270, it became the residence of a number of enterprising settlers, through when it attained a position of much commercial celebrity Of these settlers the principal families, fourteen in number, were known as the tribes of Galway. They were of Norman, Saxon, or Welsh descent, and became so exclusive in their relationships that dispensations were frequently requisite for the canonical legality of marriages among them. The town rapidly increased from this period in wealth and commercial rank, far surpassing in this respect the rival city of Limerick. Richard II. granted it a charter of incorporation with liberal privileges, which was confirmed by his successor. It had the right of coinage by Act of Parliament, but there is no evidence to show that it exercised the privilege. Another charter, granted in 1545, extended the jurisdiction of the port to the islands of Aran, permitted the exportation of all kinds of goods except linens and woollens, and confirmed all the former privileges. Large numbers of Cromwell's soldiers are said to have settled in the town; and there are many traces of Spanish blood among the population. Its municipal privileges were extended by a charter from James I., whereby the town, and a district of two miles round in every direction, were formed into a distinct county, with exclusive jurisdiction and a right of choosing its own magistrates. During the civil wars of 1641 the town took part with the Irish, and was surrendered to the Parliamentary forces under Sir Charles Coote; after which the ancient inhabitants were mostly driven out, and their property was given to adventurers and soldiers, chiefly from England. On the accession of James II. the old inhabitants entertained sanguine hopes of recovering their former rights. But the successes of King William soon put an end to their expectations; and the town, after undergoing another siege, again capitulated to the force brought against it by General Ginkell. In the beginning of the present century the walls were thrown down, and buildings erected on their site.

Galway is governed by a high sheriff, a recorder, local magistrates, and a board of 24 commissioners elected triennially. The area of the municipal borough is 955 acres. The population in 1861 was 16,967, and in 1871 15,597, of whom 14,424 were Roman Catholics. The parliamentary borough has an area of 22,493 acres, and a population of 19,843.

GAMA, Vasco da (*c.* 1460–1524), the celebrated Portuguese navigator and discoverer, was born at Sines, a small sea-town in the province of Alemtejo. No one will deny that his name deservedly stands high in the roll of naval heroes; yet it cannot be doubted that he owes the brilliancy of his reputation to his country's illustrious poet, Luiz de Camoens, by whom his discoveries in India and their results have been assigned the foremost place in the great national epic *Os Lusiadas.* Of Vasco's early history little is known. His descent, according to the *Nobiliario* of Antonio de Lima, is derived from a noble family which is mentioned in the year 1166; but the line cannot be traced without interruption farther back than the year 1280, to one Alvaro da Gama, from whom was descended Estevão da Gama, Alcaide Mór of Sines, whose third son, the subject of this notice, was born probably about the year 1460. About this period died Prince Henry the Navigator, son of João I., who had spent his life in fostering the study of navigation, and to whose intelligence and foresight must be traced back all the fame that Portugal gained on the seas in the 15th and 16th centuries. Explorers sent out at his instigation discovered the Western Isles, and unknown regions on the African coast, whence continually came reports (which by and by affected Da Gama's history) of a great monarch, "who lived east of Benin, 350 leagues in the interior, and who held both temporal and spiritual dominion over all the neighbouring kings," a story which tallied so remarkably with the accounts of "Prester John" which had been brought to the Peninsula by Abyssinian priests, that João II. steadfastly resolved that both by sea and by land the attempt should be made to reach the country of this potentate. In the hope of making this discovery, Pedro Covilham and Affonso de Payva were despatched eastward by land; while Bartholomeu Dias, in command of two vessels, was sent westward by sea. Neither of the landward travellers ever returned to his country; but Covilham, who, in his fruitless search for a mythical sovereign, reached the Malabar coast and the eastern shores of Africa, sent back to Lisbon, along with the tales of the rich lands he had visited, this intelligence, "that the ships which sailed down the coast of Guinea ought to be sure of reaching the termination of the continent by persevering in a course to the south." King João was now seized with an ardent desire of reaching these eastern countries by the route indicated by Covilham. That there was in truth such an ocean highway was confirmed by Dias, who shortly after returned (in 1487) with the report that when sailing southward he was carried far to the east by a succession of fierce storms, past—as he discovered only on his return voyage—what he perceived to be the southern extremity of the African continent, and to which, on account of the fearful weather he had encountered, he gave the name of the Cape of Storms, an appellation which to the king, who was then elated with high hopes of enriching his kingdom by the addition of eastern possessions, appeared so inauspicious that he changed it to that of Cape of Good Hope. The state of João's health, however, and concerns of state, prevented the fitting out of the intended expedition; and it was not till ten years later, when Manoel had succeeded to the throne, that the preparations for the great voyage were completed,—hastened, doubtless, by Columbus's discovery of America in the meanwhile. For the supreme command of this expedition the king selected Vasco da Gama, who had in his youth fought in the wars against Castile, and in his riper years gained distinction as an intrepid mariner. The fleet, consisting of four vessels specially built for this mission, sailed down the Tagus on the 8th July 1497, after prayers and confession made by the officers and crews in the presence of the king and court, in a small chapel on the site where now stands the church of S. Maria de Belem, afterwards built to commemorate the event. Four months later it cast anchor in St Helena Bay, South Africa, rounded the Cape in safety, and in the beginning of the next year reached Melinda. Thence, steering eastward, under the direction of a pilot obtained from Indian merchants met with at this port, Gama arrived at Calicut, on the Malabar coast, on the 20th May 1498, and set up, according to the custom of his country, a marble pillar as a mark of conquest and a proof of his discovery of India. His reception by the zamorin, or ruler of Calicut, would have in all probability been favourable enough, had it not been for the jealousy of the Moorish traders who, fearing for their gains, so incited the Hindus against the new comers that Gama, after escaping from enforced detention on shore, was obliged to fight his way out of the harbour. Having seen enough to assure him of the great resources of this new country, he returned home in September 1499 with a glowing description of it. The king received him with every mark of distinction, created him a noble, and ordered magnificent fêtes to be held in his honour in the principal towns of the kingdom, "for he had brought back (not without severe loss in ships and in men) the solution of a great problem, which was destined to raise his country to the acme of prosperity." In prosecution of Gama's discoveries another fleet of 13 ships was immediately sent out to India by Manoel, under Alvarez Cabral, who, in sailing too far westward, by accident discovered Brazil, and on reaching his destination established a factory at Calicut. The natives, again instigated by the Moorish merchants, rose up in arms, and murdered all whom Cabral had left behind. To avenge this outrage a powerful armament of ten ships was fitted out at Lisbon, the command of which was at first given to Cabral, but was afterwards transferred to Gama on his urgent petition; for, "Sire," he said, "the king of Calicut arrested me and treated me with contumely, and because I did not return to avenge myself of that injury he has again committed a greater one, on which account I feel in my heart a great desire and inclination to go and make great havoc of him." In the beginning of 1502 the fleet sailed, and on reaching Calicut Gama immediately bombarded the town, enacting deeds of inhumanity and savagery too horrible to detail, and equalled only by the tortures of the Inquisition. Gama was naturally "very disdainful, ready to anger, and very rash;" but no peculiarities of disposition—nothing whatever—can excuse such acts as his, which have justly left a stain on his character that neither time nor the brightness of his fame as a navigator can in the slightest degree obliterate. From Calicut he proceeded in November to Cochin, "doing all the harm he could on the way to all that he found at sea," and having made favourable trading terms with it and with other towns on the coast, he returned to Lisbon in September 1503, with richly laden ships. He and his captains were welcomed with great rejoicings; "but to Dom Vasco the king gave great favours, and all his goods free and exempt; he granted him the anchorage dues of India, made him admiral of its seas for ever, and one of the principal men of his kingdom." Soon after his return Vasco retired to his residence in Evora, and for twenty years took no part in public affairs, either from pique at not obtaining, as is supposed by some, so high rewards as he expected, or because he had in some way offended Manoel. During this time the Portuguese conquests increased in the East, and were presided over by successive viceroys. The fifth of these was so unfortunate that Gama was recalled from his seclusion by Manoel's successor, João III., created count of Vidigueira, and nominated viceroy of India, an honour which in April 1524 he left Lisbon to fill. Arriving at Goa in September of the same year, he immediately set himself to correct, with vigour and firmness, the many abuses and evil practices which had crept in under the rule of his predecessors. He was not destined, however, to prosecute far the reforms he had inaugurated, for, on the Christmas-eve following his arrival he died, while at Cochin, after a short illness, and was buried in the Franciscan monastery there. In 1538 his body was conveyed to Portugal and entombed in the town of Vidigueira, of which he was count, with all the pomp and honour due to one who had been the king's representative.

The important discoveries of Vasco da Gama had the immediate result of enriching Portugal, and raising her to one of the foremost places among the nations of Europe, and by degrees the far greater one of hastening the colonization and civilization of the East by opening its commerce to the great Western powers.

For further information the following works may be consulted:—*The Three Voyages of Vasco da Gama and his Viceroyalty*, by Gaspar Correa (Hakluyt Society); *Calcoen* (*i.e.*, *Calicut*), *A Dutch Narrative of the Third Voyage of Vasco da Gama*, written by some unknown seaman of the expedition, printed at Antwerp about 1504, reprinted in facsimile, with introduction and translation, by J. Ph. Berjeau, London, 1875; *Discoveries of Prince Henry of Portugal*, by R. H. Major; *The Lusiads* of Camoens; Cooley, *History of Maritime Discovery*; Barros, *Decades*; Alvaro Velho, *Roteiro da viagem que em descobrimento da India pelo cabo de Bōa Esperança fez dom Vasco da Gama em* 1479, the manuscript of which is preserved at Coimbra, and a translation of which by Ferdinand Denis may be found in E. Charton's *Voyageurs Anciens el Modernes*, vol. iii., 1855; Castan Leda, *Historia do Descobrimento da India*, Coimbra, 1551 (largely based on Alvaro Velho's MSS.). (H. O. F.)

GAMALIEL (גַּמְלִיאֵל, *i.e.*, God is a rewarder, Γαμαλιήλ), a Hebrew proper name, which occurs more than once in the Old Testament (Numb. i. 10; ii. 20), is repeatedly met with in the history of later Judaism. Of the persons designated by it the most important are enumerated below:—

1. GAMALIEL, or Rabban Gamliel the elder, as he is invariably called in the Talmud to distinguish him from his grandson, Rabban Gamaliel or Gamliel of Jabneh (Jamnia), was the son of Rabbi Simeon, and the grandson of Rabbi Hillel. Of his biography little is known beyond the facts that, early in the 1st century, he lived and taught in Jerusalem, where Saul of Tarsus was for some time his pupil; and that he was a member of the Sanhedrim, which body he successfully counselled to moderation in their treatment of the followers of Jesus.[1] He appears to have died before the destruction of the city. The Talmudists speak of him as having enjoyed the confidence of Cypros, the wife of Agrippa, and as having been president of the Sanhedrim during the reigns of Tiberius, Caligula, and Claudius; but the latter representation at least is certainly unhistorical, as may be learned from the New Testament and from Josephus, where it is invariably the high priest who presides over the council. Gamaliel the elder is also represented by Jewish tradition as having in some respects modified the provisions of the law with respect to divorce and marriages of widows, and as having made some new arrangements with regard to the calendar; but there is reason to believe that in this last statement he has been mistaken for Gamaliel of Jabneh. The fact that he is spoken of in the records of Judaism as having been the first of the seven "rabbans" (rabban being a honorific form of the title rabbi) is of itself almost conclusive against the late and otherwise improbable Christian tradition to the effect that he ultimately became a Christian and received baptism at the hands of Peter and John (*Clem. Recog.*, i. 65; Photius, cod. 171, p. 199). Compare Ewald, *Gesch. d. V. Isr.*, vi. 256 *sq.*; Derenbourg, *Hist. de Palestine*, p. 239 *sqq.*; Schürer, *NTliche Zeitgesch.*, p. 458.

2. GAMALIEL of Jabneh ranks with his grandfather, Gamaliel the elder, as one of the seven great rabbans of the Talmudists. His father also was named Simeon. On the death of Rabbi Johanan ben Zacai, Gamliel was chosen to succeed him as head of the famous school

[1] The criticisms of Baur and others upon the speech, as recorded in Acts v. 34–39, do not affect the general fact as now stated.

which had transferred itself to Jamnia or Jabneh shortly before the destruction of Jerusalem. For a considerable period after that event Jabneh became in some sense the metropolis of Judaism, and Gamliel, as head of the supreme judicial and legislative body which sat there, may be said to have been the first nasi or "prince" of the rabbinical period. An interesting account of his position as legislator will be found in chapter xx. of Derenbourg's *Histoire de Palestine*. As representing the Jewish nation and the Jewish faith, he visited Rome in the autumn of 95 A.D., and the Talmud abounds with references to the incidents of that journey. Gamliel was the friend of Rabbi Akiba, and the master of Aquila (the "Onkelos" of the Babylonian Talmud). He died about 115 A.D. (see Ewald, *Gesch. d. V. Isr.*, vii. 388).

3. A third GAMALIEL, son of Jehudah-ha-Nasi, is mentioned in *Aboth*, ii. 2, as having specially insisted on the necessity of combining with the study of the law some active employment in order to the maintenance of a healthy moral tone.

GAMBIA, GAMBRA, BA DIMMA, or FURA, an important river of Western Africa, which enters the Atlantic about 13° 50′ N. lat. Its sources are in the central plateau of the Futa Jallon highlands, a tract of country about 240 miles inland, which also contains the head waters of the Senegal, the Faleme, the Rio Grande, and some tributaries of the Niger. Flowing almost due N. for the first 200 miles of its course, it turns somewhat abruptly to the W., and continues in that direction through a country of great fertility. Steamers can proceed up the river as far as Yaba Tenda; the channel remains navigable for boats 300 miles from the mouth to the falls of Barraconda; and above the falls it is again navigable, as was shown by Governor Macdonnell's expedition in 1851, for at least 160 miles farther. The principal affluent is the Neries, which, coming from the north, joins the main stream about 30 or 35 miles above the falls. At Fattatenda, a short distance below the falls, the river has a breadth, even in the dry season, of about 320 feet, with a depth of from 13 to 20 feet. In the rainy season it rises from 20 to 50 feet, and the whole country downwards to the sea is laid under water, and receives a rich alluvial deposit.

The British colony of Gambia comprises a considerable territory mainly on the left bank at the mouth of the river, Elephant's Island about 100 miles from the sea, and Macarthy's Island still further inland. The whole area under British authority is 21 square miles. The population in 1851 was stated at 5693, in 1861 at 6939, and in 1871 at 14,190 (7306 males and 6884 females). In the 15 years from 1860 to 1874 the total gross revenue was £268,232, making an annual average of £17,802; and the gross amount of public expenditure in the same period was £255,291, making an annual average of £17,019, or a total surplus of revenue over expenditure of £2941. In 1862, 1863, and 1864 the liabilities exceeded the assets by £3638, £4817, and £5492 respectively, but there is no funded debt. The Gambia settlement, which formerly cost the imperial revenue from £20,000 to £25,000 per annum, now provides for its own defence,—an armed police force, recruited mainly from the Mahometan tribe of the Houssas, having been substituted since 1869 for the imperial troops. The parliamentary grant, which had averaged about £4200 per annum from 1860 to 1867, was reduced to £1500 in 1868, and finally withdrawn in 1871, and all expenses are met by the local revenue. The Gambia district was originally united with Sierra Leone on the dissolution of the African Company in 1822; in 1843 it was made a separate colony, the first governor being Henry Frowd Seagram; in 1868 it was reunited to Sierra Leone; and it is now governed by an administrator. The capital of the colony is Bathurst, a town on the eastern side of St Mary's Island.

St Mary's Island lies at the mouth of the river on the south side, close to the mainland, from which it is separated by a stretch of mangrove swamp and a narrow arm of the river called Oyster Creek. It is about 15 miles in length by less than a mile in breadth, and consists of a slightly elevated plain of sandy soil, which in the dry season becomes a bed of hot and shifting dust. There are naturally not many trees on the island, though a few cocoa-nuts, palms, papaws, willows, bananas, oleanders, and guavas manage to maintain a precarious existence. The Barbados pride, however, flourishes luxuriantly (Captain Hewitt). Bathurst is on the whole a well-built town, the principal material employed being a dirty red sandstone coated with whitewash. It lies about 12 or 14 feet above the level of the river. The market house is built of iron, and the market place was planted with trees in 1869. Besides the Government house and the barracks, there is a hospital founded by General Macdonnell, a court-house, and an Episcopal church completed about 1869. The population of the town is of a very motley description, including, besides the white officials, and traders to the number of about 50, half-castes of all shades, liberated negroes, Jolloffs, Barras, and other local tribes. The part of the mainland immediately contiguous to St Mary's is known as British Combo, an area of about 6 miles long by from 2 to 3 miles broad having been secured by treaty with the king of Combo in 1853.

M'Carthy's Island lies about 180 or 200 miles above St Mary's. It is about 5½ miles in length and 1 in breadth. There are two or three "factories," a considerable trading town, peopled partly by liberated Africans, a fort, a Methodist church, and a schoolhouse. Though this was the last spot actually in British possession, it was long understood by Gambia traders that they were under British protection much farther up the stream; but, according to the despatches of Lord Carnarvon in 1877, they must proceed at their own risk as soon as they advance beyond British territory. St James's Island, which was the seat of the British factory in the 18th century, is about 17 miles from St Mary's. It still bears traces of European occupation, but is gradually being washed away by the river.

The chief exports are ground nuts, wax, hides, ivory, gold dust, palm oil, and gum arabic; but even these are obtained in quantities that look ridiculously small when the natural richness of the country through which the Gambia flows is considered. At the close of the 18th century only two or three ships were employed in the trade; in 1839 no fewer than 239 merchant vessels visited the river; and in 1871 75 British and 154 foreign vessels entered, with a total tonnage of 51,853 tons. During the four rainy months, from July to October, the native trader conveys his employer's rice or corn up the river, and receives in exchange the pagnes or country cloths; in November he barters these same cloths for ground nuts, hides, and wax; and for the rest of the year, till the rainy season comes round again, he supplies the natives with arms, powder, rum, Madras handkerchiefs, and other European productions. The French traders, however, who are gradually getting a large share of the commerce into their hands, have introduced the custom of money transactions, and the innovation is well received by the natives.

The trade in ground nuts is of comparatively recent development. In 1836 the value exported was only £838; in 1837 it reached £8053, and in 1840 no less than £15,209. In 1860 the value was £79,611, and in 1861 £101,060. The average quantity between 1850 and 1860 was 11,196 tons; between 1870 and 1877 it was 14,000 tons. The supply is greatly affected by the political state of the country in which the nuts are grown. Most of the necessary tillage is performed by the tribe of the Sera-Woullis, who come down from the interior in great numbers, and return home when they have earned what they desire. The French markets are the principal destination of the nuts. American traders deal mainly in hides, horns, and beeswax; and the honey is chiefly purchased for the German market. The Roman Catholics maintain a mission and a small convent in the Gambia, and the Wesleyans have long had a number of stations. The latter have done great service to education in the colony,—their 10 schools, as far back as 1860, being attended by 1273 scholars. It was not till 1869 that, even at Bathurst, a Government school was established; but there are now several schools in connexion with the Episcopal church. The Roman Catholics began the erection of a large schoolhouse in 1873.

The Gambia was visited by the Carthaginian explorer Hanno, and it became early known to the Portuguese discoverers; but it was not till 1618 that English traders began to turn their attention to this quarter. In that year a company was formed for the exploration of the river. Richard Thompson was sent out in the "Catherine," and succeeded in reaching Kassan, a Portuguese trading town, but he never returned, and his fate is not known. Two years afterwards, Richard Jobson advanced beyond the falls of Barraconda; and he was followed, about 40 years later, by Vermuyden, a Dutch merchant. In 1723 Captain Stibbs was sent out by the African Company to verify Vermuyden's reports of gold; he proceeded 60 miles above the falls. The treaty of Versailles in 1783 assigned the right of trade in the Gambia to Britain, reserving the single port of Albreda for the French; while at the same time it assigned the Senegal to France, and reserved the port of Portendic for the British. By the treaty of Paris in 1851 this arrangement was re-established, and it remained in force till 1857, when an exchange of possessions was effected, and the Gambia became a purely British river. In 1870 there was a proposal to transfer the colony to the French; but it led to nothing more than a voluminous diplomatic correspondence.

See Astley's *Collection*, vol. ii.; R. R. Madden's Report to the Government in 1841; T. E. Poole, *Life in Sierra Leone and the Gambia*, 1850; L. Borel, *Voyage à la Gambie*, 1865; and the Parliamentary Papers relating to Her Majesty's Colonial Possessions.

GAMBIER, Gambir, or Pale Catechu. See Catechu.

GAMBIER, James, Baron (1756–1833), English admiral, was born on the 13th October 1756, at the Bahamas, of which his father, John Gambier, was at that time lieutenant-governor. He entered the navy in 1767 as a midshipman on board the "Yarmouth," under the command of his uncle; and, his family interest obtaining for him rapid promotion, he was raised in 1778 to the rank of post-captain, and appointed to the "Raleigh," a fine 32-gun frigate. At the peace of 1783 he was placed on half-pay; but, on the outbreak of the war of the French Revolution, he was appointed to the command of the 74-gun ship "Defence," under Lord Howe; and in her he had an honourable share in the action off Ushant, on the 1st June 1794. In recognition of his services on this occasion, Captain Gambier received the gold medal, and was made a colonel of marines; the following year he was advanced to the rank of rear-admiral, and appointed one of the lords of the Admiralty. In this office he continued for six years, till, in February 1801, he, a vice-admiral of 1799, hoisted his flag on board the "Neptune," of 98 guns, as third in command of the Channel Fleet under Admiral Cornwallis, where, however, he remained for but a year, when he was appointed governor of Newfoundland and commander-in-chief of the ships on that station. In May 1804 he returned to the Admiralty, and, with a short intermission in 1806, continued there during the naval administration of Lord Melville, of his uncle, Lord Barham, and of Lord Mulgrave. In November 1805 he was raised to the rank of admiral; and in the summer of 1807, whilst still a lord of the Admiralty, he was appointed to the command of the fleet ordered to the Baltic, which, in concert with the army under Lord Cathcart, reduced Copenhagen, and enforced the surrender of the Danish navy, consisting of nineteen ships of the line, besides frigates, sloops, gunboats, and naval stores. This service was considered by the Government as worthy of special acknowledgment; the naval and military commanders, officers, seamen, and soldiers received the thanks of both Houses of Parliament, and Admiral Gambier was rewarded with a peerage.

In the spring of the following year he gave up his seat at the Admiralty on being appointed to the command of the Channel Fleet; and in that capacity he witnessed the partial, and prevented the total, destruction of the French fleet in Basque Roads, on the 12th April 1809. It is in connexion with this event, which might have been as memorable in the history of the British navy as it is in the life of Lord Dundonald (see Dundonald), that Lord Gambier's name is now best known. A court-martial, assembled by order of a friendly Admiralty, and presided over by a warm partisan, "most honourably acquitted" him on the charge "that, on the 12th April, the enemy's ships being then on fire, and the signal having been made that they could be destroyed, he did, for a considerable time, neglect or delay taking effectual measures for destroying them;" but this decision was in reality nothing more than a party statement of the fact that a commander-in-chief, a supporter of the Government, is not to be condemned or broken for not being a person of brilliant genius or dauntless resolution. No one now doubts that the French fleet should have been reduced to ashes, and might have been, had Lord Gambier had the talents, the energy, or the experience of many of his juniors. He continued to hold the command of the Channel Fleet for the full period of three years, at the end of which time—in 1811—he was superseded. In 1814 he acted in a civil capacity as chief commissioner for negotiating a treaty of peace with the United States; for his exertions in which business, he was honoured with the Grand Cross of the Bath. In 1830 he was raised to the high rank of admiral of the fleet, and he died 19th April 1833.

Although he had the good fortune to attain the very highest service rank, Lord Gambier is assuredly not one of those admirals whose memory the British navy treasures or idolizes. His predilection was for a life on shore; and during the great war he so utilized his family interest that he remained for nearly half the time a member of the Admiralty. And whether afloat or ashore, he had neither the genius nor the strength of mind fitted for high command or high office. Personally he was a man of earnest, almost morbid, religious principle, and of undoubted courage; but the administration of the Admiralty has seldom given rise to such flagrant scandals as during the time when Lord Gambier was a member of it; and through the whole war, the self-esteem of the navy suffered no such wound as during Lord Gambier's command in the Bay of Biscay.

The so-called *Memorials, Personal and Historical, of Admiral Lord Gambier*, by Lady Chatterton (1861), has no historical value. The life of Lord Gambier is to be read in Marshall's *Royal Naval Biography*, in Ralfe's *Naval Biography*, in Lord Dundonald's *Autobiography of a Seaman*, in the Minutes of the Courts-Martial, and in the general history of the period.

GAMBOGE, the drug *Cambogia*, a gum-resin procured from *Garcinia Morella*, Desrous., var. *pedicellata*, a diœcious tree with leathery, laurel-like leaves, small yellow flowers, and usually square-shaped and four-seeded fruit (see R. Jamie, *Pharm. Journ.*, 3d ser., vol. iv. p. 802), a member of the natural order *Guttiferæ*, and indigenous to Camboja (see Cambodia, vol. iv. p. 725), and parts of Siam and of the south of Cochin China, formerly comprised in Cambojan territory. The juice, which when hardened constitutes gamboge, is contained in the bark of the tree, chiefly in numerous ducts in its middle layer, and from this it is procured by making incisions, bamboo joints being placed to receive it as it exudes. Gamboge occurs in commerce in cylindrical pieces, known as pipe or roll gamboge, and also, usually of inferior quality, in cakes or amorphous masses. It is of a dirty orange externally; is hard and brittle, breaks with a conchoidal and reddish-yellow, glistening fracture, and affords a brilliant yellow powder; is odourless, and has a taste at first slight, but subsequently acrid; forms with water an emulsion; and consists of from 20 to 25 per cent. of gum soluble in water, and from 70 to 75 per cent. of a resin, *gambogic acid*, soluble in alcohol and ether, and, according to Johnston, of the formula $C_{20}H_{23}O_4$, together with moisture about 5 per cent., and a trace of ligneous fibre. Its commonest adulterations are rice-flour and pulverized bark. Some quantity of gamboge is shipped from Kâmpot in Camboja, but the principal places of export are Bangkok in Siam, and Saigon in Cochin China. Gamboge is a powerful hydragogue purgative, less drastic only than elaterium and croton oil. Like aloes, it appears to exert its chief influence on the lower bowel (*Brit. and For. Med.-Chir. Rev.*, i., 1853, p 128), and in combination with compound colocynth pill it has been recommended by Dr Symonds as one of the most efficient purgatives in torpor of the colon. The researches of Christison, Pabo, and Daraszkiewicz go to prove that gambogic acid alone is less cathartic than the same weight of gamboge; according to the last-mentioned experimenter and Schaur, the presence of bile in the intestines is requisite for the development of its action. In cerebral affections, as apoplexy, when great debility is not present, gamboge has proved to be a valuable counter-irritant purgative. It is sometimes employed as an anthelmintic, but appears to be devoid of any specific influence on entozoa. Some authorities regard it as decidedly diuretic in action. By Christison and others it has been found highly serviceable in dropsy. Abeille (quoted in *Brit. and For. Med.-Chir. Rev.*, 1853, ii. p. 279) administered it for that disease, in alcoholic solution, in divided doses of 6 grains per diem, increased by 2 grains daily, and given two hours prior or subsequent to meals. With the relief of the dropsy he observed that the patient's toleration of these large quantities ceased. As gamboge is apt to occasion vomiting and griping, it is usually administered in combination with milder remedies. It is an ingredient of the *pilula cambogiæ composita* of pharmacy. In overdoses it acts as an acrid poison, provoking violent emesis and catharsis, and abdominal pain, coldness of the extremities, and ulceration and mortification of the intestines, eventuating in death. Gamboge is used as a pigment, and as a colouring matter for varnishes. It appears to have been first brought into Europe by merchants from the East, at the close of the 16th century. Bontius, writing in the year 1658, mentions it under the name of *guttagemou*, a word derived by Rost from the Malay *gutáh*, gum, and Javanese *jamu*, medicinal. By the Chinese gamboge (*tang-hwang* and *shiê-hwang*) is understood to be "serpent-bezoar," a substance vomited up by serpents, or the product of a species of ratan, analogous to the tabasheer of the bamboo (F. P. Smith, *Contrib. towards the Mat. Med. . . of China*, 1871). Varieties of gamboge are yielded by *Garcinia Morella*, Desrous., a native of S. India and Ceylon, and by the Indian species *G. pictoria*, Roxb., and *G. travancorica*, Beddome.

See Christison, "Obs. on a new variety of Gamboge from Mysore," *Pharm. Journ.*, ser. i. vol. vi. pp. 60 69, and "On the Gamboge Tree of Siam," *ib.*, vol. x. p. 235; F. Mason, "On the Gamboge of the Tenasserim Provinces," *ib.*, vol. vii. p. 398; Pereira, *Materia Medica*, vol. ii. pt. ii.; D. Hanbury, "On the Species of *Garcinia* which affords Gamboge in Siam," *Trans. Linn. Soc.*, xxiv., 1864, 487-490; E. J. Waring, *Man. of Pract. Therapeutics*, 3d ed., 1871; J. L. de Lanéssan, "Étude sur le Genre Garcinia (Clusiacées) et sur l'Origine et les Propriétés de la Gomme Gutte," *Coll. des Thèses soutenues à la Faculté de Médecine de Paris*, 1872, vol. x., No. 63; Flückiger and Hanbury, *Pharmacographia*, 1874; H. GAME LAWS. This expression is applied in England to a series of statutes of modern date, establishing a peculiar kind of property in wild animals. These statutes, it is well known, are regarded with great dislike by a large and important section of the people—partly on account of their alleged injurious economic effects, and partly on account of their harsh and exceptional character. It will be well to state first the principles of the common law, and then to show how far they have been superseded by recent legislation. By the very nature of the case, wild animals cannot be made the subject of that absolute kind of ownership which is generally signified by the term property. The substantial basis of the law of property is physical possession, the actual power of dealing with things as we see fit, and we can have no such power over animals in a state of nature. Accordingly, the common law recognized nothing like property in wild animals, until they had, as it were, been reduced into possession. Wild animals reclaimed or confined become property, but the moment they escape from confinement the property is gone, and the rights of the owner are lost. Even bees, which might well be described as domesticated and not wild animals, do not become property until they are hived. "Though a swarm lights on any tree," says Bracton, "I have no more property therein than I have in the birds which make their nests thereon." The owner of a confined animal which escapes does indeed retain his property while he is in pursuit of the fugitive; *i.e.*, no other person can, in the meantime, establish a right of property against him by capturing the animal, just as a swarm of bees "which fly from and out of my hive are mine so long as I can keep them in sight, and have power to pursue them." Again, the law recognized a right in wild animals *propter impotentiam*, *i.e.*, when they were young and unable to move from place to place. With these exceptions wild animals were *res nullius*, capable of being made the property of any person reducing them into possession. A prior right to acquire property in such animals was, however, allowed to the owner (or occupier) of the soil. Thus it is said that "if A starts a hare in the ground of B, and hunts it and kills it there, the property continues all the while in B." B is said to have a right of property in the wild animals on his land *ratione soli*. But "if A starts a hare on the ground of B, and hunts it into the ground of C and kills it there, the property is in A, and not in B or C." That is to say, the so-called property in wild animals *ratione soli* consists in this, that if one of them is started and killed by a trespasser it belongs to the owner (or occupier) of the soil. If the animal goes to another man's land this inchoate right is transferred to the other man. And the inchoate right of the owner becomes an actual right of property only when the animal is both started and killed by the trespasser on the same man's land. Such right as the owner has belongs to the occupier when the land is given without reserve to a tenant for a term.

These principles, it will be observed, apply to all wild animals, and no distinction is made between game and other animals. The laws of the forest, however, established in derogation of the common law a different kind of property in certain classes of wild animals. For an account of these see FOREST LAW (vol. ix. p. 408). The forest code affected definite districts of the country, and the right which they protected was the exclusive right of hunting the animals of the forest within those districts.

The game laws as above defined have virtually taken the place of the forest laws. The latter protected the privilege of the king and his favourites to hunt certain animals in certain districts; the former have extended and protected the right of an owner of the soil to the chase of certain animals on his own estate. The means adopted have been to make trespass (in itself only a civil wrong) a criminal offence punishable with great severity, and to restrict, by a system of licences, the right as well of killing as of selling game. The principal Acts are 1 & 2 William IV. c. 32 (the Game Act), 9 Geo. IV. c. 69 (the Night Poaching Act), 23 & 24 Vict. c. 90 (Game Licences Act), and the Hares Killing Act, 11 & 12 Vict. c. 29. The Game Act repeals a large number of statutes on the subject, most of them passed in the 18th century. Game is defined to include "hares, pheasants, partridges, grouse, heath or moor game, black game, and bustards," and the same definition is found in the Night Poaching Act. A close time is fixed for certain birds of game:—for partridges from 1st February to 1st September; pheasants, 1st February to 1st October; black game, 10th December to 20th August; grouse, 10th December to 12th August; bustard, 1st March to 1st September; and the possession of such game after 10 days in dealers, and 40 days in other persons, from the expiration of the season is made illegal. The Act makes no difference in the effect of a game certificate (now "game licence"); that is to say, the licence authorizes the holder to kill game, subject to the law of trespass as modified by this Act. A temporary section reversed, as to all existing leases, the presumption of law that the game, unless specially reserved, belongs to the tenant; but the presumption remains as to all future leases. But when the game has been reserved to the landlord, or any assignee of his, then the occupier shall be punished for killing it, or for authorizing any other person to do so. This section no doubt was rendered necessary by the fact that the law of trespass, which is the pivot of the Game Act, could not be made to include the case of a farmer shooting game on his own ground; but it is open to the remark that in effect it converts a mere breach of contract into a crime. Persons holding game certificates (licences) may sell game to persons licensed to deal therein. Various sections of the Act define the penalties to which persons killing or selling game without a licence shall be subject, and it should be noticed that it is a punishable offence even to buy game except from a licensed dealer.

The section relating to trespass (§ 30 of the Game Act) enacts that, "if any person whatsoever shall commit any trespass by entering or being in the day time upon any land in search or pursuit of game, or woodcocks, snipes, quails, landrails, or conies,[1] such person shall, on conviction thereof before a justice of the peace, forfeit and pay such sum of money, not exceeding two pounds, as to the justice shall seem meet, together with the costs of the conviction;" and that if any persons, to the number of five or more together, shall commit any trespass by entering or being in the day time upon any land in search of or pursuit of game or woodcocks, &c, "each shall, on conviction, forfeit a sum not exceeding five pounds. The leave of the occupier shall be no defence when the game belongs to the landlord or other persons; and by § 31, trespassers in pursuit of game, &c., may be required to leave the land, to tell their names and abodes, and if they refuse may be arrested. The owner of the right of shooting may take from them any game found in their possession. The sections against trespassers, however, do not include any person hunting or coursing upon any land with hounds or greyhounds." This act applies only to England.

The Poaching Acts are still more severe. The Night Poaching Act enacts that, "if any person shall, after the passing of this Act, by night unlawfully take or destroy any game or rabbits in any land, whether open or enclosed, or shall by night unlawfully enter or be on any land, whether open or enclosed, with any gun, net, engine, or other instrument for the purpose of destroying game, such offender shall, upon conviction thereof before two justices of the peace, be committed for the first offence to the common gaol or house of correction for any period not exceeding three calendar months, there to be kept to hard labour, and at the expiration of such period shall find sureties" for his not so offending again. For a second offence the punishment is six months with hard labour, &c., with one year's further imprisonment in default of sureties, a third offence is a misdemeanour, and the punishment is penal servitude for not more than seven years, or imprisonment for not more than two years. A later Act, 7 & 8 Vict. c. 29, §1, applies the penalties to the unlawful taking or destroying game on a highway by night. "Night" is declared to commence at the expiration of the first hour after sunset and to conclude at the beginning of the last hour before sunrise. Finally, the Poaching Prevention Act (25 & 26 Vict. c. 114) gives power to a constable, "on any highway, street, or public place, to search any person whom he may have good cause to suspect of coming from any land where he shall have been unlawfully in search or pursuit of game, or any persons aiding or abetting such person, and having in his possession any game unlawfully obtained, or any gun, part of gun, or nets or engines used for the killing or taking game; and also to stop and search any cart or other conveyance in or upon which such constable or peace officer shall have good cause to suspect that any such game, or any such article or thing, is being carried by any such person." If any such thing be found the constable is to detain it, and apply for a summons against the offender, summoning him to appear before two justices, where, on conviction, he may be fined not more than £5, and shall forfeit the game, guns, &c., found in his possession. This Act is available by night as well as day. It should be noted in all cases where the unlawful taking or destroying of game is mentioned, that such taking is made unlawful only by the provisions of the Acts relating to certificates, or by the law relating to trespass. A person provided with a certificate can still kill game where he pleases, unless he commits a trespass—the only exception being that of the tenant whose landlord has reserved the game in his lands. Thus it may be inferred that a poacher provided with a certificate could not be brought within the limits of the Act relating to poaching on highways.

Game certificates are now regulated by 23 & 24 Vict. c. 90. Section 4 enacts that "any person, before he shall in Great Britain take, kill, or pursue, or aid or assist in any manner in the taking, killing, or pursuing, by any means whatever, or use any dog, gun, net, or other engine for the purpose of taking, killing, or pursuing any game, or any woodcock, snipe, quail, landrail, or any coney, or any deer, shall take out a proper licence to kill game under this Act"—subject to a penalty of £20. There are, however, certain exceptions and exemptions. As to licences to deal in game, any person who shall have obtained a licence to deal in game from the justices of the peace under the provisions of 1 & 2 Will. IV. c. 32, and 2 & 3 Vict. c. 35, shall annually and during the continuance of such licence, and before he shall be empowered to deal in game under such licence, obtain a further licence to deal in game under this Act, and only those who have obtained licence from the justices shall be licensed under the Act, *i.e.*, by the Inland Revenue. By 11 & 12 Vict. c. 29 any occupier or owner having the right of killing game may, by himself or by any person authorized by him in writing, kill hares without paying duty or taking out licence.

Most of the Acts cited above apply to Scotland as well as England, and when they do not there are special enactments for Scotland having substantially the same effect. The more important statutes specially affecting Scotland are the 13 Geo. III. c. 54, which fixes a close time for killing, selling, buying, &c., muirfowl, heathfowl, partridge, and pheasant; the 2 & 3 Will. IV. c. 68 (the Trespass Act); the 11 & 12 Vict. c. 30 (Hares Killing Act); and the 40 & 41 Vict. c. 28. The last is to some extent a departure from the general policy of the game laws, being an attempt to provide compensation to tenants for damage caused by game. In effect it will be found to belong to the class of "permissive" statutes. The important section of the 4th :—

[1] These animals, although not included in the statutory definition of game, are by this section partially admitted to the benefit of the Act.

"Where, under any lease made subsequently to the commencement of this Act, or where, by presumption of common law, upon any land occupied under a lease made subsequently to the commencement of this Act, the lessor shall reserve or retain the sole right of hunting, killing, or taking rabbits, hares, or other game, or any of them, the lessee shall be entitled to compensation for the damage done to his crops in each year by the rabbits and hares, or other game, to which the lessor may have reserved or retained the whole right, in excess of such sum as may have been set forth in the lease as the amount of annual damage for which it is agreed no compensation shall be due; and if no such sum shall be set forth, then in excess of the sum of forty shillings."

Scotch law, differing in this respect from English law, infers that, when the lease contains no stipulations as to game, the landlord reserves the right of killing game to himself. The Act contains provisions for settling claims of damage either by arbitration or by action at law. Leases made before the Act are not to be affected thereby. The old Act of 1621, "aneut hunting and haulking," is cited in the schedule of the last-mentioned Act; it "ordaines that no man hunt nor haulk at any time hereafter who hath not a plough of land in heritage, under the pain of £100." It is, of course, practically obsolete. (E. R.)

GAMES. The public games of Greece and Rome were athletic contests and spectacles of various kinds, generally connected with and forming part of a religious observance. Probably no institution exercised a greater influence in moulding the national character, and producing that unique type of physical and intellectual beauty which we see reflected in Greek art and literature, than the public contests of Greece. For them each youth was trained in the gymnasium, they were the central mart whither poet, artist, and merchant each brought his wares, and the common ground of union for every member of the Hellenic race. It is to Greece then that we must look for the earliest form and the fullest development of ancient games, and we propose in the present article to treat principally of the Greek ἀγῶνες. The shows of the Roman circus and amphitheatre were at best a shadow, and in the later days of the empire a travesty, of the Olympia and Pythia, and require only a cursory notice. "Corruptio optimi fit pessima." From the noblest spectacle in the world, the Greek Olympia, the downward course of public games can be traced, till we reach the ignoblest, the Roman amphitheatre, of whose horrors we may still form a faint picture from its last survival, the Spanish bull-fight.

The earliest games of which we have any record are those at the funeral of Patroclus, which form the subject of the twenty-third Iliad. They are noticeable both as showing that the belief that the dead would be appeased or gratified by the same exhibitions which pleased them in life was a common heritage of Greeks and Romans from their Aryan progenitors, and as already including all the distinctive competitions which we find in historical times,—the chariot-race, archery, boxing, wrestling, and putting the weight. Each of the great Grecian games was held near some shrine or consecrated spot, and is connected by myth or legend with some hero, demigod, or local deity.

The Olympian games were the earliest, and to the last they remained the most celebrated of the four national festivals. Olympia was a naturally enclosed spot in the rich plain of Elis, bounded on the N. by the rocky heights of Kronos, and on the S. and W. by the Alpheus and its tributary the Kladeus. There was the grove of Altis, in which were ranged the statues of the victorious athletes, and the temple of Olympian Zeus with the chryselephantine statue of the god, the masterpiece of Phidias. There Hercules (so ran the legend which Pindar has introduced in one of his finest odes), when he had conquered Elis and slain its king Augeas, consecrated a temenos and instituted games in honour of his victory. A later legend, which probably embodies historical fact, tells how, when Greece was torn by dissensions and ravaged by pestilence, Iphitus inquired of the oracle for help, and was bidden restore the games which had fallen into desuetude; and there was in the time of Pausanias, suspended in the temple of Hera at Olympia, a bronze disk whereon were inscribed, with the regulations of the games, the names of Iphitus and Lycurgus. From this we may safely infer that the games were a primitive observance of the Eleians and Pisans, and first acquired their celebrity from the powerful concurrence of Sparta. In 776 B.C. the Eleians engraved the name of their countryman Corœbus as victor in the foot race, and thenceforward we have an almost unbroken list of the victors in each succeeding Olympiad or fourth recurrent year. For the next fifty years no names occur but those of Eleians or their next neighbours. After 720 B.C. we find Corinthians and Megareans, and later still Athenians and extra-Peloponnesians. Thus what at first was nothing more than a village bout became a bond of union for all the branches of the Doric race, and grew in time to be the high feast to which every Greek gathered, from the mountain fastnesses of Thessaly to the remotest colonies of Cyrene and Marseilles. It survived even the extinction of Greek liberty, and had nearly completed twelve centuries when it was abolished by the decree of the Christian emperor Theodosius, in the tenth year of his reign. The last Olympian victor was a Romanized Armenian named Varastad.

Let us attempt to call up the scene which Olympia in its palmy days must have presented as the great festival approached. Heralds had proclaimed throughout Greece the truce of God, which put a stop to all warfare, and ensured to all a safe conduct during the sacred month. So religiously was this observed that the Spartans chose to risk the liberties of Greece, when the Persians were at the gates of Pylæ, rather than march during the holy days. Those white tents which stand out against the sombre grey of the olive groves belong to the Hellanodicæ, or ten judges of the games, chosen one for each tribe of the Eleians. They have been here already ten months, receiving instruction in their duties. All, too, or most of the athletes must have arrived, for they have been undergoing the indispensable training in the gymnasium of the Altis. But along the "holy road" from the town of Elis there are crowding a motley throng. Conspicuous in the long train of pleasure-seekers are the θεωροί or sacred deputies, clad in their robes of office, and bearing with them in their carriages of state offerings to the shrine of the god. Nor is there any lack of distinguished visitors. It may be Alcibiades, who, they say, has entered no less than seven chariots; or Gorgias, who has written a famous ἐπίδειξις for the occasion; or the sophist Hippias, who boasts that all he bears about him, from the sandals on his feet to the dithyrambs he carries in his hand, are his own manufacture; or Action, who will exhibit his picture of the Marriage of Alexander and Roxana—the picture which gained him no less a prize than the daughter of the Hellanodices Praxonides; or, in an earlier age, the poet-laureate of the Olympians, Pindar himself. Lastly, as at the mediæval tournament, there are "store of ladies whose bright eyes rain influence;" matrons, indeed, are excluded on pain of death, but maidens, in accordance with Spartan manners, are admitted to the show.

At daybreak the athletes presented themselves in the Bouleuterion, where the presidents were sitting, and proved by witnesses that they were of pure Hellenic descent, and had no stain, religious or civil, on their character. Laying their hands on the bleeding victim, they swore that they had duly qualified themselves by ten months' continuous training in the gymnasium, and that they would use no fraud or guile in the sacred contests. Thence they proceeded to the stadium, where they stripped to the skin and anointed themselves. A herald proclaimed—"Let the runners put their feet to the line," and called on the spectators to challenge any disqualified by blood or character. If no objection was made, they were started by the note of the trumpet, running in heats of four, ranged in the places assigned them by lot. The presidents seated near the goal adjudged the victory. The footrace was only one of twenty-four Olympian contests which Pausanias enumerates, though we must not suppose that these were all exhibited at any one festival. Till the 77th Olympiad all was concluded in one day, but afterwards the feast was extended to five. The order of the games is for the most part a matter of conjecture, but, roughly speaking, the historical order of their institution was followed. We will now describe in this order the most important.

(1.) The *foot-race.* For the first 13 Olympiads the δρόμος, or single lap of the stadium, which was 200 yards long, was the only contest. The δίαυλος, in which the course was traversed twice, was added in the 14th Olympiad, and in the 15th the δόλιχος, or long race, of 7, 12, or, according to the highest computation, 24 laps, over 3 miles in length. We are told that the Spartan Ladas, after winning this race, dropped down dead at the goal. There was also, for a short time, a race in heavy armour, which Plato highly commends as a preparation for active service. (2.) *Wrestling* was introduced in the 18th Olympiad. The importance attached to this exercise is shown by the very word *palæstra*, and Plutarch calls it the most artistic and cunning of athletic games. The practice differed little from that of modern times, save that the wrestler's limbs were anointed with oil and sprinkled with sand. The third throw, which decided the victory, passed into a proverb, and struggling on the ground, such as we see in the famous statue at Florence, was not allowed, at least at the Olympia. (3.) In the same year was introduced the πένταθλον, a combination of the five games enumerated in the well-known pentameter ascribed to Simonides:—

ἅλμα, ποδωκείην, δίσκον, ἄκοντα, πάλην.

Only the first of these calls for any comment. The only leap practised seems to have been the long jump. The leapers increased their momentum by means of ἁλτῆρες or dumb-bells, which they swung in the act of leaping. By the help of them, and of the spring-board, enormous distances were covered, though the leap of 55 feet with which Phayllus is credited is simply incredible. It is disputed whether a victory in all five contests, or in three at least, was required to win the πένταθλον. (4.) *Boxing* was added in the 23d Olympiad. The rules were much the same as those of the modern ring, except that the boxer's fists and wrists were armed with straps of leather. The force of the blow was thereby increased; but no arm so terrible as the cestus of the Romans can ever have been admitted in Greek contests, seeing that the death of an antagonist not only disqualified a combatant, but was severely punished. In the *pancratium*, a combination of wrestling and boxing, the use of these straps, and even of the clenched fist, was disallowed. (5.) The *chariot-race* had its origin in the 23d Olympiad. It was held in the hippodrome, a race-course 1200 feet long by 400 broad, laid out on the left side of the hill of Kronos. The whole circuit had to be traversed twelve times. In the centre near the further end was the pillar or goal (the *spina* of the Romans), round which the chariots had to turn. "To shun the goal with rapid wheels" has been well selected by Milton as the most graphic feature of the Olympian games. So dangerous indeed was the manœuvre that, according to Pausanias, a mysterious horror attached to the spot, and horses when they passed it would start in terror without visible cause, upsetting the chariot and wounding the driver. The number of chariots that might appear on the course at once is uncertain. Pindar (*Pyth.*, v. 46) praises Arcesilaus of Cyrene for having brought off his chariot uninjured in a contest where no fewer than forty took part. The large outlay involved excluded all but rich competitors, and even kings and tyrants eagerly contested the palm. Thus in the list of victors we find the names of Cylon, the would-be tyrant of Athens, Pausanias the Spartan king, Archelaus of Macedon, Gelon and Hiero of Syracuse, and Theron of Agrigentum. Chariot-races with mules, with mares, with two horses in place of four, were successively introduced, but none of these present any special interest. Races on horseback date from the 33d Olympiad. As the course was the same, success must have depended on skill as much as on swiftness. Lastly, there were athletic contests of the same description for boys, and a competition of heralds and trumpeters, introduced in the 93d Olympiad.

The prizes were at first, as in the Homeric times, of some intrinsic value, but after the 6th Olympiad the only prize for each contest was a garland of wild olive, which was cut with a golden sickle from the kallistephanos, the sacred tree brought by Hercules "from the dark fountains of Ister in the land of the Hyperboreans, to be a shelter common to all men and a crown of noble deeds" (Pindar, *Ol.*, iii. 18). Greek writers from Herodotus to Plutarch dwell with complacency on the magnanimity of a race who cared for nothing but honour and were content to struggle for a corruptible crown. But though the Greek games present in this respect a favourable contrast to the greed and gambling of the modern race-course, yet to represent men like Milon and Damoxenus as actuated by pure love of glory is a pleasing fiction of the moralists. The successful athlete received in addition to the immediate honours very substantial rewards. A herald proclaimed his name, his parentage, and his country; the Hellanodicæ took from a table of ivory and gold the olive crown and placed it on his head, and in his hand a branch of palm; as he marched in the sacred revel to the temple of Zeus, his friends and admirers showered in his path flowers and costly gifts, singing the old song of Archilochus, τήνελλα καλλίνικε, and his name was canonized in the Greek calendar. Fresh honours and rewards awaited him on his return home. If he was an Athenian he received, according to the law of Solon, 500 drachmæ, and free rations for life in the Prytaneum; if a Spartan, he had as his prerogative the post of honour in battle. Poets like Pindar, Simonides, and Euripides sung his praises, and sculptors like Phidias and Praxiteles were engaged by the state to carve his statue. We even read of a breach in the town walls being made to admit him, as if the common road were not good enough for such a hero; and there are well-attested instances of altars being built and sacrifices offered to a successful athlete. No wonder then that an Olympian prize was regarded as the crown of human happiness. Cicero, with a Roman's contempt for Greek frivolity, observes with a sneer that an Olympian victor receives more honours than a triumphant general at Rome, and tells the story of the Rhodian Diagoras, who, having himself won the prize at Olympia, and seen his two sons crowned on the same day, was addressed by a Laconian in these words:—"Die, Diagoras, for thou hast nothing short of divinity to desire." Alcibiades, when setting forth his services to the state, puts first his victory at Olympia, and the prestige he had won for Athens by his magnificent display. But perhaps the most remarkable evidence of the exaggerated value which the Greeks attached to athletic prowess is a casual expression which Thucydides employs when describing the enthusiastic reception of Brasidas at Scione. The Government, he says, voted him a crown of gold, and the multitude flocked round him and decked him with garlands, *as though he were an athlete.*

The above description of the Olympian games will serve generally for the other great festivals of Greece. Without entering on any detailed account of these, it will be sufficient here to glance at the most prominent characteristics of each.

The *Pythian* games, second only to the Olympian in importance, were founded after the first Sacred War out of the spoils of Cirrha, 595 B.C. Originally a local festival held every eighth year in honour of the Delphic god, with no other contests but in the harp and the pæan—in fact a sort of Greek Eisteddfod—they developed into a common ἀγών for all Greece (so Demosthenes calls them), with all the games and races of Olympia, from which they were distinguished only by their musical and poetical competitions. They were held under the superintendence of the Amphictyones in the autumn or first half of every third Olympian year. The prizes were a wreath of laurel and a palm.

The *Nemean* games, originally a warlike gathering and review, were held in honour of Nemean Zeus at the grove of Nemea, between Cleonæ and Phlius, in the second and fourth year of each Olympiad. They date from about 570 B.C. The prize was a chaplet of parsley.

The *Isthmian* games, founded a little earlier than the Nemean, partook at first of the nature of mysteries. They were held on the narrowest part of the Isthmus of Corinth in honour of Poseidon in the first and third year of each Olympiad. Their prize was a wreath of pine leaves. The importance of the Isthmian games in later times is shown by the fact that Flamininus chose the occasion for proclaiming the liberation of Greece, 196 B.C. That at a later anniversary (67 A.D.) Nero repeated the proclamation of Flamininus, and coupled with it the announcement of his own infamous victory at Olympia, shows alike the hollowness of the first gift and the degradation which had befallen the Greek games, the last faint relic of Greek worth and independence.

The *Ludi Publici* of the Romans included feasts and theatrical exhibitions as well as the public games with which alone we are concerned. As in Greece, they were intimately connected with religion. At the beginning of each civil year it was the duty of the consuls to vow to the gods games for the safety of the commonwealth, and the expenses were defrayed by the treasury. Thus, at no cost to themselves, the Roman public were enabled to indulge at the same time their religious feelings and their love of amusement. Their taste for games naturally grew till it became a passion, and under the empire games were looked upon by the mob as one of the two necessaries of life. The ædiles who succeeded to this duty of the consuls were expected to supplement the state allowance from their private purse. Political adventurers were not slow to discover so ready a road to popularity, and what at first had been exclusively a state charge devolved upon men of wealth and ambition. A victory over some barbarian horde or the death of a relation served as the pretext for a magnificent display. But the worst extravagance of private citizens was eclipsed by the reckless prodigality of the Cæsars, who squandered the revenues of whole provinces in catering for the mob of idle sight-seers on whose favour their throne depended. But though public games played as important a part in Roman as in Greek history, and must be studied by the Roman historian as an integral factor in social and political life, yet, regarded solely as exhibitions, they are comparatively devoid of interest, and we sympathize with Pliny, who asks his friend how any man of sense can go day after day to view the same dreary round of fights and races.

It is easy to explain the different feelings which the games of Greece and of Rome excite. The Greeks at their best were actors, the Romans from first to last were spectators. It is true that even in Greek games the professional element played a large and ever-increasing part. As early as the 6th century B.C. Xenophanes complains that the wrestler's strength is preferred to the wisdom of the philosopher, and Euripides, in a well-known fragment, holds up to scorn the brawny swaggering athlete. But what in Greece was a perversion and acknowledged to be such, the Romans not only practised but held up as their ideal. No Greek, however high in birth, was ashamed to compete in person for the Olympic crown. The Roman, though little inferior in gymnastic exercises, kept strictly to the privacy of the palæstra; and for a patrician to appear in public as a charioteer is stigmatized by the satirist as a mark of shameless effrontery.

Roman games are generally classified as *fixed*, *extraordinary*, and *votive*; but for our present purpose they may be more conveniently grouped under two heads according to the place where they were held, viz., the circus or the amphitheatre.

For the Roman world the circus was at once a political club, a fashionable lounge, a rendezvous of gallantry, a betting ring, and a playground for the million. Juvenal, speaking loosely, says that in his day it held the whole of Rome; and there is no reason to doubt the precise statement of P. Victor, that in the Circus Maximus there were seats for 350,000 spectators. Of the various *Ludi Circences* it may be enough here to give a short account of the most important, the *Ludi Magni* or *Maximi*.

Initiated according to legend by Tarquinius Priscus, the *Ludi Magni* were originally a votive feast to Capitoline Jupiter, promised by the general when he took the field, and performed on his return from the annual campaign. They thus presented the appearance of a military spectacle, or rather a review of the whole burgess force, which marched in solemn procession from the Capitol to the forum and thence to the circus, which lay between the Palatine and Aventine. First came the sons of patricians mounted on horseback, next the rest of the burghers ranged according to their military classes, after them the athletes, naked save for the girdle round their loins, then the company of dancers with the harp and flute players, next the priestly colleges bearing censers and other sacred instruments, and lastly the simulacra of the gods, carried aloft on their shoulders or drawn in cars. The games themselves were fourfold:—(1) the chariot race; (2) the *ludus Troiæ*; (3) the military review; and (4) gymnastic contests. Of these only the first two call for any comment. (1.) The chariot employed in the circus was the two-wheeled war car, at first drawn by two, afterwards by four, and more rarely by three horses. Originally only two chariots started for the prize, but under Caligula we read of as many as twenty-four heats run in the day, each of four chariots. The distance traversed was fourteen times the length of the circus or nearly five miles. The charioteers were apparently from the first professionals, though the stigma under which the gladiator lay never attached to their calling. Indeed a successful driver may compare in popularity and fortune with a modern jockey. The drivers were divided into companies distinguished by the colours of their tunics, whence arose the faction of the circus which assumed such importance under the later emperors. In republican times there were two factions, the white and the red; two more, the green and the blue, were added under the empire, and for a short time in Domitian's reign there were also the gold and the purple. Even in Juvenal's day party spirit ran so high that a defeat of the green was looked upon as a second Cannæ. After the seat of empire had been transferred to Constantinople these factions of the circus were made the basis of political cabals, and frequently resulted in sanguinary tumults, such as the famous Nika revolt (532 A.D.), in which 30,000 citizens lost their lives. (2.) The Ludus Troiæ was a sham fight on horseback in which the actors were patrician youths. A spirited description of it will be found in the 5th Æneid. See also Circus.

The two exhibitions we shall next notice, though occasionally given in the circus, belong more properly to the amphitheatre. *Venatio* was the baiting of wild animals who were pitted either with one another or with men—captives, criminals, or trained hunters called *bestiarii*. The first certain instance on record of this amusement is in 186 B.C., when M. Fulvius exhibited lions and tigers in the arena. The taste for these brutalizing spectacles grew apace, and the most distant provinces were ransacked by generals and proconsuls to supply the arena with rare animals—giraffes, tigers, and crocodiles. Sulla provided for a single show 100 lions, and Pompey 600 lions, besides elephants, which were matched with Gætulian hunters. Julius Cæsar enjoys the doubtful honour of inventing the bull-fight. At the inauguration of the Colosseum 5000 wild and 4000 tame beasts were killed, and to commemorate Trajan's Dacian victories there was a butchery of 11,000 beasts. The *naumachia* was a sea fight, either in the arena, which was flooded for the occasion by a system of pipes and sluices, or on an artificial lake. The rival fleets were manned by prisoners of war or criminals, who often fought till one side was exterminated. In the sea fight on Lake Fucinus, arranged by the emperor Claudius, 100 ships and 19,000 men were engaged.

But the special exhibition of the amphitheatre was the *munus gladiatorium*, which dates from the funeral games of Marcus and Decimus Brutus, given in honour of their father, 264 B.C. It was probably borrowed from Etruria, and a refinement on the common savage custom of slaughtering slaves or captives on the grave of a warrior or chieftain. Nothing so clearly brings before us the vein of coarseness and inhumanity which runs through the otherwise noble character of the Roman, as his passion for gladiatorial shows. We can fancy how Pericles, or even Alcibiades, would have loathed a spectacle that Augustus tolerated and Trajan patronized. Only after the conquest of Greece we hear of their introduction into Athens, and they were then admitted rather out of compliment to the conquerors than from any love of the sport. In spite of numerous prohibitions from Constantine downwards, they continued to flourish even as late as St Augustine. To a Christian martyr, if we may credit the story told by Theodoret and Cassiodorus, belongs the honour of their final abolition. In the year 404 Telemachus, a monk who had travelled from the East on this sacred mission, rushed into the arena and endeavoured to separate the combatants. He was instantly despatched by the prætor's orders; but Honorius, on hearing the report, issued an edict abolishing the games, which were never afterwards revived. See GLADIATORS. (F. S.)

GAMES, GAMING. Looking here at these in their legal aspects, it will be seen that from very early times the law of England has attempted to exercise some control over the sports and pastimes of the people—particularly those involving an element of gambling. Certain games were either prohibited altogether, or reserved for people of some position in society. The Act 33 Henry VIII. c. 9, increasing the severity of still older enactments, deals with the whole subject in great detail, and it is interesting to notice that the reason assigned for prohibiting unlawful games was that they interfered with other exercises more useful to the state. The Act is entitled a "Bill for the maintaining artillery and the debarring unlawful games;" and it recites that, since the last statutes, "crafty persons have invented many and sundry new and crafty games and plays, as loggetting in the fields, slide-thrift, otherwise called shove-groat, as well within the city of London as elsewhere in many other and divers parts of this realm, keeping houses, plays, and alleys for the maintenance thereof, by reason whereof archery is sore decayed, and daily is like to be more and more minished, and divers bowyers and fletchers, for lack of work, gone and inhabit themselves in Scotland and other places out of this realm, there working and teaching their science, to the pursuance of the same, to the great comfort of estrangers and detriment of this realm." Accordingly penalties are declared against all persons keeping houses for unlawful games, and all persons resorting thereto. It is further provided that "no manner of artificer or craftsman of any handicraft or occupation, husbandman, apprentice labourer, servant at husbandry, journeyman or servant of artificer, mariners, fishermen, watermen, or any serving man, shall play at the tables, tennis, dice, cards, bowls, clash, coyting, loggetting, or any other unlawful game out of Christmas under the pain of xxs. to be forfeit for every time; and in Christmas to play at any of the said games in their masters' houses or in their masters' presence; and also that no manner of person shall at any time play at any bowl or bowls in open places out of his garden or orchard" (§ 16). The social evils of gambling (impoverishment, crime, neglect of divine service) are incidentally alluded to in the preamble, but only in connexion with the main purpose of the statute—the maintenance of archery. Blackstone, commenting on this and subsequent statutes, declares that "the principal ground of modern complaint is the gambling in high life" (vol. iv. c. 13), and he cites the various statutes which, up to his time, had been passed against this pernicious vice. Some of these went so far as to make the mere winning or losing of money at play a criminal offence. By the Act 18 Geo. II. c. 34 (repealed by 8 and 9 Vict. c. 109), if any man be convicted upon information or indictment of winning or losing at play or by betting at any one time £10 or £20 within 24 hours, he shall be fined five times the sum for the benefit of the poor of the parish. And the evil of gambling, *i.e.*, betting or wagering, is the ostensible object against which the later statutes on gaming are directed. A bet or wager was, however, at common law as valid as any other kind of contract, and the distinction between bets depending on gaming and bets depending on other contingencies was long retained, and has, in fact, not yet entirely disappeared. Besides the Act last mentioned, the Acts 9 Anne c. 14, 2 Geo. II. c. 28, and 13 Geo. II. c. 34 prohibited particular games.

The modern statutes are the following—8 and 9 Vict. c. 109, 16 and 17 Vict. c. 119, and 17 and 18 Vict. c. 38.

The 8 and 9 Vict. c. 109 (Act to amend the law relating to games and wagers) repeals, *inter alia*, so much of the old law of Henry VIII. as makes it unlawful to play at any mere games of skill. And it provides that, to prove any house to be a common gaming-house, it "shall be sufficient to show that it is kept or used for playing therein at any unlawful game, and that a bank is kept there by one or more of the players exclusively of the others, or that the chances of any game played therein are not alike favourable to all the players, including among the players the banker or other person by whom the game is managed, or against whom the other players stake, play, or bet." Gambling, it will be noticed, is still in this definition connected with some kind of game; the later Act, 16 and 17 Vict c. 119 (for the suppression of betting-houses), enacts that any house used for the purpose of "betting with persons resorting thereto" shall be deemed to be a common gaming-house. To return to the former Act, it provides that proof that the gaming was for money shall not be required, and that the presence of cards, dice, and other instruments of gaming shall be *prima facie* evidence that the house was used as a common gaming-house. The keeping of houses for the game of billiards is to be authorized under licence from the justices to be granted at the general licensing sessions, and the conditions are in general the same as to time of opening, &c., as those of the victuallers' licences. Any persons winning money by cheating at any game or wager shall be deemed guilty of obtaining money by false pretences. The 16 and 17 Vict. c. 119, besides bringing betting-houses within the statutory definition of gaming-houses, makes it a specific offence to publish advertisements, handbills, placards, &c., showing that any house is kept or opened for the purpose of betting. With reference to the definition of betting-house in this statute, "a place opened, kept, or used for the purpose of *the owner, occupier, &c., thereof*, betting with persons resorting thereto," it may be mentioned that it was avowedly framed for the purpose of hitting houses open to all and sundry, as distinguished from large but legally private betting-clubs like Tattersall's. The reason for this distinction, of course, is that the former are frequented mainly by a poorer class of persons, who cannot afford the luxury of gambling, and will be tempted by their losses to defraud their employers. The Act of 17 and 18 Vict. gives additional facilities for enforcing the preceding Acts, and increases the severity of the penalties. The keeper of a gaming-house may be fined up to £50 and costs, and on default of payment may be sent to gaol for twelve months. Finally, the Vagrant Act, 1873 (36 and 37 Vict. c. 38), contains the following clause: "Every person playing or betting by way of wagering or gaming on any street, road, highway, or other open and public place, or in any open place to which the public have, or are permitted to have, access, at or with any table or instrument of gaming, or any coin, card, token, or other article used as an instrument or means of gaming, at any game or pretended game of chance, shall be deemed a rogue and vagabond." The original Act of 1868, of which this is an amendment, was passed to repress the practice of playing pitch and toss in the streets, which, it seems, had grown to the dimensions of a nuisance in the colliery districts.

The general result of all these enactments may be briefly stated thus. Apart from statute, no games are unlawful in themselves. Games were originally made unlawful in the interest of the more useful military exercises which they threatened to supplant. The prohibition has been retained and extended on account of the vice of gambling, and severe penalties have been enacted against houses at which persons can play unlawful games. Betting-houses in general were brought within the definition of gaming-houses, and finally betting or gaming was prohibited in any public place. It must be admitted that these distinctions are based on a most invidious principle. Practically gambling is forbidden to the poor and connived at in the rich.

It may be asked, What games, as such, are lawful under these various statutes, and what are unlawful? The author of an excellent and amusing little work on *Gaming and Gamesters' Law*,[1] gives the following as the result of a careful examination of all the Acts. The following are lawful games:—backgammon, bagatelle, billiards, boat-races, bowls, chess, cricket, croquet, curling, dominoes, draughts, fives, football, foot-races, golf, knurr and spell, putting the stone, quoits, rackets, rowing, skittles, tennis, whist, wrestling. The following are doubtful—boxing, cudgel-playing, and single-stick. The following are absolutely unlawful—ace of hearts, basset, dice (except backgammon), hazard, lotteries (except art-union lotteries), Pharaoh (or faro), boulet (or roly poly). An Act of Geo. II., which prohibited horse-racing for prizes under £50 value, has since been repealed.

To turn now to the civil aspects of the case. Gambling apart from gaming, *i.e.*, simple wagering or betting, was not at common law illegal, and the Act of Anne did not affect wagers other than gaming wagers. In fact, the courts were constantly being called upon to enforce contracts by way of wagers, and were as constantly exercising their ingenuity to discover excuses for refusing. A writer on the law of contracts[2] discovers here the origin of that principle of "public policy" which plays so important a part in English law. Wagering contracts were rejected because the contingencies on which they depended tended to create interests hostile to the common weal. A bet on the life of the emperor Napoleon was declared void because it gave one of the parties an interest in keeping the king's enemy alive, and also because it gave the other an interest in compassing his death by unlawful means. A bet as to the amount of the hop-duty was against public policy, because it tended to expose the condition of the king's revenue to all the world. A bet between two hackney coachmen, as to which of them should be selected by a gentleman for a particular journey, was void, because it tended to expose the customer to their importunities. When no such subtlety could be invented, the law, however reluctantly, was compelled to enforce the fulfilment of a wager. Now, however, by the Act 8 and 9 Vict. c. 109, cited *supra*, all agreements by way of wager are void, and money lost on them cannot be recovered by action at law. There still remains, as hinted above, a distinction between gaming and other wagers. The 5 and 6 Will. IV. c. 41 treats securities (*e.g.*, promissory notes) given for money lost at gaming as being given for an illegal consideration; under the 8 and 9 Vict. c. 109, securities given for betting are held to be given for a *void*, or for no consideration. Thus a third person, coming into possession of a note given for a bet, would have to prove that he gave value for it if the bet was a gaming bet under the statute of Anne; if it was not a gaming bet, he would be presumed to have given consideration for it until it was actually proved that he had not.

The 8 and 9 Vict. c. 109 exempts all subscriptions, or contributions, or agreements to subscribe or contribute towards any plate, prize, or sum of money to be awarded to the winner of any lawful game. (E. R.)

GANDERSHEIM (in Eberhard's Chronicle, Gandersem), a town of Germany at the head of a circle in the duchy of Brunswick, situated on the Gande, a sub-tributary of the Weser, about 48 miles S.W. of Brunswick. It is a small place numbering, according to the census of 1875, only 2454 inhabitants; but it carries on the manufacture of linen, cigars, beet-root sugar, and beer, and possesses not only an old palace built by the dukes of Brunswick in the 16th century, but an abbey which ranks among the most famous in Germany.

The abbey of Gandersheim was founded in 856, according to Eberhard's Chronicle, by the duke Ludolf of Saxony and his wife Oda, who removed to the new domicile the nuns whom they had shortly before established at Brunshausen. Their own daughter Hathumoda was the first abbess, who was succeeded on her death by her sister Gerberga. Under Gerberga's government King Louis III. granted a privilege, by which the office of abbess was to continue in the ducal family as long as any member was found competent and willing to accept the same. Otto III. gave the abbey a market, a right of toll, and a mint; and after the bishop of Hildesheim and the archbishop of Mainz had long contested with each other about its supervision, Pope Innocent III. declared it altogether independent of both. The abbey was ultimately recognized as holding directly of the empire, and the abbess had a vote in the diet as a member of the Rhenish bench of bishops. The conventual estates were of great extent, and among the feudatories who could be summoned to the court of the abbess were the elector of Hanover and the king of Prussia. Protestantism was introduced in 1568, and Magdalena, the last Roman Catholic abbess, died in 1589; but Protestant abbesses were appointed to the foundation, and continued to enjoy their imperial privileges till 1802, when Gandersheim was incorporated with Brunswick. The last abbess was a princess of the ducal house, and kept her rank till her death. The memory of Gandersheim will long be preserved by its literary memorials. Hroswitha, the author of the famous ecclesiastical dramas, was a member of the sisterhood in the 9th century; and the rhyming Chronicle of Eberhard of Gandersheim ranks as in all probability the earliest historical work composed in Low German. The Chronicle, which contains an account of the first period of the monastery, is edited by Wieland, in *Monumenta Germ. historica* (Vernacular section, vol. ii., 1877), and has been the object of a special study by Paul Hasse, Göttingen, 1872. See also "Agii vita Hathumodæ abbatissæ Gandershemensis primæ," in J. G. von Eckhart's *Veterum monumentorum quaternio*, Leipsic, 1720; and Hase, *Mittelalterliche Baudenkmäler Niedersachsens*, 1870.

GANDIA, an ancient wall-encircled city of Spain, in the province and archbishopric of Valencia, is beautifully situated in the fertile huerta or garden of Gandia, about 3 miles from the mouth of the river Alcoy. Its most prominent buildings are a large collegiate church, a college of the Escuelas Pias, and a palace of the dukes of Gandia. There is some trade in the produce of the district, especially in fruit; and linen and silk are manufactured to a limited extent. St Francis de Borgia or Borja, third general of the Jesuit order, was duke of Gandia, and spent some years of his life there. Population about 7000.

GANDO, a kingdom of north-western Africa in the Sudan, comprising that part of the territory watered by the Quorra or Niger which extends from the Birni and Say in the N.

to Idda in the S. It was established by the Fulah or Fulatah on the dissolution of the Houssa kingdom of Katchena by the death in 1817 of Sheik Othman dan Foddie. The political unity of the various parts of the kingdom is with difficulty maintained, and the process of disintegration has begun. Among the separate districts or provinces are Libtako in the north, Yaga, Saberma, Gurma, Dendima, a great part of Yoruba with the town of Ilori, Yauri, part of Nupe or Nyffe, and part of Borgu. The chief town is Gando, situated on the Sokoto, the first considerable affluent of the Niger from the east, not far from the town of Sokoto, which is the capital of the powerful kingdom of that name. Rabba, Egga, Busah, Igbegbo, and Bida are among the more important towns. The whole Gando territory is estimated at 81,500 square miles, and its population at 5,800,000. See Barth's *Travels in Central Africa*, and Baikie, "Journey from Bida to Kano," in *Journ. Roy. Geog. Soc.*, 1867.

GANGANELLI. See CLEMENT XIV.

GANGES, a river of northern India, formed by the drainage of the southern ranges of the Himálayas. This mighty stream, which in its lower course supplies the great river system of Bengal, rises in the Garhwál state, and falls into the Bay of Bengal after a course of 1500 miles. It issues, under the name of the Bhágirathí, from an ice cave at the foot of an Himálayan snow bed near Gangotri, 10,300 feet above the level of the sea. During its earlier passage through the southern spurs of the Himálayas, it receives the Jahnavi from the north-west, and subsequently the Alaknanda, after which the united stream takes the name of the Ganges. Deo Prayág, their point of junction, is a celebrated place of pilgrimage, as is also Gangotri, the source of the parent stream. At Sukhi it pierces through the Himálayas, and turns south-west to Hardwár, also a place of great sanctity. It proceeds by a tortuous course through the districts of Dehra Dún, Sahāranpur, Muzaffarnager, Bulandshahr, and Farrukhabad, in which last district it receives the Rámgangá. Thus far the Ganges has been little more than a series of broad shoals, long deep pools, and rapids, except, of course, during the melting of the snows and throughout the rainy season. At Allahábád, however, it receives the Jumna, a mighty sister stream, which takes its rise also in the Himálayas to the west of the sources of the Ganges. The combined river winds eastwards by south-east through the North-Western Provinces, receiving the Gumti and the Gográ. The point of junction of each of these streams has more or less pretension to sanctity. But the tongue of land at Allahábád, where the Jumna and the Ganges join, is the true Prayág, *the* place of pilgrimage, to which hundreds of thousands of devout Hindus repair to wash away their sins in the sacred river. Shortly after passing the holy city of Benares, the Ganges enters Behar, and after receiving an important tributary, the Son, from the south, passes Patná, and obtains another accession to its volume from the Gandak, which rises in Nepál. Further to the east, it receives the Kusí, and then, skirting the Rájmahál hills, turns sharply to the southward, passing near the site of the ruined city of Gaur. By this time it has approached to within 240 miles, as the crow flies, from the sea. About 20 miles further on, it begins to branch out on the level country, and this spot marks the commencement of the delta, 220 miles in a straight line, or 300 by the windings of the river, from the Bay of Bengal. The main channel takes the name of the Padma or Padda, and proceeds in a south-easterly direction, past Pábná to Goalandá, above which it is joined by the Jamuná or main stream of the Brahmaputra. The vast confluence of waters rushes towards the sea, receiving further additions from the hill country on the east, and forming a broad estuary known under the name of the Meghná, which enters the Bay of Bengal near Noákháli. This estuary, however, is only the largest and most easterly of a great number of mouths or channels. The most westerly is the Húglí or Hooghly which receives the waters of a number of distributary channels that start from the parent Ganges in the neighbourhood of Murshidábád. Between the Húglí on the west and the Meghná on the east lies the delta. The upper angle of it consists of rich and fertile districts, such as Murshidábád, Nadiyá, Jessor, and the 24 Parganás. But towards its southern base, resting on the sea, the country sinks into a series of great swamps, intercepted by a network of innumerable channels. This wild waste is known as the Sundarbans, from the sundari tree, which grows in abundance in the sea-board tracts. The most important channel of the Ganges for commerce is the Húglí, on which stands Calcutta, about 90 miles from the mouth. Beyond this city, the navigation is conducted by native craft,—the modern facilities for traffic by rail, and the increasing shoals in the river, having put an end to the previous steamer communication, which plied until about 1860 as high up as Allahábád. Below Calcutta important boat routes through the delta connect the Húglí with the eastern branches of the river, both for native craft and steamers. The Ganges is essentially a river of great cities: Calcutta, Monghyr, Patná, Benares, and Allahábád, all lie on its course below its junction with the Jumna; and the ancient capitals, Agra and Delhi, are on the Jumna, higher up. The catchment basin of the Ganges is bounded on the N. by a length of about 700 miles of the Himálayan range, on the S. by the Vindhyá mountains, and on the E. by the ranges which separate Bengal from Burmah. The vast river basin thus enclosed embraces 432,480 square miles. The flood discharge of the Ganges at Rájmahal, after it has received all its important tributaries, was formerly estimated at 1,350,000 cubic feet per second. According to the latest calculations, the length of main stream of Ganges is 1540 miles, or with its longest affluent, 1680; breadth at true entrance, 20 miles; breadth of channel in dry season, 1¼ to 2½ miles; depth in dry season, 30 feet; flood discharge, 1,800,000 cubic feet per second; ordinary discharge, 207,000 cubic feet; longest duration of flood, about 40 days The average descent of the river from Allahábád to Benares is 6 inches per mile; from Benares to Calcutta, between 4 and 5 inches; from Calcutta to the sea, 1 to 2 inches. Great changes take place from time to time in the river bed, which alter the face of the country. Extensive islands are thrown up, and attach themselves to the mainland, while the river deserts its old bed and seeks a new channel, it may be many miles off. Such changes are so rapid and on so vast a scale, and the corroding power of the current on the bank so irresistible, that in Lower Bengal it is considered perilous to build any structure of a large or permanent character on the margin. Many decayed or ruined cities attest the changes in the river bed in ancient times; and within our own times the main channel which formerly passed Rájmahál has turned away from it, and left the town high and dry. 7 miles from the bank.

GANGI, a town of Italy, in the province of Palermo, and circondario of Cefalu, about 22 miles inland from the town of Cefalu. It occupies the slope of a hill on the southern flanks of the Nebrode or Monte Marone, and the ridge of the hill is crowned by a striking fortress with three towers, only one of which, however, is entire. The inhabitants, who in 1871 numbered 12,921, cultivate grain and manufacture cheese in sufficient quantities to maintain a moderate trade. Gangi Vetere or Old Gangi, in the vicinity, is identified, according to a conjecture of Cluverius, with the ancient Enguium or Engyum. The foundation of Enguium was ascribed by Diodorus Siculus and Plutarch to a Cretan settlement, and Plutarch relates that relics of Meriones and Ulysses were exhibited in his time in the town. Having sided with the Carthaginians in the Second Punic War, it was saved from the vengeance of Marcellus by the entreaties of a certain Nicias. At the close of the republic it was a municipal town, with considerable celebrity on account of the temple of the Great Mother, as Cicero calls her.

GANGOTRI, a celebrated place of Hindu pilgrimage, situated among the Himálaya Mountains, in the state of Gárhwal, on the Ganges, which is here not above 15 or 20 yards broad, with a moderate current, and not in general above 3 feet deep. The course of the river runs N. by E.; and on the bank near Gangotri there is a small temple about 8 or 10 feet high, in which are two images representing the Ganges and Bhágirathí rivers. The bed of the river adjoining the temple is divided off by the Brahmans into three basins, where the pilgrims bathe. One of these portions is dedicated to Brahma, another to Vishnu, and the third to Siva. The pilgrimage to Gangotri is considered efficacious in washing away the sins of the devotee, and ensuring him eternal happiness in the world to come. The water taken from this sacred spot is exported by pilgrims to India, and sold at a high price. It is drawn under the inspection of a Brahman, to whom a trifling sum is paid for the privilege of taking it, and the vessels are then sealed. The elevation of the temple above the sea is 10,319 feet. Long. 78° 59′ E., lat. 30° 59′ N.

GANGPUR, a tributary state of Chutiá Nágpur, Bengal, situated between 21° 47′ 5″ and 22° 32′ 20″ N. lat., and 85° 10′ 15″ and 85° 34′ 35″ E. long. It is bounded on the N. by Lohárdagá district and Jashpur state; on the E. by Singbhum district; on the S. by Bonái and Bámrá states and Sambalpur district; and on the W. by Ráipur district. Gangpur state consists of a long undulating table-land about 700 feet above the sea, sloping downwards from the higher plateau of Chutiá Nágpur to the N., and dotted with detached ranges and isolated peaks rising to a height of 2240 feet. The area is 2484 square miles. The chief products are rice, sugar-cane, oil-seeds, and tobacco, besides lac, *tasar* silk, resin, and catechu, yielded by the jungles. Diamonds and gold are occasionally found in the bed of the river Ib. Coal is known to exist, but is not worked. The population in 1872 numbered 73,637, viz., 37,751 males and 35,886 females. Of the total population 45,208, or 61·3 per cent., belong to various aboriginal hill tribes, such as Bhuiyás, Uráons, &c.; 9843, or 13·4 per cent., are semi-Hinduized aborigines; 18,349, or 24·9 per cent., are Hindus; and 231 are Mahometans. The state yields the rájá an estimated annual revenue of £2000, and pays an annual tribute to the British Government of £50.

GANGRENE. See Mortification.

GANILH, Charles (1758–1836), a distinguished political economist, was born at Allanche in Cantal, on the 6th January 1758. He was educated for the profession of law, and practised as *avocat*. During the troubled period which culminated in the taking of the Bastille on 14th July 1789, he came prominently forward in public affairs, and was one of the seven members of the permanent Committee of Public Safety which sat at the Hôtel de Ville. He was imprisoned during the Reign of Terror, and was only released by the counter-revolution of the 9th Thermidor. During the first consulate he was called to the tribunate, but was excluded in 1802. In 1815 he was elected deputy for Cantal, and finally left the chamber on its dissolution in 1823. He died in 1836. Ganilh is best known as the most vigorous defender of the mercantile school in opposition to the views of Adam Smith and the English economists. His works, though interesting from the clearness and precision with which these peculiar opinions are presented, do not now possess much value for the student of political economy. The most important are the treatises, *Des Systèmes d'Économie Politique* (1st ed., 1809; 2d ed., 1821, 2 vols.), in which the rival doctrines of economics are stated and compared, and *Théorie de l'Économie Politique, fondé sur les faits*, which introduces largely the element of statistical detail. Other works are—*Essai politique sur le revenu public des peuples de l'antiquité et du moyen âge* (2 vols., 1st ed., 1806; 2d ed., 1823); *De la Législation* (1817); and *Dictionnaire Analytique d'Économie Politique* (1st vol., 1826)—"a work," says Blanqui, "unworthy of him." A considerably higher estimate of Ganilh's merits than that given by Blanqui will be found in Kantz's laborious *Geschichtliche Entwick. d. National-Œkonomik* (sec. 85, pp. 598, 599).

GANJAM, a district of Madras, situated between 18° 18′ and 19° 40′ 30″ N. lat., and between 83° 51′ 30″ and 19° 40′ 30″ E. long, bounded on the N. by Purí district in Orissa; on the E. by the Bay of Bengal, on the S. by Vizagapatam district, and on the W. by the estates of Kalahandi, Patná, and Jáipur. The district is exceedingly mountainous and rocky, but is interspersed with open valleys and fertile plains. Pleasant groves of trees in the plains give to the scenery a greener and less Indian appearance than is usually met with in the districts to the south. The mountainous tract known as the Máliyás, or chain of the eastern *ghâts*, has an average height of about 2000 feet,—its principal peaks being Singhâráj (4,976 feet), Mahendragiri (4923), and Deodanga (4534). The chief rivers are the Rushikuliyá (with its tributary the Mahánadi), the Vamsadári, and the Lánguliyá; besides numerous mountain streams and torrents. The sea and river fisheries afford a livelihood to a considerable section of the population. The hilly region abounds in forests consisting principally of *sál*, with satin-wood, ebony, and sandal-wood in smaller quantities. The district abounds in game both large and small.

Ganjam formed part of the ancient kingdom of Kalinga. Its early history is involved in obscurity, and it was not till after the Gajapati dynasty ascended the throne of Orissa, that this tract became even nominally a part of their dominions. Owing to the nature of the country, the rising Mahometan power was long kept at bay; and it was not till nearly a century after the first invasion of Orissa that a Mahometan governor was sent to govern the Chikakol Sarkárs, which included the present district of Ganjam. In 1753 Chikakol, with the Northern Sarkárs, were made over to the French by Salabat Jang for the maintenance of his French auxiliaries. In 1759 Masulipatam was taken by an English force sent from Bengal, and the French were compelled to abandon Ganjam and their other factories in the north. In 1765 the Northern Sarkárs (including Ganjam) were granted to the English by imperial firman, and in August 1768 an English factory was founded at Ganjam, protected by a fort. The present district of Ganjam was constituted in 1802. In the earlier years of British rule considerable difficulty was experienced in administering the district. The country was continually in a state of confusion and disturbance; and on more than one occasion, the refractory large landholders had to be coerced by means of regular troops. In 1816 Ganjam was overrun by the Pindáris; and in 1836 occurred the Gúmsur campaign, when the British first came into contact with the aboriginal Kandhs, the suppression of whose practice of human sacrifice was successfully accomplished. A petty rising of a section of the Kandhs occurred in 1865, which was, however, suppressed without the aid of regular troops.

The census of 1872 gives the area at 8500 square miles, including 3359 square miles occupied by the Máliyá or mountain region, and the population at 779,112 males and 740,976 females,—total, 1,520,088 (with 4562 villages, and 341,404 houses), classified thus according to religion:—Hindus, 1,513,673; Mahometans, 4826; Christians, 1043; Buddhists or Jains, 45; "others," 501. The

Kandhs and Sauras are the aboriginal tribes inhabiting the mountains. Of the plains population two-thirds are estimated as belonging to the Urugá race, the remainder being mostly Telegus. Of the plains country, with an area of 5141 square miles, or 3,290,240 acres, about one-third is under cultivation, one-third cultivable, and one-third waste. A considerable extent of land is under cultivation in the Máliyás, but no revenue is derived from this tract. Rice forms the staple product, and is largely exported. The other crops are cereals of various sorts, pulses and oilseeds, fibres, sugar-cane (said to be the best in India), tobacco, indigo, chilies, &c. Holdings are small, and the peasantry are generally poor and in debt to the village money-lender. Five towns contain a population exceeding 5000:—Berhampur, 21,670; Parla Kimidi, 15,958; Chikakol, 15,587; Báruvá, 6739; Takkali Raghunandapuram, 5206. Ganjam town, the former administrative headquarters of the district, has a population of only 4163. The means of internal communication consist of 661 miles of road in the plains, and 323 miles of hill roads, besides a short tidal canal 9 miles long, connecting the Chilká lake with the Rushikuliyá river. Salt manufacture is a Government monopoly, yielding about £200,000 annually. The revenue has rapidly increased of late years, having advanced from £216,196 in 1860–61 to £338,705 in 1875–76. The chief receipts are the salt and land revenue, which yielded £196,396 and £117,348 respectively in 1875–76. The expense of administering the district amounted to £23,970 in 1860–61, and to £28,123 in 1875–76. For the protection of person and property there were, in 1875–76, 27 magisterial and 13 civil and revenue courts. Murder is unusually prevalent in Ganjam, no less than 26 cases having occurred in 1875. Education is backward, only about 3·3 per cent. of the population of the plains being able to read and write. In 1875 there were 334 Government or aided schools in the plains, attended by 6909 pupils, besides 17 schools in the hills, with 860 pupils.

GANNAL, Jean Nicolas (1791–1852), a distinguished French technical chemist, was born at Sarre-Louis, July 28, 1791. At the age of fourteen he was placed in a druggist's establishment, where he acquired a knowledge of chemical manipulation. In 1808 he entered the medical department of the French army, and in the campaign of 1812 he witnessed the disastrous retreat from Moscow. After the downfall of the empire he obtained a situation at the École Polytechnique in Paris, and subsequently acted as chemical assistant to Thénard. Having commenced research in industrial chemistry, he devised a method for the refining of borax, by which the price of that salt was reduced from 6 francs to 60 centimes per lb. He was the first to introduce into printing the use of elastic rollers, which he formed of a mixture of gelatin and sugar, and his process for the melting of tallow and hardening it with acids prepared the way for the manufacture of wax-candles. In 1823 he took out a patent for the making of glue and gelatin. His experiments with the latter substance demonstrated the incorrectness of the opinion, held by Darcet and others, that it possessed highly nutritive properties. He obtained one of the Montyon prizes of the Institute in 1827 for the employment of chlorine in the treatment of catarrh and phthisis, and again in 1835 for his discovery of the efficacy of injections of solutions of acetate and chloride of aluminium in preserving anatomical preparations. Turning his attention next to embalmment, he showed that it could be accomplished without mutilation of the body, and with greater economy than after the old methods, by injecting into one of the carotid arteries solutions of aluminium salts. Gannal died at Paris in 1852. The following are among his works:—

Du Chlore employé comme Remède contre la Phthise pulmonaire, 1832, 8vo, *Sur la Gélatine*, 1834 and 1836, 2 pts. 8vo; *Sur la Conservation des Parties animales*, 1836, 8vo; *Mémoire . . . sur l'Application d'un nouveau Système d'Inhumation dans les Cimitières*, 1842, 4to; *Histoire des Embaumements et de la Préparation des Pièces d'Anatomie normale*, 1837 and 1841, 8vo; *M. Gannal et M. le Docteur Pasquier*,—a pamphlet relative to the embalmment of the duke of Orleans, in which Gannal's process was not employed, 1842, 8vo; and *Lettre à l'Institut*, 1843 and *Nouvelle Lettre aux Médecins*, 1844, on embalming, 8vo.

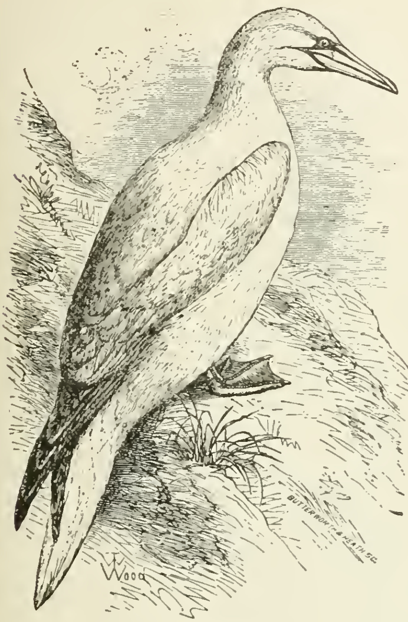
GANNAT, a town of France, capital of an arrondissement in the department of Allier, is situated on the Andelot, an affluent of the Allier, 33 miles S. by W. of Moulins. The vicinity is very pleasant, but the town is badly built and the streets are crooked and narrow. It possesses a tribunal of primary instance, a hospital, and a secondary school. There are limeworks, tanneries, cutleries, and some trade in corn, fruits, wine, and cattle. The town was formerly surrounded by walls, and what remains of its old castle is now used as a prison. The church of Sainte-Croix possesses a choir in the pure Auvergne style of the 11th century, and also some fine paintings. The population in 1876 was 5042.

GANNET (Anglo-Saxon, *ganot*) or Solan Goose,[1] the *Pelecanus bassanus* of Linnæus and the *Sula bassana* of modern ornithologists, a large sea-fowl long known as a numerous visitor, for the purpose of breeding, to the Bass Rock at the entrance of the Firth of Forth, and to certain other islands off the coast of Britain, of which four are in Scottish waters—namely, Ailsa Craig, at the mouth of the Firth of Clyde; the group known collectively as St Kilda; Suleskerry, some 40 miles north-east of the Butt of Lewis; and the Stack and Skerry, about the same distance westward of Stromness. It appears also to have two stations off the coast of Ireland, the Skellig Islands and the Stags of Broadhaven, and it resorts besides to Lundy Island in the Bristol Channel—its only English breeding-place. Further to the northward its settlements are Myggenæs, the most westerly of the Faroes, and various small islands off the coast of Iceland, of which the Vestmannaeyjar, the Reykjanes Fuglaskér, and Grimsey are the chief. On the western side of the Atlantic it appears to have but five stations, one in the Bay of Fundy, and four rocks in the Gulf of St Lawrence. On all these seventeen places the bird arrives about the end of March or in April and departs in autumn when its young are ready to fly; but even during the breeding-season many of the adults may be seen on their fishing excursions at a vast distance from their home, while at other times of the year their range is greater still, for they not only frequent the North Sea and the English Channel, but stray to the Baltic, and, in winter, extend their flight to the Madeiras, while the members of the species of American birth traverse the ocean from the shores of Greenland to the Gulf of Mexico.

Apparently as bulky as a Goose, and with longer wings and tail, the Gannet weighs considerably less. The plumage of the adult is white, tinged on the head and neck with buff, while the outer edge and principal quills of the wing are black, and some bare spaces round the eyes and on the throat reveal a dark blue skin. The first plumage of the young is of a deep brown above, but paler beneath, and each feather is tipped with a triangular white spot. The

[1] The phrase *ganotes bæð* (Gannet's bath), a periphrasis for the sea, occurs in the *Anglo-Saxon Chronicle*, in reference to events which took place 975 A.D., as pointed out by Prof. Cunningham, whose learned treatise on this bird (*Ibis*, 1866, p. 1) nearly exhausts all that can be said of its history and habits. A few pages further on (p. 13) this writer remarks:—"The name Gannet is intimately connected with our modern English Gander, both words being modifications of the ancient British 'gan' or 'gans,' which is the same word with the modern German 'Gans,' which in its turn corresponds with the old High German 'Kans,' the Greek χήν, the Latin *anser*, and the Sanskrit 'hansa,' all of which possess the same signification, viz., a Goose. The origin of the names Solan or Soland, Sulan, Sula, and Haf-sula, which are evidently all closely related, is not so obvious. Martin [*Voy. St. Kilda*] informs us that 'some imagine that the word Solan comes from the Irish Souler, corrupted and adapted to the Scottish language, *qui oculis irretortis e longinquo respiciat prædam*.' The earlier writers in general derive the word from the Latin *solea*, in consequence of the bird's supposed habit of hatching its egg with its foot; and in a note intercalated into Ray's description of the Solan Goose in the edition of his Itineraries published by the Ray Society, and edited by Dr Lankester, we are told, though no authority for the statement is given, that 'the Gannet, *Sula alba*, should be written Solent Goose, *i.e.*, a channel goose.'" Hereon an editorial note remarks that this last statement appears to have been a suggestion of Yarrell's, and that it seems at least as possible that the "Solent" took its name from the bird.

nest is a shallow depression, either on the ground itself or on a pile of turf, grass, and seaweed—which last is often conveyed from a great distance. The single egg it contains has a white shell of the same chalky character as a Cormorant's (vol. vi. p. 407). The young are hatched blind and



Gannet, or Solan Goose.

naked, but the slate-coloured skin with which their body is covered is soon clothed with white down, replaced in due time by true feathers of the dark colour already mentioned. The mature plumage is believed not to be attained for some three years. Towards the end of summer the majority of Gannets, both old and young, leave the neighbourhood of their breeding-place, and, betaking themselves to the open sea, follow the shoals of herrings and other fishes (the presence of which they are most useful in indicating to fishermen) to a great distance from land. Their prey is almost invariably captured by plunging upon it from a height, and a company of Gannets fishing presents a curious and interesting spectacle. Flying in a line, each bird, when it comes over the shoal, closes its wings and dashes perpendicularly into the waves, whence it emerges after a few seconds, and, shaking the water from its feathers, mounts in a wide curve, and orderly takes its place in the rear of the string, to repeat its headlong plunge so soon as it again finds itself above its prey.[1]

[1] The large number of Gannets, and the vast quantity of fish they take, has been frequently animadverted upon, but the computations on this last point are perhaps fallacious. It seems to be certain that in former days fishes, and herrings in particular, were at least as plentiful as now, if not more so, notwithstanding that Gannets were more numerous. Those frequenting the Bass were reckoned by Macgillivray at 20,000 in 1831, while in 1869 they were computed at 12,000, showing a decrease of two-fifths in 38 years. On Ailsa in 1869 there were supposed to be as many as on the Bass, but their number was estimated at 10,000 in 1877 (*Report on the Herring Fisheries of Scotland*, 1878, pp. xxv. and 171),—being a diminution of one-sixth in eight years, or nearly twice as great as on the Bass.

Structurally the Gannet presents many points worthy of note, such as its closed nostrils, its aborted tongue, and its toes all connected by a web—characters which it possesses in common with most of the other members of the group of birds (*Steganopodes*) to which it belongs. But more remarkable still is the system of subcutaneous air-cells, some of large size, pervading almost the whole surface of the body, communicating with the lungs, and capable of being inflated or emptied at the will of the bird. This peculiarity has attracted the attention of several writers—Montagu, Professor Owen (*Proc. Zool. Soc.*, 1831, p. 90), and Macgillivray; but a full and particular account of the anatomy of the Gannet is still to be desired.

In the southern hemisphere the Gannet is represented by two nearly allied but somewhat smaller forms—one, *Sula capensis*, inhabiting the coast of South Africa, and the other, *S. serrator*, the Australian seas. Both much resemble the northern bird, but the former seems to have a permanently black tail, and the latter a tail the four middle feathers of which are blackish-brown with white shafts.

Apparently inseparable from the Gannets generically are the smaller birds well known to sailors as Boobies from the extraordinary stupidity they commonly display. They differ, however, in having no median stripe of bare skin down the front of the throat; they almost invariably breed upon trees, and are inhabitants of warmer climates. One of them, *S. cyanops*, when adult has much of the aspect of a Gannet, but *S. piscator* is readily distinguishable by its red legs, and *S. leucogaster* by its upper plumage and neck of deep brown. These three are widely distributed within the tropics, and are in some places exceedingly abundant. The fourth, *S. variegata*, which seems to preserve throughout its life the spotted suit characteristic of the immature *S. bassana*, has a much more limited range, being as yet only known from the coast of Peru, where it is one of the birds which contribute to the formation of guano. (A. N.)

GANS, EDWARD (1798–1839), a distinguished jurist, was born at Berlin, on the 22d March 1798. His father, a banker in Berlin, was of Jewish descent. He was educated first at Berlin, then at Göttingen, and finally at Heidelberg, where he met Thibaut, the celebrated lawyer, and Hegel, by whom he was much attracted. He attended Hegel's lectures at Berlin and became thoroughly imbued with the principles of the Hegelian philosophy. In 1825 he travelled for some months in England and France, and on his return was named professor extraordinarius at Berlin. At this period the historical school of jurisprudence was coming to the front, and Gans, already, from his Hegelian tendencies, predisposed to treat law historically, applied the method to one special branch of legal relations—the right of succession. His great work, *Erbrecht in weltgeschichtlichen Entwicklung* (4 vols. 1825, 1825, 1829, and 1835), is still of permanent value, not only on account of its extensive survey of facts, but through the admirable manner in which the general theory of the slow evolution of legal relations is presented. In 1830, and again in 1835, Gans visited Paris, and formed an intimate acquaintance with the knot of brilliant writers and lecturers, Cousin, Villemain, Michelet, and Quinet, who then made Paris the centre of literary culture and criticism. The liberality of his views, especially on political matters, drew upon Gans the displeasure of the Prussian Government, and in 1835 his course of lectures on the history of the last fifty years, afterwards published (*Vorlesungen über d. Geschichte d. letzten fünfzig Jahre*), was prohibited. He died at Berlin in 1839. In addition to the works above mentioned, there may be noted the treatise on the right of possession (*Ueber die Grundlage des Besitzes*, 1829), a portion of a systematic work on the Roman civil law (*System der Römischen Civil-rechts*, 1827), and a collection of his miscellaneous writings (*Vermischte Schriften*, 1832). Gans edited the *Philosophie der Geschichte* in Hegel's *Werke*, and contributed an admirable preface.

See on the life and works of Gans, *Revue de Deux Mondes*, Dec. 1839.

GÄNSBACHER, JOHANN BAPTIST (1778–1844), a musical composer of repute, was born in 1778 at Sterzing in Tyrol. His father, a schoolmaster and teacher of music, undertook his son's early education, which the boy continued under various masters till 1802, when he became the pupil of the celebrated Abbate Vogler. To his connexion with this artist and with his fellow pupils, more perhaps than to his own merits, Gänsbacher's permanent place in the history of music is due; for it was during his second stay with Vogler, then (1810) living at Darmstadt, that he became acquainted with Weber and Meyerbeer, who had also been attracted by the abbate's reputation, and the close friendship which sprang up among the three young musicians, and was dissolved by death only, has become celebrated in the history of their art. But although Gänsbacher owes the greater part of his reputation to this circumstance, he was himself by no means without merit. He creditably filled the responsible and difficult post of director of the music at St Stephen's Cathedral, Vienna, from 1823 till his death (July 13, 1844); and his compositions betray the musician of high gift and accomplishment. They consist chiefly of church music, not less than 17 masses, besides litanies, motets, offertories, &c., being amongst the number. He also wrote several sonatas, a symphony, and one or two minor compositions of a dramatic kind.

GANYMEDE (Greek, Γαννμήδης, Latin, *Ganymedes*) affords a typical example of the manner in which myth-making continued as a living process through the whole of Greek history. In the thought of the primitive Indo-Germanic race, occupied with the simplest cares of living, a very frequent subject was naturally the rain; and their thought has been preserved to us in the form of mythology. As the rain descends to earth it is the chief blessing to men, while in the clouds it gladdens the dwellers there. Hence arises the idea of a drink for the gods—the soma of the Hindus, the meth of the Norsemen, and the nectar of the Greeks—which plays such an important part in the *Rig Veda*, the *Edda*, and the Homeric poetry. The guardian and giver of the divine drink occurs in many forms, sometimes as a bird, sometimes as a divine being. Just as the eagle brings nectar to Zeus in Crete, so Odin takes the form of an eagle to steal the meth from Guttung for the use of the gods. The same divinity that in heaven distributes the drink to the gods is on earth the genius that presides over the due supply of water. Hence among the Greeks Ganymede, as this genius is called, exists in heaven as the Aquarius of the zodiac (Hyginus, fab. 224), while on earth he is, as Pindar (fr. 267 [110]) tells us, the genius of the fountains of the Nile, which was *par excellence* the life-giving and fertilizing river of the earth.

But the form under which the Ganymede myth most commonly appears has its origin in Asia Minor and in Crete. Homer (*Il.*, xx. 232) says that Ganymede was a son of Tros, and that the gods on account of his beauty carried him off to heaven to dwell among the immortals and pour out the wine for Zeus. The *Little Iliad* again makes him the son of Laomedon, and says that Zeus gave his father a golden vine in exchange for him. In the Trojan Ganymede there is not much trace left of the old kindly genius who distributes the blessing out of the clouds. We may indeed, when we remember that the Greeks admired personal beauty as almost divine (*cf.* Hdt., v. 47), be able to see in this translation the good genius returning alive to heaven after his sojourn on earth, an idea that occurs in the mythology of almost every race. But now he seems rather to represent the everlasting youth and beauty that attend on the gods, and to be the male counterpart of Hebe, who was worshipped in Phlius under the name Ganymeda (Pausanias, ii. 13). More and more the myth grows away from its earliest form, and as Greek manners altered the darkest side of their social system attached itself to it. Through the Ionian Greeks the Asiatic custom of secluding women had spread to the mother country and superseded the old heroic manners. The presence of women at meal-times, customary in the time of Homer (*Od.*, iv. 221), was now discontinued. Beautiful young male slaves waited at banquets, and the feeling grew that the gods also observed this custom. Ganymede was now conceived as the favourite of Zeus. So early as the Hymn to Aphrodite, Zeus himself carries off Ganymede on account of his beauty; and Theognis (about 500 B.C.) speaks of the love of Zeus for Ganymede as a well-known tale. In Crete especially, where the love of boys was systematized and legalized, and from which the habit spread over the whole of Greece, does the myth find nourishment and growth. On the one hand, Zeus was represented to have himself, in the form of an eagle, carried off Ganymede; on the other hand, it was said that Minos, the primitive ruler and lawgiver of Crete, had been the ravisher of Ganymede. In this way it was attempted to give dignity and antiquity to a borrowed and loathsome custom. The rapidity with which the habit spread all over Greece makes the mythical embodiment of it fill an important place in the painting, sculpture, and literature of Greece in its decline. Thus it comes that the name which once denoted the good genius that gives the best gifts to man was adopted in the vulgar Latin under the form Catamitus to signify the most degraded of men (on this subject *v.* Böttiger, *Kunst-Mythol.*, ii. 35, 61).

It is significant that in Greek art not one very early representation of the myth occurs (Overbeek, *Kunst-Mythologie*, p. 515); but in the middle and later periods it becomes a favourite subject. Two moments especially are represented—(1) Ganymede carried off by the eagle, where the eagle is sometimes Zeus's messenger, but at other times obviously Zeus himself, as is shown by the sensual passion apparent in both figures (Jahn, *Archæolog. Beiträge*, p. 20), and (2) Ganymede feeding or caressing the eagle.

Besides Preller's and Jacobi's elaborate works, see Kuhn, *Herabkunft des Feuers*; Braun, *Naturgesch. der Sage*; Hartung, *Religion u. Myth. der Griechen*; Schwartz, *Ursprung der Myth.*; and on the derivation of the name see Kuhn's *Zeitsch.*, ii. and v.

GAP (the ancient *Vapincum*), a town of France, capital of an arrondissement and also of the department of Hautes Alpes, is situated on the right bank of the Luye, 46 miles S.E. of Grenoble. It stands in a wide valley about 2400 feet above sea-level, and is surrounded by an amphitheatre of hills, over which tower the snow-covered mountains of the Alps. In the vicinity are fine walnut avenues and vineyards, but the town, with the exception of a few modern houses, is badly built and has a somewhat miserable appearance. The chief public buildings are the Gothic cathedral, containing the tomb of the celebrated Constable de Lesdiguières, the court-house, the town-hall, the bishop's palace, the barracks, and the theatre. In 1866 a statue in black marble was erected in front of the barracks to Baron de Ladoucette, a former prefect of the Hautes Alps. Gap is the seat of a court of primary jurisdiction, and has a communal college, a diocesan seminary, a public library, and a museum of antiquities, natural history, botany, and geology. The manufactures comprise woollen, linen, and silk goods, leather, and dressed skins. In the vicinity are some marble quarries, which were known to the Romans. The town became the seat of a bishopric in the 4th century, and its bishops were for a long period styled princes and counts of Gap. In former times it suffered greatly from the devastations of the Lombards and Moors, from the plague, and from earthquakes; and in 1692 it was almost burned to the ground by Duke Victor Amadeus of Savoy. The population in 1876 was 7249.

GARAT, DOMINIQUE JOSEPH (1749–1833), was born at Bayonne, 8th September 1749. After receiving a good education under the direction of a relation who was a curé, he came to Paris, where he obtained introductions to the most distinguished writers of the time, and became a contributor to the *Encyclopédie Méthodique* and the *Mercure de France.* He gained considerable reputation by an éloge on L'Hôpital in 1778, and was afterwards three times crowned by the Academy for éloges on Suger, Montausier, and Fontenelle. In 1785 he was named professor of history at the Athenæum, where his lectures enjoyed an equal popularity with those of Laharpe on literature. Being chosen a deputy to the states-general in 1789, he rendered important service to the popular cause by his narrative of the proceedings of the Assembly contributed to the *Journal de Paris.* Possessing strongly optimist views, a mild and irresolute character, and indefinite and changeable convictions, he played a somewhat undignified part in the great political events of the time, and became a pliant tool in carrying out the designs of others. He succeeded Danton as minister of justice in 1792, and in this capacity had entrusted to him what he called the *commission affreuse* of communicating to Louis XVI. his sentence of death. In 1793 he became minister of the interior, and during the Reign of Terror he was imprisoned, but he received his liberty after the revolution of the 9th Thermidor, and was named minister of public instruction. In 1798 he was appointed ambassador to Naples, and in the following year he became a member of the Council of the Ancients. After the revolution of the 18th Brumaire, he was chosen a senator by Napoleon and created a count. During the Hundred Days he was a member of the chamber of representatives, and strongly opposed the recall of the Bourbons. In 1803 he was chosen a member of the Institute of France, but after the restoration of Louis XVIII. his name was, in 1816, deleted from the list of members. After the revolution of 1830 he was named a member of the new Academy of Moral and Political Science. He died at Ustaritz near Bayonne, April 25, 1853. His writings are characterized by elegance, grace, and variety of style, and by the highest kind of rhetorical eloquence; but his grasp of his subject is superficial, and as his criticisms have no root in fixed and philosophical principles they are not unfrequently whimsical and inconsistent. He must not be confounded with his elder brother Dominique (1735–1799), who was also a deputy to the states-general.

The works of Garat include, besides those already mentioned, *Considérations sur la Révolution française*, Paris, 1792; *Mémoires sur la Révolution, ou Exposé de ma conduite*, 1795; *Mémoires sur la vie de M. Suard, sur ses écrits, et sur le XVIII^me siècle*, 1820; éloges on Joubert, Kléber, and Desaix; several notices of distinguished persons; and a large number of articles in periodicals.

GARAT, PIERRE-JEAN (1764–1823), one of the most famous singers of his time, nephew of the former, was born at Ustaritz, 25th April 1764. Gifted with a voice of exceptional timbre and compass, he devoted himself, from an early age, to the cultivation of his musical talents. On account of his manifesting a distaste for the legal profession, for which his father wished him to study, he was deprived of his allowance, but he obtained through the patronage of a friend the office of secretary to Comte d'Artois, and was afterwards engaged to give musical lessons to the queen of France. After the Revolution he became a professional singer, and on account of a song which he had composed in reference to the misfortunes of the royal family he was thrown into prison. On regaining his liberty he went to Hamburg, where he at once achieved extraordinary success; and by his subsequent appearances in Paris, and his visits to Italy, Spain, Germany, and Russia, he made for himself a reputation as a singer unequalled by any other of his own time. He was a keen partisan of the composer Gluck in opposition to Handel. On the institution of the Conservatoire de Musique, he became its professor of singing. He is also the composer of a number of songs, many of which have considerable merit. He died 1st March 1823.

GARAY, JÁNOS (1812–1853), Hungarian poet and author, was born 10th October 1812, at Szegszárd, in the county of Tolna. From 1823 to 1828 he studied at Fünfkirchen, and subsequently, in 1829, at the university of Pesth. Here, having become acquainted with the works of the best German authors, he devoted himself to literary pursuits, and in 1834 brought out an heroic poem, in hexameters, under the title *Csatár.* After this he issued in quick succession various historical dramas, among which the most successful were *Arbócz*, *Ország Ilona*, and *Báthori Erzsébet*,—the first two published at Pesth in 1837, and the last in 1840. From 1833 to 1836 Garay was, moreover, associated with the literary journal *Regélö* (Taleteller), and in 1837 assisted in the editorship of the periodical *Rajzolatok* (Sketches). At the beginning of 1838 he removed to Presburg, where he was for some time engaged in editing the political journal *Hirnök* (Herald). He returned to Pesth in 1839, when he was elected a corresponding member of the Hungarian Academy of Sciences. In 1842 he was admitted into the Kisfaludy Society, of which he became second secretary. Garay enriched Hungarian literature with numerous lyrical poems, ballads, and tales. The first collection of his poems was published at Pesth in 1843; and his prose tales appeared in 1845, under the title of *Tollrajzok* (Sketches with the Pen). His historical ballads and legends, styled *Arpádok*, Pesth, 1847 (2d ed. 1848), showed him to be a master in the art of ballad writing. Some of his lyrical poems also are excellent, as, for example, *Balatoni Kagylók* (Shells from the Balaton Lake), Pesth, 1848. His legend *Bosnyák Zsófia*, Pesth, 1847, as also his poetical romance *Frangepán Kristófné* (Christopher Frangepan's Wife), Pesth, 1846, gained the prize of the Kisfaludy Society. His last and most famous work was an historical poem in 12 cantos, with the title *Szent László* (Saint Ladislaus), Eger, 1852 (2d ed. Pesth, 1853, 3d ed. 1863). In 1848 Garay was nominated professor of Hungarian language and literature to the university of Pesth, but in the following year he resigned that post. In 1850 he became enfeebled in health, and at length unfit for further literary efforts. After about four years' illness, he died on the 5th November 1853, in great want, in the forty-second year of his age. A collective edition of his poems was published at Pesth the year after his death by F. Ney (2d ed. 1860), and several of his poems have been translated by Kertbeny.

See *Garay János összes költeményei*, 2d ed., Pesth, 1860; and *Dichtungen von Johann Garay*, 2d ed., Vienna, 1856.

GARBO, RAFFAELLINO DEL (1466–1524), a Florentine painter. His real name was Raffaello Capponi; Del Garbo was a nickname, bestowed upon him seemingly from the graceful nicety (*garbo*) of his earlier works. He was a scholar of Filippino Lippi, with whom he remained till 1490, if not later. He showed great facility in design, and excited hopes which the completed body of his works fell short of. He married and had a large family; embarrassments and a haphazard manner of work ensued; and finally he lapsed into a very dejected and penurious condition. Three of his best tempera pictures are in the Berlin Gallery; one of the Madonna standing with her Infant between two musician-angels, is particularly attractive. We may also name the oil-painting of the Resurrection done for the church of Monte Oliveto, Florence, now in the academy of the same city, ordinarily reputed to be Raffaellino's masterpiece: the ceiling of the Caraffa Chapel in the church of the Minerva, Rome; and a Coronation of the Virgin in the Louvre, which is a production of much merit, though with somewhat over-studied grace. Angelo Allori was his pupil.

GARÇAO, PEDRO ANTONIO CORREA (1724–1772), Portuguese lyric and dramatic poet, was born in the neighbourhood of Lisbon on the 24th of April 1724. Almost nothing of his biography is known except that he lived a life of quiet domesticity and learned leisure, in a rural retreat at Fonte-Santa near the capital, till about his thirty-sixth year, when he was imprisoned on an obscure charge which is believed to have arisen out of some expressions in his writings that had given offence to a despotic Government. After languishing in confinement for eighteen months, he was released by death on the 10th of November 1772. His works, which include sonnets, odes, satires, and epistles, as well as dramatic pieces, were published for the first time in a collected form in 1778 (*Obras poeticas de P. A. C. Garçao*), and are regarded by the Portuguese as having marked a period of revival in their national literature. While, however, in an age of great degeneracy he succeeded in exhibiting purity and refinement of taste, he cannot be said to have given any indications of an original or powerful genius. His dramas are confessedly imitations from foreign models; while his odes, epistles, and satires, which have earned for him the title (shared by Ferreira) of "the Portuguese Horace," at once reveal the source of their inspiration. His endeavour, moreover, occasionally to approach the classic style more nearly by substituting quantity for rhyme can hardly be regarded as very successful.

GARCIA, MANOEL (1775–1832), or, in full, Manoel Garcia del Popolo Vicente, was born in 1775 at Seville. He began artistic life as chorister at the cathedral of Seville, and simultaneously studied music under the best masters of his native city. At the age of seventeen he made his début on the stage at Cadiz, in an operetta of his own composition. Soon afterwards he appeared at Madrid in his twofold capacity of singer and composer. His reputation being thus established, he proceeded to Paris, where he appeared for the first time, in 1808, in Paer's opera *Griselda.* Here also he was received with great applause, his style of singing being especially appreciated. This he further improved by careful study of the Italian method in Italy itself, where he continued his successes. His opera, *The Caliph of Bagdad*, was favourably received at Naples in 1812, but his chief successes were again due to his perfection as a vocalist. In 1824 he went to London, and thence proceeded to America (1825) with a company of excellent artists, amongst whom were his son Manoel and his daughter Maria, better known under her subsequent name of Malibran. He extended his artistic tour as far as Mexico, and was on the point of returning to Europe in order to retire from public life, when he was robbed of his well-earned wealth by brigands on his way to Vera Cruz. Settled again in Paris he soon retired from the stage, and devoted himself exclusively to teaching. He died in 1832. His method of teaching was unsurpassed, and some of the most celebrated singers of the early part of the century were amongst his pupils. He also wrote an excellent book on the art of singing called *Metodo di canto.* Amongst his pupils were his children (already mentioned), who, as well as his daughter Paulina, worthily continued his name in the musical world.

GARCILASO DE LA VEGA (1503–1536), soldier and poet, was born at Toledo in 1503. His father, Garcilaso (Garcias Laso or Garcilasso) de la Vega, was counsellor of state to Ferdinand and Isabella, and for some time their ambassador at the court of Rome; by his mother he was descended from the illustrious house of Guzman. At the age of seventeen he received a military appointment as a "contino" or guardsman to Charles V., and in that capacity took part in the war against the insurgent comuneros, having been present at the battle of Olias near Toledo, where he received a wound in the face. He afterwards served in the north of Italy, and gained great distinction by his bravery, particularly at the battle of Pavia in 1525. His marriage with a lady of the household of Queen Eleanor, which took place in the following year, suspended only for a very short time his activity in military and diplomatic employments; he took part in the repulse of the Turks from Vienna in 1529, was present at the splendid ceremonial connected with the coronation of the emperor at Bologna in 1530, and was charged with a secret mission to Paris in autumn of the same year. In 1531 he accompanied the duke of Alva to Vienna, where, for having been in some way privy to the clandestine marriage of his nephew to one of the ladies of the court, he was imprisoned for some months on an island in the Danube. It was during this captivity that he composed the fine "cancion" commencing "Con un manso ruido de agua corriente y clara." Released and restored to favour in June 1532, he at once went to Naples on the staff of Don Pedro de Toledo, the newly-appointed viceroy, by whom he was twice sent on public business of importance to Barcelona, in 1533 and in 1534. After having accompanied the emperor on his Tunis expedition in 1535, where he fought bravely and received two severe wounds, he was employed as a confidential agent at Milan and Genoa in negotiations connected with the proposed invasion of Provence, and afterwards joined the expedition itself when it took the field. Being with Charles in the neighbourhood of Fréjus during the retreat from Marseilles, Garcilaso de la Vega was ordered to silence a small fort at the village of Muy, which had been harassing the movements of the army. In the successful discharge of this duty he received a wound on the head which, twenty-one days afterwards, at Nice, proved fatal (October 14, 1536). His literary remains, few in number, but destined to exert a powerful influence on the subsequent development of the poetry and general literature of his native country, were committed to the charge of his friend Boscan, who was preparing them for publication along with his own when death overtook him in 1540. The volume ultimately appeared at Barcelona in 1543, and has often been reprinted. Garcilaso's share in it consists principally of three *eglogas* or pastorals, which the Spaniards regard as among the finest works of the kind in their language, and which for sweetness of versification and delicacy of expression take a high rank in modern European literature. In addition to the pastorals, there are thirty-seven sonnets, five canciones, two elegies, and an epistle in versi sciolti, in all of which the influence of Boscan is plainly felt, as well as that of the Italian models whom both poets avowedly imitated, Petrarch, Bembo, Ariosto, and Sannazaro. The poems rapidly gained a wide popularity; and within a century of their appearance they had been edited and commented on as classics by Sanchez, Herrera, and Tamayo de Vargas. "Imitated by Lope de Vega in every possible way, praised more and cited oftener than any other poet by the genius of Cervantes, Garcilaso de la Vega has come down to us enjoying a general national admiration such as is given to hardly any other Spanish poet, and to none that lived before his time" (Ticknor). An English translation of his works was published by Wiffen in 1823.

GARCILASO INCA DE LA VEGA (1540–1616), historian of ancient Peru, was born at Cuzco in 1540. His father was a cadet of the illustrious family of La Vega, who had gone to Peru in the suite of Pedro de Alvaredo, soon after the conquests of Pizarro; his mother was of the Peruvian blood-royal, a circumstance of which he was not a little proud, as giving a right to the title which he claimed by invariably subscribing himself "Inca." In 1560 he removed to Spain, and, having entered the military service, was engaged in the wars against the Moors and Turks. Disappointed in the inadequate recognition of his services by the crown, he retired while still a young man into private life at Cordova, where he gave himself to literature, and produced the learned historical work by which he is now known, the *Comentarios Reales que tratan del Origen de los Yncas, reyes que fueron del Peru, de su Idolatria, Leyes, &c.; con la Historia general de Peru.* The first part was published in 1609, and the second within a few months of his death, which occurred in 1616. His thorough acquaintance with the language and traditions of his maternal ancestors gave his work an altogether peculiar value. It is, accordingly, the source from which all subsequent writers on the subject have most largely drawn, and still continues to be the chief original authority upon ancient Peru. An inaccurate English translation was published by Sir Paul Rycaut in 1688. There is also a French translation, which was published in 1727.

GARD, a department in the south of France, consisting of part of the old province of Languedoc, is bounded N. by the departments of Lozère and Ardèche, E. by the Rhone, which separates it from Vaucluse and Bouches-du-Rhône, S. by Hérault and the Mediterranean, and W. by Aveyron. It lies between 43° 27′ 25″ and 44° 27′ 20″ N. lat., and between 3° 15′ 39″ and 4° 50′ 44″ E. long. The western and northern districts of the department are occupied by the range of the Cévennes, which on the frontier of Lozère attain a height of 5120 feet. The whole of this region is celebrated for its fruitful valleys, its gorges, its beautiful streams, its vines, and its chestnut, mulberry, and other fruit trees, with which the mountains are often clothed to their summits. From the Cévennes the land gradually declines to the Rhone and Mediterranean. The southern portion, which extends to the sea, and was probably at one time covered by it, is a low plain with numerous lakes and marshes. Besides the Rhone, which bounds the department on the E., and the Ardèche, the lower portion of which forms part of its boundary on the N., the principal rivers are the Cèze, Gard, Vidourle, and Hérault. The most northern of these is the Cèze, which rises in the Cévennes, and after a course of about 50 miles in an E.S.E. direction falls into the Rhone below Bagnols. The Gard, or Gardon, from which the department takes its name, is also an affluent of the Rhone, and rising in the Cévennes from several sources, traverses the centre of the department, having a length of about 60 miles. In the upper part of its course it flows through a succession of deep mountain gorges, and from the melting of the snows on the Cévennes is subject to inundations, which often cause great damage. Its waters not unfrequently rise 18 or 20 feet in a few hours, and its bed is sometimes increased in width to nearly a mile. The Vidourle flows in a S.S.E. direction from its source near Le Vigan, and after a course of about 50 miles falls into the sea. Below Sommières it forms the western boundary of the department. The Hérault has its source and part of its course in this department. The Canal de Beaucaire extends from the Rhone at the town of that name to Aigues Mortes, which communicates with the Mediterranean by means of the Grand-Roubine canal. The climate is generally very mild but is rather changeable, and cold and violent storms of wind are not uncommon. The department is rich in minerals, which constitute one of the chief sources of its wealth. Iron, coal, and argentiferous lead mines are extensively worked; and manganese, zinc, and antimony are found. Great quantities of salt are obtained from the salt marshes along the coast. The gypsum and other quarries employ a considerable number of workmen. The fisheries are very productive. The manufactures are extensive, and include silk, cotton, and woollen fabrics, ironware, hats, gloves, paper, leather, earthenware, and glass. The chief grain crops are wheat, oats, rye, and barley. Lentils, pease, and potatoes are also grown. Gard is famed for its cattle, its breed of small horses, and its sheep, the wool of which is of a very fine quality. The principal fruit trees are the olive and mulberry. The vine is extensively cultivated, and yields excellent red and white wines. Gard is divided into the arrondissements of Nîmes, Alais, Uzès, and Le Vigan, with 38 cantons and 347 communes. The chief town is Nîmes. The total area is 2256 square miles, and the population in 1866 was 429,747, and in 1876 423,804.

GARDA, LAKE OF, the Italian LAGO DI GARDA and ancient *Benacus*, the largest and most eastern of the great lakes of northern Italy. It is enclosed by Alpine ridges on both sides, except towards the south, where it widens out into the Lombard plain. The northern extremity belongs to the Austrian district of Tyrol, while the remainder is divided between the two old Italian provinces of Venetia and Lombardy. The length of the lake is about 38 miles; its width varies from 2 or 3 miles in the north to 11 or 12 in the south; and its area is estimated at 135 square miles. The ordinary elevation of the surface above the level of the sea is 320 feet, but this is increased by 3 or 5 feet by the melting of the Alpine snows at the beginning of summer. The greatest depths are about 900 or 1000 feet. At the northern extremity it receives the waters of the Sarca, a comparatively small Tyrolese stream, and at the south-eastern corner, at Peschiera, its surplus is conveyed by the Mincio to the Po. Navigation on the one hand is frequently rendered dangerous by sudden bursts of storm, while on the other hand it is facilitated by the two regular winds called the Ora or Andar and the Sover, of which the former blows from the south from midday to midnight, and the latter from the north from midnight to midday. Especially in its southern quarters, the lake is very rich in fish, the more important species being the salmon-trout, the carpione (*Salmo punctatus*), the trout, the sardina (*Alausa vulgaris*), the eel, and the arvole. The principal towns and villages along the Riviera or western side of the lake are—Desenzano, in the south; Salo, with 4500 inhabitants; Maderno, with 1500 inhabitants; Toscolano, with 2000, famous for its paper-mills, introduced in 1386; Gargnano, with 4000; Limone; and Riva, at the northern extremity, with about 6000. Proceeding south along the eastern side we find Torbole, Malcesine, Torri, Garda, which gives its name to the lake, Lacize, and Peschiera. Desenzano and Torri are the chief seats of the fish trade. Steamers ply regularly from Desenzano to Riva, and from Riva to Peschiera. The scenery of the Garda is not so fine as that of the Lake of Como, but it is remarkable for the luxuriance of the vegetation, especially on the beautiful promontory of Sirmione, which projects from the southern shore, and still contains the ruins of the villa once inhabited by Catullus. The lemon ripens its fruit at several places round the lake, though the trees require to be carefully covered, and even artificially warmed, during the frosts. The whole number is estimated at about 18,000, and each may produce about 1000 lemons.

The lake was well known to the Romans as Benacus (Βήνακος), and its storms are described by Virgil in the familiar line—

"*Fluctibus et fremitu assurgens, Benace, marino.*"

In several ancient inscriptions the name Benacenses occurs; and some antiquaries on no more authority have supposed that there must have been a town of its own name on the lake. According to a not improbable hypothesis there was formerly a navigable channel from the Adriatic to the Benacus; and we know from inscribed stones preserved in the Museo Filarmonico of Peschiera (the ancient *Ardelica*) that a rich corporation of shipowners existed in the town (*Collegium naviculariorum Ardelicensium*). If such a passage to the sea was available in the later Roman period, it must at least have disappeared before the end of the 15th century; for when in 1438 the Venetians wished to bring their vessels from the Adige to the lake they conveyed them overland from the neighbourhood of Mori to Torbole. This Herculean undertaking was proposed by Blasio de Arboribus and Nicolo Sorbolo, and it was successfully accomplished at a cost of 15,000 ducats. As early as 1827 a steamboat of 28 horse-power, the "Arciduca Ranieri," was launched on the lake at Desenzano by a Milan company; and in 1834 it was superseded by another of 18 horse-power. In 1830 Francesco Montagni of Riva built a boat, the "Manubrio," the machinery of which was moved by 8 horses going round and round on the deck; but in 1839 he gave it up as unprofitable. In 1873 there were four steamboats on the lake in the service of the railway company of Upper Italy, besides thirty-one vessels with a total tonnage of about 400 tons, and about 500 fishing boats. The Italian Government also maintained four gunboats at Peschiera.

See Dal Pozzo, *Lago, Fortezza, e Rocca di Garda e Gardesana*, Verona, 1678; Volta Serafino, *Descrizione del Lago di Garda*, Mantua, 1828; Ercolani, *Guida al Lago di Garda*, Milan, 1846; Bignami, *Il Lago di Garda*, Milan, 1873.

GARDAIA, or GHARDAYA (in the local documents Taghardeit), a town of North Africa in the Algerian Sahara, situated on a hill in the middle of the Wadi Mezab, on the route between Morocco and Tripoli, about 36 miles W.N.W. of Wargla, in 32° 28′ N. lat., and 4° 39′ E. long., at a height of 1755 feet above the sea-level. Gardaia is well built of limestone, and defended by a bastioned wall pierced with seven gates. There is a Jewish quarter inhabited by about 200 families who hold a large part of the industry of the town in their hands; but the principal inhabitants are the Beni Mezab, who speak the *awal domsab*, a dialect of the Berber language slightly modified by Arabic. According to native accounts the town was founded in 952 of the Hegira. In modern times the Turks under Raiss Salah Bey attempted to subjugate the inhabitants, but their invasion was successfully repulsed. Aghrem Baba Saád, a small ruined town to the west of Gardaia, is the fortified post in which the Beni Mezab took refuge. At the time of Duveyrier's visit in 1859, Gardaia paid a tribute of 45,000 francs to the French. The population is estimated at from 13,000 to 14,000.

GARDELEGEN (formerly GARDELEBEN and GARDLEBEN), the chief town of a circle in the government district of Magdeburg, Prussian Saxony, is situated on the right bank of the Milde, 28 miles N.N.W. of Magdeburg. The inhabitants are employed in agriculture, linen and woollen manufacture, button-making, calico-printing, and brewing. The chief buildings are the hospital founded in 1285, and the higher borough school. The population in 1875 was 6389.

Gardelegen is a place of great antiquity. In 633 it was destroyed by Dervan, duke of the Wends, but it was rebuilt in 924 by King Henry I. For a long time it was the seat of a line of margrave princes. It remained a free town until 1478. It suffered considerably in the Thirty Years' War, and in 1775 it was burned by the French. On the neighbouring heath Margrave Louis I. gained in 1343 a victory over Otto the Wild of Brunswick.

GARDENING. See HORTICULTURE.

GARDINER, a city of the United States in Kennebec county, State of Maine, is situated at the junction of the Kennebec and Cobosse rivers, 10 miles S. by E. of Augusta. The water-power of the Cobosse river is much utilized for manufactures, and the town has saw-mills, paper-mills, iron foundries, a woollen factory, a tannery, a pottery, and manufactories of sashes and blinds, and is the headquarters of the ice-business on the Kennebec. It is connected with Pittston, on the other side of the river, by a bridge 900 feet in length. The population in 1870 was 4497.

GARDINER, COLONEL JAMES (1687–1745), a Scottish soldier, was born at Carriden in Linlithgowshire, January 10, 1687. At the age of fourteen he entered a Scottish regiment in the Dutch service, and was afterwards present at the battle of Ramillies, where he was wounded. He subsequently served in different cavalry regiments, and in 1730 was advanced to the rank of lieutenant-colonel, and in 1743 to that of colonel. He fell at the battle of Prestonpans, September 1, 1745. The circumstances of his death are described in Sir Walter Scott's *Waverley*. In his early years he was distinguished for his recklessness and profligacy, but, in 1719, a supernatural vision, as he regarded it, led to his conversion; and from that time he lived a life of great devoutness and of thorough consistency with his Christian profession. His life was written by Dr Philip Doddridge.

GARDINER, STEPHEN (1483–1555), bishop of Winchester and lord chancellor of England, was born at Bury St Edmunds in 1483. He is believed to have been the illegitimate son of Dr Woodville, bishop of Salisbury brother of Elizabeth Woodville, queen of Edward IV. If so, he lost his father when he was only one year old; but his education seems to have been carefully provided for. He was sent to Cambridge and studied at Trinity Hall, where he greatly distinguished himself in the classics, especially in Greek. He afterwards devoted himself to the canon and civil law, in which subjects he attained so great a proficiency that no one could dispute his pre-eminence. He received the degree of doctor of civil law in 1520, and of canon law in the following year. Ere long his abilities attracted the notice of Cardinal Wolsey, who made him his secretary, and in this capacity he is said to have been with him at More Park in Hertfordshire, when the conclusion of the celebrated treaty of the More brought Henry VIII. and the French ambassadors thither. It is stated, and with great probability, that this was the occasion on which he was first introduced to the king's notice, but he does not appear to have been actively engaged in Henry's service till three years later. In that of Wolsey, he undoubtedly acquired a very intimate knowledge of foreign politics, and in 1527 he and Sir Thomas More were named commissioners on the part of England in arranging a treaty with the French ambassadors for the support of an army in Italy against the emperor. That year he accompanied Wolsey on his important diplomatic mission to France, the splendour and magnificence of which are so graphically described by Cavendish. Among the imposing train who went with the cardinal—including, as it did, several noblemen and privy councillors—Gardiner alone seems to have been acquainted with the real heart of the matter which made this embassy a thing of such peculiar moment. Henry was then particularly anxious to cement his alliance with Francis I., and gain his co-operation as far as possible in the object on which he had secretly set his heart—a divorce from Catherine of Aragon. In the course of his progress through France he received orders from Henry to send back his secretary Gardiner, or, as he was called at court, Master Stevens, for fresh instructions; to which he was obliged to reply that he positively could not spare him as he was the only instrument he had in advancing the king's "secret matter." Next year Gardiner, though still nominally in the service of Wolsey, was sent to Italy along with Edward Fox, provost of King's College, Cambridge, to promote the same business with the pope. His despatches on this occasion are still extant, and whatever we may think of the cause on which he was engaged, they certainly give a wonderful impression of the zeal and ability with which he discharged his functions. Here his perfect familiarity with the canon law gave him an advantage over all with whom he had to negotiate. Clement VII., who was then at Orvieto, and had just recently escaped from captivity at St Angelo at the hands of the imperialists, did not wish to offend the king of England, but was still more in dread of the emperor. He only desired to temporize. But Gardiner would not allow him to take refuge in an evasive policy. What was to be thought, he said, of a spiritual guide who either could not or would not show the wanderer his way? The king and lords of England would be driven to think that God had taken away from the Holy See the key of knowledge, and that pontifical laws which were not clear to the pope himself might as well be committed to the flames.

In short, it was owing to Gardiner's vigorous advocacy that the celebrated commission was issued to Cardinals Wolsey and Campeggio to try the cause in England. After obtaining it he was recalled, but early in the following year, 1529, as Campeggio delayed proceeding, he was sent once more to Rome. This time, however, his efforts were unavailing. The pope would make no further concessions, and would not even promise not to revoke the cause to Rome, as he did very shortly after. Gardiner's services, however, were fully appreciated. He was appointed the king's secretary. He had been already some years archdeacon of Taunton, and the archdeaconry of Norfolk was added to it in March 1529; which two years later he resigned for that of Leicester. In 1530 he was sent to Cambridge to procure the decision of the university as to the unlawfulness of marriage with a deceased brother's wife, in accordance with the new plan devised for settling the question without the pope's intervention. In this he succeeded, though not without a good deal of artifice, more creditable to his ingenuity than to his virtue. In November 1531 the king rewarded him for his services with the bishopric of Winchester, vacant by Wolsey's death. The promotion was unexpected, and was accompanied by expressions from the king which made it still more honourable, as showing that if he had been in some things too subservient, it was from no abject, self-seeking policy of his own. Gardiner had, in fact, ere this remonstrated boldly with his sovereign on some points, and Henry now reminded him of the fact. "I have often *squared* with you, Gardiner," he said familiarly, "but I love you never the worse, as the bishopric I give will convince you." It must be owned, however, that his next distinguished service was not a very creditable one; for he was, not exactly, as is is often said, one of Cranmer's assessors, but, according to Cranmer's own expression, "assistant" to him as counsel for the king, when the archbishop, in the absence of Queen Catherine, pronounced her marriage with Henry null and void on the 23d May 1533. Immediately afterwards he was sent over to Marseilles, where an interview between the pope and Francis I. took place in September, of which event Henry stood in great suspicion, as Francis was ostensibly his most cordial ally, and had hitherto maintained the justice of his cause in the matter of the divorce. Here he intimated the appeal of Henry VIII. to a general council in case the pope should venture to proceed to sentence against him. He also made a like appeal in behalf of Cranmer. Next year he and other bishops were called upon to vindicate the king's new title of "Supreme Head of the Church of England." The result was his celebrated treatise *De Vera Obedientia*, the ablest, certainly, of all the vindications of royal supremacy. In 1535 he had an unpleasant dispute with Cranmer about the visitation of his diocese. During the next few years he was engaged in various embassies in France and Germany. He was indeed so much abroad that he had little influence upon the king's councils. But in 1539 he was much concerned in the drawing up and passing through the House of Lords of the severe statute of the Six Articles, which led to the resignation of Bishops Latimer and Shaxton and the persecution of the whole Protestant party. In 1540, on the death of Cromwell, earl of Essex, he was elected chancellor of the university of Cambridge. A few years later he attempted, in concert with others, to fasten a charge of heresy upon Archbishop Cranmer in connexion with the Act of the Six Articles; and but for the personal intervention of the king he would probably have succeeded. He was, in fact, though he had supported the royal supremacy, a thorough opponent of the Reformation in a doctrinal point of view, and it was suspected that he even repented his advocacy of the royal supremacy. He certainly had not approved of Henry's general treatment of the church, especially during the ascendency of Cromwell, and he was frequently visited with storms of royal indignation, which he schooled himself to bear with patience. In 1544 a relation of his own, named German Gardiner, whom he employed as his secretary, was put to death for treason in reference to the king's supremacy, and his enemies insinuated to the king that he himself was of his secretary's way of thinking. But being warned of his danger he sought an interview with Henry, in which he succeeded in clearing himself of all injurious imputations. That he was party to a design against Queen Catherine Parr, whom the king was at one time on the point of committing to the Tower, rests only upon the authority of Foxe, and seems a little doubtful. It is certain, however, that his name was omitted at the last in Henry VIII.'s will, though the king was believed to have intended making him one of his executors.

Under Edward VI. Gardiner was completely opposed to the policy of the dominant party both in ecclesiastical and in civil matters. The religious changes he objected to both on principle and on the ground of their being moved during the king's minority, and he resisted Cranmer's project of a general visitation. His remonstrances, however, were met by his own committal to the Fleet, and the visitation of his diocese was held during his imprisonment. Though soon afterwards released, it was not long before he was called before the council, and, refusing to give them satisfaction on some points, was thrown into the Tower, where he continued during the whole remainder of the reign, a period slightly over five years. During this time he in vain demanded his liberty, and to be called before parliament as a peer of the realm. His bishopric was taken from him and given to Dr Poynet, a chaplain of Cranmer's who had not long before been made bishop of Rochester. At the accession of Queen Mary, the duke of Norfolk and other state prisoners of high rank were in the Tower along with him; but the queen, on her first entry into London, set them all at liberty. Gardiner was restored to his bishopric and appointed lord chancellor, and he set the crown on the queen's head at her coronation. He also opened her first parliament, and for some time was her leading councillor. He was now called upon, at the age of seventy, to undo not a little of the work in which he had been instrumental in his earlier years,—to vindicate the legitimacy of the queen's birth and the lawfulness of her mother's marriage, to restore the old religion, and to recant what he himself had written touching the royal supremacy. At least this, it may be presumed, was the time when he wrote, if, as we are told, he really did write, a *Palinodia* or retractation of his book *De Vera Obedientia*, which, however, does not seem to be now extant, so that how far he had changed his sentiments we cannot very well judge. That he should have really changed them to some extent is not at all unnatural; and in relation to the divorce of Catherine of Aragon, we may well believe that it was his earlier and not his later action that ever troubled his conscience. Yet as to the royal supremacy, it seems that he would have advised Queen Mary to retain it; but her own desire was so great to give up ecclesiastical jurisdiction to the pope that he could not press the matter. A less agreeable task which fell to him was the negotiation of the queen's marriage treaty with Philip, to which he shared the general repugnance, though he could not oppose her will.

In executing it, however, he took care to make the terms as advantageous for England as possible, and to make express provision that the Spaniards should in nowise be allowed to interfere in the government of the country. After the coming of Cardinal Pole, and the reconciliation of the realm to the see of Rome, his influence suffered some eclipse, though he still remained in high favour. How far he was responsible for the persecutions which afterwards arose is a debated question. There is no doubt that he sat in judgment on Bishop Hooper, and on several other Protestants whom he condemned to the flames. But being placed on a commission along with a number of other bishops to administer a severe law, it does not appear that he could very well have acted otherwise. On the bench he is said to have used every effort to induce the accused to make concessions and accept a pardon; and a remarkable instance of his clemency is recorded by the church historian Fuller, who, notwithstanding his prejudices, acknowledges a debt of gratitude to him for preserving one of his own ancestors from the persecuting zeal of others. It would seem, moreover, that when he saw the results of the cruel proceedings against heretics, he very soon got tired of them. The persecutions raged with the greatest vehemence during his absence at the Calais peace conferences in 1555, and when he came back he declared he would have no further hand in them, so that those afterwards apprehended in his diocese were removed into that of London in order to be adjudged to the flames. In October 1555 he again opened parliament as lord chancellor, but towards the end of the month he fell ill and grew rapidly worse till the 12th November, when he died about the age of seventy-two.

Perhaps no celebrated character of that age has been the subject of so much ill-merited abuse at the hands of popular historians. That his virtue was not equal to every trial may be admitted, but that he was anything like the morose and narrow-minded bigot he is commonly represented there is nothing whatever to show. He has been called ambitious, turbulent, crafty, abject, vindictive, bloodthirsty, and a good many other things besides, not quite in keeping with each other; in addition to which it is roundly asserted by Bishop Burnet that he was despised alike by Henry and by Mary, both of whom made use of him as a tool. How such a mean and abject character submitted to remain five years in prison rather than change his principles is not very clearly explained; and as to his being despised, we have seen already that Henry VIII., at least, did not consider him despicable. The truth is, there is not a single divine or statesman of that day whose course throughout was so thoroughly consistent. He was no friend to the Reformation, it is true, but he was at least a conscientious opponent. In doctrine he adhered to the old faith from first to last, while as a question of church polity, the only matter for consideration with him was whether the new laws and ordinances were constitutionally justifiable.

His merits as a theologian it is unnecessary to discuss; it is as a statesman and a lawyer that he stands conspicuous. But his learning even in divinity was far from commonplace. The manual set forth in 1543 by royal and parliamentary authority, entitled *A necessary Doctrine and Erudition for any Christian Man*, was chiefly from his pen; and at a later date he was the author of various tracts in defence of the Real Presence against Cranmer, some of which, being written in prison, were published abroad under a feigned name. Controversial writings also passed between him and Bucer, with whom he had several interviews in Germany, when he was there as Henry VIII.'s ambassador.

He was a friend of learning in every form, and took great interest especially in promoting the study of Greek at Cambridge. He was, however, opposed to the new method of pronouncing the language introduced by Sir John Cheke, and wrote letters to him and Sir Thomas Smith upon the subject, in which, according to Ascham, his opponents showed themselves the better critics, but he the superior genius. In his own household he loved to take in young university men of promise; and many whom he thus encouraged became distinguished in after life as bishops, ambassadors, and secretaries of state. His house, indeed, was spoken of by Leland as the seat of eloquence and the special abode of the muses.

He lies buried in his own cathedral at Winchester, where his effigy is still to be seen. (J. GA.)

GARE-FOWL[1] (Icelandic, *Geirfugl*; Gaelic, *Gearbhul*), the Anglicized form of the Hebridean name of a large sea-bird, formerly a visitor to certain remote Scottish islands, the GREAT AUK of most English book-writers, and the *Alca impennis* of Linnæus. Of this remarkable creature mention has been already made at some length (BIRDS, vol. iii. pp. 734, 735), but since the species has a mournful

Gare-Fowl, or Great Auk.

history and several egregious misconceptions prevail concerning it, a few more details may not be unacceptable, particularly as many of them have been hitherto confined to works not easily accessible to the general reader, and the presumed extinction of the bird gives it especial interest. In size it was hardly less than a tame Goose, and in appearance it much resembled its smaller and surviving relative the Razor-bill (*Alca torda*); but the glossy black of its head was varied by a large patch of white occupying nearly all the space between the eye and the bill, in place of the Razor-bill's thin white line, while the bill itself bore eight or more deep transverse grooves instead of the smaller number and the ivory-like mark possessed by the species last named. Otherwise the coloration was similar in both, and there is satisfactory evidence that the Gare-fowl's winter-plumage differed from that of the breeding-season just as is ordinarily

[1] The name first appears, and in this form, in the *Account of Hirta* [St Kilda] *and Rona, &c.*, by the Lord Register, Sir George M'Kenzie, of Tarbat, printed by Pinkerton in his *Collection of Voyages and Travels* (iii. p. 730), and then in Sibbald's *Scotia Illustrata* (1684). Martin soon after, in his *Voyage to St Kilda*, spelt it "Gairfowl." Prof. Owen has adopted the form "Garfowl," without, as would seem, any precedent authority.

the case in other members of the family *Alcidæ* to which it belongs. The most striking characteristic of the Gare-fowl, however, was the comparatively abortive condition of its wings, the distal portions of which, though the bird was just about twice the linear dimensions of the Razor-bill, were almost exactly of the same size as in that species—proving, if more direct evidence were wanting, its inability to fly.

The most prevalent misconception concerning the Gare-fowl is one which has been repeated so often, and in books of such generally good repute and wide dispersal, that a successful refutation seems almost hopeless. This is the notion that it was a bird possessing a very high northern range, and consequently to be looked for by Arctic explorers. How this error arose would take too long to tell, but the fact remains indisputable that, setting aside general assertions resting on no evidence worthy of attention, there is but a single record deserving any credit at all of a single example of the species having been observed within the Arctic Circle, and this, according to Prof. Reinhardt, who has the best means of ascertaining the truth, is open to grave doubt.[1] It is clear that the older ornithologists let their imagination get the better of their knowedge or their judgment, and their statements have been blindly repeated by most of their successors. Another error which, if not so widely spread, is at least as serious, since Prof. Owen (*Encycl. Brit.*, ed. 8, xvii. p. 176; *Palæontology*, p. 400) has unhappily given it countenance, is that this bird "has not been specially hunted down like the dodo and dinornis, but by degrees has become more scarce." Now, if any reliance can be placed upon the testimony of former observers, the first part of this statement is absolutely untrue. Of the Dodo all we know is that it flourished in Mauritius, its only abode, at the time the island was discovered, and that some 200 years later it had ceased to exist—the mode of its extinction being open to conjecture, and a strong suspicion existing that though indirectly due to man's acts it was accomplished by his thoughtless agents (*Phil. Trans.*, 1869, p. 354). The extinction of the *Dinornis* lies beyond the range of recorded history. Supposing it even to have taken place at the very latest period as yet suggested—and there is much to be urged in favour of such a supposition—little but oral tradition remains to tell us how its extirpation was effected. That it existed after New Zealand was inhabited by man is indeed certain, and there is nothing extraordinary in the proved fact that the early settlers (of whatever race they were) killed and ate Moas. But evidence that the whole population of those birds was done to death by man, however likely it may seem, is wholly wanting. The contrary is the case with the Gare-fowl. In Iceland there is the testimony of a score of witnesses, taken down from their lips by one of the most careful naturalists who ever lived, the late John Wolley, that the latest survivors of the species were caught and killed by expeditions expressly organized with the view of supplying the demands of caterers to the various museums of Europe. In like manner the fact is incontestable that its breeding-stations in the western part of the Atlantic were for three centuries regularly visited and devastated with the combined objects of furnishing food or bait to the fishermen from very early days, and its final extinction, according to Sir Richard Bonnycastle (*Newfoundland in* 1842, i. p. 232) was owing to "the ruthless trade in its eggs and skin." No doubt that one of the chief stations of this species in Icelandic waters disappeared, as has been before said (Birds, *loc. cit.*), through volcanic action—

> "A land, of old upheaven from the abyss
> By fire, to sink into the abyss again"—

and that the destruction of the old Geirfuglaskér drove some at least of the birds which frequented it to a rock nearer the mainland, where they were exposed to danger from which they had in their former abode been comparatively free; yet on this rock (Eldey = fire-island) they were "specially hunted down" whenever opportunity offered, until the stock there was wholly extirpated in 1844, and whether any remain elsewhere must be deemed most doubtful.

A third misapprehension is that entertained by Mr Gould who, in his *Birds of Great Britain*, says that "formerly this bird was plentiful in all the northern parts of the British Islands, particularly the Orkneys and the Hebrides. At the commencement of the present century, however, its fate appears to have been sealed; for though it doubtless existed, and probably bred, up to the year 1830, its numbers annually diminished until they became so few that the species could not hold its own."

Now of the Orkneys, we know that Low, who died in 1795, says in his posthumously-published *Fauna Orcadensis* that he could not find it was ever seen there; and on Bullock's visit in 1812 he was told, says Montagu (*Orn Dict. App.*), that one male only had made its appearance for a long time. This bird he saw and unsuccessfully hunted, but it was killed soon after his departure, while its mate had been killed just before his arrival, and none have been seen there since. As to the Hebrides, St Kilda is the only locality recorded for it, and the last example known to have been obtained there, or in its neighbourhood, was that given to Fleming (*Edinb. Phil. Journ.*, x. p. 96) in 1821 or 1822, having been some time before captured by Mr Maclellan of Glass. That the Gare-fowl was not plentiful in either group of islands is sufficiently obvious, as also is the impossibility of its continuing to breed "up to the year 1830."

But mistakes like these are not confined to British authors. As on the death of an ancient hero myths gathered round his memory as quickly as clouds round the setting sun, so have stories, probable as well as impossible, accumulated over the true history of this species, and it behoves the conscientious naturalist to exercise more than common caution in sifting the truth from the large mass of error. Americans have asserted that the specimen which belonged to Audubon (now at Vassar College) was obtained by him on the banks of Newfoundland, though there is Macgillivray's distinct statement (*Brit. Birds*, v. p. 359) that Audubon procured it in London. The account given by Degland (*Orn. Europ.*, ii. p. 529) in 1849, and repeated in the last edition of his work by M. Gerbe, of its extinction in Orkney, is so manifestly absurd that it deserves to be quoted in full:—"Il se trouvait en assez grand nombre il y a une quinzaine d'années aux Orcades; mais le ministre presbytérien dans le Mainland, en offrant une forte prime aux personnes qui lui apportaient cet oiseau, a été cause de sa destruction sur ces îles." The same author claims the species as a visitor to the shores of France on the testimony of Hardy (*Annuaire Normand*, 1841, p. 298), which he grievously misquotes both in his own work and in another place (*Naumannia*, 1855, p. 423), thereby misleading an anonymous English writer (*Nat. Hist. Rev.*, 1865, p. 475) and numerous German readers.

Since the former notice of this species in the general article Birds (*ut supra*), the only important contribution to our knowledge of it that has appeared is a paper by Mr John Milne, published in *The Field* newspaper, and since reprinted for private circulation. This gentleman visited Funk Island, one of the former resorts of the Gare-fowl, or "Penguin," as it was there called, in the Newfoundland seas, a place where bones had before been obtained by Stuvitz, and natural mummies so lately as 1863 and 1864. Landing on this rock at the risk of his life, he brought off a rich cargo of its remains, belonging to no fewer than fifty

[1] The specimen is in the Museum of Copenhagen; the doubt lies as to the locality where it was obtained, whether at Disco, which is within, or at the Fiskernäs, which is without, the Arctic Circle.

birds, some of them in size exceeding any that had before been known. His collection has since been dispersed, most of the specimens finding their way into various public museums in this country.

A literature by no means inconsiderable has grown up respecting the Gare-fowl. Neglecting works of general bearing, few of which are without many inaccuracies, the following treatises may be especially mentioned:—J. J. S. Steenstrup, "Et Bidrag til Geirfuglens Naturhistorie og særligt til Kundskaben om dens tidligere Udbredningskreds," *Naturh. Foren. Vidensk. Meddelelser* [Copenhagen], 1855, p. 33; E. Charlton, "On the Great Auk," *Trans. Tyneside Nat. Field Club*, iv. p. 111; "Abstract of Mr J. Wolley's Researches in Iceland respecting the Gare-fowl," *Ibis*, 1861, p. 374; W. Preyer, "Ueber *Plautus impennis*," *Journ. für Orn.*, 1862, pp. 110, 337; K. E. von Baer, "Ueber das Aussterben der Thierarten in physiologischer und nicht physiologischer Hinsicht," *Bull. de l'Acad. Imp. de St Pétersb.*, vi. p. 513; R. Owen, "Description of the Skeleton of the Great Auk," *Trans. Zool. Soc.*, v. p. 317; "The Gare-fowl and its Historians, *Nat. Hist. Rev.*, v. p. 467; J. H. Gurney, jun., "On the Great Auk," *Zoologist*, 2d ser. pp. 1442, 1639; H. Reeks, "Great Auk in Newfoundland," &c., *op. cit.*, p. 1854; V. Fatio, "Sur l'Alca impennis," *Bull. Soc. Orn. Suisse*, ii. pp. 1, 80, 147; "On existing Remains of the Gare-fowl," *Ibis*, 1870, p. 256; J. Milne, "Relics of the Great Auk," *Field*, 27 March, 3 and 10 April 1875. Lastly, reference cannot be omitted to the happy exercise of poetic fancy with which the late Prof. Kingsley was enabled to introduce the chief facts of the Garefowl's extinction (derived from one of the above-named papers) into his charming *Water Babies*. (A. N.)

GARESSIO, Garesso, or Garezzo, in Latin *Garexium*, a town of Italy about 18 miles S.E. of Mondovi, in the valley of the Tararo. The Roman remains which are discovered from time to time bear witness to its high antiquity; during the Middle Ages it was the seat of a marquisate, which in 1509 was sold to the Spinola family, and its double walls gave it some importance as a defensible position. Besides a castle, it possesses three old monastic buildings, one of which, the Carthusian convent of Casotto, is an edifice of much magnificence. Population in 1870 nearly 7000.

GAR-FISH is the name given to a genus of fishes (*Belone*) found in nearly all the temperate and tropical seas, and readily recognized by their long, slender, compressed and silvery body, and by their jaws being produced into a long, pointed, bony, and sharply-toothed beak. About fifty species are known from different parts of the globe, some attaining to a length of 4 or 5 feet. One species is common on the British coasts, and is well known by the names of "long-nose," "green-bone," &c. The last name is given to those fishes on account of the peculiar green colour of their bones, which deters many people from eating them, although their flesh is well flavoured and perfectly wholesome. The Skipper (*Scomberesox*) and Halfbeak (*Hemirhamphus*), in which the lower jaw only is prolonged, are fishes nearly akin to the gar-pikes. See Ichthyology.

GARGANEY [1] (North-Italian, *Garganello*), or Summer-Teal, the *Anas querquedula* and *A. circia* of Linnæus (who made, as did Willughby and Ray, two species out of one), and the type of Stephens's genus *Querquedula*. This bird is one of the smallest of the *Anatidæ*, and has gained its common English name from being almost exclusively a summer-visitant to this country, where nowadays it only regularly resorts to breed in some of the East-Norfolk waters called Broads, though possibly at one time found at the same season throughout the great Fen-district. About the same size as the common Teal (*A. crecca*), the male is readily distinguished therefrom by its peculiarly-coloured head, the sides of which are nutmeg-brown, closely freckled with short whitish streaks, while a conspicuous white curved line descends backwards from the eyes. The upper wing-coverts are bluish-grey, the scapulars black with a white shaft-stripe, and the wing-spot (*speculum*) greyish-green bordered above and below by white. The female closely resembles the hen Teal, but possesses nearly the same wing-spot as her mate. In Ireland or Scotland the Garganey is very rare, and though it is recorded from Iceland, more satisfactory evidence of its occurrence there is needed. It has not a high northern range, and its appearance in Norway and Sweden is casual. Though it breeds in many parts of Europe, in none can it be said to be common; but it ranges far to the eastward in Asia—even to Formosa, according to Swinhoe—and yearly visits India in winter. Those that breed in Norfolk arrive somewhat late in spring and make their nests in the vast reed-beds which border the Broads—a situation rarely or never chosen by the Teal. The labyrinth or bony enlargement of the trachea in the male Garganey differs in form from that described in any other Drake, being more oval and placed nearly in the median line of the windpipe, instead of on one side, as is usually the case.

[1] The word was introduced by Willughby from Gesner (*Orn.*; lib. iii. p. 127), but, though generally adopted by authors, seems never to have become other than a book-name in English, the bird being invariably known in the parts of this island where it is indigenous as "Summer-Teal."

GARHWÁL, a district of British India, in the Kumáon division, under the jurisdiction of the lieutenant-governor of the North-Western Provinces, situated between 29° 16′ 15″ and 31° 5′ 30″ N. lat., and 78° 18′ 45″ and 80° 8′ E. long, and bounded on the N. by Chinese Tibet, on the E. by Kumáon district, on the S. by Bijnor district, and on the W. by Independent Garhwál or Tehri. Garhwál district consists almost entirely of rugged mountain ranges running in all directions, and separated by narrow valleys, which may almost be described as gorges or ravines. The only level portion of the district consists of a narrow strip of waterless forest, between the southern slopes of the hills and the fertile plains of Rohilkhand. The highest mountains are in the north of the district, the principal peaks being Nandá Devi (25,661 feet), Kamet (25,413), Ircoul (23,382), Dunagiri (23,181), Badrinath (22,901), and Kedarnath (22,853). The Alaknanda, one of the main sources of the Ganges, receives with its affluents the whole drainage of the district. The river is regarded as of peculiar sanctity, and is annually resorted to by thousands of devout Hindus. At Deoprayág the Alaknandá joins the Bhágirathí, and thenceforward the united streams bear the name of the Ganges. Navigation is impracticable in all the rivers, owing to the velocity of their currents, and the existence of shoals and rapids. Cultivation is principally confined to the immediate vicinity of the rivers, which are employed for purposes of irrigation; but out of a total estimated area of 5500 square miles in 1872, only 209 were returned as under cultivation. Agriculture, however, is carried on with great skill and industry, by terracing out the hill sides. Wheat, rice, and *manduá* are the staple crops, the surplus produce being exported to Tibet. Tea planting is also carried on under European supervision.

The census of 1872 disclosed a population in the Garhwál district of 310,288 (115,745 males and 154,537 females), distributed among 3944 villages and 57,293 houses. The Hindus numbered 308,398, or no less than 99·3 per cent. of the population, the Mahometans 1799, and Christians 85. The two great Hindu temples of Badrináth and Kedarnáth, which lie hidden among the recesses of the snowy range, attract large numbers of pilgrims, who considerably add to the prosperity of the district. No place in Garhwál contains as many as 5000 inhabitants. Srinagar is the largest town, but the administrative headquarters is at Pauni. Trade is principally carried on with Tibet, by way of the Mána and Níti passes, sheep and goats being used as beasts of burden. The chief exports are grain, *gur*, cloth, and tobacco; the imports salt, borax, wool, gold, and precious stones. Good hill roads, from 10 to 12 feet in width, intersect the district in every direction, the total length being about 1000 miles. The land revenue in 1875 amounted to £9555. Only a small force of regular police is stationed at headquarters, and there is little crime of any kind.

Education has made greater progress among these mountain valleys than in the plain districts beneath them. In 1875 73 schools afforded education to 3609 pupils.

Garhwál originally consisted of 52 petty chieftainships, each chief with his own independent fortress (*garh*). Between 400 and 500 years ago, one of these chiefs, Ajai Pál, ruler of Chandpur, reduced all the minor principalities under his own sway, and founded the Garhwál kingdom. He and his ancestors ruled over Garhwál and the adjacent state of Tehri, in an uninterrupted line till 1803, when the Gúrkhás invaded Kumáon and Garhwál driving Prithimán Sáh, the Garhwál chief, into the plains. For twelve years the Gúrkhás ruled the country with a rod of iron, until a series of encroachments by them on British territory, led to the war with Nepál in 1814. At the termination of the campaign, Garhwál and Kumáon were converted into British districts, while the Tehri principality was restored to Pridhimán Sáh, whose grandson still holds it. Since the annexation, Garhwál has rapidly advanced in material prosperity. Cultivation has rapidly increased, and the spread of tea-culture has opened the country to British capital and enterprise, which are converting this long harassed tract into an important and wealthy district.

GARLIC (Greek, σκόροδον; Latin, *Allium*; Italian, *Aglio*; French, *Ail*; German, *Knoblauch*), *Allium sativum*, Linn., a bulbous perennial plant of the tribe *Hyacinthineœ* of the natural order *Liliaceœ*, indigenous apparently to the south of Europe and to the East, having entire, obscurely keeled leaves, a deciduous spathe, a bulbiferous globose umbel, and whitish flowers, with exsert pistil and stamens. The bulb, which is the only part eaten, has membranous scales, in the axils of which are 10 or 12 cloves, or smaller bulbs. From these new bulbs can be procured by planting out in February or March. The bulbs are best preserved hung in a dry place. If of fair size, twenty of them weigh about 1 ℔. To prevent the plant from running to leaf, Pliny (*Nat. Hist.*, xix. 34) advises to bend the stalk downward, and cover with earth; seeding, he observes, may be prevented by twisting the stalk. Garlic is cultivated in the same manner as the SHALLOT (*q. v.*). It is stated to have been grown in England before the year 1548. The percentage composition of the bulbs is given by Mr E. Solly (*Trans. Hort. Soc. Lond.*, new ser., iii. p. 60) as water 84·09, organic matter 13·38, and inorganic matter 1·53,—that of the leaves being water 87·14, organic matter 11·27, and inorganic matter 1·59. The bulb has a strong and characteristic odour, and an acrid taste, and yields an offensively smelling oil, essence of garlic, identical with allylic sulphide $(C_3H_5)_2S$ (see Hofmann and Cahours, *Journ. Chem. Soc.*, x. p. 320). This, when garlic has been eaten, is evolved by the excretory organs, the activity of which it promotes. From the earliest times garlic has been used as an article of diet. It formed part of the food of the Israelites in Egypt (Numb. xi. 5), and of the labourers employed by Cheops in the construction of his pyramid, and is still grown in Egypt, where, however, the Syrian is the kind most esteemed (see Rawlinson's *Herodotus*, ii. 125). It was largely consumed by the ancient Greek and Roman soldiers, sailors, and rural classes (*cf.* Virg., *Ecl.*, ii. 11), and, as Pliny tells us (*N. H.*, xix. 32), by the African peasantry. Galen eulogizes it as the rustic's *theriac* (see F. Adams's *Paulus Ægineta*, p. 99), and Alexander Neckam, a writer of the 12th century (see Wright's edition of his works, p. 473, 1863), recommends it as a palliative of the heat of the sun in field labour. "The people in places where the simoon is frequent," says Elphinstone (*An Account of the Kingdom of Caubul*, p. 140, 1815), "eat garlic, and rub their lips and noses with it, when they go out in the heat of the summer, to prevent their suffering by the simoon." "O dura messorum ilia," exclaims Horace (*Epod.*, iii.), as he records his detestation of the popular esculent, to smell of which was accounted a sign of vulgarity (*cf.* Shakespeare, *Coriol.*, iv. 6, and *Meas. for Meas.*, iii. 2). In England garlic is seldom used except as a seasoning, but in the southern countries of Europe it is a common ingredient in dishes, and is largely consumed by the agricultural population. Garlic was placed by the ancient Greeks on the piles of stones at cross-roads, as a supper for Hecate (Theophrastus, *Characters*, Δεισιδαιμονίας); and according to Pliny garlic and onions were invocated as deities by the Egyptians at the taking of oaths. The inhabitants of Pelusium in Lower Egypt, who worshipped the onion, are said to have held both it and garlic in aversion as food. Garlic possesses stimulant and stomachic properties, and was of old, as still sometimes now, employed as a medicinal remedy. Pliny (*N. H.*, xx. 23) gives an exceedingly long list of complaints in which it was considered beneficial. Dr Sydenham valued it as an application in confluent smallpox, and, says Cullen (*Mat. Med.*, ii. p. 174, 1789), found some dropsies cured by it alone. The volatile oil has proved efficacious in indigestion, and in some stages of bronchitis, especially in the acute form of the disease in infants, also in chronic colds, and as a rubefacient and nervine tonic; and poultices of the pounded pulp are recommended for the convulsions and suffocative catarrh of infants (Wood, *Treat. on Therapeutics*, p. 451, 1874). With lemon-juice garlic has also been resorted to for the cure of diphtheria (*Brit. and For. Med.-Chir. Rev.*, 1860, i. p. 281). The wild "Crow Garlic" and "Field Garlic" of Britain are the Linnean species *Allium vineale* and *A. oleraceum* respectively.

See Phillips, *Hist. of Culinary Vegetables*, vol. ii.; Pereira, *Materia Medica*, vol. ii. pt. i.; M'Intosh, *The Book of the Garden*, vol. ii., 1855, p. 29.

GARNET (German, *Granat*; French, *Grenat*), a mineral the name of which is derived from the Latin *granatum*, the pomegranate, or, as Lydgate calls it, "garnet appille" (see Halliwell, *Dict.*, i. p. 392), on account of the resemblance of its granular varieties to the seeds of that fruit. Several sorts of garnets, with other stones, seem to have been included under the terms ἄνθραξ and *carbunculus*, employed by Theophrastus and Pliny. Garnet occurs in crystals, mostly dodecahedral or trapezohedral, very rarely octahedral,[1] of the isometric, regular, or cubical system, also in pebbles and grains (as in alluvial deposits), and massive, with a granular or coarse lamellar structure. It varies in diaphaneity from transparent to nearly opaque; is red, red-brown, or black in colour, less frequently white, yellow, pink, or green; has a vitreous to resinous lustre, a white streak, dodecahedral cleavage, hardness of 6·5 to 7·5, specific gravity of 3·15 to 4·30,[2] and an uneven sub-conchoidal fracture; and is brittle and sometimes friable, or, in the compact cryptocrystalline varieties, tough. Before the blowpipe it gives a brown, green, or black (often magnetic) glass, which hydrochloric acid decomposes, with the separation of gelatinous silica. Previous to melting, the mineral is but little affected by the acid. The least fusible forms are the lime-iron garnets. It has been shown by Professor Church that, although unaffected by exposure to a full red heat for a quarter of an hour, iron garnet may by fusion have its specific gravity lowered from 4·059 to 3·204. By almost complete fusion a specimen of almandine garnet examined by him had its specific gravity increased from 4·103 to 4·208. Long-continued ignition effected only a slight increase in the density of various specimens of lime garnet (see *Journ. Chem. Soc.*, vol. xvii. p. 388). Garnets, which through the isomorphism of their constituents are extremely variable in chemical composition, are silicates of the general formula $R''_3R^{iv}_2.Si_3O_{12}$, or $3R''O,R^{iv}_2O_3.3SiO_2$, in which R'' = calcium, magnesium, iron, and manganese, and R^{iv} = aluminium, iron, and chromium. Occasionally rarer metals

[1] See Max Bauer, "Ueber die selteneren Krystallformen des Granats," *Zeitschr. der deut. geolog. Ges.*, Bd. xxvi., 1874, pp. 119–37, pl. i.

[2] On the specific gravity of several varieties of garnet, see Prof. A. H. Church, *Geological Mag.*, new ser., vol. ii., 1875, p. 321.

are present; yttrium, for instance, has been found in garnets from Brevig, Norway. Three principal groups have been recognized, called, according to their chief sesquioxide basic components, alumina, iron, and chrome garnets, which have the general formula $R''_3Al_2.Si_3O_{12}$, $R''_3Fe_2.Si_3O_{12}$, and $R''_3Cr_2.Si_3O_{12}$, respectively. These are further classed, by the predominance of one or other of their contained protoxides, into numerous subordinate groups, as lime-alumina garnet, $Ca_3Al_2.Si_3O_{12}$, *e.g.*, grossularite, topazolite, and essonite; magnesia-alumina garnet, comprising pyrope, the typical specimens of which contain a small percentage of chromium; iron-alumina garnet, *e.g.*, almandite, common garnet in part, and allochroite; manganese-alumina garnet, as spessartite and romanzovite; lime-iron garnet, which includes andradite, melanite, or black garnet, which may be titaniferous, as at Frascati, and pyreneite, aplome, and common garnet in part; lime-magnesia-iron garnet $(CaMg)_3Fe_2.Si_3O_{12}$, or bredbergite; and lime-chrome garnet, or ouvarovite. Colophonite, a yellow-brown to honey-yellow or almost pitch-black mineral, with a resinous lustre, commonly considered to be a lime-iron garnet, according to Wichmann and Des-Cloiseaux must be regarded as for the most part granular vesuvian.

Garnet is a wide-spread mineral, and is found in micaceous, talcose, chloritic, and hornblendic schists, and in syenitic gneiss, syenite, granite, dolomite, and crystalline limestone; sometimes as pyrope, in serpentine; also in felspar-porphyry, and in volcanic rocks. In Cornwall it is met with chiefly in greenstone, or in close proximity thereto. It is an essential ingredient of the rock eklogite. Grossularite, a greenish to grey-green garnet, is found at Rezbanya in Hungary, and the Wilui river, Siberia; topazolite and essonite at Mussa, Piedmont, the latter also in Ceylon, Piedmont, and Elba; pyrope in Bohemia, and at Zöblitz in Saxony; and almandite in Ceylon, Pegu, Brazil, and Greenland. Spessartite is obtained at Haddam, Ct., and elsewhere; melanite in Vesuvian and other lavas; aplome at Breitenbrunn and Schwarzenberg in Saxony; the fine green garnet ouvarovite chiefly at Saranovskaja, 14 versts from Bissersk in the Urals, and at New Idria in California; and white garnet in the Urals. Numerous other localities for garnet might be mentioned. Precious garnet, almandite or almandine (so termed, it is said, from being cut at Alabanda in Caria, whence the appellation *alabandicus* employed by Pliny), essonite or cinnamon-stone, grossularite, grossularia, or gooseberry stone, and pyrope or Bohemian garnet are the varieties of the mineral employed as gems. They are shaped by means of garnet powder or emery on a copper wheel, and polished on lead with tripoli. Carbuncles are almadine garnets cut *en cabochon*; when of large size, and free from black spots, they may be worth as much as £20 apiece. The deep red or precious garnet often has a density close to that of the ruby, for which stone it has been sold. The Syriam or Pegu garnets, possibly the *amethystizontas* of Pliny (*Nat. Hist.*, xxxvii. 25), commonly designated amethystine or oriental garnets, vary in colour from a deep red to a violet-purple, and may occur 3 inches in diameter. They are usually cut with four large and four small facets, and may fetch very high prices, a single specimen, of a fiery-red hue, measuring 1 inch by $\frac{6}{10}$ inch, having been sold for £40, and another, of octagonal form, for £140. Pyrope is a dark hyacinth-red to blood-red gem, much esteemed in Austria, Transylvania, and Turkey. Viewed by transmitted light it appears of a yellowish-red tint, more especially at the edges. Essonite, yellow to hyacinth-red in colour, is a softer and more fusible garnet than the other kinds used in jewellery. It is commonly called hyacinth, and has frequently been mistaken, as also sold, for true hyacinth or jacinth, which is a zirconium silicate, and may be distinguished by its density of 4·05–4·75, that of essonite being about 3·60–3·66. The garnet was much used as a jewel in ancient times. Antique intaglios on garnet are recognized by their usually fragmentary condition, due to their brittleness, and by a softness of colour, imparted to them by time, which defies imitation by even the ablest artists (Castellani). The bust of Hadrian in the Odescalchi museum, the Venus Genetrix in the cabinet of Abbé Pullini at Turin, and the representation of Sirius on the celebrated Marlborough stone, are among the finer examples of engraving in garnet. Garnet, where abundant, has been used in the smelting of iron ores. For polishing purposes it is sometimes substituted for emery. The large dull-coloured "carbunculus of India," according to Pliny (*l.c.*), used to be hollowed out into vessels that would hold as much as a pint. Garnet has been obtained as a furnace-product, and otherwise artificially. What is known as "white garnet" is the mineral leucite.

Schrauf, *Hdb. d. Edelsteinkunde*, Vienna, 1869; A. Castellani, *Gems*, 1871; J. D. Dana, *A System of Mineralogy*, 5th ed., pp. 265–72, New York, 1874; C. F. Naumann, *Elemente der Mineralogie*, 10th ed., by Dr F. Zirkel, pp. 532–5, Leipsic, 1877. On so-called garnets from the river Bobrowska, Urals, see Church, *Mineralog. Mag.* ii., 1879, p. 191. (F. H. B.)

GARNIER, Germain (1754–1821), an able writer on political economy, was born at Auxerre, on 8th November 1754. He was educated for the law, and obtained when young the office of *procureur* at Chatelet. He acted for some time as secretary to Mme. Adelaide, aunt of Louis XVI., and by his fine presence and manners acquired considerable reputation and power at court. On the calling of the states-general he was named as deputy for Chatelet, and in 1790 he appears to have been a member of the monarchical club in Paris. After 1792 he withdrew to the Pays de Vaud, and did not return till 1795. In public life, however, he seems to have been singularly fortunate. In 1797 he was on the list of candidates for the Directory; in 1800 he was prefect of Seine et Oise; in 1804 he was made senator; and from 1809 to 1811 he acted as president of the senate. After the restoration he obtained a peerage, and on the return of Louis XVIII., after the Hundred Days, he became minister of state and member of privy council. He died at Paris, 4th October 1821. Garnier was somewhat advanced in years before he began to take any interest in political economy; his previous efforts in literature had been of an altogether different kind. At court he was, when young, noted for his facile power of verse-writing, and he translated Mrs Radcliffe and Mrs Montague.

Garnier is best known by his admirable translation, with notes and introduction, of Smith's *Wealth of Nations* (1st ed 1805, 2d ed. 1822), and by his *Histoire de la Monnaie* (2 vols., 1819), which contains much sound and well-arranged material. His *Abrégé des Principes de l'Écon. Polit.* (1796) is a very clear and instructive manual. Of high value also is the *Description géographique, physique, et politique du départe ment de Seine-et-Oise* (1822), drawn up from his instructions. Other works are *De la Propriété* (1792), and *Histoire des Banques d'Escompte* (1806).

GARNIER, Marie Joseph François (1839–1873), usually called Francis Garnier, a French officer and explorer, was born at St Étienne, July 25, 1839, and perished by assassination in Tong-king, December 7, 1873. He entered the navy, and after voyaging in Brazilian waters and the Pacific he obtained a post on the staff of Admiral Charner, who from 1860 to 1862 was campaigning in Cochin-China. After some time spent in France he returned to the East, and in 1852 he was appointed inspector of the natives in Cochin-China, and entrusted with the administration of the town of Cho-len or Sho-len. It was at Garnier's suggestion that the Marquis de Chasseloup-Laubat determined to send a mission through Laos to Tibet, but as he was not considered old enough to be put in command, the chief authority was entrusted to Captain Doudart de Lagrée. In the course of the expedition—to quote the words of Sir Roderick Murchison addressed to the youthful traveller when, in 1870, he was presented with the Victoria Medal of the Royal Geographical Society of London—from Cratieh in Cambodia to Shanghai 5392 miles were traversed, and of these 3625 miles, chiefly of country unknown to European geography, were surveyed with care, and the positions fixed by astronomical observations, nearly the whole of the observations being taken by Garnier himself. Volunteering to lead a detachment to Talifu the capital of Sultan Suleiman, the sovereign of the Mahometan rebels in Yunnan, he successfully carried out the more than adventurous enterprise. When shortly afterwards Lagrée died, Garnier naturally assumed the command of the expedition, and he conducted it in safety to the Yang-tze-Kiang, and thus to the Chinese coast. On his return to France he was received with enthusiasm. The preparation of his narrative was interrupted by the Franco-German war, and during the siege of Paris he served as principal staff officer to the admiral in command of the eighth "sector." His experiences during the siege were published anonymously in the feuilleton of *Le Temps*, and appeared separately as *Le Siége de Paris, journal d'un officier de marine*, 1871. Returning to Cochin-China he found the political circumstances of the country unfavourable to further exploration, and accordingly he went to China, and in 1873 followed the upper course of the Yang-tze-Kiang to the waterfalls. He was next commissioned by Admiral Dupré, governor of Cochin-China, to Tong-king to found a French protectorate or a new colony. On November 20, 1873, he took Hanoï, the capital of Tong-king, and on December 7th he was slain.

The narrative of the principal expedition appeared in 1873, as *Voyage d'exploration en Indo-Chine effectué pendant les années* 1866, 1867, *et* 1868, *publié sous la direction de M. Francis Garnier, avec le concours de M. Delaporte et de MM. Joubert et Thorel*, 2 vols. An account of the Yang-tze-Kiang from Garnier's pen is given in the *Bulletin de la Soc. de Géog.*, 1874. His *Chronique royale du Cambodje* was reprinted from the *Journal Asiatique* in 1872. See *Ocean Highways*, 1874, for a memoir by Colonel Yule.

GAROFALO, BENVENUTO. See TISIO.

GARONNE, the ancient *Garumna*, a river of southern France, which rises in the Spanish Pyrenees not far from the massif of Maladetta, flows through the fine gorge called the Val d'Aran, partly loses itself under the calcareous rocks that form the gulf of Clédes, enters France near the Pont du Roi, and proceeds in a general north-west direction till it falls into the Bay of Biscay. Rafts can be sent down the river from the Spanish frontier; boats can pass with the stream from the confluence of the Salat to Toulouse; from Toulouse downwards regular navigation with boats can be maintained; and seafaring vessels can sail up as far as Castets, 32 miles above Bordeaux. At Bec d'Ambes, near the confluence of the Dordogne, the river widens out to a breadth of from 2 to 4 miles, and takes the name of the Gironde. This estuary presents an almost uninterrupted succession of islands and banks, which divide it into two nearly equal branches, and render the navigation somewhat difficult. At the mouth stands the famous tower of Cordouan, which dates from 1584–1610, and ranks as one of the finest lighthouses on the coast of France. The current at Toulouse, when the water is at its lowest, amounts to 1271 cubic feet per second, but in the ordinary state of the river it is 5297 cubic feet. During ordinary flood it rises about 25 feet; but in exceptional cases, as in 1855 and 1856, this increases to 28 or even 30 feet, and as the banks of the river are low the inundations are very extensive. The principal affluents on the right are the Salat, the Ariége, the Tarn, the Lot, the Dropt, and the Dordogne; and on the left the Neste, the Bouge, the Save, the Gimoné, the Gers, the Baise, and the Ciron.

GARONNE, HAUTE-, or UPPER GARONNE, is one of the frontier departments in the south of France, being continuous with Spain along the line of the Pyrenees. To the N. lies the department of Tarn-et-Garonne, to the E. are those of Tarn, Aude, and Ariége, and to the W. those of Gers and Hautes-Pyrénées. The form of the department is very irregular. Its greatest length is 99 miles from N.E. to S.W., and its greatest breadth about 56 miles; but its area only amounts to 629,000 hectares, or 2428 English square miles. The northern portion is a fertile but mountainous stretch of country, with continual interchange of hill and valley nowhere thrown into striking relief; while towards the south the land rises gradually to the Pyrenees, which there attain a height of upwards of 11,000 feet. All the streams by which the department is watered—the Neste, the Salat, the Lers, the Logue, the Touche, &c.—belong to the system of the river from which it takes its name. Except in the mountainous region the climate is mild, the mean annual temperature being rather higher than that of Paris. The rainfall, which averages 23 inches at Toulouse and 26 at St Gaudens, is distributed over 125 days. The winds are often violent. Thick forests of oak, fir, and pine exist in the mountains, and furnish timber for shipbuilding. The arable land (360,241 hectares, or 890,207 acres) is well adapted for the cultivation of wheat, maize, and other grain crops; and the produce of cereals is generally much more than is required for the local consumption. Oats, buckwheat, barley, flax, colza, and potatoes are all grown; fruit is plentiful, and about 54,000 hectares, or 133,441 acres, are occupied by vineyards, though the wine is only of medium quality. As pasture land is abundant, a good deal of attention is given to the rearing of cattle and sheep; and owing to the mountainous character of the southern region asses and mules are favourite beasts of burden, and may be estimated at 24,000 in number. Iron, lead, copper, and coal are among the mineral productions, as well as marble, both white and variegated, granite, freestone, lime, and slate. The manufactures are various though not individually extensive, and include iron and copper utensils, earthenware, woollen, cotton, and linen goods, leather, paper, watches, mathematical instruments, &c. Railway communication is furnished by the line from Bordeaux to Cette which passes by Toulouse, and there sends off branch lines leading to Albi, Auch, Foix, St Giron, and Bagnères de Luchon. The Canal du Midi traverses the department for 32 miles. There are four arrondissements—Toulouse, Villefranche, Muret, and St Gaudens, subdivided into 39 cantons and 585 communes. The chief town, Toulouse, contained 120,208 in 1875; but there is no other town of even 5000 inhabitants in the department, the largest being St Gaudens with 4087. The population of Haute-Garonne in 1801 was 405,574, including the arrondissement of Castelsarrasin with 60,545 inhabitants, which was detached in 1806; in 1851 it was 481,610, and in 1875, 477,730.

GARRICK, DAVID (1716–1799), the greatest actor of his age, and the most successful of English theatrical managers, was descended from a good French Protestant family of Bordeaux which had settled in England on the revocation of the edict of Nantes. His father, Captain Peter Garrick, was on a recruiting expedition when his celebrated son was born at Hereford on February 19, 1716–17. The captain usually resided at Lichfield on half pay, but, in order to benefit his large family, he accepted an offer to proceed on service to Gibraltar, in place of a brother officer who was desirous of returning to England. This kept him many years absent from home, and the letters written to him by "little Davy," acquainting him with the doings at Lichfield, are highly interesting memorials of the future Roscius. In his nineteenth year, after receiving a good education at the grammar school of Lichfield, David was sent to the establishment at Edial, opened in June or July 1736 by Samuel Johnson, his senior by seven years. The Edial academy was shut in about six months, and on the 2d of March 1736–7 master and pupil, Johnson and Garrick, left Lichfield for London, the one to commence the study of the law, and the other to try his tragedy of *Irene*—Johnson, as he afterwards said, "with twopence halfpenny in his pocket," and Garrick "with three-halfpence in his." Seven days afterwards, however, Garrick was entered of Lincoln's Inn, but after remaining for a few months in London, he resided for some time with Mr Colson, a distinguished teacher at Rochester afterwards Lucasian (professor at Cambridge). Captain Garrick, who had returned from Gibraltar, died about a month after his son's arrival in London. Soon afterwards a rich uncle, a wine merchant at Lisbon, in his will left David a sum of £1000, and he and his brother entered into partnership as wine merchants in

London and Lichfield. The concern was not prosperous—though Foote's assertion that he had known Garrick with three quarts of vinegar in the cellar calling himself a wine merchant need not be taken literally—and before the end of 1741 he had spent nearly half of his £1000. His passion for the stage completely engrossed him; he tried his hand both at dramatic criticism and at dramatic authorship, and made his first appearance on the stage late in 1740–1, *incognito*, as harlequin at Goodman's Fields, where Woodward, being ill, allowed him to take his place during a few scenes. When the manager of the same theatre, Giffard, took a party of players to Ipswich, Garrick accompanied them, and there made his first essay as an actor under the name of Lyddal, in the part of the black Aboan (in Southerne's *Oroonoko*). His success on the provincial boards determined his future career. On the 19th of October 1741 he made his appearance at Goodman's Fields in the character of Richard III., and gained the most enthusiastic applause. His staid and sedate brother, and his sisters at Lichfield, were scandalized at this derogation from the provincial dignity of the family; and Garrick, greatly distressed at the shock they had received by the intelligence (which, however, he expected), hastened to give up his interest in the wine company. Each night added to his popularity on the stage. He was received by the best company in town. While his Richard was still calling forth general admiration, he won new applause in Lear and Pierre, as well as in several comic characters (including that of Bayes). Glover ("Leonidas") attended every performance; Lyttelton, Pitt, and several other members of parliament had shown him the greatest civility. From December 2d he appeared in his own name. Pope went to see him thrice during his first performances, and pronounced that "that young man never had his equal as an actor, and he will never have a rival." Before next spring he had supped with "the great Mr Murray, counsellor," and hoped to do so with Mr Pope through Murray's introduction, while he was dining with Halifax, Sandwich, and Chesterfield. "There are a dozen dukes of a night at Goodman's Fields," writes Horace Walpole. *The Lying Valet* being at this time brought out with success, the honours of dramatic author were added to those of the stage. His fortune was now made, and while the managers of Covent Garden and Drury Lane resorted to the law to make Giffard close his little theatre, Garrick was engaged by Fleetwood for Drury Lane for the season of 1742. In the meantime, having very advantageous terms offered him for performing in Dublin during part of the summer, he went over to that city, where he found the same homage paid to his merit which he had received from his own countrymen. From September 1742 to April 1745 he continued at Drury Lane, after which he again went over to Ireland, and remained there the whole season, as joint-manager with Sheridan, in the direction and profits of the theatre-royal in Smock Alley. From Dublin he returned to England, and fulfilled a short engagement in 1746–7 with Rich at Covent Garden. This was his last series of performances as a hired actor; for in the close of that season Fleetwood's patent for the management of Drury Lane expired, and Garrick, in conjunction with Lacy, purchased the property of the theatre, together with the renovation of the patent, and in the winter of 1747 opened it with a strong company of actors, the prologue for the occasion being written by his old preceptor Johnson.

For a time, at least, "the drama's patrons" were content with the higher entertainment furnished them; in the end Garrick had to "please" them, like most other managers, by gratifying their love of show. Garrick was surrounded by many players of eminence; and he had the art, as he was told by Miss Clive, "of contradicting the proverb that one cannot make bricks without straw, by doing what is infinitely more difficult, making actors and actresses without genius." The naturalness of his own acting was its great charm. As Churchill says in the *Rosciad*, which remains the chief literary monument of Garrick's pre-eminence among his fellows, he who is "pleased with Nature, must be pleased with thee." Booth, Quin, and the old tragedians were remarkable for a style of stately declamation, sonorous, and often graceful and impressive, but wanting the versatility and rapid changes of passion that, when exhibited by Garrick, at once captivated the audience. "It seemed," said Richard Cumberland, "as if a whole century had been stepped over in the passage of a single scene; old things were done away, and a new order at once brought forward, bright and luminous, and clearly destined to dispel the barbarisms of a tasteless age, too long superstitiously devoted to the illusions of imposing declamation." Garrick's French descent and his education may have contributed to give him the vivacity of manner and versatility of conception which distinguished him as an actor; and nature had given him an eye, if not a stature, to command, and a mimic power of wonderful variety. The list of his characters in tragedy, comedy, and farce is large, and would be extraordinary for a modern actor of high rank; it includes not less than seventeen Shakespearean parts. As a manager, though he committed some grievous blunders, he did good service to the theatre and signally advanced the popularity of Shakespeare's plays, of which not less than twenty-four were produced at Drury Lane under his management. Many of these were not pure Shakespeare; but not every generation has the same notions of the way in which he is best honoured. He purified the stage of much of its grossness, and introduced a relative correctness of costume and decoration unknown before.

After, about the year 1745, escaping from the chains of an unreturned passion for the beautiful but reckless actress "Peg" Woffington, Garrick had, in 1749, married Mademoiselle Violette (Eva Maria Veigal), a German lady who had attracted the admiration of the court of Vienna as a dancer, and was patronized in England by the countess of Burlington. This lady Garrick called "the best of women and wives," and he lived most happily with her in his villa at Hampton (acquired by him in 1754, and adorned by the famous Shakespeare temple), whither he was glad to escape from his house in Southampton Street. Their union was childless, and Mrs Garrick survived her husband, living in great respect until 1822. Having sold the moiety of his theatre for £35,000, Garrick took leave of the stage by playing a round of his favourite characters—Hamlet, Lear, Richard, Lusignan, and Kitely, as the graver; Archer, Abel Drugger, Sir John Brute, Benedick, Leon, and Don Felix, as those of a lighter cast. He ended the series with Don Felix (in *The Wonder*) on June 10, 1776. But he was not long to enjoy his opulent and well-earned repose, for he died in London on the 20th of January 1779. He was buried in Westminister Abbey with imposing solemnities, and amidst an unexampled concourse of people of all ranks. Johnson, whose various and not always consistent criticisms on Garrick are scattered through the pages of Boswell, spoke warmly of the elegance and sprightliness of his friend's conversation, as well as of his liberality and kindness of heart; and his death, which came upon him unexpectedly, "eclipsed," Johnson said, "the gaiety of nations, and impoverished the public stock of harmless pleasure." But the most accurate and discriminating character of Garrick, slightly tinged with satire, is that drawn by Goldsmith in his poem of *Retaliation*. As a literary man Garrick was very happy in his epigrams and slight occasional poems. He had the good taste to recognize, and the spirit to make public his recognition of, the excellence of Gray's *Odes* at a time when they were either ridiculed or neglected. His dramatic pieces (*The Lying Valet*, *Lethe*, *The Guardian*, *Miss in her Teens*, *Irish Widow*, &c.), and his alterations and adaptation of old plays, which together fill four volumes, evinced his knowledge of stage effect and his appreciation of lively dialogue and action; but he cannot be said to have added one new or original character to the drama. He was joint author with Colman of *The Clandestine Marriage*, in which he is said to have written his famous part of Lord Ogleby. The excellent farce, *High Life below Stairs*, appears to have been wrongly attributed to Garrick, and to be by Townley, a clergyman. As a matter of course he wrote many prologues and epilogues.

Garrick's correspondence (published, with a short memoir by Boaden, in 2 vols. 4to), and the notices of him in the memoirs of Hannah More and Madame D'Arblay, and above all in Boswell's *Life of Johnson*, bear testimony to his general worth, and to his many fascinating qualities as a friend and companion. The earlier biographies of Garrick are by Arthur Murphy (2 vols. 1801) and by the bookseller Tom Davies (2 vols., 4th ed., 1805), the latter a work of some merit, but occasionally inaccurate and confused as to dates. Mr Percy Fitzgerald's *Life* (2 vols. 1868) is full and spirited. A charming essay on Garrick appeared in the *Quarterly Review*, July 1868. (R. CA.—A. W. W.)

GARRISON.

WILLIAM LLOYD GARRISON, whose name is inevitably identified with the struggles which led up to the abolition of slavery in the United States, was born in Newburyport, Mass., December 10, 1805. Every surrounding of his youth contributed to the development of sturdy and sterling qualities of character. His birthplace had been the scene of heroic deeds, and had echoed to the voices of religious martyrs. His father was a sea-captain of great bravery and ability, and his mother belonged to the persecuted sect of Baptists, so that he took in the ideas of courage in personal danger and hate of oppression almost with his earliest food. It was a period so near the Revolutions in America and France that love of liberty and patriotism still moved the best minds to consideration of the questions of the day which were concerned in problems of the government and rights of the people. It is not strange, then, that with the Declaration of Independence ringing in his ears, with his heroic and ascetic ancestry and his superior mental endowments, he should see the injustice of slavery, and early array himself against such an institution, and be enabled to speak with a voice of thunder in the cause of those in bondage.

But, like many another leader, he had to come up through the ranks. Long hours of the day, while still a child in years and strength, he sat with great thoughts indefinitely forming in his brain, but trying conscientiously to learn the trade of shoemaker, to which his mother had apprenticed him. This was so distasteful to him that he next tried cabinet making, and then the art of printing, a trade that fascinated him at first, and afterwards afforded him the means of supplying the lack of college education. As he picked up the small pieces of lead he learned to spell, to form sentences of his own, and the power of words to convince and convict. The papers on which he worked as a printer contained many anonymous articles written in the composing stick of William Lloyd Garrison. He had his own views, even then, on all the political and ethical questions of the day, and expressed them in articles for his own paper, "The Newburyport Herald," and for various papers published in Boston. After mastering the printer's trade he launched his little boat—"The Free Press"—in his native town; but, probably because its tone was too high it was not patronized, and the ambitious young enthusiast had to abandon both his paper and his town and seek a wider field in Boston with "The National Philanthropist." This was the first paper ever established to teach the evils of intemperance and preach the new gospel of total abstinence. He was but twenty-five years of age at the time, and the custom of serving wine on the table was followed in the best of houses, so that he must have had, even so young, a finely developed taste for the martyrdom of espousing unpopular causes. That he was to be a radical in all the ideas he ever advanced was forecast in the motto he chose for his paper—"Moderate drinking is the down-hill road to drunkenness."

The political situation at this time, 1828, seemed to young Mr. Garrison to demand the election of John Quincy Adams as President, and, with the ardor already characteristic of him, he bent all his energies to this purpose. Going to Bennington, Vt., he started a campaign paper supporting Mr. Adams, but did not neglect his "total abstinence" evangelizing, and found room in his large heart and brain for still another idea; no less a one than the emancipation of the slave. The columns of the little "Journal of the Times," under Garrison's editorship, and Benjamin Lundy's "Genius of Universal Emancipation," published in Baltimore, were the only mediums for the dissemination of these ideas in the country. But the message sent out by them was uncompromising, and caused no little discussion among public men. Already it was whispered around that this Garrison was an uncomfortable man to have about; that he threatened to upset things, and confused preconceived ideas.

It was inevitable that Garrison and Benjamin Lundy should come together, and that an ideal partnership should be formed. Mr. Lundy was a Quaker, simple-minded, full of zeal and unselfish devotion, and with a serene conviction that he was following the guidance of the Spirit. He travelled, lectured and edited his little sheet, which appeared but once a month, and carried the light of liberty into the very capitol and confused and confounded the law-makers, who held slaves in the very seat of liberty. After the inauguration of Adams, Mr. Garrison went to Baltimore, assumed the editorship of "The Genius of Universal Emancipation," and immediately began to issue the paper weekly. He also changed its tone, making it radical and aggressive. He demanded immediate emancipation of all slaves, and would accept no compromise. He preached that if slavery was wrong, it was fundamentally wrong, and should be abolished at once. Mr. Lundy's teaching looked to the gradual freeing of the slaves; he believing that to be the only way to accomplish the result to the injury of no one concerned. But Mr. Garrison, from the first moment of conviction, had got at the root of the matter: the system was wrong, and the very laws of the Creator demanded that it should be righted — not some other time, but now. So the paper appeared expressing both the radical views of Mr. Garrison and the conservative ones of Mr. Lundy, each signing his own articles. Garrison's forcible arguments and unqualified demands made an instant impression, and created some alarm. Almost under the windows of Mr. Garrison's office was the great slave market of Baltimore, and his utterances in the paper struck blows directly on the auctioneer's block, and were a menace to the commercial prosperity of the city.

As an immediate result Mr. Garrison was exceedingly unpopular, and was feared and hated at the same time. The converts that had been made by Mr. Lundy's mild doctrine were timid, and were frightened into withdrawal of their support of the paper by the aggressive policy of this new agitator. Even the most ardent and faithful adherents of the abolition idea were not ready to admit the feasibility of immediate emancipation, and considered Garrison's ultraism the rankest nonsense and folly, believing he would defeat his own object by his radical doctrines.

But that Mr. Garrison was right in his estimate of the amount of public sentiment that slumbered, and needed only to be awakened by his clarion voice was amply proven. Within a few months abolition was discussed from one end of the land to the other. This audacious man had to be stopped, and opportunity was found in a libel suit, instituted by Mr. Francis Todd, a domestic slave trader, whom Garrison had denunciated. He was found guilty, and, being unable to pay his fine, was sent to jail abandoned by his half-hearted adherents.

In the South exultation was open, and in the North he was considered a fanatic. But during his imprisonment, and because of it, he gained the friendship of John G. Whittier and other men who afterwards became noted abolitionists. On his release from prison the partnership between himself and Mr. Lundy was dissolved by mutual consent, and with the warmest admiration on both sides that strengthened into a lifelong friendship. After a course of lectures throughout northern cities, in all of which he was coldly received except by the free colored people and a few individuals, mostly quakers, he decided to begin the publication of a new paper, to be called "The Liberator," in Boston. This threatened the cotton traffic, and arrayed the commercial interests and consequently the press, and, in most instances, the pulpit against him.

That "The Liberator" was feared by the slaveholder is proved by the efforts made to suppress it. In Georgetown, D. C., it was made a penal offense to receive a copy of the seditious paper from the post office, aud vigilance committees were formed in various localities to detect and prosecute people who distributed it. In the North public sentiment was apathetic, though the converts made were men who were capable of carrying on the crusade in case Garrison's voice were hushed.

In 1831 Mr. Garrison was instrumental in forming the New England Anti-slavery Society, composed of twelve members. After an unsuccessful attempt to establish a college for colored people in New Haven, Conn., Mr. Garrison, in the spring of 1833, went to England to secure the co-operation of English abolitionists, of which Wilberforce was the most distinguished member. When he returned he organized the National Anti-slavery Society, the movement having grown sufficiently strong to warrant such a proceeding. This society convened in Philadelphia in December, 1833, and had delegates from eleven different States. John G. Whittier, Garrison and the Rev. Samuel J. May were the most distinguished men present, or rather the ones who afterwards became so. A constitution drafted by Garrison was adopted by unamimous vote and signed by all the delegates, sixty-two in number. It was a document filled with strong conviction and high and definite purpose fully stated, and was one calculated to make all thoughtful people consider the subject without predjudice; yet such was the violence of opposition to the abolition movement that it was received with abuse and ridicule. But the next year, 1834, was made memorable by the freeing of 800,000 slaves in the British West Indies. The American press and pulpit predicted the direst results from this proceeding, but the joy of the abolitionists was unbounded when the great event was accomplished without bloodshed, and nearly a million blacks made the equals in rights with white men. Necessarily this occurrence brought new recruits to the ranks of the anti-slavery party, notably from among the students of Lane University, Cincinnati, of which Dr. Lyman Beecher was the head. But the eminent preacher, although practically converted to abolition, failed to sustain his pupils in their open espousal of such an unpopular cause.

The history of William Lloyd Garrison is the history of the struggle to free the slaves, and from the time he published "The Genius of Universal Emancipation" until the Emancipation Proclamation was signed, the events of his life followed the progress of public sentiment and were inextricably bound up in it.

With 1835 began the pro-slavery mobs. In the same year the Southern press grew aggressive and threatening. The lives of Abolitionists were in danger, and Garrison was attacked in Boston, and was confined in prison over night to save him from the violence of a "respectable mob." This event and the outrages that followed culminating in the Alton tragedy, made many powerful friends for the Abolitionists.

The division in the American Anti-slavery Society was occasioned by the appointment of a woman on the business committee. This was led by Mr. Lewis Tappan. Its effect was to cripple the society by having the forces divided. The press, too, took advantage of it to heap obloquy on the head of Mr. Garrison. The worst effect on Mr. Garrison personally was the alienation from him of men with whom he had worked for years in harmony, particularly Mr. Arthur Tappan, who had secured his release from prison in Baltimore. Another friend, Mr. Rogers, editor of the "Herald of Freedom," fell away from him about the same time for a personal difference; but these troubles and obstacles only drove him on more relentlessly, for abolition had clarified his soul for the one purpose for which he existed. He refused to affiliate with the Liberty party, a political body which grew out of the discussions that were current. His policy was non-resistance and aimed at converting the great body of existing parties on a moral ground. He fought strenuously against the Anti-slavery Society's using their growing strength for political preferment. For this also he alienated many who were at one with him on every other point. It seemed as if he were almost as much alone as in the beginning, and was destined to remain to the end the single voice lifted up against the individual sin of owning slaves, untrammeled by any other consideration. It was by the moral sentiment of the country that he hoped to eliminate slavery, and to this idea, he and the small band who clung to him remained faithful throughout the conflicting agitations which followed. They allied themselves to no political party, yet out of them grew first the Liberty party, then the Free Soil and lastly the Republican, which absorbed all these ideas into a triumphant culmination of the common cause. Garrison and those who remained with him in this moral agitation were always at the head and front—the color bearers of the movement, and the target for scorn and vituperation. But moral sentiment was growing rapidly.

In 1844 Garrison took a stride forward in attacking the Constitution of the United States for its authorizing the slave traffic. This created great consternation at the time, but the North was growing accustomed to bombardments of all sorts from Garrison, directed against the institution of slavery, and was being gradually prepared for the struggle of '61.

The secession of the Southern States and formation of the Confederacy changed his views on the subject of freedom by violence. He saw that the purpose of disunion was the perpetuity of slavery, and that only by war could such a calamity be averted. To him and his teachings is due the fact that the North realized this and that the moral sentiment was ready, in the emergency, to rise and meet the occasion.

With the agitations of the fifties, which culminated in the Civil War, Mr. Garrison had but little actively to do. His voice had ever been lifted against violence, and he preached at the individual sinner, awakening approval of the system at a time when the war with Mexico, the admission of California, the free-soil movement in Kansas and the operations of the Fugitive Slave law were stirring animosities to the point of bloodshed. The moral sentiment had been roused to resistance against the encroachments of slave territory. He saw the effects of "Uncle Tom's Cabin" and the Dred Scott Decision, and John Brown's Raid, the compromises to avert war and one year before the beginning of the struggle, saw Abraham Lincoln inaugurated by a party pledged to protect the owners of slaves in the rights of property. But he never deviated one iota from his precepts and practices. He was still hoping for the extermination of slavery by creating such a moral sentiment that it could not exist longer.

After the war began by the attack on Fort Sumter, he changed his views and saw that bloodshed had been forced by the South and urged the North to fight, though he himself never took up arms. He could not do so consistently, and forever deplored the necessity for our terrible internecine strife.

William Lloyd Garrison seemed to have been born for a public life. His work for the good of mankind overshadows his private character. But that he fulfilled his domestic duties with equal faithfulness is well known. In his early manhood he married Miss Helen Benson, daughter of George Benson, of Brooklyn, Connecticut. She was a noble woman and sacrificed ease and comfort to help her husband in a cause with which she thoroughly sympathized. He lived in Boston until 1864, and then removed to a more retired life in Roxbury, Massachusetts. After a stormy life he enjoyed the fruits of peace with his wife and children, surrounded by loving friends and solaced for all his hardships by the approval of a nation which delighted to honor him.

There were seven children in this household, five reaching maturity. The eldest was named George Thompson, in honor of the great English emancipator, who was mobbed with Mr. Garrison while trying to lecture in Boston on the unpopular cause. The charge that Mr. Garrison was an infidel was never thought of in his early years, but was brought out as a last resort by the enemies of abolition, who sought to throw discredit upon his teachings. He never made any distinct statement of his religious views. He had one thing to do, which was so simple and direct, and so in accord with divine light, that he had no time for self-analysis or for troubling about splitting the hairs of creeds. He was condemned for doing what every minister in the North did during the war—pleading the cause of the slaves on the Sabbath day. In this he affiliated more nearly with the Quakers, with whom he was closely associated during many years of his life, than with other religionists. It is not to be denied that as a body the Quakers at this time were far in advance of the orthodox churches in the recognition of the sin of slavery, and most of Mr. Garrison's active followers were from this sect. It is not strange, then, that he came to be more and more closely allied to these people in belief and practice, though he always contended that it was not the word of God which was at fault, but the preachers' interpretation of it, and that any sanction of slavery came not from the Bible but from the Devil. He had to come at last to the opinion that the churches were falling away from their true position and he dared not betray his own mission for a perverted church. As he got farther from church organizations he claimed that he grew nearer to God. He felt in spite of all church opposition that truth and justice would eventually triumph. Still his pure and lofty purpose did not save him from the charge of infidelity and further persecutions on that account. But in spite of this, his teachings crept finally into the churches and influenced the utterings from the pulpits. He thus spurred up the lagging orthodoxy of the day and brought the Christian churches into unity with the purposes of God.

For his views on other questions Mr. Garrison believed in the freedom of speech and the press and in the fearless inquiry into all ethical and intellectual problems. He admitted that many men might be sincere and right in their beliefs though differing widely from each other. Necessarily many new ideas found welcome in his heart and brain which were formulated into a sort of eclectic creed of his own that embraced even some of the tenets of spiritualism. He was an "infidel" because he refused to be labelled or claimed by any denomination. Before his death an eminent preacher said of him: "It would be a serious charge against Christianity to say that it is so narrow as to exclude such men as Mr. Garrison."

After the close of the war Mr. Garrison was the recipient of the greatest honors which could be bestowed upon him, but perhaps the occasion of his visit to Charleston, where he met the freedmen for whom he had labored so long, was the crowning joy of his life. "The Liberator" which had existed since 1831 was discontinued in 1865, having served its purpose and having no further excuse for existence. He refused to belong to any anti-slavery society after the war, saying that slavery was ended, agitation was ended, and urged that the energies of sympathizers should be turned to the new question that had sprung up—education, enfranchisement and employment of the freedmen. In the last number of "The Liberator" he published the ratification of the Thirteenth Amendment forever prohibiting slavery.

Mr. Garrison was never an orator in the rhetorical sense of the term, but he was so much in earnest and his words were so accurately chosen because of his integrity of character that he always impressed his hearers as being an eloquent man. His writings have a same convincing quality. In person he inspired profoundest respect and admiration in those who met him, even if they differed radically from the views he held. They always thought: "Here is a man who is terribly in earnest, whose intellect compels attention." His benevolence was so large that all his life up to sixty years of age had been spent in unremunerative toil, so that at the close of the war for the Union, he was a poor man. The sum of $30,000 was raised and presented to him in 1868 as a testimonial of the value of his services to the cause of abolition, thus making him secure of a modest competence in his old age. His heart was very tender for the helpless, especially for children and animals, and his respect for women profound.

After the close of the war Mr. Garrison lived a quiet life, going to England for his health in 1867, and to visit two of his children who were in Paris. The attentions of people of note were showered abundantly upon him. A breakfast was given in his honor in St. James' Hall in London, at which the most distinguished men in England were present.

The great emancipator died May 24, 1879, aged 74 years, at Roxbury, Massachusetts, surviving his wife three years and leaving four children living. He was buried in the cemetery at Forest Hills.

Of his writings a book of sonnets and other poems, some of which were written while in prison in Baltimore, appeared, and a volume of lectures and papers on Emancipation was issued in 1852. Several histories of his life have been written, one by a lifelong friend and co-laborer and another by his children.

GARTER, ORDER OF THE. See KNIGHTHOOD.

GARTH, SIR SAMUEL (1670?–1719), a physician and poet of the age of Anne, was born of a good Yorkshire family, in 1670, it is said, but more probably at an earlier date. He was a student of Peterhouse, Cambridge, where be resided until he was received into the College of Physicians in 1691. In 1696 he became a prominent supporter of the new scheme of providing dispensaries for the relief of the sick poor, as a protection against the greed of the apothecaries. This labor having exposed him to the animosity of many of his own profession, and especially of the last named body, he published in 1699 a mock heroic poem, *The Dispensary*, in six cantos, which had an instant success, passing through three editions within the year. Garth became the leading physician of the Whigs, as Radcliffe was of the Tories. In 1714 he was knighted by George I., and he died on the 18th of January 1718–1719. Garth was a wealthy man, leaving estates in Warwickshire, Oxfordshire, and Buckinghamshire. He wrote little besides his best known work *The Dispensary*, and *Claremont*, a moral epistle in verse. In 1717 he edited a translation of Ovid's *Metamorphoses*, himself supplying the fourteenth and part of the fifteenth book. The subject of his mock heroic epic is treated in a cumbrous style; and even in his own day Garth was accused of flatness and poverty of thought.

GAS AND GAS-LIGHTING

ALL artificial light is obtained as a result either of combustion or of incandescence; or it might be more accurate to classify illuminating agents as those which emit light as a result of chemical action, and those which glow, from the presence of a large amount of heat, without thereby giving rise to any chemical change. The materials whence artificial light of the nature of flame has been derived are principally bodies rich in carbon and hydrogen. Wax, fats, and oils, on exposure to a certain amount of heat, undergo destructive distillation, evolving inflammable gases; and it is really such gases that are consumed in the burning of lamps and candles, the wicks bringing small proportions of the substances into a sufficient heat. Wood and coal also, when distilled, give off combustible gases; and ordinary gas-lighting only differs from illumination by candles and lamps in the gas being stored up and consumed at a distance from the point where it is generated.

Inflammable gas is formed in great abundance within the earth in connexion with carbonaceous deposits, such as coal and petroleum; and similar accumulations not unfrequently occur in connexion with deposits of rock-salt; the gases from any of these sources, escaping by means of fissures or seams to the open air, may be collected and burned in suitable arrangements. Thus the "eternal fires" of Baku, on the shores of the Caspian Sea, which have been known as burning from remote ages, are due to gaseous hydrocarbons issuing from and through petroleum deposits. In the province of Szechuen in China, gas is obtained from beds of rock-salt at a depth of 1500 or 1600 feet: being brought to the surface, it is conveyed in bamboo tubes and used for lighting as well as for evaporating brine; and it is asserted that the Chinese used this naturally evolved gas as an illuminant long before gas-lighting was introduced among European nations. At a salt mine in the comitat of Marmaro in Hungary, gas is obtained at a depth of about 120 feet, and is used for illuminating the works of the mine. Again at Fredonia (New York State) a natural emission of gas was discovered in a bituminous limestone, over the orifice of which a gasholder has been erected, and thus about 1000 cubic feet of a gas composed of marsh gas and hydride of ethyl has been made available for illumination. In the city of Erie (Pa.) there are 13 gas-wells, each yielding from 10,000 to 30,000 feet per day, the gas escaping from one of them at a pressure of 200 lb per square inch. At Bloomfield, Ontario co., New York, there is a spring which yields daily no less than 800,000 feet of gas of an illuminating power equal to 14½ candles. The city of East Liverpool (Ohio) is entirely illuminated, and to a large extent heated, by gas-wells which exist in and around the town. The light is of extraordinary brilliancy, and is so abundant and free that the street lamps are never extinguished, and much of the manufacturing steam-power of the town, which embraces 22 potteries, giving employment to 2000 hands, is derived from the gas. The first "well," 450 feet deep, was opened in 1859, and up to the present year (1879) neither it nor any of those tapped at later dates show any sign of failing. In many other parts of America similar gas-wells exist; and several such natural jets of gas have been observed in England.

By general consent the merit of the discovery and application of artificial gas belongs to Great Britain, and the name most honourably connected with the beginning and early stages of gas-lighting is that of a Scotchman—Robert Murdoch. But previous to Murdoch's time there occur numerous suggestive observations and experiments as to inflammable air and its sources. In the *Philosophical Transactions* of the Royal Society for 1667 the existence of a "burning spring" in the coal district of Wigan is noticed by Thomas Shirley, who traced its origin to the underlying coal. In the same *Transactions* for 1739 is printed a letter addressed to the Hon. Robert Boyle, who died in 1691, in which the Rev. John Clayton details a series of experiments he made in distilling coal in a retort, showing, not only that he had observed the inflammable gases evolved, but that he collected and stored them for some time in bladders. In Dr Stephen Hales's work on *Vegetable Staticks*, published in 1726, more precise statements are made as to the distillation of coal, he having obtained from 158 grains of Newcastle coal 180 inches of inflammable air. In 1787 Lord Dundonald, in working a patented process for obtaining coal-tar, experimented with the gas evolved in the process, and occasionally used it for lighting up the hall of Culross Abbey. None of these observations, however, led to distinct practical results; and it was not till the year 1792 that Robert Murdoch, then residing at Redruth in Cornwall, began the investigations into the properties of gases given off by various substances which eventuated in the establishment of coal-gas as an illuminating agent. In 1797 he publicly showed the system he had matured, and in 1798, being then employed in the famous Soho (Birmingham) workshop of Boulton & Watt, he fitted up an apparatus for the manufacture of gas in that establishment, with which it was partly lighted. Thereafter the apparatus was extended, and the gas manufactured by it was introduced to other neighbouring workshops and factories. Among others who helped most materially to develop the infant art in England were Dr Henry of Manchester, and Mr Clegg, who, succeeding Mr Murdoch at Boulton & Watt's, introduced many improvements in gas manufacture, and ultimately became the most skilful and famous gas engineer in the United Kingdom.

In 1801 M. Lebon introduced gas distilled from wood into his own house in Paris, and the success of his experiment attracted so much notice and comment as to give rise to an impression that he is entitled to the credit of the invention. Lebon's experiment came under the notice of Mr F. A. Winsor, who took up the subject with a zeal and unwearying patience which led to a recognition of the advantages of the system, and the breaking down of the powerful prejudice which existed in England against the innovation. In 1803, through Winsor's efforts, the Lyceum Theatre was lighted with gas; but it was not till 1810 that he succeeded in forming a public company for manufacturing gas, and in obtaining an Act of Parliament for the Gas-Light and Coke Company. In 1813 Westminster Bridge was first lighted with gas, and in the following year the streets of Westminster were thus illuminated, and in 1816 gas became common in London. So rapid was the progress of this new mode of illumination that in the course of a few years after its introduction it was adopted by all the principal towns in the kingdom, for lighting streets as well as shops and public edifices. In private houses it found its way more slowly, partly from an apprehension of danger attending its use, and partly from the annoyance which was experienced in many cases through the careless and imperfect manner in which the service pipes were at first fitted up.

Sources of Gas.

Artificial gas is now distilled from a variety of substances, among which are coal, shale, lignite, petroleum, turf, wood, resins, oils, and fats; and it is also prepared by carburetting or impregnating with volatile hydrocarbons other non-luminiferous gases. Of the very numerous systems of gas-making which have been proposed since the early part of the century, none can compete for general purposes with the ordinary coal-gas process, when a supply of the raw material can be obtained at a moderate expense.

Coal-Gas.—Coals, varying greatly as they do in chemical constitution, differ also, as might be expected, as widely in their value and applicability for the manufacture of gas. Taking the leading varieties of coal to be included under anthracite, bituminous coal, and lignite or brown coal, we find that it is the class bituminous coal alone that yields varieties really serviceable for gas-making. Anthracite may be regarded as a natural coke from which the volatile constituents have been already driven off, and the more anthracitic any coal is, the less is it capable of yielding gas. Lignite also is rarely used for distillation, owing to the large proportion of oxygen and the amount of water in its composition. Of the bituminous coals again, it is only the caking or pitch coals, and the cannel or parrot coals, that are in practice used in gas-works. These also vary within very wide limits in their gas-making value, not only from the great difference among them in yield of gas, but also in the illuminating value of the gas they evolve. As a rule the coals which yield the largest percentage produce also the most highly illuminating qualities of gas. The cannel coals, which are specially recognized as "gas-coal," are most abundantly developed in Scotland and in Lancashire, and the fact of the unequalled qualities of Scotch cannel and of the allied substance, bituminous shale, for gas-making, has had the effect of rendering illumination by gas much more general and satisfactory in Scotland than in any other country It is only a very imperfect valuation of any gas-coal that can be made from chemical analysis, the really satisfactory test being actual experiment. According to H. Fleck, the coal most available for gas-making should contain to every 100 parts of carbon 6 parts of hydrogen, of which 4 parts are available for forming hydrocarbon compounds. It is desirable that coal used for distillation in gas retorts should be as far as possible free from sulphur, that in the case of coking coal the amount of ash should be small, and the proportion of oxygen should also be low, since that element abstracts hydrogen to form injurious watery vapour. The amount of ash present, however, in the best forms of Scotch cannel is large; and consequently the resulting coke, if the residue can be so called, is of comparatively little value. Unless coal can be stored in sheds which protect it from the weather, it ought to be used as soon as possible after being raised, rain and sunshine being detrimental to its gas-making qualities. The following table exhibits the chemical analysis and gas-yielding properties of a few of the principal and typical examples of coal for gas-making :—

Composition of Coals used in Gas-Making.

Variety of Coal.		Disposable Hydrogen.	Carbon.	Hydrogen.	Nitrogen.	Sulphur.	Oxygen.	Ash.

When the bowl of an ordinary clay pipe is filled with small fragments of bituminous coal, luted over with clay and placed in a bright fire, immediately smoke is seen to issue from the stalk which projects beyond the fire. The smoke soon ceases, and if a light is then applied to the orifice of the stalk, the issuing gas burns with a bright, steady flame, while a proportion of a black, thin, tarry liquid oozes out from the stalk. After the combustion ceases there is left in the bowl of the pipe a quantity of char or coke. This simple operation is, on a small scale, an exact counterpart of the process by which the destructive distillation of coal is accomplished in the manufacture of gas. The products of the distillatory process classed in the gas-works as gas, tar, and ammoniacal liquor, with a solid residue of coke, are in themselves mixtures of various definite chemical compounds; and as may be evident from the following list, these substances are very numerous and complex :—

Products of the Distillation of Coal at high-red heat.

I. *Illuminating Gases.*

Acetylene, C_2H_2	Gases.
Ethylene, C_2H_4	Gases.
Propylene, C_3H_6	Gases.
Butylene, C_4H_8	Gases.
Benzol, C_6H_6..............	Vapours.
Naphthalin, $C_{10}H_8$	Vapours.
Hydrogen, H..............	Dilunets.
Light carburetted hydrogen, CH_4..............	Dilunets.
Carbonic oxide, CO	Dilunets.
Carbonic acid, CO_2	Impurities.
Ammonia, NH_3	Impurities.
Cyanogen, C_2N_2	Impurities.
Bisulphide of carbon, CS_2 ...	Impurities.
Sulphuretted hydrogen, H_2S	Impurities.
Oxygen, O	Impurities.
Nitrogen, N	Impurities.
Aqueous vapour, H_2O..............	Impurities.

II. *Components of Tar.*

Benzol, C_6H_6	Liquid hydrocarbons.
Toluol, C_7H_8	Liquid hydrocarbons.
Cumol, C_9H_{12}	Liquid hydrocarbons.
Cymol, $C_{10}H_{14}$	Liquid hydrocarbons.
Naphthalin, $C_{10}H_8$ ...	Solid hydrocarbons.
Anthracene, $C_{14}H_{10}$...	Solid hydrocarbons.
Pyrene, $C_{16}H_{10}$..............	Solid hydrocarbons.
Crysene, $C_{18}H_{12}$	Solid hydrocarbons.
Carbolic acid, C_6H_6O.	
Cresylic acid, C_7H_8O	
Rosolic acid, $C_{20}H_{16}O_3$.	
Pyridine, C_5H_5N.	
Aniline, C_6H_7N.	
Picoline, C_6H_7N.	
Lutidine, C_7H_9N.	
Collidine, $C_8H_{11}N$.	
Leucoline, C_9H_7N.	

III. *Ammoniacal Liquor.*

Ammonium carbonate, $2NH_4.CO_3$.
,, sulphydrate, $NH_4.HS$.
Ammonium sulphocyanate, $NH_4.NCS$.
,, cyanide, $NH_4.NC$.
,, chloride, $NH_4.Cl$.

IV. *Coke and Ash in Retort.*

The proportions in which coal yields these products may be indicated by the case of a cannel giving off 11,000 feet per ton of gas of a density of 0·600. From 100 parts of such a coal there would be yielded—

Gas	22·25
Tar	8·50
Ammonia water	9·50
Coke	59 75

The proportions, however, and even the nature of these products of distillation are greatly modified by the temperature at which the distillation is effected, a low red heat yielding a small proportion of non-condensible gas but a large amount of heavy hydrocarbon oils, whence the distillation of shales and coal in the paraffin manufacture is conducted at a low red heat. By excessive heat, on the other hand, the compounds evolved become simpler in their chemical constitution, carbon is deposited, pure hydrogen is given off, and the gain in amount of gas produced is more than counterbalanced by its poverty in illuminating properties.

Of the gases and vapours which pass out of the retorts in a highly heated condition, some portion, consisting of tarry matter and ammoniacal liquor, precipitates almost immediately by simple cooling, and other injurious constituents must be removed by a system of purification to which the gaseous products are submitted. What thereafter passes on as ordinary gas for consumption still contains some percentage of incombustible matters—aqueous vapour, oxygen, nitrogen, and carbonic acid. The combustible portion also is separable into two classes, viz., non-luminous supporters of combustion, and the luminiferous constituents,—the former embracing hydrogen, marsh gas (light carburetted hydrogen), and carbonic oxide, while the latter includes the hydrocarbon gases acetylene, ethylene (olefiant gas or heavy carburetted hydrogen), propylene, butylene, and vapours of the benzol and naphthalin series

Formerly it was the habit to regard the proportion of heavy carburetted hydrogen (ethylene and its homologues) as the measure of the illuminating power of a gas. It has, however, been pointed out by Berthelot that the proportion of such compounds in some gas of good luminous qualities is exceedingly small; and in particular he cites the case of Paris gas, which, according to his analysis, contains only a mere trace of acetylene, ethylene, and other hydrocarbons, with 3 to 3·5 per cent. of benzol vapours. Subsequent experiments of Dittmar have proved that a mixture of pure ethylene and hydrogen burnt in the proportion of 3 volumes of hydrogen to 1 of ethylene yields little more light than ordinary marsh gas, while benzol vapour to the extent of only 3 per cent. in hydrogen, gives a brilliantly luminous flame. Frankland and Thorne have more recently determined the illuminating power of a cubic foot of benzol vapour burnt for 1 hour in various combinations, with the following results :—

With hydrogen it gave the light of		.... 69·71	candles.
,, carbonic oxide	,,	.... 73·38	,,
,, marsh gas	,,	.... 92·45	,,
,, ,, (second series)	,,	.... 93·94	,,

Thus it is highly probable that the illuminating value of coal-gas depends much more on the presence of benzol vapour than on the proportion of the heavy gaseous hydrocarbons, and the estimation of benzol in the gas is a point which has hitherto been comparatively neglected. In view of the inference that the presence of benzol vapour is so intimately related to illuminating power, the fact observed by Dittmar that water readily and largely dissolves it out of any gas mixture is of great consequence. When benzolated hydrogen containing 6 per cent. of benzol vapour was shaken up with water, the percentage of the vapour was found on analysis to be reduced to less than 2.

The average composition of the gas supplied to London is, on the authority of the late Dr Letheby, thus stated:—

	Ordinary Gas, 12 Candles.	Cannel Gas, 20 Candles.
Hydrogen	46·0	27·7
Light carburetted hydrogen	39·5	50·0
Condensible hydrocarbons	3·8	13·0
Carbonic oxide	7·5	6·8
Carbonic acid	0·6	0·1
Aqueous vapour	2·0	2·0
Oxygen	0·1	0·0
Nitrogen	0·5	0·4

Cannel gas is now, however, supplied only to the Houses of Parliament and to certain of the Government offices.

Manufacture of Coal-Gas.

The series of operations connected with the preparation and distribution of coal-gas embrace the processes of distillation, condensation, exhaustion, scrubbing or washing, purification, measuring, storing, and distribution by the governor to the mains, whence the consumers' supply is drawn. In connexion with consumption, pressure of the gas, measurement of the amount consumed, and the burners and other arrangements for lighting are the most important considerations.

Site and Arrangement of Works.—The choice of a site for a gas establishment is necessarily conditioned by local circumstances; but the facts that a considerable area is required, and that, at best, the works do not improve the amenity of any neighbourhood, are important considerations. A central position with respect to the area to be supplied is certainly desirable, but in the circumstances it is seldom to be obtained. Of even greater consequence for a large work is ready access to a railway or other means of transport; and most of the great establishments are now connected by sidings with lines of railway, whereby coals, &c., are delivered direct from the waggons to the store or retort-house, and in the same way the coke and residual products are removed. Where the arrangement is practicable, it is also desirable that the works should be erected at the lowest level of the area to be supplied, since coal-gas, being specifically lighter than atmospheric air, acquires a certain amount of pressure as it rises in pipes, which pressure facilitates its distribution, and it is much easier to control than to beget pressure. In the planning of works, regard must be given to economy of space and to labour-saving arrangements, so that the cost of manual labour may be minimized, and operations proceed in an orderly, methodical, and easily-controlled manner. The accompanying ground plan of gas-works (fig. 1) has been kindly furnished by Mr James Hislop of Glasgow, a gas engineer of known skill and experience; and while it shows arrangements of the most approved character, it will also enable the reader to recognize the position of the various erections and apparatus as they follow each other, and as they will now be described.

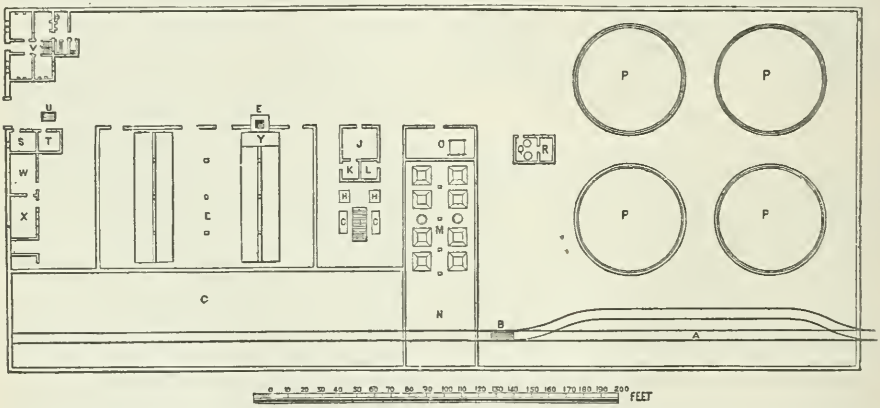

Fig. 1.—Ground-Plan of Gas-Works.

Retorts.—Retorts for destructive distillation of coal are formed of cast iron, clay, brick, or wrought iron. Various shapes have been adopted in the construction of these vessels; nor have their forms been more varied than the modes in which they have been disposed in the furnaces. In many instances they have been constructed of a cylindrical shape varying in length and diameter. Those first employed were of iron, with the axis vertical, but experience soon showed that this position was extremely inconvenient, on account of the difficulty which it occasioned in removing the coke.

The retorts were therefore next placed in a horizontal position, as being not only more favourable to the most economical distribution of the heat, but better adapted to the introduction of the coal and the subsequent removal of the coke. At first the heat was applied directly to the lower part of the retort; but it was soon observed that the high temperature to which it was necessary to expose it, for the perfect decomposition of the coal, proved destructive to the lower side, and rendered it useless long before the upper part had sustained much injury. The next improvement was, accordingly, to interpose an arch of brickwork between it and the furnace, and to compensate for the diminished intensity of the heat by a more equally diffused distribution of it over the surface of the retort. This was effected by causing the flue of the furnace to return towards the mouth of the retort, and again conducting it in an opposite direction, till the heated air finally escaped into the chimney. This arrangement was continued so long as iron retorts were in use, but on the general adoption of clay retorts the furnaces were constructed to allow the fire to play freely around them.

The cylindrical form of retort *a* (fig. 2) was long in favour on account of its great durability, but it is not so well fitted for rapid decomposition of the coal as the elliptical *b*, or

Fig. 2.

the flat-bottomed or D-shaped retorts *d*, which are now principally in use. Retorts are also made of a rectangular section with the corners rounded and the roof arched. Elliptical retorts are varied into what are called ear-shaped or kidney-shaped *c*, and it is not unusual to set retorts of different forms in the same bench, for the convenience of filling up the haunches of the arch which encloses them.

The length of single retorts varies from 6 to 9 feet, but they are now in some cases made 19½ feet in length and 12½ inches in internal diameter, these being charged from both ends.

Every retort is furnished with a separate mouthpiece, usually of cast iron, with a socket *b* (fig. 3) for receiving the stand-pipe or ascension-pipe, and there is a movable lid attached to the mouth, together with an ear-box cast on each side of the retort for receiving the ears which support the lid. Fig. 3 shows a form of mouthpiece attached to the retort *a*, and also the method of

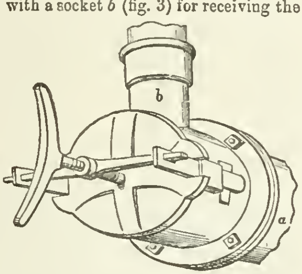

Fig. 3.

screwing the lid to the mouthpiece. That part of the lid which comes in contact with the edge of the mouthpiece has applied to it a lute of lime mortar and fire clay, and when the lid is screwed up, a portion of this lute oozes out round the edges and forms a gas-tight joint.

Except for small works, where the manufacture is intermittent, and where, consequently, the retort heat has to be got up frequently, iron retorts are now little used. Clay retorts, which at present are in most general use, wear out quickly; they very frequently crack so seriously on the first application of heat that they must be removed from the bench before being used at all, and in scarcely any case are they in action perfectly free from cracks. Numerous attempts have been made to introduce retorts built of brick; but the difficulty of making and keeping the joints air-tight has proved a serious obstacle to their use. In the

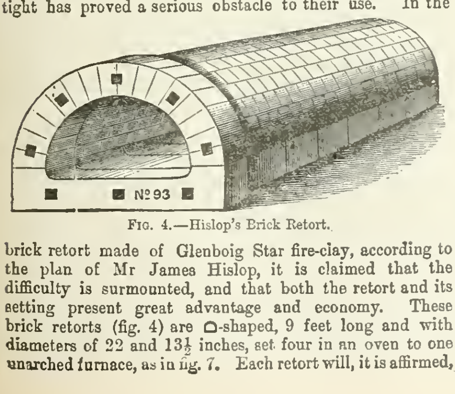

Fig. 4.—Hislop's Brick Retort.

brick retort made of Glenboig Star fire-clay, according to the plan of Mr James Hislop, it is claimed that the difficulty is surmounted, and that both the retort and its setting present great advantage and economy. These brick retorts (fig. 4) are ⌓-shaped, 9 feet long and with diameters of 22 and 13½ inches, set four in an oven to one unarched furnace, as in fig. 7. Each retort will, it is affirmed, carbonize 500 tons cannel coal, or 2000 tons per oven of four, without any repairs whatever. Decayed bricks may be removed from these retorts and new ones inserted, and when thoroughly repaired they are again equal to new. Thus the durability of each retort is so great that they are calculated to cost about ⅛th of a penny per 1000 cubic feet of gas generated, as against 1d. in the case of moulded retorts, and 7d. with iron retorts, for the same production of gas. In the Hislop retort the arched bricks are made plain, without groove or rebate joints—being thus stronger, more readily put together, and also cheaper. Carbon does not collect so rapidly on brick retorts as on those of clay, the bricks being harder pressed and better burned. On first lighting brick retorts, a charge of coke, breeze, and tar mixed makes them perfectly gas-tight.

Retort Setting.—A furnace or bed of retorts is composed of a group or setting, heated by a separate fire. The furnace is lined with the most refractory fire-bricks, and while the whole brickwork is made of such strength and solidity as ensures the safety of the retorts, the internal construction is so planned that the heat has the utmost possible amount of direct play on the retorts. The number of retorts to one furnace varies from 1 to 15, from 4 to 7 being the number most commonly adopted; and these are variously arranged to bring them all as close to the furnace heat as practicable. In some retort-houses the furnaces are built in two stages or stories, from the upper of which the retorts are charged and drawn, while at the lower level the glowing coke is removed and quenched. The whole range of furnaces constitutes the retort bench, having a common flue which leads to the chimney shaft by which the products of combustion are carried away. The gas-coal for charging the retorts is broken into fragments about 1 ℔ in weight or thereby. Figs. 5 (elevation) and 6 (section) illustrate the

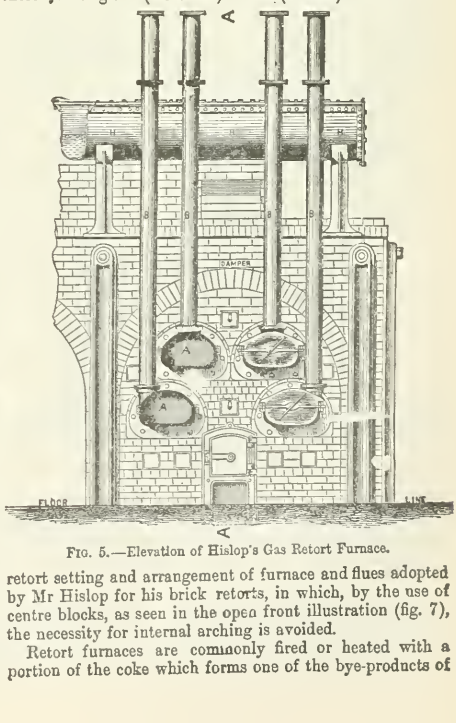

Fig. 5.—Elevation of Hislop's Gas Retort Furnace.

retort setting and arrangement of furnace and flues adopted by Mr Hislop for his brick retorts, in which, by the use of centre blocks, as seen in the open front illustration (fig. 7), the necessity for internal arching is avoided.

Retort furnaces are commonly fired or heated with a portion of the coke which forms one of the bye-products of the gas manufacture; but in works where shale and rich cannel coals are distilled, common coal must be used in the furnaces. At the Ivry Gas Works of the *Compagnie*

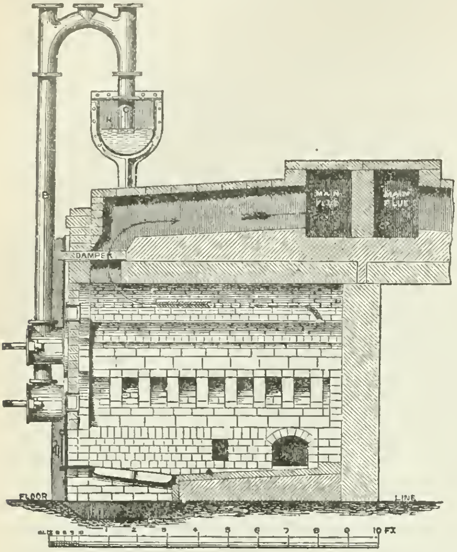

Fig. 6.—Section of Retort Bed on line A A of fig. 5.

Parisienne d'Éclairage et de Chauffage par le Gaz, the retorts are heated by gas on a method modified from the Siemens regenerative gas furnace. Sectional illustrations of a retort setting on this plan, and a description of the various arrangements connected with the regenerators and the controlling of the air and gas currents, will be found in the article Furnace, vol. ix. pp. 846, 847.

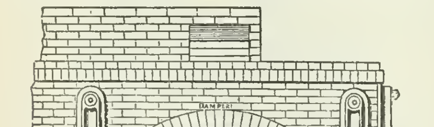

Fig. 7.—Retort Setting in Hislop's Furnace.

Ordinarily the work of charging and drawing the retorts is accomplished by manual labour, by means simply of shovels for charging, and long iron rakes for drawing the spent charge. In the larger works it is usual to charge the retorts with a scoop semi-cylindrical in form, made a little shorter than the retort, and of such a diameter that it can with ease be pushed in and overturned within the retort. The scoop deposits the coal neatly over the sole of the retort, and of course the lid is much more quickly replaced than can be done with shovel charging. Numerous attempts have been made to introduce purely mechanical means of feeding retorts, hitherto with indifferent success,—such devices as a travelling endless sole and a rotating sole having been tried without good effect. A charging machine and a drawing machine, worked by hydraulic power, have been introduced by Mr Foulis, the engineer of the Glasgow Corporation Gas Works, but after prolonged trial both in Glasgow and in Manchester, these have not yet proved satisfactory in action. In West's patent the charging is effected by the introduction of a small waggon within the retort, which distributes the charge evenly and uniformly Neither has it, however, met general acceptance.

The retorts are kept at a bright red heat, and for coal with a high percentage of volatile matter a higher temperature is requisite than is needed for coal less rich in gas. As the retorts in one setting are necessarily subject to somewhat different amounts of heat, the charges in those nearest the furnace fire, and consequently most highly heated, must be drawn more frequently than the others, as otherwise the quality of the gas would be deteriorated, and a large proportion of sulphur compounds would be given off from the overburnt coke.

In drawing a charge the lid is first slightly opened and the escaping gas lighted, to prevent an explosion or "rap" that would otherwise ensue. The gas is prevented from escaping outward by the ascension pipe dipping into the hydraulic main as afterwards explained; but in some cases special valves are fitted on the ascension pipe to prevent a back rushing of the gas. A carbonaceous deposit forms on the sides of the retorts, which requires to be periodically removed by "scurfing" with chisels, or burning it off with free admission of air or steam.

The Hydraulic Main.—From the retorts the gas, after its production, ascends by means of pipes called ascension-pipes B (figs. 5 and 6) into what is termed the condensing or hydraulic main HH, which is a large pipe or long reservoir placed in a horizontal position, and supported by columns in front of the brick-work which contains the retorts A. This part of a gas apparatus is intended to serve a twofold purpose:—first, to condense the tar and some ammoniacal liquor, and secondly, to allow each of the retorts to be charged singly without permitting the gas produced from the others, at the time that operation is going on, to make its escape. To accomplish these objects one end of the hydraulic main is closed by a flange; and the other, where it is connected with the pipes for conducting the gas towards the tar vessel and purifying apparatus, has, crossing it in the inside, a partition occupying the lower half of the area of the section, by which the condensing vessel is always kept half full of liquid matter. The stand-pipes are connected by a flange with a dip-pipe C, arising from the upper side of the condensing main HH, and as the lower end of it dips about 2 inches below the level of the liquid matter, it is evident that no gas can return and escape when the mouthpiece on the retort is removed, until it has forced the liquid matter over the bend, a result which is easily prevented by making it of a suitable length. The tar which is deposited in the hydraulic main overflows at the partition, and is carried by a pipe to the tar well.

Condensation.—The gas as it passes on from the hydraulic main is still of a temperature from 130° to 140° Fahr., and consequently carries with it heavy hydrocarbons, which, as its temperature falls, would be deposited. It is therefore a first consideration in ordinary working to have these condensable vapours at once separated, and the object of the condenser is to cool the gas down to a temperature nearly that of the surrounding atmosphere. The first contrivances employed for the purpose of condensation were all constructed on the supposition that the object would be best attained by causing the gas to travel through a great extent of pipes surrounded by cold water, and winding through it like the worm of a still, or ascending upwards and downwards in a circuitous manner. An improvement on this form of condenser, and one now in general use, is represented in fig. 8. It consists of a series of upright

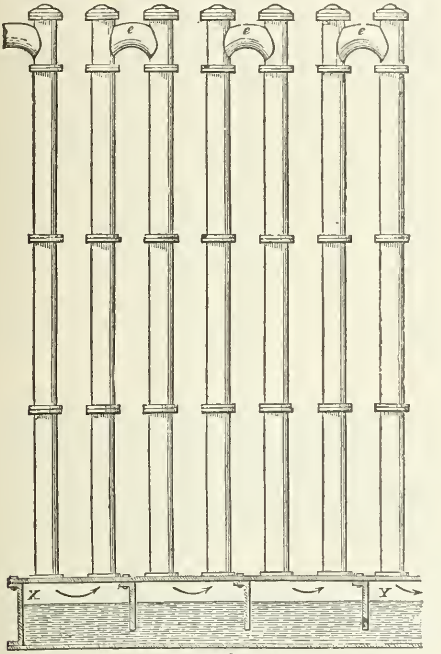

Fig. 8.

pipes connected in pairs at the top by semicircular pipes *e*, *e*, and terminating at the bottom in a trough X Y containing water, and divided by means of partitions in such a way that, as the gas enters the trough from one pipe, it passes up the next pipe and down into the next partition, and so on to the end of the condenser. The cooling power of this air condenser, as it is called, is sometimes assisted by allowing cold water to trickle over the outer surface of the pipes. Annular tubes for condensing are also used, in which the gas is exposed to a much greater cooling surface, and in some large works the condensers are cooled by a current of water. In passing through the pipes the gas is considerably reduced in temperature, and the tar and ammoniacal liquor condense, the tar subsiding to the bottom of the troughs, and the ammoniacal liquor floating on the surface. In course of time the water in the trough is entirely displaced by these two gaseous products, and as they accumulate they pass off into the tar-tank, from which either liquor can be removed by means of a pump adapted to the purpose. The New York Gas Lighting Company employ a multitubular condenser, consisting of two sets of eight boxes, each containing 100 tubes 3 inches diameter by 15 feet long. Through each set of tubes, up one and down another, the gas travels, cooled by an external stream of water, while it traverses the 240 feet of piping in the condenser.

The practice of condensation and separation of tarry matter by rapid cooling is condemned by Mr Bowditch and many eminent authorities, on the ground that thereby a proportion of light hydrocarbons are thrown down with the heavier deposit, which on another method of treatment would form part of the permanent gas and materially enrich its quality. A system of treating gas has accordingly been introduced by Messrs Aitken & Young, in which the gas, kept at a high temperature, is carried from the retorts into an apparatus termed an analyser, which consists of an enclosed series of trays and chambers arranged in vertical series, in principle like a Coffey still, the lower portion of which is artificially heated. In action the analyser separates the heavier carbonaceous part of the tarry matter in the lower part or chambers, and as the gas gradually ascends from one tray or tier to another, it is at once cooling and depositing increasingly lighter fluids, while it is meeting and being subjected to the purifying action of the light hydrocarbons already deposited. Thus on entering the analyser it meets, at a high temperature, heavy tar deposits, and it passes out of the apparatus cooled down to nearly atmospheric temperature after being in contact with the lightest fluid hydrocarbons.

Exhaustion.—To the subsequent progress of the gas considerable obstructions are interposed in connexion with its further purification and storing in the gas-holders, and the result of which would be that, were it not artificially propelled, there would be a pressure in the retort equal to the amount of the resistance the gas meets with in its onward progress. The relief of this back pressure not only improves the quality of the gas, but also increases its amount by about 10 per cent. Among the numerous methods of exhaustion which have been proposed since the operation was first introduced in 1839, there are several rotary exhausters, having more or less of a fan action, and recently an apparatus on the principle of a Giffard's injector has been introduced, chiefly in Continental works. A most efficient form is found in the piston exhauster, a kind of pumping engine with slide valves, which exhausts the gas in both the upward and the downward strokes of its piston. The action of the exhauster is controlled by a governor, which passes back a proportion of the gas when the apparatus is working too fast for the rate of production in the retorts; and "pass by" valves are arranged to carry the gas onward without passing through the exhauster should it cease to work from accident or any other cause.

Purification.—The operations embraced under this head have for their object the removal from the gas of ammonia, sulphuretted hydrogen, and carbonic acid as the main impurities, with smaller proportions of other sulphuric and of cyanogen compounds.

The agencies adopted are partly mechanical and partly chemical, the separation of the ammonia being first effected in the "scrubber," from which the gas passes on to complete its purification in the "purifiers." In early times the purifying was performed in a single operation by the use of milk of lime in the wet purifier, a form of apparatus still in use where wet purifying is permissible.

The Wet Purifier.—This apparatus was supplied with a cream of lime and water, but, although it was a most efficient purifying agent, the ammonia now of so much value was lost by its use, and the "blue billy," as the saturated liquid holding the impurities was termed, created an intolerable nuisance, and could be in no harmless way got rid of. Except in small works, wet purifying is not now practised.

The Scrubber.—The object sought in an ordinary scrubber is to cause a large amount of gas to come in contact with the smallest possible quantity of water, so as at once to dissolve out ammoniacal gases, which are exceedingly soluble in water, to obtain a strong ammoniacal liquor from the scrubber, and at the same time, as far as possible, to

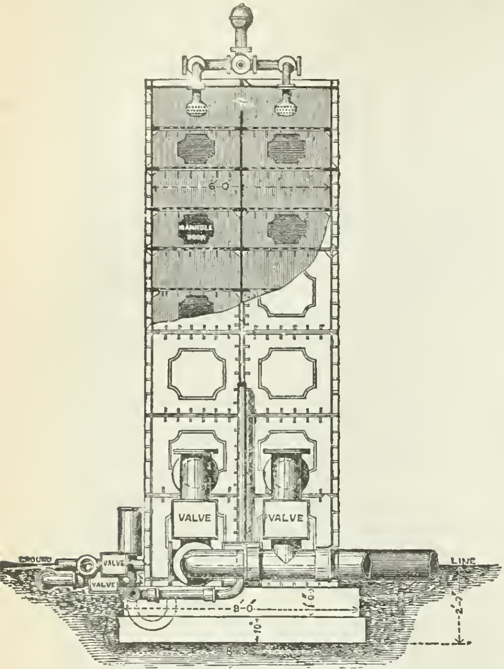

Fig. 9.—Hislop's Scrubber—Sectional Elevation.

prevent the heavy hydrocarbons from being acted on,—they being also soluble in water. The ordinary form of scrubber

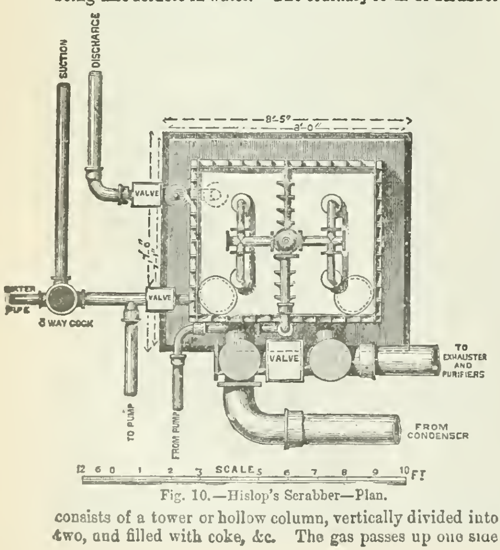

Fig. 10.—Hislop's Scrubber—Plan.

consists of a tower or hollow column, vertically divided into two, and filled with coke, &c. The gas passes up one side and down the other, and from the top a constant small stream of weak ammoniacal liquor trickles down. Such a scrubber, it is stated, is subject to clogging by deposits of tar, and equally efficient work is done without that drawback by an apparatus in which perforated iron plates occupy the place of the coke, and in the Livesey scrubber layers of thin deal boards are employed. These boards are set in tiers perpendicularly, slightly crossing each other, with about ½ of an inch between each tier. Anderson's washer is a form of scrubber recently introduced, in which the interior is occupied with a series of rotating whalebone brushes, which dip into troughs of ammoniacal liquor, and in their revolution meet and agitate the gas in its passage upwards through the tower or column. The scrubber shown in section and plan in figs. 9 and 10 is a form introduced by Mr James Hislop. It contains 10 tiers of trays of cast iron, perforated with ¾-inch holes at a distance of 2 inches from centre to centre. The gas passes upwards through these, meeting in its course a shower of ammoniacal liquor pumped up and distributed by the rose arrangement shown in fig. 9. The bottom part of the scrubber, to the height of the first course of plates, is filled with liquor, which is repumped till it reaches the strength desired for the manufacturer of ammonia sulphate.

The Purifiers.—The ordinary lime purifier, by which sulphuretted hydrogen and carbonic acid are abstracted from the gas, consists of a large rectangular vessel seen in section in fig. 11. Internally it is occupied with ranges

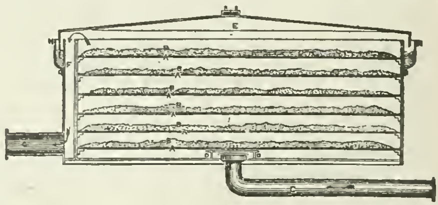

Fig. 11.—Section of Lime Purifier.

of wooden trays or sieves A, made in the form of grids of ½-inch wood, with about half an inch between the bars. These are covered with slightly moistened slaked lime B to the depth of about 6 inches, and from three to six tiers of such sieves are ranged in each purifier. The gas enters at the bottom by a tube C, the mouth or inlet being protected from lime falling into it by a cover D, and it forces its way upward through all the trays till, reaching the lid or cover E, it descends by an internal pocket F to the exit tube G, which leads to the next purifier. The edges of the lid dip into an external water seal or lute H whereby the gas is prevented from escaping. The purifiers are generally arranged in sets of four, three being in use, through which the gas passes in succession while the fourth is being renewed; and to control the course of the gas current among the purifiers, the following ingenious arrangement of centre valves and pipes was devised by Mr Malam (fig. 12).

It has a cover fitting within it in such a way as to communicate with the pipe a and either of the four inlet pipes, and also to communicate between one of the outlet pipes and the pipe h, which carries off the purified gas. The inlet pipes, b, d, f, admit the gas from the central case to the bottom of the purifiers; and the outlet pipes, c, e, g, return the gas from the purifiers back to the case, after it has passed up through the layers of lime, and descended at the back of a partition plate in each purifier to the outlet pipes at the bottom. a is the main inlet pipe for conveying the gas from the scrubber or the condenser, and h is the main outlet pipe for conveying the gas to the gasholder. The central cylinder contains water to the depth of 10 inches, and the ten pipes rise up through the bottom to the height of 12 inches, so that the mouth of each is

2 inches above the surface of the water. The cover which fits into the cylinder is 4 feet 3 inches in diameter, and is divided into five parts, the first of which, 1, fits over the inlet pipe *a*, and over either of the inlet pipes leading to the purifiers. The partitions 2,

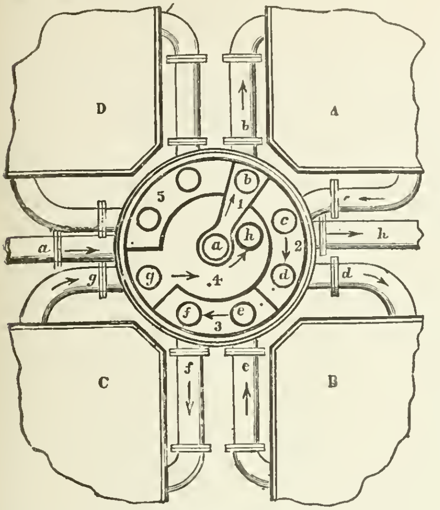

Fig. 12.

3, and 5 fit each over an inlet and an outlet pipe, while one partition, 4, fits over one outlet pipe from one purifier, and over the pipe *h*, which leads to the gas-holder. In fig. 12 the arrangement is such as to open a communication between the inlet pipe *a* and the purifier A. Now supposing the gas to have passed from the scrubber into the centre of the cylinder, its only means of escape is to pass down the pipe *b* into the purifier A, where it ascends through the layers of lime, and passing over the top of a dividing plate, descends and escapes from the bottom of the purifier by the pipe *c* back to the cylinder. Here its only means of escape is by the pipe *d*, which conducts it to the purifier B, in which it ascends and descends as before, returning by the pipe *e* to the cylinder, whence it proceeds by the pipe *f* into the purifier C, then along the pipe *g*, which is shut off from communication with any pipe except *h*, by which it is conveyed away to the gas-holder. By this arrangement the three purifiers A B C are being worked, while a fourth purifier D is being emptied and recharged with lime. When it is found, on testing the gas, that the lime is unfit for its office, the purifier A is thrown out of work, and D is brought in. The frame is then shifted so as to bring the triangular division 1 over *d*, by which means B C D will be the working purifiers, and A will be thrown out of use. In this way, by shifting the frame round its centre over each of the four outlet pipes, any three of the purifiers can be brought into action.

The "oxide" method of purifying the gas, originally introduced by M. Laming, and shortly afterwards patented by Mr Hills, is now largely used in ordinary gas-works. It is based upon the property of the hydrated oxide of iron to decompose sulphuretted hydrogen, a portion of the sulphur forming a sulphide with the iron. Quicklime is also used to separate carbonic acid, and the oxide of iron is mixed with sawdust or cinders (breeze) for the purpose of increasing the surfaces of contact, and this mixture is placed in the purifiers. When a sufficient quantity of gas has passed through it, the purifiers are opened, and the mixture is exposed to the air, under which new condition it combines with oxygen, and again becomes fitted for use in the purifiers. The chemical changes which occur in these operations are thus stated. The mixture of hydrated oxide of iron, &c., absorbs sulphuretted hydrogen, forming ferrous sulphide and water, and liberating sulphur, thus:— $Fe_2O_3 + 3H_2S = 2FeS + S + 3H_2O$. The ferrous sulphide, by exposure to the air, absorbs oxygen, and its sulphur is separated in an uncombined form, $2FeS + 3O = Fe_2O_3 + 2S$ The mixed material can be again employed in the purification of the gas, and the process may be repeated until the accumulation of sulphur mechanically impairs the absorbent powers of the mixture. The sulphocyanogen which accompanies the gas is retained by the oxide of iron, and gradually accumulates in the mixture. For the separation of the carbonic acid, which is unaffected by this treatment, the gas next passes on to a dry lime purifier.

The gas is now ready for use, and it is passed on through the station meter to register the amount made and stored in the gas-holders. At this stage it may be interesting to compare the composition of the gas as it exists at different stages of the manufacture, as these show the result of the successive purifying processes. Taking 1000 cubic feet, the figures are—

Storing and Distribution.

The Gas-holder.—This, which is frequently designated the gasometer, though incorrectly, since it does not in any way measure gas, but simply stores it for consumption, consists of two portions—the "tank" T (fig. 13) and the "holder" G. The tank is a cylindrical pit, surrounding a central core, which is usually covered with concrete *c* at top, and has its sides built of masonry or brick-work, *p*, *b*. The tank is water-tight, and is filled to a high level with water, above which project two tubes *m m*, one being the inlet and the other the supply pipe which leads to the main governor.

Formerly gas-holders were made of heavy plate iron, strengthened by angle-iron and stays, and of so great a

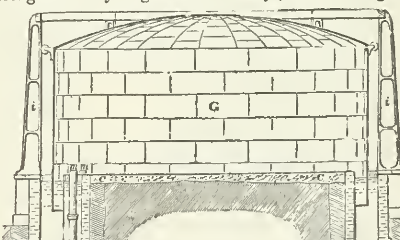

Fig. 13.—Section of Gas-holder.

weight as to require a complex system of equilibrium chains and counterbalancing weights to relieve the gas from the great pressure to which it would otherwise be subjected. They are now made so light that they require to be loaded in oraer to supply the required pressure, and their rise and fall are regulated by means of guide-rods *i i* round the tank. For economy of space holders in which different segments "telescope" over each other are now much employed. This form of holder consists of two or even three separate parts,—the upper having the form of the common gas-holder, and the other being open at the top as well as the bottom. They are connected by the recurved upper edge of the lower fitting into a channel which runs round the bottom of the upper, whereby the entire structure is rendered air-tight at the line of junction. Holders of great capacity are now erected in connexion with large works. The Imperial Company in London possesses two, at Bromley and Hackney, telescopic in form,—the outer segment measuring 200 feet in diameter by 35 feet deep, and the inner 197 feet by 35. These holders are each capable of storing 2 million cubic feet of gas, which at sp. gr. 480 would weigh 73 tons. A still larger holder is at the Fulham station of the Gas Light Company, it being 223 feet in diameter and rising 66 feet, with a capacity equal to 3 million cubic feet.

The Governor.—An efficient control of the pressure of the gas, along its whole course from the gas-holder to the point of consumption, is an object of great importance for the avoiding of leakage, for eqnal distribution, and for supplying the burners at that pressure which yields the largest illuminating effect. Uncontrolled pressure may supply certain levels in a proper manner, but will leave low-lying districts insufficiently supplied, while the pressure in high districts will be excessive. The variations from simple difference of level may be very great. Thus, with a pressure of 1·7 inch at the Leith works, the gas would be delivered in some parts of Edinburgh at a pressure of 4·5 inches. The varying consumption from dusk onwards also greatly affects unregulated pressure. To control and correct these and other irregularities and disturbances governors are now used,—at the works or station for delivering the gas to the mains, in districts to correct variations owing to level, and beyond the consumers' meters for controlling house supply; while in certain forms of burners a regulating apparatus is also inserted. The principle on which all governors are based consists in causing the gas by its own pressure to act on some form of sensitive surface which opens or closes a valve or aperture in proportion to the variations of pressure exerted on it. Fig. 14 is a diagrammatic section of the common form of station governor.

The course of the gas is indicated by arrows, *d* being the inlet and *e* the outlet pipe; *c* is a valve of conical form fitted to the seat *i* and raised or depressed by the weight *f* working by a cord over a pulley; *bb* is the bell or holder,—a cylindrical vessel of sheet iron which rises and falls in the exterior vessel *aa*, in which water is contained to the level represented. The gas, entering at *d*, passes through the valve, fills the upper part of the inverted vessel *bb*, which it thus partially raises, and escapes by *e*. If the pressure from the holder be unduly increased or diminished, the buoyancy of *bb* will be increased or diminished in like proportion, and the valve being by this means more or less closed, the quantity of gas escaping at *e* will be unaltered. And not only will the governor accommodate itself to the varying pressure of the holder, but also to the varying quantities of gas required to escape at *e* for the supply of the burners. Thus, if it were necessary that less gas should pass through *e*, in consequence of the extinction of a portion of the lights, the increased pressure thus produced at the holder would raise the governor, and partially shut the valve, leaving just sufficient aperture for the requisite supply of gas.

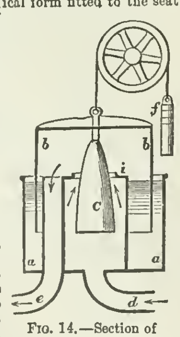

Fig. 14.—Section of Governor.

Numerous improvements have been made on the ordinary station governor. In the form invented and manufactured by D. Bruce Peebles, the bell or holder is enclosed in a gas-tight case or chamber, and a small portion of the inlet gas flows in and out of this chamber above the holder. The pressure of this small quantity of gas is regulated by passing it through a small separate governor; and, acting on the outer surface of the holder, this, in a very delicate and sensitive manner, performs the duty of weights in the older forms of governor. An arrangement similar in principle is applied to the district governor by Bruce Peebles, the minimum day pressure being secured by means of a stopcock or screw-valve on the apparatus, and the maximum night pressure is controlled by a small subsidiary governor. The principle of the small governor, which thus plays an important part in regulating large flows of gas, will be explained under consumers' governors, the apparatus being shown in section in fig. 18 below.

Supply Pipes.—The street main and service pipes are tubes of malleable or of cast iron, the gauge of which must be arranged according to the quantity of gas to be supplied, the length it has to travel, and the pressure under which it is carried forward. Practical gas-engineers possess elaborated tables of data for the regulation of the size of their various supply pipes. Notwithstanding the utmost care and accuracy in the laying and fitting of street mains, leakage at joints is a constant source of annoyance. Under the most favourable conditions there is a discrepancy of from 7 to 8 per cent. between the gas made and the amount accounted for by consumption, and the greater part of that loss is due to leakage in street pipes. To convey the gas from the main pipes and distribute it in houses, pipes of lead or of block tin are generally used.

Consumers' Meters.—Of these there are two forms in actual use, the "wet" and the "dry." The former, the invention of Mr Clegg, is represented in the two sections (figs. 15 and 16), where *cc* represents the outside case, having the form

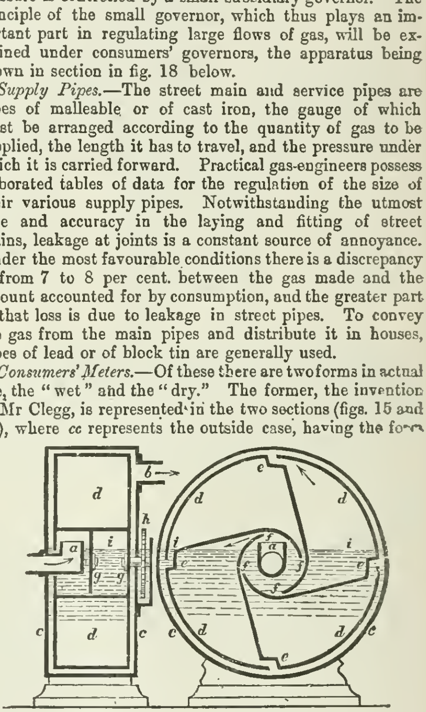

Fig. 15. Fig. 16.

of a flat cyclinder; *a* is the inlet tube and *b* the outlet pipe; *g*, *g* are two pivots, and *h* a toothed wheel fixed upon the pivots and connected with a train of wheel-work to register its revolutions. The pivots are fixed to and support a cylindrical drum-shaped vessel *ddd*, having openings *e*, *e*, *e*, *e*, internal partitions *ef*, *ef*, *ef*, *ef*, and a centre piece *ffff*. The machine is filled with water, which is poured in at *h* up to the level of *i*; and, on gas being admitted under a small pressure at *a*, it enters into the upper part of the centre piece, and forces its way through such of the openings *f* as are from time to time above the surface of the water. By its action upon the partition which curves over the opening *a*, a rotatory motion is communicated to the cylinder,—the gas from the opposite chamber being at the same time expelled by one of the openings *e*, and afterwards escaping at *b*, as already mentioned. Wet meters work easily, and, when well set and properly supplied with water, measure the gas with much accuracy. But excess or deficiency of water impairs their measuring power, which may also be affected by the meter being lifted off the level. The freezing of the water also frequently occasions trouble, and the action of the water on the gas passing through it by dissolving out part of the valuable illuminating hydrocarbons on the one hand, and diffusing watery vapour through it on the other, doubly affects its illuminating power.

The dry meter is free from the defects just mentioned, but does not pass the gas with such steadiness as the wet meter. The ordinary dry meter consists of an oblong box enclosing two measuring cylinders, with leather sides which contract and expand as they are being emptied and filled, on the principle of ordinary bellows. The pressure of the gas entering this meter is sufficient to keep it in operation, and by a system of valves the one cylinder is in process of filling as the other is being emptied through the service pipe. The chambers communicate by means of lever arms with a crank which turns a train of wheels in connexion with the indicator dials on the face of the machine.

Consumers' Governor.—In order to consume gas in a perfectly uniform and economical manner, it is essential that the pressure at the burners should be always invariably the same. That pressure is liable, however, to variation from a number of causes, such as fluctuation in the number of lights in use, either in the house or in the neighbourhood, or the application or withdrawal of pressure at the works' governor. And as all good burners are fitted with regard to a fixed standard quality and pressure of gas to be consumed, if this is not maintained the conditions of maximum illuminating power are lost. A consumers' governor secures uniformity of pressure at all the burners supplied by the pipe on which it is placed. The principle of the governor is identical with that of the station governor already described, increased pressure in both cases causing the orifice through which the gas escapes to be contracted. The mechanical arrangements by which this contraction of orifice is effected are various. In some instances they are in direct contact with the separate burners, while other governors are applied to the supply pipes of a whole establishment. They are separable into pressure governors, which, like the station governors, give a constant or uniform pressure under all variations of consumption, and volumetric governors which pass a constant volume or amount of gas under all variations of pressure.

Of pressure governors the forms devised by Sugg and Bruce Peebles are in extensive use, the latter especially being much applied to street lamps. In Sugg's consumers' governor (fig. 17)

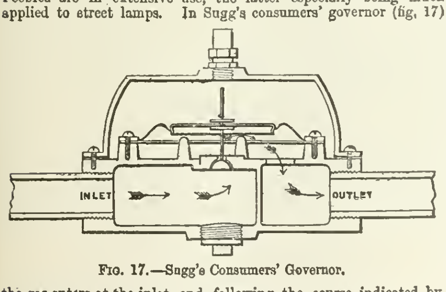

Fig. 17.—Sugg's Consumers' Governor.

the gas enters at the inlet, and, following the course indicated by the arrows, passes through the regulating plate of the governor into the gas-holder, and thence, by the opening provided for it, it reaches the outlet. The gas-holder has suspended from a disc in the crown a half-ball valve, which closes or opens the opening in the regulating plate as the gas-holder rises or falls. A weight placed on the top of the holder fixes the pressure required to raise it. As a consequence, if the pressure of the gas on the inlet is greater than that required to lift the holder, then the latter rises, carrying the half-ball valve with it, till such time as the opening left between the sides of the valve of the regulating plate is sufficient to allow the passage of the necessary quantity of gas to balance the holder. On the other hand, if the pressure at the inlet falls below that required to lift the holder, the full opening of the regulating plate allows all the gas there is to pass through the governor to the burners. Where a very perfect control is desirable, the parts of the governor are made in duplicate, and a double control is thus established. With certain structural differences the action of the Bruce Peebles governor (fig. 18) is the same. The gas enters at 1,

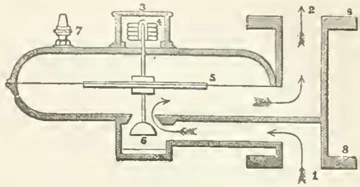

Fig. 18.—Consumers' Governor (Peebles).

and passes out at 2 into the pipe leading to the burners. To adjust the governor the brass cap 3 is unscrewed, and the weights 4 taken off or put on until the desired pressure, of say 5-tenths, at the burners is obtained, when the brass cap is again screwed to its place. The weights now keep the valve 6 open so long as 5-tenths pressure is not exceeded in the main; but any variations in the main above that pressure act at once on the diaphragm 5, and partly close or open the valve, thus maintaining under all circumstances a steady outlet pressure.

Of volumetric governors the best known is Giroud's glycerin rheometer, which consists of a closed cylindrical casing containing a very light metal dome or ball dipping into a circular channel filled with glycerin. In the upper part of the dome is a small orifice through which the gas passes, and on its top is fixed a conical valve which works in a seat at the top of the casing. As the pressure from the supply side rises or falls, the bell responsively moves up or down, opening or closing by the conical valve the orifice by which the gas passes outward; and so delicately is this compensation adjusted that the gas passed is the same in amount however different the pressure. Bruce Peebles has invented a simple and inexpensive form of volumetric governor (fig. 19), in which the use of glycerin is dispensed with. It consists of a conical dome resting on a needle-pointed stud, the cone having an orifice at C, and there is besides a variable consumption channel at the side A B A, which can be controlled by the external screw. As soon as the stopcock is opened the gas fills the interior of the cone, and momentarily closes the valve; but, finding its way by the vertical passage, or through the hole C, in the cone, it reaches the chamber above the cone. The cone is therefore now surrounded by gas at the same pressure, and, having nothing to support it, falls, and lets gas pass to the burner. But this only takes place to an extent that allows a differential pressure to be established sufficient to support the cone, which is then equilibriated between two pressures; and the difference between these two pressures remains constant, however much the initial pressure of the gas may vary, unless, of course, it gets so low as not to be able to raise the cone.

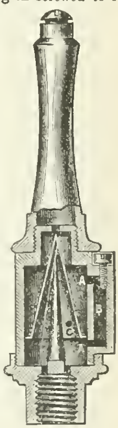

Fig. 19.—Volumetric Governor (Peebles).

Burners.—The question of the arrangements by which the maximum illuminating power may be developed in the consumption of gas, being one which principally affects individual consumers, has not received the attention which their importance merits. As a rule, gas-fitters are ignorant of the principles involved in the economical use of gas, and are often prejudiced by the assertions of certain inventors; and thus it happens that, owing to defective fittings, unregulated pressure, and imperfect burners, an enormous loss of illuminating power is suffered. In their report to the Board of Trade in 1869, the referees under the City of London Gas Act state, of a large number of burners examined by them, that

"The diversity as to illuminating power was surprisingly great, and such as will appear incredible to any one who has not ascertained the facts by careful experiment. They also found the kinds of burners in common use are extremely defective, thereby entailing upon the public a heavy pecuniary loss, as well as other disadvantages. In order to examine this important matter more fully, the referees, with the ready permission of the proprietors, inspected several large establishments in the city, where, owing to the prevalence of night work, an unusually large amount of gas was consumed. The inspection in every case confirmed the apprehensions which the referees had formed from their examination of the burners which they had procured from the leading gas-fitting establishments. In the offices of two of the leading daily newspapers (establishments which consume more gas than any other), they found that the burners principally in use gave only 55 per cent. of light compared with the Sugg-Letheby burner, or with Leoni's Albert Crutch burner, and yet the price of the last-named burner is almost identical with that of the very bad burners employed in these offices. Tested by the Bengel burner, or by Sugg's new burner, the amount of light given by these imperfect burners is only between 47 and 49 per cent. of what is obtainable from the gas."

In a communication to the Philosophical Society of Glasgow in 1874 Dr Wallace, the official gas examiner of that city, dealing with the rich cannel gas of a minimum illuminating power of 25 candles there supplied, estimated that there is in ordinary consumption a loss of 40 per cent. of illuminating power which, under favourable circumstances, might be obtained, and that in practice, while not more than 16-candle power is procured, from 20 to 23-candle illumination ought to be readily obtainable.

This universal wasteful misuse of gas is not merely a question of economy, although the aggregate pecuniary loss must be very great. It affects in no small degree the health and comfort of the consumers of gas; the products of combustion of the purest gas vitiate the atmosphere, and overheat the apartments in which it is burned. Moreover, the light from gas properly burned is much steadier and purer, and less trying to the eyesight, than that wastefully consumed.

The principal circumstances which demand attention in the fitting of burners are the average pressure and illuminating power of the gas to be consumed. How pressure may be controlled has already been shown in connexion with governors. The quality or illuminating power of gas has a most important bearing on the nature of burners proper for use, so that a clear distinction must be drawn between common coal-gas and cannel-gas, the burners for the one kind being quite unsuited for the other variety. The maximum amount of light is obtained from any gas just at that point where the flame is on the verge of smoking, and the conditions under which 14-candle gas would be perfectly consumed would, with 26 or 30-candle gas, produce a large amount of smoke. Indeed, the richer gas is, the greater is the difficulty in developing its full illuminating power, and at all times it must be burned in a much thinner sheet or stream than is proper in the case of poor gas, which requires less access of air for its complete luminiferous combustion. The opening or slit in burners used for common gas is therefore much larger than in those devoted to the consumption of cannel-gas.

There are two principal kinds of burners in use—Argand and flat-flame burners. The Argand burner in its usual form is useful only for common or low illuminating power gas, and it has, in the hands of various inventors, especially by Mr William Sugg of London, been so improved that for amount and steadiness of light it leaves little further improvement to be hoped for. The common Argand consists of an annular tube with a circle of small holes pierced in the end of the ring. It thus produces a circular or tubular flame, which requires to be protected with a glass chimney, by which the admission of air is regulated. The burner made by Sugg in 1869, known as the Sugg-Letheby, or Sugg's No. 1, is the standard burner adopted for the United Kingdom in Acts of Parliament, and the same standard has been adopted in the United States, in Canada, and in various European states. At the time it was made, the Sugg No. 1 was esteemed the best known burner, but since that time Mr Sugg has perfected his London Argand, whereby with London gas results equal to about 2 candles better than the standard are obtained. Fig. 20 is a sectional view of Sugg's London Argand with the latest improvements.

At the point at which the gas enters is a brass nose-piece A, screwed to fit the usual three-eighth thread, intended by the manufacturers of all kinds of gas fittings to receive the burner. This is drilled through its length, and slightly trumpeted at the top so as to fit the cone-shaped piece of metal projecting from the roof of the inlet chamber B. The outside of the upper portion of the nose-piece A is screwed to fit the inside of the inlet chamber B, and thus, by an adjustment of this screw by means of paper washers put on the shoulder at AB, it is possible to enlarge or decrease the area of the passage through which the gas has to pass in order to supply three tubes (two of which, C and D, only are shown in the drawing), by which it is further conducted to the combustion chamber E. This chamber is made of steatite, a material which is capable of resisting the corroding action of heat or damp, and is a good non-conductor of heat. It is pierced with a number of holes, so arranged as regards size and number that the quantity of gas the burner is required to consume shall pass out at an inappreciable or the least possible pressure. This is in order that the oxygen of the atmosphere, slowly ascending through the centre opening F, the annulus formed by the edge of the air cone G, and the outside of the combustion chamber E, shall combine with the burning gas by natural affinity only, leaving the nitrogen to pass freely out at the top of the flame. H is one of the three springs which are intended to keep the chimney glass steady in its place. JJ are two of three stubs or rests for a screen, globe, or moon; and K is a peg to steady the current of air which passes up the centre opening F.

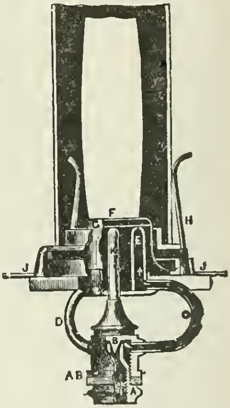

Fig. 20.—Sugg's London Argand Burner.

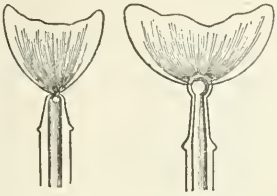
With the view of competing in illuminating power with the electric light, Mr Sugg has recently devised a modified form of Argand burner calculated to yield a large illuminating power by increased but still economical consumption of gas. These burners are made of two or more concentric Argand rings, the outer being of large diameter, and in operation they give out a large solid, white, steady flame. With London gas, a two-ring burner consuming 19 feet per hour yields 80-candle light; 3-ring burners which consume 23 feet give 100 candles; 4-ring burners fed with 45 feet of gas gave an illumination equal to 200 candles.

As regular pressure is essential for the proper use of these burners, a self-acting governor is frequently fitted to them. The pressure at which the best results are obtained with London gas is about ·7 inch. In a series of experiments with Argand burners made by Mr John Pattinson of Newcastle-on-Tyne the following results were obtained:—

Burner.	Cubic feet per hour.	Illuminating power in Candles.	Illuminating power per 5 cubic feet per hour.
Sugg-Letheby Standard	5·0	14·10	14·10
Sugg's London Argand	5·0	15·90	15·90
Sugg's Improved London Argand	4·5	16·08	17·86
Silber's Argand	5·0	17·80	17·80
Common Argand	5·0	11·20	11·20
Do. do.	7·0	17·80	12·70

Flat-flame burners, or burners which spread their flame in a broad thin sheet, are of two principal kinds known respectively as "fishtail" (fig. 21) and "batwing" (fig. 22) burners. The fishtail or union burner has two orifices drilled in its surface, which are inclined towards each other at an angle of 90°, so that the issuing currents impinge and spread the flame in a broad sheet. The gas in the batwing issues from a narrow slit cut right across the surface. In the best forms of all kinds of burners now in use steatite or adamas (pottery) tops are employed. In Sugg's Christiania burner the slit is circular, and the light issues in two thin sheets which coalesce in their upper luminiferous part, producing a most beneficial result when common gas is consumed. The common metal and steatite-tipped burners in use permit the current of gas to strike against their orifices without any control or regulation, but in the numerous patented forms of both fishtail and batwing jets certain mechanical obstructions, or small governors, are inserted, which break or retard the current. Screws, wire gauze, calico, cotton wool, iron filings, and constriction of the lower part of the burner are all devices in use. Of all these one of the simplest and most effective is the plan on which the Brönner burner is constructed, which is simply to have the opening at the lower part of the burner smaller than the upper orifice. For different qualities and pressures of gas the Brönner burner presents a great variety of combinations by having several distinct sizes of lower constriction which can be adjusted to a large number of tip orifices. Thus, with six distinct openings at each end, 36 combinations can be made. As Argand burners are not suited for measuring the illuminating power of rich cannel-gas, flat flame-burners have to be employed; and in the Act of Parliament under which the Glasgow Corporation supplies gas, it is provided that "all the gas supplied by the corporation shall be at least of such quality as to produce from a union jet burner, capable of consuming 5 cubic feet of gas per hour under a pressure equal to a column of water ·5 of an inch in height, a light equal in intensity to the light produced by 25 sperm candles of 6 in the pound, burning 120 grains per hour."



FIGS. 21, 22.—Flat-flame Burners.

Dr Wallace, in a communication on the "Economical Combustion of Coal-Gas" (*Proc. Phil. Soc. Glasgow*, vol. ix.), tabulates an extensive series of experiments made with flat-flame burners of various sizes with about 28-candle gas at different degrees of pressure. The general result of these experiments shows, that, to obtain the highest luminiferous effect with burners of small aperture, a low pressure of gas (not more than ·5 inch) must be maintained, although, as the size of the jet increases within certain limits, the pressure may be increased with favourable results. With 9 sizes of Bray's regulator fishtail (a burner having an obstruction consisting of a double fold of cotton cloth) Dr Wallace obtained the following results, calculated to 5 cubic feet per hour:—

Burner	0	1	2	3	4	5	6	7	8
At ½-inch pressure......	14·5	17·4	20·0	23·6	25·0	26·15	27·0	28·16	29·08
At 1-inch ,, ...	11·7	13·3	17·6	20·6	23·6	26·2	28·7	30·2	32·0
At 1½-inch ,, ...	8·8	9·8	13·9	17·5	19·4	23·7	25·9	gas	blows.

The gas used in the ½-inch experiments was 27·72-candle standard, for the 1-inch series it was 29·05, and for the 1½-inch set it was 28·61-candle. With 30 combinations of Brönner burners Dr Wallace obtained from 28·2-candle gas at 1 inch pressure an average of 25·7, and at 1½-inch 25·8-candle power, most of the combinations giving fairly equal results.

Of all burners the ordinary fishtails, and they are the most frequently used, give the most inferior results when used for burning common coal-gas. The results tabulated below are derived from the series of experiments by Mr Pattinson of Newcastle already quoted. The experiments were made with 14·10-candle gas, from which it must be remembered 17·86-candle power was developed in Sugg's improved London Argand:—

	Cubic feet per hour.	Illuminating power.	Illuminating power at 5 ft. per hour.
Fishtail, No. 3, steatite top ...	4	3·0	3·75
,, ,, metal top	3·5	4·10	5·85

,, ,, No. 8..........	5·0	11·80	11·80
,, ,, ,, ...	7·0	14·21	10·15
Batwing, Brönner's. No. 4	4·0	10·10	12·62
,, ,, ,, ...	5·0	11·60	11·60
,, Sugg's. ,, ...	4·0	8·40	10·50
,, ,, ,, ...	5·0	10·90	10·90

From these experiments it appears that there are burners in common use which, consuming the same amount of gas, differ in light-giving effect from 3·75 to 12·62-candles, one giving more than three times as much light as the other; and if we take the best Argand burner into account, the range of variation is from 3·75 to 17·80, or as one to five nearly. Another important deduction from these observations is that large-sized burners as a rule give much more illuminating power than the smaller sizes. Thus a burner passing 7 feet of gas per hour will almost invariably distribute more light than two each burning 3·5 feet.

Gas Testing.—The universally recognized and practised method of valuing gas is by comparing its light with that yielded by a standard light, which can be obtained as nearly as possible of an unvarying intensity. In making such a photometric comparison it is essential that the conditions under which the lights to be compared are burned shall be uniform, and that the materials be consumed at a definite rate. The standard recognized by legislative authority in Great Britain and America is the burning of a sperm candle 6 to the lb. consuming at the rate of 120 grains of sperm per hour, compared with gas burning at the rate of 5 cubic feet per hour. The burner prescribed for common gas is the Sugg-Letheby-Argand, in Acts of Parliament defined as a 15-holed Argand with a 7-inch glass chimney; and for rich cannel-gas a union or fishtail jet passing 5 feet per hour is employed. The apparatus employed for making the comparison is generally the Bunsen photometer, or some modification of that instrument; and the ratio of comparative illumination is established by the well-known principle that the intensity of light diminishes in inverse proportion to the square of the distance from its source. The Bunsen photometer consists of a bar of wood 98 inches long, with a candle holder at one end and at the other the standard gas burner. A balance for weighing the candle as it burns, an indexed meter for the gas, and a clock are also provided. The bar is graduated from the centre to each end, and on it is set a sliding holder into which a screen of prepared paper is placed. The screen is so prepared that a spot or disc is more opaque than the remainder of the paper, so that when light passes through it from one side, that particular spot is seen distinctly darker than the rest. When, however, equal amounts of light fall on it from both sides the spot disappears, and the whole surface presents a uniform appearance. Therefore, with both candle and gas burning under the stipulated conditions in a darkened chamber, by moving the screen on the graduated bar from the one light and towards the other till the dark spot on the paper disappears, the comparative illuminating power of the light is ascertained by the position of the screen on the graduated bar, or by a simple arithmetical calculation. Thus, the lights being 100 inches apart, if at the conclusion of the experiment the screen is 20 inches from the candle and 80 from the gas jet, since 80^2 is 16 times 20^2, the gas is 16-candle power.

Comparisons of the quality of gas are also made by the jet photometer, an apparatus which depends on the principle that gas of uniform quality burned at invariable pressure, through a small orifice, yields a flame of uniform height. If the flame is to be maintained at a uniform height the pressure in the pipes must increase as the quality of the gas decreases. The jet photometer forms a ready and convenient means of ascertaining any variations in the quality of gas supply; but it is not available for purposes of comparison.

Analysis of gas does not yield so satisfactory evidence of its illuminating value as photometric comparisons, but various methods of ascertaining the proportion of luminiferous olefines contained in any gas are occasionally practised. The absorption of the heavy hydrocarbons by chlorine or by bromine, and Dr Fyfe's durability test, are of theoretical rather than practical importance.

Residual Products.—Under this term are embraced coke, ammoniacal liquor, and gas-tar, all of which are sources of income in the gas manufacture. Indeed the value of these products has increased so rapidly of late years, and they now form the basis of manufactures of such consequence, that the residual products can scarcely be regarded as of secondary importance, and they will certainly play no small part in determining the future maintenance of gas-lighting in the face of other competing systems. The change in the valuation of ammonia and tar liquors is well illustrated by the circumstance that, during the year 1878, the corporation of Bradford was offered £10,000 per annum for these products, which about eight years previously had been disposed of for a yearly payment of £800.

Coke is a substance which varies much in value, according to local circumstances, and the nature of the coal distilled. When shale is used, there remains in the retorts an ashy residue which is absolutely worthless; and the coke of cannel coal is also comparatively of little value, owing to the amount of ash it yields. Indeed, in Scotch works where ashy cannel alone is distilled, the retorts have to be partly fired with common coal. The coke obtained from the distillation of caking coal, on the other hand, is of high value, and after a supply is set aside for heating the retorts there generally remains from 65 to 85 per cent. of the whole amount to be disposed of by sale.

Ammoniacal liquor is more abundantly produced by the distillation of cannel than by common coal, from 18 to 22 ℔ of ammonia, as sulphate, being obtained from each ton of cannel distilled, as against about 16 ℔ derived from ordinary coal. Gas liquor is now almost the sole source of ammonia, which, among other purposes, is very largely employed as an agricultural fertilizer

Tar liquor yields by destructive distillation a wide range of products possessing a great and increasing industrial value. The cannel coals, and other varieties rich in volatile matter, are also the kinds which yield the largest proportion of tar. In the distillation of coal-tar, after some ammoniacal and watery vapours have been given off, there is distilled over a proportion of highly volatile fluid hydrocarbons which consist principally of benzol; and afterwards a large amount of a light oil, known as coal naphtha (also a mixture of various hydrocarbons), is obtained. At this point the residue in the retort is called artificial asphalt, and as such is a commercial article; but if the heat is forced, and the distillation continued, a large amount of "heavy" or "dead oils" is obtained, and the mass left in the still is "hard pitch." The heavy oils are a mixture of naphthalin, phenol (carbolic acid), cresol (cresylic acid), and anthracene, &c. The benzol obtained in the first stage of the distillation is the basis of aniline and its various dyes; naphtha is used as a solvent, and for lighting and other purposes; carbolic acid, in addition to its employment as an antiseptic, is the basis of many valuable dyes; anthracene forms the source of the now most important dye, artificial alizarin; and most of the substances have other applications of minor importance.

The relative position and value of the various products of the gas manufacture is exhibited by the following condensed statement of the position and operations of the various London gas companies during the year 1875:—

Total capital of the companies	£12,516,009
Capital called up	11,005,589
Total gas rental	2,606,818
Cost of coal	1,455,407
Receipts for coke and breeze	492,927
,, for tar	162,151
,, for ammonia	111,951

Gas produced	14,888,133 thousand feet.
Gas sold	13,622,639 ,, ,,
Coal carbonized (4 per cent. cannel)	1,505,000 tons.
Coke produced, 34 bushels per ton	1,417,654 chaldrons.
Coke used as fuel in retorts, 31 per cent.,	440,685 ,,
Coke sold, 69 per cent.	976,969 ,,
Average yield of gas per ton of coal	9,892 cubic feet.

Gas from Sources other than Coal.

Petroleum-Gas.—Petroleum being a substance obtained in great abundance, notably in America, is used, not only directly as an illuminating agent, but also for the production of gas; and as an enricher of common coal-gas it is applied at several works in New York and Brooklyn. Its preparation is effected by distilling it first at a low temperature into a rich vapour, which, when passed into highly heated retorts, is converted into permanent gas of an illuminating power about five times greater than common gas, and which is, moreover, absolutely free from ammonia, sulphur compounds, and carbonic acid. On account of its great richness, petroleum-gas must be consumed in special burners of very fine aperture, at a rate varying from 5 to 2 feet per hour.

Oil-Gas.—In the early stages of gas manufacture many attempts were made to substitute gas distilled from inferior oils for coal-gas. The oil was distilled by allowing it to percolate into highly heated retorts, in which a quantity of coke or a like porous solid was placed, and the distillate was a richly luminiferous gas free from hurtful impurities. Although oil in this form yields a convenient and powerful illuminant, its direct combustion is much more economical; and as all oils and fats are highly valuable for many purposes besides illumination, they cannot compete with gas coal as a source of gas. Nevertheless the New York Gas Light Company manufactured oil-gas exclusively from 1824 till 1828, and sold their product at $10 per 1000 feet. The distillation of suint from wool washing, and of recovered spent soap, are examples of the application of oleaginous substances for gas-making.

Resin-Gas.—In its treatment and results resin, as a source of gas, is very similar to oil. It yields a pure gas of great illuminating power, and for twenty years (1828–48) it was supplied in New York at $7 per 1000 feet. Previous to the civil war of 1861–65 it was a good deal used on the European continent.

Wood-Gas.—The original experiments of Lebon, it will be remembered, were made with wood-gas, but he failed to obtain from his product an illuminating power that would compare with that of coal-gas. Lebon's failure was in later years shown to arise from distilling at a temperature which gave off chiefly carbonic acid with non-luminous carbonic oxide and light carburetted hydrogen, leaving in the retort a tar which the application of a higher heat would have resolved into highly luminiferous gases and vapours. Pettenkofer, who pointed out the fact, devised a system of wood-gas making in which the products of the low-heat distillation were volatilized by passing through a range of red-hot pipes; but now it is found that ordinary retorts, properly heated and fed with small charges, answer perfectly well for the operation. Wood-gas, owing to its high specific gravity and the proportion of carbonic oxide it contains, must be burned at considerable pressure, in apecially constructed burners with a large orifice. It is largely used in Germany, Switzerland, and Russia, where wood is more easily obtained than coal. It was used at Philadelphia gas-works in 1856, where it was affirmed to be cheaper and of greater luminosity than coal-gas.

Peat-Gas is evolved under circumstances the same as occur in connexion with the wood-gas manufacture, but the amount of moisture contained in peat is a serious obstacle to its successful use in this as in most other directions. Earnest and persistent efforts have been made to use peat as a source of gas, but these have met but little commercial success. To a limited extent it is used in various German factories which happen to be situated in the immediate neighbourhood of extensive peat deposits.

Carburetted Gas.—Under this head may be embraced all the methods for impregnating gaseous bodies with vapours of fluid or solid hydrocarbons. The objects aimed at in the carburetting processes are—(1) to increase the illuminating power of ordinary coal-gas; (2) to render non-luminous combustible gases, such as water-gas, luminiferous; and (3) so to load non-combustible gases with hydrocarbon vapour as to make the combination at once luminiferous and a supporter of combustion. The plans which have been proposed, and the patents which have been secured for processes of carburetting, coming under one or other of these heads, have been almost endless; and while the greater part of them have failed to obtain commercial success, they are sufficient to indicate that there is still a possibility of doing much to increase the effect and cheapen the cost of production of gas. Further, although for extensive use none of the gas-making plans can compete with coal-gas manufacture, some of them are of much value for private establishments, country houses, factories, and similar places, where connexion with coal-gas works cannot be obtained.

The carburetting of common coal-gas with the vapour of benzol obtained by the distillation of gas-tar was originally suggested by Lowe as early as 1832, and subsequently by the late Charles Mansfield, who showed that by passing gas over sponge saturated with benzol a very great addition was made to the illuminating power; and he introduced an apparatus by which common gas could thus be benzolized at a point very near the burner. The facts, however, that benzol is a highly inflammable liquid, that the benzolized gas varied in richness owing to the gas taking up much more benzol when the carburetter was newly charged than it did afterwards, and consequently that it often produced a smoky flame, and that sulphur compounds accumulated in the carburetter, as well as the trouble connected with charging the apparatus, all combined to prevent the extensive introduction of the process. In later times the value of benzol for aniline manufacture and other purposes would have been a serious bar to its use. Mr Bowditch introduced the use of a heavier hydrocarbon—a mixture of naphthalin with cymol—which he called carbolin, and which possesses the advantage of giving off no inflammable vapour at ordinary temperatures, and is, moreover, a substance for which no commercial demand exists. The carburetting appliance had to be placed in immediate proximity to the burners, and either heated by them direct, or by a small subsidiary jet, as the vapour of naphthalin solidifies on a very small fall of temperature and chokes up pipes. Carburetting by means of a solid block of naphthalin introduced into a gas-tight box, and partly volatilized by a strip of copper passing from the burner flame into the box, has recently been proposed, and is now being carried into effect with every prospect of great increase of illuminating power, and consequent economy, by the Albo-Carbon Light Company.

The efforts to introduce carburetted water-gas have been numerous and persistent; and the sanguine statements of the various inventors have led to the loss of much capital through experiments undertaken on a great scale which have always resulted unfavourably. The whole of the proposed processes depended on the decomposition of water by passing it over highly-heated surfaces in presence of glowing charcoal, whereby free hydrogen, carbonic oxide, and carbonic acid gases are produced, the carbonic acid being eliminated by a subsequent process of purification. The combustible gas so obtained was in earlier experiments charged with luminiferous hydrocarbons by being passed into a retort in which coal, resin, or oil was being distilled, as in Selligue's and other processes; or, as in White's hydrocarbon process, both steam and coal were treated together in a special form of retort. Since the introduction of American petroleum, however, most methods of carburetting water-gas have been by impregnating it with the vapour of gasolin, the highly volatile portion of petroleum which comes over first in its distillation for the preparation of "kerosene" lamp oil. Water-gas has been proposed, not only as an illuminating agent, but at least as much as a source of heat; but the heat expended in the decomposition of water is much greater than can in practice be given out by the resulting gases.

Several of the processes introduced for rendering ordinary atmospheric air at once combustible and luminiferous, by saturating it with the vapour of gasolin, have been so satisfactory that this air-gas is now largely used both in America and Europe for lighting mansions, churches, factories, and small rural districts. The general principle of the air-machines will be understood from the following description of the "sun auto-pneumatic" apparatus (Hearson's patent), which is in extensive use throughout Great Britain. Hearson's machine is cylindrical in form (fig. 23), and is

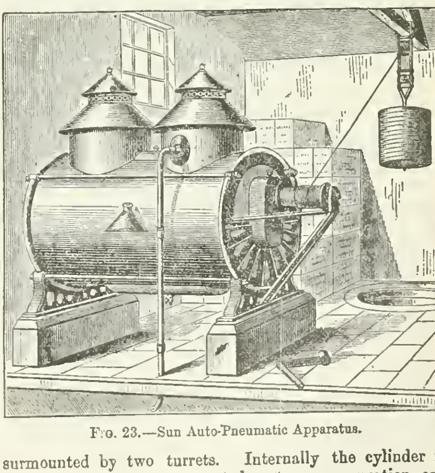

FIG. 23.—Sun Auto-Pneumatic Apparatus.

surmounted by two turrets. Internally the cylinder is divided into two compartments by a transverse portion, one being occupied by a rotary blower, an apparatus similar in construction to the drum of a water-meter, and the other by an elevator or dipper wheel, the function of which is to raise gasolin into the blower chamber, where the gasolin must be maintained at a constant level. The blower and the elevator mechanism are set in operation by being mounted on a spindle which passes through and outside the cylinder, and is turned either by a weight attached to a length of steel wire or, where convenient, by hydraulic power. The turrets contain (1) a gas-holder which supplies gas while the machine is being wound up, should any light be then burning, and (2) a governor to regulate the pressure of the issuing gas. The apparatus works only when gas is being burned, and moves in proportion to the demand on it up to its limit of production. There is therefore no necessity for storing, as indeed would be impracticable with this form of carburetted gas. The function of the blower is not only, by its revolution, to press forward the gas into the supply pipes, but also to carburet the air by exposing continually renewed thin films of the liquids to its influence on the moist metallic surfaces. The revolution of the blower, moreover, maintains an unceasing agitation in the gasolin, vaporizes the liquid in an equal and uniform manner, and keeps the entire volume at the same temperature throughout. The quantity of gasolin operated on being comparatively large, the temperature of the liquid decreases only slowly, and is in ordinary conditions sufficiently recouped from the external air to keep it in good working order throughout any length of time.

M. Tessie du Motay, who for many years advocated a modified system of lime-light, latterly abandoned that system in favour of a form of carburetted gas. His system necessitates two sets of pipes and a special form of burner,—one pipe supplying ordinary coal-gas or highly carburetted hydrogen, and the other leading in a supply of oxygen, whereby a powerful, steady, white light is maintained at the burner. Philipps of Cologne has also utilized oxygen in a comparatively pure state for burning in a lamp with a wick a mixture of heavy hydrocarbons, which in common air would burn with a very smoky flame.

Other sources of gas, such as tar, and even fæcal matters, have been proposed; and many modified forms of gaseous illumination have been brought forward which, even to name here, would occupy space out of proportion to their importance.

The Future of Coal-Gas.

The processes involved in the preparation, distribution, and consumption of coal-gas still remain essentially the same as when the system was first elaborated; but in all details of the industry numerous improvements have been introduced, resulting in marked economy and efficiency of the system. In the meantime new applications of importance have been found for coal-gas in connexion with heating and cooking, and as a motive power in gas-engines. Further, collateral industries have been superadded to the gas manufacture, which in themselves are of such value and importance that, were the distillation of coal as a source of artificial light to cease, it would certainly continue to be practised as a source of the raw materials of the coal-tar colours, and of carbolic acid, &c. Were coal-gas to cease to be made primarily and principally for artificial illumination, and to become more a heating and cooking agent, or were it to fall into the position of being a mere collateral product of the manufacture of tar, it is certain that the manufacturing processes would be very materially modified. Costly cannel-gas, with its high illuminating power, is no better suited for a gas engine than common gas; and for heating purposes a much greater yield of gas might be obtained, which, in burning, would evolve more heat than is sought in making illuminating gas. But as matters now stand, the fact that illumination, heat, motive power, and dye-stuffs are all obtained by means of the manufacture as at present conducted is a consideration of much weight in dealing with rival systems of artificial lighting.

Throughout the whole experience of gas manufacture the efforts of inventors have been directed, not only to improve the manufacture of coal-gas, but also to supersede its ordinary processes, and to supplant it by gas yielded by other raw materials or by new systems of illumination. The persistent efforts which have been made to improve coal-gas, and the success which many of the plans exhibit in their experimental stage, warrant the conclusion that the processes and results of the manufacture are still susceptible of much improvement. When it is considered how exceedingly small is the total proportion of illuminants in coal-gas to the bulk of the materials dealt with, it is not difficult to imagine that modifications of processes may be devised whereby a great increase of lighting effect might be practically available, and at the same time a greater percentage of the total heat-giving power of the coal secured for domestic and manufacturing purposes. Notwithstanding the confessed imperfections of the system of coal gas-making,—the evil odours which attach to the works, the yet more offensive exhalations given off from streets through which the main-pipes are led, the destructive accidents which occasionally occur from gas explosions, and the heat and sulphurous fumes evolved during its combustion,—not one of the numerous substitutes which have been proposed has been able to stand in competition against it in any large town or city where coal is a marketable commodity. As against the system of electric lighting, which is now being brought into competition with it, the ultimate fate of gas may be different. It may be regarded as already demonstrated that for busy thoroughfares—almost, it may be said, for open-air lighting generally—and for large halls and enclosed spaces, electric lighting will, in the near future, supersede gas. The advantages of the electric light for such positions in brilliancy, penetration, and purity are so manifest that its use must ultimately prevail, irrespective of the question of comparative cost, and of the fact that municipalities and wealthy corporations have an enormous pecuniary stake in gas-property. That the electric light will be equally available for domestic illumination is, however, not yet so certain; and until it is demonstrated that a current may be subdivided practically without limit, that the supply can adapt itself to the demand with the same ease that the pressure of gas is regulated, and that the lights can be raised and lowered equally with gas-lights—till these and other conditions are satisfied, the disuse of gas-lighting is still out of sight. Should these conditions, however, be satisfied, there can be little doubt that gas-lighting will enter on a period of severe competition and struggle for existence; and in the end the material which at one time was regarded as a most troublesome and annoying waste—the gas-tar—will, in all probability, exercise a decisive influence on the continuance of the gas manufacture.

GASCOIGNE, GEORGE (*c.* 1535–1577), one of the great pioneers of Elizabethan poetry, was born about 1535—as is believed, in Westmoreland. He was the son and heir of Sir John Gascoigne. He studied at Cambridge, and was admitted to Gray's Inn in 1555. His youth was unsteady, and his father disinherited him. In 1565 he had written his tragi-comedy of *The Glass of Government*, not printed until 1576. In 1566 his first published verses were prefixed to a book called *The French Littleton*, and he brought out on the stage of Gray's Inn two very remarkable dramas, *Supposes*, the earliest existing English play in prose, and *Jocasta*, the first attempt to naturalize the Greek tragedy. Of the latter only the second, third, and fourth acts were from his hand. Soon after this he married. In 1572 there was published *A Hundred sundry Flowers bound up in one small Posy*, a pirated collection of Gascoigne's lyrics, he having started in March of that year to serve as a volunteer under the Prince of Orange. He was wrecked on the coast of Holland and nearly lost his life, but obtained a captain's commission, and acquired considerable military reputation. An intrigue, however, with a lady in the Hague, nearly cost him his life. He regained his position, and fought well at the siege of Middleburg, but was captured under the walls of Leyden, and sent back to England after an imprisonment of four months. In 1575 he issued an authoritative edition of his poems under the name of *Posies*. In the summer of the same year he devised a poetical entertainment for Queen Elizabeth, then visiting Kenilworth; this series of masques was printed in 1576 as *The Princely Pleasures*. Later on in 1575 he greeted the queen at Woodstock with his *Tale of Hemetes*, and presented her on next New Year's day with the MS. of the same poem, which is now in the British Museum. He completed in 1576 his two most important works, *The Complaint of Philomene*, and *The Steel Glass*, the first of which had occupied him since 1562; they were printed in a single volume. Later on in the same year he published *A delicate Diet for dainty-mouthed Drunkards*. He fell into a decline and died at Stamford on the 7th of October 1577. We are indebted for many particulars of his life to a rare poem published in the same year by George Whetstone, and entitled *A Remembrance of the Well-employed Life and Godly End of George Gascoigne, Esquire*. In his poem of *The Steel Glass*, in blank verse, Gascoigne introduced the Italian style of satire into our literature. He was a great innovator in point of metrical art, and he prefixed to the work in question a prose essay on poetry, which contains some very valuable suggestions. His great claim to remembrance was well summed up in the next generation by Thomas Nash, who remarked in his preface to Greene's *Menaphon*, that "Master Gascoigne is not to be abridged of his deserved esteem, who first beat the path to that perfection which our best poets aspired to since his departure, whereto he did ascend by comparing the Italian with the English." The works of Gascoigne were collected in 1587, and partly republished in 1810 and 1821. The best modern edition of the principal poems is that edited, with full bibliographical notes, by E. Arber in 1868.

GASCOIGNE, SIR WILLIAM, was chief-justice of England in the reign of Henry IV. Both history and tradition testify to the fact that he was one of the great lawyers who in times of doubt and danger have asserted the principle that the head of the state is subject to law, and that the traditional practice of public officers, or the expressed voice of the nation in parliament, and not the will of the monarch or any part of the legislature, must guide the tribunals of the country. The judge was a descendant of an ancient Yorkshire family. The date of his birth is uncertain, but it appears from the Year Books that he practised as an advocate in the reigns of Edward III. and Richard II. On the banishment of Henry of Lancaster, Gascoigne was appointed one of his attorneys, and soon after Henry's accession to the throne was made chief-justice of the Court of King's Bench. After the suppression of the rising in the north in 1405, Henry eagerly pressed the judge to pronounce sentence upon Scrope, the archbishop of York, and the earl marshal Thomas Mowbray, who had been implicated in the revolt. The judge absolutely refused to do so, asserting the right of the prisoners to be tried by their peers. Although both were afterwards executed, the chief-justice had no part in the transaction. The often told tale of his committing the Prince of Wales to prison has of course been doubted by modern critics, but it is both picturesque and characteristic. The judge had directed the punishment of one of the prince's riotous companions, and the prince who was present and enraged at the sentence struck or grossly insulted the judge. Gascoigne immediately committed him to prison, using firm and forcible language, which brought him to a more reasonable mood, and secured his voluntary obedience to the sentence. The king is said to have approved of the act, but there appears to be good ground for the supposition that Gascoigne was removed from his post or resigned soon after the accession of Henry V. He died in 1419, and was buried in the parish church of Harewood in Yorkshire. Some biographies of the judge have stated that he died in 1412, but this is clearly disproved by Foss in his *Lives of the Judges*; and although it is clear that Gascoigne did not hold office long under Henry V., it is not absolutely impossible that the scene in the fifth act of the second part of Shakespeare's *Henry IV.* has some historical basis, and that the judge's resignation was voluntary.

GASCONY, an old province in the S.W. of France, nearly identical with the *Novempopulania* or *Aquitania Tertia* of the Romans. Its original boundaries cannot be stated with perfect accuracy, but it included what are now the departments of Landes, Gers, and Hautes-Pyrénées, and parts of those of Haute-Garonne and Ariége. Its capital was Auch. About the middle of the 6th century there was an incursion into this region of *Vascons* or *Vasques* from Spain, but whether of a hostile kind or not is uncertain; but as the original inhabitants, in common with those of the rest of Aquitaine were also *Vasques*, it is probable that the province owes its name Gascony less to this new incursion than to the fact that its inhabitants continued so long to maintain their independence. In 602 they suffered defeat from the Franks and were compelled to pay tribute, but they continued to be governed by their own hereditary dukes, and gradually extended the limits of their dominions to the Garonne. The province was overrun by Charlemagne but never completely subdued, and in 872 it formally renounced the authority of the French kings; but through the extinction of the male line of hereditary dukes of Gascony in 1054 it came into the possession of the dukes of Guienne (or Aquitaine), with which province its history was from that time identified (see AQUITANIA and GUIENNE).

GASKELL, ELIZABETH CLEGHORN (1810–1865), one of the most distinguished of England's women-novelists, was born at Cheyne Row, Chelsea, September 29, 1810. She was the second child of William Stevenson, of whom an account is given in the *Annual Biography and Obituary* for 1830. Mr Stevenson, who began life as classical tutor in the Manchester Academy, and preached also at Doblane, near that town, afterwards relinquished his ministry and became a farmer in East Lothian; and later, on the failure of his farming enterprises, he kept a boarding-house for students in Drummond Street, Edinburgh, where he also became editor of the *Scots Magazine*, and contributed largely to the *Edinburgh Review*. At the time of his daughter's birth Mr Stevenson had been appointed Keeper of the Records to the Treasury, and was living in Chelsea, still a diligent contributor to various periodicals of the day. Mrs Stevenson, Mrs Gaskell's mother, was a Miss Holland, of Sandlebridge in Cheshire, an aunt of the late Sir Henry Holland. She died at the birth of her daughter, who was in a manner adopted, when she was only a month old, by her mother's sister, Mrs Lumb. This lady had married a wealthy Yorkshire gentleman, but a few months after her marriage, and before the birth of her child, discovered that her husband was insane, and fled from him to her old home in the little market town of Knutsford, in Cheshire. Mrs Lumb's own daughter having died, she transferred all her affection to the little Elizabeth, between whom and her there existed through life the strongest bond of affection. During Elizabeth's childhood at Knutsford she was visited now and then by her sailor-brother; but while she was still a girl he went to India, where he somewhat mysteriously, and without any apparent motive, disappeared, and all further trace of him was lost. She was afterwards sent for about two years to a school kept by a Miss Byerley at Stratford-on-Avon, and on leaving school went for a time to live with her father, who had married again. Under his guidance she continued her studies, reading with him in history and literature, and working, chiefly by herself, at Latin, Italian, and French, in all of which she was in later life proficient. Having tenderly nursed her father in his last illness, she returned to her aunt at his death in 1829; and, with the exception of one or two visits to Newcastle, London, and Edinburgh, she continued to live at Knutsford till her marriage. She had at this time a reputation for great beauty; and even in later life her exquisitely-shaped soft eyes retained their light, and her smile its wonderful sweetness. Her marriage to the Rev. William Gaskell, M.A., of Cross Street Chapel, Manchester, took place August 30, 1832, at Knutsford church; and during the earlier years of her married life Mrs Gaskell lived very quietly in Manchester, surrounded by a few intimate and cultured friends, and devoting all her time and abilities to the cares of a necessarily frugal household. Among these friendships, that with Miss Catherine Winkworth and her sisters was perhaps the longest and most cherished. From the first, although she never visited the poor as a member of any organized society, she sought by all means in her power to relieve the misery which, in a town like Manchester, she was constantly witnessing. She gave the most devoted help and tender sympathy to such cases of individual distress as came under her notice. She assisted Mr Travers Madge in his missionary work amongst the poor, and was the friend and helper of Thomas Wright, the prison philanthropist. She also made several individual friendships among poor people, and knew personally one or two types of the Chartist working-man. She was specially interested in the young working-women of Manchester, and for some years held a weekly evening class at her own house for talking with them and teaching them. Of Mrs Gaskell's seven children, two were still-born, and another, her only son, born between the third and fourth of her four living daughters, died at the age of ten months. The death of this baby is said to have been the cause of Mrs Gaskell's beginning to write, when she was urged by her husband to do so, in order to turn her thoughts from her own grief. She began by writing a short paper called "An Account of Clopton Hall," for William Howitt's *Visits to Remarkable Places.* This was followed by one or two short stories, such as the "Sexton's Hero," for the *People's Journal*; and then she wrote *Mary Barton, a Tale of Manchester Life.* On its completion, she sent it to one publisher in London who rejected it unread, and then to Messrs Chapman and Hall, who, after keeping the manuscript for a year without acknowledgment, wrote to her accepting the novel for publication, and offering the authoress £100 for the copyright. The appearance of *Mary Barton* in 1848 caused great excitement in Manchester, and a strong partisanship was felt for and against its anonymous author. After its publication Mrs Gaskell paid several visits in London, where she made many friends, among whom we may mention Dickens, Forster, Mrs Jameson, Lord Houghton, Mrs Stowe, Ruskin, and Florence Nightingale. Her friendship with Charlotte Bronte also dates from about this time, when the two authoresses met at the house of Sir James and Lady Kay Shuttleworth, near Bowness, in Westmoreland, and Mrs Gaskell received her first impressions of the shy "little lady in a black silk gown," who afterwards became personally her dear friend,—although, from a literary point of view, they could hardly help being rivals,—and the story of whose life, when it was ended, Mrs Gaskell was destined to write with such consummate care and tender appreciation. But *Mary Barton* was to prove only the first of a series of scarcely less popular publications, which appeared either independently or in periodicals such as *Household Words.* It was followed in 1850 by *The Moorland Cottage. Cranford* and *Ruth* appeared in 1853; *North and South*, in 1855; *The Life of Charlotte Bronte*, in 1857; *Round the Sofa*, in 1859; *Right at Last*, in 1860; *Sylvia's Lovers*, in 1863; and *Cousin Phillis* and *Wives and Daughters*, in 1865.

During these years—years of increasing worldly prosperity and literary distinction—Mrs Gaskell often went abroad, chiefly to Paris and Rome, but once for a long visit to Heidelberg, and once also to Brussels, to collect information about Charlotte Bronte's school-days. In Paris her genius was warmly appreciated; and, while she was a guest among them, Guizot, Montalembert, and Odillon Barrot vied in doing her honour. Of her visits in England some of the pleasantest were to Oxford, where she counted among her friends Mr Jowett and Mr Stanley (dean of Westminster). At other times, when she was busy writing one of her novels, she would leave home with one or two of her children, and carry her manuscript to some quiet country place, where she could write undisturbed. When she was at home, although she was enthusiastically interested in the political questions of the day, and her warm, impulsive nature made her ready at any time to give personal help and sympathy where it seemed to be needed, Mrs Gaskell refrained from taking active part in public movements or social reforms, if we except, indeed, the great sewing-school movement in Manchester at the time of the cotton famine in 1862. Her life was thoroughly literary and domestic. She read much: Goldsmith, Pope, Cowper, and Scott were the favourite authors of her girlhood; in later life she admired Ruskin and Macaulay extremely, and delighted in many old French memoirs of the time of Madame de Sévigné, whose life she often planned to write. It is remembered of her that one day, when she was reading George Eliot's first and anonymous story *Amos Barton*, she looked up and said, "I prophesy that the writer of this will be a great writer some day." The prospect of the awful cotton famine in Manchester in 1862 set Mrs Gaskell anxiously thinking what could be done to relieve the coming distress, and she decided, "without any suggestions from others, on a plan of giving relief and employment together to the women mill-hands, which was an exact prototype of the great system of relief afterwards publicly adopted, namely, the sewing-schools." When these were formed, Mrs Gaskell "merged her private scheme in the public one, and worked most laboriously in the sewing-school nearest her home." This was but three years before her death. Still busy writing her novel *Wives and Daughters*, she was staying with her children at Holybourne, Alton, in Hampshire, a house which she had just purchased as a surprise and gift to her husband, when she died suddenly of heart disease, about 5 o'clock on Sunday evening, November 12, 1865. Her remains were carried to the churchyard of the Old Presbyterian Meeting-house at Knutsford, where her childhood and girlhood had been spent, and which she had left as a bride, three-and-thirty years before. A memorial tablet in memory of Mrs Gaskell was erected by her husband's congregation, in Cross Street Chapel, Manchester—a tribute not only to her genius, and the spirit in which it was exercised, but to the "tenderness and fidelity" of the wife and mother who had lived long amongst them.

With this knowledge of the facts of Mrs Gaskell's life, it is not difficult to trace the sources of her inspirations. Some of her shorter tales, it is true, seem to have been suggested merely by her readings; and, carefully as she collected their materials, these are the least satisfactory of her writings. But by far the most of what she wrote was founded on observation and experience. Mrs Gaskell has reproduced, with slight variations, in her novel *North and South*, the incident in her father's youth, when he and his friend and fellow-student, the Rev. George Wicke of Monton, believing it wrong to be "hired teachers of religion," resigned their ministries and sought a livelihood otherwise. The beautiful story in "Mary Barton" of the two working-men who brought the baby from London to Manchester is a version of an anecdote about Mrs Gaskell's own infancy, of her being taken to Knutsford, after her mother's death, by a friend who chanced to be travelling that way. The little county town of "Cranford"—with its population of widows and maiden ladies, and its horror of the masculine portion of society—is Knutsford, so long Mrs Gaskell's home. In *Cranford* every character, if not every incident, is real; and the pathetic little story of *Poor Peter* can have been suggested only by the disappearance of that sailor brother who used to visit Mrs Gaskell in her girlhood, and whose mysterious loss also must have interested her always afterwards in "disappearances"—the title of one of her papers in *Household Words*. Pleasant months spent at Morecambe Bay and Silverdale initiated her in the mysteries of rural and farm life. Her visits to France were the origin of her tales of the Huguenots and the French refugees at the time of the Revolution. The Edinburgh of her girlhood appears in one or two of her stories, briefly but vividly sketched. Her schooldays at Stratford-on-Avon are remembered in *Lois the Witch*; and, if only in a little story like the visit to Heppenheim, we can trace her excursions from Heidelberg along the broad, white Bergstrasse. But it is most of all in *Mary Barton*, a story of the trials and sorrows of the poor in Manchester, whom she had had so many opportunities of observing, that Mrs Gaskell gave her personal knowledge and experience to the world. Her severest critic, Mr W. R. Greg, admits Mrs Gaskell's knowledge of her subject, but objects to the impression left by the novel on the mind of the reader as inaccurate and harmful. "Were *Mary Barton*," he says, "to be only read by Manchester men and master manufacturers, it could scarcely fail to be serviceable, because they might profit by its suggestions, and would at once detect its exaggerations and mistakes;" but on the general public he fears its effect will be "mischievous in the extreme." One doubts whether a calm solution of a great economic difficulty, such as that which Mrs Gaskell treats of, could ever be given in a novel; and certainly the warm-hearted, impulsive authoress of *Mary Barton* had no such aim in view. It is probable that she wrote without any distinct economic theories. Earnest, benevolent intentions she no doubt had, but she was far more of an artist than a reformer. Had it not been so, *Mary Barton* would not rank so high in the literature of fiction as it does. It is no work of occasion, the chief interest of which departs when the occasion itself is over. It is a thoroughly artistic production, and for power of treatment and intense interest of plot has seldom been surpassed. It is as the authoress of *Mary Barton* that Mrs Gaskell will be remembered. Of her other works, *Ruth* is singularly inferior to its predecessor; but *North and South*, which takes the side of the master manufacturers, as *Mary Barton* did that of the men, has been scarcely less popular with the public. Perhaps the two best of Mrs Gaskell's productions, each in its own way, are the exquisitely humorous *Cranford* and *Cousin Phillis*, which has been fitly called an idyll in prose. *Wives and Daughters*, even in its uncompleted state, is artistically almost faultless, and full of a quiet restful beauty entirely its own. George Sand was a great admirer of this novel, and Mrs Gaskell's family still cherish a saying of hers about it:—"It is a book," she once said to Lord Houghton, "that might be put into the hands of an innocent girl, while at the same time it would rivet the attention of the most *blasé* man of the world." Her one work which is not a novel—her *Life of Charlotte Bronte*—it is difficult to praise too highly, either as a biography proper, or as a narrative written with the consummate skill of the novelist. Some people, indeed, have thought that Mrs Gaskell transgressed the bounds of the biographer in publishing so many details of Miss Bronte's domestic and private life; but the case was a peculiar one. The character of Charlotte Bronte's writings made it advisable that her reader, in order properly to understand her, should be admitted to some of the hitherto hidden facts of her short, sad life. Mrs Gaskell, knowing and esteeming Charlotte Bronte in the character of friend, daughter, and wife, hoped in some degree to justify to the world the morbid, unhealthy tone which pervaded her genius; and surely, if any hand was to draw the curtain, none could have done it more tenderly than that of her friend. (F. M.)

GASSENDI, Pierre (1592–1655), one of the most eminent French philosophers, was born of poor but respectable parentage at Champtercier, near Digne, in Provence, on the 22d January 1592. At a very early age he gave indications of remarkable mental powers, and at the instance of his uncle, the curé of his native village, he was sent to the college at Digne. He made rapid progress in his studies, showing particular aptitude for languages and mathematics, and it is said that at the age of sixteen he was invited to lecture on rhetoric at the college. He cannot have retained this post for any length of time, for soon afterwards he entered the university of Aix, to study philosophy under Fesaye. In 1612 he was called to the college of Digne to lecture on theology. Four years later he received the degree of doctor of theology at Avignon, and in 1617 he took orders as a priest. In the same year he was called to the chair of philosophy at Aix, and seems gradually to have withdrawn from theological study and teaching.

At Aix he lectured principally on the Aristotelian philosophy, conforming as far as possible to the orthodox methods. At the same time, however, he prosecuted his favourite studies, physics and astronomy, and by the discoveries of Galileo, Kepler, and others became more and more dissatisfied with the Peripatetic system. It was, indeed, the very period of violent revolt against the authority of Aristotle, and Gassendi shared to the full the practical and empirical tendencies of the age. He, too, began to draw up in form his objections to the Aristotelian philosophy, but did not at first venture to publish them. The portion shown to his friends Peiresc and Gantier, however, was so vehemently approved by them that in 1624, after he had left Aix for a canonry at Grenoble, he printed the first part of his *Exercitationes paradoxicæ* *adversus Aristoteleos.* A fragment of the second book was published later (1659), but the remaining five, requisite to complete the work, were never composed, Gassendi apparently thinking that after the *Discussiones Peripateticæ* of Patricius little field was left for his labours.

The *Exercitationes* on the whole seem to have excited more attention than they deserved. They contain little or nothing beyond what had been already advanced against Aristotle by the more vigorous of the Humanists, by Valla and Vives, by Ramus and Bruno. The first book expounds clearly, and with much vigour, the evil effects of the blind acceptance of the Aristotelian dicta on physical and philosophical study; but, as is the case with so many of the anti-Aristotelian works of this period, the objections do not touch the true Aristotelian system, and in many instances show the usual ignorance of Aristotle's own writings. The second book, which contains the review of Aristotle's dialectic or logic, is throughout Ramist in tone and method.

After a short visit to Paris in 1628, Gassendi travelled for some years in Flanders and Holland with his friend Luillier. During this time he wrote, at the instance of Mersenne, his examination of the mystical philosophy of Robert Fludd (*Epistolica dissertatio in qua præcipua principia philosophiæ Ro. Fluddi deteguntur*, 1631), an essay on parhelia (*Epistola de Parheliis*), and some valuable observations on the transit of Mercury which had been foretold by Kepler. He returned to France in 1631, and two years later received the appointment of provost of the cathedral church at Digne. Some years were then spent in travelling through Provence with the duke of Angoulême, governor of the department. The only literary work of this period is the *Life of Peiresc*, which has been frequently reprinted, and was translated into English. In 1642 he was again engaged by Mersenne in controversy, on this occasion against the celebrated Descartes. His objections to the fundamental propositions of Descartes were published in 1642; they appear as the fifth in the series contained in the works of Descartes. In these objections Gassendi's already great tendency towards the empirical school of speculation appears more pronounced than in any of his other writings. In 1645 he was invited by the archbishop of Lyons, brother of Cardinal Richelieu, to the chair of mathematics in the Collége Royal at Paris. He accepted this post, and lectured for many years with great success. In addition to some controversial writings on physical questions, there appeared during this period the first of the works by which he is best known in the history of philosophy. He evidently found himself more in harmony with Epicurus than with any other philosopher of antiquity, and had collected much information regarding the Epicurean system. In 1647 Luillier persuaded him to publish some of his works, which took the form of the treatise *De Vita, Moribus, et Doctrina Epicuri libri octo.* The work was well received, and two years later appeared his commentary on the tenth book of Diogenes Laertius (*De Vita, Moribus, et Placitis Epicuri, seu Animadversiones in X. librum Diog. Laer.*). In the same year the more important *Syntagma philosophiæ Epicuri* was published.

In 1648 Gassendi had been compelled from ill-health to give up his lectures at the Collége Royal. He travelled for some time in the south of France, spending nearly two years at Toulon, the climate of which suited him. In 1653 he returned to Paris and resumed his literary work, publishing in that year his well-known and popular lives of Copernicus and Tycho Brahe. The disease from which he suffered, lung complaint, had, however, established a firm hold on him. His strength gradually failed, and he died at Paris on the 24th October 1655, in the sixty-third year of his age.

His collected works, of which the most important is the *Syntagma Philosophicum* (*Opera*, i. and ii.), were published in 1655 by Montmort (6 vols. fol., Lyons). Another edition, also in 6 folio volumes, was published by Averanius in 1727. These volumes sufficiently attest the wide extent of his reading and the versatility of his powers. The first two are occupied entirely with his *Syntagma Philosophicum*; the third contains his critical writings on Epicurus, Aristotle, Descartes, Fludd, and Lord Herbert, with some occasional pieces on certain problems of physics; the fourth, his *Institutio Astronomica*, and his *Commentarii de Rebus Celestibus*; the fifth, his commentary on the tenth book of Diogenes Laertius, the biographies of Epicurus, Peiresc, Tycho Brahe, Copernicus, Peurbach, and Regiomontanus, with some tracts on the value of ancient money, on the Roman calendar, and on the theory of music, to all which is appended a large and prolix piece entitled *Notitia Ecclesiæ Diniensis*; the sixth volume contains his correspondence. The *Lives*, especially those of Copernicus, Tycho, and Peiresc, have been justly admired. That of Peiresc has been repeatedly printed; it has also been translated into English. Gassendi was one of the first after the revival of letters who treated the *literature* of philosophy in a lively way. His writings of this kind, though too laudatory and somewhat diffuse, have great merit; they abound in those anecdotal details, natural yet not obvious reflexions, and vivacious turns of thought, which made Gibbon style him, with some extravagance certainly, though it was true enough up to Gassendi's time—"le meilleur philosophe des litterateurs, et le meilleur litterateur des philosophes."

Gassendi will always retain an honourable place in the history of physical science. He certainly added little original to the stock of human knowledge, but the clearness of his exposition and the manner in which he, like his greater contemporary, Bacon, urged the necessity and utility of experimental research, were of inestimable service to the cause of science. To what extent any place can be assigned him in the history of philosophy is more doubtful. His anti-Aristotelian writing has been already noticed. The objections to Descartes—one of which at least, through Descartes's statement of it, has become famous—have no speculative value, and in general are the outcome of the crudest empiricism. His labours on Epicurus have a certain historical value, but the inherent want of consistency in the philosophical system raised on Epicureanism is such as to deprive it of all genuine worth. Along with strong expressions of empiricism (*nihil in intellectu quod non prius fuerit in sensu*) we find him holding doctrines absolutely irreconcilable with empiricism in any form. For while he maintains constantly his favourite maxim "that there is nothing in the intellect which has not been in the senses," and while he contends that the imaginative faculty, "phantasia," is the counterpart of sense, that, as it has to do with material images, it is itself, like sense, material, and essentially the same both in men and brutes, he at the same time admits that the intellect, which he affirms to be immaterial and immortal—the most characteristic distinction of humanity—attains notions and truths of which no effort of sensation or imagination can give us the slightest apprehension (*Op.*, ii. 383). He instances the capacity of forming "general notions;" the very conception of universality itself (*ib.*, 384), to which he says brutes, who partake as truly as men in the faculty called "phantasia," never attain; the notion of God, whom he says we may imagine to be corporeal, but understand to be incorporeal; and lastly, the reflex action by which the mind makes its own phenomena and operations the objects of attention.

The *Syntagma Philosophicum*, in fact, is one of the eclectic systems which unite, or rather place in juxtaposition, irreconcilable dogmas from various schools of thought.

It is divided, according to the usual fashion of the Epicureans, into logic (which, with Gassendi as with Epicurus, is truly *canonic*), physics, and ethics. The logic, which contains at least one praiseworthy portion, a sketch of the history of the science, is divided into theory of right apprehension (*bene imaginari*), theory of right judgment (*bene proponere*), theory of right inference (*bene colligere*), theory of right method (*bene ordinare*). The first part contains the specially empirical positions which Gassendi afterwards neglects or leaves out of account. The senses, the sole source of knowledge, are supposed to yield us immediately cognition of individual things; phantasy (which Gassendi takes to be material in nature) reproduces these ideas; understanding compares these ideas, which are particular, and frames general ideas. Nevertheless, he at the same time admits that the senses yield knowledge—not of things—but of qualities only, and holds that we arrive at the idea of thing or substance by induction. He holds that the true method of research is the analytic, rising from lower to higher notions; yet he sees clearly, and admits, that inductive reasoning, as conceived by Bacon, rests on a general proposition not itself proved by induction. He ought to hold, and in disputing with Descartes he did apparently hold, that the evidence of the senses is the only convincing evidence; yet he maintains, and from his special mathematical training it was natural he should maintain, that the evidence of reason is absolutely satisfactory. The whole doctrine of judgment, syllogism, and method is a mixture of Aristotelian and Ramist notions.

In the second part of the *Syntagma*, the physics, there is more that deserves attention; but here, too, appears in the most glaring manner the inner contradiction between Gassendi's fundamental principles. While approving of the Epicurean physics, he rejects altogether the Epicurean negation of God and particular providence. He states the various proofs for the existence of an immaterial, infinite, supreme Being, asserts that this Being is the author of the visible universe, and strongly defends the doctrine of the foreknowledge and particular providence of God. At the same time he holds, in opposition to Epicureanism, the doctrine of an immaterial, rational soul, endowed with immortality and capable of free determination. It is altogether impossible to assent to the supposition of Lange (*Gesch. des Materialismus*, 3d ed., i. 233), that all this portion of Gassendi's system contains nothing of his own opinions, but is solely introduced from motives of self-defence. The positive exposition of atomism has much that is attractive, but the hypothesis of the *calor vitalis*, a species of *anima mundi* which is introduced as physical explanation of physical phenomena, does not seem to throw much light on the special problems which it is invoked to solve. Nor is his theory of the weight essential to atoms as being due to an inner force impelling them to motion in any way reconcilable with his general doctrine of mechanical causes.

In the third part, the ethics, over and above the discussion on freedom, which on the whole is indefinite, there is little beyond a milder statement of the Epicurean moral code. The final end of life is happiness, and happiness is harmony of soul and body, *tranquillitas animi et indolentia corporis.* Probably, Gassendi thinks, perfect happiness is not attainable in this life, but it may be in the life to come.

The *Syntagma* is thus an essentially unsystematic work, and clearly exhibits the main characteristics of Gassendi's genius. He was critical rather than constructive, widely read and trained thoroughly both in languages and in science, but deficient in speculative power and original force. Even in the department of natural science he shows the same inability steadfastly to retain principles and to work from them; he wavers between the systems of Brahe and Copernicus. That his revival of Epicureanism had an important influence on the general thinking of the 17th century may be admitted; that it has any real importance in the history of philosophy cannot be granted.

Gassendi's life is given by Sorbière in the first collected edition of the works, by Bugerel, *Vie de Gassendi*, 1737 (2d ed., 1770), and by Damiron, *Mémoire sur Gassendi*, 1839. An abridgment of his philosophy was given by his friend, the celebrated traveller, Bernier (*Abrégé de la Philosophie de Gassendi*, 8 vols., 1678; 2d ed., 7 vols., 1684). The most complete surveys of his work seem to be those of Buhle (*Geschichte der neuern Philosophie*, iii., 1, 87-222), and Damiron (*Mémoires pour servir à l'Histoire de Philosophie au 17me Siècle.*) See also Ritter, *Geschichte der Philosophie*, x. 543-571; Feuerbach, *Gesch. d. neu. Phil. von Bacon bis Spinoza*, 127-150. (R. AD.)

GASTEIN, a beautiful and picturesque valley in the Austrian duchy of Salzburg, celebrated for its mineral springs. It is a side valley of the upper Salzach valley, and is about 25 miles long and 1¼ miles broad. It has an elevation of between 3000 and 3500 feet. Behind it, to the south, tower the mountains Malnitz or Nassfeld-Tauern, 7820 feet high, and the Ankogel, 10,700 feet high, and from the right and left of these mountains two smaller ranges run northwards forming its two side walls. The river Ache traverses the valley, and near Wildbad-Gastein forms two magnificent waterfalls, the upper, the Kesselfall, 200 feet, and the lower, the Bärenfall, 280 feet in height; and near these falls another called the Schleierfall, 250 feet high, is formed by the stream which drains the Pockhart-See. The principal villages are Böckstein, Hof-Gastein, and Wildbad-Gastein, and the population of the whole valley is about 3800. Hof-Gastein, with a population of about 1000, possesses gold and silver mines which in the 16th century yielded 1180 ℔ of gold and 9500 ℔ of silver annually. They are now, however, much neglected and many of the old mines are covered by glaciers. The village contains a military hospital, and in the open platz there is a bust of the emperor Francis I. who, in 1828, caused a conduit of upwards of 5 miles long to be constructed for the purpose of conveying the mineral waters thither from Wildbad. Wildbad, the principal watering-place, is visited by upwards of 3000 persons annually, and among its visitors is the present emperor of Germany. The thermal springs, which were known as early as the 7th century, issue from the granite mountains, and have a temperature of 117° Fahr. They are made use of in cases of nervous affections, general debility, and skin diseases; but the reason of their efficacy is somewhat mysterious, as chemical analysis discovers only a slight difference in the ingredients from those of ordinary spring water. The village is formed chiefly of wooden houses rising above one another in terraces. A number of stone houses have, however, been built of late; and there are several fine villas, one of which was constructed by the archduke John of Austria, and has a botanical garden.

The baths of Gastein first came into fame through a successful visit paid to them by Duke Frederick of Austria in 1436. The valley from the 11th century belonged to the dukes of Peilstein, and on the extinction of their line in 1219 it came into possession of Bavaria, whence it passed in 1297 by purchase to Salzburg. A convention was held at Wildbad-Gastein in August 1865, between the emperor Francis Joseph of Austria and King William of Prussia, at which an arrangement was signed in reference to the relations of Austria and Prussia to Schleswig-Holstein and Lauenburg (see AUSTRIA).

The principal books on Gastein are Reissacher, *Der Kurort Wildbad-Gastein*, 1865; Bunzel, *Bad-Gastein*, 1872; Hönigsberg, *Gastein*, 1873; and *A Month at Gastein*, London, n.d.

GATAKER, THOMAS (1574-1654), a learned English divine, was born in London in 1574, and educated at St John's College, Cambridge. From 1601 to 1611 he held the appointment of preacher to the society of Lincoln's Inn, which he resigned on obtaining the rectory of Rotherhithe. In 1642 he was chosen a member of the

Assembly of Divines at Westminster. The parts of the Assembly's annotations upon the Bible which were executed by him are those on Isaiah, Jeremiah, and the Lamentations. At Westminster he disapproved of the introduction of the Covenant, and declared himself in favour of Episcopacy. He was also one of the forty-seven London clergymen who disapproved of the trial of Charles I. He died in 1654. His principal works, besides some volumes of sermons, are —*On the Nature and Use of Lots*, 1616, a curious treatise which gave rise to much controversy; *Dissertatio de Stylo Novi Testamenti*, 1648; *Cinnus, sive Adversaria Miscellanea, in quibus Sacræ Scripturæ primo, deinde aliorum Scriptorum, locis aliquam multis lux redditur*, 1651, to which was afterwards subjoined *Adversaria Posthuma*; and his edition of *Marcus Antoninus*, which, according to Hallam, is the "earliest edition of any classical writer published in England with original annotations," and for the period at which it was written possesses remarkable merit. The best edition of his works is that published at Utrecht in 1668.

GATCHINA, a town of Russia, in the government of St Petersburg and district of Tsarskoselo, 29 miles W. of St Petersburg, in 59° 34′ N. lat. and 30° 6′ E. long. It is situated in a flat, well-wooded, and partly marshy district, and on the south side of the town are two lakes, distinguished as the White and the Black. Among its more important builings are the imperial palace, which was founded in 1770 by Prince Orloff, and executed according to the plans of the Italian architect Rinaldi, the four Greek churches, the Protestant church, a foundling asylum, a military orphanage founded in 1803 by Maria Feodorina, a school for horticulture, a public hospital for 1500 patients, founded by Paul I., an asylum for the families of twenty blind men, and another for fifty poor peasants. In one of the Greek churches are preserved several relics originally brought from Rhodes to Malta by the grand-master Lille Adam; and the so-called priory is shown where the knights of Malta assembled under the mastership of the emperor Paul I. Gatchina is a junction on the railway between St Petersburg and Warsaw, but its trade is of no great development. Among the few industrial establishments is a porcelain factory. The inhabitants in 1860 numbered 9184, of whom 2255 were members of the National Church, 1431 Protestants, 182 Catholics, and 50 Jews. By 1867 the total had sunk to 8337; but according to the *St Petersburg Calendar* for 1878 it has again risen to 8890.

GATES, Horatio (1728–1806), an American general, was born at Maldon in Essex, England, in 1728. He entered the English army at an early age, and soon obtained considerable promotion. He was severely wounded while accompanying General Braddock in his unfortunate expedition against the French settlements on the Ohio in 1755, and he took part in the expedition against Martinico in January 1762. After the peace of 1763 he purchased an estate in Virginia, where he resided till the commencement of the revolutionary war in 1775, when he was named by congress adjutant-general. In 1776 he was appointed to command the army on Lake Champlain; but, his conduct there not having been approved of, he was superseded in the following spring; yet in August he was sent to oppose General Burgoyne, whom he totally defeated on the 16th of October, and compelled to surrender his whole army,—an achievement which was, however, largely due to the previous manœuvres of Schuyler, whom Gates superseded. After obtaining the chief command in the southern districts, Gates was totally defeated at Camden, in South Carolina, by Lord Cornwallis, on the 16th of August 1780. On this account he was superseded by General Greene; but an investigation into his conduct terminated in acquitting him fully and honourably of all blame, on the ground that his defeat had been unavoidable in the disorganized state of the army under his command. After this he again retired to his Virginian estate, whence he removed to New York in 1800. On his arrival he was immediately admitted to the freedom of the city, and then elected a member of the State legislature. Before his departure from Virginia he granted emancipation to his slaves, accompanying their manumission with a provision for those who needed assistance. He died on the 10th of April 1806.

GATESHEAD, a municipal and parliamentary borough and market-town of England, county of Durham, is situated on the right bank of the Tyne, opposite Newcastle, of which it practically forms a part, being united with it by three bridges. The town consists of two principal and nearly parallel streets, from which others diverge in various directions. A great fire which occurred in 1854 was taken advantage of for the carrying out of improvements in the old part of the town, and it is now much less crowded than formerly. In the suburbs there are a considerable number of fine mansions. The parish church, recently restored, is an ancient cruciform edifice surmounted by a lofty tower; and several of the other churches and chapels are handsome buildings. The Wesleyan and Primitive Methodists, the Congregationalists, Baptists, Presbyterians, and Roman Catholics are all represented. The town possesses a fine cemetery, a well laid out public park, a new town-hall, a grammar school, a hospital (St Edmund's) for fifteen indigent persons, a reformatory, a mechanics' institute, and a dispensary. There are large iron works (including foundries and factories for engines, boilers, chains, and cables), shipbuilding yards, glass manufactories, chemical, soap, and candle works, brick and tile works, breweries and tanneries. The town also contains the principal depôt of the North-Eastern Railway, with large stores and locomotive works. Extensive coal mines exist in the vicinity; and at Gateshead Fell are large quarries for grindstones, which are much esteemed and are exported to all parts of the world.

The large number of Roman relics found at Gateshead would seem to indicate that it was originally an outwork of the Roman station at Newcastle. The name is mentioned as early as 1080, and in 1164 the bishop of Durham granted to its burgesses equal privileges with those of Newcastle. On the dissolution of the see of Durham in 1552, an Act was passed for uniting the town to the borough of Newcastle, but on the restoration of the rights of the bishopric it was again placed under that jurisdiction, being governed, from 1317 to 1695, with the exception of that short intermission, by a bailiff nominated by the bishop. From 1695 to 1826, when it became a municipal borough, it was governed by two stewards, elected by the inhabitants. Gateshead returns one member to parliament. The population of the municipal borough, which in 1861 was 33,587, was 48,627 in 1871.

GATH, one of the five chief cities of the Philistines. Its site appears to have been known in the 4th century, but the name is now lost. Eusebius (in the *Onomasticon*) places it near the road from Eleutheropolis (Beit Jibrîn) to Diospolis (Ludd) about 5 Roman miles from the former. The Roman road between these two towns is still traceable, and its milestones remain in places. East of the road at the required distance rises a white cliff, almost isolated, 300 feet high, and full of caves. On the top is the little mud village of Tell-es-Sâfi ("the shining mound"), and round it are the mounds which mark the site of the crusading castle of Blanchegarde (Alba Custodia), built in 1144. Tell-es-Sâfi was known by its present name as far back as the 12th century, but it appears probable that the strong site here existing represents the ancient Gath. The cliff stands on the south bank of the valley of Elah, and Gath appears to have been near this valley (1 Sam. xvii. 2, 52). The name Gath, meaning a "winepress," designates several other places in Palestine.

GATTY, Mrs Alfred (1809–1873), daughter of the Rev. Dr Scott, chaplain to Lord Nelson, was born at Burnham, Essex, in 1809. In 1839 Margaret Scott was married to the Rev. Alfred Gatty, D.D., vicar of Ecclesfield near Sheffield, sub-dean of York Cathedral, and the author of various works both secular and religious. In 1842 she published in association with her husband a life of her father, the Rev Dr Scott; but her first independent work was *The Fairy Godmother and other Tales*, which appeared in 1851. This was followed in 1855 by the first of five volumes of *Parables from Nature*, the last being published in 1871. It is under the *nom de plume* of Aunt Judy, as a pleasant and instructive writer for children, that Mrs Gatty is most widely known. Previous to commencing *Aunt Judy's Magazine* in May 1866, she had brought out *Aunt Judy's Tales* and *Aunt Judy's Letters*; and among the other children's books which she subsequently published, were *Aunt Judy's Song Book for Children* and *The Mother's Book of Poetry*. Besides other excellences her children's books are specially characterized by wholesomeness of sentiment and cheerful humour. Her miscellaneous writings include, in addition to several volumes of tales, *The Old Folks from Home*, an account of a holiday ramble in Ireland; *The Travels and Adventures of Dr Wolff the Missionary*, in which she was assisted by her husband; *British Sea Weeds*; *Waifs and Strays of Natural History*; *A Book of Emblems*; and *The Book of Sun-Dials*. She died October 3, 1873.

GAUDEN, John (1605–1662), the reputed author of the *Eikon Basilike*, was born in 1605 at Mayfield in Essex, of which parish his father was vicar. He was educated at Bury St Edmunds, and afterwards at St John's College, Cambridge. He obtained about 1630 the vicarage of Chippenham in Cambridgeshire, and the rectory of Brightwell in Berkshire. At the breaking out of the civil war he was domestic chaplain to Robert Rich, second earl of Warwick, one of the parliamentary leaders, and, being selected to preach before the House of Commons in 1640, was presented with a silver tankard for his discourse. In 1641 he was appointed by the parliament to the deanery of Bocking, in Essex. He became master of the Temple in 1659, in succession to Dr Ralph Brownrigg, bishop of Exeter, and after the Restoration in November 1660 was appointed to the same diocese. Between 1642, the date of his first printed work, and 1660 he published some thirteen or more books, of which number, however, only one appeared prior to the execution of the king. Soon after his appointment to the see of Exeter, he privately laid claim to the authorship of the *Eikon Basilike*, a work commonly attributed at the time to Charles I. This claim Gauden put forth in a correspondence with the Lord Chancellor Hyde, earl of Clarendon, and the earl of Bristol, from 21st December 1660 to 31st March 1662. The letters of Gauden among them have been published in Dr Maty's *Review* in 1782, and again in the Appendix to vol. iii. of the *Clarendon Papers*. In the year 1693 a Mr Arthur North of London, who had married a sister of Dr Gauden's daughter-in-law, published a series of letters which he had found among his sister-in-law's papers, and which added materially to the strength of the bishop's claim. They consisted of the other side of the correspondence referred to above, viz., a letter from Secretary Sir Edward Nicholas to Gauden in January 1660–1, two from the bishop to Chancellor Hyde in December 1661 and the duke of York in January 1661–2, and one from Hyde to the bishop in March 1661–2. These letters, however, have been regarded with considerable suspicion by late writers on the subject, and have even been pronounced to be forgeries by some, who have pointed out that the two letters written by Gauden himself to Clarendon and the duke of York were found in the bishop's house, not among the papers of the persons to whom they were directed. The letter also from Clarendon to Gauden, though written nine months after his obtaining his earldom, is signed Edward Hyde, a blundering anachronism which points to the unskilful hand of a forger. The whole question of the claims of Charles I. and Dr Gauden was discussed at great length and with considerable ability and ingenuity from 1824 to 1829 by Dr Christopher Wordsworth, master of Trinity College, Cambridge, on behalf of the king, and the Rev. H. J. Todd on the side of Dr Gauden. Fresh evidence, however, has lately turned up in the shape of letters and papers of Charles II. and his ministers, written soon after the execution of the king, which go far to invalidate if not entirely destroy the claim of Dr Gauden, and prove that those persons to whom he most confidently appealed in support of his pretensions were the strongest upholders of the king's authorship at the time immediately subsequent to the appearance of the work. In 1662, on the death of Brian Duppa, bishop of Winchester, Dr Gauden applied to be translated from Exeter to that see, but his claims were set aside in favour of George Morley, bishop of Worcester, and the vacancy thus created was filled by the bishop of Exeter. He only lived four months after this last promotion, and dying on 20th September 1662, was buried in Worcester Cathedral. His will is preserved in the Prerogative Office of Canterbury.

He left a widow, the daughter of Sir William Russell of Chippenham, who after her husband's death wrote a letter to her son John on the subject of the king's book, and enclosed in it a narrative of the whole claim. This was published with the correspondence mentioned above by Mr North in 1693. She also erected a monument to the bishop's memory in Worcester Cathedral, representing him with the *Eikon Basilike* in his hand.

GAUDICHAUD-BEAUPRÉ, Charles (1789–1854), a French botanist, was born at Angoulême, September 4, 1789. He studied pharmacy first in the shop of a brother-in-law at Cognac, and then under Professor Robiquet at Paris, where from Desfontaines and L. C. Richard he acquired a knowledge of botany. In April 1810 he was appointed dispenser in the military marine, and from July 1811 to the end of 1814 he served at Antwerp. In September 1817 he joined the corvette "Uranie," as pharmaceutical botanist to the circumpolar expedition commanded by De Freycinet (see vol. ix. p. 777). The wreck of the vessel on the Falkland Isles, at the close of the year 1819, deprived him of more than half the botanical collections he had made in various parts of the world. In 1830–33 he visited Chili, Peru, and Brazil, and in 1836–37 he acted as botanist to "La Bonite" during its circumnavigation of the globe. His theory accounting for the growth of plants by the supposed coalescence of elementary "phytons" involved him, during the latter years of his life, in much controversy with his fellow-botanists, more especially M. de Mirbel. He died January 16, 1854.

Besides his *Botanique du Voyage autour du Monde, exécuté pendant les Années* 1836–1837, 4 vols. fol., with plates, which included several previous works, Gaudichaud-Beaupré wrote "Lettres sur l'Organographie et la Physiologie," *Arch. de Botanique*, ii., 1833; "Recherches générales sur l'Organographie," &c. (prize essay, 1835), *Mém. de l'Académie des Sciences*, t. viii., and kindred treatises, besides memoirs on the potato-blight, the multiplication of bulbous plants, the increase in diameter of dicotyledonous vegetables, and other subjects; and *Réfutation de toutes les Objections contre les nouveaux Principes Physiologique*, 1852. See *Biographie Universelle*, t. xvi., 1856.

GAUERMANN, Friedrich (1807–1862), an Austrian painter, son of the landscape painter Jacob Gauermann (1773–1843), was born at Wiesenbach near Gutenstein, in Lower Austria, 20th September 1807. It was the intention of his father that he should devote himself to agriculture, but the example of an elder brother, who, however, died early, fostered his inclination towards art, and though he had enjoyed no special instruction his first attempts at copying nature were so successful that his father was persuaded to permit him to choose a profession which seemed so much to accord with his natural bent. Under his father's direction he began studies in landscape, and he also diligently copied the works of the chief masters in animal painting which were contained in the academy and court library of Vienna. In the summer he made art tours in the districts of Styria, Tyrol, and Salzburg. Two animal pieces which he exhibited at the Vienna Exhibition of 1824 were regarded as remarkable productions for his years, and led to his receiving commissions in 1825 and 1826 from Prince Metternich and Caraman, the French ambassador. His reputation was greatly increased by his picture The Storm, exhibited in 1829, and from that time his works were much sought after and obtained correspondingly high prices. His Field Labourer was regarded by many as the most noteworthy picture in the Vienna exhibition of 1834, and his numerous animal pieces have entitled him to a place in the first rank of painters of that class of subjects. The peculiarity of his pictures is the representation of human and animal figures in connexion with appropriate landscapes and in characteristic situations so as to manifest nature as a living whole, and he particularly excels in depicting the free life of animals in wild mountain scenery. Along with great mastery of the technicalities of his art, his works exhibit patient and keen observation, free and correct handling of details, and bold and clear colouring. He died at Vienna, 7th July 1862. Many of his pictures have been engraved, and after his death a selection of fifty-three of his works was prepared for this purpose by the Austrian *Kunstverein* (Art Union).

GAUGE, in the mechanical arts, is the name applied to a great variety of instruments, of which the object may be broadly stated to be the affording of increased facilities for comparing any two dimensions or distances. Wherever it is necessary for this to be done with a degree of accuracy unattainable by such means as the ordinary measuring rule affords, or for the same dimensions to be frequently measured with a maximum of speed and certainty, there will the hand-craftsman at once avail himself of some form of gauge. At the present day a due appreciation of the value of gauges is of growing importance to the mechanician, since they enable him greatly to improve the "fit" of the several portions of his machinery, whilst at the same time the labour expended in fitting is materially reduced. Indeed the system of making all similar parts "to gauge," so that in any number of machines they are interchangeable, is now effecting more than any other single cause for the improvement and cheapening of mechanical substitutes for manual labour.

The gauges which come within the province of this article differ in two main particulars, according as they refer the measurements which can be made by them to some definite and established standard of length, or take cognizance only of an arbitrary or haphazard one. The obvious advantage of being able to record, and at any time again obtain with certainty, the thickness of a plate of metal, or any other gauged dimension, would have led one to suppose that for all except mere temporary purposes the gauges used would invariably be of the first kind—Standard Gauges, as we shall distinguish them. But the fact is unhappily far otherwise, at least as regards the important manufactures of sheet metal and wire (which cannot be easily measured without some form of gauge), the result being that the thickness and diameters of these are expressed by various complicated and irregular series of numbers and letters, which have no reference either to each other or to any standard system of measurement. Of these arbitrary series the B.W.G. or Birmingham Wire Gauge may be taken as the type. The largest size of which it takes account is known as No. 0000, after which come 000, 00, 0, and then the numerals from 1 to 36, which last is the smallest size. It is frequently used for gauging the thickness of sheet metal as well as for wire, in spite of the existence of the Birmingham Plate Gauge, which has an equally arbitrary series of its own, consisting of the same numbers (from 1 to 36) used in the reverse manner, the low numbers being the small sizes. Other arbitrary wire gauges also tend to add to the general confusion, amongst which may be mentioned the Lancashire Gauge, which takes an alphabet and a half, in addition to the numerals up to 80, for expressing the sizes of steel wire which are referred to it, but which nevertheless does not apply to "music wire," or "needle-wire," or sundry other special kinds of wire, which are favoured with separate gauges of their own. Of late years careful comparisons have more than once been independently made with a view to ascertaining the standard value of these incongruous systems, but the discrepancies in the results only prove what might have been predicted, viz., that errors have crept in, and that those which profess to be alike differ amongst themselves, whilst there exists no satisfactory means of rectifying these errors. Their gradual and entire abolition therefore seems to be the only chance of real improvement, and it is earnestly to be hoped that the Standard Gauge originally suggested by Sir J. Whitworth, which is now largely employed, may soon entirely supersede them. In this system the sizes are directly referred to the English imperial standard of length, each being expressed by the number of thousandth parts of an inch which it contains. Thus No. 36 wire means wire ·036 of an inch in diameter. Under the old systems this might have been either No. 20, No. 62, No. 3, or No. 18.

Examples of some of the usual forms of gauges are given below. For wire the simplest gauge consists of a steel plate with a series of holes drilled through it, each hole being numbered according to the series to which the gauge refers. By means of the Notched Gauge (fig. 1) sheet metal can be gauged by a similar mode of obtaining a more or less accurate fit. Rough gauges on the same principle are constantly employed also in workshop practice for comparing together internal or external diameters, &c.; and

FIG. 1

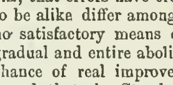

FIG. 2

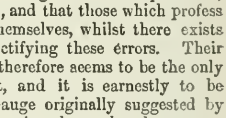

FIG. 3

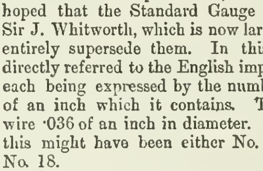

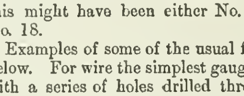

FIG. 4

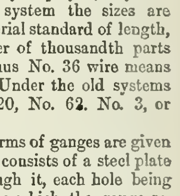

FIG. 5

they serve the purpose well enough so long as the object is a mere comparison, without taking account of the amount of any minute difference which may exist. When a measurement of such differences is required, or direct reference to a standard system, recourse must be had to some form of gauge provided with means for enlarging them sufficiently to be readily recognizable. Sliding or Calliper Gauges, such as fig. 3, fulfil this requirement by having the graduated scale affixed to one of their arms and a vernier in connexion with the other. A V-gauge, which, instead of a series of notches round its edge, has only one long tapering notch, by the graduations of which the diameter of any wire that will enter it can be read off, is simple and tolerably efficient. So also is the kindred arrangement (fig. 5), in which a wire or plate can be inserted between a fixed pin and the edge of a revolving cam with graduated face. But perhaps on the whole the best and handiest form is the Micrometer Gauge (fig. 2), which, by means of a micrometer screw with a divided head, measures to the one-thousandth part of an inch, and in careful hands can render visible even smaller fractions. Gauges consisting of two arms jointed together like pincers are also used in certain trades, minute differences in the width of the jaws being magnified and rendered visible on a graduated arc at the opposite ends of the arms.

For special purposes gauges of many other forms are employed, some of which are of much greater delicacy, but these cannot be described here. The only others which remain to be mentioned are those of which the Plug and Collar Gauges (fig. 4) are the type, sets of which are now to be found in almost all mechanical workshops where the value of standard dimensions is recognized. Each gives only the one external or internal dimension for which it is made, but it gives that with the highest attainable accuracy, so that by carefully preserving a comparatively small number of these for reference, and using them in conjunction with measuring machines, the most minute differences can be measured and noted in terms of the standard, so that exact sizes can at any future time be again obtained without appreciable error. (C. P. B. S.)

GAUHÁTI, a town in Kámrúp district, Assam, the chief town of the province, situated on the left or south bank of the Brahmaputra, lat. 26° 11′ 18″ N., long. 91° 47′ 26″ E. Gauháti, which is the most populous town in the Brahmaputra valley, was the seat of the British administration of Assam up to 1874, when the headquarters were removed to Shillong in the Khási hills, 67 miles distant, with which it is connected by an excellent cart road. Gauháta is an important centre of river trade, and the largest seat of commerce in Assam. A regiment of native infantry is permanently cantoned there. Two much frequented places of Hindu pilgrimage are situated in the immediate vicinity, the temple of Kámákhyá on a hill 2 miles west of the town, and the rocky island of Umánánda in the mid-channel of the Brahmaputra. Population (1872), 11,492; municipal revenue, £2727.

GAUL, the name given by the Romans to the country lying between the Rhine and the Pyrenees. When the Greeks first became acquainted with the south-west of Europe they applied to the whole of it, in a somewhat vague sense, the term Celtice (ἡ Κελτική), calling its inhabitants Celts (Κελτοί). Later we find Galatia (Γαλατία) and Gallia (Γαλλία), with the corresponding Galati (Γαλάτοι) and Galli (Γάλλοι), used as nearly synonymous with the earlier name. The shorter of these two forms the Romans adopted; and in the opening chapter of Cæsar's well-known *Commentaries*, we have our first definite account of the limits of the country and its divisions, as then understood. According to this authority, Gaul was in his day divided among three peoples, more or less distinct from one another, the Aquitani, the Gauls, who called themselves Celts, and the Belgæ. The first of these extended from the Pyrenees to the Garumna (Garonne); the second from that river to the Sequana (Seine) and its chief tributary the Matrona (Marne), reaching eastward presumably as far as the Rhenus (Rhine); and the third from this bounding line to the mouth of the last-named river, thus bordering on the Germans. By implication Cæsar recognizes a fourth division, the Provincia, lying to the south in the basin of the Rhodanus (Rhone), and stretching westwards as far as Tolosa (Toulouse) in the basin of the Garonne—a portion of Gaul that had been subdued and made a Roman province about fifty years before Cæsar entered on his career of conquest there. By far the greater part of the country was a plain watered by numerous rivers, the chief of which have already been mentioned, with the exception of its great central stream, the Liger or Ligeris (Loire). Its principal mountain ranges were Cebenna or Gebenna (Cevennes) in the south, and Jura, with its continuation Vosegus or Vogesus (Vosges), in the east. The tribes inhabiting Gaul in Cæsar's time, and belonging to one or other of the three races distinguished by him, were numerous. Prominent among them, and dwelling in the division occupied by the Celts, were the Helvetii, the Sequani, and the Ædui, in the basins of the Rhodanus and its tributary the Arar (Saône), who, he says, were reckoned the three most powerful nations in all Gaul; the Arverni in the mountains of Cebenna; the Senones and Carnutes in the basin of the Liger; the Veneti and other Armorican tribes between the mouths of the Liger and Sequana. The Nervii, Bellovaci, Suessiones, Remi, Morini, Menapii, and Aduatici were Belgic tribes; the Tarbelli and others were Aquitani; while the Allobroges inhabited the north of the Provincia, having been conquered in 121 B.C.

The ethnological relations of Cæsar's three great Gallic races have given rise to much discussion. Greek writers, who, in consequence of the planting of the colony of Massilia (Marseilles) on its southern coast at so early a period as 600 B.C., had gained some knowledge of Gaul before the Romans, speak of its inhabitants as Ligurians; and it is certain that a people of this name occupied at one time the coast-line of Europe from the western slopes of the maritime Alps to the Rhone. By many these Ligurians are regarded as having once spread themselves over a much wider area, peopling extensive tracts of Europe as well as Northern Africa. Subsequently, another race, coming probably across the Pyrenees from Spain, subdued south-western Gaul and ruled as far north as the Garonne—the Basques of the two slopes of these mountains remaining to our own day their lineal representatives. Later still, but at a date which history does not venture to fix, one of those great waves of population that are believed to have rolled in succession from east to west brought into northern and central Gaul, it may be at an interval of centuries, the two great branches of the Celtic race, the Gadhelic or Gaelic and the Cymric—the one represented in Britain by the Irish and Scottish Highlanders, the other by the Welsh. Reading Cæsar's brief statements by the light thus afforded, ethnologists now generally hold that his Aquitani were Iberians, largely intermingled with intrusive Gauls; that his Gauls belonged to the Gaelic division of the Celtic race, and his Belgæ to the Cymric (both of them, however, being affected by the presence of races whose territory they had overrun, and the latter by the addition of a German element derived from their proximity to the Rhine); and that the natives of the Provincia were Ligurians, with so large an intermixture of Celts as to make the latter the dominant race. Neither the Greek colony of Massilia, nor those colonies sent out by it, can be supposed to have seriously affected the Gaulish nation from the point of view we are now discussing. It was in a different manner, as a civilizing agency, that they made their presence felt.

Such, it would appear, was Gaul ethnologically when made a part of the Roman empire by Julius Cæsar shortly before the commencement of the Christian era; and, as has often been remarked, such in the main it is still. Some recent scientific inquirers find grounds, however, for concluding that the opinion, so prevalent not only in England but in France itself, that the physical and mental characteristics of the modern Frenchman are chiefly derived from the ancient Gauls, is only in part well founded. The Gauls, they say, like the Romans after them, were strong enough to impose their language on a race or races they had subjugated; but in the attempt to absorb them they themselves have suffered and continue to suffer so much that the day may yet come when the older race will all but regain its superiority. Slowly but surely, according to the researches of M. Roget, Baron de Belloguet, the blue-eyed, fair-haired, long-headed Celt has for many generations been giving place throughout France, in a direction proceeding from south to north, to a more ancient, dark-eyed, black-haired, round-headed man—a similar phenomenon being also noticeable among the Germans.

Northern Italy, in consequence of an intrusion of Gauls at some early date, received from the Romans the name of Gallia Cisalpina or Citerior, to distinguish it from Gaul proper, called also Gallia Transalpina or Ulterior. Afterwards when the Roman element gained the upper hand, Togata was sometimes substituted for Cisalpina; while in contradistinction, Gallia Braccata was applied to the Provincia from the *braccæ* or trousers worn by the natives, and Gallia Comata to the rest of the country, from the inhabitants wearing their hair long. The Gaulish emigrations into Spain on the one hand, and into Britain on the other, scarcely come under the present article; still less can we refer here to the inroads of that restless race into various parts of eastern Europe and western Asia. But it may be remarked in passing that so extensive were the conquests of the Gauls that, in the beginning of the third century before our era, their empire, if much less compact, was scarcely less extensive than that of Rome in her palmiest days.

For some time after the death of Cæsar little attention could be paid to Gaul by the ruling powers at Rome; but in 27 B.C. Augustus, now master of the Roman world, took measures to Romanize it thoroughly. The old division into four provinces was retained, and made subservient to administrative purposes. The Provincia, however, received the name of Gallia Narbonnensis, from the Roman town of Narbo (Narbonne); the boundaries of Aquitania were extended to the Liger; what remained of Cæsar's Gauls were constituted the province of Gallia Lugdunensis, so named from its capital, the new settlement of Lugdunum (Lyons); and the northern division was called Gallia Belgica. This arrangement remained nearly unchanged till the 4th century, when the four provinces were broken up into seventeen, each with a capital and a number of other towns of more or less importance, the names of which may be found in the larger geographical and historical works that treat of the period. While an integral part of the Roman empire Gaul often played no mean part in the contests that took place for the imperial purple; and it was during one of these that Claudius Civilis, a Romanized Gaul, made a gallant attempt to achieve the independence of his country. His efforts, however, were not supported by the mass of the people, and the movement was crushed by Vespasian. Perhaps the most noteworthy event of those centuries was the insurrection of the Bagaudæ or peasant banditti, in the reign of Diocletian. Ruined and driven to despair by the exactions of the imperial treasury, men scoured the country in marauding bands, plundering wholesale. Though the revolt was suppressed, the lesson it ought to have taught Rome was unheeded, and thus the seeds of future troubles remained in the soil. In the declining days of the empire Gaul became a prey to the Visigoths in the south, the Burgundians in the east, and the Franks in the north-east. When order had arisen out of the confusion that ensued, the country was found to have taken under a new name a still more conspicuous place in the political system of Europe.

What is known of the ancient religion of the Gauls will be found under DRUIDISM (vol. vii. p. 477), and brief notices of their institutions and customs, as well as some particulars regarding the introduction of Christianity among them, are given in the article FRANCE (vol. ix. p. 527).

GAUNT, JOHN OF. See LANCASTER, DUKE OF.

GAUR, or, more commonly, GOUR, the name of a mediæval city in Bengal, of which the scattered relics cover a large area in the district of Malda, commencing not far south of the modern civil station of that name.

The name Gaur is a form of the ancient *Gauḍa* (meaning the country "of sugar"), a term which was applied to a large part of modern Bengal, and specifically to that part in which these remains lie. We have the names of dynasties, and partial lists of the kings of these dynasties, which bore the title of *Gaureshara*, lord of Gaur, or Gauḍa, before the first Mahometan invasion. The last of these dynasties, that of the Senas, or of the Vaidyas, superseded its predecessor, the dynasty of the Pálas, about the middle of the 11th century. The most eminent of this dynasty, by name Lakshmanasena, who flourished at the end of the century, is alleged in inscriptions to have extended his conquests to Kanauj (in the Doab), to Nepaul, and to the shores of Orissa; and this king is said by tradition to have founded the royal city in Gauḍa which in later days reverted to a form of this ancient name (Gaur), but which the founder called after his own name *Lakshmanavati*, or as it sounded in the popular speech *Lakhnaoti*. The fifth from this king, according to Lassen's (more or less imperfect) list, Lakshmaniya (*c.* 1160–1198), transferred the royal residence to Navadvípa, *hod.* Nadiya (on the Hoogly river 70 miles above Calcutta), possibly from apprehension of the rising tide of the Mahometan power; but here it overtook him. Nadiya was taken about 1198–99 (the precise date is disputed) by Mahommed Bakhtiyár Khilji, the general of the slave king Kutbuddín Aibak of Delhi, who became established as governor of Bengal, and fixed his capital at Lakhnaoti. Here he and his captains are said to have founded mosques, colleges, and monasteries. Lakhnaoti continued for the most part to be the seat of the rulers who governed Bengal and Behar, sometimes as confessed delegates of the Delhi sovereigns, sometimes as practically independent kings, during the next 140 years. From about the year 1338, with the waning power of the Delhi dynasties, the kingdom of Bengal acquired a substantive independence which it retained for more than two centuries. One of the earliest of the kings during this period, by name Iliyás (Elias) Sháh, whose descendants reigned in Bengal with brief interruptions for nearly 150 years, transferred the seat of government to Pandua (*c.* 1350), a place about 16 miles N. by E. of Gaur, and to the neighbouring fortress of Ekdála, a place often named in Mahometan notices of the history of Bengal down to the 16th century. At Pandua several kings in succession built mosques and shrines, which still exhibit architecture of an importance unusual in Bengal proper. After some occasional oscillation the residence was again (*c.* 1446) transferred to Gaur, by which name the city is generally known thenceforward, that of Lakhnaoti disappearing from history. The 24th and last of those whom history recognizes as independent kings of Bengal was Mahmúd Sháh (1533–4 to 1538–9). In his time the city more than once changed hands, during the struggles between the Afghan Sher Sháh and the (so-called) "Great Moghul" Humayún, son of Báber; and on one occasion (1537–8), when Sher Sháh was operating against Gaur, we first hear of the Portuguese in the inner waters of Bengal. A party of that nation, who had been sent with presents to the court of Gaur, had been detained as prisoners by the suspicious Mahmúd. But in the straits arising during his resistance to Sher Sháh, the Frank prisoners were able to render him good service.

Mahmúd was followed by several Pathán adventurers, who temporarily held the provinces of the delta with more or less assertion of royal authority. One of these, Suleimán Kiráni (1564–5), abandoned Gaur for Tanda, a place somewhat nearer the Ganges. It is mentioned by Ralph Fitch, the earliest of English travellers in India, who calls it "Tanda in the land of Gouren," standing a league from the Ganges. Mu'nim Khán, Kháukhánán, a general of Akbar's, when reducing these provinces in 1575, was attracted by the old site, and resolved to re-adopt it as the seat of local government. But a great pestilence (probably cholera) broke out at Gaur, and swept away thousands, the general-in-chief being himself among the victims. On his death the deprived Pathán prince, Dáúd, set up his standard again. But he was defeated by the forces of Akbar in a battle at Rajmahl, and taken prisoner. After him no other assumed the style of king of Bengal. Tanda continued for a short time to be the residence of the governors under the "Great Moghuls," but this was transferred successively to Rajmahl and Dacca, in repeated alternation, and finally to Moorshedabad. Gaur cannot have been entirely deserted, for the Nawab Shújá-uddín, who governed Bengal 1725–1739, built a new gate to the citadel. But in history Gaur is no longer heard of, till its extensive remains attracted the curiosity of the English,—the more readily as the northern end of the site approaches within 4 miles of the important factory that was known as English Bazar (among the natives as Angrezábád), which is said to have been built of bricks from the ruins, and which is now the nucleus of the civil station of Malda.

The first specific notice of the city of Gaur, from actual knowledge, is contained in the Persian history called *Tabaqát-i-Násirí*, which has been partially translated in Elliot's *History of India* (ed. by Dowson), and is in course of complete translation by Major H. G. Raverty. The author, Minháj-i-Saráj, visited Lakhnaoti in 1243, but the only particular regarding the city that he mentions is that Ghiyás-uddín 'Iwaz, the fourth Mahometan ruler of Lakhnaoti (who called himself sultan, and according to this writer, struck coin in his own name), besides founding mosques, &c., carried embanked roads across the low country east and west of the city for a space of ten days' journey. These works in part still exist. "Radiating north, south, and east of the city, ... embankments are to be traced running through the suburbs, and extending in certain directions for 30 or 40 miles" (Ravenshaw, p. 3)

The extent of ground over which the remains of Gaur are spread is astonishing; and a large part of it would appear to be still, as when described a century ago, covered with dense wood or with rank jungle of grass and reeds, though in later years cultivation has somewhat extended over the site. What may be called the site of Gaur proper is a space of an oblong form, extending from north to south $7\frac{1}{2}$ miles, with a breadth varying from $1\frac{1}{2}$ to 2 miles. This area is washed on one of its long sides (the western) by a stream called the Bhagirathi, which undoubtedly occupies a former bed of the Ganges (not to be confounded with the Bhagirathi further south, contributing to form the Hoogly on which Calcutta stands). Roughly parallel to the eastern side, but at a distance varying from 2 to 6 miles, runs the

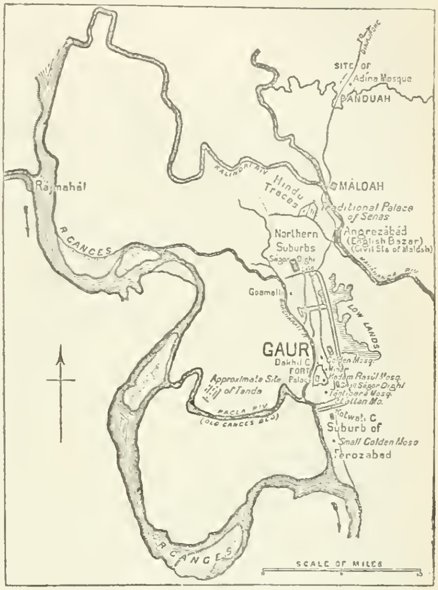

Chart of Gaur and its Environs.

river Mahánanda, whilst extensive swamps and sheets of water are interposed between this river and the city. The extensive area of which we speak has been defended on north, west,[1] and south, by a rampart and ditch, whilst on the east side there is a double embankment of great size, with two ditches of immense width, and in some parts three. It is not quite clear from the descriptions in what degree these latter great works were intended respectively for defence or for protection from floods; but the latter must have been the main purpose. The Ain-i-Akbari (*c.* 1590) alludes to the fact that "if the earthen embankment broke, the town was under water." The position of the city, midway between two rivers of deltaic character, is low, and any rise in those rivers would raise the level of the marshes. Still the mass of these banks, as much as 200 feet thick at base, and 40 feet in height, is greater than any present exposure to flood seems sufficient to explain. It has sometimes been supposed that the Ganges, since the foundation of Gaur, has flowed to the eastward, in what is now the bed of the Mahánanda. If this were so, the massive character of the embankments would be more intelligible. It would appear, however, that the positive testimony to this circumstance, which was at one time supposed to exist, depended on a mistaken reading of the passage, referred to above, of the *Tabaqát-i-Násirí.*

[1] This was so according to Buchanan; but Mr Ravenshaw says "the western face is now open, and probably always was so, having been well protected by the Ganges . . . . which ran under its walls." The plans *all* show an *embankment* on this side, and Creighton gives a section of it, 30 feet high.

These great embankments have been originally faced throughout with masonry, whilst the crest shows numerous traces of edifices; but the whole of the earthworks are now overgrown with dense jungle. The Ganges now flows at a distance varying between 5 and 12 miles to the west of the enclosed area of the city, but there seems to be no doubt than in the earlier centuries of its occupation the great river washed its western wall, where now the Bhagirathi flows.

On this side, near the southern end, stood the citadel or royal fortress, stretching for a mile along the river bank, and marked out by the remains of a huge rampart of irregular trace, 180 feet wide at the base, and once faced with masonry, with numerous circular bastions. Shapeless masses of ruin fill the interior. The palace itself formed a rectangular inner enclosure of 2100 feet by 750, girt by a splendid brick wall, 18 feet thick at bottom, 8½ feet thick at top, and 42 feet in height. To the northward the western embankment is prolonged far beyond the northern limit of the city, and about 3 miles north of the latter we encounter a vast line of earthwork stretching from the prolongation just mentioned, in an irregular curve eastward and then south-eastward to the vicinity of the Mahánanda river, in all for more than 6 miles. This also was probably intended chiefly as a defence against inundation of the suburbs. A huge excrescence protruding from the line, and overgrown with forest trees, encloses an area of nearly a square mile, which tradition points out as the palace of one of the Sena kings. Still north of this, and extending to the banks of the Kalindri river, some 3 miles further, are found traces of ancient Hindu buildings.

Turning again to the southern extremity of Gaur, for 6 or 7 miles to the south of the city there seems to have extended, still under the protection of a western embankment, a continuous chain of suburbs. In the northern portion, at least, of these, "prostrate domes, mingled with carved lintels and innumerable bricks, are seen lying in confusion on all sides, and show how dense has been the population" (Ravenshaw, p. 26). Thus from north to south, the whole extent of ground bearing indications of urban occupancy is hardly less than 20 miles. We may, however, feel confident that, as in the case of Delhi, these traces comprehend a space within which the royal city occupied various localities in various ages. Traditions, collected by Dr Francis Buchanan, placed the residence of the older Sena kings on the sites at the extreme north near the Kalindri. The southern part of the fortified area of Gaur, with the citadel and palace, was evidently, as we shall see from the dates of the buildings, the seat of the later kings who immediately preceded the absorption of Bengal into the Moghul empire in the last half of the 16th century. The exact side occupied by Mahommed Bakhtiyár Khilji and his successors does not seem to have been determined.

Throughout the interior length of Gaur run embanked roads, whilst the whole area is thickly dotted with excavated tanks of all sizes, up to the great *Ságar Dighí* (or "Ocean Tank"), a rectangular sheet of water measuring little short of a mile by half a mile. This vast work is probably to be referred to the Hindu age. The former existence of six ghauts of masonry can be traced on its banks, which are densely wooded to the water's edge. Numerous excavated channels also run in every direction, the earth from which appears to have served to raise the inhabited surface. The remaining buildings of importance are scattered at wide intervals over the area, but the soil is throughout covered with fragments of brick, &c., in a manner which leaves no doubt of the former density of population. But Gaur has repeatedly been a quarry of building material. The old Lakhnaoti was robbed to build the mediæval capital of Pandua, and the later Gaur probably to build Rajmahl, whilst in more recent times their brick and stone were transported as merchandise to Malda, Moorshedabad, Hoogly, Rungpore, and even (as regards the more valuable kinds of stone) to Calcutta. In the revenue returns of Bengal, at the time of its transfer to the Company, there was an entry of an annual levy of 8000 rupees, as "Gaur brick royalty," from landholders in the neighbourhood of Gaur who had the exclusive right of dismantling its remains. The bricks of Gaur, Rennell says, are of extraordinary solidity of texture and sharpness of edge. The facilities which the site affords for water carriage during the rainy season greatly aided this systematic spoliation. That no Hindu buildings remain from the earlier cities is probably to be accounted for by this process of destruction.

We have quoted a Mahometan visitor to Gaur in the middle of the 13th century. The next such mention perhaps occurs in the travels of the Venetian Nicolo Conti, who somewhat early in the 14th century ascended the Ganges 15 days' voyage to a city of great size and wealth called *Cernove.* On both banks of the stream were most charming villas, and plantations, and gardens. The name looks like *Shahr-i-nao*, which we know from coins to have been the name of a royal city of Bengal about 1380–85, and which Mr Ed. Thomas believes to have been merely that given to one of the re-foundations of Gaur. A more detailed and certain account is given by De Barros, when describing the adventures of the Portuguese party in 1537–38, to which allusion has been made above (dec. iv. liv. ix. cap. i.):—

"The chief city of this kingdom (of Bengala) is called *Gouro.* It is situated on the waters of the Ganges, and is said to be three of our leagues in length, and to contain 200,000 inhabitants.[1] On the one side it has the river for its defence, and on the landward faces a wall of stone and lime of great height, besides having, where the river comes not, a great ditch full of water, in which great boats can swim. The streets are broad and straight, and the main streets have trees planted in rows along the walls, to give shade to the passengers. And the population is so great, and the streets so thronged with the concourse and traffic of people, especially of such as come to present themselves at the king's court, that they cannot force their way past one another, and thus such as hap to fall among the horsemen, or among the elephants which are ridden by the lords and noblemen, are often killed on the spot, and crushed under the feet of those beasts. A great part of the houses of this city are stately and well wrought buildings."

The earliest detailed notice of the ruins that we hear of is a MS. one, by Mr Reuben Burrows, the mathematician (1787), which is quoted by the editor of Creighton's drawings as being in the India Library. Rennell gives some account of the ruins in his *Memoir of a Map of Hindustan* (1788), and the plan of them is roughly laid down, on a small scale, in his Bengal Atlas (No. 15). Mr Henry Creighton, who for many years managed an indigo factory among the ruins (1786–1806), made many drawings of them, with notes and a detailed map, on a large scale. Dr Buchanan states that engravings from Creighton's drawings had been published by a Mr Moffat in Calcutta before the compilation of his own statistical work. Of this we have seen no copy. It is probably the same as "the set of eight views of the ruins of Gour and Rajmehal," which is advertised in the *Calcutta Gazette*, 6th December 1798 (see Seton-Karr's *Selections*, vol. iii. p. 529). A work, however, was published in London in 1817, from the materials left by Mr Creighton, called the *Ruins of Gour Described*, &c.; and this contained the most accessible data on the subject till Mr Ravenshaw's work. There is in the India Office a MS. volume (1810) by Major William Francklin of the Bengal army, containing notices of the remains and translations of a good many

[1] So in De Barros, Lisbon edition of 1777, vol. viii. p. 458, "duzentos mil vizinhos." But in the English version of Faria y Sousa's *Asia Portuguesa* by Stevens (1695), i. p. 417, a passage abridged from De Barros has "*one million* and two hundred thousand *families.*" The last word is probably a mistranslation, but the *million* seems required.

inscriptions. The MS. purports to have been accompanied by maps and drawings, but these are not now forthcoming. Dr Francis Buchanan has described the remains, with his usual somewhat dry precision, in his statistical survey of northern Bengal and Behar, executed between 1809 and 1816, but only published, with a title-page that bears the name of Montgomery Martin, and no reference to the real author, in 1838 (*Eastern India*, &c., vol. iii. pp. 68 *sq.*). Mr James Fergusson has a short chapter, containing the only critical account of the architecture of Gaur, in his *History of Indian Architecture.* Lastly, since the greater part of this article was compiled, there has been published a splendid volume (*Gaur: its Ruins and Inscriptions*, 4to) from the photographs and notes of the late J. A. Ravenshaw of the Bengal Civil Service.

Before concluding we may indicate a few of the most notable remaining buildings:

1. One of the most pleasing remains, as regards architectural design, is a minaret or tower of stone and brick, standing immediately west of the citadel. It is 84 feet in height and 21 in diameter at the base. For two-thirds of the height the form is that of a 12-sided polygon, and above that circular, the two forms being divided by a bold cornice. There is now no inscription attached, but tradition assigns it to Firoz Shah, and a native history of Bengal compiled in the last century attributes it specifically to a king of that name, who reigned 1488–1490. Mr Fergusson indeed considers the architecture to belong to an earlier period; and it is remarkable that the researches of Mr E. Thomas in coins, and of the late Mr Henry Blochmann in lapidary inscriptions, have recently established the existence of a King Shamsuddín Firoz, whose coinage at Lakhnaoti shows his reign to have extended from 1302 to 1318. If the work be really due to this prince, it is by much the oldest building of importance now remaining at Gaur. But the point is very doubtful.

2. The *Dákhil Darwáza*, or Gate of Entrance, is the northern gate of the citadel. It is a noble structure, though entirely built of small bricks. The tunnel under the rampart is 112 feet long by 14 wide, and the height of the archway is 34 feet. An inscription copied by Francklin ascribes the work to Bárbak Sháh, and the erection to 1466. The grandiose palace wall is believed to be of the same period.

3. The *Lattan*(?), or the *Painted Masjid*, a quadrangular edifice in the southern part of the city, cased inside and out with bricks beautifully enamelled in blue, green, and white. It is covered by one large dome. The work is ascribed to 1470–1481.

4. The *Tánti-Pára Masjid*, or Mosque of the Weaver's Quarter. This is now much dilapidated, but Ravenshaw's photograph indicates it to have been one of the most beautiful buildings in Gaur. The niched panels in carved brickwork which adorn its piers are very rich and delicate. It is also, if an inscription given by Francklin be justly assigned to it, the work of Yúsuf Shah, 1475–76.

5. The *Sona Masjid*, or Golden Mosque. This is probably the most important structure remaining at Gaur. It stands in the city to the north of the citadel, within a spacious court enclosed by a stone wall. The material is described as a dark grey stone, approaching to black, with sculpture in beautiful flower-work. The mosque measures 180 feet by 80, and the interior architecture consists of massive intersecting arcades, each intersection being covered by a dome, of which domes there were 44 altogether. In spite of the extraordinary solidity of the building it appears to have suffered greatly since Francklin described it in 1810. The date is fixed by an inscription which existed in his time to 1525.

6. Tombs of Shah Husain (d. 1521), and of his son Nasrat Shah, the builder of No. 5 (d. 1533–34). Of the tombs themselves nothing remains, and their materials are said to have been carried to Fort William in the last century. In Creighton's time, though the tomb of Husain Shah was already gone, there remained a beautiful edifice which had formed the gateway of the enclosure, faced with brick-work richly moulded, and glazed with blue and white. Of Shah Hussin (reigned 1494–1521) Dr Blochmann says, "Whilst the names of other Bengal kings scarcely ever occur in legends, and remain even unrecognized in the geographical names of the country, the name of 'Husain Shah the Good' is still remembered from the frontier of Orisa to the Brahmaputra" (*Proc. As. Soc. Bengal*, 1873, p. 291).

7. The mosque of the *Qadam Rasúl*, or Footstep of the Prophet, so named from a representation of Mahomet's footmark in stone which was formerly enshrined there. The work of Nasrat Sháh, 1530.

We thus see that all the buildings, with the very doubtful exception of the minaret, go back no further than the last half of the 15th century. If the age of the architecture is disappointing, the better knowledge of details which we derive from Mr Ravenshaw's book enhances our appreciation of it. The buildings are in brick, in stone, and in both combined. Excepting the great gateways, they lack height enough for stateliness; the character is rather decorated solidity. The façades generally present a series of pointed arches, with very massive piers between, which are sometimes complicated polygons, but more usually rectangular; the mouldings have little relief, but the surfaces are adorned with panels filled with beautiful "embossed brick-work." These seem to be rich floral patterns moulded in terra cotta, and probably finished with the chisel. The curvilinear roof, imitated from the use of the bamboo, of which Mr Fergusson speaks as an unpleasing characteristic of architecture in Bengal, is little seen in Gaur,—almost the only indication of it being a slight upward camber in the upper lines of the façade, in which the versed-sine is about $\frac{1}{30}$th of the chord. In some of the buildings great brilliance has been produced by the profuse use of encaustic tiles in bright colours. The art of making these exists now in India nowhere nearer than in Sind; but indeed the manufacture of terra cotta, or of ordinary brick of the superior character which Rennell attributes to Gaur, is equally a lost art in Bengal. Where the facing is entirely of stone, as in the Great Golden Mosque, and in a smaller one bearing the same name, the ornamentation seems imitated from the terra-cotta work; the relief, however, is much less, owing probably to the hardness of the material. What this material is, or whence, is not quite clear. The older accounts speak of black and other marbles; Buchanan and later writers of "black hornblende," "potstone," and what not; Mr Ravenshaw, in the case of one building, of "granite and marbles." The black stone is probably basalt from the Rajmahl hills, but more precise information is desirable.

In conclusion, we may notice briefly the other neighbouring sites occupied as capitals, which may be regarded as appendages of Gaur.

Pandua, commonly called *Parruah* or *Porruah*, was so occupied, with occasional intervals, for nearly a century. Its ruins and tanks extend over a narrow area of nearly 6 miles in length, which is now more of a wilderness than even the site of Gaur. The high road from Malda to Dinajpore passes through it from end to end, but the forest which besets the ruins is so dense on both sides, and so infested with tigers, that single travellers shun the road by night. Mr Ravenshaw employed a gang of 200 men to clear the jungle for his photographs, but even then could only get partial views. The buildings exhibit the same general character as at Gaur, but most of them are older, and seem (for most of them are absolutely overgrown and penetrated by jungle-growth) to show the style in a freer and purer form. Many of them also contain fragments of older Hindu buildings, very probably pillaged from old Lakhnaoti. By far the finest and most important building in the whole Gaur group of cities, and indeed in Bengal, is the Adina mosque at Pandua, standing close to the high road. It is a quadrangular cloister of two stories, measuring externally 500 feet by 300, of brickwork faced througbout with "black hornblende." The cloisters are divided by pillars into intersecting aisles, and each intersection has been covered by a dome. Of these domes there have been originally 375, but most have fallen. According to Buchanan's description the carved windows have been borrowed from Buddhist structures, but judging from the poor drawings which he gives, and from the photographs of Mr Ravenshaw made under great difficulties, the combination has been carried out with good artistic effect. The edifice must no doubt be monotonous, but from what we can see is far from deserving the condemnation which Buchanan passes on it. The Adina is the work of Sikandar Sháh, the son of Iliyás (1358–1390), and his tomb is in an adjunct of the mosque. There is a curious notice of it in Valentijn's (Dutch) *East Indies* (v. p. 169).

Ekdálah, which was the fortified retreat of the kings who ruled at Pandua, has been lately identified by Mr E. V. Westmacott as still bearing the name, near Chiramon, in the Dinajpore district, about 20 miles north of Pandua. It stands on high ground rising like an island out of the inundated plain; it exhibits traces of embankments and buildings, and is about 5 miles distant from one of the ancient embanked roads running towards Pandua and Gaur.

Tanda, the last city of the Gaur group occupied as a capital, stood a few miles west of the citadel of Gaur, as may be gathered from Rennell and Buchanan. Dr Hunter (*New Statist. Acc. of Bengal*, vii. p. 65) says its very site has not been accurately determined. It is possible that it may have been cut away by the waters of the Ganges, a branch of which has flowed near; but Buchanan had evidently visited it, and Creighton marks the rampart roughly in his map of Gaur. *Jannatábád* was a name given by Humáyún to Gaur; and other names of royal cities appear on coins, such as *Firuzábád*, *Husainábád*, *Shahr-i-nao*, &c., which are probably names officially attached to new foundations of portions of the great Gaur group of cities, but which gained no popular currency.

In addition to the works quoted in this article, the papers of Mr E. Thomas and Mr H. Blochmann in the journals of the Royal and Bengal Asiatic Societies have been consulted. (H. Y.)

GAUSS, Carl Friedrich (1777–1855), an eminent German mathematician, was born of humble parents at Brunswick, April 23, 1777, and was indebted for a liberal education to the notice which his talents procured him from the reigning duke. His name became widely known by the publication, in his twenty-fifth year (1801), of the *Disquisitiones Arithmeticæ*. In 1807 he was appointed director of the Göttingen observatory, an office which he retained to his death: it is said that he never slept away from under the roof of his observatory, except on one occasion, when he accepted an invitation from Humboldt to attend a meeting of natural philosophers at Berlin. In 1809 he published at Hamburg his *Theoria Motus Corporum Cœlestium*, a work which gave a powerful impulse to the true methods of astronomical observation; and his astronomical workings, observations, calculations of orbits of planets and comets, &c., are very numerous and valuable. He continued his labours in the theory of numbers and other analytical subjects, and communicated a long series of memoirs to the Royal Society of Sciences at Göttingen. His first memoir on the theory of magnetism, *Intensitas vis magneticæ terrestris ad mensuram absolutam revocata*, was published in 1833, and he shortly afterwards proceeded, in conjunction with Professor Wilhelm Weber, to invent new apparatus for observing the earth's magnetism and its changes; the instruments devised by them were the declination instrument and the bifilar magnetometer. With Weber's assistance he erected in 1833 at Göttingen a magnetic observatory free from iron (as Humboldt and Arago had previously done on a smaller scale), where he made magnetic observations, and from this same observatory he sent telegraphic signals to the neighbouring town, thus showing the practicability of an electromagnetic telegraph. He further instituted an association (Magnetische Verein), composed at first almost entirely of Germans, whose continuous observations on fixed term-days extended from Holland to Sicily. The volumes of their publication, *Resultate aus der Beobachtungen des Magnetischen Vereins*, extend from 1836 to 1839; and in those for 1838 and 1839 are contained the two important memoirs by Gauss, *Allgemeine Theorie der Erdmagnetismus*, and the *Allgemeine Lehrsätze*—on the theory of forces attracting according to the inverse square of the distance. The instruments and methods thus due to him are substantially those employed in the magnetic observatories throughout the world. He co-operated in the Danish and Hanoverian measurements of an arc and trigonometrical operations (1821–48), and wrote (1843, 1846) the two memoirs *Ueber Gegenstände der höhern Geodäsie*. Connected with observations in general we have (1812–26) the memoir *Theoria combinationis observationum erroribus minimis obnoxia*, with a second part and a supplement. Another memoir of applied mathematics is the *Dioptrische Untersuchungen*, 1840. Gauss was well versed in general literature and the chief languages of modern Europe, and was a member of nearly all the leading scientific societies in Europe. He died at Göttingen early in the spring of 1855. The centenary of his birth was celebrated (1877) at his native place, Brunswick.

Gauss's collected works have been recently published by the Royal Society of Göttingen, in 7 vols. 4to, Gött., 1863–71, edited by E. J. Schering,—(1) the *Disquisitiones Arithmeticæ*, (2) *Theory of Numbers*, (3) *Analysis*, (4) *Geometry and Method of Least Squares*, (5) *Mathematical Physics*, (6) *Astronomy*, and (7) the *Theoria Motus Corporum Cœlestium*. They include, besides his various works and memoirs, notices by him of many of these, and of works of other authors in the *Göttingen gelehrte Anzeigen*, and a considerable amount of previously unpublished matter, *Nachlass*. Of the memoirs in pure mathematics, comprised for the most part in vols. ii., iii., and iv. (but to these must be added those on *Attractions* in vol. v.), it may be safely said there is not one which has not signally contributed to the progress of the branch of mathematics to which it belongs, or which would not require to be carefully analysed in a history of the subject. Running through these volumes in order, we have in the second the memoir, *Summatio quarundam serierum singularium*, the memoirs on the theory of biquadratic residues, in which the notion of complex numbers of the form $a+bi$ was first introduced into the theory of numbers; and included in the *Nachlass* are some valuable tables. That for the conversion of a fraction into decimals (giving the complete period for all the prime numbers up to 997) is a specimen of the extraordinary love which Gauss had for long arithmetical calculations; and the amount of work gone through in the construction of the table of the number of the classes of binary quadratic forms must also have been tremendous. In vol. iii. we have memoirs relating to the proof of the theorem that every numerical equation has a real or imaginary root, the memoir on the *Hypergeometric Series*, that on *Interpolation*, and the memoir *Determinatio Attractionis*—in which a planetary mass is considered as distributed over its orbit according to the time in which each portion of the orbit is described, and the question (having an implied reference to the theory of secular perturbations) is to find the attraction of such a ring. In the solution the value of an elliptic function is found by means of the *arithmetico-geometrical mean*. The *Nachlass* contains further researches on this subject, and also researches (unfortunately very fragmentary) on the lemniscate-function, &c., showing that Gauss was, even before 1800, in possession of many of the discoveries which have made the names of Abel and Jacobi illustrious. In vol. iv. we have the memoir *Allgemeine Auflösung*, on the graphical representation of one surface upon another, and the *Disquisitiones generales circa superficies curvas*. And in vol. v. we have a memoir *On the Attraction of Homogeneous Ellipsoids*, and the already mentioned memoir *Allgemeine Lehrsätze*, on the theory of forces attracting according to the inverse square of the distance. (A. CA.)

GAUSSEN, François Samuel Robert Louis (1790–1863), a Protestant theological writer of some repute, was born at Geneva on the 25th of August, 1790. His father Georges Marc Gaussen, a member of the council of two hundred, was descended from an old Languedoc family which had been scattered at the time of the religious persecutions in France. At the close of his university career, Louis was ordained in 1816 to the ministry of the Swiss Reformed Church at Satigny near Geneva, where he formed intimate relations with J. E. Cellérier, who had preceded him in the pastorate, and also with the members of the dissenting congregation at Bourg-de-Four (Église du temoignage), which had been formed under the influence of the preaching of the Haldanes in 1817. In 1819 he published in conjunction with Cellérier a French translation of the Second Helvetic Confession, with a preface expounding the views he had reached upon the nature, use, and necessity of confessions of faith; and in 1830, for having discarded the official catechism of his church as being insufficiently explicit on the divinity of Christ, original sin, and the doctrines of grace, he was censured and suspended by his ecclesiastical superiors. In the following year, for having taken part in the formation of a Société Évangélique, which contemplated, among other objects, the establishment of a new theological hall, he was finally deprived of his charge. After some time devoted to travel in Italy and England, he returned to Geneva and ministered to an independent congregation until 1836, when he became professor of systematic theology in the college which he had helped to found. This post he continued to occupy until 1857, when he retired from the active duties of the chair. His death occurred at Les Grottes, Geneva, on the 18th of June 1863. His best known work, entitled *La Théopneustie ou Pleine Inspiration des Saintes Écritures*, an elaborate defence of the doctrine of "plenary inspiration," was originally published at Paris in 1840, and rapidly gained a wide popularity in France, as also, through translations, in England and America. It was followed in 1860 by a supplementary treatise on the canon (*Le Canon des Saintes Écritures au double point de vue de la Science et de la Foi*), which, though also popular, has hardly been so widely read. Gaussen was also the author of two published series of sermons, of an exposition of Daniel, and of a variety of occasional publications of a missionary or polemical character. His lectures on Genesis, Exodus, Joshua, Jonah, and Luke were published posthumously.

GAUTIER, Théophile (1811–1872), was born at Tarbes in the year 1811. He was educated at the grammar school of that town, and afterwards at the Collége Charlemagne in Paris, where it does not appear that he particularly distinguished himself, though in later life his remarkable literary faculty and instinct enabled him to give to much of his work an air of scholarship and almost of erudition. He very early devoted himself to the study of the older French literature, especially that of the 16th and the early part of the 17th century. This study qualified him well to take part in the romantic movement, and enabled him to astonish Sainte-Beuve by the phraseology and style of some literary essays which, when barely eighteen years old, he put into the great critic's hands. In consequence of this introduction he at once came under the influence of the great romantic *cénacle*, to which, as to Victor Hugo in particular, he was also introduced by his gifted but ill-starred schoolmate Gérard de Nerval. With Gérard, Petrus Borel, Corot, and many other less known painters and poets whose personalities he has delightfully sketched in the articles latterly collected under the titles of *Histoire du Romantisme*, &c., he formed a minor romantic clique who were distinguished for a time by the most extravagant eccentricity. A flaming crimson waistcoat and a great mass of waving hair were the outward signs which qualified Gautier for a chief rank among the enthusiastic devotees who attended the rehearsals of *Hernani* with red tickets marked "Hierro," performed mocking dances round the bust of Racine, and were at all times ready to exchange word or blow with the *perruques* and *grisâtres* of the classical party. In Gautier's case, however, whatever they might be in others, these freaks were not inconsistent with real genius and real devotion to sound ideals of literature. He began (like Thackeray, to whom he presents in other ways some striking points of resemblance) as an artist, but soon found that his true powers lay in another direction. His first considerable poem, *Albertus* (1830), displayed a good deal of the extravagant character which accompanied rather than marked the movement, but also gave evidence of uncommon command both of language and imagery, and in particular of a descriptive power hardly to be excelled. The promise thus given was more than fulfilled in his subsequent poetry, which, in consequence of its small bulk, may well be noticed at once and by anticipation. The *Comédie de la Mort*, which appeared soon after (1832), is one of the most remarkable of French poems, and though never widely read has received the suffrage of every competent reader. Minor poems of various dates, published in 1840, display an almost unequalled command over poetical form, an advance even over *Albertus* in vigour, wealth, and appropriateness of diction, and abundance of the special poetical essence which is so often absent in the most finished poetical work. All these good gifts reached their climax in the *Émaux et Camées*, first published in 1856, and again, with additions, just before the poet's death in 1872. These poems are in their own way such as cannot be surpassed. Gautier's poetical work contains in little an expression of his literary peculiarities. There are, in addition to the peculiarities of style and diction already noticed, an extraordinary feeling and affection for beauty in art and nature, and a strange indifference to anything beyond this range—an indifference nearly absolute, and which has doubtless injured the popularity of his work to almost as great a degree as that in which it has increased its special excellence and its charm to those who have a taste for it.

But it was not, after all, as a poet that Gautier was to achieve either profit or fame. Thrown as he was into circles which were nothing if not literary, it was natural that he should attempt all literary forms, and certain, considering his powers, that he should be successful in all. For the theatre, however, he had but little gift, and his dramatic efforts (if we except certain masques or ballets in which his exuberant and graceful fancy came into play) are by far his weakest. For a time he acted as secretary to Balzac, but found this occupation uncongenial enough, though it left some traces in his independent work. His first novel of any size, and in many respects his most remarkable work, was *Mademoiselle de Maupin* (1835). Unfortunately this book, while it establishes his literary reputation on an imperishable basis, was unfitted by its subject, and in parts by its treatment, for general perusal, and created even in France a prejudice against its author which he was very far from really deserving. During the years from 1833 onwards, his fertility in novels and tales was very great. *Les Jeune France* (1833), which may rank as a sort of prose *Albertus* in some ways, displays the follies of the youthful romantics in a vein of humorous and at the same time half-pathetic satire. *Fortunio* (1838) perhaps belongs to the same class. *Jettatura*, written somewhat later, is less extravagant and more pathetic. A crowd of minor tales display the highest literary qualities, and rank with Mérimée's at the head of all contemporary works of the class. First of all must be mentioned the ghost story of *La Morte Amoureuse*, a gem of the most perfect workmanship For many years Gautier continued to write novels. *La Belle Jenny* (1864) is a not very successful attempt to draw on his English experience, but the earlier *Militona* (1847) is a most charming picture of Spanish life. In *Spirite* (1866) he endeavoured to enlist the fancy of the day for supernatural manifestations, and a *Roman de la Momie* (1856) is a learned study of ancient Egyptian ways. His most remarkable effort in this kind, towards the end of his life was *Le Capitaine Fracasse* (1863), a novel of the school of Dumas projected nearly thirty years before. This book contains some of the finest instances of his literary power.

It was, however, neither in poems nor in novels that the main occupation of Gautier as a literary man consisted. He was early drawn to the more lucrative task of feuilleton writing, and for more than thirty years he was among the most expert and successful practitioners of this art. Soon after the publication of *Mademoiselle de Maupin*, in which he had not been too polite to journalism, he became irrevocably a journalist. The rest of his life was spent either in Paris or in travels of considerable extent to Spain, the Netherlands, Italy, Turkey, England, Algeria, and Russia, all undertaken with a more or less definite purpose of book making. Having absolutely no political opinions, he had no difficulty in accepting the second empire, and received from it considerable favours, in return for which, however, he in no way prostituted his pen, but remained a literary man pure and simple. He died in October 1872. Accounts of his travels, criticisms of the theatrical and literary works of the day, obituary notices of his contemporaries, and above all art criticism, occupied him in turn. In the last department he has never had a superior, nor perhaps, except in the cases of Diderot and a great living English critic, an equal. It has sometimes been deplored that this engagement in journalism should have diverted Gautier from the performance of more capital work in literature. Perhaps, however, this regret springs from a certain misconception. Gautier's power was literary power pure and simple, and it is as evident in his slightest sketches and criticisms as in *Émaux et Camées* or *La Morte Amoureuse.* On the other hand, his weakness, if he had a weakness, lay in his almost total indifference to the matters which usually supply subjects for art and therefore for literature. He was neither immoral, irreligious, nor unduly subservient to despotism, but morals, religion, and politics (to which we may add science and material progress) were matters of no interest to him. He was to all intents a humanist, as the word was understood in the 15th century. But he was a humorist as well, and this combination, joined to his singularly kindly and genial nature, saved him from some dangers and depravations as well as some absurdities to which the humanist temper is exposed. As time goes on it may be predicted that, though Gautier may not be widely read, yet his writings will never cease to be full of indescribable charm and of very definite instruction to men of letters. Besides those of his works which have been already cited, we may notice *Une larme du Diable* (1839), a charming mixture of humour and tenderness; *Les Grotesques*, a volume of early criticisms on some oddities of 17th century literature; *Caprices et Zigzags*, miscellanies dealing in part with English life; *Constantinople, Voyage in Russie, Voyage in Espagne*, brilliant volumes of travel; *Ménagerie Intime* (1869), and *Tableaux de Siège* (1872), his two latest works, which display his incomparable style in its quietest but not least happy form. (G. SA.)

GAUZE, a light, transparent, silken fabric, woven in an open manner with very fine yarn. It is said to have been originally made at Gaza in Palestine, whence the name. In the weaving of gauze the warp threads, in addition to being crossed as in plain weaving, are twisted in pairs from left to right and from right to left alternately, after each shot of weft, thereby keeping the weft threads at equal distances apart, and retaining them in their parallel position. The textures are woven either plain, striped, or figured; and the material receives many designations, according to its appearance and the purposes to which it is devoted. A thin cotton fabric, woven in the same way, is known as leno, to distinguish it from muslin made by plain weaving. Silk gauze was a prominent and extensive industry in the west of Scotland during the second half of the 18th century, but on the introduction of cotton weaving it greatly declined. In addition to its use for dress purposes silk gauze is much employed for bolting or sifting flour and other finely ground substances. The term gauze is applied generally to transparent fabrics of whatever fibre made, and to the fine woven wire-cloth used in safety-lamps, sieves, window-blinds, &c.

GAVARNI, French caricaturist, was born at Paris in 1801, and died in 1866. His true name was Chevalier (Sulpice Guillaume), and he is said to have taken the *nom de plume* under which he is known from the place where he made his first published sketch. His parents were poor, and he started in life as a workman in an engine-building factory. At the same time he attended the free school of drawing. Here his natural talent was developed, and he acquired that training of the hand without which an artist is unable to work up his best inspirations. In his first attempts to turn his abilities to some account he met with many disappointments, but was at last entrusted with the drawing of some illustrations for a journal of fashion. Gavarni was then thirty-four years of age. His sharp and witty pencil gave to these generally commonplace and unartistic figures a life-likeness and an expression which soon won for him a name in fashionable circles. Gradually he gave greater attention to this more congenial work, and finally ceased working as an engineer to become the director of the journal *Les Gens du Monde.* His ambition rising in proportion to his success, Gavarni from this time followed the real bent of his inclination, and began a series of lithographed sketches, in which he pourtrayed the most striking characteristics, foibles, and vices of the various classes of French society. The letterpress explanations attached to his drawings were always short, but were forcible and highly humorous, if sometimes trivial, and were admirably adapted to the particular subjects. The different stages through which Gavarni's talent passed, always elevating and refining itself, are well worth being noted. At first he confined himself to the study of Parisian manners, more especially those of the Parisian youth. To this vein belong *les Lorettes, les Actrices, les Coulisses, les Fashionables, les Gentilshommes bourgeois, les Artistes, les Débardeurs, Clichy, les Étudiants de Paris, les Balivernеries Parisiennes, les Plaisirs Champêtres, les Bals masqués, le Carnaval, les Souvenirs du Carnaval, les Souvenirs du Bal Chicard, la Vie des jeunes hommes, les Patois de Paris.* He had now ceased to be director of *Les Gens du Monde*; but he was engaged as ordinary caricaturist of *Le Charivari*, and, whilst making the fortune of the paper, he made his own. His name was exceedingly popular, and his illustrations for books were eagerly sought for by publishers. *Le Juif Errant*, by Eugène Sue (1843, 4 vols. 8vo), the French translation of Hoffman's tales (1843, 8vo), the first collective edition of Balzac's works (Paris, Houssiaux, 1850, 20 vols. 8vo), *Le Diable à Paris* (1844–46, 2 vols. 4to), *Les Français peints par eux-mêmes* (1840–43, 9 vols. 8vo), the collection of *Physiologies* published by Aubert in 38 vols. 18mo (1840–42),—all owed a great part of their success at the time, and are still sought for, on account of the clever and telling sketches contributed by Gavarni. A single frontispiece or vignette was sometimes enough to secure the sale of a new book. Always desiring to enlarge the field of his observations, Gavarni soon abandoned his once favourite topics. He no longer limited himself to such types as the *lorette* and the Parisian student, or to the description of the noisy and popular pleasures of the capital, but turned his mirror to the grotesque sides of family life and of humanity at large. *Les Enfants terribles, les Parents terribles, les Fourberies de femmes, la Politique des femmes, les Maris vengés, les Nuances du sentiment, les Rêves, les Petits Jeux de Société, les Petits malheurs du bonheur, les Impressions de ménage, les Interjections, les Traductions en langue vulgaire, les Propos de Thomas Vireloque*, &c., were composed at this time, and are his most elevated productions. But whilst showing the same power of irony as his former works, enhanced by a deeper insight into human nature, they generally bear the stamp of a bitter and even sometimes gloomy philosophy. This tendency was still more strengthened by a visit to England in 1849. He returned from London deeply impressed with the scenes of misery and degradation which he had observed among the lower classes of that city. In the midst of the cheerful atmosphere of Paris he had been struck chiefly by the ridiculous aspects of vulgarity and vice, and he had laughed at them. But the debasement of human nature which he saw in London appears to have affected him so forcibly that from that time the cheerful caricaturist never laughed, or made others laugh again. What he had witnessed there became the almost exclusive subject of his drawings, as powerful, as impressive as ever, but better calculated to be appreciated by cultivated minds than by the public, which had in former years granted him so wide a popularity. Most of these last compositions appeared in the weekly paper *L'Illustration*. In 1857 he published in one volume the series entitled *Masques and Visages* (1 vol. 12mo), and in 1869, about two years after his death, his last artistic work, *Les Douze Mois* (1 vol. fol.), was given to the world. Gavarni was much engaged, during the last period of his life, in scientific pursuits, and this fact must perhaps be connected with the great change which then took place in his manner as an artist. He sent several communications to the Académie des Sciences, and till his death, which happened on the 23d of November 1866, he was eagerly interested in the question of aerial navigation. It is said that he made experiments on a large scale with a view to find the means of directing balloons; but it seems that he was not so successful in this line as his fellow-artist, the caricaturist and photographer, Nadar.

Gavarni's *Œuvres choisies* were edited in 1845 (4 vols. 4to) with letterpress by J. Janin, Th. Gautier, and Balzac, followed in 1850 by two other volumes named *Perles et Parures*; and some essays in prose and in verse written by him were collected by one of his biographers, Ch. Yriarte, and published in 1869. The book written by E. and J. de Gonwurt, *Gavarni, l'homme et l'œuvre* (1873, 8vo), must be mentioned here. J. Claretie has also devoted to the great French caricaturist a curious and interesting essay. A catalogue *raisonné* of Gavarni's works has been published by J. Armelhault and E. Bocher, Paris, 1873, 8vo.

GAVELKIND is a peculiar system of tenure prevailing chiefly in the county of Kent, but found also in other parts of England. In Kent all land is presumed to be holden by this tenure until the contrary is proved. It is more correctly described as socage tenure, subject to the custom of gavelkind. The chief peculiarities of the custom are the following. (1.) A tenant can aliene his lands by feoffment at fifteen years of age. (2.) There is no escheat on attainder for felony, or as it is expressed in the old rhyme—

"The father to the bough,
The son to the plough."

(3.) Generally the tenant could always dispose of his lands by will. (4.) In case of intestacy the estate descends not to the eldest son but to all the sons in equal shares. "Every son is as great a gentleman as the eldest son is." It is to this remarkable peculiarity that gavelkind no doubt owes its local popularity. The 4 & 5 Vict. c. 35, for commuting manorial rights in respect of lands of copyhold and customary tenure, contains a clause specially exempting from the operation of the Act "the custom of gavelkind as the same now exists and prevails in the county of Kent." Gavelkind is one of the most interesting examples of the customary law of England, and it is no doubt correctly traced to the Saxon land-law prevailing before the Conquest. Its survival in this instance in one part of the country is regarded as a concession extorted from the Conqueror by the superior bravery of the men of Kent.

GAVIAL. See Crocodile.

GAY, John (1688–1732), one of the most eminent of the secondary English poets, was a native of Devonshire, born in 1688 at Frithelstock, near Torrington, where his family had been long settled. His father dying when the future poet was only about six years of age, and leaving four children, the prospects of the family were unpromising and John, after receiving his education at the grammar school of Barnstaple, was put apprentice to a silk mercer in London. He disliked the employment, obtained his discharge, and embarked in a literary life, varied only by incessant efforts to obtain the patronage of the great. How he lived up to his twenty-second year is not stated. In 1710 he published his poem of *Wine*, an enumeration of the charms of the "enlivening grape," written in the grave, mock-heroic, and minutely descriptive style, which he afterwards displayed with greater power in his *Trivia*. In 1712 he was received into the household of the duchess of Monmouth in the capacity of secretary. Next year he published his *Rural Sports*, inscribed to Pope; and this seems to have led to a friendship between the poets uninterrupted and sincere. The superiority of Pope was freely conceded. There could be no rivalry on the part of Gay, and Pope appears to have exerted himself on every occasion to serve his friend. Gay's ambition was limited to a life of ease, fine-dressing, and a luxurious table, in all of which he had marvellous success, but little contentment. In the years 1713 and 1714, besides the *Rural Sports*, he produced a comedy, *The Wife of Bath*, which was acted only three nights; *The Fan*, a poem; and *The Shepherd's Week*, a series of six pastorals drawn from English rustic life. Pope is believed to have incited his friend to this task in order to cast ridicule on the Arcadian pastorals of Ambrose Philips, who had been lavishly praised in the *Guardian* (ignoring the claims of Pope) as the first pastoral writer of the age, and the true English Theocritus. The malicious wit was completely successful, but Gay's ludicrous pictures of the English swains and their loves were found to be interesting and amusing without reference to their sarcastic origin. The poem was popular, and the author's reputation considerably advanced. In this fortunate year Gay was appointed secretary to the earl of Clarendon, ambassador to the court of Hanover; but the death of Queen Anne, August 1, 1714, soon put an end to his hopes of permanent official employment. He then tried the drama, and produced his farce of *What d'ye Call it?* which was acted with little success in February 1714–15. In 1716 appeared his *Trivia, or the Art of Walking the Streets of London*, a poem in three books, for which he acknowledged having received several hints from Swift. It is an excellent *town* poem, containing graphic and humorous descriptions of the London of that period. In January 1716–17 the comedy of *Three Hours after Marriage* was brought on the stage, and emphatically condemned. In this piece Gay was assisted by Pope and Arbuthnot. Pope is distinctly visible in his allusions to Dennis the critic, and it is remarkable that three such men should have produced a play so dull, unnatural, and gross. Gay was taken to Aix by Mr Pulteney in 1717. In 1720 he collected his poems and published them by subscription, by which he is said to have realized £1000. Secretary Craggs also presented him with some South Sea stock; and Gay called in his friends to advise as to the investment of his riches Erasmus Lewis, according to Johnson, advised him to intrust his money to the funds, and live upon the interest Arbuthnot bade him intrust it to Providence, and live upon the principal; while Pope directed him, and was seconded by Swift, to purchase an annuity. This was Pope's own prudent system; but Gay, like many others who ask advice, followed none, but took his own way. He embarked all in South Sea stock; and, refusing to sell out before the bubble burst, he lost the actual principal as well as the anticipated profit. The calamity overwhelmed him; his life was despaired of; but his friends exerted themselves to cheer and succour the desponding bard. Lord Burlington entertained him for months in his princely house at Chiswick; and Pope Arbuthnot and the other members of the circle were unceasing in their attentions. By the beginning of 1724 he had a new play ready, a tragedy called the *Captives*, which was patronized by the Princess (afterward Queen) Caroline and the Prince of Wales. In 1726 he published his famous *Fifty-one Fables in Verse.* His next work was the *Beggar's Opera*, performed in 1727, written in ridicule of the Italian Opera, which for a time it drove off the English stage. Swift suggested the subject, and Pope is believed to have added some poignancy to the satirical songs; but Gay's own *bonhomie* and voluptuous style colour the whole. The play ran to the end of the season, sixty-two nights, four of which were for the benefit of the author, and produced to him the handsome sum of £693, 13s. 6d. The same year he sold his copyright of the *Opera*, with that of the *Fables*, for 90 guineas. The success of *The Beggar's Opera* induced Gay to attempt a continuation of the operatic style. He wrote another piece, *Polly*, with no satirical design, as he states; but the lord chamberlain prohibited its representation. The poet then resorted in 1729 to publication by subscription; his friends were again active —the duchess of Queensberry even bearding royalty in resentment of the refusal of the licence; and Gay must have cleared above £1000 by what was deemed his oppression. The duke of Queensberry received Gay into his house, and the duchess treated him with equal respect for his talents and character. This clever, beautiful, and eccentric woman—the idol of the poets—appears nowhere to more advantage than in her affectionate patronage of Gay, and her long-cherished regret for his loss. The poet died, after a short illness, December 4, 1732, and the duke and duchess of Queensberry honoured his remains with a splendid funeral and monument in Westminster Abbey. A week before his death another opera, *Achilles*, had been brought out with applause, and this, with a new volume of *Fables*, was published in 1733, the profits going to his sisters, two widow ladies, who inherited by the poet's death no less than £6000. As late as 1743 appeared the posthumous comedy of *The Distrest Wife*, and the farce of *The Rehearsal at Gotham* in 1753. Pope and Swift—always ready to blame the court and courtiers, though far from averse to their society—have censured Mrs Howard, afterwards countess of Suffolk, for not more zealously promoting the interests of Gay by her supposed influence with the king. One offer was made to the poet,—the situation of gentleman-usher to the Princess Louisa, a child,—but he declined it on account of his being, as he writes to Swift, so far advanced in life. He was only thirty-nine; but all Gay's friends seem to have treated the offer as an indignity. When the queen's establishment was made up in 1727, they expected some more important office for their favourite associate, though it is not easy to discover what appointment about the court could have been better adapted to one so easy, so natural, and helpless. Mrs Howard, it is now known, had very little influence with her royal master. The real power was in the hands of the queen, and the philosophical Caroline was content that his Majesty (who hated *bhoetry* and *bhainting*, and looked upon poets as mechanics) should possess what mistresses he pleased, provided that the state power and patronage continued with herself and Walpole. But it may be safely said that no man could have acquired such a body of great and accomplished friends as those which rallied round Gay and mourned his loss, without the possession of many valuable and endearing qualities. His poetry is neither high nor pure; but he had humour, a fine vein of fancy, and powers of observation and local painting which bespeak the close poetical student and the happy literary artist. (R. CA.)

GAY, MARIE FRANCOISE SOPHIE, MADAME (1776-1852), daughter of M. Nichault de Lavalette (who was attached to the household of Monsieur, afterwards Louis XVIII.), and of Francesca Peretti, a Florentine lady, was born at Paris 1st July 1776. Under the guidance of her father, a man of taste and culture, she received a very careful education. In 1793 she was married to M. Liottier, an exchange broker, but she was divorced from him in 1799, and shortly afterwards was married to M. Gay, receiver-general of the department of the Roër or Ruhr. This union brought her into more intimate relations with many distinguished personages whom she had previously known; and her circle of acquaintanceship gradually extended, until her *salon* came to be frequented by all the distinguished litterateurs, musicians, actors, and painters of the time, among whom she made herself remarked by her beauty, her vivacity, and her sprightly wit tempered by fine tact and genuine amiability. Her first literary production was a letter written in 1802 to the *Journal de Paris*, in defence of Madame de Staël's novel *Delphin*; and in the same year she published anonymously her first novel *Laure d'Estell. Léonie de Montbreuse*, which appeared in 1813, is considered by Sainte-Beuve her best work; but *Anatolie*, which appeared in 1815, has perhaps a higher reputation. These and several of her other works, amongst which may be specially named *Les Salons célèbres*, possess an interest beyond their intrinsic merits—chief of which are purity and elegance of style—for their portraitures of French society especially during the period of the directory and the consulate, and of many of the distinguished personages whose intimacy she enjoyed. Madame Gay wrote several theatrical pieces which had considerable success. She was also an accomplished player on the pianoforte and harp, and composed both the words and music of a number of *romances.* For an account of her daughter Delphine Gay, Madame de Girardin, see GIRARDIN.

Besides the works already mentioned, she is the author of *Les Malheurs d'un amant heureux*, 1818; *Théobald, épisode de la guerre de Russie*, 1828; *Le Moqueur amoureux*, 1830; *Un Mariage sous l'Empire*, 1832; *Scènes du jeune âge*, 1833; *Physiologie du ridicule*, 1833; *La Duchesse de Châteauroux*, 1834; *Souvenirs d'une vieille femme*, 1834; *La Comtesse d'Egmont*, 1836; *Marie de Mancini*, 1840; *Marie-Louise d'Orléans*, 1842; *Ellénore*, 1844-46; *Le Faux Frère*, 1845; *Le Comte de Guiche*, 1845; and *Le Mari confident*, 1849. See Theophile Gautier, *Portraits Contemporains*; and Sainte-Beuve, *Causeries du Lundi*, vol. vi.

GAYÁ, a district of British India in the Patná division, under the lieutenant-governor of Bengal, situated between 24° 17′ and 25° 19′ N. lat., and between 84° 4′ and 86° 5′ E. long. It is bounded on the N. by Patná, on the E. by Monghyr, on the S.E. and S. by Hazáribágh, and on the W. by Sháhábád districts. Generally speaking, Gayá consists of a level plain, with a ridge of prettily wooded hills along the southern boundary, whence the country falls with a gentle slope towards the Ganges. Rocky hills occasionally occur, either detached or in groups, the loftiest being Máher hill about 12 miles S.E. of Gayá town, with an elevation of 1620 feet above sea-level. The eastern part of the district is highly cultivated; the portions to the north and west are less fertile; while in the south, the country is thinly peopled, and consists of hills, the jungles on which are full of wild animals. The principal river is the Son, which marks the boundary between Gayá and Sháhábád, navigable by small boats throughout the year, and by craft of 20 tons burden in the rainy season. The other rivers are the Pímpún, Phálgú, and Jamná, and a number of smaller streams. Two branches of the Son canal system, the eastern main canal and the Patná canal, intersect the district.

The census of 1872 takes the area of Gayá district at 4718 square miles, and returns the population at 954,129 males and 995,621 females,—total, 1,949,750, residing in 6530 villages or towns, and 327,845 houses. Classified according to religion, there are 1,729,890 Hindus, 219,332

Mahometans, 203 Christians, and 316 "others." Amongst the higher castes there is an unusually large proportion of Bráhmans, a circumstance due to the number of sacred places which the district contains. The Gayáwáls, or priests in charge of the holy places, are held in high esteem by the pilgrims; but they are not pure Bráhmans, and are looked down upon by those who are. They live an idle and dissolute life, but are very wealthy, from contributions extorted from the pilgrims. The ruined city of Buddh Gayá, about 6 miles south of Gayá town, marks the residence of Sakya Sinha, the founder of the Buddhist religion, who flourished in the 6th century B.C., and an ancient tree is pointed out as the identical fig tree under which the sage sat in abstraction for five years, until he attained to the state of Buddha. Another place of religious interest is a temple of great antiquity, which crowns the highest peak of the Baraber hills, and at which a religious fair is held each September, attended by from 10,000 to 20,000 pilgrims. At the foot of the hill are numerous rock caves excavated about 200 B.C.

Seven towns in Gayá district contain upwards of 5000 inhabitants, viz., Gayá, 66,843; Jahánábád, 21,022, Dáudnagar, 10,058: Tikárí, 8178; Sherghátí, 7033; Hasúá, 6119; and Rajauli, 5012. About four-fifths of the surface is cultivated. Rice forms the great agricultural staple, the area under cultivation being estimated at about 900,000 acres, yielding an outturn of over 400,000 tons. Wheat occupies about 170,000 acres, producing a crop of 60,000 tons, of which one-half is exported. Oil seeds are grown on about 35,000 acres, and opium on between 60,000 and 70,000 acres. Cotton, sugar-cane, chilies, and vegetables are also grown. Droughts are common, and in the famine of 1866 Gayá suffered severely. The scarcity of 1873–74 did not affect the district to any great extent. Manufactures consist of common brass utensils, black stone ornaments, pottery, *tasar* silk cloth. Formerly cloth-weaving and paper-making were important manufactures in the district, but these industries have now almost entirely died out. The chief exports are food grains, oil seeds, indigo, crude opium (sent to Patná for manufacture), saltpetre, sugar, blankets, brass utensils, &c. The imports are salt, piece goods, cotton, timber, bamboos, tobacco, lac, iron, spices, and fruits. The principal trade route is along the Patná branch road. The total net revenue of the district in 1876–77 was £188,426, of which £136,692 was derived from the land; the net civil expenditure, £23,878. The district and municipal police of all ranks numbered 923, besides a rural force of 6790 men paid by the landholders and villagers. The number of schools in 1873–74 was 446, attended by 8139 pupils. The climate of Gayá is dry and healthy,—the average annual temperature being about 80° F., and average annual rainfall 35·59 inches.

GAYÁ, the chief town and administrative headquarters of the above district, situated on the bank of the Phálgú river, lat. 24° 47′ 15″ N., long. 85° 3′ 10″ E. The population in 1872 numbered 66,843:—Hindus, 52,265; Mahometans, 14,444; Christians, 134. The municipal income in 1871 was £2716, and the expenditure £2351. The town consists of two distinct parts, adjoining each other; the part containing the residences of the priests is Gayá proper; and the other, which is the business quarter, is called Sáhibganj. The civil offices and residences of the European inhabitants are situated here. Gayá derives its sanctity from incidents in the life of Buddha connected with the adjoining district. But a local legend also exists concerning a pagan monster of great sanctity, named Gayá, who wickedly tried to save sinners from deserved perdition. Brahma in order to get rid of Gayá induced him to lie down in order that a feast might be held on his body; and once down, he placed a large stone on him to keep him there. The tricked demon struggled violently, and, in order to pacify him, Brahma promised that the gods should take up their permanent residence in him, and that any one who made a pilgrimage to the spot were he lay should be delivered from the terrors of the Hindu place of torment. This may possibly be a Brahmanic rendering of Buddha's life and work. There are forty-five sacred spots in and around town, which are visited by from 100,000 to 200,000 pilgrims annually.

GAY-LUSSAC, JOSEPH LOUIS (1778–1850), one of the most distinguished of modern physicists and chemists, was born at St Léonard, in the department of Haute Vienne, on the 6th of December 1778. His father, Antoine Gay, who was procureur du roi and judge at Pont-de-Noblac, had added to the common family name the distinctive title Lussac, from a small property he had in the neighbourhood of St Léonard. The family consisted of two sons, of whom Joseph Louis was the elder, and three daughters. Intended for the bar, young Gay-Lussac prosecuted his early studies in Latin and other elementary subjects at home, under the superintendence of the Abbé Bourdeix and other masters, until 1794, when he was sent to Paris, where he worked very hard for three years preparing for admission to the École Polytechnique. After a brilliant examination he was received into this institution on December 27, 1797, whence on the 22d of November 1800 he was transferred to the school Des Ponts et Chaussées. Shortly afterwards he was assigned to Berthollet, who had returned from Napoleon's Egyptian expedition, and who was desirous of having an able student from the École Polytechnique to aid him in his researches. The results expected by the author of the *Statique Chimique* were not verified by his assistant's experiments, which seem to have been recorded without any consideration of the theorizer's feelings. It was on this occasion, according to Arago, that Berthollet, at first nettled to find that his ideas were not confirmed, delivered himself as follows: "Young man, it is your destiny to make discoveries. You shall be henceforth my companion. I wish—it is a title of which I am sure I shall have cause some day to be proud—I wish to be your father in science."

Gay-Lussac accordingly entered on a long series of researches upon certain physical phenomena, which though of constant recurrence in experimental inquiries, had up to this time been very imperfectly examined. In his first memoir (*Ann. de Chimie*, t. xliii., 1802) he shows that different gases are dilated in the same proportion when heated from 0° to 80° (Réaumur). He does not seem to have been aware of Dalton's experiments on this subject, which were indeed very far from being accurate; but he states in a footnote that "le cit. Charles[1] avait remarqué depuis 15 ans la même propriété dans ces gaz; mais, n'ayant jamais publié ses résultats, c'est par le plus grand hasard que je les ai connus." In return for his having thus rescued from oblivion the remark which his fellow-citizen, probably wisely, did not think worth recording, some recent authors have changed the title of the law from that of Gay-Lussac to that of Charles. The investigations recorded in this memoir were followed by experiments on the improvements of thermometers and barometers, on the tension of vapours, their mixture with gases, and the determination of their density, evaporation, hygrometry, and capillarity. In course of these researches, which engaged him for a couple of years, he acquired not only dexterity in manipulation and the contrivance of experiments, but a great deal of valuable knowledge of physics. During the interval, in the year 1802, he had been nominated Fourcroy's demonstrator at the École Polytechnique, and as he had in this capacity to lecture frequently for the professor, he was beginning to acquire reputation as a teacher and expounder of chemistry and physics, by the clearness, precision, and care which his lectures evinced. In 1803–4 certain results respecting terrestrial magnetism had been obtained during two balloon ascents, which appeared of so much interest that the French Academy was desirous of having them repeated. Through Berthollet and Chaptal the balloon which had been used in Egypt was obtained, and fitted up with various instruments; the observations were entrusted to Gay-Lussac and Biot,

[1] The inventor of the "Charlière," or hydrogen balloon.

who made their first ascent from the garden of the Conservatoire des Arts et Metiers, on August 24, 1804. In this ascent an altitude of 4000 metres was attained, but unexpected difficulties were encountered, and the results were not decisive. Not satisfied with the expedition, Gay-Lussac got a larger balloon provided with every requisite, and made an ascent by himself on September 16 of the same year. On this occasion the balloon rose to a height of 7016 metres, an altitude greater than any which had been formerly reached, and surpassed only by a few later ascents. At this great elevation of nearly 23,000 feet, and with the thermometer at 9½° C. below freezing, Gay-Lussac remained for a considerable time making observations on temperature, on the moisture of the air, on magnetism, and other points. He observed particularly that he had considerable difficulty in breathing, that his pulse was quickened, and that by the absence of moisture in the air his mouth and throat became so parched that it was painful to swallow even a piece of bread. The experiments on magnetism for which the ascent was primarily made were imperfect, but they led him to the conclusion that the magnetic effect at all attainable elevations above the earth's surface remains constant.[1] Having collected samples of air at different elevations he, on his return to Paris, proceeded to analyse them; and in conjunction with Alexander von Humboldt, whom he had associated with himself in this investigation, he published several papers on eudiometric analysis and related topics. The memoir, which was read to the Institute on October 1, 1804, contained the germ of what was afterwards Gay-Lussac's most important generalization. The authors observed that when oxygen and hydrogen combine together by volume, it is in the proportion of one volume of the former to two volumes of the latter. Prior to this the numerous experiments on the volume composition of water had always brought out various complicated ratios, though approaching the simple one more or less closely. It was not, however, till 1808, that Gay-Lussac announced the law of combination by volume in its general form. Shortly after these investigations were completed, Gay-Lussac got leave of absence to accompany Von Humboldt on a scientific journey to Switzerland, Italy, and Germany. Provided with physical and meteorological instruments, they left Paris March 12, 1805, and travelled by Lyons, Chambery, and Mont Cenis to Genoa, and thence to Rome, where they arrived on July 5. After a short stay at Rome in the residence of William von Humboldt, during which Gay-Lussac made a few chemical analyses, they departed for Naples in company with Leopold von Buch, afterwards so eminent as a geologist. During this visit Gay-Lussac had the opportunity of studying on the spot volcanic eruptions and earthquakes. Vesuvius, which was in violent action, he ascended six times. After this the party went back to Rome, and then started for Florence on September 17, 1805. A few days having been spent there, they went on to Bologna and thence to Milan, which they reached on October 1, and there they had the pleasure of meeting Volta. The party crossed the St Gotthard on October 14–15, in the midst of a storm which prevented their seeing anything, and after some delay reached Göttingen, where they were received with much attention by Blumenbach, the famous naturalist. On November 16 they arrived at Berlin, where the winter and the following spring were spent. In this way Gay-Lussac became acquainted with the best society in Berlin, and was especially intimate with Klaproth and Erman. In spring he hurriedly returned to Paris. The death of an Academician had left a vacant place, and he was hopeful that he might be elected to fill it. Arago remarks that it is curious that Gay-Lussac should have found it necessary to be on the spot to ensure success. What he had already done for science might have been considered sufficient, apart from personal considerations, but there were prejudices which might have acted unfavourably, if he had not been present to meet them. These were, however, successfully overcome, and he entered the Academy in 1806. In the following year was inaugurated the Société d'Arcueil, a small group of scientific men who used to assmble at Berthollet's house. Gay-Lussac was an original member of this society, which is of interest chiefly on account of its having been the means of publishing some papers which have since proved of great historical interest. The results of his magnetic observations made along with Humboldt were published in vol. i. of its *Mémoires* (1807); and vol. ii. (1809) contains the important memoir on gaseous combination, in which he pointed out that, when gases combine with one another by volume or by measure, they do so in the very simplest proportions, 1 to 1, 1 to 2, 2 to 3, and so on, and that the volume of the product in the gaseous state bears a very simple ratio to that of the constituents. This law, which, along with Humboldt, he had shown to be true of water, he extended to several other gases, and he even deduced from the vapour density of compounds that of certain elements, more particularly, carbon, mercury, and iodine, which had not been ascertained by direct experiment.

It would take too much space to give in detail the criticism which the enunciation of the principle evoked, more particularly from Dalton, who would not accept Gay-Lussac's position, and affirmed his belief that "gases do not unite in equal or exact measures in any one instance; when they appear to do so, it is owing to the inaccuracy of our experiments."[2] There was at that time the difficulty that the specific gravity of gases and vapours had been imperfectly determined, and the necessary consequence of Gay-Lussac's law, that the specific gravity and combining weight of elements should be expressed by the same number, could not be experimentally confirmed. Moreover, Dalton rested combination on atomic and not on combining weights, and the numbers he employed were in almost every instance very different from those which more accurate analysis has since determined. But the imperfect character of the then available data, and the amount of seemingly adverse experimental evidence, only throw a stronger light on the genius of Gay-Lussac in divining a law which, as science has progressed, has been duly confirmed, and which not only forms the most important control of the combining weight of chemical substances, but, when interpreted by the kinetic theory of gases, shows that the physical molecules (that is to say, the portions of the substance which are not broken up into smaller parts during the motion which we call heat) exist in equal numbers in equal volumes of different gases at the same temperature and pressure. This law, which has as high a claim as the other to bear the name of Gay-Lussac, is also sometimes deprived of that honour, and called the law of Avogadro, who, long afterwards, by his more extended researches, caused the importance of the law to be recognized by chemists.

The next events in Gay-Lussac's scientific career are connected with what may be called his rivalry with Davy, who in matter of age (b. December 17, 1778) was almost exactly his contemporary. In 1808 when Davy, having isolated potassium and sodium, was awarded Napoleon's prize for the most important discovery in voltaic electricity, the emperor is said to have asked how it was that these discoveries were made abroad and French prizes were carried away. Having

[1] The numerous observations made in both ascents are recorded in the *Journal de Physique* for 1804, vol. 59.

[2] *New System of Chemical Philosophy*, Manchester, 1810, part ii., p. 559.

been informed that there was no battery of power equal to that used by Davy, he caused a very large one to be made, and presented it to the École Polytechnique. While waiting for it, Gay-Lussac and Thénard succeeded in preparing potassium by a direct chemical action, in which fused potash was brought in contact with red-hot iron. This method enabled chemists to prepare the alkali metals in quantity, and Gay-Lussac and Thénard availed themselves of it to examine the properties of potassium very completely, and not only so, but also to use it as a means of decomposing other substances. It was in this way that they separated boron from boracic acid, an element which was also prepared by Davy with the same materials. It is worth notice that Davy admitted the advantage of the method of Gay-Lussac and Thénard, though he seems to have subsequently regarded their appropriation of the newly-discovered metal as not altogether warranted.[1] The researches with the great battery after it was made did not come up to their expectations; the power fell far short of what had been anticipated, and they confined themselves rather to an examination of the phenomena presented by the apparatus itself, than to using it as an engine for effecting important decompositions.

In 1809 was published the second investigation parallel to one by Davy, namely, upon hydrochloric (or, as it was then called, muriatic) acid, and chlorine, then called oxymuriatic acid. This memoir was read to the Institute, and was also published in the second volume of the *Mémoires d'Arcueil*. Gay-Lussac and Thénard describe a crowd of reactions they had tried for determining the characters of these bodies. They pointed out differences between the muriatic and other acids, and indicated that the anomalies which it presented were explicable either on the hypothesis of water being an essential constituent of the acid, or on that of the oxymuriatic acid being a simple gas. At the end of their memoir, however, they decided in favour of oxymuriatic acid being compound, although they had failed to get oxygen from it by heating it with carbon. The explanation of this decision seems to be that, while they themselves were influenced to some extent by Lavoisier's oxygen theory of acids, some of the other members of the Arcueil Society, such as Laplace and Berthollet, were keen Lavoisierians, and were prepared to oppose any criticism which might lead to a modification of the great Frenchman's opinion on so vital a point. To admit the existence of an acid without oxygen might have led to a loss of the whole scientific position which France had gained by Lavoisier's defeat of phlogiston. Davy who was not under the same influence, declared, as the result of his inquiries, that oxymuriatic acid gas was simple, and that therefore there may be acids without oxgyen. Sometime after, Gay-Lussac and Thénard agreed with this view, which they could do with less hesitation, as they had themselves indicated it in their own memoir.

Among the investigations which Gay-Lussac undertook with Thénard in the years 1810–1811, and which ultimately yielded most valuable results, must be mentioned those upon organic chemistry, and especially upon the analysis of fixed organic compounds. Before this time the only way of determining the composition of organic substances was to explode them with oxygen, and as this method was practicable only in the case of bodies which were gaseous, or could be readily volatilized, the great majority of fixed organic substances still remained unexamined. Gay-Lussac and Thénard introduced the plan of adding some oxidizing agent to the substance and burning it in a tube. They used chlorate of potassium, and the products of combustion were collected over mercury. The results obtained were in some cases very accurate, but the process was difficult of execution, and it is singular that the authors should have preferred it to combustion with oxide of copper, which they also tried. In 1815, however, Gay-Lussac employed the latter agent for the examination of cyanogen, and the other method was abandoned. The final improvements were made some years later by Liebig, when working in Gay-Lussac's laboratory. By their original method Gay-Lussac and Thénard determined the composition of fifteen organic substances, including sugar, starch, gum, wax, oil, various woods, resin; mucic, oxalic, tartaric, citric and acetic acids; and albumen, fibrin, gelatin, and casein. Gay-Lussac succeeded also, in 1811, in obtaining pure hydrocyanic acid. He described its physical properties, but did not announce anything about its composition till 1815, when he published his celebrated memoir in which he described cyanogen as a compound radical, prussic acid as a compound of this radical with hydrogen alone, and the prussiates as compounds of the radical with metals. He also showed how to prepare free cyanogen, and explained Berthollet's oxyprussic acid to be really chloride of cyanogen. The proof that prussic acid contains hydrogen and no oxygen was a most important support to the hydrogen acid theory, while the isolation of the radical cyanogen was of equal importance for the subsequent epoch of compound radicals in organic chemistry.

In 1813–14 Gay-Lussac published his memoirs on iodine. This was the third investigation which involved a rivalry with Davy, and it was also that about which there was most feeling. Courtois had discovered the substance in 1811, and had given some of it for examination to Clément-Désormes. He had only published a brief notice of it when Davy arrived in Paris, having obtained express permission of Napoleon to pass through France on his way to Italy. Davy got a few fragments of this curious substance, and after a brief examination with a very limited portable laboratory which he had with him, perceived its analogy to chlorine, and drew the conclusion that it must be a simple body of similar character. Gay-Lussac, it is said, having heard of Davy's making experiments with it, went off to Courtois, got a specimen, and proceeded to examine it. He also saw its likeness to chlorine, but his previous decision respecting that body hampered him, and it was with some hesitation that he ultimately acknowledged its elemental character. Whether or not Gay-Lussac was actuated by the motive ascribed to him by Arago—that it would be a reflexion on French science were the settlement of the characters of this substance to be left to a foreigner visiting Paris—it is not necessary to enquire; but Davy seems to have felt that Gay-Lussac was competing, and not altogether fairly, with him. In a letter to Clément he gives a brief account of his work, and lays claim to the first revelation of the elemental character of iodine, and again in a subsequent letter to his brother, which contains a short review of the Parisian chemists and their reception of him, the only complaint he makes is that Gay-Lussac had played him a trick in trying to appropriate the discovery of the character of iodine and of hydriodic acid. Quite apart, however, from this claim on Gay-Lussac's part, the memoirs remain models of investigation and description. Davy quite freely admitted that full light might be expected on the subject from its

[1] Gay-Lussac and Thénard made no claim, of course, to the discovery of potassium and sodium, though several important discoveries followed from their experiments. Thus, in addition to boron, they got also the fluoride of boron; and by the rapid combustion of the alkali metals in dry oxygen they got their peroxides, by means of which Thénard subsequently prepared the peroxide of hydrogen. At first, however, they seem to have thought that the alkali metals contained hydrogen, and it was not for a couple of years that they accepted Davy's view of their simplicity. Indeed, about this time there appears to have been considerable uncertainty about the elemental character of the metals, it being thought that they contained hydrogen, an idea which, on account of its retrograde nature, was criticized by Davy as a kind of phlogistic revival.

having been taken in hand by so able and accurate a chemist as Gay-Lussac.

The year 1815 saw the completion of the research on cyanogen already referred to, and with it concludes the period of Gay-Lussac's most important discoveries. Having now attained a leading if not the foremost place among the scientific men in the French capital, his advice was often required on important questions. His attention was thus turned in part from purely scientific subjects to points of practical interest. In these new fields, however, he displayed the same powers which he had exercised so sedulously in the pursuit of scientific truth; in fact he was now to introduce and establish scientific accuracy where there had been previously only practical approximations. The most important of these later discoveries were the method of estimating the amount of real alkali in potash and soda by the volume of standard acid required for neutralization; the method of estimating the amount of available chlorine in bleaching powder by a solution of arsenious acid; directions for the use of the centesimal alcoholometer, published in 1824, and specially commended by the commission of the Institute appointed to report on it, as displaying all the accuracy and exhaustive treatment of the author; and lastly, the perfecting of the method of assaying silver by a standard solution of common salt, a volume on which was published in 1833. This last has superseded the old method of assaying silver by cupellation, as being more rapid, more accurate, and easier of execution; and indeed all these processes are so complete and satisfactory, and are besides so identified with their author's name, that his reputation is secured by them, quite independently of his earlier work. In what has been said above, only the more important of Gay-Lussac's discoveries have been alluded to. To enter into an account, however brief, of all his labours, would occupy more space than can be allowed here. Indeed the list of his papers in the Royal Society's catalogue amounts to 148, besides those of which he was joint-author with Von Humboldt, Thénard, Welter, and Liebig; and they embrace every department of the science as cultivated fifty years ago. Among his later researches may be mentioned those on fermentation, and those executed by Liebig in conjunction with him, after the young German chemist had gained the coveted admission to Gay-Lussac's private laboratory during the years 1823–24. The latter include improvements on organic analysis, and the examination of fulminic acid. Gay-Lussac continued his work, and published the results in the *Annales de Chimie*, of which he had been joint-editor for some thirty years, up till almost his death, which took place at Paris on May 9, 1850.

Some of the appointments he held have been already referred to. After having acted as Fourcroy's demonstrator, he was made professor of chemistry at the École Polytechnique. From 1808 to 1832 he was professor of physics at the Sorbonne, and he only resigned that office when he was made professor of chemistry at the Jardin des Plantes. Besides being on the commission of arts and manufactures, and the "administration" of gunpowder and nitre, he was appointed assayer for the mint in 1829. In 1831 he was elected to the chamber of deputies as member for Haute Vienne, and finally, in 1839, entered the chamber of peers.

Gay-Lussac's scientific work is remarkable not only for its range but for its intrinsic worth, its accuracy of detail, its experimental ingenuity, its descriptive clearness, and the soundness of its inferences. He did not hesitate to criticize his own results, and replace them by others more accurate either of his own or of another's discovery; he improved and invented physical and chemical apparatus: the barometer, thermometer, cathetometer, alcoholometer, and the burette, which still bears his name, all bear witness to his ingenuity and practical skill. He devised new analytical methods; he discovered new substances, such as fluoride of boron, and iodic, hydrosulphocyanic, dithionic, and hyposulphurous acids; he enlarged and corrected the knowledge of those already discovered; he examined the physical conditions of chemical action; he searched into the causes of chemical combination and chemical change. That he had the power of grasping the law underlying a few facts is nowhere more evident than in the memoir on gaseous combination, his most important contribution to science. That he missed the opportunity of assigning the chief limit to Lavoisier's hypothesis, must be ascribed partly at least to the influence of others. Authority decided it, perhaps against his secret convictions.

From Arago's and other notices one gathers that Gay-Lussac was reticent, patient, persevering, accurate to punctiliousness, perhaps a little cold and reserved, and not unaware of his great ability. But he was also bold and energetic, not only in his work, but equally so in defence and support of his friends. His earliest childish adventures, as told by Arago, herald the fearless aeronaut and undaunted investigator of volcanic eruptions. The endurance he exhibited under the laboratory accidents which befell him shows the power of will with which he could face the prospect of becoming blind and useless for the prosecution of the science which was his very life, and of which he is one of the most distinguished ornaments. It was only at the very end, when the disease from which he suffered left him no hope, that he complained with some bitterness of the hardship of leaving this world when so many discoveries were making, and when so many more were likely to be made.

The more important of Gay-Lussac's papers are scattered through journals difficult of access. The most complete list of them is contained in the Royal Society's catalogue of scientific papers; lists are also given at the end of Hoefer's article in the *Biographie Générale*, and in Poggendorff's *Biographisch-literarisches Handwörterbuch*, Leipsic, 1863. Accounts of various portions of Gay-Lussac's discoveries and views will be found in such works as Thomson's *History of Chemistry*, vol. ii., London, 1830; Kopp's *Geschichte der Chemie*, Brunswick, 1843–47; Kopp's *Entwickelung der Chemie*, Munich, 1871; Dumas, *Leçons sur la Philosophie Chimique*, Paris, 1837, and reprinted Paris, 1878; Ladenburg, *Vorträge über die Entwickelungsgeschichte der Chemie*, Brunswick, 1869; Forbes, *A Review of the Progress of Mathematical and Physical Science in more recent times*, Edinburgh, 1858. The chief authorities for the life of Gay-Lussac are Arago (*Œuvres*, Paris, 1855, t. iii.); Biot (*Abstracts, Royal Society*, vol. v., 1843–50, p. 1013); P. A. Cap (*Le Muséum d'Histoire Naturelle*, Paris, 1854, pt. 1, p. 137). (J. F.)

GAZA, an ancient city of Philistia, close to the sea and to the south boundary of the Holy Land. The Hebrew is more correctly rendered in English as Azzah (Deut. ii. 23), and means "strong." The modern Arabic form of the name is Ghazzeh. The town stands on an isolated hill about 100 feet high, and has now a population of 1800 souls. It is divided into four quarters, the eastern suburb consisting entirely of mud houses. A magnificent grove of very ancient olives forms an avenue 4 miles long north of the city. On the south-east are a few palms. There are many lofty minarets in various parts of the town, and a fine mosque built of ancient materials. A 12th century church towards the south side of the hill has also been converted into a mosque. On the east is shown the tomb of Samson (an erroneous tradition dating back to the Middle Ages). The ancient walls are now covered up beneath green mounds of rubbish. The water supply is from wells sunk through the sandy soil to the rock; of these there are more than twenty—an unusual number for a Syrian town. The land for the 3 miles between Gaza and the sea consists principally of sand dunes. There is no natural harbour, but traces of ruins near the shore mark the site of the old

Majuma Gazæ or Port of Gaza, now called el Mineh, which in the 5th century was a separate town and episcopal see, under the title Constantia or Limena Gaza. In the 7th century there were numerous families of Samaritans in Gaza, but they became extinct at the commencement of the present century. Hâshem, the father of Mahomet, lies buried in the town. On the east are remains of a race-course, the corners marked by granite shafts with Greek inscriptions on them. To the south is a remarkable hill, quite isolated and bare, with a small mosque and a grave-yard. It is called el Muntâr, "the watch tower," and is supposed to be the mountain "before (or facing) Hebron," to which Samson carried the gates of Gaza (Judg. xvi. 3). The bazaars of Gaza are considered good. An extensive pottery exists in the town, and black earthenware peculiar to the place is manufactured there. The climate is dry and comparatively healthy, but the summer temperature often exceeds 110° Fahr. The surrounding country is partly cornland, partly waste, and is inhabited by wandering Arabs. From the 5th to the 12th century Gaza was an episcopal see of the Latin Church, but even as late as the 4th century an idol named Marnas was worshipped in the town.

GAZA, Theodorus (*c.* 1400–1478), one of the leaders of the revival of learning in the 15th century, was born at Thessalonica about the year 1400. On the capture of his native city by the Turks in 1430 he removed to Mantua, where he rapidly acquired a competent knowledge of Latin under the teaching of Victorino de Feltre, supporting himself meanwhile by giving lessons in Greek, and by copying manuscripts of the ancient classics. About 1440 he became professor of Greek in the newly founded university of Ferrara, to which students in great numbers from all parts of Italy were soon attracted by his fame as a teacher. He had taken some part in the councils which were held in Ferrara (1438), Florence (1439), and Siena (1440), with the object of bringing about a reconciliation between the Greek and Latin Churches; and in 1450, responding to the invitation of Pope Nicholas V., he went to Rome, where he was for some years employed by his patron in making Latin translations from Aristotle and other Greek authors. From 1456 to 1458 he lived at Naples under the patronage of Alphonso the Magnanimous; and shortly after the latter date he was appointed by Cardinal Bessarion to a benefice in the south of Italy, where the later years of his life were spent, and where he died at an advanced age in 1478. Gaza stood high in the opinion of most of his learned contemporaries, but still higher in that of the scholars of the succeeding generation. His Greek grammar, in Greek (*γραμματικῆς εἰσαγωγῆς βίβλια δ*), first printed at Venice in 1495, and afterwards partially translated by Erasmus in 1521, although in many respects defective, especially in its syntax, has done good service in the cause of sound learning. His translations were very numerous, including the *Problemata, De Historia Animalium, De Partibus Animalium,* and *De Generatione Animalium* of Aristotle, the *Historia Plantarum* and *De Causis Plantarum* of Theophrastus, the *Problemata* of Alexander Aphrodisias, the *De Instruendis Aciebus* of Ælian, and some of the *Homilies* of Chrysostom. He also turned into Greek Cicero's *De Senectute* and *Somnium Scipionis*,—with much success, in the opinion of Erasmus; with more elegance than exactitude, according to the colder judgment of modern scholars. He was the author also of two small treatises entitled *De Mensibus* and *De Origine Turcarum.*

GAZELLE. See Antelope.

GAZETTE, The London, is the official newspaper of the Government, and is published every Tuesday and Friday. It contains proclamations, orders, regulations, and other acts of state, and is received as evidence thereof in legal proceedings. It also contains notices of proceedings in bankruptcy, dissolutions of partnership, &c. The Bankruptcy Act, 1869, requires the order of adjudication to be published in the *Gazette*, and makes the *Gazette* conclusive evidence of adjudication. Other statutes, dealing with special subjects, have similar provisions. Unless by virtue of such statutes, the *Gazette* is not evidence of anything but acts of state. The Scotch law of evidence would appear not to be so stringent. Gazettes are also published in Edinburgh and Dublin.

GEBER. After all the research and criticism that have been expended on this the first and most interesting personage in the modern history of chemistry, little is definitely known about him, and about the origin of the works which pass under his name. It has been a very general tradition to regard Geber as an Arabian, but until the publication in recent years by European scholars of the works of Arabian historians and bibliographers, the probable source of the tradition has not been known. It seems to be pretty generally believed that the Geber of Western Europe is the same as the person who is called in full Abu Musa Dschabir (or Jabir) Ben Haijan Ben Abdallah el-Sufi el-Tarsusi el-Kufi, who was reckoned the most illustrious of the alchemists by the Arabs, and who is mentioned in the *Kitab-al-Fihrist* (10th cent.), by Ibn Khallikan (13th cent.), by Haji Khalfa (17th cent.), and other writers. If this be correct, Geber must have flourished in the 8th century, for, according to Haji Khalfa, Dschabir Ben Haijan died in the 160th year of the Hegira, which corresponds with the year beginning October 19, 776 A.D. This date is incidentally confirmed by other writers, though there are difficulties arising from the date of his teacher Kalid Ben Jezid, and his patron Dschaafar ess-Sadik. His birthplace was Tarsus, or, as others say, Kufa; and he is said to have resided at Damascus and at Kufa. This account, though apparently the most trustworthy, does not agree with the statements of D'Herbelot, quoted seemingly from native sources, that Geber was born at Harran in Mesopotamia, was a Sabæan by religion, and lived in the 3d century of the Hegira. Nor does it agree with that of Leo Africanus, who in 1526 gave a description of the Alchemical Society of Fez, in Africa, and told how the chief authority of that society was a certain Geber, a Greek, that had apostatized to Mahometanism, and lived a century after Mahomet. Leo's story has circulated very widely, but its accuracy has been impugned by Reiske and Asseman, and the works of both Leo and D'Herbelot have been rejected as authorities by Wüstenfeld. Other writers have tried to show that Geber was a native of Spain, or at least lived at Seville, but this has probably arisen from confusing Geber the chemist with other persons of the same or similar name. From the doubt encircling the personality of Geber, some have gone the length of questioning whether such a person ever existed but in name, and this view has been again expressed by Steinschneider, who mentions "Abu Musa Dschabir Ben Haiyan, commonly called Geber, an almost mythical person of the earliest period of Islam, renowned as an alchemist." While Steinschneider here exhibits notable scepticism with respect to Dschabir's very existence, he exhibits equal credulity in his belief that this mythical Dschabir is identical with Geber. In the present state of the question there is no alternative but to accept the account given in the Fihrist, and admit the possibility of Dschabir and Geber being one and the same. Confirmation of this view is to be sought in a comparison of the works ascribed to Geber with those bearing the name of Dschabir. The latter are divisible into two classes, those mentioned in Arabic bibliographies, and those existing in manuscript in European libraries. To Dschabir is assigned the authorship of an immense number of works on chemistry and many other topics besides Titles of 500 of these are given in the Fihrist, and have been reproduced by Hammer-Purgstall, but nothing else is known about them. Haji Khalfa also enumerates the titles of several alchemical works by Dschabir, and other works are mentioned by other writers. Again Arabic MSS. on alchemy bearing the name of Dschabir Ben Haijan exist at Leyden, at Paris, in the British Museum, and elsewhere; but these have not been critically examined as to their date, age, authenticity, contents, &c. It is not known if they correspond with the lists already mentioned, or with the Latin MSS. or the printed versions. The Latin MSS. are contained in the Vatican, at Leyden, Oxford, and other places. Of these the Vatican MS. is the alleged basis of some of the printed editions; and the Bodleian MSS. have been described by W. H. Black, but no collation of the text of these writings for critical purposes has as yet been made. The oldest of the MSS. dates from the 14th century; but if the works ascribed to Roger Bacon, Albertus Magnus, and others be genuine, Geber's name and writings must have been known and esteemed at a still earlier period. The works which purport to have been written by Geber, and which have been printed, bear the following names:—*Summa perfectionis*; *Liber investigationis*, or *De investigatione perfectionis*; *De inventione veritatis*; *Liber Fornacum*; *Testamentum*. None of the editions appear to contain the whole of these tractates; there are usually found only two or three of them, but the English translation contains them all except the *Testament*, which is considered spurious by some writers. The printed editions of these works are very numerous, but they are all uncommon, and some of them are exceedingly rare. No approximately complete list is contained in any bibliography, and very few writers have seen more than half a dozen at most. The most complete catalogue from personal inspection is given by Beckmann. It contains twelve editions, but that does not comprise nearly all those which are known. While some of the editions correspond exactly, being merely reprints, there are important differences among others. What light these variations may throw upon the origin of the text has never been investigated. A critical edition of the works with the various readings would be necessary before deciding that what is found in them is really Geber's, and dates back eleven centuries. It may be that some of the knowledge of chemistry credited to Geber was really interpolated at a later date. It is quite possible that the account given of the various acids, salts, and metals, and of the apparatus and operations, may have been modified or extended. But, on the other hand, the general theory that runs through the whole of the writings is in all probability original. The theory is that the metals are composed of the same elements, and that by proper treatment the less perfect can be gradually developed into the more perfect metals. This theory is very clearly, and one may even say logically, worked out, and it was the leading idea in chemistry down to the 16th century at least. In carrying out this theory practically, certain materials were employed and were subjected to operations, and the knowledge acquired about them took shape by degrees. Though subsequent workers added to what was known, Geber's reputed works are so clear, so precise, so complete, that they differ in a most striking manner from the works of even the best writers in the later alchemical period, and make it difficult to account for their existence at all. Older writings there are none; subsequent writings as clear as Geber's do not appear until far more was known; the unsolved problem therefore remains, Who was Geber, and how does it happen that his works stand quite alone in chemical literature?

The following are a few of the authorities which may be consulted:—Abulfeda, *Annales Moslemici*, Copenhagen, 1790, with Reiske's note; Beckmann, *Geschichte der Erfindungen*, 1803, v. 272; Black, *Catalogue of MSS. bequeathed to the University of Oxford by Elias Ashmole*, 1845; D'Herbelot, *Bibliotheque Orientale*, Paris, 1697; Haji Khalfa, *Lexicon*, ed. Fluegel, London, 1835-58; Hammer-Purgstall, *Literaturgeschichte der Araber*, Vienna, 1850; Ibn-Khallikan, *Biographical Dictionary*, by De Slane, Paris, 1843, vol. i. pp. 300-1; *Kitab-al-Fihrist*, ed. Fluegel, 1871-72; Kopp, *Beiträge zur Geschichte der Chemie*, Brunswick, 1875, part iii.; *Laboratory*, 1867, vol. i. pp. 71-76; Leo Africanus, *Africæ Descriptio*, Leyden, 1632; Steinschneider, "Die toxicologischen Schriften der Araber," in Virchow's *Archiv*, Berlin, 1871, Bd. 52; Wüstenfeld, *Geschichte der Arabischen Aerzte*, Göttingen, 1840. See also article ALCHEMY. (J. F.)

GEBWEILER, in French *Guebwiller*, a town of the German imperial province of Alsace-Lorraine, in the district of Upper Alsace, situated about 13 miles south of Colmar, at the mouth of the Blumenthal or "Vale of Flowers." It communicates by a branch line with the railway between Strasburg and Basel. Among the principal buildings are the Roman Catholic church of St Leodgar, dating from the 12th century, the Evangelical church, the synagogue, the town-house, and the old Dominican convent now used as a market and concert-hall. The spinning, weaving, bleaching, and dyeing of cotton is the chief industry, but woollen goods and silk ribbons, as well as machinery, are also manufactured. Gebweiler is mentioned as early as 774. It belonged to the religious foundation of Murbach, and in 1759 the abbots chose it for their residence. At the French Revolution of 1789, however, the chapter house was laid in ruins, and though the archives were rescued and removed to Colmar, the library perished in the devastation. Population in 1871, 11,104; in 1875, 11,622.

GECKO, the common name applied to all the species of *Geckotidæ*, an extensive family of lizards belonging to the Pachyglossæ, or "thick-skinned" sub-order of Gray. The geckoes are small creatures, seldom exceeding 8 inches in

Leaf-tailed Gecko (*Phyllurus platurus*).

length including the tail. With the head considerably flattened, the body short and thick, the legs not high enough to prevent the body dragging somewhat on the ground, the eyes large and almost destitute of eyelids, and the tail short and in some cases nearly as thick as the body, the geckoes altogether lack the litheness and grace characteristic of most lizards. Their colours also are dull, and to the weird and forbidding aspect thus produced the general prejudice against those creatures in the countries where they occur, which has led to their being classed with toads and snakes, is no doubt to be attributed. Their bite was supposed to be venomous, and their saliva to produce painful cutaneous eruptions; even their touch was thought sufficient to convey a dangerous taint. It is needless to say that in this instance the popular mind was misled by appearances. The geckoes are not only harmless, but are exceedingly useful creatures, feeding on insects and worms, which, owing to the great width of their œsophagus, they are enabled to swallow whole, and in pursuit of which they do not hesitate to enter human dwellings, where they are often killed on suspicion. The structure of the toes in those lizards forms their most characteristic anatomical feature. These organs are flattened out into broad discs, and are furnished with transverse lamellar plates, by means of which the geckoes are enabled to run with ease on the smoothest surface, and to imitate the fly in remaining suspended on ceilings or on the under surfaces of leaves. Most of the species have nails to their toes, and these in their sharpness and retractility bear considerable resemblance to the claws of feline animals. They are nocturnal in their habits; but when not exposed to the hot sunshine they are able to pursue their prey by day. They hibernate; and two fatty masses in front of the pubis are supposed to furnish the means of nourishment during this period. Many of the species possess to a limited extent the chameleon faculty of changing colour, while their colouring generally may be regarded as protective; a few Indian forms are said to become luminous in the dark. The geckoes form an extensive family, including 60 genera and 200 species, found throughout the warmer regions of the earth, two only being inhabitants of Europe, and even these occur also in the north of Africa. Unlike most lizards, they are found in the remotest oceanic islands, a fact which leads Mr Wallace (*Geographical Distribution of Animals*) to suppose that they possess exceptional means of distribution.

GED, William (? –1749), the inventor of the art of stereotyping, was born at Edinburgh about the beginning of the 18th century. In 1725 he first put in practice the art which he had discovered; and some years later he entered into a partnership with a London capitalist, with a view to employing it on a great scale. The partnership, however, turned out very ill; and Ged, broken-hearted at his want of success, died at London, October 19, 1749. The only books which he produced by means of stereotyping were two prayer-books for the university of Cambridge, and an edition of Sallust. See Life by Nichols, 1781.

GEDDES, Alexander (1737–1802), a learned theologian, biblical critic, and miscellaneous writer, was born at the farm of Arradoul, in the parish of Rathven, Banffshire, Scotland, on the 14th of September 1737. At the age of fourteen he entered the small Roman Catholic seminary at Scalan in a remote glen of the Banffshire highlands, where he remained till October 1758, when he was sent to the Scottish College in Paris for the further prosecution of his studies. Here to considerable acquirements in biblical philology and school divinity he succeeded in adding a good knowledge of most of the literary languages of Europe. Returning to Scotland after an absence of six years, he for a short time officiated as a priest in Dundee, but in May 1765 received and accepted an invitation to become resident in the family of the earl of Traquair, where, with abundance of leisure and the free use of an adequate library, he made further progress in his favourite biblical studies. After a second visit to Paris which extended over some months, and which was employed by him in reading and making extracts from rare books and manuscripts in the public libraries, he in 1769 was appointed to the charge of the Catholic congregation of Auchinhalrig in his native county. During the period of a ten years' incumbency there he displayed a liberality of spirit which caused considerable scandal to his stricter brethren; and the freedom with which he fraternized with his Protestant neighbours once and again called forth the rebuke of his bishop (Hay). Ultimately, on account of his occasional attendance at the parish church of Cullen, where his friend Buchanan was minister, he was deprived of his charge and forbidden the exercise of ecclesiastical functions within the diocese. This happened in 1779; and in 1780 he went with his friend Lord Traquair to London, where he spent the rest of his life, with the exception of a few weeks devoted to travel on the Continent. Before leaving Scotland he had received the honorary degree of LL.D. from the university of Aberdeen, a compliment seldom before paid to any Catholic, and had been made an honorary member of the Society of Antiquaries, in the institution of which he had taken a very active part. Shortly after his arrival in London Geddes received an appointment in connexion with the chapel of the imperial ambassador, which he held until the chaplaincy was suppressed some years afterwards. Having been introduced to Lord Petre, to whom he broached his long-cherished scheme for the publication of a new Catholic version of the Scriptures on the basis of the Vulgate, he met with every encouragement from that nobleman, who assigned to him an annual salary of £200, and, moreover, undertook to provide the needful books. Supported also by such scholars as Kennicott and Lowth, Geddes in 1786 published a *Prospectus of a new Translation of the Holy Bible, from corrected Texts of the Originals, compared with the ancient Versions, with various Readings, explanatory Notes, and critical Observations*, a considerable quarto volume, in which the defects of previous translations were fully pointed out, and the means were indicated by which these might be removed. It attracted considerable notice of a favourable kind, and led to the publication in 1788 of *Proposals for Printing*, with a specimen, and in 1790 of a *General Answer to Queries, Counsels, and Criticisms*. The first volume of the translation itself, which was entitled *The Holy Bible; or the Books accounted sacred by Jews and Christians; otherwise called the Books of the Old and New Covenants; faithfully translated from corrected Texts of the Originals, with various Readings, explanatory Notes, and critical Remarks*, appeared in 1792, and was the signal for a storm of hostility on the part of both Catholics and Protestants. It was obvious enough—no small offence in the eyes of some—that as a critic Geddes had identified himself with Houbigant, Kennicott, and Michaelis; but others did not hesitate to stigmatize him as the would-be "corrector of the Holy Ghost." Three of the vicars-apostolic almost immediately warned all the faithful against the "use and reception" of his translation, on the ostensible ground that it had not been examined and approved by due ecclesiastical authority; and by his own bishop (Douglas) he was in 1793 suspended from the exercise of his orders in the London district. The second volume of the translation, completing the historical books, published in 1797, found no more friendly reception; but this circumstance did not discourage him from giving forth in 1800 the volume of *Critical Remarks on the Hebrew Scriptures, corresponding with a New Translation of the Bible, containing the Pentateuch*, of which it is enough to say that, while fully saturated with all the best learning of its time, it presented in a somewhat brusque and injudicious manner the then novel and startling views of Eichhorn and his school on the primitive history and early records of mankind. Dr Geddes was engaged on a critical translation of the Psalms, which he had completed down to the 118th, when he was seized with a lingering and painful illness which ultimately proved fatal on the 26th of February 1802. Although for many years he had been under ecclesiastical censures, he had never for a moment swerved from a consistent profession of faith as a Catholic; and on his death-bed he duly received the last rites of his communion. It would appear, however, that the report which gained currency that before his death he had made recantation of his "errors" was entirely destitute of foundation in fact. In his lifetime he enjoyed the friendship of several eminent Continental scholars, and his death was noticed as being a loss to science in the *Gelehrte Zeitung* of Gotha and in other foreign journals.

Besides pamphlets on the Catholic and slavery questions, as well as several fugitive *jeux d'esprit*, and a number of unsigned articles in the *Analytical Review*, Geddes also published a metrical translation and adaptation of *Select Satires of Horace* (1779), and a verbal rendering of the *First Book of the Iliad of Homer* (1792). The *Memoirs* of his life and writings by his friend Dr Mason Good appeared in 1803, and his unfinished work on the Psalms in 1807.

GEELONG, one of the leading towns in Victoria, coeval with Melbourne in the history of Australian settlement, is pleasantly situated on Corio Bay, an extensive western arm of Port Phillip, 45 miles S.W. of Melbourne, in 39° 8' S. lat. and 144° 21' E. long. The town slopes to the bay on the north side and to the Barwon river on the south, and its position in this respect, as well as the shelter it obtains from the Bellarine range of hills, renders it the healthiest town in the colony. Its streets are wide and laid out at right angles, and there are many handsome public and private buildings. It has a botanical garden, and two parks maintained by the municipality. The public buildings comprise a mechanics' institute (with a library containing nearly 12,000 volumes), a public library, a town hall, a fire-brigade establishment, a handsome and commodious hospital, a supreme court, and orphan and benevolent asylums. The town is supplied with water from large state-constructed reservoirs in the Brisbane ranges, some 25 miles distant. As a manufacturing centre Geelong is of considerable importance. It contains extensive woollen mills and tanneries on the Barwon river, and paper of good quality is largely made in the neighbourhood. Geelong harbour has area and depth enough to hold all the navies of the world. The bar at the entrance has been cut (at an expense of £6000) to admit vessels of heavy draught, and some of the largest wool ships are able to load at the wharves, which are connected by railway with all parts of the colony. The population of the city proper is a little over 12,000, but with the adjacent boroughs of Geelong West, Chilwell, and Newtown the total is increased to 24,000.

GEESTEMÜNDE, a seaport in the Prussian province of Hanover, in the district or *Landdrostei* of Stade, situated, as the name indicates, at the mouth of the Geeste, a right-hand affluent of the estuary of the Weser. It lies about 32 miles N. of Bremen, and is the terminus of a railway from that city. The interest of the place is purely naval and commercial, its origin dating no further back than 1857, when the construction of the harbour was commenced. The great basin opened in 1863 has a length of 1785 English feet, a breadth of 410, and a depth of nearly 23, and can accommodate 24 or 25 of the largest ships of the line; and the petroleum basin opened in 1874 has a length of 820 feet and a breadth of 147. To the left of the great basin lies a canal, which has a length of 13,380 feet and a breadth of 155; and from this canal there strikes off another of similar proportions. The whole port is protected by powerful fortifications, and it lies outside of the limit of the German customs. Since 1864 the trade has been almost trebled, the number of vessels being 617 sea-going ships entering in 1875 and upwards of 2000 river craft. Among the industrial establishments of the town are ship-building yards, foundries, engineering works, and steam mills. The population, exclusive of the garrison, was 3218 in 1871, and 3436 in 1875; and if the neighbouring commune of Geestendorf be included, the total for 1871 was 9148, and for 1875 10,425.

GEFLE, Latinized as *Gevalia*, a seaport town of Sweden, at the head of the Gefleborglån, about a mile from the shore of the gulf of Bothnia, near the mouth of the Gefle-Å, 50 miles E. of Fahlun, and about the same distance N. of Upsala. With the former city it has been connected by railway since 1859, and with the latter and Stockholm since 1874. As the river at that place is divided into three channels, the town consists of four portions, communicating with each other by wooden bridges. In 1869 it was almost destroyed by fire, but it has been rebuilt, and may still be reckoned one of the prettiest, as it is certainly one of the busiest, of Swedish towns. The principal buildings are the castle, originally founded in the 16th century by King John III., but rebuilt since its destruction by fire in 1727; a beautiful council-house erected by Gustavus III., who held a diet in the town in 1792; a hospital, an exchange, and a freemason's lodge in the Gothic style. An orphan asylum, a gymnasium, removed to Gefle from Stockholm in 1668, and a public library may also be mentioned. Possessing an excellent harbour, and recently restored wharves to which large vessels have easy access, Gefle is the great port for the Dalecarlian district, and thus ranks in Sweden next to Stockholm and Gottenburg. It has about 100 ships of its own, and carries on a good trade in the export of timber, tar, flax, and linen, and in the import of grain, salt, coal, &c. The manufactures of the town include sailcloth and linen, tobacco, leather, iron wares, and machinery. In 1873 the population was 16,265.

GEIGER, ABRAHAM (1810–1874), one of the ablest leaders of the modern Jewish school of theology and criticism, was born at Frankfort-on-the-Main, May 24, 1810. After receiving from his father and uncle the elements of an ordinary rabbinical education, he was in his eleventh year sent to the gymnasium, whence in 1829 he passed to the university of Heidelberg, which he soon afterwards exchanged for that of Bonn. As a student he greatly distinguished himself both in philosophy and in philology, and at the close of his course wrote on the relations of Judaism and Mahometanism a prize-essay which was afterwards published, in 1833, under the title *Was hat Mohammed aus dem Judenthum aufgenommen?* In November 1832 he went to Wiesbaden as rabbi of the synagogue there, and, still pursuing the line of scientific study upon which he had entered during his undergraduate course, became in 1835 one of the most active promoters of the *Zeitschrift für Jüdische Theologie*, which appeared from 1835 to 1839, and again from 1842 to 1847. In 1838 he removed to Breslau, where he continued to reside for the next twenty-five years, and where he wrote some of his most important works, including his *Lehr- und Lesebuch zur Sprache der Mischna* (1845), his *Studien* from Maimonides (1850), his translation into German of the poems of Juda ha-Levi (Abu'l Hassan) in 1851, and the *Urschrift und Uebersetzungen der Bibel in ihrer Abhängigkeit von der innern Entwickelung des Judenthums* (1857). The last-named work especially attracted much attention at the time of its appearance, and may be said to have marked a new departure in the methode of studying the records of Judaism. In 1863 Geiger became head of the synagogue of his native town, whence he removed in 1870 to Berlin, where, in addition to his duties as chief rabbi, he took the principal charge of the newly established seminary for Jewish science. The *Urschrift* was followed by a more exhaustive handling of one of its topics in *Die Sadducäer und Pharisäer* (1863), and by a more thoroughgoing application of its leading principles in an elaborate history of Judaism (*Das Judenthum u. seine Geschichte*) in 1865–71. Geiger also contributed frequently on Hebrew, Samaritan, and Syriac subjects to the *Zeitschrift der deutschen morgenländischen Gesellschaft*, and from 1862 until his death (which occurred on the 23d of October 1874) he was editor of a periodical entitled *Jüdische Zeitschrift für Wissenschaft und Leben*. He also published a Jewish prayer-book (*Israelitisches Gebetbuch*) which is well known in Germany, besides a variety of minor monographs on historical and literary subjects connected with the fortunes of his people. An *Allgemeine Einleitung* and five volumes of *Nachgelassene Schriften* were edited by his son L. Geiger in 1875.

GEIJER, Erik Gustaf (1783–1847), Sweden's greatest historian, was born at Ransäter in Värmland, January 12, 1783, of a family that had immigrated from Austria in the time of Gustavus Adolphus. At sixteen he left Carlstad gymnasium for the university of Upsala, where in 1803 he carried off the Swedish Academy's great prize for an *Äreminne öfver Riksförståndaren Sten Sture*. He graduated in 1806, and in 1810 returned from a year's residence in England to become "docent" in his university. Soon afterwards he accepted a post in the public record office at Stockholm, where, with eleven friends, he founded the "Gothic Society," to whose organ *Iduna* he contributed a number of prose essays and the songs *Manhem*, *Vikingen*, *Den siste kampen*, *Den siste skalden*, *Odalbonden*, *Kolargossen*, and others, whose simplicity and earnestness, warm feeling, and strong patriotic spirit are dearer to his nation for the fine melodies to which he set them. About the same time he issued a volume of hymns (1812), of which several are inserted in the Swedish Psalter. Geijer's lyric muse was soon after silenced by his call to be assistant to Fant, professor of history of Upsala (1815), whom he succeeded in that chair in 1817. In 1824 he was elected to the Swedish Academy. A single volume of a great projected work, *Svea Rikes Häfder*, itself a masterly critical examination of the sources of Sweden's legendary history, appeared in 1825. Geijer's researches in its preparation had severely strained his health, and he went the same year on a tour through Denmark and part of Germany, his impressions from which are recorded in his *Minnen* (1834). In 1832–36 he published three volumes of his *Svenska folkets historia*, a clear view of the political and social development of Sweden down to the close of Queen Christina's reign. The acute critical insight, just thought, and finished historical art of these two incomplete works of Geijer entitle him to the first place among Swedish historians. His chief other historical and political writings are his *Kort teckning af Sveriges tillstånd och af de fornämste handlande personer under tiden från Karl XII.'s död till Gustaf III.'s anträde af regjeringen* (Stockh. 1838), and *Feodalism och republikanism, ett bidrag till Samhällsförfattningens historia* (1844), which led to a controversy with the historian Fryxell regarding the part played in history by the Swedish aristocracy. Geijer also edited, with the aid of Schröder, a continuation of Fant's *Scriptores svecicarum medii ævi* (1818–25), and, by himself, Thorild's *Samlade skrifter* (1819–25), and *Konung Gustaf III.'s efterlemnade Papper* (3 vols. 1843–45). Geijer's academic lectures, of which the last three, published in 1845, under the title *Om vår tids inre samhällsforhållanden, i synnerhet med afseende på Fäderneslandet*, involved him in another controversy with Fryxell, exercised a great influence over his students, who especially testified to their attachment after the failure of the prosecution for alleged anti-Trinitarian heresies in his *Thorild, tillika en philosophisk eller ophilosophisk bekännelse* (1820). A number of his extempore lectures, recovered from notes, were published by Ribbing in 1856. Failing health forced Geijer to resign his chair in 1846, after which he removed to Stockholm for the purpose of completing his *Svenska folkets historia*, and died there 23d April 1847. His *Samlade skrifter* (13 vols. 1849-55; new ed. 1873–75) include a large number of philosophical and political essays contributed to reviews, particularly to *Literaturbladet* (1838–39), a periodical edited by himself, which attracted great attention in its day by its pronounced liberal views on public questions, a striking contrast to those he had defended in 1828–30, when, as again in 1840–41, he represented Upsala university in the Swedish diet.

Geijer's style is strong and manly. His genius bursts out in sudden flashes that light up the dark corners of history. A few strokes, and a personality stands before us instinct with life. His language is at once the scholar's and the poet's; with his profoundest thought there beats in unison the warmest, the noblest, the most patriotic heart. Geijer came to the writing of history fresh from researches in the whole field of Scandinavian antiquity, researches whose first-fruits are garnered in numerous articles in *Iduna*, and his masterly treatise *Om den gamla nordiska folkvisan*, prefixed to the collection of *Svenska folkvisor* which he edited with A. A. Afzelius (3 vols. 1814–16). The development of freedom is the idea that gives unity to all his historical writings. This idea is not subjective; he traces it in the darkest annals of his country. Sweden, he repeats, is the only European land that has not been trod by foreign armies, that has never accepted the yoke of serfdom. There, on the whole, the king has ever been the people's faithfullest ally, and all his great designs for the country's external and internal gain have been carried out "by the help of God and Sweden." Throughout life Geijer was what he professed to be, a seeker; and to no philosophic system did he yield absolute allegiance. Yet his writings mark a new era in Swedish history, the rise of a "critical school" whose aim is to draw the truth without distortion, and present reality without a foil.

For Geijer's biography, see his own *Minnen* (1834), which contains copious extracts from his letters and diaries; Malmström, *Minnestal öfver E. G. Geijer*, addressed to the Upsala students, June 6, 1848, and printed among his *Tal och esthetiska afhandlingar* (1868), and *Grunddragen af Svenska vitterhetens häfdar* (1866–68); and S. A. Hollander, *Minne af E. G. Geijer* (1869).

GEIKIE, Walter (1795–1837), a Scotch subject-painter, was born at Edinburgh, November 9, 1795. In his second year he was attacked by a nervous fever by which he permanently lost the faculty of hearing, but through the careful attention of his father he was enabled to obtain a good education. His artistic talent was first manifested, while he was still very young, by attempts to cut out representations of objects in paper, and to draw figures with chalk on floors and walls. Before he had the advantage of the instruction of a master, he had attained considerable proficiency in sketching both figures and landscapes from nature, and in 1812 he was admitted into the drawing academy of the board of Scotch manufactures, where he made very rapid progress in the use of the pencil. He first exhibited in 1815, and was elected an associate of the Royal Scottish Academy in 1831, and a fellow in 1834. He died on the 1st August 1837, and was interred in the Greyfriars Churchyard, Edinburgh. Owing to his want of feeling for colour Geikie was not a successful painter in oils, but he sketched in India ink with great truth and humour the scenes and characters of Scottish lower-class life in his native city. The characteristics he depicts are somewhat obvious and superficial, but his humour is never coarse, and he is surpassed by few in the power of representing the broadly ludicrous and the plain and homely aspects of humble life. A series of etchings which exhibit very high excellence were published by him in 1829–31, and a collection of eighty-one of these was republished posthumously in 1841, with a biographical introduction by Sir Thomas Dick Lauder, Bart.

GEILER, or GEYLER, von Kaisersberg Johann (1445–1510), one of the greatest of the popular preachers of the 15th century, was born at Schaffhausen, March 16, 1445, but from 1448 passed his childhood and youth at Kaisersberg in Upper Alsace, from which place his current designation is derived. In 1460 he entered the university of Freiburg in Baden, where, after graduation, he lectured for some time on the Sentences of Petrus Lombardus, the Commentaries of Alexander Halensis, and several of the works of Aristotle. A living interest in theological subjects, which had been awakened within him by the study of Gerson, led in 1471 to his removal to the university of Basel at that period a centre of attraction to some of the most earnest spirits of the time. Made a doctor of theology in 1475, he received a professorship at Freiburg in the following year; but his tastes began to incline him more strongly to the vocation of a preacher, while his fervour and eloquence soon led to his receiving numerous invitations to the larger towns. Ultimately he accepted in 1478 a call to the cathedral of Strasburg, where he continued to work with few interruptions until within a short time of his death, which occurred on the 10th of March 1510. The beautiful pulpit erected for him in 1481 in the nave of the cathedral, when the chapel of St Lawrence had proved too small, still bears witness to the popularity he enjoyed as a preacher in the immediate sphere of his labours, and the testimonies of Sebastian Brandt, Beatus Renanus, Reuchlin, Melanchthon, and others who survived him, abundantly show how powerful, how healthy, and how widespread had been the influence of his personal character. His sermons—bold, incisive, abounding in quaint illustrations, nor altogether wanting in instances of what would now be called bad taste—taken down as he spoke them, and circulated (sometimes without his knowledge or consent) by his friends, told perceptibly on the German thought as well as on the German speech of his time.

Among the many volumes published under his name only two appear to have had the benefit of his revision, namely, *Der Seelen Paradies von waren und volkomnen Tugenden*, and that entitled *Das irrig Schaf*. Of the rest, probably the best known is a series of lectures on his friend Seb. Brandt's well-known work the *Navicula* or *Speculum Fatuorum*, of which an edition was published at Strasburg in 1511 under the following title:—*Navicula sive speculum fatuorum præstantissimi sacrarum literarum doctoris Joannis Geiler Keysersbergii concionatoris Argentinensis in sermones juxta turmarum seriem divisa; suis figuris jam signita; atque a Jacobo Othero diligenter collecta. Compendiosa vitæ ejusdem descriptio per Beatum Rhenanum Selestatinum.*

See Von Ammon, *Geyler's Leben, Lehren, und Predigten* (1826); Stöber, *Essai Historique et Littéraire sur la Vie et les Sermons de Geiler* (1834); and C. Schmidt in Herzog's *Real-Encycl.*, iv. 714 (1855).

GEISSLER, Heinrich (1814–79), a distinguished practical physicist, was born at the village of Igelshieb in Saxe-Meiningen, Germany, where he was educated as a glass-blower. After many years spent in travelling from city to city in the exercise of his craft, he settled at Bonn, where he speedily gained a high reputation, not only for his surpassing skill and ingenuity of conception in the fabrication of physical apparatus, but for his comprehensive knowledge, acquired chiefly in later life, of the natural sciences. With Plücker, in 1852, by means of an ingeniously contrived instrument, in which mercury was made to compensate for the expansion of the glass, he ascertained the maximum density of water to be at 3·8° C. He also determined the coefficient of expansion for ice between $-24°$ and $-7°$, and for water freezing at 0°. In 1869, in conjunction with Vogelsang, he proved the existence of liquid carbon dioxide in cavities in quartz and topaz, and later he obtained amorphous from ordinary phosphorus by means of the electric current. He is best known as the inventor of the sealed glass tubes which bear his name, by means of which are exhibited the phenomena accompanying the discharge of electricity through highly rarefied vapours and gases (see Electricity, vol. viii. p. 64). Among other apparatus contrived by him are his vaporimeter, mercury air-pump, balances, normal thermometer, and areometer. From the university of Bonn, on the occasion of its jubilee, he received the honorary degree of doctor of philosophy. He died on the 24th of January 1879, in the sixty-fifth year of his age. See A. W. Hofmann, *Ber. d. deut. chem. Ges.*, 1879, p. 148.

GELA, an ancient city on the south coast of Sicily, on a river of the same name, near the site of the modern Terranuova between Girgenti and Camerina. Founded by a joint colony of Cretans and Rhodians (the latter mainly from the city of Lindus), it soon rose to wealth and power, and by 582 B.C. it was able to become the mother-city of Agrigentum, by which it was however destined before long to be surpassed. The most important among its rulers were the following:—Cleander, who subverted the oligarchy and made himself despot (505–498 B.C.); Hippocrates, his brother, who raised Gela to its highest pitch of eminence (498–491 B.C.); Gelon, who immediately succeeded Hippocrates, and rapidly pursued the same career of aggrandizement till in 485 B.C. he got possession of Syracuse, and gave the first blow to his native city by removing the seat of government to his new conquest; and finally Hiero, the brother of Gelon, who succeeded to the sovereignty in 478 B.C. The decadent Gela was laid waste by Phalaris of Agrigentum, and in the time of Strabo it was nothing more than a heap of ruins. Æschylus died at Gela in 456 B.C.; and it was the birthplace of Apollodorus, a comic poet of note.

GELASIUS, the name of two popes.

Gelasius I. succeeded Felix III. in 492, and confirmed the estrangement between the Eastern and Western Churches by insisting on the removal of the name of Acacius, bishop of Constantinople, from the diptychs. He was also the first decidedly to assert the supremacy of the papal over the imperial power, and the superiority of the pope to the general councils. He is the author of *De duabus in Christo naturis adversus Eutychen et Nestorium.* Five of his letters have also come down to us, and he is most probably the author of *Liber Sacrementorum*, published at Rome in 1680; but the so-called *Decretum Gelasii de libris recipiendis et non recipiendis* is evidently a forgery. Gelasius died in 496, and was canonized, his day being the 18th November.

Gelasius II. (Giovanni da Gaeta) was of noble descent, and was born at Gaeta about 1050. He received his theological education in the abbey of Monte Casino, and afterwards held the office of chancellor under Urban II., and of cardinal-deacon under Pascal II. On the death of Pascal II. he was elected pope by the cardinals, 18th January 1118, and when his person was seized by Cencius Frangipani, a partisan of the emperor Henry V., he was almost immediately set at liberty through the general uprising of the people in his behalf. The sudden appearance of the emperor, however, compelled him to leave Rome for Gaeta, and the imperial party chose an anti-pope, Burdinus, archbishop of Braga, under the name of Gregory VIII. Gelasius, at a council held at Capua, fulminated bulls of excommunication against his ecclesiastical rival and the emperor; and under the protection of the Norman princes he was able to return to Rome, where he stayed for a time in partial concealment, but having barely escaped capture by the Frangipani while celebrating mass in the church of St Praxede, he left the city, and after wandering through various parts of Italy and France died in the abbey of Clugny, January 19, 1119.

GELATIN. When intercellular connective tissue, as met with in skin, tendons, ligaments, and the fasciæ of the muscles, of which it forms the basis, is treated with water, preferably hot, or in presence of dilute acids, for some time, a solution is obtained which in cooling solidifies to a jelly. The dissolved substance bears the name of *Gelatin* or *Glutin*.

The same substance is obtained when the matrix of bones is submitted to similar treatment, after previous removal of the lime salts by means of mineral acids. Again, when unossified cartilage, as for instance the bone-cartilages of the vertebrate fœtus, is treated with water or dilute acids, a solution is obtained which also gelatinizes on cooling. The coagulation in this case, however, is due, not to gelatin, but to a closely allied substance called chondrin. At one time it was supposed that in each of these three cases the gelatinizing materials obtained were formed by the hydration or by a physical metamorphosis of a different substance pre-existing in the respective tissues, to which the names *collagen*, *ossein*, and *chondrogen* were given respectively—the two former yielding gelatin, and the last chondrin.

Further experiments have made it more probable that gelatin and chondrin do not differ essentially from their parent tissues, analyses of tendons and of gelatin or isinglass (a very fine form of gelatin obtainable from the sturgeon) agreeing within the range of experimental error. At the same time, as Foster observes in the case of chondrin, the fact that its extraction from cartilage requires an amount of boiling with water, much more than would be necessary to dissolve the same amount of dried product, points rather the other way. Most probably the change which occurs is of a purely physical character.

True gelatigenous tissue occurs in all mature vertebrates, with the single exception, according to Hoppe-Seyler, of that in other respects anomalous vertebrate, *Amphioxus lanceolatus.* In the embryo it does not appear till late in fœtal life, chondrin being found instead; and the change which brings gelatin into the place of chondrin is effected, not by a metamorphosis of the latter, but by its removal, and the independent formation of gelatin. The tissue in question was believed to be peculiar to *Vertebrata* until Hoppe-Seyler discovered it in the bodies of *Octopus* and *Sepiola.* By boiling these cephalopoda with water he obtained large quantities of gelatin free from chondrin, but in an extension of his experiments to other invertebrates, as cockchafers and *Anodon* and *Unio*, no such tissue could be detected. Gelatin, as such, is not met with in any of the normal fluids of the body, but occurs in the blood in cases of *leukhœmia.*

Various qualities of impure gelatin are prepared on the large scale by boiling up the hides of oxen, skins of calves, and spongy parts of horns; from any of the crude gelatins the pure substance may be obtained by bleaching with sulphurous acid and steeping repeatedly in warm water, when in the state of soft jelly.

Pure gelatin is an amorphous, brittle, nearly transparent substance, faintly yellow, tasteless, and inodorous, neutral to vegetable colours, and unaltered by exposure to dry air. Submitted to analysis it exhibits an elementary composition agreeing closely with that of chondrin, containing in round numbers C 50, H 7, N 18, O + S 24 per cent.; whilst chondrin contains about 3 per cent. less nitrogen and more oxygen.

Nothing is known with any certainty as to its chemical constitution, or of the mode in which it is formed from albuminoids. Besides a similarity in elementary constituents, it exhibits in a general way a connexion with that large and important class of animal substances called *proteids*, being, like them, amorphous, soluble in acids and alkalies, and giving in solution a left-handed rotation of the plane of polarization. Nevertheless, the ordinary well-recognized reactions for proteids are but faintly observed in the case of gelatin, and the only substances which at once and freely precipitate it from solution are corrosive sublimate, strong alcohol, and tannic acid.

According to Wanklyn, gelatin is distinctly differentiated from such substances as *casein* and *albumin* by a marked difference in behaviour when treated successively with boiling potash and alkaline permanganate. All nitrogenous organic substances yield large quantities of ammonia when decomposed by boiling with these solutions; but whereas albuminoids give up their ammonia at two successive stages, one of which is achieved by the action of potash alone, the other on the subsequent addition of permanganate, gelatin yields the same amount after the action of permanganate alone, as the total obtainable by the successive actions of the two reagents. Now, as there appear to be good grounds for believing the molecule of albuminoids to contain one or more urea-residues, and as urea, and presumably therefore a urea-residue, would yield its ammonia to potash alone, Wanklyn concludes that gelatin differs in constitution from albuminoids by containing no urea. On the other hand, as Foster observes, the behaviour of gelatin as a food (see below), in diminishing the amount of fat used by an animal fed partly on it, as well as the quantity of nitrogen abstracted from other sources, is readily intelligible on the hypothesis that it splits into a urea and a fat moiety.

Although gelatin in a dry state is unalterable by exposure to air, its solution exhibits, like all the proteids, a remarkable tendency to putrefaction; but a characteristic feature of this process in the case of gelatin is that the solution assumes a transient acid reaction. The ultimate products of this decomposition are the same as are produced by prolonged boiling with acid (see below). It has been found that oxalic acid, over and above the action common to all dilute acids of preventing the solidification of gelatin solutions, has the further property of preventing in a large measure this tendency to putrefy when the gelatin is treated with hot solutions of this acid, and then freed from adhering acid by means of carbonate of lime. Gelatin so treated has been called *metagelatin.*

Strange to say, in spite of the marked tendency of gelatin solutions to develop ferment-organisms, and undergo putrefaction, the stability of the substance in the dry state is such that it has even been used, and with some success, as a means of preserving perishable foods. The process, invented by Dr Campbell Morfit, consists in impregnating the foods with gelatin, and then drying them till about 10 per cent. or less of water is present. Milk gelatinized in this way is superior in several respects to the products of the ordinary condensation process, more especially in the retention of a much larger proportion of albuminoids.

Gelatin has a marked affinity for water, abstracting it from admixture with alcohol, for example. Solid gelatin steeped for some hours in water absorbs a certain amount and swells up, in which condition a gentle heat, as that of the water-bath, serves to convert it into a liquid; or this may be readily produced by the addition of a trace of alkali or mineral acid, or by strong acetic acid. In the last case, however, or if we use the mineral acids in a more concentrated form, the solution obtained has lost its power of solidifying, though not that of acting as a glue. By prolonged boiling of strong aqueous solutions at a high, or of weak solutions at a lower temperature, the characteristic properties of gelatin are impaired and ultimately destroyed. After this treatment it acts less powerfully as a glue, loses its tendency to solidify, and becomes increasingly soluble in cold water; nevertheless the solutions yield on precipitation with alcohol a substance identical in composition with gelatin.

By prolonged boiling in contact with hydrolytic agents, such as sulphuric acid or caustic alkali, it yields quantities of *leucin* and *glycocoll* (so-called "sugar of gelatin," this being the method by which glycocoll was first prepared), but no *tyrosin.* In this last respect it agrees with its near allies, chondrin and elastin, and differs from the great body of proteids, the characteristic solid products of the decomposition of which are leucin and tyrosin. At the same time the formation of glycocoll differentiates it from chondrin, from which, moreover, it can be readily distinguished by its non-precipitability by acetate of lead.

When it is mixed with copper sulphate a bright green liquid is formed, from which the copper cannot be thrown down free of organic matter. Addition of potash to the liquid merely changes the colour from green to violet, which by boiling is further transformed into a pale red, but without any precipitation of hydrate. Hence the inapplicability of Trommer's sugar test in presence of gelatin, the cuprous oxide being soluble in gelatin solutions.

Treated with strong oxidizing agents, such as a mixture of sulphuric acid and bichromate of potash, or binoxide of manganese, it exhibits a close resemblance in behaviour to casein, formic and valerianic acids being the principal products, along with a small quantity of benzoic aldehyde. When solution of gelatin is mixed with chromate of potash alone, it forms a medium very sensitive to light, which converts it into an insoluble yellow mass.

As bones are capable of yielding one-third of their weight of solid gelatin, it follows that, if gelatin had a value equivalent to albuminoids, the bones of an animal would contain one-fifth of the total nutritive material in its body. Accordingly, at a time when gelatin was in high esteem for its food-value, recourse was had largely to this source, more especially in France, for a cheap nutritive soup for soldiers, pauper establishments, and hospitals. To prepare such a soup the bones may be either simply boiled in water under pressure, as in a Papin's digester, or without pressure, or they may be previously freed from salts of calcium by treatment with dilute hydrochloric acid. On the large scale the crushed bones are submitted to the combined action of steam at high pressure and a current of water percolating through the fragments. The bones, preferably in a fresh condition, or preserved by thorough drying or by antiseptic agents such as brine, are crushed by passing them between solid iron cylinders grooved longitudinally and kept revolving. They are then packed into a cylindrical cage, which can be lowered into a cylindrical jacket of rather larger diameter than itself, the whole closing with a well-fitting lid. A pipe for the entrance of water, regulated by a stopcock, projects from the top of the outer cylinder, and is connected before the lid is put on with an adjustable nozzle, through which the water trickles down among the caged bones. Another pipe is connected with the bottom of the apparatus for the passage of high-pressure steam. The gelatin solution may be removed at intervals by means of a stopcock at the bottom. The quantity of water percolating through the bones is carefully regulated in accordance with the varying pressure of the steam, so as to produce a soup of nearly uniform consistence.

As to the nutritive value of such a soup very different opinions have been entertained at different times. It was at the time of the first French Revolution, when the question of the improvement of the diet of soldiers and people was much discussed, that attention began to be directed to gelatin as a cheap and useful food; and at that time such men as Proust and D'Arcet were trying improved methods of extracting it from bone. The discovery of nitrogen as a constituent of foods generally led to its being regarded as the special criterion of food-value, and, as this element was found to exist in large proportion in gelatin, the percentage of gelatin extractable from any substance was held as determining its worth as food.

In 1802 a commission appointed by the Academy to investigate the question reported that, though it might to a certain extent replace flesh in soups, yet it could not be taken as the measure of food-value. Meanwhile experiments on men and dogs, especially by Donné, Gannal, Edwards, and Balzac, along with the results of hospital rations at St Antoine and St Louis, showed the impossibility of feeding upon gelatin alone, and in general its unsatisfactory character as a food. Accordingly, a second commission was appointed by the Academy in 1841, who reported very strongly against the use of gelatin at all as an article of diet, alleging that, besides being valueless itself, it actually diminishes the value of otherwise nutritious food; but this latter part of the indictment was overturned by the Netherlands' commission (*Compt. Rend.*, 1844). It ended by the Academy in 1850 declaring that gelatin was positively injurious to the digestive organs; and the natural result of this extreme reaction was of course a complete cessation of its use as food.

In Germany, Liebig had declared, in his *Thierchemie* (1843), that gelatin, being a product of the decomposition of albumen, could not take the place of albumen as food, though it might be conceived to be useful for the growth of gelatinous tissue. Boussingault's experiments on ducks (*Ann. Chem. Phys.*, 1846) showed that, contrary to what should happen if the report of the French Academy were true, gelatin did not pass unaltered into their fæces, but that a large increase of uric acid was found in their urine, a result which was confirmed by Frerichs and Bischoff, who found in the urine of dogs fed on gelatin large amounts of urea—uric acid in birds and urea in mammals being the characteristic forms in which nitrogen is eliminated from the system of these animals. The conclusion they arrived at was that the use of gelatin as a food was limited to its power of undergoing decomposition in the body, like the carbohydrates, to yield heat, but that it cannot replace the other nitrogenous constituents of the body. In 1853 Dr Donders of Utrecht published a treatise on foods, in which he dealt with gelatin, and expressed opinions that have pretty much held their ground since, and only been confirmed in detail by subsequent investigators. Large quantities of gelatin, he says, are detrimental to digestion. In moderate quantity it gets decomposed in the body, and acts as a food probably by diminishing the otherwise necessary amount of albumen, the sole use of which, he remarks, is not merely to form tissues. In 1860 Bischoff and Voit published the result of their experiments on the subject, which completely established the fact that gelatin can take the place of albumen to a limited extent, in a way that fat cannot, so that the body-weight maintains itself on a smaller supply of albumen and that gelatin has a function therefore of a higher character than a mere heat-producer like starch and sugar. In a more recent memoir by Voit, from which the previous historical sketch is mostly borrowed (*Zeitschrift für Biologie*, viii., 1872), the results of an extensive series of careful experiments are given, in which the same conclusion comes out. He finds, moreover, that the saving of albumen is even more marked when a moderate amount of fat accompanies the gelatin, but that no combination of fat and gelatin can replace albumen or prevent the animal from losing flesh; but, on the contrary, when a dog was fed on equal parts of gelatin and fat it lost more flesh than when fed on gelatin alone. Fed on gelatin alone, it after a time evinced such a repugnance to the food that it would rather starve than feed; and, if it was induced to eat, vomiting and diarrhœa were the results. The time which gelatin takes for its complete metamorphosis in the body is far less than in the case of albumen, never exceeding 24 hours, in the course of which time all its nitrogen may be found in the urine and fæces.

A parallel series of experiments to determine how far gelatin could replace fats or carbohydrates in food showed that, though it could not be substituted for them to any large extent, it does somewhat diminish the amount of fat used up. As Voit puts it at the end of his paper, gelatin cannot, any more than fats or carbohydrates, take the place of that moiety of albumen which he calls the organic albumen,—the part which goes to build the organs and tissues; it cannot produce new blood-corpuscles to replace those that are worn out, or form muscles or any tissues, not even the gelatigenous. What it is capable of doing is to act as a substitute to some extent for that other and far larger part of the albumen of food which, never at any time forming part of any organ, circulates in the blood, and is carried to all the tissues, undergoing continual metamorphoses.

A later series of experiments by Etzinger, a pupil of Voit, was undertaken in order to elucidate the action of the digestive fluids on gelatin or gelatigenous tissue. Direct experiments showed that these substances are scarcely altered by prolonged contact with a dilute (0·3 per cent.) solution of hydrochloric acid at the ordinary temperature of the body. But when gelatin or tissues yielding it, such as *ligamentum nuchæ*, tendons, and bones were treated at the same temperature with an artificial gastric juice made by acidifying with acid of the above strength glycerin extract of pigs' stomach, a large quantity of these substances speedily disappeared to form a solution which did not gelatinize. The solution thus obtained exhibits physical and chemical characters so analogous to those of the peptones formed by a similar process from albuminoids that it has been called by some authors *gelatin-peptone*.

In a quite recent research by Hofmeister (*Zeitschrift für Physiol. Chem.*, ii. [5] 299, 1878) an attempt has been made to study the product formed in this digestion transformation. Taking the soluble gelatin obtained by prolonged boiling of gelatin in water to be the same material as is produced by the action of gastric juice, the author found that from the solutions so obtained two distinct substances could be separated, one precipitable by perchloride of platinum, which he calls *semiglutin*, and the other not so precipitable, and also more soluble in alcohol, which he calls *hemicollin*. Semiglutin forms definite salts with platinum and copper, analyses of which agree pretty well with the formula $C_{55}H_{85}N_{17}O_{22}$ as the simplest expression for the substance. Similarly the copper-salt of hemicollin gave results indicating for hemicollin a formula $C_{47}H_{70}N_{14}O_{19}$. Both of these substances yield leucin and glycocoll when treated by boiling with hydrochloric acid and stannous chloride. Further, this author states that, according to his analyses, collagen differs from gelatin by one molecule of water, and from the sum of the molecules of semiglutin and hemicollin by three molecules of water, so that a probable empirical formula for gelatin would be $C_{102}H_{151}N_{31}O_{39}$, agreeing pretty fairly with the percentage numbers given in an earlier part of this article.

See Hoppe-Seyler, *Medicinisch-Chemische Untersuchungen*, 1866 and 1871, and his *Physiologische Chemie*, just being published; Gmelin's *Handbook*, vol. xviii., 1871; Watts's *Dictionary of Chemistry*, vol. ii. For the digestion of gelatin, see Carl Voit, *Zeitschrift für Biologie*, viii. 297, 1872; Etzinger, same work, x. 84, 1874; and for constitution of collagen, Hofmeister, *Zeitsch. für Physiol. Chemie*, ii. [5] 299, 1878. (D. C. R.)

Industrial Relations of Gelatin.

Glue.—Glue is a form of gelatin, which, on account of its impure condition, is employed only as an adhesive medium for wood, leather, paper, and like substances. There is, however, no absolute distinction between glue and gelatin, as they merge into each other by imperceptible degrees; and although the dark-coloured varieties of gelatin which are known as ordinary glue are in no case treated as food, yet for several purposes the fine transparent kinds, prepared chiefly for culinary use, are employed also as adhesive agents. Neither again, except in respect of its source, is there any chemical or physical distinction between these two substances and isinglass or fish glue, and therefore the preparation and industrial applications of these three varieties of commercial gelatin—glue, gelatin, and isinglass—will be here noticed.

The gelatin-yielding substances in the animal kingdom are very numerous, comprising the skins of all animals, tendons, intestines, bladders and fish sounds, bones, horns, and hoofs. Chondrin, the substance yielded by cartilaginous tissue, which is simply an impure variety of gelatin (see above), has greatly inferior power of adhesion. In the preparation of ordinary glue the materials used are the parings and cuttings of hides from tan-yards, the ears of oxen and sheep, the skins of rabbits, hares, cats, dogs, and other animals, the parings of tawed leather, parchment, and old gloves, and many other miscellaneous scraps of animal matter. Taking tan-yard refuse to be the principal material, it is first steeped for some weeks in a pit with lime water, and afterwards carefully dried and stored. The object of the lime steeping is to remove any blood and flesh which may be attached to the skin, and to form a lime soap with the fatty matter it contains. So prepared the "scrows" or glue pieces, as they are termed, may be kept a long time without undergoing change. Before being boiled, the glue pieces are thoroughly washed. They are then placed in hemp nets and introduced into an open boiler, which has a false bottom, and a tap by which liquid may be run off. The boiler is heated by direct firing, a series of boilers being arranged in the manner best fitted to obtain the greatest possible heating effect from one fire. As the boiling proceeds test quantities of liquid are from time to time examined and when a sample is found on cooling to form a stiff jelly, it is ready to draw off. Usually the first boiling occupies about eight hours, and when the liquid has been drawn off, more water is added and the boiling process repeated. In this way the gelatinous matter is only exhausted after six separate boilings, occupying about two days, the last boiling yielding a darker-coloured glue than the first. It is essential that the boiling out of a charge should not be continued longer than is necessary for yielding a sufficiently stiff gelatinous solution, as it is found that, when the liquid is long exposed to a heat at or above boiling point, the gelatin loses its power of congealing. From the boiler the sufficiently concentrated solution is run to a tank or "setting back," in which a temperature sufficient to keep it fluid is maintained, and in this way any impurity is permitted to subside. The glue solution is then run into wooden troughs or coolers about 6 feet long by 2 feet broad and 1 foot deep, in which it sets to a firm jelly. When set, a little water is run over its surface, and with knives of suitable form it is detached from the sides and bottom, cut into uniform slices about an inch thick, and squares of these are placed on nets stretched between upright wooden frames or hurdles for drying. The drying operation, which requires very special care, is best done in the open air; the plastic masses must, however, be protected from rain. Frost and strong dry heat are equally injurious, and the best results are obtained in spring and autumn weather, when the glue dries in from twelve to eighteen days. When the pieces have become quite hard and sonorous, they are washed to remove dust from their surface, and to give them a glazed or polished appearance. A good quality of glue should be free from all specks and grit, and ought to have a uniform, light brownish-yellow, transparent appearance, and it should break with a glassy fracture. Steeped for some time in cold water it softens and swells up without dissolving, and when again dried it ought to resume its original properties. Under the influence of heat it entirely dissolves in water, forming a thin syrupy fluid with a not disagreeable smell. The adhesiveness of different qualities of glue, on which quality its value depends, differs considerably; and there are several methods of measuring the comparative value of commercial samples, the most reliable of which are based on actual experiment. Glue is also made from bones by first boiling them to remove the fatty matter they contain, and then treating them with strong hydrochloric acid till they become quite soft and translucent. In this condition, after they are washed and the acid neutralized, they are enclosed in a covered vessel and submitted to the action of steam, by which a concentrated gelatinous solution is first obtained. At a subsequent stage the whole mass is boiled by direct heat, and a further quantity of glue is so procured. The glue yielded by bones has a milky hue, owing to the phosphate of lime it carries with it.

Commercial Gelatin.—Gelatin, as a commercial product, is prepared in a manner similar to that followed in the manufacture of glue; but the materials used are selected with great attention to purity, and the various operations are carried out with the most scrupulous care and cleanlines. In the manufacture of the well-known sparkling gelatin of Messrs Cox of Gorgie, near Edinburgh, the following is the process followed, according to their patent obtained in 1844. The shoulders and cheeks of ox-hides are preferred, but other parts may be used. The hide and skin pieces are cleansed in water, cut in small pieces by a machine, and reduced to pulp in a pulp mill. The pulp is pressed between rollers, mixed with water, and then subjected to heat varying from 150° to 212° F., whereby gelatin is produced. When a very pure quality is required, liquid gelatin is mixed with a small quantity of ox blood at a temperature not exceeding 160° or 170°, and further heated. The albumen of the blood becomes coagulated, and rises as a scum; the heat is then withdrawn, after which the scum is removed and the purer liquor allowed to settle, and afterwards it is run into coolers to congeal and dry. The gelatin is evaporated *in vacuo* to avoid the injury caused by long subjection to heat; but it may also be dried on a steam-heated surface. In Nelson's process the gelatin is extracted by steam heat from hide pieces which have been submitted to the bleaching action of sulphurous acid. The strained and purified product is spread in a thin layer on a marble slab till it partly solidifies, when it is cut up and washed to free it from all traces of acid. It is again redissolved at the lowest possible temperature, then resolidified and dried in thin sheets on nets. Heuze of Berlin prepares a pure transparent gelatin, having a fine meaty flavour, from very impure materials, by intimately mixing with the hot solution of impure dark-coloured gelatinous material a mixture of wood charcoal and animal charcoal, leaving the whole together for some hours, then redissolving and straining off the clarified gelatin.

Isinglass.—Isinglass or fish glue, in its raw state, is the swimming-bladder or sound of various species of fish. The sounds undergo no other preparation than careful drying, but in the drying they are variously treated and made up, so that the isinglass comes into commerce under the names of "leaf," "staple," "book," "pipe," "lump," "honeycomb," and other designations, according to its form. The finest isinglass, which comes from Russia, is prepared by cutting open the sounds, steeping them in water till the outer membrane separates from the inner, then washing the latter and exposing it to dry in the air. Russian isinglass is obtained from several species of sturgeon (*Acipenser*), found in the Volga and other tributaries of the Caspian Sea, in the Black Sea, and in the Arctic Ocean. Brazilian isinglass, obtained from Brazil and Guiana, is the produce of a large fish, *Silurus parkerii*, and probably some other species; and Manila and East Indian isinglass are yielded by species of fish not yet satisfactorily determined. The sounds of the common cod, the hake, and other *Gadidæ* are also used as a kind of isinglass. The principal uses to which isinglass is applied are for jellies and confections, and as a clarifying or filtering medium for wine, beer, and other liquids. When used for culinary and confectionery purposes, isinglass is rolled into thin sheets and cut into fine shreds to facilitate its solution. For clarifying liquids its fibrous structure is of great value, as it forms a fine network in the liquid in which it is disseminated, and thereby mechanically carries down all the minute particles which render the liquid thick and turbid. Isinglass dissolved in strong acetic acid forms a powerful cement, much used for repairing glass, pottery, and similar small objects.

Uses of Gelatin.—The gelatin derivable from bones enters very largely into human food, in the stock for soups, &c., and as prepared gelatin, "calves foot jelly," and isinglass. In addition to the uses already alluded to, gelatin has many other applications in the arts. It is employed as a sizing agent in paper-making, and by painters it is also used for sizing or priming, and for preparing tempera colours. Further, it is used in the preparation of elastic moulds of undercut work, and in the manufacture of inking rollers for printing. Gelatin treated with bichromate of potash, under the influence of light, undergoes a remarkable chemical and physical change, whereby it is rendered entirely inabsorbent of and insoluble by water. The change is due to the oxidizing effect of the bichromate; and the circumstance has given rise to the numerous so-called carbon-processes introduced into photography by Swan, Johnson, Woodbury, Albert, Edwards, and others, in all of which an image is produced in gelatin oxidized by chromium compounds. An insoluble glue may be prepared by adding to dissolved glue, just before using, a proportion of a solution of bichromate of potash, and such a preparation forms a useful waterproofing medium. Glue may be kept liquid at ordinary temperatures by the addition of concentrated acetic acid or of weak nitric acid. Dumoulin's liquid glue, which possesses powerful adhesive properties, is composed of glue in the proportion of 2 ℔ dissolved in 1 quart of water with 7 oz. of nitric acid (sp. gr. 1·335) added. Mouth or lip glue is prepared by adding ½ ℔ or thereby of sugar to each pound of dissolved glue. It forms solid but easily dissolved cakes, and as it can be sufficiently softened by the tongue, it is for many purposes extremely convenient. Transparent gelatin, brightly coloured by dyeing substances, and cast in excessively thin sheets, is largely used for ornamental wrappings for bon-bons, &c.

Various adhesive but non-gelatinous substances are, on account of their properties, known commercially as glue, and are used as substitutes for ordinary glue. Thus marine glue, employed in shipbuilding and for other purposes, is a compound of india-rubber and shell-lac dissolved in coal-tar naphtha. Glue substitutes are also prepared from the albuminoids casein and gluten, but they are not likely to become substances of any considerable commercial importance. (J. PA.)

GELDERLAND, GELDERN. See GUELDERLAND, GUELDERS.

GELÉE, CLAUDE. See CLAUDE OF LORRAINE.

GELL, SIR WILLIAM (1777–1836), classical scholar and antiquarian, was born at Hopton in Derbyshire in 1777. After the usual preliminary education, he entered Emmanuel College, Cambridge, taking his B.A. degree in 1798, and afterwards becoming a fellow. About the beginning of the century he was sent on a diplomatic mission to Greece; and on his return in 1803 he was knighted. In the following year he published his *Topography of Troy and its Vicinity, illustrated and explained by drawings and descriptions.* His *Geography and Antiquities of Ithaca* was published in 1807. In 1810 appeared *The Itinerary of Greece, with a Commentary on Pausanias and Strabo, and an account of monuments of antiquity existing in that country.* This was followed in 1816 by the *Itinerary of the Morea, being a description of the routes of that peninsula*, a new edition of which was published in 1823, under the title of *Narrative of a Journey in the Morea.* His best known work is *Pompeiana, or Observations on the Topography, Edifices, and Ornaments of Pompeii*, in which he was assisted by Mr J. P. Gandy. The first part of this was published in 1817–19, and was translated into French in 1828; the second part appeared in 1830–31. It was followed in 1834 by the *Topography of Rome and its Vicinity.* In Italy, whither he had retired on account of his health, he became acquainted with Queen Caroline, and his noble and disinterested behaviour during her trial exhibits his moral character in a very favourable light. The queen showed her sense of his co-operation in her defence by appointing him one of her chamberlains in 1820. He died at Naples in 1836. His drawings, representing a very large series of views of classical ruins and localities, and executed, if not with much artistic skill, yet with great detail and exactness, are now in the print room of the British Museum.

GELLERT, CHRISTIAN FÜRCHTEGOTT (1715–1769), German fabulist, hymn-writer, and moral philosopher, was born 4th July 1715 at Hainchen, in the Saxon Erzgebirge. He was educated at the university of Leipsic, where in 1751 he was appointed an extraordinary professor of philosophy, a position which he occupied till his death, 13th December 1769. He wrote a romance, *Leben der schwed. Gräfin von G . . .* (2 vols., Leipsic, 1746), of little value, and several pastorals and comedies of, if possible, even less. His best works were his *Fabeln und Erzählungen* and *Geistliche Oden und Lieder.* Both are marked by a simple and easy directness of style. The latter express the maxims of a liberal piety, and were received by Catholics and Protestants with equal favour. They are still widely popular in Germany. The best known is the hymn entitled "Die Ehre Gottes aus der Natur." Not a little of Gellert's fame is due to the time when he lived and wrote. The German literature of the period was dominated by the pedant Gottsched and his school. A band of high-spirited youths, of whom Gellert was one, resolved to free themselves from the conventional trammels of such dictators, and began that revolution which was finally consummated by Schiller and Goethe. Gellert's share in the attempt was enhanced by the excellence of his personal character, his gentle piety, and his singular knack of gaining the reverence and love of young people. Part of his influence was also doubtless attributable to his position as a professor, and to his widely popular lectures.

See Gellert's *Sämmtliche Werke* (first edition, 10 vols., Leipsic, 1769–74, last edition, Berlin, 1867). His *Sämmtliche Fabeln und Erzählungen* and his *Geistliche Oden und Lieder* have often been published separately; the latest editions being those of Leipsic, 1874, and Berlin, 1873. See translation by J. A. Murke, Gellert's *Fables and other Poems* (London, 1851). Lives of Gellert have been written by J. A. Cramer (Leipsic, 1774) and by Döring (2 vols., Leipsic, 1833).

GELLIUS, AULUS, author of the *Noctes Atticæ*, was born in the first half of the 2d century of the Christian era, most probably in Rome, and died about 180. Nothing is known of his personal history except from incidental notices in his own book. He studied grammar and rhetoric at Rome and philosophy at Athens, after which he returned to Rome, and held there a judicial office. His only work, the *Noctes Atticæ*, takes its name from having been begun during the long nights of a winter which he spent in Attica. He afterwards continued it at Rome. It is compiled out of an "Adversaria," or common-place book, in which he had jotted down everything of unusual interest that he heard in conversation or read in books, and it comprises notes on grammar, geometry, philosophy, history, and almost every other branch of knowledge. The work, which is utterly devoid of sequence or arrangement, is divided into twenty books. All these have come down to us except the eighth, of which nothing remains but the index. The *Noctes Atticæ* is valuable for the insight it affords into the nature of the society and pursuits of those times, and for the numerous excerpts it contains from the works of lost ancient authors.

The *editio princeps* of Aulus Gellius appeared at Rome in 1469, and was speedily followed by many others in various cities of Italy, especially Venice. The best editions are those of Gronovius (Leyden, 1706), Lion (Göttingen, 1824–1825), and Hertz (Leipsic, 1853). Aulus Gellius has been translated into English by Beloe (London, 1795); into French by the Abbé de Verteuil (Paris, 1776–89), and by Victor Verger (Paris, 1820–30); into German by Walterstern (Lemberg, 1785), and by Weiss, 2 vols. (Leipsic, 1875–76).

GELON, succeeded Hippocrates as tyrant of Gela in 491 B.C., and, by supporting the plebs of Syracuse in their quarrels against the aristocracy, became tyrant also of that city in 485 B.C. He used his power so discreetly that under him Syracuse attained an extraordinary degree of wealth and influence. The great event in Gelon's subsequent history was his defeat of the Carthaginians under Hamilcar at Himera, according to tradition on the same day that the Greeks defeated Xerxes at Salamis, 480 B.C., the result of his victory being that he obtained the lordship of the whole of Sicily. After Gelon had thus established his power, he made a show of resigning it; but his proposal was rejected by the multitude, and he reigned without opposition till his death 478 B.C. His memory was held in such respect that, 150 years after his death, when Timoleon was erasing from Sicily every vestige of the tyrants that had once reigned there, he spared the statues of Gelon. See SYRACUSE.

GELSEMIUM, a drug, consisting of the root of *Gelsemium* (or as sometimes less correctly called *Gelseminum*) *sempervirens*, a climbing shrub of the natural order *Loganiaceæ*, having a milky juice, opposite, lanceolate shining leaves, and axillary clusters of from one to five large, funnel-shaped, very fragrant yellow flowers, whose perfume has been compared to that of the wallflower. The fruit is composed of two separable jointed follicles, containing numerous flat-winged seeds. The stem often runs underground for a considerable distance, and indiscriminately with the root it is used in medicine. The plant is a native of the United States, growing on rich clay soil by the side of streams near the coast, from Virginia to the south of Florida. In the United States it is commonly known as the wild, yellow, or Carolina jessamine, although in no way related to the true jessamines, which belong to the *Oleaceæ*. It was first described in 1640 by John Parkinson, who grew it in his garden from seed sent by Tradescant from Virginia; at the present time it is but rarely seen, even in botanical gardens, in Great Britain.

The root, on analysis by Kollock in 1855, was found to contain an alkaloid (now called *Gelsemine* or *Gelsemia*), a dry acrid resin, $\frac{1}{2}$ per cent. of a volatile oil heavier than water, fatty resin, fixed oil, yellow colouring matter, gallic acid, starch, albumen, gum, pectic acid, extractive matter, lignin, and 3·17 per cent. of mineral matter, consisting chiefly of salts of potassium, calcium, magnesium, iron, and silica. The leaves and flowers were found to contain the same ingredients in less quantity. Eberle, who examined the root in 1869, states that the central woody portion of the root does not contain any alkaloid, and that therefore the bark is the physiologically active portion. In addition to the above, Wormley, in 1870, discovered in the root a crystalline substance named by him gelseminic acid, whose solution in alkalies exhibits a powerful blue fluorescence. It has, however, since been shown by Sonnenschein to be identical with æsculin, a crystalline glucoside found in the bark of the horse chesnut, *Æsculus Hippocastanum*. The active properties of gelsemium root have been proved by Wormley and Bartholow to depend upon the alkaloid *gelsemine* ($C_{11}H_{19}NO_2$), which in the pure state is a colourless, odourless solid, not yet obtained in a crystalline form, readily soluble in ether and chloroform, less so in alcohol, and very sparingly in water, except in the presence of hydrochloric acid, and having an intensely persistent bitter taste, perceptible in a solution containing only $\frac{1}{1000}$th part of it by weight.

The readiest and best test for gelsemine, detecting the smallest traces, appears to be the cherry-red colour developed when ceroso-ceric oxide is added to its solution in concentrated sulphuric acid. The dose of the alkaloid is from $\frac{1}{60}$th to $\frac{1}{20}$th of a grain; larger quantities are poisonous, $\frac{1}{8}$th of a grain having proved fatal in an hour and a half to a strong cat.

The pharmaceutical preparation known as gelsemin consists chiefly of the resin, combined with uncertain proportions of the other constituents of the root, and is prepared by precipitation with water from the strong tincture.

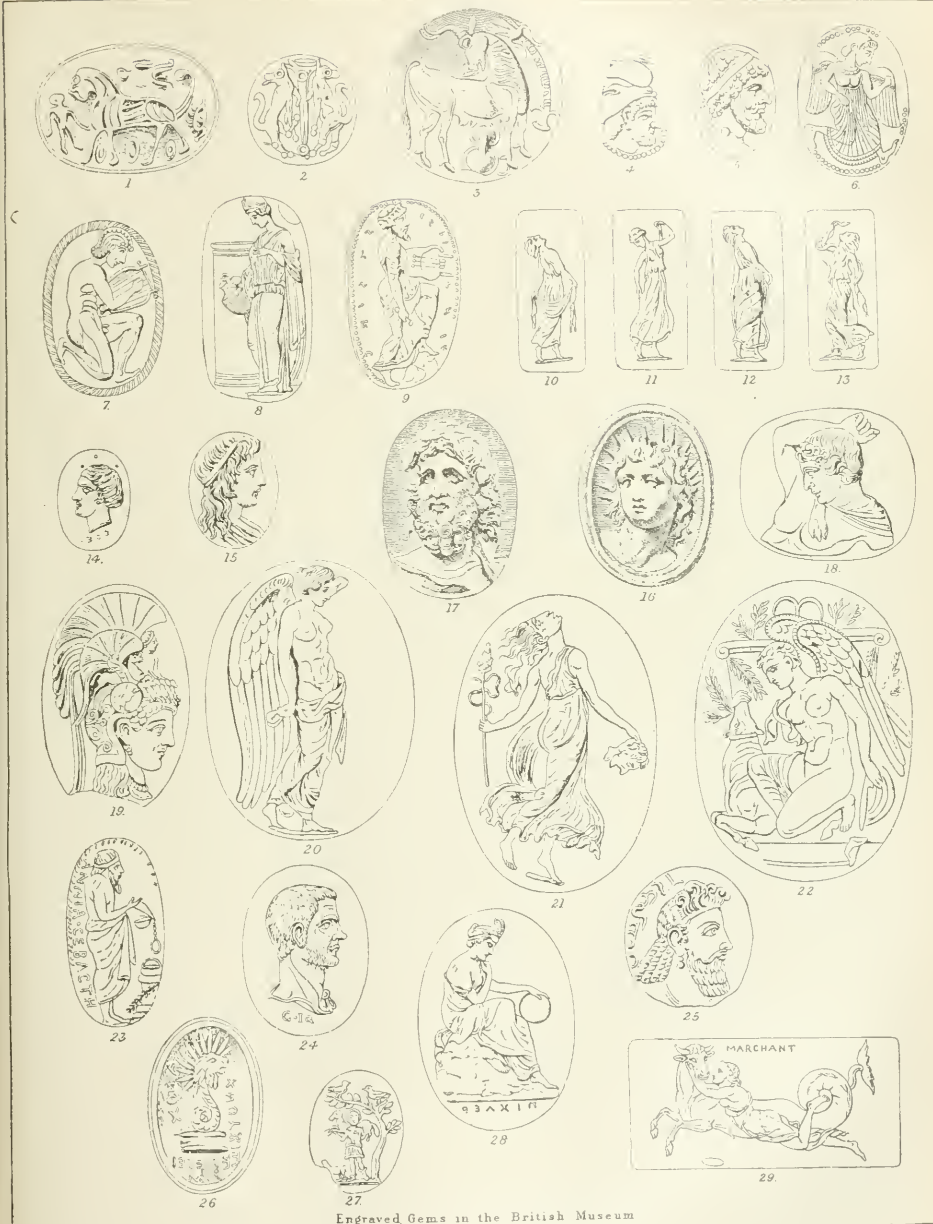
The medicinal properties of the root were discovered by accident, the infusion having been administered instead of that of some other root, with the result of curing the fever for which it was taken. It was then experimented upon by the American eclectic practitioners. In 1852 Professor W. Proctor called the attention of the medical profession to its valuable properties; and in 1864 it was placed on approval in the secondary list, and in 1873, so rapidly had it risen in favour, in the primary list of remedies of acknowledged value in the United States pharmacopœia. It has latterly attracted considerable attention in England as a remedy for certain forms of facial neuralgia, especially those arising from decayed teeth, or involving branches of the fifth nerve. In the United States it is more particularly valued for controlling nervous irritability in fevers of a malarial type, in which it is said to excel every other known agent. The physiological action of the drug has been carefully examined by Bartholow, Ott, and Ringer and Murrell, from whose investigations it appears that it has a paralysing action on the motor centres, affecting successively the third, fifth, and sixth nerves, its fatal action being due to its causing paralysis of the respiratory muscles, and thus producing death by asphyxia. In large doses it produces alarming symptoms, which occasionally terminate fatally. These appear to vary slightly in different cases, but the more prominent are pain in the forehead and in the eyeballs, giddiness, ptosis, a feeling of lightness in the tongue slurred pronunciation, laboured respiration, wide dilatation of the pupils, and impossibility of keeping an erect posture. The mind in most cases remains clear until shortly before death. The earliest and most prominent symptom of a fatal or dangerous dose is the drooping of the eyelids, which indicates the immediate administration of stimulants, for when the paralysis of the tongue which ensues extends to the epiglottis, deglutition becomes impossible, and the epiglottis is apt, unless the sufferer be placed in a forward position to flap back and close the windpipe. The antidotes which have been found the most successful are carbonate of ammonia, brandy, aromatic spirits of ammonia, and morphia. It has been found that death may be averted by keeping up artificial respiration until the poison is eliminated by the kidneys.

Ges.*, xi. 1182; Bentley and Trimen, *Med. Plants*, pt. xix. No. 181.

GEMINIANI, Francesco (*c.* 1680–1762), a celebrated violinist, born at Lucca about 1680. He received lessons in music from Alessandro Scarlatti, and studied the violin under Lunati, and afterwards under Corelli. In 1714 he arrived in London, where his performance and compositions attracted much attention. He was taken under the special protection of the earl of Essex. After visiting Paris and residing there for some time, he returned to England in 1755. In 1761 he went to Dublin, where a servant robbed him of a musical manuscript on which he had bestowed much time and labour. His vexation at this loss is said to have hastened his death, which took place at Dublin on 17th September 1762. He appears to have been a first-rate violinist, but most of his compositions are dry and deficient in melody. His *Art of Playing the Violin* is a good work of its kind, but his *Guida Armonica* is a miserable production. He published a number of solos for the violin, three sets of violin concertos, twelve violin trios, *The Art of Accompaniment on the Harpsichord, Organ, &c.*, *Lessons for the Harpsichord*, and some other works. His musical opinions had no foundation in truth or principle.

GEMISTUS, or PLETHO, Georgius, held high office under the Byzantine emperors during the first half of the 15th century, and derived his name, which signifies the Replete, from the extraordinary amount of his erudition. He is, however, chiefly memorable for having been the first person who introduced Plato to the Western world. This took place upon his visit to Florence in 1438, as one of the deputies from Constantinople on occasion of the general council. Cardinal Bessarion became his disciple; he produced a great impression upon Cosmo de' Medici; and though not himself making any very important contribution to the study of Plato, he effectually shook the exclusive domination which Aristotle had exercised over European thought for eight centuries. He promoted the union of the Greek and Latin Churches as far as possible, but his efforts in this direction bore no permanent fruit. He probably died before the capture of Constantinople. The most important of his published works are a treatise on the distinction between Plato and Aristotle as philosophers, and one on the religion of Zoroaster. In addition to these he compiled several volumes of excerpts from ancient authors, and wrote a number of works on geography, music, and other subjects, many of which still exist in MS. in various European libraries.

GEMS (ψῆφοι, gemmæ), engraved with designs, whether adapted for sealing (σφραγίς, sigillum, intaglio), or mainly for artistic effect (imagines ectypæ, cameo), exist in a very large number of undoubtedly genuine examples, extending from the mists of Babylonian antiquity to the decline of Roman civilization, and again starting with a new but unnatural impulse on the revival of art. Apart from workmanship they possess the charms of colour deep, rich, and varied, of material unequalled for its endurance, and of scarcity which in many instances has been enhanced by the strangeness of the lands whence they came, or the fortuity of their occurrence. These qualities united within the small compass of a gem were precisely such as were required in a seal as a thing of constant use, so inalienable in its possession as to become naturally a personal ornament and an attractive medium of artistic skill, no less than the centre of traditions or of religious and legendary associations. As regards the nations of classical antiquity all seals are classed as gems, though in many cases the material is not such as would strictly come under that heading. On the other hand, gems properly so called were not always seals. Many of the Babylonian cylinders could not have been so employed without great difficulty, and when Herodotus (i. 195) speaks of every Babylonian wearing a seal (σφρηγίς), it may have been in most cases no other than a talisman having an inherent power derived from the subject of its design, consisting perhaps mostly of figures of protecting deities. He adds that every Babylonian carried also a staff on which it was unlawful for him not to have the figure of an apple, a rose, a lily, an eagle, or something else, as his badge or ἐπίσημον, from which it may perhaps be inferred that having selected some such badge for his staff he would necessarily have the same for the seal with which he attested his name. But if that had been the case, then the great mass of existing cylinders could not have been seals in the ordinary sense. In Greece and Rome within historic times, gems were worn engraved with designs to show that the bearer was an adherent of a particular worship, the follower of a certain philosopher, or the attached subject of an emperor. It cannot be said that these gems may not have been used systematically as seals, but it is clear that they primarily served a different purpose. Again, when the sense of personal ornament naturally attaching to a seal increased, and the resources both of material and skill were enlarged, the process of engraving gems in cameo, that is, with the design in relief mostly in such stones as by their differently coloured layers could be made to present a variety of surfaces, came largely into fashion (see article Cameo, and figs. 18, 19 in Plate I.). As a rule these cameos are of a date subsequent to that of Alexander the Great; but there are exceptions in an Egyptian cameo in the Louvre, said to belong to the 12th dynasty, about 3000 B.C., and in some few Etruscan scarabs, which having designs in intaglio on the face have also reliefs engraved on the back, apparently in the same archaic manner of art as the intaglios. Such a scarab in carnelian was found at Orvieto in 1874 in a tomb along with vases dating from the beginning of the 5th century B.C., and it will be seen from the engraving of this gem (*Archäol. Zeit.*, 1877, pl. xi., fig. 3, compare figure of Siren on back of scarab engraved in Wieseler, *Denkmäler der alten Kunst*, No. 752) that, while the design on the face presents evidently the same subject which occurs on a scaraboid found in the treasury of Curium in Cyprus by General Cesnola (see his *Cyprus*, pl. xxxix., fig. 5, p. 381), the half-length figure of a Gorgon on the back seems to be the same in subject and treatment as a carnelian fragment, apparently cut from the back of a scaraboid, now in the British Museum. As further examples of the same rare form of cameo, the following scaraboids in the British Museum may be mentioned:—(1) a carnelian cut from back of a scaraboid, with head of Gorgon surrounded by wings; (2) carnelian scaraboid: Gorgon running to left, on face of gem an intaglio of Thetis giving armour to Achilles; (3) carnelian scaraboid:



Engraved Gems in the British Museum

Matt W. Webb del.t

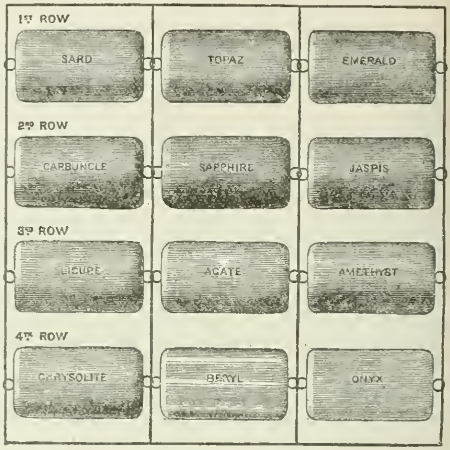
Eng.d by Leopold Lowenstam

head of negro in profile, on face an intaglio of a harp; (4) steatite scaraboid: head of Achelous, full face, with intaglio of citharist (Plate I., No. 13); (5) scaraboid in burnt carnelian: head of Achelous, full face, with intaglio of Ajax carrying body of Patroclus; and four porcelain scaraboids from Camirus, each with a negro's head in relief on the back.

In gem engraving the principal modern implement is a wheel or minute copper disc, driven in the manner of a lathe, and moistened with olive oil mixed with emery or diamond dust. There is no proof of its use among the ancients, but M. Soldi, a practical authority on the subject, believes (*Revue Arch.*, 1874, xxviii. p. 147) that it was known before the time of Pliny, whose expression *fervor terebrarum*, as applied to the cutting of very hard stones, would fittingly characterize the rapid movement of the wheel. At the same time these words, apparently the only ancient statement on the question, may equally refer to the motion of the drill, an instrument of constant use in antiquity, which in this case was employed to drive an iron tool fitted with a diamond point or splinter. In intaglios, when the larger spaces had been sunk with the drill, the design was worked out in detail by a tool with a diamond point, and finally polished, but not, it would appear, to the extent to which polishing is carried in modern work, for this reason, no doubt, that their finer tools left less of roughness to be smoothed away. Still a gem highly polished in the interior of the design need not be taken to be modern on that account, since it is known that many genuine ancient gems have been repolished in modern times, and since it is not known whether ancient engravers may not sometimes have resorted to excess of this process; while on the other hand an intaglio dim in the surface of its design is not necessarily antique, since modern engravers have observed this peculiarity, and have imitated it with a success which, were there no other suspicions, might escape detection. Except in the hardest stones, much of the ancient gem engraving seems to have been done by a simple copper tool duly moistened and supplied with emery (σμίρις or σμύρις, naxium). The Ethiopians in the time of Xerxes employed a flint instrument, if that is what Herodotus means (vii. 69) when he says that their arrows were tipped "not with iron but with a sharp stone, with which they also engrave their seals." With such a tool steatite could be easily engraved, and it should be remembered that among very early gems this material is of frequent occurrence, while in the later art of Greece and Rome it can scarcely be said to exist; and the inference is that, when processes had been invented to cut harder stones, the softer substances were discarded. Still it would not be correct to found more than a general argument as to the comparative ages of gems on the different degrees of resistance in the stones themselves, even when dealing with the works of one nationality, much less so in a review of ancient gems as a whole, for this reason, among others, that the decline of art is in technical matters often very like its infancy. It would be easy to show from published criticisms how certain classes of rude intaglios have been regarded now as the very earliest efforts of the art, now as debased; and at times it is difficult to choose between these judgments. In the present state of knowledge it may seem idle to inquire where the infancy of the art was passed. One thinks in Egypt, which otherwise is known for its intimate skill in working hard stones. Another says Assyria, which doubtless had a civilization as remote as that of Egypt, but has left no similar evidence of the mastery of obdurate substances. The architectural and the artistic remains of the two nations present this broad distinction, that they are of much harder material in the one case than in the other, whence it would be reasonable to expect that at least the invention of the pointed tools had proceeded from Egypt, though of course if the idea of engraving gems originated with soft stones and simple implements such as flints, that origin may well have been in Assyria. Possibly the marked difference in the shape of the gems peculiar to these two nations bespeaks little contact between them in this matter. The favourite shapes in Assyria were the cylinder pierced lengthways, and sometimes fitted with a swivel so as to be used as a seal, and the cone also pierced but not requiring a swivel, since the design was cut on its base. When inscribed, a cylinder generally states three things,—the name of the owner, his father's name, and the name of his protecting deity. But there are exceptions, as for example, a cylinder in the Bibliothèque at Paris inscribed, "Alchaloum, servant of Jehastukur," which from the Semitic form of name "Alchaloum" has been thought to have belonged to a Jewish captive in Babylon. A cylinder supposed to be the seal of Sennacherib, in the British Museum, is not inscribed. Another, purporting to be the seal of Igli, son of Uruck, the oldest king of Assyria, is rejected by M. Oppert as not having any such antiquity. An agate seal from Khorsabad reads, "Nipishi, of King Tiglath Pileser, king of Assyria, son of Haou Liklikhus, king of Assyria." But, as has already been said, many of the cylinders could not have been employed as seals without difficulty, and it appears to result from the most recent study of the designs on them that frequently their main function was to act as talismans in the system of magic generated among the Chaldæans. In what seems to be the oldest examples the design is sunk by a pointed tool pushed backward and forward in long straight lines. In the next stage round cavities are sunk here and there in the design by means of a drill, when greater depth is required, while the shallow parts are worked out with the pointed instrument. By practice in utilizing both methods the Assyrians reached whatever skill they could boast in this branch of art. The materials are hæmatite, jasper, calcedony, sard, basalt, agate, lapis lazuli, rock crystal, alabaster, porcelain, quartz, glazed clay. Mr King classes them under four periods, beginning as early as 2234 B.C.

In Egypt the favourite form of gem was a scarab (beetle), having a flat surface underneath, on which was engraved a hieroglyphic design. The common materials are green jasper and porcelain. From the soft nature of the porcelain, and from the strict adherence to the scarab shape, it may be inferred that they were used much less as seals than as a sort of badges or ornaments, and this is confirmed by the finding of large numbers of them in foreign countries, as at Camirus in Rhodes and in Etruria, where the hieroglyphics could not have been understood. No doubt it may be true that these specimens had been manufactured by Phœnicians for export to these countries merely as articles of ornament, but had the originals been strictly held by the Egyptians to be seals, it would have been the height of dishonesty in the Phœnicians to reproduce them in this way. In Egypt, however, the art of gem engraving was not confined altogether to scarabs, as may be seen among other interesting exceptions in the oblong intaglio of green jasper in the Louvre (*Gazette Archéol.*, 1878, p. 41) with a design on both sides, representing on the obverse, as known from the cartouche, Thothmes II. (1800 B.C.) slaying a lion, and on the reverse the same king drawing his bow against his enemies from a war chariot. In the Louvre also is an Egyptian gem, said to belong to the 12th dynasty, 3000 B.C. But uninteresting in themselves as are the scarabs of Egypt, they have this accidental importance in the history of gem engraving that they furnished the Phœnicians with a model which they first improved as regards the intaglio by a freer spirit of design, gathered partly from Egypt and partly from Assyria (see the Phœnician scarabs from Tharras in Sardinia and from Cyprus). The scarab thus improved they communicated to the Etruscans, under whose skilful hands it received often a degree of delicacy in the workmanship which has not been equalled in the gems of any other country. The best specimens are due to the influence of Greek art in the 6th century B.C. or somewhat later. The subjects engraved are Greek in origin, and the habit of inscribing the names of the subjects is an early Greek habit, but with this difference, that the Greeks would be correct in the naming, while the Etruscan artists are perhaps as often wrong as right. The name of Tydeus, for instance (TYTE), is assigned in one case to a figure scraping himself with a strigil, and in another to a fallen warrior, who otherwise would be identified as Capaneus. Again a figure washing his hair is called Peleus, and Achilles sulking becomes Theseus, to the exercise of much ingenuity in times past. With these and other examples it should no longer be necessary to cast about for an unusual form of the legend of the Seven against Thebes, when five only of their names are found beside five figures on what is the most celebrated of existing scarabs—a carnelian in the Berlin Museum (Winckelmann, *Alte Denkmäler*, No. 105). Another scarab of first importance is a banded onyx in Florence representing the Salii carrying their shields, inscribed *Angils* and *Alce*. For Etruscan scarabs see ETRURIA, vol. viii. p. 640.

While the Phœnicians have left actual specimens to show with what skill they could adopt the systems of gem engraving prevailing at their time in Egypt and Assyria, the Israelites, on the other hand, have left records to prove, if not their skill, at least the estimation in which they held engraved gems. "The sin of Judah is written with a pen of iron and with the point of a diamond" (Jerem. xvii. 1). To pledge his word Judah gave Tamar his signet, bracelets, and staff (Gen. xxviii. 18); whence, if this passage be compared with the frequent use of "seal" in a metaphorical sense in the Bible, and with the usage of the Babylonians already cited from Herodotus, it may be concluded that among the Israelites also every man of mark at least wore a signet. Their acquaintance with the use of seals in Egypt and Assyria is seen in the statement that Pharaoh gave Joseph his seal as a badge of investiture (Gen. xli. 42), and that the stone which closed the den of lions was sealed by Darius with his own signet and with the signet of his lords (Daniel vi. 17). Then as to the stones which were most prized, Ezekiel (xxviii. 13), speaking of the prince of Tyre, mentions the sardius, topaz, and diamond, the beryl, onyx, and jasper, the sapphire, emerald, and carbuncle, stones which again occur in that most memorable of records, the description of the breastplate of the high priest (Exodus xxviii. 16–21, and xxxix. 8). Twelve stones grouped in four rows, each with three specimens, may be arranged on a square, measuring a palm, not a span, so as to have the rows placed either vertically or horizontally. If they are to cover the whole square, then they must be cut in an oblong form, and if the names engraved on them are to run lengthwise, as is the manner of Assyrian cylinders, then the stones, to be legible, must be grouped in four horizontal rows of three each. There is in fact no reason to suppose that the gems of the breastplate were in any other form than that of cylinders such as abounded to the knowledge of the Israelites, with this possibility, however, that they may have been cut lengthways into half-cylinders like a fragmentary one of sard in the British Museum, which has been mounted in bronze, and, as a remarkable exception, has been set with three small precious stones now missing. It could not have been a seal, because of this setting, and because the inscription is not reversed. It reads: "Nabu . . . . [son of] Iddina-Nergal (?). . . . son of Nabu-zira-iddin . . . . Khi (?)-su-ba . . . . ," according to Mr Pinches. The names of the twelve tribes, not their standards, as has been thought, may have been engraved in this fashion, just as on the two onyx stones in the preceding verses (Exodus xxviii. 9–11), where there can be no question but that actual names were incised. On these two stones the order of the names was according to primogeniture, and this, it is likely, would apply to the breastplate also. The accompanying diagram will show how the stones,



Jewish High Priest's Breastplate.

supposing them to have been cylinders or half cylinders may have been arranged consistently with the descriptions of the Septuagint. In the arrangement of Josephus the jasper is made to change places with the sapphire, and the amethyst with the agate, while our version differs partly in the order and partly in the names of the stones, but probably in all these accounts the names had in some cases had other meanings than those which they now carry. From the fact that to each tribe was assigned a stone of different colour, it may be taken that in each case the colour was one which belonged prescriptively to the tribe and was symbolic, as in Assyria, where the seven planets appropriated each a special colour (see Brandis in the Berlin *Hermes*, 1867, p. 259 *sq.*, and De Sacy, *Revue Archéologique*, 1869, and compare Revelation xxi. 13, where the twelve gates are grouped in four threes, and 19, 20, where the twelve precious stones of the walls are given). The precious stones which occur among the cylinders of the British Museum are sard, emerald, lapis lazuli (sapphire of the ancients), agate, onyx, jasper, and rock crystal. Both Ælian (*Var. Hist.*, iv. 34) and Diodorus (i. 75) speak of an object known as an image of truth worn round the neck of the judge, who of course was a priest, in ancient Egypt; but how far this may have suggested or corresponded with the Jewish breastplate is not to be made out.

The records of gem-engravers in Greece begin in the island of Samos, where Mnesarchus, the father of the philosopher Pythagoras, earned by his art more of praise than of wealth. Thence also came Theodorus, who made for Polycrates the seal of emerald (Herodotus, iii. 41), which, according to the curious story, was cast in vain into the deep sea on purpose to be lost. That the design on it was a lyre, as is stated in one authority, is unlikely, now that Benndorf's ingenious reading of Pliny (*Nat. Hist.*, xxxiv. 83) has shown that the portrait statue of Theodorus made by himself was in all probability a figure holding in one hand a graving tool, and in the other, not, as previously supposed, a quadriga so diminutive that a fly could cover it with its wings, but a scarab with the engraving of a quadriga on its face (*Zeitschrift für die Oesterreich. Gymnasien*, 1873, pp. 401–411), whence it is not unreasonable to conclude that this scarab in fact represented the famous seal of Polycrates. Shortly after 600 B.C. there was a law of Solon's forbidding engravers to retain impressions of the seals they made, and this date would fall in roundly with that of Theodorus and Mnesarchus, as if there had in fact been just about then a special activity and unusual skill. That the art had been practised perhaps for several centuries before in Greece is probable from the general usage of sealing implied in Solon's law, from the extraordinary degree to which it obtained soon after his time, and from the influence which was exercised on the Greeks in such matters by the Phœnicians, Egyptians, and Assyrians. Yet it is singular to find, as Pliny points out (xxxiii. 4), no direct mention of seals in Homer, not even in the passage (*Iliad*, vi. 168) where Bellerophon himself carries the tablets on which were written the orders against his life. Then as regards the rings or seals of Prometheus, of Midas, of Minos (which like that of Polycrates was thrown into the sea in vain), of Phocus, and of Orestes, the legends may not all have come down from a very early period, but that of Phocus can at least be traced back to the time of Polygnotus, while that of Prometheus may be taken to have inspired the seal (engraved *Rev. Arch.*, 1878, pl. xx.) on which the Titan is seen bound and submitting to the vulture. Or, conversely, such a gem may have suggested the legend of the ring which he bore as proof of his former punishment. There is no need to put it much later than 600 B.C., and it is a specimen of a class of lentoid gems which of late years have been found in small numbers chiefly in the Greek islands. Two more of them from the British Museum collection are engraved in Pl. I., figs. 2 and 3. As a rule the materials are comparatively soft, most frequently steatite and hæmatite, while the designs consist mainly of animals so turned and twisted as to cover almost the entire surface of the gem. Certain exceptional cases, where the design is taken from legend or mythology, may be seen in the *Revue Archéologique*, 1878, pl. xx., Nos. 1–3; for the ordinary subjects see *Revue Arch.*, 1874, pl. xii.; Schliemann, *Mycenæ*, pp. 112, 202, 362; Cesnola, *Cyprus*, pl. xxxvii. 9, and pl. xxxviii. 21, 23; and for gold signets with designs in this stage of art see Schliemann, *Mycenæ*, p. 223; Cesnola, *Cyprus*, pl. xxxiv. 2; and *Revue Arch.*, 1874, pl. iv., No. 44, in which volume is an interesting article on early engraved gems by Count Gobineau. In most cases the designs though heraldic rather than natural, with a prevalence of animal forms perhaps due to notions of heraldry, are yet so singularly free from Egyptian or Assyrian influence that they must be assigned as essentially Greek productions, possibly from a period when Oriental examples had lost sway. "Not to carry the image of a god on your seal" was a saying of Pythagoras; and, whatever his reason for it may have been, it is interesting to observe him founding a maxim on his father's profession of gem engraving (Diogenes Laert., viii. 1, 17).

From the time of Theodorus to that of Pyrgoteles in the 4th century B.C. is a long blank as to names, but not altogether as to gems, the production of which may be judged to have been carried on assiduously from the constant necessity of seals for every variety of purpose. The references to them in Aristophanes, for example, the lists of them in the ancient inventories of treasures in Athens, and the number of them found by General Cesnola in the treasure chambers of Curium in Cyprus confirm this frequent usage during the period in question. To it belong in particular the inscribed gems mentioned in ARCHÆOLOGY (vol. ii. p. 353), including the Woodhouse intaglio there figured (p. 358), which may be referred to as perhaps the very finest example of Greek gem engraving that has come down to us. It would stand early in the 5th century B.C., a date which would also suit the head of Eos from Ithome in Messenia (Pl. I., fig. 14), the head (fig. 5), the citharist (fig. 9), while the scarabs (figs. 6, 7), though apparently of Etruscan origin, obviously reflect the character of archaic Greek art, as far as concerns the shallow cutting and the delicate execution of minute details. The touch which isolates a design and literally arrests the eye they do not possess, but by comparison they render it more distinct as it exists in the Woodhouse gem already mentioned, and in figs. 8, 10–13, and 15 in Plate I., all of which may be assigned to the end of the 5th century B.C. Singularly beautiful in this class are the two Cesnola gems (*Cyprus*, pl. xxxix. figs. 1, 2), the latter, simple and even awkward in parts, yet on the whole conceived by a Greek mind imbued with the poetry of art, while the former is rather a triumph of faultlessness, delicate as the colour of the stone on which it is engraved.

By the beginning of the 4th century B.C. every element of archaism had vanished; but gems of this period are scarce, except in the collection of St Petersburg, which has obtained them exclusively from tombs in the Crimea. Foremost among them are the two by Dexamenus of Chios, the one, a calcedony with the figure of a stork flying, and inscribed in two lines, the letters carefully disposed above each other, ΔΕΞΑΜΕΝΟΣ ΕΠΟΙΕ ΧΙΟΣ (*Compte-rendu de la Commiss. Arch. St Petersburg*, 1861, pl. vi. fig. 10), and the other, an agate with a stork standing on one leg, inscribed ΔΕΞΑΜΕΝΟΣ simply (*Compte-rendu*, 1865, pl. iii. fig. 40). A third gem, apparently by the same Dexamenus, is a carnelian belonging to Admiral Soteriades in Athens, and has a portrait head, bearded and inscribed ΔΕΞΑΜΕΝΟΣ ΕΠΟΙΕ (*Compte-rendu*, 1868, pl. i. fig. 12). Apart from the splendour of their workmanship, those three gems are interesting for the variety of their inscriptions. Thus a name standing alone in the nominative case, when it does not describe the subject of the design, will indicate the artist. Again, when the nationality of the artist is added it should follow the verb as a rule, which, however, is not without exceptions. ΕΠΟΙΕ for ΕΠΟΙΕΙ is an archaism. The design of a stork flying occurs on an agate scarab in the British Museum from the old Cracherode collection, and therefore beyond all suspicion of having been copied from the more recently discovered Kertch gem. The condition of the surface and the skill of execution are both interesting. Reckoned among the best of the Crimea gems, and that is equivalent to saying among the best of all gems, are the following:—(1) a burnt scaraboid with an eagle carrying off a hare; (2) a gem with scarab border and the figure of a youth seated playing on the trigonon, very much resembling the Woodhouse intaglio (both engraved, *Compte-rendu* 1871, pl. vi. figs. 16, 17); (3) a scaraboid with border and the design of a horse running at speed, with which may be compared a carnelian scaraboid in the British Museum from the old Hamilton collection, and again on this account above suspicion, if the great beauty of the work were not alone convincing; the horse is here stung by a gadfly; (4) an ovoid calcedony, mounted on a chain to be worn as a collar, with an intaglio of a Gorgon (3 and 4 engraved, *Compte-rendu*, 1860, pl. iv. figs. 6 and 10). In these, and in almost all Greek gems belonging to this period of excellence, the material is of indifferent quality, consisting of agate, calcedony, or carnelian, just as in the older specimens. Brilliant colour and translucency are as yet not a necessary element, and accordingly the design is worked out solely with a view to its own artistic merit.

At this stage appears the name of Pyrgoteles, of whom it is said that he alone was permitted to engrave the portrait head of Alexander the Great. The portrait head of

Alexander given in Pl. I., fig. 16, is not likely to represent the art of this time, but more probably belongs to the age of Augustus who used this design as a seal. On the other hand the ancient pastes (figs. 20–22) will convey a notion of the gem engraving of the time of Alexander. Still it should be observed that one of the special difficulties of the subject is to account for the scarcity of gems from this period of wealth, luxury, and artistic activity in all directions. Possibly not a few belong to it which it is thought safer to class as Roman. This much at least is certain, that Roman art altogether was a prolongation, hardly a development, of the Macedonian art. Those Roman engravers may have been conscious of this who boldly placed on their productions the names of celebrated Greek artists, as for instance on a garnet in the British Museum, having a figure perhaps of Jason and inscribed with the name of Phidias (ΦΕΙΔΙΑΣ ΕΠΟΕΙ); others elsewhere profess to be the work of Polycletus or of Scopas. The same effrontery was seen in sculpture, and unfortunately has revived again in the gem engraving of comparatively recent times, as may be seen in a calcedony intaglio of the head of Alexander the Great in the British Museum, which, though clearly modern, claims to be the work of Pyrgoteles.

From literary sources are known the engravers Apollonides, Chronius, Tryphon, Satyreius, and Dioscurides, but the date of the last-mentioned only is certain. He lived in the time of Augustus, whose portrait he executed, and did not, it may be supposed, inscribe his own name on it in full. On the other hand, if, as Pliny states, it became a custom afterwards to seal with this portrait of Augustus, it would be natural enough to place on the copies of it made for that purpose the name of Dioscurides. With this view of the case may be reconciled two gems bearing his signature in the British Museum—the one a jacinth, the other a sard—and both obviously portraits which, though more resembling Julius Cæsar than Augustus, might yet be regarded as unsuccessful portraits of the latter. Of the two the jacinth, which is from the Blacas collection, is doubted by Brunn; the other is a higher class of work, and yet even it presents some difficulties that require the theory of an imitator, most probably a Roman one. The obtrusive display of the wreath and the fringe of drapery round the bust are details which, apart from the style of workmanship, are objectionable. That the name of this engraver has been often added to modern gems is true enough, and in some cases also it may have been in modern times inscribed on perfectly ancient gems. Even among those which appear to be in all respects antique there are differences in the spelling and form of the letters not to be accounted for if they had come from his hand, but intelligible if they had been made by ancient copyists. Abbreviations such as ΔΙΟΣΚ for Dioscurides, or ΕΠΙΤ for Epitynchanus, are always suspicious. ΕΠΙΤΥΤΧΑ, on a beautiful cameo of the young Marcellus, might seem to have been abbreviated by the accident which broke off the lower part of the gem, but the inscription does not bear examination except as the work of a modern hand. Not necessarily modern is the inscription ΔΙΟΣΚΟΥΡΙΔ, on a fragmentary amethyst, with a head which may perhaps have been meant for Alexander the Great, whose portrait, as has been said, was used as a seal by Augustus, and may have been executed for him by Dioscurides. It is possibly an ancient copy of this seal, with the addition of the name of the original artist to show that it is so. With regard to the question whether a name standing in the genitive case may indicate the engraver, the evidence is affirmative, if for no other reason than that the names are most frequently Greek, while the owners or collectors of gems in Italy were Romans. Collecting was a passion with wealthy Romans, but their names have not survived on gems. Names like Aulus or Gnæus, written in Greek letters, cannot indicate a Roman of position, but on the contrary show that it was to the naturalized Greeks that the Romans looked for their engravers. When, for instance, one gem reads ΣΟΛΩΝΟΣ and another ΣΟΛΩΝ ΕΠΟΙΕΙ, it is fair to conclude that we have to do in both with an engraver named Solon, if the inscriptions are genuine. The former occurs on a gem found with jewellery at Pompeii (*Bullet. d'Inst. Arch.*, 1863, p. 91), so that if the other examples of it, *e.g.*, on the Strozzi Medusa in the British Museum, and on the so-called head of Mæcenas, be inventions of the 16th or 17th centuries, they are at least correct in reproducing a name which is now seen on one undoubtedly ancient intaglio. Obviously one or more gems so inscribed must have existed in the 16th or 17th centuries, and this fact alone of the existence of several gems with the same name would suggest if not actually prove that it was the name of an engraver. The other inscription, ΣΟΛΩΝ ΕΠΟΙΕΙ, on an intaglio of Diomedes carrying off the Palladium, though known since the year 1660, has not always passed unchallenged. The Medusa just mentioned is a gem of extraordinary pretensions, but very unsatisfactory when compared with good Greek work. In the matter of names the evidence as to the Greek usage, though very slight, is not at variance with what may be gathered from the coins where the names of the die-sinkers appear either in the nominative or genitive case.

In the discussions as to what is or is not proper in the way of engravers' signatures, frequent reference is made to the inscription ΕΥΤΥΧΗΣ ΔΙΟΣΚΟΥΡΙΔΟΥ ΑΙΓΕΑΙΟΣ ΕΠ, which occurs twice—on a pale amethyst said last century to belong to the prince of Avella, and on an amethyst in the Marlborough collection. The design on the two is identical, consisting of a helmeted bust of Minerva in full face. Unless what was formerly the Avella gem is now the gem belonging to the Marchese Strozzi of Florence, then this again must be a third example. Professor Maskelyne in his *Catalogue* quotes Mr King as agreeing with him that the Marlborough gem (No. 81) is not a copy as Brunn supposed, but may be regarded as an original work of Eutyches till the Avella gem be proved to exist elsewhere. But Stephani insists on the inscription being a modern production, especially on account of the contraction ΕΠ for ΕΠΟΙΕΙ, which he says had arisen through the last letters ΟΙΕΙ being hidden from the modern copyist, either owing to the setting, or from some other cause. The gem which Cyriacus of Ancona and a contemporary of his saw and described in the early part of the 15th century had the full inscription, and possibly it was from an inexact impression of it that the Marlborough gem was made (*Compte-rendu*, 1861, p. 157). Another celebrated Marlborough gem with the head of the dog-star Sirius, inscribed ΓΑΙΟΣ ΕΠΟΙΕΙ, is condemned by Professor Maskelyne in his *Catalogue* (No. 270), as it deserves to be. Apparently meant for the same engraver, though written differently, is the ΓΝΑΙΟΣ on the beryl in the British Museum with the head of Hercules, as to which Köhler's adverse judgment appears to be entirely just. ΣΚΥΛΑΞ, which is found on an amethyst head of Pan in the British Museum executed with wonderful exactness of detail, is not disputed, except as to whether it is the name of the engraver or the owner. Among the other names which have been more or less the subject of discussion are those of Hyllus, who also claims to be a son of Dioscurides, Epitynchanus, Agathopus, Euodus, Felix, Mycon, Allion, Admon, Onesas, Protarchus, and Alexas.

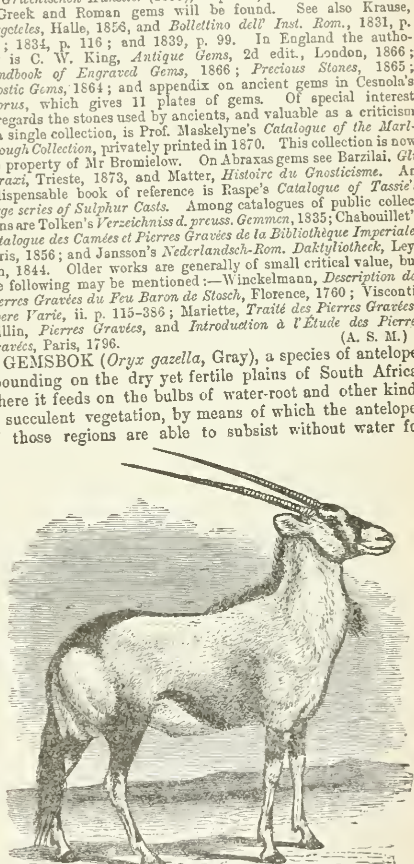
The habit of gem collecting is recorded first in the instance of Ismenias, a musician of Cyprus, who appears to have lived in the 4th century B.C. But though individual collectors are not again mentioned till the time of Mithradates, whose cabinet was carried off to Rome by Pompey, still it is to be inferred that they existed, if not pretty generally, yet in such places as Cyrene, where the passion for gems was so great that the poorest person owned one worth 10 minas, and where, according to Ælian (*Var. Hist.*, xii. c. 30), the skill in engraving was astonishing. The first cabinet (dactyliotheca) in Rome was that of Scaurus, a step-son of Sulla. Cæsar is said to have formed six cabinets for public exhibition, and from the time of Augustus all men of refinement were supposed to be judges both of the art and the quality of the stones. To this pretension is doubtless due most of the existing gems engraved on large beautiful jacinths, garnets, sards, beryls, and amethysts, leaving, as regards purely technical skill, nothing to be desired. Except in portraiture, and in grylli or conceits, in which various things are combined into one, often with much skill, the subjects were as a rule only variations or adaptations of old types handed down from the Greeks. When new and distinctly Roman subjects occur, such as the finding of the head on the Capitol, or Faustulus, or the she-wolf with the twins, both the stones and the workmanship are poor. In such cases, where the design stirs a genuine national interest, it may happen that very little of artistic rendering will be acceptable rather than otherwise, and much more is this true when the design is a symbol of some article of faith, as in the early Christian gems. There both the art and the material are at what may be called the zero of engraving; that is to say, it has reached the point beyond which barbarousness or folly sets in. The usual subjects on the early Christian gems are the fish, anchor, ship, dove, the good shepherd, and, according to Clemens, the lyre. Under the Gnostics, however, with whom there was more of speculation than of faith, symbolism was developed to an extent which no art could realize without the aid of writing. A gem was to them a talisman more or less elaborate, and the difficulty is to make out how they carried them. Many specimens exist, but none show signs of mounting. The materials are usually hæmatite or jaspar. As regards the designs, it is clear that Egyptian sources have been most drawn upon. But the symbolism is also largely associated with Mithraic worship. The name Abraxas or Abrasax, which, from its frequency on these gems, has led to their being called also "Abraxas gems," is, when the Greek letters of which it is composed are treated as Greek numerals, equal to 365, the number of days in a year, and the same is the case with ΜΕΙΘΡΑΣ.

More interesting, from the occasionally forcible portraiture and the splendour of some of the jacinths employed, are the Sassanian gems, which as a class may be said to represent the last stage of true gem engraving in ancient times. In the middle ages and onwards metal stamps were found more serviceable for the purpose of sealing, and though engraved gems still continued to be a luxury of the great, the old traditions were broken through, as may be seen, for example, in the large crystal in the British Museum representing Susanna and the Elders, made by order of the French king Lothair, 954-986. With the revival of classical tastes under the patronage of popes and princes in the Cinquecento period, it was natural that this branch of art should have a new career of activity, which, after a lapse during the 17th century, again during the last century revived under an even greater amount of encouragement from men of wealth and rank. In this last period the names of engravers who succeeded best in imitating classical designs were Piehler (Pl. I., fig. 28), Natter, and the Englishmen Marchant (fig. 29) and Burch. Compared with the Greek gems on the same plate, it will be seen that what at first sight is attractive as refined and delicate is after all mere pretence of refinement, and entirely devoid of the ancient spirit. The success with which modern engravers imposed on collectors is recorded in many instances, of which one may be taken as an instructive type. In the Bibliothèque in Paris (Chabouillet's catalogue, No. 2337) is a gem familiarly known as the signet of Michelangelo, the subject being a Bacchanalian scene. So much did he admire it, the story says, that he copied from it one of the groups in his paintings in the Sistine chapel. The gem, however, is evidently in this part of it a mere copy from Michelangelo's group, and altogether is a later production.

The gems engraved in Plate I. show a progressive development of the art from the earliest times down to last century. They are all in the British Museum, and are enlarged to about a half more than their real size. No. 1, Porcelain scarab, from Camirus in Rhodes; No. 2, Carnelian, lentoid gem, from Ialyssus, in Rhodes; No. 3, Crystal, lentoid, also from Ialyssus; No. 4, Paste scaraboid, from Tharras, in Sardinia; No. 5, Carnelian, head of a king; No. 6, Crystal scarab, Gorgon; No. 7, Carnelian scarab, Citharist; No. 8, Sard, female figure with water jar; No. 9, Steatite scaraboid, Citharist; Nos. 10-13, Four sides of an amethyst, Mænads; No. 14, Agate, Eos; No. 15, Carnelian, unknown; No. 16, Carnelian, head of Alexander the Great, as Helios; No. 17, Sard, head of Zeus; No. 18, Sardonyx cameo, Actæon; No. 19, Sardonyx cameo, head of Athena; No. 20, Paste, Victory; No. 21, Paste, Mænad; No. 22, Paste, Victory sacrificing bull; No. 23, Agate scaraboid, Priest; No. 24, Amethyst, head of Brutus (?) from Rhodes, inscribed C. I. Q.; No. 25, Jacinth, Sassanian portrait; No. 26, Gnostic gem; No. 27, Christian gem, the Good Shepherd; No. 28, Modern gem, by Pichler; No. 29, Modern gem, by Marchant.

Literature.—See M. A. Levy, *Siegel und Gemmen*, with three plates of gems having Phœnician, Aramaic, and old Hebrew inscriptions, Breslau, 1869; and, on the same subject, De Vogüé, in the *Revue Archéologique*, 1868 (xvii.), p. 482, pl. 14-16; De Saulcy, in the *Rev. Arch.*, 1869 (xx.), p. 101, "Recherches sur le costume chez les Juifs;" Victor Ancessi, *L'Égypte et Moïse*, Paris, 1875, giving on plate 7 a fanciful restoration of an Egyptian breastplate; Soldi, in the *Rev. Arch.*, 1874 (xxviii.), p. 147, on Babylonian cylinders; Count Gobineau, in the *Rev. Arch.*, 1874 (xxvii.), p. 111 and p. 179, on early Oriental gem engraving. Fr. Lenormant, in the *Rev. Arch.* 1874 (xxviii.), pl. 12, gives five examples of early lentoid gems, and seven more gems of the same class are given by A. S. Murray in the *Rev. Arch.*, 1878, pl. 20. On Greek and Roman gems the principal authorities are Köhler, *Gesammelte Schriften*, iii. and v., and Stephani, in his notes to these volumes, and in the *Compte-rendu de la Commission Imperiale de St Petersbourg*, 1870-1, p. 215 and pp. 221-224. Opposed to them is Brunn, in his *Geschichte der Griechischen Künstler* (1859), ii. p. 443, where a full discussion of Greek and Roman gems will be found. See also Krause, *Pyrgoteles*, Halle, 1856, and *Bollettino dell' Inst. Rom.*, 1831, p. 105; 1834, p. 116; and 1839, p. 99. In England the authority is C. W. King, *Antique Gems*, 2d edit., London, 1866; *Handbook of Engraved Gems*, 1866; *Precious Stones*, 1865; *Gnostic Gems*, 1864; and appendix on ancient gems in Cesnola's *Cyprus*, which gives 11 plates of gems. Of special interest as regards the stones used by ancients, and valuable as a criticism of a single collection, is Prof. Maskelyne's *Catalogue of the Marlborough Collection*, privately printed in 1870. This collection is now the property of Mr Bromielow. On Abraxas gems see Barzilai, *Gli Abraxi*, Trieste, 1873, and Matter, *Histoire du Gnosticisme*. An indispensable book of reference is Raspe's *Catalogue of Tassie's large series of Sulphur Casts*. Among catalogues of public collections are Tolken's *Verzeichniss d. preuss. Gemmen*, 1835; Chabouillet's *Catalogue des Camées et Pierres Gravées de la Bibliothèque Imperiale*, Paris, 1856; and Jansson's *Nederlandsch-Rom. Daktyliotheek*, Leyden, 1844. Older works are generally of small critical value, but the following may be mentioned:—Winckelmann, *Description des Pierres Gravées du Feu Baron de Stosch*, Florence, 1760; Visconti, *Opere Varie*, ii. p. 115-386; Mariette, *Traité des Pierres Gravées*; Millin, *Pierres Gravées*, and *Introduction à l'Étude des Pierres Gravées*, Paris, 1796. (A. S. M.)

GEMSBOK (*Oryx gazella*, Gray), a species of antelope, abounding on the dry yet fertile plains of South Africa, where it feeds on the bulbs of water-root and other kinds of succulent vegetation, by means of which the antelopes of those regions are able to subsist without water for



Gemsbok.

months together. It is a large and powerful animal, measuring about 5 feet in length and over 3 feet in height at the shoulders. Its horns, situated on the same plane with its forehead, exceed 2 feet in length, are almost straight, and are obscurely ringed throughout their lower half. The colour of the upper part of the body is a rusty grey, and of the under part white, while these are separated from each other by a well-defined black band on each side. These bands unite on the breast, and are continued as a single black band until reaching the lower jaw, when they again divide and form two transverse bands on the head, terminating at the base of the horns. The head otherwise is white, as also are the limbs, with the exception of the thighs, which are black. The striking appearance presented by this antelope is in great part due to the absence of any blending in the different colours of its body. The gemsbok avoids the woods, living on the open plains in pairs, or in small groups of four or five. Possessing powerful weapons of attack in its long spear-like horns, and with ample courage to use them, this animal, especially when wounded, is a formidable antagonist both to man and to the numerous beasts of prey which are attracted to the karroos of the Cape by the presence of this and other ruminant species. It is said to defend itself not unfrequently with success against the lion. Its flesh is esteemed as a delicacy, and its hide forms a valuable leather.

GENDARMERIE, a body of troops or police in France, composed of *gendarmes*, or men-at-arms. In the days of chivalry they were mounted and armed cap-a-pie, and attended each by five soldiers of inferior rank and more lightly armed. They were then furnished by the fiefs, and marched in the train of the knights and esquires. In 1439 this feudal gendarmerie was replaced by the *compagnies d'ordonnance* which Charles VII. formed when the English were driven out of France, and which were distributed throughout the whole extent of the kingdom for preserving order and maintaining the king's authority. These companies, fifteen in number, were composed of 100 lances or gendarmes fully equipped, each of whom was attended by at least three archers, one *coutillier* (soldier armed with a cutlass) and one *varlet* (soldier's servant). The states-general of Orleans (1439) had voted a yearly subsidy of 1,200,000 livres in perpetuity to keep up this national soldiery, which replaced the bands of mercenaries who for about a century had made France their prey. The number and composition of the *compagnies d'ordonnance* were changed more than once before the reign of Louis XIV. This sovereign on his accession to the throne found only eight companies of gendarmes; but after the victory of Fleurus (1690), which had been decided by their courage, he increased their number to sixteen. The four first companies were designated by the names of *Gendarmes écossais*, *Gendarmes anglais*, *Gendarmes bourguignons*, and *Gendarmes flamands*, from the nationality of the soldiers who had originally composed them; but at that time they consisted entirely of French soldiers and officers. These four companies had a captain-general, who was the king. The fifth company was that of the queen; and the others bore the name of the princes who respectively commanded them. This organization lasted till 1787, when Louis XVI. dissolved it, only retaining the *Gendarmes écossais* in his body-guard. The great Revolution swept away all these institutions of the monarchy, and, with the exception of a short revival of the *Gendarmes de la garde* at the Restoration, the word gendarmerie had thenceforth an altogether different meaning. It has been since that time employed to denote a military police, whose duties are to watch over the public safety, keep order, and enforce the execution of the laws. This police force superseded the old *maréchaussée*.

The law of the 28th Germinal, An VI. (17th April 1797), and the royal ordinance of the 29th October 1820, organized the gendarmerie, and laid down the general rules that are still in force, dividing it into legions and companies, and the latter into brigades. In time of war a colonel of gendarmerie, with the title of *grand-prévôt*, is attached to the army with a detachment of gendarmes, for maintaining discipline among the soldiers. Though placed under the control of the minister of war, the gendarmerie is also at the disposal of the minister of the interior as a police force, of the minister of justice as agents to secure the execution of judicial sentences and police regulations, and also of the minister of marine and colonies for enforcing his authority over marines and sailors in the colonies and sea-towns of France. The gendarmerie of Paris constitutes a special corps established first in 1802, and successively called *Gendarmerie de Paris*, *Garde royale*, and *Garde municipale*. Suppressed by the provisional Government in 1848, the Garde de Paris was soon reorganized. It is now composed of 6 squadrons of cavalry and 24 companies of infantry, and is officially styled *Garde républicaine de Paris*. Both in the *Garde républicaine* and in the *légions*, the gendarmes consist for the most part of deserving soldiers of the regular army, who have been drafted into this service, where, with other privileges, they have a much higher rate of pay than the soldiers of the line. Their total numbers are about 40,000, made up of the Garde de Paris as above, 31 provincial legions, 1 legion of gendarmerie mobile, and the *Gendarmerie coloniale*.

Russia also has a gendarmerie, a secret police appointed in all towns of the empire to watch over Russian subjects of all ranks and classes, and to report to the chancery office such information as they receive from their detectives and secret agents.

For the history of the old French gendarmerie before 1789 see Chéruel, *Dictionnaire historique des institutions de la France*, 2 vols., and Lacroix, *Vie militaire et religieuse au moyen âge et à l'époque de la Renaissance*; and for the present gendarmerie, *Réorganisation de la Gendarmerie*, 1871, and *Annuaire militaire*, 1877.

GENEALOGY. *Biblical.*—The word "genealogy" (γενεαλογία), which occurs twice in the New Testament (1 Tim. i. 4; Tit. iii. 9; compare also Heb. vii. 3, 6) in the ordinary concrete sense of "pedigree" or "list of ancestors," is of somewhat frequent occurrence in the authorized version of the Old Testament scriptures, but only in Chronicles-Ezra-Nehemiah, where the words יַחַשׂ and הִתְיַחֵשׂ, which are peculiar to that work, are invariably rendered "genealogy" and "to reckon by genealogy." This translation, however, is of somewhat doubtful accuracy; for, whatever the original meaning of the root יחשׂ may have been,[1] there seems to be no room for doubt that the noun and the verb connected with it were used in later Hebrew simply to denote respectively the roll and the act of registration, and that the "book" alluded to in Neh. vii. 5 (in A. V. "register of the genealogy") was genealogical only in so far as the individuals registered in it were classified according to their "houses," "families," and "tribes." While a catalogue of this sort was admirably fitted to be a permanent record of tribal relations in Israel, as these subsisted at the time of its compilation, there is not any reason to suppose that it made any attempt to trace them through previous generations.[2] The scripture genealogies, properly

[1] According to Ewald (*Gesch. d. V. Isr.* i. 261, *cf. Alt.* 363) it meant properly "to count." In the LXX. the Hithpael is rendered differently in each passage where it occurs; ἐγενεαλογήθη is only once given. In Ezra ii. 62 the translation is γραφὴν αὐτῶν οἱ μεθωεσείμ (Vulg., scripturam genealogiæ suæ); in Neh. vii. 64 it is γραφὴ ἑαυτῶν τῆς συνοδίας (scripturam suam in censu). It may be added that the habit of taking a written census of sections of the population, or even of the entire nation, was obviously not unfamiliar to the Jews. This appears from numerous indications in the earlier historical books, *e.g.*, Num. i. 18, where the word (used here only) is וַיִּתְיַלְדוּ, as well as in Chronicles-Ezra-Nehemiah. Compare also Ezek. xiii. 9 and Ps. lxxxvii. 6.

[2] When, for example, we read in 1 Chr. vii. 6, 7 that Benjamin had three sons (Bela, Becher, and Jediael); in viii. 1, 2 that he had five (Bela, Ashbel, Aharah, Nohah, and Rapha); in Numb. xxvi. 38 again that he had five, but that their names were Belah, Ashbel, Ahiram, Shupham, and Hupham; and, finally, in Gen. xlvi. 21 that they numbered ten "souls" (Bela, Becher, Ashbel, Gera, Naaman, Ehi, Rosh, Muppim, Huppim, and Ard); or when the descendants of Bela are variously given, in 1 Chr. vii. 7 as Ezbon, Uzzi, Uzziel, Jerimoth, and Iri: in 1 Chr. viii. 3–5, as Addar, Gera, Abihud, Abishua, Naaman, Ahoah, Gera, Shephuphan, and Huram; and in Numb. xxvi. 40 as Ard and Naaman, the simple explanation (after all due allowance for corruptions in the text has been made) seems to be, that in the course of a long history the Benjamite tribe included a varying number of families or clans with varying names. Similar instances might be indefinitely multiplied. It ought to be added, however, that criticism has not yet by any means completed its task on the book of Chronicles in its genealogical bearings. See Wellhausen, *Geschichte Israels*, i. 230 *sq.*, 187

so called, are rather to be sought for in these תּוֹלְדוֹת (A. V. "generations;" Gen. ii. 4; v. 1; vi. 9; x. 1, &c.; Ex. vi. 16, 19, &c.; Num. iii. 1) so frequently met with in some other canonical books, and so specially characteristic of the first book of the Pentateuch as apparently to have suggested to the Alexandrian translators its distinctive name of γένεσις. These begin with the antediluvian period, and indeed with "the generations (or genealogy) of the heavens and of the earth." The descendants of Adam are traced through the lines of Cain and of Seth respectively to the seventh and to the ninth generation. In the two lists the frequent similarity of the names has not escaped observation; nor has the symmetry of the numbers (in one case, a series of seven, the seventh branching into three; in the other a series of ten, in which the seventh is peculiarly prominent, while the tenth branches into three). The very ancient tradition which they embody is not at present so generally believed to convey actual personal history as once it was, but by those who view them as more or less ideal in their character their significance has been very variously estimated,—some seeing in them the survival of ancient myths, perhaps solar in their character; others interpreting them as representing successive dynasties, or immigrations, or stages of culture within a given area in prehistoric times; while such interpreters as Philo allegorize them in a purely spiritual sense. The same differences of view find expression when the genealogies of the immediately post-diluvian period come to be considered. In Gen. xi. a series of nine generations (or, according to the LXX., ten) from Shem to Abraham is given; the symmetrical number again attracts notice, and in the list some names at least can be identified as having belonged to special nationalities; Arphaxad, for example, is probably equivalent to the Arrhapachitis of Ptolemy (vi. 1). That this "genealogy" was in intention ethnographical rather than personal finds confirmation from the expansion which it receives in the very interesting sketch of a *genealogia universalis* in Gen. x., where the sons of Shem, besides Arphaxad, are said to have been Elam, Asshur, Lud, and Aram, while from Aram were descended Uz, Hul, Gether, and Mash or Meshech (compare 1 Chron. i. 17); and again, among the sons of Joktan, the (younger) brother of Peleg, are found Hazarmaveth, Sheba, Ophir, and Havilah. Throughout Gen. x., indeed, a thorough consciousness of a purely ethnographical purpose is manifest, and in many instances the device of using personal names to convey ethnological statements is entirely dropped (Gen. x. 13, 14, 16–18). Historians and critics are not yet entirely at one as to the view which ought to be taken of the genealogies which begin with Abraham. As is well known, these follow the line of Isaac, but give also the collateral lines of Ishmael and of the children of Keturah, and again trace the descendants not only of Jacob but also of Esau; and so much at least is unanimously held that, even if strictly historical so far as the children of Israel are concerned, they cannot be supposed to be complete for the centuries of the sojourn in Egypt. There seems no reason to doubt, however, that the distribution into tribes (שְׁבָטִים or מַטּוֹת) families (מִשְׁפָּחוֹת) and houses (בֵּית־אָבוֹת) lay at the basis of the organization of the Israelites from the earliest period of their independent national life, so that at any given time each man would be able to tell what house he belonged to, what other houses belonged to the same family, and what other families belonged to the same tribe with himself. There are indications of repeated censuses, in which the people were systematically enrolled for fiscal and military purposes; but, on the other hand, it must be said that there seems to be no adequate evidence that the שֹׁטְרִים, or "officers," so frequently mentioned in the Pentateuch, had functions at all corresponding to those of a heralds' college, if indeed it can be regarded as made out that they were scribes at all. The statements which are continually made as to the unbroken continuity and exhaustive fulness of the genealogical records of the twelve tribes of Israel are not borne out by any sober reading of the facts of history, as these have come down to us; and, even in the case of the Aaronic and Davidic families, there are some circumstances that warn against too absolute confidence in the strict literality of the lists which have reached our hands. It is certain, indeed, that from the beginning of the post-exile period (Ezr. ii. 62, Neh. vii. 64) great importance was attached to purity of lineal descent in the case of priests; and even in the time of Josephus (*Cont. Ap.*, i. 7) members of the priestly caste were in the habit of proving their legitimacy by means of public documents, which he refers to as δημοσίαι δέλτοι. But a comparison of the pedigree (whether official or personal) of Jehosadak (1 Chr. vi. 3–15; *cf.* Ezra vii. 1) with the enumeration of Aaron's successors in the high priesthood, as given by Josephus and repeated in the *Seder Olam*, suggests that, for the period preceding the captivity at least, the materials for a complete list must have been somewhat defective. That in the case of the house of David, in like manner, some real uncertainty existed would seem to be a legitimate inference, not only from the Chronicler's obscurity, but also from the not easily reconcilable discrepancy between the genealogies given in Mat. i. and in Luke iii. And this is not inconsistent with the fact, of which there are many indications in the New Testament (and even, though more faintly, in the Mishna), that among the Jews the consciousness of tribal distinctions disappeared very slowly. When Anna is represented as belonging to the tribe of Asher and Elizabeth as a daughter of Aaron, Paul as a Benjamite and Barnabas as a Levite; or when, as is vouched for by a not very late tradition, the "desposyni" in the time of Domitian claimed to have the royal blood of David in their veins, it would obviously be just as rash to infer (as Jerome seems to have done) that every successive link in the long series of their genealogies was accurately known to the persons themselves, or recognized by their contemporaries, as it would be unscientific altogether to ignore the presumption arising out of the very fact that tribal distinctions were asserted. With reference even to the most undisputed of the Biblical genealogies, it is important to remember, in the first place, that in them phrases implying sonship are not to be interpreted so strictly as they would be with us; and, secondly, that, in order to aid the memory by means of successions of symmetrical numbers, it was quite usual to manipulate a long list by dropping or even by introducing names at discretion.

Classical.—A passing reference only is needed to the intricate genealogies of gods and sons of gods which form so conspicuous a feature in classical literature. In every one of the numerous states into which ancient Greece was divided there were aristocratic families who were accustomed to claim descent, through eponymous heroes, from the primitive deities. Many of these families were, as families, undoubtedly of great antiquity even at the beginning of the historical period; and in several instances they continued to maintain a conspicuous and separate existence for centuries. The element of family pride is prominent in the poetry of the Megarian Theognis; and in an inscription belonging to the 2d century B.C. we find a member of the Spartan family of Gytheates represented as the thirty-ninth in direct descent from the Dioscuri and the forty-first from Hercules. Even in Athens, long after the constitution had become thoroughly democratic, some of the clans continued to be known as εὐπατρίδαι; and Alcibiades, for example, as a member of the phratria of the Eurysacidæ, traced his origin through many generations to Eurysaces, who was represented as having been the first of the Æacidæ to settle in Attica. It is very doubtful, however, whether such pedigrees as this were very seriously put forward by those who claimed them; and it is certain that, almost along the whole line, they were unsupported by evidence. We have the authority of Pollux (viii. 111) for stating that the Athenian γένεα, of which there were thirty in each φρατρία, were organized without any exclusive regard being had to blood-relationship; they were constantly receiving accessions from without; and the public written registers of births, adoptions, and the like do not appear to have been preserved with such care as would have made it possible to verify a pedigree for any considerable portion even of the strictly historical period (see Schoemann, *Griechische Alterthümer*, i. 137, 338).[1]

The great antiquity of the early Roman (patrician) gentes is indisputable; and the rigid exclusiveness with which each preserved its *hereditates gentilitiæ* or *sacra gentilitia* is sufficiently illustrated by the fact that towards the close of the republic there were not more than fifty patrician families (Dionys., i. 85). Yet even in these it is obvious that, owing to the frequency of resort to the well-recognized practice of adoption, while there was every guarantee for the historical identity of the family, there was none (documents apart) for the personal genealogy of the individual. There is no evidence that sufficient records of pedigree were kept during the earlier centuries of the Roman commonwealth. In later times, it is true, even plebeian families began to establish a prescriptive right (known as the jus imaginum) to preserve in their halls the busts of those of their members who had attained to curule office, and to exhibit these in public on appropriate occasions. Under these imagines majorum[2] it became usual to inscribe on the wall their respective tituli, the relationship of each to each being indicated by means of connecting lines; and thus arose the stemmata gentilitia, which at a later time began to be copied into family records. In the case of plebeian families (whose stemmata in no case went farther back than 366 B.C.), these written genealogies were probably trustworthy enough; but in the case of patricians who went back to Æneas,[3] so much cannot, it is obvious, be said; and from a comparatively early period it was clearly recognized that such records lent themselves too readily to the devices of the falsifier and the forger to deserve much confidence or reverence (Pliny, *H. N.*, xxxv. 2; Juv. viii. 1). The many and great social changes which marked the closing centuries of the Western empire almost invariably militated with great strength against the maintenance of an aristocracy of birth; and from the time of Constantine the dignity of patrician ceased to be hereditary.

Modern.—The passion for genealogizing, which has been and is a marked characteristic of all the aristocracies of modern Europe, can be directly traced to the influence of feudalism and the principles of hereditary privilege which that system, in its later phases at least, so peculiarly encouraged. Along with the sharp separation of those families which alone were regarded as capable of holding real property or filling the higher offices of state, or indeed of engaging in any of what were reckoned as the more ennobling pursuits of life, arose the necessity for being able to determine with accuracy who were and who were not the persons entitled by birth to take a place within the privileged caste. When, for example, the practice arose of holding tournaments, in which no one was allowed to take part who could not give evidence of gentle descent, the necessity for the professional genealogist became at once apparent. It was not, however, until about the end of the 15th century that the vanguard of the great army of writers upon this fertile subject began to appear. It was perhaps natural that, finding as they did the gulf of separation between noble and base to be so great as it was, they should have leapt to the conclusion that it had existed from the first; at all events their knowledge and their ignorance combined to support them in their conjecture. As they forced their way up the stream of time, indeed, they were met at a comparatively early stage by a great barrier—consisting less in the paucity and inaccessibility of authentic documents than in what one might almost call the fatal fact of the absence of family names. Prior to the middle of the 11th century these were entirely unknown; the documents speak merely of Eberhardus, Fridericus, Ernestus, and the like, with at most the addition of the title. About 1050 began the custom of using surnames, but it made way so very slowly that, even at the close of the 12th century, it had not diffused itself beyond the ranks of the higher nobility, and throughout the 13th the old habit of self-designation by the Christian name merely was still exemplified in a vast number of instances.[5] The difficulty, however, in an age when the laws of evidence were so imperfectly understood, did not count for much with the courtly genealogists of the 15th and following centuries. The insuperable obstacle which barred their advance along the path of sober research only furnished them with a pretext for all the sooner making their escape into the region of imagination and conjecture, where no impediments occurred in tracing the ascending series until the name of the first created person was reached. The appended bibliography will help to make clear the degrees by which genealogists have gradually been brought to confine themselves to the limits of the verifiable. At present, if we understand by a genealogy a tabulated and, as far as possible, an exhaustive statement of all the ramifications of a series of human generations, and by genealogical science that branch of history which aims at securing fulness and accuracy in the accounts men give of the antecedents of families which have attained to distinction, the modern genealogist cannot but be conscious that he occupies a comparatively narrow field, and one from which the larger interests of mankind are daily further receding. In the more ancient meaning of the word genealogy indeed, when it is used to denote that grander task of the historian which consists in tracing the origin, not of privileged families or castes merely, but of races and groups of races, and even of the species itself, the subject is one that has an ever widening and deepening significance; but in this sense it does not call for treatment apart from the biological sciences.

Among the earliest of the genealogists of modern times may be mentioned Benvenuto de San Georgio (*Montisferrati Marchionum et Principum regiæ propaginis successionumque series*, 1515), Phili-

[1] All the earlier Greek historians appear to have constructed their narratives on assumed genealogical bases. The four books of Hecatæus of Miletus dealt respectively with the traditions about Deucalion, about Hercules and the Heraclidæ, about the early settlements in Peloponnesus, and about those in Asia Minor. The works of Hellanicus of Lesbos bore titles (Δευκαλιώνεια and the like) which sufficiently explain their nature; his disciple, Damastes of Sigeum, was the author of genealogical histories of Trojan heroes; Apollodorus Atheniensis made use of three books γενεαλογικῶν by Acusilaus of Argos; Pherecydes of Leros also wrote γενεαλογίαι. See Nicolai, *Griechische Literaturgeschichte*, i. 254 *sq.*; Schubart, *Quæstt. geneal. historicæ*, 1832; Marckscheffel, *De Genealogica Græcorum poesi*, 1840.

[2] The chief authority on this subject is Polybius (vi. 53).

[3] At the funeral of Drusus the images of Æneas, of the Alban kings, of Romulus, of the Sabine nobles, of Attus Clausus, and of "the rest of the Claudians" were exhibited.—Tac., *Ann.* iv. 9.

[4] The Roman stemmata had, as will be seen afterwards, great interest for the older modern genealogists. Reference may be made to Glandorp's *Descriptio Gentis Antoniæ* (1559); to the *Descriptio Gentis Juliæ* (1576) of the same author; and to Hübner's *Tabellen*. See also Ruperti's *Tabulæ Genealogicæ sive stemmata nobiliss. gent. Rom.* (1794, 1811); Drumann's *Geschichte Roms* (1834); and Becker's *Handbuch d. röm. Alterthümer*, vol. ii.

[5] Gatterer, *Abriss der Genealogie*, sec. 41 (1788). According to this author, there is only one class of cases in which it is possible to trace a pedigree beyond the 11th century,—those cases, namely, where a family happens to have established a fund for the deliverance of the souls of certain ancestors (Christian names specified) from purgatory.

bert Pingonius (*Arbor gentilitia Sabaudiæ Saxoniæque Domus*, 1521), Gebwiler (*Epitome regii ac vetustissimi ortus Caroli V. et Ferdinandi I. omniumque Archiducum Austriæ et Comitum Habsburgensium*, 1527), Meyer (*Flandricarum rerum tomi X. de origine, antiquitate, nobilitate, ac genealogia Comitum Flandriæ*, 1531), and Du Boulay (*Généalogies des tres illustres et tres puissants Princes les Ducs de Lorraine*, 1547). Georg Rüxner's *Anfang, Ursprung, und Herkommen des Thurniers in Teutscher Nation* (1532) was also genealogical in its character. Later in the same century several works of a much wider scope than any of the preceding appeared, the list being headed by Reineccius or Reineck of Helmstadt, whose voluminous compilations include a *Syntagma de familiis quæ in monarchiis tribus prioribus rerum potitæ sunt* (4 vols. fol., 1574–80), and an *Historia Julia seu Syntagma heroicum* (3 vols. fol., 1594–97); this writer was followed by Henninges (*Genealogiæ Saxonicæ*, 1587, and *Theatrum genealogicum ostentans omnes omnium ætatum familias Monarcharum, Regum, Ducum, Marchionum, Principum, Comitum, atque illustrium Heroum et Heroinarum; item Philosophorum, Oratorum, Historicorum quotquot a condito mundo usque ad hæc nostra tempora vixerunt*, 1598), Reusner (*Opus genealogicum catholicum de præcipuis familiis Imperatorum, Regum, Principum, Comitum*, &c., 1589-92, and *Stemma Wittichindeum*, 1592), Eytzing or Aitsingerus (*Paralipomena quibus Bavarica, Turcica, Anglica, Belgica, et Bohemica imperatorum, regum, ducum, marchionum, comitum, aliorumque Europæ procerum atque heroum stemmata continentur*, 1592), and others. In 1580 François de Rosières published at Paris the *Stemmata Lotharingiæ ac Barri ducum*, in which he professed to have proved the direct descent of the princes of Lorraine from Charlemagne; for having in this instance indulged in inconvenient as well as unscrupulous falsehood, he was arrested by the parliament of Paris, and thrown into the Bastille, from which he was not released till 1583, the book meanwhile having been suppressed. The 17th century was extraordinarily prolific in genealogical literature; in England it produced, amongst many similar works, Milles's *Catalogue of Honor* (1610) and Dugdale's *Baronage* (1675–76); of Continental writers the following are probably the most worthy of notice:—Emmius (*Genealogia Universalis*, 1620), André Duchesne (whose writings include an *Histoire Généalogique de la Maison de Montmorency et de Laval*, 1624, and an *Histoire Généalogique de la Maison de Vergi*, 1625), Pierre d'Hozier (*Généalogie de la Maison de la Rochefoucauld*, 1654), Rittershusius (*Genealogiæ Imperatorum, Regum, Ducum, Comitum, aliorumque Procerum ab anno MCCCC*, 1658, and *Brevis Exegesis Historica genealogiarum præcipuorum orbis Christiani procerum*, 1674, continued by Imhoff in the *Spicilegium Rittershusianum*, 1683), Spener (*Theatrum nobilitatis Europææ*, 1668, and *Insignium Theoria*, 1690), Lohmeier (*Historische Stammtafeln der kaiserlichen, königlichen, und fürstlichen Geschlechten*, 1690), Anselme de Sainte Marie (*Histoire Généalogique de la Maison de France*, 1694); but these, along with those of Bucelin, Dangeau, François Duchesne, Le Laboureur, Menestrier, Morgan, are only a few of the names which during the 17th century became associated more or less worthily with this branch of research. The pedigree of the Urquharts of Cromartie given by Sir T. Urquhart in his *Promptuary of Time* (1652) may perhaps be called an extreme specimen of the uncritical methods that characterized too much of the work of the genealogists of the period. Full bibliographies down to this date are given by J. F. Reimmann, *Historia litteraria de fatis studii genealogici apud Hebræos, Græcos, Romanos, et Germanos, in qua scriptores harum gentium potissimi enumerantur et totus Genealogiæ cursus ab orbe condito ad nostra usque tempora deducitur* (1702), and *Historiæ litterariæ exotericæ et acroamaticæ particula, s. de libris genealogicis vulgatioribus et rarioribus commentatio; accedit disquisitio historica de necessitate Scepticismi in studio genealogico* (1710); also by Joh. Hübner, *Bibliotheca genealogica; ein Verzeichniss aller alten u. neuen genealogischen Bücher von allen Nationen in der Welt* (1729). To the 18th century belong the *Peerage* (1709) and *Baronetage* (1720) of Collins, the *Genealogische Tabellen* (1725–1733) of Hübner, which in part were further elucidated by Lenzen (*Historisch-genealogische Untersuchungen und Erläuterungen der ersten 34 Hübnerischen Tabellen*, 1756), the works of J. L. L. Gebhardi, especially his continuation of Lohmeier and *Der Mohammedanischen und Heidnischen hohen Häuser historische und genealogische Erläuterung* (1731), and those of Gatterer (*Handbuch der Genealogie und Heraldik*, 1761, and *Abriss der Genealogie*, 1788), the latter being the first and still a useful manual upon the theory of genealogy. Of works belonging to the present century, one of the earliest was the *Atlas historique, généalogique, chronologique, et géographique* (1803–4) of Le Sage; and one of the greatest, bearing upon the general subject, was the famous Benedictine *L'Art de vérifier les dates* (1820–38). During recent years the stricter principles of criticism which have become characteristics of all modern historical investigation have made themselves felt in a very marked manner in the field of genealogical research. A wise scepticism has been increasingly shown with regard to all assertions which had not the support of adequate "diplomatic" evidence; and with the increased desire have come enlarged facilities for consulting ancient documents, either directly or by means of authentic reprints. So far as England is concerned, the improved arrangements with regard to the public records, and the various publications of the record commissioners, have brought the materials for a successful prosecution of this and cognate branches of antiquarian science within the reach of every zealous student; and although, in current *Peerages*, assertions which probably had no origin but in vanity, and certainly have no evidence except that of long unquestioned tradition, are still perpetuated, such statements can mislead none except the very unsophisticated. The principal and almost the only sources from which authentic family history can be drawn are such documents as the Domesday books; the chartularies, leiger books, registers, necrologies, calendars, and chronicles of the various monasteries, records which convey both directly and indirectly a vast amount of information as to the pedigrees of founders and patrons; also the tournament and crusade rolls sometimes found in these establishments; the various sorts of Chartæ Antiquæ, such as title deeds and enrolments in Chancery and other courts of justice; the books and rolls which record the returns to the successive inquisitions made into the state of the "Knights' Fees" which were granted at the time of the Norman Conquest; the Placita, in which are recorded decisions of parliament and other courts; the Rotuli, including charter rolls, patent rolls, pipe rolls, and many others; the Inquisitiones post mortem, sometimes inaccurately termed escheats; the records of heralds' visitations; monumental inscriptions, coats of arms, seals, &c. These sources are indicated with considerable fulness and discrimination in Grimaldi's *Origines Genealogicæ, or the Sources where English Genealogies may be traced from the Conquest to the Present Time* (1828), and, after him, by Sims in the *Manual for the Genealogist, Topographer, Antiquary, and Legal Professor*, 1856.[1]

The earliest printed "British Peerage" was that of Milles, entitled *Catalogue of Honor*, published in folio in 1610; but Camden's *Britannia* (1586) also contained many genealogies. Among recent works the best known are those of J. and J. B. Burke (*A Genealogical and Heraldic Dictionary of the Peerage and Baronetage of the United Kingdom*, 1822; 40th ed., 1877), of Lodge (*The Genealogy of the Existing British Peerage*, 1832–33; 48th ed., 1879), of Dod, and of Debrett; but the number of publications (inclusive of those of the London Genealogical and Historical Society) which have been, and continue to be, issued on this attractive subject is very great. For a bibliography approaching to completeness reference may be made to the privately printed *Catalogue of Works on the Peerage and Baronetage of England, Scotland, and Ireland*, prepared by Sir C. G. Young (1827), to Moule's *Bibliotheca Heraldica* (1822), or to Sims's *Manual for Genealogists*. In any list, however brief, the names of Dugdale (*The Baronage of England*, 1675–76) and of Collins (*A Peerage of England*, 1709; *The English Baronage*, of which only the first volume was ever completed, 1727) deserve a special place. The works of Sir R. Douglas on *The Peerage of Scotland* and *The Baronage of Scotland* appeared respectively in 1764 and 1796; that of John Lodge, on *The Peerage of Ireland*, in 1754. On the knightage of Great Britain and Ireland the most accessible writers are again Burke and Dod; but the work of Sir N. H. Nicolas (*A History of the Orders of Knighthood of the British Empire*, 4 vols. fol., 1842) is of more importance. As being somewhat of an innovation in genealogical literature, Burke's work on the commoners of Great Britain and Ireland may be mentioned here (*A Genealogical and Heraldic History of the Commoners of Great Britain and Ireland enjoying territorial possessions or high special rank but uninvested with heritable honours*, 1833–38).

For the purposes of genealogical research in the United States of America one society at least has been formed, "The New England Historical and Genealogical Society," under the auspices of which an annual *Register* is published. Among numerous other publications bearing upon this subject may be mentioned J. F. Holgate's *American Genealogy* (1851), Whitmore's *American Genealogy* (1868), Webster's *Genealogy* (1877), and Thomas's *Genealogical Notes* (1878). (J. S. BL.)

GENELLI, GIOVANNI BUONAVENTURA (1798–1868), was born at Berlin, September 28, 1798, and died at Weimar, November 13, 1868. He was the son of Janus Genelli, a painter whose landscapes are still preserved in

[1] According to Grimaldi, in 1828 there were 294 peers, exclusive of the royal family. Of these thirty-five claimed to have traced their descent to beyond the Conquest, forty-nine to a date prior to the year 1100, twenty-nine to the 12th century, thirty-two to the 13th, twenty-six to the 14th, seventeen to the 15th, twenty-six to the 16th, and thirty to the 17th. In the case of forty-five noblemen no satisfactory conclusion could be drawn as to the commencement of their pedigree. The pedigree of the Percys is one of the most full and complete genealogies of the kingdom. In Scotland the house of Mar is probably that which can at once carry its nobility to the remotest period (1093), and authenticate it by the best evidence

the Schloss at Berlin, and grandson to Joseph Genelli, a Roman embroiderer employed to found a school of gobelins by Frederick the Great. Buonaventura Genelli first took lessons from his father and then became a student of the Berlin Academy. After serving his time in the guards he went with a stipend to Rome, where he lived ten years a friend and assistant to Koch the landscape painter, a colleague of Hähnel, Reinhard, Overbeck, and Führich, all of whom made a name in art. In 1830 he was commissioned by Dr Härtel to adorn a villa at Leipsic with frescos, but quarrelling with this patron he withdrew to Munich, where he earned a scanty livelihood at first, though he succeeded at last in acquiring repute as an illustrative and figure draughtsman. In 1859 he was appointed a professor at Weimar, where he ended his days. Genelli painted few pictures, and it is very rare to find his canvasses in public galleries, but there are six of his compositions in oil in the Schack collection at Munich. These and numerous water-colours, as well as desighs for engravings and lithographs, reveal an artist of considerable power whose ideal was the antique, but who was also fascinated by the works of Michelangelo. Though a German by birth, his spirit was unlike that of Overbeck or Führich, whose art was reminiscent of the old masters of their own country. He seemed to hark back to the land of his fathers and endeavour to revive the traditions of the Italian Renaissance. Subtle in thought and powerfully conceived, his compositions are usually mythological, but full of matter, energetic and fiery in execution, and marked almost invariably by daring effects of foreshortening. Impeded by straitened means, the artist seems frequently to have drawn from imagination rather than from life, and much of his anatomy of muscle is in consequence conventional and false. But none the less Genelli merits his reputation as a bold and imaginative artist, and his name deserves to be remembered beyond the narrow limits of the early schools of Munich and Weimar.

GENERATION, a term in general biology or physiology synonymous with the Greek βιογένεσις and the German *Zeugung*, may comprehend the whole history of the first origin and continued reproduction of living bodies, whether plants or animals; but it is frequently restricted to the sexual reproduction of animals. The subject, in its most comprehensive aspect, would naturally be divided into the following branches, viz. :—(1) the first origin of life and living beings, (2) non-sexual or agamic reproduction, and (3) gamic or sexual reproduction. The first two of these topics have already been shortly treated of in the articles ABIOGENESIS and BIOLOGY; the third and more extensive division, including (1) the formation and fecundation of the ovum, and (2) the development of the embryo in different animals, it has been deemed expedient to refer to the heading REPRODUCTION.

GENESIS. See PENTATEUCH.

GENET (*Genetta*), a genus of carnivorous mammals belonging to the *Viverridæ* or family of civets. It contains six species, all of which are found exclusively in Africa, with the exception of the common genet (*Genetta vulgaris*), which occurs also throughout the south of Europe and in Palestine, where Tristram notes it as occurring on Mount Carmel. The fur of this species is of a dark grey colour, thickly spotted with black, and having a dark streak along the back, while the tail, which is nearly as long as the body, is prettily ringed with black and white. The genet is abundant in the south of France and in Spain, where it frequents the banks of streams, and feeds on the smaller mammals and on birds. In the vertically slit pupil of its eyes, and in the complete retractility of its claws, it approximates, along with the other species, to the cats, and correspondingly differs from the true civets, while the anal pouch which is so fully developed in the civet exists as a mere depression in the present genus, and contains only a faint trace of the highly characteristic odour of the former. In south-western Europe and in Africa it is sought after for its soft and

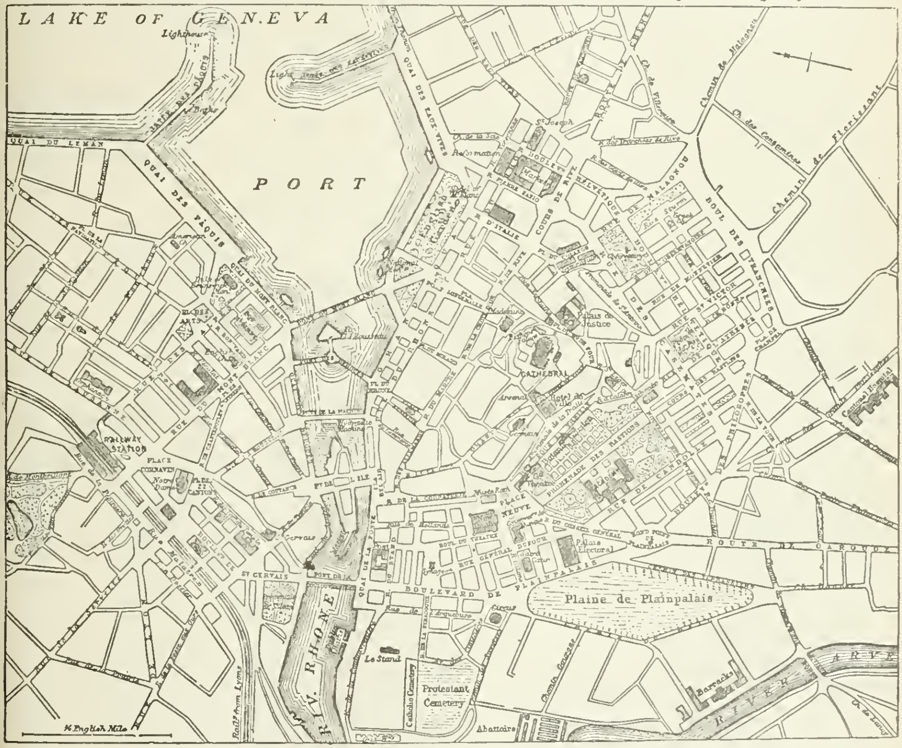
Genet.

beautifully spotted fur, while in Constantinople it has been tamed and kept like a cat for destroying mice and other vermin.

GENEVA (in French *Genève*, in German *Genf*, in classical Latin *Geneva*, and in Low Latin, by metathesis, *Gebenna* or *Gevenna*), a city and canton of Switzerland,—the canton being, with one exception, the smallest, and the city, without exception, the largest within the limits of the confederation.

The canton of Geneva has an area of 279·4 square kilometres, or 107·8 square miles, considerably less than that of Rutland, the smallest of the English counties, and this includes 11½ square miles of water-surface belonging to the lake. The greater part of its frontier is conterminous with France, the department of Haute-Savoie lying to the south, and that of Ain to the west and north; while it is connected with the Swiss canton of Vaud (Waadt) along a line of not more than 3½ miles. The area belongs to the basin of the Rhone, which flows for about 4 miles through the canton, and then for nearly 2 miles forms the boundary towards France. With the exception of the Arve, the Rhone tributaries are mere mountain streams, of which the largest is the London in the extreme west. Market gardens, orchards, and vineyards occupy a large proportion of the soil, whose apparent fertility, however, is due not so much to its natural qualities as to the noble industry of the cultivators. Besides building materials such as sandstone, slate, &c., the only mineral to be found within the canton is bituminous shale, the products of which can be used for petroleum and asphalte (see *Les Gisements bitumineux du canton de Genève*, Paris, 1877). While Geneva is, as has been stated, almost the smallest of the Swiss cantons, the size of the city makes the density of its population far greater than that of any other. In 1870 it had, inclusive of strangers, 93,239 inhabitants, or 871 to the square mile; and this had increased by 1876 to 99,352 inhabitants, or 921 to the square mile. At the earlier date, 43,639 were Protestants and 47,868 Roman Catholics,—the remaining fraction comprising 961 Jews, and 771 of various Christian sects. The prevailing language is French; but the German element, represented in 1870 by 978 households, is on the increase.

The city of Geneva is situated at the south-western extremity of the beautiful lake of the same name, whence the noble current of the Rhone flows westward under the five bridges by which the two halves of the town communicate with each other. To the south lies the valley of the Arve, which unites with that of the Rhone a little distance further down; and behind the Arve the grey and barren rocks of the Lesser Salève rise like a wall, which in turn is overtopped by the distant and ethereal snows of Mont Blanc. To the north-west the eye takes in the long line of the Jura, with a pleasant stretch of country between it and the lake. The actual site of the town, apart from the river and the lake, is not so picturesque as that of man other places in Switzerland. Though the central plateau, crowned as it is by the cathedral, gives a certain relief to the general view from the water, a large proportion of the town is built on the alluvial flats along the river. But what Geneva lacks in picturesqueness it now makes up in an appearance of prosperity and comfort,—presenting fine quays, well-ordered pleasure grounds, good streets, and substantial houses, and, in the number and extent of its modern suburbs, giving evidence that its prosperity is not a thing of the past. Since the demolition of the fortifications in 1848, it ha pushed eastward to Eaux Vives, and westward into Plainpalais, and an almost continuous succession of houses link it on the south with the village of Carouge beyond the Arve



Plan of Geneva.

In the strict sense of the words, Geneva is not a city of great buildings. It possesses, indeed, a great many edifices, both public and private, which may fittingly be described as handsome, elegant, or even beautiful, but it has almost nothing to which the memory reverts as to a masterpiece of architectural art. Being a favourite resort for wealthy foreigners from many lands, it has been enriched with a countless variety of hotels and villas, many of which are palatial in their dimensions, their construction, and their environment, and its principal institutions have been installed in buildings not unworthy of a modern capital; but none of these things compensate for the absence of the grander and more characteristic legacies of the Middle Ages and the Renaissance. The artistic blight of that Calvinism which was too sternly enamoured with the beauty of holiness to be mindful of any other beauty has left indelible effects on the central city of the creed; though it is probable that all the blame does not lie at the door of Calvinism, which certainly did not find in the Genevese a people whose æsthetic faculties had been too strongly developed in the previous periods of their history. The cathedral itself is a second-rate building; and though, as Mr Freeman remarks, "it is an excellent specimen of a small cathedral whose style and plan are peculiarly its own, and which has undergone only very few alterations," its main interest is moral and historical. According to a tradition, at least as likely to be true as false, it occupies the site of a temple of Apollo; and the present building is the third church of St Peter which has been erected on the spot. As a foundation the cathedral is said to date from the middle of the 10th century; but (even apart from documents still extant which relate to the works) the transition from the Romanesque to the Gothic style is sufficient evidence that it belongs architecturally to the 12th and the 13th. The most glaring alteration to which it has been subjected is the substitution for the original façade (1749–1756) of a portico with Corinthian pillars, copied after the Pantheon at Rome, which, while effective and simple enough in itself, is altogether out of keeping with the rest of the design. In its general plan the church is a Latin cross, having a width of about 65 feet and a length of 187. It is lighted by 86 windows,—those of the choir still preserving painted glass of the 15th century, and some of the others being filled with modern work in commemoration of the jubilee of 1835. Of the internal decorations, the little that has been left comprises portions of the carved stalls, and a few sepulchral monuments—most of them removed from their original sites—Agrippa d'Aubigné's, Michel Roset's, Theodore de Beza's, the duke and duchess of Rohan's, &c. Among the older secular buildings in Geneva are the Hôtel de Ville, the court-house, and the arsenal. The first, which is popularly called the Maison de Ville, or Town House, is situated to the west of St Peter's. It is first mentioned in 1448, but most of the structure dates from the 16th and 17th centuries. There is nothing remarkable, except their plainness, about the several halls or chambers—the hall of the lost footsteps, the chamber of the great council, &c. The *Salle des Festins* is now known as the Alabama Chamber, in memory of the arbitration decided within its walls in 1872. To the historian the building is interesting, not only for its associations, but for the magnificent series of archives which it contains. It was in front of the house that the works of Rousseau were publicly burned in 1762. (See *Nouv. Descr. du Hôtel de Ville*, 1877.) The court-house was formerly a hospital, and has been appropriated to its present purpose only since 1858. As a building it dates from 1709, and is a good specimen of the Mansard style in vogue at the time. Among the structures of modern date the most noteworthy are the academic or university buildings, the Athénée, the Rath museum, the conservatorium, the electoral palace, the new theatre, the hall of the reformation, and the Russian church. The first stone of the academic buildings was laid in 1868. They consist of three blocks forming three sides of a square, and occupy an excellent position near the botanic gardens in the Promenade of the Bastions. The Athénée, a highly ornamental building, was founded for the accommodation of the old society of the arts by the wealthy Genevese, J. G. Eynard (1775–1863), well known for his generous devotion to the cause of Greek independence. It was in 1824 and 1826 that, in accordance with his wishes, the sisters of the deceased Simon Rath (1766–1819), a general in the Russian service, devoted a large part of their fortune to the erection of the museum which preserves the name of the family. The building is in the Greek style, with a Corinthian portico and a flight of steps, and it contains a collection of copies of the cardinal masterpieces of ancient art and valuable works of the modern Swiss school. The conservatorium, whose foundation was due to Bartholony, a Genevese financier, owes its reputation as a musical school to Bovy Lysberg (1821–1873). The Fol museum, famous for its Greek and Etruscan vases, occupies the old Academy buildings in the Grand' Rue.

Among the larger benevolent institutions are the civic hospital, with an endowment of 3½ million francs, a lunatic asylum, a deaf and dumb institute, and an orphanage; and upwards of 200 distinct societies for philanthropic purposes are at work in the state.

From a comparatively early date the Genevese have given considerable attention to education. In 1429 François Versonnex endowed and restored the "great school," which continued to flourish till the Reformation, and was attended by numerous foreign pupils. An academy and college were established by Calvin and Beza in 1558, and soon became famous. Since 1875 the academy has ranked as a university, having five faculties,—a scientific, a literary, a legal, a theological, and a medical. Though medical teaching was long practised in Geneva by its more eminent physicians, according as circumstances suggested, there was no regular provision for this department till 1874, when a staff of 13 professors and 10 privat-docents was instituted. An anatomical theatre has been erected by the cantonal hospital, and a maternity hospital and a *policlinique* or dispensary are supported by the property of the suppressed religious corporations. In the winter session of 1876–7 the university had 142 regularly enrolled students and 182 unattached auditors; and in the summer session the students numbered 155 and the auditors 147. Of the 297 regular students, no fewer than 126 were foreigners, and only 106 were Genevese proper, while among the auditors the proportion of foreigners was still greater, or 187 as compared with 95. The canton of Geneva has no normal school, but there are two colleges (one in the town and one at Carouge), a gymnasium, and a high school for girls, and in those institutions the training of teachers is an object of attention. The Genevese college had 1134 pupils in 1876–7,—309 being foreigners, and of these 139 French. In all the primary schools, with the exception of those of Carouge, Plainpalais, and Eaux Vives, the mixed system is in vogue. Nearly all the communes, from Lancy in 1848 to Plainpalais in 1877, have been provided with educational libraries, the total number of the books in 1867 being upwards of 20,000. The "public library," formerly located in the Rue Ardaine and now in the university buildings, is an admirable institution, thoroughly deserving the title of public, as its books, without any needless formality, are at the service of even the casual reader. The first nucleus of the collection, which now numbers about 75,000 volumes, was Bonivard's bequest in 1568.

As early as the 14th century, Geneva was the seat of a flourishing silk trade, and its woollen fabrics were largely exported. Four times a year the streets of the town were filled with the traffic of its fairs, which were visited by the merchants of Venice, Florence, and Genoa, of France and German Switzerland. In the 16th century hats, ribbons, velvets, woollens, and gold and silver plate, were among the principal products of Genevese industry; the guild of armourers or *heaumiers* was a powerful corporation; and watchmaking was already carried to a high degree of perfection, under the influence of Charles Cusin, who had settled in the town in 1587. By 1685 there were 100 master watchmakers with 300 workmen, and 80 master jewellers with 200 workmen. In the 17th century the silk trade made great progress, and towards its close calico-printing was introduced by the Fazy family. During the 18th century the number of wealthy immigrants from Italy gave an impetus to the various architectural industries, but at the same time the political troubles tended to scatter the industrial population. Voltaire introduced a number of Genevese watchmakers to Ferney; the French sought to make Versoix a manufacturing centre; and the Government of Savoy established a royal watch factory at Carouge. Since the restoration of Genevese independence in 1813 the principal industries of the city and canton have steadily developed. According to the census of 1860, there were 515 master watchmakers and jewellers in the canton, and the number of workers in the trade was 4876, of whom 4004 were men and 872 women. As early as 1827, about 240 persons were employed in the manufacture of musical boxes, and this number had by 1873 increased to at least 1080 of both sexes, capable of turning out 13,000 boxes in a year. Among the minor industries are wood and ivory carving, the making of tools and scientific instruments, iron-smelting and engineering, and the manufacture of tobacco, soda water, and various chemical stuffs. Banking operations are conducted on a large scale, and printing and publishing have long been of prime importance to the city. Printing was introduced in 1478 by Steinschaben of Schweinfurth; and by 1563 there were 20 printing establishments in the city. Robert Stephen, having fled from Paris, was received a citizen of Geneva in 1556; but his son Henry found that the attentions of the consistory could be nearly as offensive and dangerous as those of the Sorbonne, and the great printing establishment over which he presided came to an untimely end. For details on the contributions made by Genevese inventors to the progress of the various arts, the reader may refer to Elie-François Wartmann's interesting brochure, *Notice historique sur les inventions faits à Genève*, Geneva, 1873.

It would be hard to find a city of the same size as Geneva which could claim the honour of being the birthplace of a greater number of eminent men; and still harder perhaps to find one that had extended its hospitality to so many foreigners of distinction. In the roll of its celebrities the first place is due to Jean Jacques Rousseau, who, in spite of its treatment of him, retained considerable affection for "ma république." The house in which he was born occupied the site of No. 69 of the present Rue Rousseau. Though M. Marc Monnier, himself a Genevese, has found materials for a volume on *Les poëtes de Genève*, such names as Mulhauser (1806–71), author of the dramatic poems *Sempach* and *Philibert Berthelier*, or Petit Senn (1792–1870), whose *Bluettes et Boutades* (1846) has gone through a number of editions, have hardly more than local reputation. Rodolphe Toepffer, the humoristic novelist, has attained a wider popularity, which may almost be called European. But the really famous Genevese are mostly men who have devoted themselves to the sciences, or to the more utilitarian forms of literature. Among the theologians are Mestrezat, the opponent of the Jesuits; Diodati, the translator of the Bible; the Tronchins, the Turrettines (Fr. and J. A.), Ed. Diodati, Felix Neff, Cæsar Malan, and Gaussen. Among the historical writers may be mentioned Baulacre, Mallet (of Scandinavian celebrity), De Lolme, Grénus, Sismondi, Picot, Cherbuliez, Sayous, Blavignac, and Galiffe; and among the philologists, Cramer, Leclerc, Casaubon, and Spanheim. To the medical sciences belong the names of Jean de Carro, Espine, and Charles de la Rive; and to the physical sciences Bonnet, Huber, De Luc, De Saussure, De Candolle, and Pictet. Pradier, the sculptor of the statue of Rousseau on the island in the Rhone, Chapponnière, Hornung, and Calame are the best known of the modern artists.

As far back as 1356 the town of Geneva is said to have contained 5800 inhabitants, and this by 1404 had increased to 6490, exclusive of the Bourg de Four and St Gervais outside of the fortifications. In 1545 the number is given as 12,500, but the plague and other causes had reduced it to 11,000 by 1572. After the revocation of the edict of Nantes it rose to 16,934 in 1698, no fewer than 3000 refugees having sought shelter within its walls. The 18th century was marked by a steady increase: 18,500 in 1711, 24,712 in 1782, and 26,140 in 1789. In 1850 the total was 31,238, of whom 5717 were from other parts of Switzerland, and 6513 from other parts of the world. The census of 1870 gave 46,783, or including the suburbs of Eaux Vives and Plainpalais, 61,486. The noteworthy fact about this increase is that it is due solely to immigration, for the Genevese families are far from prolific, and indeed have an indubitable tendency to die out (Galiffe, *Genève historique*, 1869).

ry. According to a well-known passage in Cæsar's *Commentaries*, he found Geneva the frontier town of the Allobroges, and when he crossed the bridge which even then spanned the river, he was no longer in the territory of the Allobroges but in that of the Helvetians. How long the little *oppidum* had been in existence before that time it is impossible even to conjecture; that the spot had in far earlier days been occupied by a cluster of crannogs may be accepted as rather more than a conjecture, though the extensive formation of new land within the historic period has completely buried whatever archæological evidence might otherwise have been available. There was a time clearly when the site of the present lower town was entirely submerged, and the waters of the lake and river found their shores along the edge of the rocky plateau of the upper town. The Allobroges were, it would appear, a Celtic people, and the name Geneva, according to the favourite etymology of modern investigators, has its explanation in the words *gen* and *ev*, the "issue" of the "waters." For several centuries of the Christian era the history of Geneva remains a blank, but remains of substructions, aqueducts, canals, inscriptions, statues, pottery, bronzes, arms, coins, &c., show that during the Roman period the town must have been a large and flourishing place, extending, if M. Galiffe is right, over the plateau of the Tranchées. Christianity must have been early introduced, the traditional apostles being Dionysius and Paracodus. In 456 the Celtic town passed under the dominion of the German Burgundians, and in 534 it was incorporated with the kingdom of the Franks. To Charles the Fat it was indebted for the right, sanctioned by Pope John VIII., of electing its bishops from among its own clergy. Optandus, the bishop whose election led to the decision of this point, was a supporter of Rodolph I., founder of Transjuran Burgundy; and it was at Geneva that Conrad the Salic caused himself to be crowned king of Burgundy in 1033. This accession of Conrad proved in several ways of moment to the town; for to him was due the first aggrandizement of the house of Savoy, and from him was derived the temporal sovereignty of its bishops. The counts of Genevois—a district to the south of the Genevan territory, now included in the French department of Haute Savoie—were partly reconciled to the loss of the authority they had previously had over the city when in 1070 they saw Guy of Faucigny Genevois, a member of their own family, elected to the episcopal see. The next bishop, however, Hubert or Humbert of Grammont, laid claim to all the rights and possessions alienated by Guy; and at length, in 1124, by the "Accord of Seyssel," the count of Genevois recognized the bishop as his superior under the emperor. Bishop Ardutius (1135–1185) had again to oppose the encroachments of the counts; but the emperor Barbarossa, to whom he appealed at the diet of Spires (1153), not only upheld his claims, but made him prince of the empire. As the bishops could not always attend in person to the civil concerns of his jurisdiction, a vidom or vidomne (*vice dominus*) was appointed, who had to judge according to the customs and usages of the city, and in difficult matters was assisted by the advice of three or four citizens, two canons of Geneva, and two nobles of the church. During the bishopric of Robert of Genevois (1277–1288), the Genevese sought protection from the encroachments of his family at the hands of the count of Savoy, Amadeus V.; and on Robert's death a contest for possession of the city took place between the count and the new bishop, William of Conflans (1288–1294). In the resulting anarchy the citizens learned to act for themselves, and in 1289 and 1291 we find the bishop complaining of certain procurators, syndics, or agents of the city who had acted as chief magistrates in peace and war. In 1293, however, the syndicate was (for the time) abolished. Between the count of Genevois, who held the castle at Bourg de Four, at the corner of the city, and the count of Savoy, who by the peace of Asti in 1290 had secured the office of vidomne, and now held the castle of the Island, both citizens and bishop were hard bestead. In 1320 the castle of Bourg de Four was demolished by Edward and Aymon, sons of the count of Savoy. When the emperor Charles IV. visited Geneva on his way to Avignon (1365), Amadeus V., the "Green Count," obtained the rank of imperial vicar over the old kingdom of Burgundy and over the city of Geneva; but William of Marcossay, who was bishop from 1366 to 1377, persuaded the emperor to abolish the vicariate by a bull at Frankfort (1366), and by a second bull at Prague (1367) to cancel all rights granted to the counts of Savoy over Geneva and its territory; and in 1371 Pope Gregory XI. caused the count to withdraw from the city his castellan and judges. The year 1387 is a memorable one in Genevese history, as the date of the publication by Bishop Adhémar Fabri (1385–1388) of the franchises which served for centuries as the Magna Charta of the city.[1] By the purchase of the countship of Genevois, Amadeus VIII. became possessor of all the country round the city; and although he accepted investiture from the bishop and took the oath of fealty, his ambition was simply biding its time. On the visit of Sigismund in 1455, he was raised to be duke of Savoy; and when Pope Martin V. shortly afterwards passed through the district, he sought to obtain complete jurisdiction over the city. Jean de Pierrescise, however, appointed bishop at the suggestion of the duke, who hoped to find in him an easy tool, was no sooner occupant of the see than he appealed to the people, obtained their vote against the alienation of the temporal rights of his predecessors, and swore in return for their support to maintain their liberties. In 1420 a bull of the emperor Sigismund formally declared that the city held directly of the empire. But by a strange turn of events, the indefatigable Amadeus did ultimately become master of Geneva,—not, indeed, by way of conquest or through the degradation of its bishopric, but by himself succeeding to the bishop's see. During the greater part of his pontificate as Felix V. he resided in Geneva; and on his resignation the council allowed him the administration of the bishoprics of Geneva and Lausanne. In the latter part of the 15th century, amid the dissensions of the house of Savoy, two facts deserve special notice for their effect on Geneva. The duke Louis, irritated against the Genevese because they had admitted his rebellious son Philip of Bresse within their walls, caused the king of France, his son-in-law, to establish a fair at Lyons, which withdrew the greater part of its traffic from the city of Lake Leman; and Bishop John Louis forming an alliance with Charles the Bold, the Swiss (for Geneva was still the last town of the Allobroges) inflicted a ransom of 20,000 crowns.

The beginning of the 16th century brought the long contest between Savoy and Geneva to a climax and a close. Into the struggle, interesting as it is, between the Mamelukes (Mamelus) or ducal party and the Eidgnots (Eidgenossen) or patriots, it is impossible to enter. The great heroes of the city are Philibert Berthelier, Pierre Lévrier, François of Bonivard, the prior of St Victor, and Besançon Hugues. To their patriotic devotion it owed its ultimate liberty, and the alliances with Freiburg and Bern, which, first formed in 1519 and 1526, were solemnly renewed in 1531. Meanwhile the Reformation was advancing in Switzerland. In 1532 Farel entered the city, and in 1535 the reformed doctrine was officially recognized as the religion of the state. In October 1536 a new actor appeared on the scene—John Calvin, then about 25 years of age. By force of intellect and strength of will he soon made himself the leader of the Protestant party, and proceeded to work out his ideal of government and society. While it rendered homage to many of the noblest elements of human nature, to purity, to honesty, to industry, to benevolence, this ideal had grievous defects; it forgot especially that all healthy moral action must be spontaneous, and that in regard to deeds as well as men it is a dangerous thing to confound the innocent with the guilty. The moral dictates of the sternest conscience of the community were to be the binding laws of every citizen. Religious observances were no longer to be the outcome of individual piety, but part of the inevitable routine of daily life. The church became the state; breach of ecclesiastical discipline was crime; innovation in dogma was treason. The Genevese as a people appear to have been naturally religious: in the old pre-Reformation times they had been distinguished for their liberality and kindness to the clergy, their appreciation of a good preacher, the abundance of their contributions for masses and prayers. Under the guidance of Calvin, this religiosity took a new and sterner cast. But a certain part of the citizens were not so willing to relinquish their liberty, and, under the name

[1] This document, consisting of 79 paragraphs, was translated into French, and published by Montyon, 8vo, 1507.

of Libertins or Liberty men, they contended earnestly against the establishment of the new régime. In 1538 they were so powerful that the four syndics were chosen from their ranks; and they had the satisfaction of seeing Calvin and Farel, on 23d April, expelled from the city by order of the little council, confirmed by the council of the two hundred and the council-general. But the Libertins did not know how to rule; anarchy and licence got possession of the city; the Catholic party recovered ground. Calvin was recalled, and, returning on 3d September 1541, at once re-established his system in all its vigour. The Libertin party again revolted; sixty of their number were condemned to death, and four who failed to make their escape were beheaded. In 1547 Jacques Gruet was executed as an utterer of threats against the dictator and a possessor of impious books; and in 1553 Michel Servetus was burned alive. To the historian of Geneva it is of comparatively little importance whether or not the main guilt of this too famous crime fell directly and solely on Calvin himself; it is condemnation enough that such a deed was possible within the walls of a city where his fiat and his veto were equally supreme. And on the other hand, it must never be forgotten that the very reason why the faggot fire in which Servetus perished has become such a beacon to after times, while the smouldering embers round a Dolet or a Vanini are only now and then stirred to a fitful glare, is that Calvin had made Geneva a city set upon a hill, and that the lurid smoke and flame showed doubly dark against the clear light of his wonderful intellect and his noble life. In some respects Geneva was never greater than under his dictatorship. It was at once the moral capital of the half of Christendom and the great frontier fortress against the invasions of Rome. Like every fortress city, it had to pay the penalty of its position, and the penalty was none the less because its garrison fought with spiritual weapons, and its martial law interfered with the liberties of the mind. In 1564, after twenty-three years of such labours as few men could rival, Calvin died, and his body was laid in the cemetery of Plainpalais; but his spirit continued to live in the constitution he had founded. The milder character of his successor, Theodore Beza, allowed free scope to the other members of the Government, and the democratic element obtained greater prominence. About 1564 Geneva appeared for a time in danger from its Catholic neighbours, and especially from the duke of Savoy; but though this prince recovered possession of the Chablais, the Genevois, and the country of Gex, and appointed Francis of Sales titular bishop of Geneva, no direct attempt was made against the independence of the city. The year 1568 is of note for a revision of the constitution, drawn up by Germain Colladon, which, while retaining in the main the Calvinistic framework, practically placed political power in the hands of a few principal families. The administration nominally consisted of the syndicate and four councils—the council of the twenty-five, the council of the sixty, the council of the two hundred, and the council general; but the council of the twenty-five, usually called the "little" or "narrow council," managed in the long run to arrogate the direction of all public affairs. During the 16th century, both before and after the Colladon revision, the variety of affairs which were considered under its jurisdiction is sufficiently amusing. It was at once the foreign office of the republic and the high court and the police court combined; and it accordingly passed, as matter of course, from the consideration of matters of state, in which the potentates of Europe were parties, to the squabbles of market women, the use of bad eggs in cakes, or the length of a minister's sermon.[1] Its private deliberations were kept strictly secret: in 1491 the betrayer of any of its transactions was judged "infamous," and in 1530 it was added that his tongue should be pierced. Torture was still retained as a legal instrument of investigation, and the penal enactments against heresy and witchcraft remained unrepealed. In 1579 the city was taken under the protection of Bern and Soleure, and in 1584 it formed an alliance with Zurich; but these agreements proved of little advantage, and in the conflicts which were always being renewed with the duke of Savoy, Geneva was left to her own resources, and the accidental assistance of Elizabeth of England or Henry IV. of France.

At length, in 1602, Charles Emmanuel of Savoy determined to seize the city by a *coup de main*, and on the night of the 11th and 12th December (O.S.) an army of 8000 men were despatched against it. As no declaration of war had been made, the citizens were taken by surprise; and the enemy had fixed their scaling ladders and were already mounting the walls before the alarm was given. But once aroused, the Genevese were not long in turning this success into discomfiture and rout, and when morning broke the city was once more safe, and a joyous crowd heard the voice of the aged Beza in the cathedral read out the grand old Psalm, "Now may Israel say, If the Lord had not been with us." Such is the famous "Escalade," the Bannockburn of the Genevese, which has since been celebrated with all possible forms of celebration.[2] By the treaty of St Julian in the following year the duke of Savoy granted the Genevese freedom of trade, restored the lands of St Victor and St Peter, and promised to build no fortress and assemble no troops within four leagues of the city, but the ambitious prince made one more attack before his death in 1620. During the rest of the 17th century the history of Geneva consists mainly of dissensions between different councils, and between the governing bodies and the people; but amid them all the city advanced in prosperity, especially after the accession to its population occasioned by the revocation of the edict of Nantes. The 18th century brought the political contest to a head. In 1707 Fatio, advocate and member of the two hundred, was appointed president of a commission charged to formulate the grievances of the people. In the document which he drew up he maintained the sovereignty of the people, the equality of all citizens, and the subordination of the magistracy as mere executive functionaries; and at the same time demanded that the council-general should meet at least once a year, and not only when the syndics chose. The councils appeared to yield, but shortly afterwards, supported by confederates from the oligarchical cities of Bern and Zurich, they crushed the popular party, and caused Fatio to be shot. How sternly they were disposed to resent interference was shown in 1731 by their sentence of perpetual imprisonment passed on Micheli Du Crest for merely giving expression to the popular opposition to the new system of fortifications carried out by the councils. The party of which he was so far a spokesman—known as the *representants*—at length, in 1734, gained a decided victory in the general council of 1734. By the edict of 1738, though the whole initiative in matters of legislation was left in the hands of the lesser councils, the actual passing of laws and fixing of taxes were entrusted to the general council, and thirty years later the people obtained the right of naming the half of the council of the two hundred. There was an important class of the inhabitants, however, who were still excluded from political rights—the so-called "natives" or descendants of the aliens who had settled in the city; and this class continued to make known its discontent. At length, in 1782, Bern, Sardinia, and France interfered in favour of the aristocratic party, and by the Act of Pacification the most important reforms in a liberal sense were again abolished. A few years later, and France was under a different régime. The Revolution at Paris was followed by a revolution at Geneva. A new constitution, accepted by the National Assembly in 1794, declared the political equality of all the Genevese; but, by a curious inconsistency, the national committee of finances divided them again into aristocrats, the *englués*, and the patriots, taxing the last class much less heavily than the others. In March 1798 it was agreed that Geneva should become a part of the French republic, and on 13th June the French authorities entered the city. By the treaty of Paris its independence was restored, and it became one of the cantons of the Swiss confederation. A new constitution declared all the citizens equal, and placed the legislative power in the hands of a representative council. As no one, however, could be an elector who paid less than 20 Swiss livres, or about 23 shillings, of direct taxes, the democratic character of the system was considerably modified. It was not till 1841 that any great change was effected. In the early part of that year the "Third of March Society" was formed to watch over the interests of the citizens, and in October the Government was forced by a popular demonstration to summon a constituent assembly.

The legislative power for the canton was now placed in a grand council, consisting of representatives elected in the ratio of 1 to every 333 inhabitants; and the executive power in a council of state consisting of 13 members chosen by and from the grand council. At the same time the city received a communal council of 81 members, and an administrative council of at most 11 members. But the new constitution was not allowed to work long. The radical party had been gathering strength, especially in St Gervais, and in 1846 the Government, finding that the attempt to suppress its opponents by force of arms was of doubtful result, gave in its resignation. A provisional Government, under the leadership of the democrat James Fazy, drew up a constitution, which was accepted by the people on 24th May 1847. The franchise was bestowed even on the pauper class of prolétaires, and the election of the council of state was entrusted to the council general or collective assembly of citizens. The old Protestant church of Geneva was abolished, and a new and almost creedless church established, the government of which was vested in a consistory elected by the universal suffrage of Protestants in the canton. For nearly fifteen years the radical party continued in power; and under its hands the physical condition of Geneva was rapidly transformed, and, for good or evil, the city was brought as much as possible into the general current of European progress. "On voudrait faire de Genève," sighed the conservative De le Rive, "la plus petite des grandes villes, et pour moi je préfère qu'elle reste la plus grande des petites villes." Unfortunately for its permanence the radical Government was lavish in its expenditure, and the finances of the canton and city got into a dangerous condition. In November 1861 Fazy was not returned to the council of state; in 1862 the conservative party obtained a majority in the great council; and in 1863, though all the other radical candidates for the council of state were carried, Fazy himself was rejected. The attempt

[1] See "Le Petit Conseil" in *Étrennes genevoises*, Geneva, 1877.

[2] See H. Hamman, *Les Représentations graphiques de l'Escalade*, Geneva, 1869; and the drama of Mulhauser, the national poet, 1865.

to invalidate the election of his opponent Chenevière led to a conflict between the parties, in which some blood was shed; and the city was consequently occupied by federal forces, and the matter submitted to the federal council. As the decree was in favour of Chenevière, Fazy retired from public life. The "independents," as the opponents of the radicals are called, came into power in 1865, and for a number of years they fully maintained their position, in spite of the difficulties thrown in their way by the Ultramontane party. Their principal antagonist was Mermillod, the vicar of the bishop of Freiburg, who was declared bishop of Geneva by the pope, and insisted on exercising his episcopal functions without regard to the Government. In February 1873 Mermillod was banished by the federal council of Switzerland, and in the same year the grand council of Geneva deprived all Roman Catholic priests who refused to take the oath of allegiance to the state. Fazy's bill for the separation of church and state was rejected in June 1876; religious corporations were abolished on 23d August, and, on the 26th of the same month, all public ecclesiastical services outside of the churches were forbidden. The cathedral of Geneva was handed over to the Old Catholics. On the 6th of November 1878 Fazy died, and two days after the "conservative-democrat" party gained a victory in the elections for the great council. The expelled curés were now allowed to return, and in December the council accepted the principle of the separation of church and state.

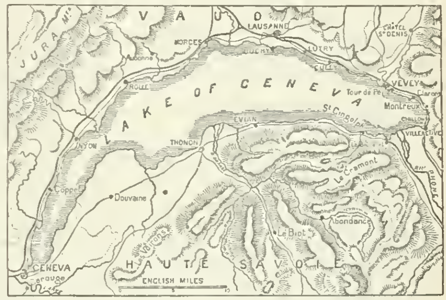
GENEVA, THE LAKE OF (the Latin *Lacus Lemanus* or Lake Leman, also known in the Middle Ages as Lac Losannete or Lake of Lausanne, and as Mer du Rhône or Sea of the Rhone), is the largest of the Swiss lakes, having an area of 578 sq. kil. or 223 sq. miles. Its general form is that of a crescent, the northern shore being almost the arc of a circle, with a radius of $21\frac{1}{2}$ miles. The eastern end of the crescent is broad and rounded, while the western tapers towards Geneva. Its maximum breadth, between Morges and Amphion, is $8\frac{1}{2}$ miles. It is divided into two portions, the Great and Little Lake, by the strait of Promonthoux, which is not much more than 2 miles across. The Great Lake is 39 miles long, with a mean breadth of 6 miles, and the Little or Western Lake is 14 miles long, with a mean breadth of rather more than 2 miles. The bottom of the larger basin forms a wide valley, which gradually deepens from 200 to 325 feet at the foot of the slopes to a maximum of 1095 feet, which it attains between Ouchy and Évian. The mean level of the surface of the lake is 1230 feet above the level of the sea. According to the elaborate soundings made in 1873 by M. Gosset, engineer of the Federal Topographic Department, the bottom is remarkably free from inequalities, almost all traces of rocks, erratic blocks, or moraines, having been covered over by a regular bed of extremely fine argillo-calcareous mud, which can be moulded and baked like potter's clay. Between the basin of the Great Lake and that of the Little Lake there runs a ridge or bar not very strongly marked, 200 feet from the surface. The maximum depth of the lesser basin is only 71 metres or 233 feet. The bottom is apparently level, but it presents numerous erratic blocks, and in one place rises to a considerable eminence, known to the Genevese fishers as the Hauts Monts.[1] The unusual blueness of the waters of the Leman has long been remarked. According to M. Forel,[2] the transparency is very much greater in winter than summer, the extreme limit of visibility of a white disk on an average for the seven winter months from October to April being 41 feet, and for the five summer months 21·6. This arises from the thermal stratification of the water keeping in suspension a greater quantity of dust and organic particles during summer. It is generally in August that the level of the lake reaches its highest limit, between 4 and 5 feet on an average above its lowest limit, which is usually reached in March. Besides this seasonal change, due to differences of influx and removal of water, several disturbances of level of a less obvious kind have attracted the attention of the Swiss physicists. Most remarkable are the *seiches*, or "movements of steady uninodal oscillation," in which the whole mass of water in the lake rhythmically swings from shore to shore. According to M. Forel,[3] there are both longitudinal and transverse *seiches*. Their effect is most distinctly seen at Geneva, where they sometimes raise the level of the water from 4 to 5 feet. They are not improbably due to several distinct causes, but the most efficient would appear to be a difference of barometric pressure in different parts of the



Lake of Geneva.

lake. In the eastern portion of the lake there is an irregular but violent current during spring and autumn, called Lardeyre or La Dière, which is supposed to be due to subterranean affluents. The principal winds are the Bise from the north-east, the stormy Bornand that rushes from the ravines of Savoy, and the dry south wind, known as the Séchard. Less use is made of the lake as a means of communication since the opening of the railway along the Swiss shore, but the lateen sails of the minor craft still brighten the landscape, and an excellent steam service is maintained by a company formed in 1873. The first steamboat, the "William Tell," was introduced on the lake in 1823; and the first saloon steamboat, the "Mont Blanc," dates only from 1876.

The Lake of Geneva is not so rich in fish as many of the smaller lakes of Switzerland.[4] Comparatively small success has attended the attempts of Professor Chavannes of Lausanne to introduce the salmon, which, like many other fishes, finds the Perte du Rhône a barrier between

[1] Further details on the conformation of the lake will be found in De la Beche's letter to Professor Pictet, published in *Bibliothèque Universelle: Sciences et Arts*, t. xii., 1817; in M. Gosset's *Carte Hydrogr. du Lac Léman*, issued as part of the *Topog. Atlas der Schweiz*, and described in *Bibl. Un.* (*Sci. et Arts*), t. lii., 1875, and in a *Note sur la Carte du Lac*, by Ed. Pictet, in the same number.

[2] "Études sur les variations de la transparence des eaux du lac Léman," in *Bibl. Un.* (*Sc. et Arts*), 1877.

[3] M. Forel's numerous studies on the subject will be found in the *Bibliothèque Universelle*, and the *Bulletin de la soc. vaud.* (Lausanne).

[4] According to G. Lunel, whose *Histoire naturelle des poissons du bassin du Léman*, (Geneva, 1874) has superseded the valuable memoir of Professor Jurine in the *Memoires de la Société de physique*, tome iii. (1825), there are 21 species:—*Perca fluviatilis*, L.; *Cottus gobio*, L.; *Lota vulgaris*, Cuv.; *Cyprinus carpio*, L.; *Cyprinopsis auratus*, L.; *Tinca vulgaris*, Cuv.; *Gobio fluviatilis*, Cuv.; *Alburnus lucidus*, Heckel; *Alb. bipunctatus*, L.; *Scardinius erythrophthalmus*, Bonap.; *Leuciscus rutilus*, L.; *Squalius cephalus*, Bonap.; *Phoxinus lævis*, Ag.; *Cobitis barbatula*, Lin.; *Coregonus fera*, Jurine; *Coregonus hiemalis*, Jurine; *Thymallus vulgaris*, Nilsson; *Salmo umbla*, L.; *Trutta variabilis*, G.L.; *Esox lucius*, L.; *Anguilla vulgaris*, Fleming.

the sea and the lake. The "fera" (*Coregonus fera*) is economically the most important species. In the mud at the bottom of the lake there exists an interesting fauna, of about 40 species, mainly belonging to the lower orders. Several of the species, as *Gammarus cœcus*, are found 1000 feet below the surface, in the reign of perpetual darkness. Two species of gastropods of the genus *Limnœus* are worthy of special note as possessing developed lungs, though they live at a depth of from 150 to 300 feet.[1]

See Rodolphe Rey, *Genève et les rives du Léman*, 3d ed. (Geneva, 1875); Egli, *Taschenbuch Schweizerischen statistiks* (Zurich, 1875); Herbst, *Der Genfer See und seine Umgebung* (Weimar, 1877).

GENEVA, a post village of Ontario county, New York, U.S., is beautifully situated at the north end of Seneca Lake, on the New York central railway and at the terminus of the Ithaca branch railway, 52 miles E.S.E. of Rochester. One of its chief features is the terraced gardens, which extend from the principal street to the shore of the lake; and there are also two fine parks. Geneva is the seat of Hobart Free College, which is under Episcopalian management, and has 9 professors and about 50 students. It has also a graded union school, attended by upwards of 1000 pupils. The prosperity of the town depends chiefly on the nurseries in the neighbourhood, which extend to nearly 10,000 acres, and from which plants to the value of more than 1,000,000 dollars are shipped annually. There are also marble-works, benching-works, and iron-works. A daily line of steamers plies between Geneva and Watkins at the head of the lake. The population in 1870 was 5521.

GENEVA CONVENTION, an agreement concluded at an international conference which was held at Geneva in 1864, under the presidency of General Dufour the Swiss plenipotentiary, for the purpose of ameliorating the condition of the sick and wounded in time of war. The credit of originating this conference must be given to two citizens of Geneva, Dunant, a physician, who published a startling account of what he had seen in two military hospitals on the field of Solferino, and his friend Moynier, chairman of the Geneva society of public utility, who took up the idea of "neutralizing the sick waggons," formed associations for its agitation, and at length pressed it upon the Governments of Europe, most of which sent representatives to the conference. The convention was drawn up and signed by them on the 22d August, and since then it has received the adherence of every European power, and one Asiatic (viz., Persia). The convention consists of ten articles, of which the last two are formal.

The others provide (1) for the neutrality of ambulances and military hospitals as long as they contain any sick; (2) for that of their staff; (3) that the neutrality of these persons shall continue after occupation of their hospitals by the enemy, so that they may stay or depart, as they choose; (4) that if they depart, they can take only their private property with them, except in case of ambulances, which they may remove entire; (5) that a sick soldier in a house shall be counted a protection to it, and entitle its occupant to exemption from the quartering of troops and from part of the war requisitions; (6) that wounded men shall, when cured, be sent back to their own country on condition of not bearing arms during the rest of the war; (7) that hospitals and ambulances shall carry, in addition to the flag of their nation, a distinctive and uniform flag bearing a red cross on a white ground, and that their staff shall wear an arm-badge of the same colours; (8) that the details shall be left to the commanders.

A second conference was held at Geneva on the same subject in 1868, and a supplementary convention drawn out, which, though not formally signed, has been acquiesced in by all the signatories of the original convention, except the pope, and which, while still unratified, was adopted provisionally by France and Germany in their war of 1870. It consists partly of interpretations of the former convention, and partly of an application of its principles to maritime wars. Its main provisions are these:—

That, when a person engaged in an ambulance or hospital occupied by the enemy desires to depart, the commander-in-chief shall fix the time for his departure, and, when he desires to remain, that he be paid his full salary; that account shall be taken in exacting war requisitions not only of actual lodging of wounded men but of any display of charity towards them; that the rule which permits cured soldiers to return home on condition of not serving again shall not apply to officers, for their knowledge might be useful; that hospital ships, merchantmen with wounded on board, and boats picking up wounded and wrecked men, shall be neutral; that they shall carry the red-cross flag and their men the red-cross armlet; that hospital ships belonging to Government shall be painted white with a green strake, those of aid societies white with a red strake; that in naval wars any strong presumption that the convention is being abused by one of the belligerents shall give the other the right of suspending it towards that power till the contrary is proved, and, if the presumption becomes a certainty, of suspending it to the end of the war.

GENEVIÈVE, or GENOVEFA, ST, patroness of Paris, flourished during the latter half of the 5th century. She was born about 425 at Nanterre near Paris, or according to another tradition at Montriere; her parents were called Severus and Gerontia, but accounts differ widely as to their social position. According to the legend, she was only in her seventh year when she was induced by Bishop (afterwards Saint) Germain d'Auxerre to dedicate herself to the religious life. On the death of her parents she removed to Paris, where she distinguished herself by the activity of her benevolence, as well as by the austerity of her sanctity. She is said to have been the recipient of supernatural revelations, and to have predicted the invasion of the Huns; and when Attila with his army was threatening the city, she gave courage to the panic-stricken inhabitants by an assurance, justified by subsequent events, to the effect that the attack would come to nothing (451). In the year 460 she caused a church to be built over the tomb of St Denis, where the abbey was afterwards raised by Dagobert I. Her death occurred in 500, or according to another account in 512, and her remains were ultimately laid in the chapel bearing her name, which has now become merged in the Pantheon or Église St. Geneviève. Charpentier published in 1687 a life of the saint based upon the statements of an anonymous author who is alleged to have written her biography only eighteen years after her death. The legends, miraculous and other, are also given in the Bollandist *Acta Sanctorum* and in the great work of Tillemont. Her festival is celebrated on the 3d of January.

The "Canonici of St Geneviève," or "Canonici of the congregation of France," constitute a religious order dating from 1614, in which year they were organized by Charles Faure, a reforming monk belonging to the abbey of St Vincent at Senlis. They rapidly came into considerable repute; and for a considerable period the chancellor of the Sorbonne was invariably chosen from their order. The "daughters of St Geneviève" were constituted in 1636 at Paris, at the instance of a pious nun of the name of Blosset, but since their union, in 1665, with the order "of the Holy Family," whose lady-foundress was called Miramion, they have been best known as Miramiones. They find their chief employment in tending the sick, and in the education of girls.

GENGA, GIROLAMO (c. 1476–1551), a painter and architect, was born in Urbino towards 1476. At the age of ten he was apprenticed to the woollen trade, but showed so much inclination for drawing that he was sent to study under an obscure painter, and at thirteen under Luca Signorelli, with whom he remained a considerable while, frequently painting the accessories of his pictures. He was afterwards for three years with Pietro Perugino, in company with Raphael, and he developed a similar style of painting. He next worked in Florence and Siena, along with Timoteo della Vite; and in the latter city he painted various compositions for Pandolfo Petrucci, the leading local statesman of the time. Returning to Urbino, he was employed by Duke Guidobaldo in the decorations of his palace, and showed

[1] For details see Forel's contributions to the *Bulletin de la soc. vaudoise des sc. nat.*, t. xiii., &c.

extraordinary aptitude for theatrical adornments. Thence he went to Rome; and in the church of S. Caterina da Siena, in that capital, is one of his most distinguished works, The Resurrection, remarkable both for design and for colouring. He studied the Roman antiquities with zeal, and measured a number of edifices; this practice, combining with his previous mastery of perspective, qualified him to shine as an architect. Francesco Maria, the reigning duke of Urbino, recalled Genga, and commissioned him to execute works in connexion with his marriage-festivities. This prince being soon afterwards expelled by Pope Leo X., Genga followed him to Mantua, whence he went for a time to Pesaro. The duke of Urbino was eventually restored to his dominions; he took Genga with him, and appointed him the ducal architect. As he neared the close of his career, Genga retired to a house in the vicinity of the city, continuing still to produce designs in pencil; one, of the Conversion of St Paul, was particularly admired. Here he died on the 11th of July 1551. Genga was a sculptor and musician as well as painter and architect; and he wrote various essays, as yet unpublished, on the arts. He was jovial, an excellent talker, and kindly to his friends. His principal pupil was Francesco Menzocchi. His own son Bartolommeo, (1518–1558), also a pupil, became an architect of celebrity. In Genga's paintings there is a great deal of freedom, and a certain peculiarity of character consonant with his versatile, lively, and social temperament. One of his leading works is in the church of St Augustine in Cesena,—a triptych in oil-colours, representing the Annunciation, God the Father in Glory, and the Madonna and Child. Among his architectural labours are the church of the Baptist in Pesaro, one of the finest edifices in that neighbourhood; the bishop's palace at Sinigaglia; the façade of the cathedral of Mantua, ranking high among the productions of the 16th century; and a new palace for the duke of Urbino, built on the Monte Imperiale. He was also concerned in the fortifications of Pesaro.

GENGIS KHAN. See JENGHIZ KHAN.

GENLIS, STÉPHANIE-FÉLICITÉ DUCREST DE SAINT-AUBIN, COMTESSE DE (1746–1830), a voluminous French writer, was born of a noble but impoverished Burgundian family, at the Château de Champcery, near Autun, on the 25th of January 1746. When six years of age, she was received as a canoness into the noble chapter of Alix, near Lyons, with the title of Madame la Comtesse de Lancy, taken from the town of Bourbon-Lancy, of which her father was at that time superior. Her entire education, however, was conducted at home under the eye of her mother by an accomplished governess. In 1758 she removed along with her mother to Paris, where her skill in music and her vivacious wit speedily attracted attention and admiration. Her marriage with the Comte de Genlis, a colonel of grenadiers, who afterwards became marquis of Sillery, took place in her sixteenth year, but was not suffered to interfere with a rapidly developing taste for acquiring and imparting knowledge. Some years later, through the influence of her aunt, Madame de Montesson, who had been clandestinely married to the duke of Orleans, she entered the Palais Royal as lady-in-waiting to the duchess of Chartres (1770); and, after having acted with great energy and zeal as governess to the daughters of the family, she was in 1781 appointed by the duke to the responsible office of "gouverneur" of his sons, a bold step which, though it led to the resignation of all the tutors as well as to much social scandal, can hardly in fairness be held to have seriously prejudiced the intellectual interests at least of those committed to her charge. The better to carry out her theory of education, she wrote several works for the use of her royal pupils, the best known of which are the *Théâtre d'Éducation* (1779–80), a collection of short comedies for young people, and *Les Annales de la Vertu* (1781). When the Revolution of 1789 occurred, Madame de Genlis showed herself not unfavourable to the movement, and is said to have had considerable influence on the conduct of the duke of Orleans; but the fall of the Girondins in 1793 compelled her to take refuge in Switzerland along with her pupil Mademoiselle d'Orleans. It was in this year that her husband, the marquis of Sillery, from whom she had been separated since 1782, perished on the scaffold. An "adopted" daughter, Pamela Berkley or Simms, had been married to Lord Edward Fitzgerald in the preceding December (see Sir Bernard Burke's *Rise of Great Families*, 1872). In 1794 Madame de Genlis fixed her residence at Berlin, but having been expelled by the orders of King Frederick William, she afterwards settled in Hamburg, where she supported herself for some years by writing and painting. After the revolution of 18th Brumaire (1799) she was permitted to return to France, and was received with favour by Napoleon, who gave her apartments at the arsenal, and afterwards assigned her a pension of 6000 francs. During this period she wrote largely, and produced what is generally considered to be her best romance, entitled *Mademoiselle de Clermont*. At the restoration she succeeded in adjusting herself once more to the new state of things, and continued to write with all her former diligence. Her later years were occupied largely with literary quarrels, notably with that which arose out of the publication of the *Dîners du Baron d'Holbach*, a volume in which she set forth with a good deal of sarcastic cleverness the intolerance, the fanaticism, and the eccentricities of the "philosophes" of the 18th century. Madame de Genlis before her death, which occurred on the 31st of December 1830, had the satisfaction of seeing her former pupil, Louis Philippe, seated on the throne of France.

The numerous works of Madame de Genlis (which considerably exceed eighty), comprising prose and poetical compositions on a vast variety of subjects and of various degrees of merit, owed much of their success to adventitious causes which have long ceased to operate, and they are now but little read. The swiftness with which they were written, their very multiplicity, and their diffuseness, all forbid us to look in them for thought of perennial value or literary art of any high order. They are useful, however (especially the voluminous *Mémoires*), as furnishing material for history; and she herself can hardly pass altogether unnoticed in the crowd which thronged the stage of public life in the confused and busy time of the French Revolution. Most of her writings were translated into English almost as soon as they were published.

GENNADIUS. Georgius Scholari or Scholarius, better known as Gennadius, a learned Greek and for some time patriarch of Constantinople, obtains a place in history through the important part played by him in the contest between Platonism and Aristotelianism which marks the transition from mediæval to modern thought. Extremely little is known of his life, and so contradictory are some of the accounts bearing on detached facts in it that it has often been supposed there were two writers of the same name living at the same period. The researches of Renaudot seem, however, to render it approximately certain that all the historical notices we possess relate to one Scholarius, and that the apparent inconsistency in the accounts is due largely to a real change in that writer's views. Scholarius first appears in history as assisting at the great council held in 1438 at Ferrara and Florence with the object of bringing about a union between the Greek and Latin Churches (see EUGENIUS IV., BESSARION). At the same council was present the celebrated Platonist, George Gemistus Pletho, the most powerful opponent of the then dominant Aristotelianism, and consequently the special object of reprobation to Gennadius. In church matters, as in philosophy, the two were opposed,—Pletho maintaining strongly the principles of the Greek Church, and being unwilling to accept union through compromise, Gennadius, more politic and cautious, pressing the necessity for union, and instrumental in drawing up a form which from its vagueness and ambiguity might be accepted by both parties. It would seem that at Florence Pletho published the work on the difference between Aristotle and Plato (see GEMISTUS) which afterwards called forth a reply from Gennadius. Of this reply only the fragments quoted by Pletho in his counter-argument (*Contra Gennadium*) have been preserved. They show that Gennadius, though Aristotelian throughout, had an accurate knowledge of Aristotle, and was more moderate than some of his contemporaries, *e.g.*, George of Trebizond. The next appearance of Gennadius is in 1453. After the capture of Constantinople by the Turks, Mahomet, finding that the patriarchal chair had been vacant for some time, resolved to elect some one to the office. The choice fell on Scholarius, who is described as a layman. While holding the episcopal office Gennadius drew up, apparently for the use of Mahomet, a symbol or confession of faith, which is very valuable as the earliest expression of the principles of the Greek Church. He also at this time had the pleasure of condemning to the flames the great work of his old opponent Pletho, the treatise on *Laws* (Nόμοι), of which considerable fragments have come down to us. The character of this work was accurately apprehended by Gennadius (see his *Letter to the Exarch Joseph*, in Gass, as below), and his opposition to it is intelligible. After a short period of office at Constantinople Gennadius is said to have resigned the episcopal dignity and to have retired into a convent. The date of his death is unknown.

The fullest account of his writings is given in Gass (*Gennadius and Pletho*, 1844), the second part of which contains Pletho's *Contra Gennadium*. See also F. Schultze, *Gesch. der Phil. d. Renaissance*, i., 1874. A list of the known writings of Gennadius is given in Fabricius, *Bibliotheca Græca*, ed. Harless, vol. xi.

GENOA, in literary Italian *Genova*, in the local dialect *Zene*, in Latin and German *Genua*, in mediæval Latin *Janua*, and in French *Gênes*, one of the most important cities of Italy, is situated in what was formerly known as Liguria, on the northern coast of the Mediterranean near the middle of the Gulf of Genoa. The latitude of its lighthouse is 44° 24′ 16″ N., and its longitude 8° 54′ 15″ E. By rail Genoa is 115 English miles N.E. of Nice and 119 miles N.W. of Leghorn. The city, as seen from the sea, is "built nobly," and deserves the title it has acquired or assumed of the Superb. Finding only a small space of level ground along the shore, it has been obliged to climb the lower hills of the Ligurian Alps, which afford many a coign of vantage for the effective display of its architectural magnificence. The original nucleus of the city is that portion which lies to the east of the port in the neighbourhood of the old pier (Molo Vecchio). In the 10th century it began to feel a lack of room within the limits of its fortifications; and accordingly, in the middle of the 12th century, it was found necessary to extend the line of circumvallation. Even this second circuit, however, was of small compass, and it was not till 1320-30 that a third line took in the greater part of the modern site of the city proper. This presented about 3 miles of rampart towards the land side, and can still be easily traced from point to point through the city, though large portions, especially towards the east, have been dismantled. The present line of circumvallation dates from 1626-1632, the period when the independence of Genoa was threatened by the dukes of Savoy. From the mouth of the Bisagno in the east, and from the lighthouse point in the west, it stretches inland over hill and dale to the great fort of Sperone, *i.e.*, the Spur, on the summits of Monte Peraldo at a height of 1650 feet,—the circuit being little less than 12 miles, and all the important points along the line being defended by forts or batteries. Of course a large portion of the enclosed area is open country, dotted only here and there with houses and gardens. There are eight gates in all,—the more important being Porta Pila and Porta Romana towards the east, and the new Porta Lanterna or Lighthouse Gate to the west.

The irregular relief of its site, and its long confinement within the limit of fortifications which it had outgrown, have both contributed to render Genoa a picturesque confusion of narrow streets, lanes, and alleys, which it would almost require the delicate diminutives of Italian to name, varied with stairways climbing the steeper slopes, and bridges spanning the deeper valleys. As there are large portions of the town which are quite inaccessible to ordinary carriages, and many even of the more important streets have very little room for traffic, porters and chairs take to a considerable extent the place of cabs, and goods are largely transported by means of mules. In the middle of the 16th century the Government gave commencement to a system of more spacious thoroughfares than had previously been in vogue by laying out the street which still bears the name of Via Nuova; in 1606 the Via Balbi, as it was ultimately called from the palaces of the Balbi family, began to stretch westwards; and at length, about 1778, a connexion between these two streets was effected by the opening up of Via Nuovissima. The line thus produced, extending as it does from the Piazza Fontane Morose westward for about a mile to the Piazza Verde is still the route most in favour with the fashionable world of Genoa. As early as the middle of the 17th century the Via Giulia was driven through the midst of the small streets between the ducal palace and the Porta d'Arco; but it was not till about 1825 that the Via Carlo Felice gave free route between the palace and the Piazza Fontane Morose. The Via Lorenzo and the long line of street which, under the names of Carlo Alberto, S. Benedetto, and Milano, runs round the port to its western extremity, also belong to this century. The spacious Via Roma, running east from Via Carlo Felice to meet the Via Assarotti, has been built since 1870; and the area of the Piazza Cavour was only about the same time cleared of the old houses. The great public promenade of Acquasola already mentioned was laid out by the architect Carlo Barabino between 1821 and 1837; and it has been connected with the gardens of the Villetta di Negri, purchased by the municipality about 1865.

Of the churches of Genoa, which number upwards of eighty, the principal is the cathedral of St Laurence (il duomo di San Lorenzo). Tradition makes its first foundation contemporary with St Laurence himself; there is distinct historic mention of a church on the site in the latter part of the 9th century; and a document of 987 implies that it was even then the metropolitan church. Reconstructed about the end of the 11th and beginning of the 12th century, it was formally consecrated by Pope Gelasius II., 18th October 1118; and since then it has undergone a large number of extensive though partial renovations. In the façade the lower part, with its three elaborate doorways in the Gothico-Moorish style, dates from the 12th century; the upper part belongs to the 14th; and the belfry which rises above the right-hand doorway was erected about 1520 by the doge, Ottaviano da Campofragoso. To the 13th century is assigned the central nave, which was, however, both lengthened and heightened in the 14th; and the cupola was erected after the designs of the architect Galeasso Alessi invited to Genoa about 1550. Among the artists who have contributed to the internal decoration the most noteworthy are Damiano of Bergamo, who represented the Slaughter of the Innocents and the Martyrdom of St Laurence in the woodwork of the choir; Lazzaro Tavarone, who painted the roof about 1622; G. B. Bianco, who furnished the bronze statue of the Madonna of the city in 1652;

Cathe-

Gian Giacomo della Porta, the sculptor of the statues of Mark and Luke in the presbyterium; and Giovanni Maria Passalo and Giovanni Angelo Montorsoli, the sculptors of the corresponding statues of Matthew and John. The stained glass windows of the choir, representing the four patron saints of the city, are the work of Giovanni Bertini. To none of the chapels in the cathedral, rich as several of them are in works of artistic value, can a higher rank be assigned than to the chapel of St John the Baptist. The main design, with its elaborate detail of columns and arabesques, and foliage and statues, was due to Pio Domenico da Bissone, who from 1450 was engaged for ten years on the work. Statues by Matteo Civitali of Lucca and Andrea Contucci of Monte San Savino, a rich and costly baldachin presented by Count Filippino Doria, and stained glass windows designed by Ulisse de' Mattei, are among the later additions to its decoration. On one day only in the course of the year are women allowed to enter the chapel; for was it not a woman who procured the death of the Baptist? Amid the profusion of ecclesiastical bric-a-brac in the nooks and niches of the cathedral, there are objects enough of considerable interest. Here, bound together by craft of goldsmith, is an octagonal bowl, brought from Cæsarea in 1101, which corresponds to the descriptions given of the Holy Grail, and was long regarded as an emerald of matchless price, but which turned out, when broken by its French purloiners, to be only a remarkable piece of ancient glass.

Of older date than the cathedral is the church of St Ambrose and St Peter, if its first foundation be correctly assigned to the Milanese bishop Honoratus of the 6th century; but the present edifice is due to the Society of Jesus, who obtained possession of the church in 1587, and employed the skill of Pellegrino Tebaldi in its restoration. Among the paintings of this church the first place is naturally given to the Circumcision and St Ignatius by Rubens, and to the Assumption of Guido Reni. The Annunziata del Guastato is one of the largest and wealthiest churches in the city. It owes its first foundation to the order of the Humiliati, but S. Marta, as it was originally

called, was a small building till it passed about 1505 into the hands of the Conventuals of St Francis, by whom the present gigantic structure was planned and partly erected. The rest of the main edifice was due to the Observantines of the same order, who came into possession in 1537, and gave the church its modern name; and the necessary funds were largely supplied by the Lomellini family. The church is a cruciform structure, with a dome, and the central nave is supported by fourteen columns in the Corinthian style. To the unfinished brick façade an incongruous portal with marble columns was added about 1843, after the plans of Carlo Barabino. Santa Maria delle Vigne probably dates from the 9th century, but the present structure was erected towards the close of the 16th. The campanile, however, is a remarkable work of the 13th century. San Siro, originally the "Church of the Apostles" and the cathedral of Genoa, was rebuilt by the Benedictines in the 11th century, and restored and enlarged by the Theatines in the 16th. Santa Maria di Carignano, or more correctly Santa Maria Assunta e SS. Fabiano e Sebastiano, belongs mainly to the 16th century, and was designed by Galeazzo Alessi in imitation of Bramante's plan for St Peter's at Rome. The expense was borne by the Sauli family. From the highest gallery of the dome—368 feet above the sea-level, and 194 feet above the ground—a magnificent view is obtained of the city and the neighbouring coast. S. Stefano dates from 969, and keeps its ancient campanile, but it has been several times rebuilt. The famous painting of the martyrdom of St Stephen, by Giulio Romano, carried off by Napoleon in 1811, was restored to the church in 1815. The Madalena, as it now stands, was built by Andrea Vannone about the close of the 16th century; and San Filippo Neri was rebuilt in the close of the 17th century at the expense of the Pallavicini family. S. Matteo, the church of the D'Oria or Doria family, was founded in 1126 by Martino Doria, and the present edifice, after the designs of Montorsoli, dates from 1543. In the crypt is the tomb of Andrea Doria the Great by the same Montorsoli, and above the main altar hangs the dagger presented to the doge by Pope Paul III.

The palaces of the Genoese patricians are famous for their sumptuous architecture and their artistic collections. The Palazzo Rosso, or Red Palace, erected in the middle of the 17th century, was in 1874 presented to the city by Maria, the wife of Raffaele de Ferrari, duke of Galliera, and her son Filippo de Ferrari, along with its library and picture gallery. The old palace of the doges, now the seat of the prefecture, was rebuilt in the 16th century, and again restored after a great fire in 1777; the neighbouring tower, from which the magistrates were summoned by toll of bell, dates from the beginning of the 14th century. A sixteenth century palace, formerly the property of the dukes of Turin, is now occupied by the municipality, and contains among its more curious treasures a bronze tablet (117 A.D.), with an inscription relating to a dispute between Genoa and a neighbouring castle, two autograph letters of Columbus, and Paganini's violin. The inscription, discovered in 1506, was printed for the first time in 1520 by Brucelli, whose works form part of Grævius's *Thesaurus*, and among its modern commentators are Serra in the Transactions of the Imperial Academy of Genoa, and Simoni and Grassi in the Transactions of the Ligurian Society of Native History. The palace which was presented in 1528 by the republic to Andrea Doria is a large building of the 15th century, restored and extended under the doge's direction, and decorated with frescos by Perino del Vaga. The royal palace, built in the middle of the 16th century for the Durazzo family, was acquired by Victor Emmanuel in 1817. Among other buildings of the same class, the Durazzo palaces in the Via Nuovissima, and the Via Balbi, the Balbi Senarega in the Via Balbi, the Sarra palace in the Via Nuova, and the Pallavicino in the Piazza Fontane Morose are worthy of note.

Benevolent institutions.

Of most historical interest among the benevolent institutions of Genoa is the hospital of Pammatone (Ospedale civile di Pammatone), a vast edifice contiguous to the public park of Acquasola. It owes its origin to the bequest in 1429 of Bartolommeo Bosco; and the excellence of the infirmary thus established caused the citizens to procure permission from Sixtus V. to divert the funds of all similar minor foundations to its support. New buildings were erected in 1626 by Giacomo Saluzzo, and still larger additions were made in 1758, under the superintendence of Andrea Orsolino. Under the same committee with the general hospital is the hospital for incurables (Ospedale dei Cronici, originally Ridotto degli Incurabili), instituted towards the end of the 15th century by Ettore Vernazza, and taken under the direct control of the civil authorities in 1500. The great poorhouse (Albergo dei Poveri), dating from about 1665, is a vast building, after designs by Stefano Scaniglia, covering no less than 215,280 square feet, and accommodating 1400 inmates, who manufacture cotton and woollen cloth, furniture, embroidery, &c. The so-called Conservatorio delle Fieschine was founded in 1763, in accordance with the will of Domenico Fieschi, as an asylum for destitute girls; and in 1783 his widow left 80,000 lire to provide a dowry of 500 lire for any of the inmates leaving the institution to be married or to take the veil. A considerable reputation has been acquired by the flower-makers of this institution.

The sums bequeathed for charitable purposes during 1863–75 amounted to 3,798,106 francs, in addition to the immense donations (about thirty millions of francs) of the deceased duke of Galliera.

The highest educational institution in Genoa is the royal university, which occupies a palace in the Via Balbi, originally built about 1623 for the Jesuit fathers entrusted by the magistrates with the supervision of education in 1572. The republic had received the right of conferring degrees from Pope Sixtus IV. as early as 1471, a privilege confirmed by the emperor Maximilian I. in 1496. On the dissolution of the Jesuits the administration of the college passed into the hands of the republic, and the provisional Government of 1797 reinaugurated it as a university in 1803. In 1808, during the French occupation, it was assimilated to the other imperial academies, so that its present organization may be said to date only from 1812. It numbers about 400 students, who have the advantage of a physical and a natural history museum, an anatomical cabinet, a meteorological observatory, a botanical garden, and a library. The library, originated by the Jesuits, numbers about 80,000 volumes, among which none is considered of greater value by the Genoese than the manuscript collection of the laws and enactments of their republic, *Liber jurium communis Januensis*. In Genoa, as elsewhere in Italy, great advance has been made both in secondary and primary education since 1867: in 1877 the city possessed two gymnasiums, a lyceum named after Christopher Columbus, three technical schools, a high school for female education opened by the municipality in 1874, a female normal school dating from 1859, a teachers' training school founded in 1861, and upwards of 40 infant schools (Asili d' Infanzia), of which the first was opened in 1840. The royal technical institute comprises three distinct sections—a professional industrial institute, an institute of mercantile marine, and a system of evening classes in mathematics, chemistry, mechanics, &c.; and a royal naval college was opened in 1873. The Ligurian academy of the fine arts owed its origin in 1751 to Francesco Maria Doria, and the *palazzo* in which its museums and galleries are situated was erected in 1831 by Carlo Barabino. A musical institute, founded by Antonio Costa and maintained by the municipality, has rooms in the convent of St Philip Neri. A society for the promotion of the fine arts dates from 1849, the Ligurian society of native history from 1857, and a society for the arts and industries of Liguria from 1871. Besides the university library there are four public libraries—the Biblioteca Civico-Beriana (40,000), presented to the municipality by Victor Emmanuel I., to whom it had been bequeathed; the Biblioteca della Missione Urbana (40,000), a noble collection rich in manuscripts of Ligurian history and Greek codices, which owes its origin to the legacy of Gerolamo Franzone in 1727; the Biblioteca Franzoniana (12,000), due to the same G. Franzone, and administered by the congregation of "Evangelical Workmen"; and, lastly, the fine library which forms part of the great legacy in the Palazzo Rosso. A museum of natural history (Museo Civico di St. Nat.), opened in the Villetta di Negro in 1873, is worthy of special note for the collections made by Giacomo Doria, Beccari, D'Albertis, and Antinori. Picture galleries are to be found in many of the ancient palaces, and in two at least, the Palazzo Rosso and the Palazzo Bianco, the collections are of great value. An excellent law forbids the removal from the city or province of any object of ancient art without the sanction of a commission under the presidency of the prefect. In 1877 the Genoese had a choice of about a dozen theatres, small and great, inclusive of those in Sampierdarena. Of these the greatest is the Carlo Felice, erected in 1826–28 under the patronage of the king whose name it bears. The National Theatre, rebuilt in 1790, dates originally from 1702, and it has an older rival in the Teatro del Falcone, which is associated with the life of Goldoni, and now serves as court theatre.

The mountainous character of the surrounding country has rendered it a difficult task to supply Genoa with sufficient means of railway communication; in the 20 miles, for example, between the city and Arquata there are eleven tunnels, that of Giovi being upwards of 2 miles long. The line to the north through the valley of the Polcevera, which joins the general Italian system at Alessandria, was opened about 1853; but it was not till 1870 that the western line was completed so as to give a continuous route from France, and it was November 1874 before the eastern section between Sestri di Levante and Spezia established a connexion with the lines along the western coast of Italy. Since that date, however, passengers and goods can be conveyed by rail from Calais to Otranto. There are two stations in the city,—one for the west and north, and the other for the east and south,—connected since 1871 by a tunnel 7518 feet in length.

Though its existence as a maritime power was originally due to its port, Genoa has only begun since 1870 to construct the conveniences necessary for the modern development of its trade. As early as 1134 the old pier (Molo Vecchio) was in existence, stretching westward into the gulf; and in 1639 the new pier (Molo Nuovo) from the other side of the gulf was commenced, after the plans of Ansaldo de Mari. Up to 1878 the former had a length of 2800 feet, and the latter was only slightly longer. The harbour thus formed was in some respects a good one; the bottom being of clay furnished excellent anchorage, and within the new pier there was depth for the largest class of vessels. But a swell was always felt whenever the wind was at any point between S.W. and S.E.

The vast bequests of the duke of Galliera have enabled the authorities to undertake (1878) an elaborate scheme for the extension and improvement of the port, including, not only a great addition of the harbour area, but also the construction of a system of wharves and warehouses, which have hitherto been surprisingly insufficient. It is difficult to believe that in one of the greatest harbours of Europe the goods should be "discharged into lighters, slowly towed by rowing boats to the side of the quays, removed by hand labour from the lighters to uncovered quays, and again transferred by hand labour to the railway." In spite of all these disadvantages the shipping trade of Genoa has rapidly increased since the consolidation of Italy. From 1815 to 1825 there was a large trade in grain, with a corresponding expansion of other branches. A sudden change was produced by a system of differential duties in favour of native grain; instead of 1000 foreign vessels with a tonnage of 95,000 as in 1821–5, there were only 760 vessels on an average in the three years 1825–8; and there was no corresponding increase in native shipping, which rose only from 55 to 70 vessels. The more liberal tariffs attached to the commercial treaties, concluded about 1852 with France, England, and Germany, gave a new impulse to foreign trade, and this was followed up by Count Cavour's law exempting all foreign grain from duty. The principal imports are petroleum, raw cotton, wool, grain, coal, metal goods, hides, tobacco, and English-cured fish. The total value imported in 1876 was £14,324,347, and in 1877 £12,066,911, while the exports for the same years amounted to £2,088,578 and £1,968,503—exclusive in both cases of goods merely in transit. During the five years 1873–7 the total number of vessels arriving at Genoa was on an average 2633 per annum, with an annual tonnage of more than 1,000,000 tons. Of these vessels about 1510 per annum sailed under the Italian flag with 533,900 tons; 421 were English with 284,390 tons, and 320 French with 105,945 tons. The opening of the St Gotthard Railway is expected to give a great impulse to Genoese trade.

Local industry. The local industry devotes itself mainly to the manufacture of cotton and silk, gold, silver, ivory, and coral, paper and leather goods, macaroni and vermicelli, sugar, and preserved fruits. The coarser cotton cloths or bordatti are the favourite wear of the Ligurian population. Iron-founding and shipbuilding are carried on in the district, and there is a growing export trade in all articles of market gardening and floriculture.

Banks. In Michelet's phrase, it may almost be said that Genoa was a bank before it was a city, and its money business is still greater than that of any other town in Italy. The Bank of St George, founded in 1407, was "one of the most ancient and celebrated banks of circulation and deposit in Europe," but it never recovered from the damage done to its credit by the appropriation of its treasure, first by the Austrians in 1740, and again by the French in 1800. It no longer exists, and the famous building of the 13th century in which it was accommodated is now used as a customs house. A new bank was founded at Genoa in 1844, which, since its union in 1855 with a similar institution at Turin, bears the name of the National Bank. It has branches at Turin, Florence, Milan, and Naples. Up till 1871 its only important rival was the Cassa di Sconto, but about this time the Genoese, in the words of the British consul, "went mad on the subject of new companies, and in a single year they started not less than thirty-three banking, trading, mining, shipping, and manufacturing concerns." The result was a series of bankruptcies. Bank after bank failed; and criminal proceedings were in several cases instituted against the bank directors. The only notes current in Genoa in 1875 were those of the National Bank and the Tuscan National Bank.

The Genoese have long been known as a hard-working and frugal people; and the lower classes of the whole Ligurian coast are inured to privation and hardships. Since about 1850 there has been a strong current of emigration to South America. About 1858 the Ligurian settlers in Monte Video, Buenos Ayres, Rio de la Plata, Rio Janeiro, Lima, and Valparaiso were estimated at 60,000; and since that date the number of emigrants leaving northern Italy by way of Genoa has increased to 80,000 or 90,000 per annum. A very considerable proportion of this number return to their native country in their latter years, and the successful adventurer usually assists his younger brethren to follow in his footsteps. A large trade has sprung up with South America, the newest feature of which is an exportation of Piedmontese wine.

According to the returns of 1876, the income of Genoa was 6,343,175 francs, including octroi dues for 4,326,000 francs. The ordinary, extraordinary, and casual expenses for 1875 were—for municipal administration, 608,461 francs; local police and sanitary expenses, 1,038,418; administration of law, 227,376; public works, 2,312,470; education, 692,662; religious worship, 12,117; and public charities, 648,468 francs. The debt of the city in 1876 was 36,731,457 francs.

The council directing the local government of the city is chosen by a body, according to the last returns, of 41,984 electors, every citizen paying 40 francs of taxes being entitled to vote, and every voter being eligible as a councillor. The head of the council is the syndic or mayor, chosen by the king from the 12 members of the giunta or administrative committee, who are themselves appointed from the entire body of the 60 municipal councillors. Besides possessing this municipal council, Genoa is also the seat of the provincial council, elected in the same way, but presided over by the prefect, or representative of the Government.

In 1848 the population of the city was 100,382; by 1862 it had increased to 127,986, but a careful census undertaken by the municipality in 1871 found no more than 120,595, exclusive, however, both of resident strangers and absent natives. The principal causes which had tended to retard the natural growth of the population were the cholera of 1866–67, and the small-pox of 1870,—the latter having actually occasioned an excess of 1178 deaths over the births for the year. To this must be added the removal of the Government arsenal to Spezia in 1870–1, and the tendency, which has gradually made itself felt since the opening of the railways, to settle in the suburban towns. The stretch of coast for miles along the gulf is an almost continuous line of country houses and mansions, and indeed, to quote the words of M. Reclus, the whole riviera from Ventimiglia to Spezia assumes more and more the aspect of a single town where the populous quarters alternate with groups of villas and gardens. Proceeding westwards we are no sooner beyond the fortifications than we find ourselves in the flourishing town of Sampierdarena, that is, San Pier d'Arena, or St Peter of the Sands. Down to the middle of last century it was mainly inhabited by the wealthier classes, but has since become the seat of great industrial and commercial activity. Its population, which in 1814 was only 5345, was upwards of 17,000 in 1877. From Sampierdarena a stone bridge of the 16th century, memorable as the spot when Masséna signed the capitulation of Genoa, leads across the Polcevera to Corneliano, a market-town with 2698 inhabitants at the census of 1871; and Corneliano in its turn connects itself with Sestri Ponente, a busy place of from 9000 to 10,000 inhabitants, with a large shipbuilding trade. Towards the east there is a similar succession of villages and towns.

History. *History.*—The early importance, both political and commercial, of Genoa is attested by the part which it played in the Second Punic War. Its supremacy amongst the neighbouring municipalities and populations is not less evident from the inscription on the bronze table still to be seen in the council-hall of the city. Its history during the dark ages, throughout the Lombard and Carolingian periods, is but the repetition of the general history of the Italian communes, which succeeded in snatching from contending princes and barons the first charters of their freedom. The patriotic spirit and naval prowess of the Genoese, developed in their defensive wars against the Saracens, led to the foundation of a popular constitution, and to the rapid growth of a powerful marine. From the necessity of leaguing together against the common Saracen foe, Genoa united with Pisa in expelling the Moslems from the island of Sardinia; but the Sardinian territory thus acquired soon furnished occasions of jealousy to the conquering allies, and there commenced between the two republics the long naval wars destined to terminate so fatally for Pisa. With not less adroitness than Venice, Genoa saw and secured all the advantages of the great carrying trade which the crusades created between Western Europe and the East. The seaports wrested at the same period from the Saracens along the Spanish and Barbary coasts became important Genoese colonies, whilst in the Levant, on the shores of the Black Sea, and along the banks of the Euphrates were erected Genoese fortresses, of which the strength some 40 years ago commanded the admiration of the young traveller Moltke. No wonder if these conquests generated in the minds of the Venetians and the Pisans fresh jealousy against Genoa, and provoked fresh wars; but the struggle between Genoa and Pisa was brought to a disastrous conclusion for the latter state by the battle of Meloria. The commercial and naval successes of the Genoese during the Middle Ages were the more remarkable because, unlike their rivals, the Venetians, they were the unceasing prey to intestine discord—the Genoese commons and nobles fighting against each other, rival factions amongst the nobles themselves striving to grasp the supreme power in the state, nobles and commons alike invoking the arbitration and rule of some foreign captain as the sole means of obtaining a temporary truce. From these contests of rival nobles, in which the names of Spinola and Doria stand forth with greatest prominence, Genoa was soon drawn into the great vortex of the Guelph and Ghibelline factions; but its recognition of foreign authority—successively German, Neapolitan, and Milanese—gave way to a state of greater independence in 1339, when the government assumed a more permanent form with the appointment of the first doge, an office held at Genoa for life, in the person of Simon Boccanera. Alternate victories and defeats of the Venetians and Genoese—the most terrible being the defeat sustained by the Venetians at Chioggia in 1380—ended by establishing the great relative inferiority of the Genoese rulers, who fell under the power now of France, now of the Visconti of Milan, until the national spirit appeared to regain its ancient vigour in 1528, when Andrea Doria succeeded in throwing off the French domination and restoring the old form of government. It was at this very period, the close of the 15th and commencement of the 16th century, that the genius and daring of a Genoese mariner, Christopher Columbus, gave to Spain that new world, which might have become the possession of his native state, had Genoa been able to supply him with the ships and seamen which he so earnestly entreated her to furnish. The government as restored by Andrea Doria, with certain modifications tending to impart to it a more conservative character, remained unchanged until the outbreak of the French Revolution and the creation of the Ligurian republic. During this long period of nearly three centuries, in which the most dramatic incident is the conspiracy of Fieschi, the Genoese found no small compensation for their lost traffic in the East in the vast profits which they made as the bankers of the Spanish crown and outfitters of the Spanish armies and fleets both in the Old World and the New.

The short-lived Ligurian republic was soon swallowed up in the French empire, not, however, until Genoa had been made to experience, by the terrible privations of the siege when Masséna held the city against the Austrians (1800), all that was meant by a participation in the vicissitudes of the French Revolution. In 1814 Genoa rose against the French, on the assurance given by Lord William Bentinck that the allies would restore to the republic its independence. It had, however, been determined by a secret clause of the treaty of Paris that Genoa should be incorporated with the dominions of the king of Sardinia. The discontent created at the time by the provision of the treaty of Paris as confirmed by the congress of Vienna had doubtless no slight share in keeping alive in Genoa the republican spirit which, through the influence of a young Genoese citizen, Joseph Mazzini, assumed forms of permanent menace not only to the Sardinian monarchy but to all the established Governments of the peninsula. Even the material benefits accruing from the union with Sardinia and the constitutional liberty accorded to all his subjects by King Charles Albert were unable to prevent the republican outbreak of 1850, when, after a short and sharp struggle the city, momentarily seized by the republican party, was recovered by General Alfonzo La Marmora. The most important of the later events in the history of Genoa has been the seizure within its port of the five Neapolitan brigands, Cipriano La Gala and his accomplices, who travelling with papal passports were arrested on board the French passenger steamer, the "Aunis," by orders of the Marquis Gualterio prefect of Genoa. Though the event threatened at first to create a rupture between the French and Italian Governments, the diplomatic discussions which it called forth, and the impression generally produced throughout Europe, had no slight share in weakening the political ties which had hitherto existed between the Papal Government and France.

Among the earlier Genoese historians the most important are Bartolommeo Fazio and Jacopo Bracelli, both of the 15th century, and Paolo Partenopeo, Jacopo Bonfadio, Oberto Foglietta, and Agostino Giustiniano of the 16th. Paganetti wrote the ecclesiastical history of the city; and Accinelli and Gaggero collected material for the ecclesiastical archæology. The memoirs of local writers and artists were treated by Soprani and Ratti. Among more general works are Bréquigny, *Histoire des Révolutions de Gênes jusqu'en 1748*; Serra, *La Storia dell' antica Liguria e di Genova* (Turin, 1834); Varesi, *Storia della republica di Genova sino al 1814* (Genoa, 1835–39); Canale, *Storia dei Genovesi* (Genoa, 1844–54), *Nuova istoria della repubblica di Genova* (Florence, 1858), and *Storia della rep. di Genova dall' anno 1528 al 1550* (Genoa, 1874); Blumenthal, *Zur Verfassungs- und Verwaltungsgeschichte Genua's im 12 Jahrhundert* (Kalbe an der Saale, 1872); Mallison, *Studies from Genoese History* (London, 1875). The *Liber iurium reipublicæ Genuensis* was edited by Ricotti in the 7th, 8th, and 9th volumes of the *Monumenta historiæ patriæ* (Turin, 1854–1857). A great variety of interesting matter will be found in the *Atti della Società Ligure di Storia patria* (13 volumes, from 1861–1878), and in the *Giornale Ligustico di Archeologia, Storia, e Bell' Arti*. The history of the university has been written by Lorenzo Isnardi, and continued by Em. Celesia (2 vols., Genoa). Belgrano, *Della vita privata dei Genovesi*, P. M. Garibaldi, *Stato meteorologico per la città de Genova* (for 1870, &c.), and Rocca, *Pesi e misure antichi di Genova*, may also be mentioned. A *Vocabulario tascabile genovese-italiano* compiled by P. F. B. is published by the deaf-mute publishing department.

GENOVA, Luchetto da (1527–1585). This is the familiar name given to the painter Luca Cambiasi (written also Cambiaso or Cangiagio), who was born at Moneglia in the Genoese state, son of a painter named Giovanni Cambiasi. He took to drawing at a very early age, imitating his father, and developed great aptitude for foreshortening. At the age of fifteen he painted, along with his father, some subjects from Ovid's *Metamorphoses* on the front of a house in Genoa, and afterwards, in conjunction with Calvi, a ceiling showing great daring of execution, in the Palazzo Doria. He also formed an early friendship with Giambattista Castello; both artists painted together, with so much similarity of style that their works could hardly be told apart; from this friend Cambiasi learned much in the way of perspective and architecture. Luchetto's best artistic period lasted for twelve years after his first successes; from that time he declined in power, though not at once in reputation, owing to the agitations and vexations brought upon him by a passion which he conceived for his sister-in-law. His wife having died, and the sister-in-law having taken charge of his house and children, he endeavoured to procure a papal dispensation for marrying her; but in this he was disappointed. In 1583 he accepted an invitation from Philip II. to continue in the Escorial a series of frescos which had been begun by Castello, now deceased; and it is said that one principal reason for his closing with this offer was that he hoped to bring the royal influence to bear upon the pope, but in this again he failed. Worn out with his disquietudes, he died in the Escorial in the second year of his sojourn. Cambiasi had an ardent fancy, and was a bold designer in a Raphaelesque mode. His extreme facility astonished the Spanish painters; and it is said that Philip II., watching one day with pleasure the offhand zest with which Luchetto was painting a head of a laughing child, was allowed the further surprise of seeing the laugh changed, by a touch or two upon the lips, into a weeping expression. The artist painted sometimes with a brush in each hand, and with a certainty equalling or transcending that even of Tintoret. He made a vast number of drawings, and was also something of a sculptor, executing in this branch of art a figure of Faith. Altogether he ranks as one of the ablest artists of his day. In personal character, notwithstanding his executive energy, he is reported to have been timid and diffident. His son Orazio became likewise a painter, studying under Luchetto.

The best works of Cambiasi are to be seen in Genoa. In the church of St George—the martyrdom of that saint; in the Palazzo Imperiali, Terralba, a Genoese suburb—a fresco of the Rape of the Sabines; in S. Maria da Carignano—a Pietà, containing his own portrait and (according to tradition) that of his beloved sister-in-law. In the Escorial he executed several pictures: one is a Paradise on the vaulting of the church, with a multitude of figures. For this picture he received 12,000 ducats, probably the largest sum that had, up to that time, ever been given for a single work.

GENOVESI, Antonio (1712–1769), an Italian writer on philosophy and political economy, was born in November 1712, at Castiglione, near Salerno. At an early age he was destined by his father for the church and began the study of philosophy and theology. He distinguished himself highly by his acuteness and diligence, and after some struggles, caused by his disinclination for an ecclesiastical life, he took orders at Salerno in 1736. He had not been long in this position when the archbishop of the town, recognizing his rare abilities, nominated him to the chair of rhetoric in the theological seminary. During this period of his life Genovesi began the study of philosophy as it existed outside the limits of theology. He read with eagerness the works of the chief modern philosophers, and was particularly attracted by Locke.

Apparently still dissatisfied with ecclesiastical life, Genovesi, resigning his post at Salerno, proceeded to Rome, undertook the study of law, and qualified as an advocate. The details of legal practice, however, proved as distasteful as theology, and for some years he gave himself entirely to the study of philosophy, attending most of the distinguished lecturers at the university of Naples. At this place, after having obtained the appointment of extraordinary professor of philosophy, he opened a seminary or private college for students. His reputation as a teacher was increased by the publication in 1743 of the first volume of his *Elements of Metaphysics*, and in 1745 of his *Logic*. Both works are imbued with the spirit and principles of the empirical school of philosophy, and the latter, an eminently practical treatise, had long a recognized position as one of the best logical text-books written from the point of view of Locke. On account of the accusations of infidelity and heresy naturally excited by his discussion of metaphysical principles, he had some difficulty in obtaining the professorship of moral philosophy, and failed to be appointed to the chair of theology; but this did not prevent him from following out his philosophical studies. He published a continuation of his *Elements of Metaphysics*; but with every new volume he experienced fresh opposition from the partisans of scholastic routine. Among these were Cardinal Spinelli, archbishop of Naples, and an Abbé Magli, whom Genovesi covered with ridicule in his work entitled *Lettere ad un Amico Provinciale.* In spite of this, Genovesi obtained the approbation of Pope Benedict XIV., of several cardinals, and of most of the learned men of Italy. Of this number was Intieri, a Florentine, who founded at his own expense, in the university of Naples, the first Italian chair of political economy, under three conditions—namely, that the lectures should be in Italian, that Genovesi should be the first professor, and that, after his death, no ecclesiastic should succeed him.

Genovesi commenced his first course of lectures on the 5th of November 1754 with great success,—the novelty and the interest of the subject, and the eloquent style and agreeable manner of the professor, attracting a crowd of auditors. He afterwards published his *Lectures on Commerce*, and Carey's *Account of the Trade of England*, translated into Italian by his brother, with notes by himself. The *Lezioni di Commercio* is the first complete and systematic work in Italian on the science which Italians have done much to advance. On the whole it is to be included among works of the Mercantile school, but in treatment of fundamental problems, such as labour and money, it is distinguished by fairness and breadth of view. Specially noteworthy are the sections on human wants as foundation of economical theory, on labour as the source of wealth, on personal services as economic factors, and on the united working of the great industrial functions. Gioja's more important treatise owes much to Genovesi's lectures.

Till his death in 1769 Genovesi continued his labours at the university of Naples, which owes much of its celebrity to the solidity and excellence of his teaching. It cannot be said that Genovesi takes a high rank in philosophy, but he did much to introduce into Italy the new order of ideas, and his exposition of philosophical doctrines is fair and lucid. His work on *Metaphysics*, divided into the four rubrics, *Ontosophy*, *Cosmosophy*, *Theosophy*, *Psychosophy*, distinguished by its solid erudition, is an excellent specimen of the precritical or dogmatic method of handling speculative problems. His merits in political economy have been indicated above. (For list of works see Fabroni's *Lives.*)

GENSERIC, or GENSERICH, king of the Vandals, and the most formidable of the Gothic invaders of the Roman empire, was the natural son of Godegiselus the founder of a Vandal kingdom in Spain, and was born at Seville about 406. Though he was only of middle stature, and had a lameness of one leg, such was his renown as a warrior that on the death of his brother Gonderic in 427 he was chosen to succeed him on the throne. At the invitation of Boniface, the Roman general in Africa, who wished to revolt against Valentinian III., Genseric in 429 crossed into Africa, and took possession of Mauretania. Soon afterwards he besieged Boniface in Hippo Regius, and compelled him after a defence of fourteen months to seek safety by a precipitate embarkation, leaving his soldiers and their families to the ruthless cruelty of the Vandals. In 435 Genseric concluded a treaty with the Romans by which he retained possession of western Numidia and Mauretania; but peace was not of long duration, and in October 439 he captured Carthage, which he made the capital of his kingdom. Genseric was an Arian, and cruelly persecuted the orthodox Catholics in Africa. In 455 at the invitation of Eudocia, who wished to be revenged on Maximus the murderer of her husband Valentinian, he fitted out an expedition against Rome, and after storming the city, gave it up during fourteen days to be pillaged by his soldiers. Eudocia and her daughters he carried captive to Carthage, where she was retained in prison till 462. Two attempts were made by the Romans to avenge themselves on the barbarians,—the first by Majorian, emperor of the West, in 457, and the second by Leo, emperor of the East, in 468. Both attempts, however, signally failed, and in 475 Leo's successor Zeno concluded a truce. Genseric's dominion ultimately included Sicily, Sardinia, Corsica, and the Balearic isles; and he even extended his conquests to Thrace, Egypt, and Asia Minor. He died in 477. He was cruel to blood-thirstiness, cunning, unscrupulous, and grasping; but he possessed great military talents, and his manner of life was austere. Though the effect of his victories was neutralized by the subsequent successes of Belisarius, his name long remained the glory of the Vandal tribes.

GENTIAN, botanically *Gentiana*, a large and typical genus of herbaceous plants forming the type of the natural order *Gentianaceæ.* The genus comprises about 180 species,—most of them perennial plants growing in hilly or mountainous districts, chiefly in the northern hemisphere, some of the blue-flowered species ascending to a height of 16,000 feet in the Himalaya mountains. The leaves are opposite, entire, and smooth, and often strongly ribbed. The flowers are furnished with a persistent calyx and corolla, which is usually 4- or 5-parted, but occasionally 10-parted; the stamens are equal in number to the lobes of the corolla. The ovary is one-celled, with two stigmas, either separate and rolled back or contiguous and funnel-shaped. The fruit when ripe separates into two valves, and contains numerous small seeds. The majority of the genus are remarkable for the deep or brilliant blue colour of their blossoms, comparatively few having yellow, white, or more rarely red flowers; the last are almost exclusively found in the Andes.

Only a few species occur in Britain. *G. Amarella* and *G. campestris* are small annual species growing on chalky or calcareous hills, and bear, in autumn, somewhat tubular pale purple flowers; the latter is most easily distinguished by having two of the lobes of the calyx larger than the other two, while the former has the parts of the calyx in fives, and equal in size. Some intermediate forms between these two species occur, although rarely, in England; one of these, *G. germancia*, Willd., has larger flowers of a more blue tint, spreading branches, and a stouter stem. Some of these forms flower in spring. *G. Pneumonanthe*, the Calathian violet, is a rather rare perennial species, growing in moist heathy places from Cumberland to Dorsetshire. Its average height is from 6 to 9 inches. It has linear leaves, and a bright blue corolla $1\frac{1}{2}$ inches long, marked externally with five greenish bands, is without hairs in its throat, and is found in perfection about the end of August. It is the handsomest of the British species; two varieties of it are known in cultivation, one with spotted and the other with white flowers. *G. verna* and *G. nivalis* are small species with brilliant blue flowers and small leaves. The former is a rare and local perennial, occurring, however, in Teesdale and the county of Clare in Ireland in tolerable abundance. It has a tufted habit of growth, and each stem bears only one flower. It is sometimes cultivated as an edging for flower borders. *G. nivalis* in Britain occurs only on a few of the loftiest Scotch mountains. It differs from the last in being an annual, and having a more isolated habit of growth, and in the stem bearing several flowers. On the Swiss mountains these beautiful little plants are very abundant; and the splendid blue colour of masses of gentian in flower is a sight which, when once seen, can never be forgotten. For ornamental purposes several species are cultivated. The great difficulty of growing them successfully renders them, however, less common than would otherwise be the case; although very hardy when once established, they are very impatient of removal, and rarely flower well until the third year after planting. Of the ornamental species found in British gardens some of the prettiest are *G. acaulis*, *G. verna*, *G. pyrenaica*, *G. bavarica*, *G. septemfida*, and *G. gelida*. Perhaps the handsomest and most easily grown is the first named, often called *Gentianella*, which produces its large intensely blue flowers early in the spring.

All the species of the genus are remarkable for possessing an intense but pure bitter taste and tonic properties. About forty species are used in medicine in different parts of the world. The name of felwort given to *G. Amarella*, but occasionally applied to the whole genus, is stated by Dr Prior to be given in allusion to these properties—*fel* meaning gall, and *wort* a plant. In the same way the Chinese call the *G. asclepiaderi*, and the Japanese the *G. Buergeri*, "dragon's gall plants," in common with several other very bitter plants whose roots they use in medicine. *G. campestris* is sometimes in Sweden and other northern countries a substitue for hops.

By far the most important of the species used in medicine is the *G. lutea*, a large handsome plant 3 or 4 feet high, growing in open grassy places on the Alps, Apennines, and Pyrenees, as well as on some of the mountainous ranges of France and Germany, extending as far east as Bosnia and the Danubian principalities. It has large oval strongly-ribbed leaves and dense whorls of conspicuous yellow flowers. Its use in medicine is of very ancient date. Pliny and Dioscorides mention that the plant was noticed by Gentius, a king of the Illyrians, living 180–167 B.C., from whom the name *Gentiana* is supposed to be derived. During the Middle Ages it was much employed in the cure of disease, and as an ingredient in counter-poisons. In 1552 Tragus mentions the use of the root as a means of dilating wounds.

The root, which is the part used in medicine, is tough and flexible, scarcely branched, and of a brownish colour and spongy texture. It has a pure bitter taste and faint distinctive odour. On account of its porous nature it has been used in modern surgery, as in the time of Tragus, as a substitute for sponge tents. The root has been several times analysed with varying results, but Kromayer in 1862 first obtained the bitter principle in a state of purity. This substance, to which the bitterness of the root is due, he called *gentiopicrin* ($C_{20}H_{30}O_{12}$). It is a neutral glucoside, crystallizing in colourless needles, and is contained in the fresh root in the proportion of about $\frac{1}{10}$th per cent., but has not been obtained in a crystalline state from the dried root. It is soluble in water and spirit of wine, but it does not dissolve in ether. It is easily decomposed, dilute mineral acids splitting it up into *glucose* and *gentiogenin*, the latter being an amorphous yellowish-brown neutral substance. It is not precipitated by tannin or subacetate of lead. A solution of caustic potash or soda forms with gentiopicrin a yellow solution, and the tincture of the root to which either of these alkalies has been added loses its bitterness in a few days. Gentian root also contains *gentianic acid* ($C_{14}H_{10}O_5$), which is inert and tasteless. It forms pale yellow silky crystals, very slightly soluble in water or ether, but soluble in hot strong alcohol and in aqueous alkaline solutions. This substance, which is also called *gentianin*, *gentisin*, and *gentisic acid*, has been shown by Ville to partake of the nature of tannin, giving the reactions of that substance with ferric chloride, gelatin, and albumen. On this account he proposes to change the name to *gentiano-tannic acid*.

The root also contains 12 to 15 per cent. of an uncrystallizable sugar, of which fact advantage has long been taken in Switzerland and Bavaria, for the production of a bitter cordial spirit called *Enzianbranntwein*. The use of this spirit, especially in Switzerland, has sometimes been followed by poisonous symptoms, which have been doubtfully attributed to inherent narcotic properties possessed by some species of gentian, the roots of which may have been indiscriminately collected with it; but it is quite possible that it may be due to the contamination of the root with that of *Veratrum album*, a poisonous plant growing at the same altitude, and having leaves extremely similar in appearance and size to those of *G. lutea*. Gentian is considered by therapeutists to be one of the most efficient of the simple bitter tonics, that is, of that class of substances which act upon the stomach so as to invigorate digestion and thereby increase the general nutrition, without exerting any direct influence upon any other portion of the body than the alimentary canal. It is used in dyspepsia, chlorosis, anæmia, and various other diseases, in which the tone of the stomach and alimentary canal is deficient, and is sometimes added to purgative medicines to increase and improve their action. In veterinary medicine it is also used as a tonic, and enters into a well-known compound called *diapente* as a chief ingredient.

GENTILESCHI, ARTEMISIA and ORAZIO DE', painters. ORAZIO (1565–1646) is generally named Orazio Lomi de' Gentileschi; it appears that De' Gentileschi was his correct surname, Lomi being the surname which his mother had borne during her first marriage. He was born at Pisa, and studied under his half-brother Aurelio Lomi, whom in course of time he surpassed. He afterwards went to Rome, and was associated with the landscape-painter Agostino Tasi, executing the figures for the landscape backgrounds of this artist in the Palazzo Rospigliosi, and it is said in the great hall of the Quirinal Palace, although by some authorities the figures in the last-named building are ascribed to Lanfranchi. His best works are Saints Cecilia and Valerian, in the Palazzo Borghese, Rome; David after the death of Goliath, in the Palazzo Doria, Genoa; and some works in the royal palace, Turin, noticeable for vivid and uncommon colouring. At an advanced age Gentileschi went to England at the invitation of Charles I., and he was employed in the palace at Greenwich. Vandyck included him in his portraits of a hundred illustrious men. His works generally are strong in shadow and positive in colour. He died in England in 1646. ARTEMISIA (1590–1642), Orazio's daughter, studied first under Guido, acquired much renown for portrait-painting, and considerably excelled her father's fame. She was a beautiful and elegant woman; her likeness, limned by her own hand, is to be seen in Hampton Court. Her most celebrated composition is Judith and Holofernes, in the Pitti palace; certainly a work of singular energy, and giving ample proof of executive faculty, but repulsive and unwomanly in its physical horror. She accompanied her father to England, but did not remain there long; the best picture which she produced for Charles I. was David with the head of Goliath. Artemisia refused an offer of marriage from Agostino Tasi, and bestowed her hand on Pier Antonio Schiattesi, continuing however to use her own surname. She settled in Naples, whither she returned after her English sojourn; she lived there in no little splendour, and there she died in 1642. She had a daughter and perhaps other children.

GENTILI, ALBERICO (1552–1608), may fairly be called the founder of the science of international law. He was the second son of Matteo Gentili, a physician of noble family and scientific eminence, and was born 14th January 1552 at Sanginesio, a small town of the march of Ancona which looks down from the slopes of the Apennines upon the distant Adriatic. After taking the degree of doctor of law at the university of Perugia, and holding a judicial office at Ascoli, he returned to his native city, and was entrusted with the task of recasting its statutes, but, sharing the Protestant opinions of his father, shared also his flight to Carniola, where Matteo was appointed physician to the duchy. The Inquisition condemned the fugitives as contumacious, and they soon received orders to quit the dominions of Austria. Alberico set out for England, travelling by way of Tübingen and Heidelberg, and everywhere meeting with the reception to which his already high reputation entitled him. He arrived at Oxford in the autumn of 1580, with a commendatory letter from the earl of Leicester, at that time chancellor of the university, and was shortly afterwards qualified to teach by being admitted to the same degree which he had taken at Perugia. His lectures on Roman law soon became famous, and the dialogues, disputations, and commentaries, which he published henceforth in rapid succession, established his position as an accomplished civilian, of the older and severer type, and secured his appointment in 1587 to the regius professorship of civil law. It was, however, rather by an application of the old learning to the new questions suggested by the modern relations of states that his labours have produced their most lasting result. In 1584 he was consulted by Government as to the proper course to be pursued with Mendoza, the Spanish ambassador, who had been detected in plotting against Elizabeth. He chose the topic to which his attention had thus been directed as a subject for a disputation when Leicester and Sir Philip Sidney visited the schools at Oxford in the same year; and this was six months later expanded into a book, the *De legationibus libri tres.* In 1588 Alberico selected the law of war as the subject of the law disputations at the annual "Act" which took place in July; and in the autumn published in London the *De Jure Belli commentatio prima.* A second and a third *Commentatio* followed, and the whole matter, with large additions and improvements, appeared at Hanau, in 1598, as the *De Jure Belli libri tres.* It was doubtless in consequence of the reputation gained by these works that Gentili became henceforth more and more engaged in forensic practice, and resided chiefly in London, leaving his Oxford work to be partly discharged by a deputy. In 1600 he was admitted to be a member of Gray's Inn, and in 1605 was appointed standing counsel to the king of Spain. He died 19th June 1608, and was buried, by the side of Dr Matteo Gentili, who had followed his son to England, in the churchyard of St Helen's, Bishopsgate. By his wife, Hester de Peigni, he left two sons and a daughter. His notes of the cases in which he was engaged for the Spaniards were posthumously published in 1613 at Hanau, as *Hispanicæ advocationis libri duo.* This was in accordance with his last wishes; but his direction that the remainder of his MSS. should be burnt was not complied with, since fifteen volumes of them found their way, at the beginning of this century, from Amsterdam to the Bodleian library.

The true history of Gentili and of his principal writings has only been ascertained quite recently, in consequence of a revived appreciation of the services which he rendered to international law. The movement to do him honour, which originated four or five years since, has in spreading through Europe encountered two curious cross-currents of opinion,—one the ultra-Catholic, which three centuries ago ordered his name to be erased from all public documents and placed his works in the *Index*; another the narrowly-Dutch, which is, it seems, needlessly careful of the supremacy of Grotius. Preceding writers had dealt with various international questions, but they dealt with them singly, and with a servile submission to the decisions of the church. It was left to Gentili to grasp as a whole the relations of states one to another, to distinguish international questions from questions with which they are more or less intimately connected, and to attempt their solution by principles entirely independent of the authority of Rome. He uses, without yielding to them implicit deference, the reasonings of the civil and even the canon law, but he proclaims as his real guide the *Jus Naturæ*, the highest common sense of mankind, by which historical precedents are to be criticized, and, if necessary, set aside.

His faults are not few. His style is prolix, obscure, and to the modern reader pedantic enough; but a comparison of his greatest work with what had been written upon the same subject by, for instance, Belli, or Soto, or even Ayala, will show that he greatly improved upon his predecessors, not only by the fulness with which he has worked out points of detail, but also by clearly separating the law of war from martial law, and by placing the subject once for all upon a non-theological basis. If, on the other hand, the same work be compared with *De Jure Belli et Pacis* of Grotius, it is at once evident that the later writer is indebted to the earlier, not only for a large portion of his illustrative erudition, but also for all that is commendable in the method and arrangement of the treatise.

The following is probably a complete list of the writings of Gentili, with the places and dates of their first publication:—*De Juris interpretibus dialogi sex*, Lond., 1582; *Lectionum et epist. quæ ad jus civile pertinent libri tres*, Lond., 1583–4: *De divers. temp. appellationibus*, Hanau, 1584; *De Legationibus libri tres*, Lond., 1585; *Legal. comitiorum Oxon. actio*, Lond., 1585–6; *De nascendi tempore disputatio*, Witteb., 1586; *Disputationum decas prima*, Lond., 1587; *Conditionum liber singularis*, Lond., 1587; *De Jure Belli comm. prima*, Lond., 1588; *secunda, ib.*, 1588–9; *tertia*, 1589; *De injustitia bellica Romanorum*, Oxon., 1590: *De Armis Romanis*, &c., Hanau, 1599; *De ludis scenicis epist. duæ*, Middleburg, 1599; *De actoribus et de abusu mendacii*, Hanau, 1599; *Lectiones Virgilianæ*, Hanau, 1600; *De nuptiis libri septem*, 1601; *Ad 1 Maccab. et de linguarum mistura*, Lond., 1604; *In tit. si quis principi, et ad leg. Jul. maiest.*, Hanau, 1604; *In tit. de Malef. et Math., et de Prof. et Med.*, Hanau, 1604; *De latin. vet. Bibl.*, Hanau, 1604; *De libro Pyano*, Oxon., 1604; *Laudes Acad. Perus. et Oxon.*, Hanau, 1605; *De unione Angliæ et Scotiæ*, Lond., 1605; *Disputationes tres, de libris jur. can., de libris jur. civ., de latinitate vet. vers.*, Hanau, 1605; *Regales disput. tres, de pot. regis absoluta, de unione regnorum, de vi civium*, Lond., 1605; *Hispanicæ advocationis libri duo*, Hanau, 1613; *In tit. de verb. signif.*, Hanau, 1614; *De legatis in test.*, Amsterd., 1661. An edition of the *Opera Omnia*, commenced at Naples in 1770, was cut short by the death of the publisher, Gravier, after the second volume. Of his numerous unpublished writings, Gentili complained that four volumes were lost "pessimo pontificiorum facinore," meaning probably that they were left behind in his flight to Carniola.

Authorities.—Several tracts by the Abate Benigni in Colucci, *Antichità Picene*, 1790; a Dissertation by W. Reiger annexed to the *Program of the Groningen Gymnasium* for 1867; an Inaugural Lecture delivered in 1874 by T. E. Holland, and the preface to a new edition of the *Jus Belli*, 1877, by the same; works by Valdarnini and Foglietti, 1875; Speranza and De Giorgi, 1876; Fiorini (a translation of the *Jus Belli*, with essay), 1877; A. Saffi, 1878. See also E. Comba, in the *Rivista Christiana*. 1876–7; and Sir T. Twiss, in the *Law Review*, 1878. (T. E. H.)

GENTILLY, a town of France, in the department of the Seine, is situated on the Bièvre, a short distance south of the fortifications of Paris. Its manufactures include biscuits, soap, vinegar, mustard, wax candles, buttons, leather, and pottery wares. It possesses a church of the 13th century, a lunatic asylum, a convent, a monastery, and several charitable institutions. The population in 1876 was 10,378.

GENTZ, FRIEDRICH VON (1764–1832), born at Breslau, May 2, 1764, aptly and accurately described by his distinguished friend Varnhagen von Ense as a writer-statesman (Schriftsteller Staatsmann). He was more than a publicist or political writer. His position was peculiar, and his career without a parellel. It is believed that no other instance can be adduced of a man exercising the same amount of influence in the conduct of public affairs, without rank or fortune, without high office, without being a member of a popular or legislative assembly, without in fact any ostenible means or instrumentality besides his pen. Born in the middle class in an aristocratic country, he lived on a footing of social equality with princes and ministers, the trusted partaker of their counsels and the chosen exponent of their policy.

His father held an employment in the Prussian civil service; his mother was an Ancillon distantly related to the statesman of that name. On his father's promotion to the mint directorship at Berlin and consequent removal to the capital, he was sent to a gymnasium there, and in due course completed his education at the university of Frankfort-on-the-Oder. He is said to have shown neither liking nor aptitude for intellectual pursuits till after his attendance on the lectures of Kant at Königsberg, in his twentieth or twenty-first year, when, suddenly lighted up as by inspiration, he set to work in right earnest, mastered the Greek and Latin languages, acquired as perfect a knowledge of French as could well be attained by one who was not a Frenchman, and a sufficient familiarity with English to enable him to translate from it with clearness and fluency. He also managed to gain an intimate acquaintance with English commerce and finance, which he afterwards turned to good account. The extent of his acquirements was rendered more remarkable by his confirmed habits of dissipation; for from the commencement to the conclusion of his career he was remarkable for the manner in which, in the midst of the gravest occupations, he indulged his fondness for female society and a ruinous passion for play. In 1786 he was appointed private secretary to the royal general directory, and was soon afterwards promoted to the rank of *Kriegsrath* (war-councillor). Like Mackintosh, he was fascinated by the French Revolution at its dawn, and, like Mackintosh, was converted to a sounder estimate of its then pending results by Burke. He broke ground in literature in 1794, by a translation of the celebrated *Essay on the French Revolution*, followed in 1794 and 1795 by translations from Mallet du Pan and Mounier. In 1795 he founded and edited a monthly journal which soon came to an untimely end. In November 1797 he published a pamphlet under the title of a *Sendscreiben* or *Missive* addressed to Frederick William III. of Prussia on his accession, pointing out the duties of the new sovereign and especially recommending the complete freedom of the press. In the course of the next three years he contributed to the *Historisches Journal* a series of articles "On the Origin and Character of the War against the French Revolution," with express reference to Great Britain. These led to his visiting England, where he formed intimate relations with Mackintosh, Lord Grenville, Pitt, and other eminent men, which proved lasting, flattering, and remunerative. The first entries in his published diary, beginning April 14, 1800, and continued (with breaks) to the end of 1828, run thus:—

"On the 14th of April, an agreeable surprise. The Jew elder, Hirsch, brought me 50 thalers for drawing up I know not what representation (*Vorstellung*). *May* 28.—Received through Baron Krüdener a watch set with (small) brilliants, a present from the emperor of Russia. *June* 1.—Received through Garlicke a letter from Lord Grenville, together with a donation of £500, the first of its kind."

The last entry for this year, 1800, is:—"At the end of the year great pecuniary embarrassment. Received £100 from Garlicke and negotiated with Carysfort."

The diary for 1801 begins:—"*February*.—Very remarkable that on the one side Lord Carysfort charged me with the translation into French of the English Notes against Prussia, and shortly afterwards Count Haugwitz with the translation into German of the Prussian Notes against England."

Frequently recurring entries of this kind illustrate his position through life. He was to all intents and purposes a mercenary of the pen, but he was so openly and avowedly, and he was never so much as suspected by those who knew him best of writing contrary to his own convictions at the time. This is why he never lost the esteem or confidence of his employers;—of Prince Metternich, for example, who, when he was officially attached to the Austrian Government, was kept regularly informed of the sources from which the greater part of his income was derived. Embarrassments of all sorts, ties and temptations from which he was irresistibly impelled to tear himself, led to his change of country; and an entry for May 1802 runs:—"On the 15th I take leave of my wife, and at three in the morning of the 20th I leave Berlin with Adam Müller, never to see it again.' It does not appear that he ever saw his wife again either; and his intimacies with other women, mostly of the highest rank, are puzzling from their multiplicity. He professes himself unable to explain the precise history of his settlement in Vienna. All he remembers is that he was received with signs of jealousy and distrust, and that the emperor, to whom he was presented by Count Colloredo, showed no desire to secure his services. Many years were to elapse before the formation of the connexion with Metternich, the most prominent feature and crowning point of his career.

Before entering into any kind of engagements with the Austrian Government he applied to the king of Prussia for a formal discharge, which was granted with an assurance that his Majesty, "in reference to his merits as a writer, coincided in the general approbation which he had so honourably acquired." A decisive proof of the confidence placed in him was his being invited by Count Haugwitz to the Prussian headquarters shortly before the battle of Jena, and commissioned to draw up the Prussian manifesto and the king's letter to Napoleon. It was in noticing this letter that Napoleon spoke of the known and avowed writer as "a wretched scribe named Gentz, one of those men without honour who sell themselves for money." In the course of 1806, he published *War between Spain and England*, and *Fragments upon the Balance of Power in Europe*, on receiving which (at Bombay) Mackintosh wrote:—"I assent to all you say, sympathize with all you feel, and admire equally your reason and your eloquence throughout your masterly fragment." The bond of union between him and Metternich was formed in 1840. This was one reason, joined to his general reputation, for his being named first secretary to the congress of Vienna in 1814, where, besides his regular duties, he seems to have made himself useful to several of the plenipotentiaries, as he notes in his diary that he received 22,000 florins in the name of Louis XVIII. from Talleyrand, and £600 from Lord Castlereagh, accompanied by "*les plus folles promesses*." He acted in the same capacity at the congress or conference of Paris in 1815, of Aix in 1818, Karlsbad and Vienna in 1819, Troppau and Laybach in 1820 and 1821, and Verona in 1822. The following entry in his diary for December 14, 1819, has exposed him to much obloquy as the interested advocate of reactionary doctrines:—"About eleven, at Prince Metternich's: attended the last and most important sitting of the commission to settle the 13th article of the Bundes-Akt, and had my share in one of the greatest and worthiest results of the transactions of our time. A day more important than that of Leipsic." The 13th article provides that in all states of the Bund the constitutional government shall be by estates instead of by a representative body in a single chamber: "in allen Bundestaaten wird eine landständische Verfassung stattfinden." Remembering what ensued in France from the absorption of the other estates in the Tiers État, it would have been strange if Gentz had not supported this 13th article. He was far from a consistent politician, but he was always a sound Conservative at heart; and his reputation rests on his foreign policy, especially on the courage, eloquence, and efficiency with which he made head against the Napoleonic system till it was struck down.

The most remarkable phase of Gentz's declining years was his passion, in his sixty-seventh year, for Fanny Elssler, the celebrated *danseuse*, which forms the subject of some very remarkable letters to his attached friend Rahel (the wife of Varnhagen von Ense) in 1830 and 1831. He died June 9, 1832. There is no complete edition of his works. The late Baron von Prokesch was engaged in preparing one when the Austrian Government interfered, and the design was perforce abandoned. (A. H.)

GEODESY

GEODESY ($\gamma\hat{\eta}$, the earth, $\delta\alpha\acute{\iota}\omega$, to divide) is the science of surveying extended to large tracts of country, having in view not only the production of a system of maps of very great accuracy, but the determination of the curvature of the surface of the earth, and eventually of the figure and dimensions of the earth. This last, indeed, may be the sole object in view, as was the case in the operations conducted in Peru and in Lapland by the celebrated French astronomers Bouguer, La Condamine, Maupertuis, Clairaut, and others; and the measurement of the meridian arc of France by Mechain and Delambre had for its end the determination of the true length of the "metre" which was to be the legal standard of length of France.

The basis of every extensive survey is an accurate triangulation, and the operations of geodesy consist in—the measurement, by theodolites, of the angles of the triangles; the measurement of one or more sides of these triangles on the ground; the determination by astronomical observations of the azimuth of the whole network of triangles; the determination of the actual position of the same on the surface of the earth by observations, first for latitude at some of the stations, and secondly for longitude.

To determine by actual measurement on the ground the length of a side of one of the triangles, wherefrom to infer the lengths of all the other sides in the triangulation, is not the least difficult operation of a trigonometrical survey. When the problem is stated thus—To determine the number of times that a certain standard or unit of length is contained between two finely marked points on the surface of the earth at a distance of some miles asunder, so that the error of the result may be pronounced to lie between certain very narrow limits,—then the question demands very serious consideration. The representation of the unit of length by means of the distance between two fine lines on the surface of a bar of metal at a certain temperature is never itself free from uncertainty and probable error, owing to the difficulty of knowing at any moment the precise temperature of the bar; and the transference of this unit, or a multiple of it, to a measuring bar, will be affected not only with errors of observation, but with errors arising from uncertainty of temperature of both bars. If the measuring bar be not self-compensating for temperature, its expansion must be determined by very careful experiments. The thermometers required for this purpose must be very carefully studied, and their errors of division and index error determined.

The base apparatus of Bessel and that of Colby have been described in FIGURE OF THE EARTH (vol. vii. p. 598). The average probable error of a single measurement of a base line by the Colby apparatus is, according to the very elaborate investigations of Colonel Walker, C.B., R.E., the Surveyor-General of India, $\pm 1{\cdot}5\mu$ (μ meaning "one millionth"). W. Struve gives $\pm 0{\cdot}8\mu$ as the probable error of a base line measured with his apparatus, being the mean of the probable errors of seven bases measured by him in Russia; but this estimate is probably too small. Struve's apparatus is simple: there are four wrought iron bars, each two toises (rather more than 13 feet) long; one end of each bar is terminated in a small steel cylinder presenting a slightly convex surface for contact, the other end carries a contact lever rigidly connected with the bar. The shorter arm of the lever terminates below in a polished hemisphere, the upper and longer arm traversing a vertical divided arc. In measuring, the plane end of one bar is brought into contact with the short arm of the contact lever (pushed forward by a weak spring) of the next bar. Each bar has two thermometers, and a level for determining the inclination of the bar in measuring. The manner of transferring the end of a bar to the ground is simply this: under the end of the bar a stake is driven very firmly into the ground, carrying on its upper surface a disk, capable of movement in the direction of the measured line by means of slow-motion screws. A fine mark on this disk is brought vertically under the end of the bar by means of a theodolite which is planted at a distance of 25 feet from the stake in a direction perpendicular to the base. Struve investigates for each base the probable errors of the measurement arising from each of these seven causes:—alignment, inclination, comparisons with standards, readings of index, personal errors, uncertainties of temperature, and the probable errors of adopted rates of expansion.

The apparatus used in the United States Coast Survey consists of two measuring bars, each 6 metres in length, supported on two massive tripod stands placed at one quarter length from each end, and provided, as in Colby's apparatus, with the necessary mechanism for longitudinal, transverse, and vertical adjustment. Each measuring rod is a compensating combination of an iron and a brass bar, supported parallel to one another and firmly connected at one end, the medium of connexion between the free ends being a lever of compensation so adjusted as to indicate a constant length independent of temperature or changes of temperature. The bars are protected from external influences by double tubes of tinned sheet iron, within which they are movable on rollers by a screw movement which allows of contacts being made within $\frac{1}{10000}$ of an inch. The abutting piece acts upon the contact lever which is attached to the fixed end of the compound bar, and carries a very sensitive level, the horizontal position of which defines the length of the bar. It is impossible here to give a full description of this complicated apparatus, and we must refer for details to the account given in full in the United States Coast Survey Report for 1854. This apparatus is doubtless a very perfect one, and the manipulation of it must offer great facilities, for it appears to be possible, under favourable circumstances, to measure a mile in one day, 1·06 mile having been measured on one occasion in eight and a half hours. In order to test to the utmost the apparatus, the base at Atlanta, Georgia, was measured twice in winter and once in summer 1872–73, at temperatures 51°, 45°, 90° F.; the difference of the first and second measurements was $+0{\cdot}30$ in., of the second and third $+0{\cdot}34$ in.,—the actual length and computed probable error expressed in metres being $9338{\cdot}4763 \pm 0{\cdot}0166$. It is to be noted that in the account of a base recently measured in the United States Lake Survey, some doubt is expressed as to the perfection of the particular apparatus of this description there used, on account of a liability to permanent changes of length.

The last base line measured in India with Colby's compensation apparatus had a length of 8912 feet only, and in consequence of some doubts which had arisen as to the accuracy of this compensation apparatus, the measurement was repeated four times, the operations being conducted in such a manner as to indicate as far as possible the actual magnitudes of the probable errors to which such measures are liable. The direction of the line (which is at Cape Comorin) is north and south, and in two of the measurements the brass component was to the west, in the other two it was to the east. The differences between the individual measurements and the mean of the four are $+{\cdot}0017$, $-{\cdot}0049$, $-{\cdot}0015$, $+{\cdot}0045$ in feet. The measurements occupied from seven to ten days each,—the average rate of such work in India being about a mile in five days.

The method of M. Porro, adopted in Spain, and by the French in Algiers, is essentially different from those just described. The measuring rod, for there is only one, is a thermometric combination of two bars, one of platinum and one of brass, in length 4 metres, furnished with three levels and four thermometers. Suppose A, B, C three micrometer microscopes very firmly supported at intervals of 4 metres with their axes vertical, and aligned in the plane of the base line by means of a transit instrument, their micrometer screws being in the line of measurement. The measuring bar is brought under say A and B, and those micrometers read; the bar is then shifted and brought under B and C. By repetition of this process, the reading of a micrometer indicating the end of each position of the bar, the measurement is made. The probable error of the central base of Madridejos, which has a length of 14664·500 metres, is estimated at $\pm 0{\cdot}17\mu$. This is the longest base line in Spain; there are seven others, six of which are under 2500 metres in length; of these one is in Majorca, another in Minorca, and a third in Iviça. The last base just measured in the province of Barcelona has a length of 2483·5381 metres according to the first measurement, and 2483·5383 according to the second.

The total number of base lines measured in Europe up to the present time is about eighty, fifteen of which do not exceed in length 2500 metres, or about a mile and a half, and two—one in France, the other in Bavaria—exceed 19,000 metres. The question has been frequently discussed whether or not the advantage of a long base is sufficiently great to warrant the expenditure of time that it requires, or whether as much precision is not obtainable in the end by careful triangulation from a short base. But the answer cannot be given generally; it must depend on the circumstances of each particular case.

It is necessary that the altitude above the level of the sea of every part of a base line be ascertained by spirit levelling, in order that the measured length may be reduced to what it would have been had the measurement been made on the surface of the sea, produced in imagination. Thus if l be the length of a measuring bar, h its height at any given position in the measurement, r the radius of the earth, then the length radially projected on to the level of the sea is $l - \frac{h}{r} l$. In the Salisbury Plain base line the reduction to the level of the sea is $-0{\cdot}6294$ feet.

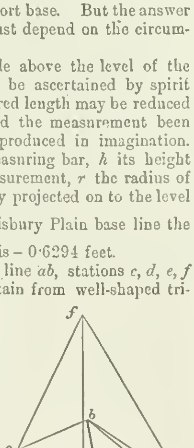

Fig. 1.

In working away from a base line ab, stations c, d, e, f are carefully selected so as to obtain from well-shaped triangles gradually increasing sides. Before, however, finally leaving the base line it is usual to verify it by triangulation thus: during the measurement two or more points, as p, q (fig. 1), are marked in the base in positions such that the lengths of the different segments of the line are known; then, taking suitable external stations, as h, k, the angles of the triangles bhp, phq, hqk, kqa are measured. From these angles can be computed the ratios of the segments, which must agree, if all operations are correctly performed, with the ratios resulting from the measures. Leaving the base line, the sides increase up to ten, thirty, or fifty miles, occasionally, but seldom, reaching a hundred miles. The triangulation points may either be natural objects presenting themselves in suitable positions, such as church towers; or they may be objects specially constructed in stone or wood on mountain tops or other prominent ground. In every case it is necessary that the precise centre of the station be marked by some permanent mark. In India no expense is spared in making permanent the principal trigonometrical stations—costly towers in masonry being erected. It is essential that every trigonometrical station shall present a fine object for observation from surrounding stations.

Horizontal Angles.

In placing the theodolite over a station to be observed from, the first point to be attended to is that it shall rest upon a perfectly solid foundation. The method of obtaining this desideratum must depend entirely on the nature of the ground; the instrument must if possible be supported on rock, or if that be impossible a solid foundation must be obtained by digging. When the theodolite is required to be raised above the surface of the ground in order to command particular points, it is necessary to build two scaffolds,—the outer one to carry the observatory, the inner one to carry the instrument,—and these two edifices must have no point of contact. Many cases of high scaffolding have occurred on the English Ordnance Survey, as for instance at Thaxted Church, where the tower, 80 feet high, is surmounted by a spire of 90 feet. The scaffold for the observatory was carried from the base to the top of the spire; that for the instrument was raised from a point of the spire 140 feet above the ground, having its bearing upon timbers passing through the spire at that height. Thus the instrument, at a height of 178 feet above the ground, was insulated, and not affected by the action of the wind on the observatory.

At every station it is necessary to examine and correct the adjustments of the theodolite, which are these:—the line of collimation of the telescope must be perpendicular to its axis of rotation; this axis perpendicular to the vertical axis of the instrument; and the latter perpendicular to the plane of the horizon. The micrometer microscopes must also measure correct quantities on the divided circle or circles. The method of observing is this. Let A, B, C .... be the stations to be observed taken in order of azimuth; the telescope is first directed to A and the cross-hairs of the telescope made to bisect the object presented by A, then the microscopes or verniers of the horizontal circle (also of the vertical circle if necessary) are read and recorded. The telescope is then turned to B, which is observed in the same manner; then C and the other stations. Coming round by continuous motion to A, it is again observed, and the agreement of this second reading with the first is some test of the stability of the instrument. In taking this round of angles—or "arc," as it is called on the Ordnance Survey—it is desirable that the interval of time between the first and second observations of A should be as small as may be consistent with due care. Before taking the next arc the horizontal circle is moved through 20° or 30°; thus a different set of divisions of the circle is used in each arc, which tends to eliminate the errors of division.

It is very desirable that all arcs at a station should contain one point in common, to which all angular measurements are thus referred,—the observations on each arc commencing and ending with this point, which is on the Ordnance Survey called the "referring object." It is usual for this purpose to select, from among the points which have to be observed, that one which affords the best object for precise observation. For mountain tops a "referring object" is constructed of two rectangular plates of metal in the same vertical plane, their edges parallel and placed at such a distance apart that the light of the sky seen through appears as a vertical line about 10″ in width. The best distance for this object is from one to two miles.

It is clear that no correction is required to the angles measured by a theodolite on account of its height above the sea-level; for its axis of rotation coincides with the normal to the surface of the earth, and the angles measured between distant points are those contained between the vertical planes passing through the axis of the instrument and those points.

The theodolites used in geodesy vary in pattern and in size—the horizontal circles ranging from 10 inches to 36 inches in diameter. In Ramsden's 36-inch theodolite the telescope has a focal length of 36 inches and an aperture of 2·5 inches, the ordinarily used magnifying power being 54; this last, however, can of course be changed at the requirements of the observer or of the weather. The probable error of a single observation of a fine object with this theodolite is about 0″·2.

Fig. 2 represents an altazimuth theodolite of an improved pattern now used on the Ordnance Survey. The

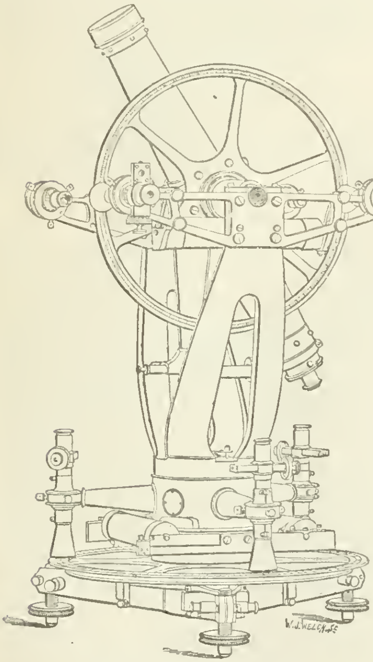

Fig. 2.—Altazimuth Theodolite.

horizontal circle of 14 inches diameter is read by three micrometer microscopes; the vertical circle has a diameter of 12 inches, and is read by two microscopes.

In the Great Trigonometrical Survey of India the theodolites used in the more important parts of the work have been of 2 and 3 feet diameter,—the circle read by five equidistant microscopes. Every angle is measured twice in each position of the zero of the horizontal circle, of which there are generally ten; the entire number of measures of an angle is never less than 20. An examination of 1407 angles showed that the probable error of an observed angle is on the average ± 0·28.

For the observations of very distant stations it is usual to employ a heliostat. In its simplest form this is a plane mirror 4, 6, or 8 inches in diameter, capable of rotation round a horizontal and a vertical axis. This mirror is placed at the station to be observed, and in fine weather it is kept so directed that the rays of the sun reflected by it strike the distant observing telescope. To the observer the heliostat presents the appearance of a star of the first or second magnitude, and is generally a pleasant object for observing.

Astronomical Observations.

The direction of the meridian is determined either by a theodolite or a portable transit instrument. In the former case the operation consists in observing the angle between a terrestrial object—generally a mark specially erected and capable of illumination at night—and a close circumpolar star at its greatest eastern or western azimuth, or, at any rate, when very near that position. If the observation be made t minutes of time before or after the time of greatest azimuth, the azimuth then will differ from its maximum value by

$$(450t)^2 \sin 1'' \frac{\sin 2\delta}{\sin z} \pm \ldots$$

in seconds of angle, omitting smaller terms. Here the symbol δ is the star's declination, z its zenith distance. The collimation and level errors are very carefully determined before and after these observations, and it is usual to arrange the observations by the reversal of the telescope so that collimation error shall disappear. If b, c be the level and collimation errors, the correction to the circle reading is $b \cot z \pm c \operatorname{cosec} z$, b being positive when the west end of the axis is high. It is clear that any uncertainty as to the real state of the level will produce a corresponding uncertainty in the resulting value of the azimuth,—an uncertainty which increases with the latitude, and is very large in high latitudes. This may be partly remedied by observing in connexion with the star its reflexion in mercury. In determining the value of "one division" of a level tube, it is necessary to bear in mind that in some the value varies considerably with the temperature. By experiments on the level of Ramsden's 3-foot theodolite, it was found that though at the ordinary temperature of 66° the value of a division was about one second, yet at 32° it was about five seconds.

The portable transit in its ordinary form hardly needs description. In a very excellent instrument of this kind used on the Ordnance Survey, the uprights carrying the telescope are constructed of mahogany, each upright being built of several pieces glued and screwed together; the base, which is a solid and heavy plate of iron, carries a reversing apparatus for lifting the telescope out of its bearings, reversing it, and letting it down again. Thus is avoided the change of temperature which the telescope would incur by being lifted by the hands of the observer. Another form of transit is the German diagonal form, in which the rays of light after passing through the object glass are turned by a total reflexion prism through one of the transverse arms of the telescope, at the extremity of which arm is the eye-piece. The unused half of the ordinary telescope being cut away is replaced by a counterpoise. In this instrument there is the advantage that the observer without moving the position of his eye commands the whole meridian, and that the level may remain on the pivots whatever be the elevation of the telescope. But there is the disadvantage that the flexure of the transverse axis causes a variable collimation error depending on the zenith distance of the star to which it is directed; and moreover it has been found that in some cases the personal error of an observer is not the same in the two positions of the telescope.

To determine the direction of the meridian, it is well to erect two marks at nearly equal angular distances on either side of the north meridian line, so that the pole star crosses the vertical of each mark a short time before and after attaining its greatest eastern and western azimuths.

If now the instrument, perfectly levelled, is adjusted to have its centre wire on one of the marks, then when elevated to the star, the star will traverse the wire, and its exact position in the field at any moment can be measured by the micrometer wire. Alternate observations of the star and the terrestrial mark, combined with careful level readings and reversals of the instrument, will enable one, even with only one mark, to determine the direction of the meridian in the course of an hour with a probable error of less than a second. The second mark enables one to complete the station more rapidly, and gives a check upon the work. As an instance, at Findlay Seat, in latitude 57° 35′, the resulting azimuths of the two marks were 177° 45′ 37″·29 ± 0″·20 and 182° 17′ 15″·61 ± 0″·13, while the angle between the two marks directly measured by a theodolite was found to be 4° 31′ 37″·43 ± 0″·23.

We now come to the consideration of the determination of time with the transit instrument. Let fig. 3 represent the sphere stereographically projected on the plane of the horizon,—*ns* being the meridian, *we* the prime vertical, Z, P the zenith and the pole. Let p be the point in which the production of the axis of the instrument meets the celestial sphere, S the position of a star when observed on a wire whose distance from the collimation centre is c. Let a

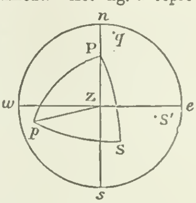

Fig. 3.

be the azimuthal deviation, namely, the angle wZp, b the level error so that $Zp = 90° - b$. Let also the hour angle corresponding to p be $90° - n$, and the declination of the same $= m$, the star's declination being δ, and the latitude ϕ. Then to find the hour angle $ZPS = \tau$ of the star when observed, in the triangles vPS. vPZ we have. since $pPS = 90 + \tau - n$,

$$\begin{aligned} -\text{Sin } c &= \sin m \sin \delta + \cos m \cos \delta \sin (n - \tau), \\ \text{Sin } m &= \sin b \sin \phi - \cos b \cos \phi \sin a, \\ \text{Cos } m \sin n &= \sin b \cos \phi + \cos b \sin \phi \sin a. \end{aligned}$$

And these equations solve the problem, however large be the errors of the instrument. Supposing, as usual, a, b, m, n to be small, we have at once $\tau = n + c \sec \delta + m \tan \delta$, which is the correction to the observed time of transit. Or, eliminating m and n by means of the second and third equations, and putting z for the zenith distance of the star, t for the observed time of transit, the corrected time is

$$t + \frac{a \sin z + b \cos z + c}{\cos \delta}$$

Another very convenient form for stars near the zenith is this—

$$\tau = b \sec \phi + c \sec \delta + n (\tan \delta - \tan \phi).$$

Suppose that in commencing to observe at a station the error of the chronometer is not known; then having secured for the instrument a very solid foundation, removed as far as possible level and collimation errors, and placed it by estimation nearly in the meridian, let two stars differing considerably in declination be observed—the instrument not being reversed between them. From these two stars, neither of which should be a close circumpolar star, a good approximation to the chronometer error can be obtained; thus let ϵ_1, ϵ_2 be the apparent clock errors given by these stars, if δ_1, δ_2 be their declinations the real error is

$$\epsilon = \epsilon_1 + (\epsilon_1 - \epsilon_2)\frac{\tan \phi - \tan \delta_1}{\tan \delta_1 - \tan \delta_2}.$$

Of course this is still only approximative, but it will enable the observer (who by the help of a table of natural tangents can compute ϵ in a few minutes) to find the meridian by placing at the proper time, which he now knows approximately, the centre wire of his instrument on the first star that passes—not near the zenith.

The transit instrument is always reversed at least once in the course of an evening's observing, the level being frequently read and recorded. It is necessary in most instruments to add a correction for the difference in size of the pivots.

The transit instrument is also used in the prime vertical for the determination of latitudes. In the preceding figure let q be the point in which the northern extremity of the axis of the instrument produced meets the celestial sphere. Let nZq be the azimuthal deviation $= a$, and b being the level error, $Zq = 90° - b$; let also $nPq = \tau$ and $Pq = \psi$. Let S′ be the position of a star when observed on a wire whose distance from the collimation centre is c, positive when to the south, and let h be the observed hour angle of the star, viz., ZPS′. Then the triangles qPS′, qPZ give

$$\begin{aligned} \text{Sin } c &= \sin \delta \cos \psi - \cos \delta \sin \psi \cos (h + \tau), \\ \text{Cos } \psi &= \sin b \sin \phi + \cos b \cos \phi \cos a, \\ \text{Sin } \psi \sin \tau &= \cos b \sin a. \end{aligned}$$

Now when a and b are very small, we see from the last two equations that $\psi = \phi - b$, $a = \tau \sin \psi$, and if we calculate ϕ' by the formula $\cot \phi' = \cot \delta \cos h$, the first equation leads us to this result—

$$\phi = \phi' + \frac{a \sin z + b \cos z + c}{\cos z}.$$

the correction for instrumental error being very similar to that applied to the observed time of transit in the case of meridian observations. When a is not very small and z is small, the formulæ required are more complicated.

The method of determining latitude by transits in the prime vertical has the disadvantage of being a somewhat slow process, and of requiring a very precise knowledge of the time, a disadvantage from which the zenith telescope is free. In principle this instrument is based on the proposition that when the meridian zenith distances of two stars at their upper culminations—one being to the north and the other to the south of the zenith—are equal, the latitude is the mean of their declinations; or, if the zenith distance of a star culminating to the south of the zenith be Z, its declination being δ, and that of another culminating to the north with zenith distance Z′ and declination δ', then clearly the latitude is $\frac{1}{2}(\delta + \delta') + \frac{1}{2}(Z - Z')$. Now the zenith telescope does away with the divided circle, and substitutes the measurement micrometrically of the quantity $Z' - Z$.

The instrument (fig. 4) is supported on a strong tripod, fitted with levelling screws; to this tripod is fixed the azimuth circle and a long vertical steel axis. Fitting on this axis is a hollow axis which carries on its upper end a short transverse horizontal axis. This latter carries the telescope, which, supported at the centre of its length, is free to rotate in a vertical plane. The telescope is thus mounted excentrically with respect to the vertical axis around which it revolves. An extremely sensitive level is attached to the telescope, which latter carries a micrometer in its eyepiece, with a screw of long range for measuring differences of zenith distance. For this instrument stars are selected in pairs, passing north and south of the zenith, culminating within a few minutes of time and within about twenty minutes (angular) of zenith distance of each other. When a pair of stars is to be observed, the telescope is set to the mean of the zenith distances and in the plane of the meridian. The first star on passing the central meridional wire is bisected by the micrometer; then the telescope is rotated very carefully through 180° round the vertical axis, and the second star on passing through the field is bisected

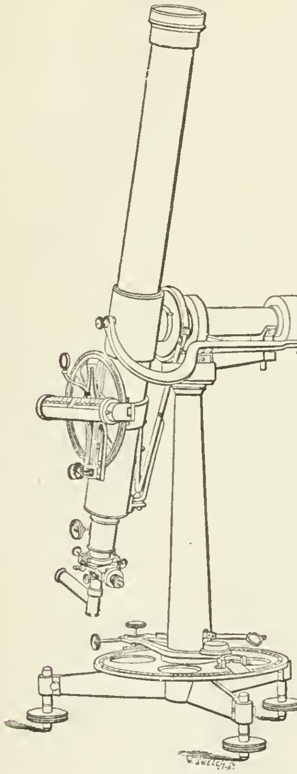

FIG. 4.—Zenith Telescope.

by the micrometer on the centre wire. The micrometer has thus measured the difference of the zenith distances, and the calculation to get the latitude is most simple. Of course it is necessary to read the level, and the observations are not necessarily confined to the centre wire. In fact if n, s be the north and south readings of the level for the south star, n', s' the same for the north star, l the value of one division of the level, m the value of one division of the micrometer, r, r' the refraction corrections, μ, μ' the micrometer readings of the south and north star, the micrometer being supposed to read *from* the zenith, then, supposing the observation made on the centre wire,—

$$\phi = \tfrac{1}{2}(\delta + \delta') + \tfrac{1}{2}(\mu - \mu')m + \tfrac{1}{4}(n + n' - s - s')l + \tfrac{1}{2}(r - r').$$

It is of course of the highest importance that the value m of the screw be well determined. This is done most effectually by observing the vertical movement of a close circumpolar star when at its greatest azimuth.

In a single night with this instrument a very accurate result, say with a probable error of about 0″·3 or 0″·4, could be obtained for latitude from, say, twenty pair of stars; but when the latitude is required to be obtained with the highest possible precision, four or five fine nights are necessary. The weak point of the zenith telescope lies in the circumstance that its requirements prevent the selection of stars whose positions are well fixed; very frequently it is necessary to have the declinations of the stars selected for this instrument specially observed at fixed observatories. The zenith telescope is made in various sizes from 30 to 54 inches in focal length; a 30-inch telescope is sufficient for the highest purposes, and is very portable. The zenith telescope is a particularly pleasant instrument to work with, and an observer has been known (a sergeant of Royal Engineers, on one occasion) to take every star in his list during eleven hours on a stretch, namely, from 6 o'clock P.M. until 5 A.M., and this on a very cold November night on one of the highest points of the Grampians. Observers accustomed to geodetic operations attain considerable powers of endurance. Shortly after the commencement of the observations on one of the hills in the Isle of Skye a storm carried away the wooden houses of the men and left the observatory roofless. Three observatory roofs were subsequently demolished, and for some time the observatory was used without a roof, being filled with snow every night and emptied every morning. Quite different, however, was the experience of the same party when on the top of Ben Nevis, 4406 feet high. For about a fortnight the state of the atmosphere was unusually calm, so much so, that a lighted candle could often be carried between the tents of the men and the observatory, whilst at the foot of the hill the weather was wild and stormy.

Calculation of Triangulation.

The surface of Great Britain and Ireland is uniformly covered by triangulation, of which the sides are of various lengths from 10 to 111 miles. The largest triangle has one angle at Snowdon in Wales, another on Slieve Donard in Ireland, and a third at Scaw Fell in Cumberland; each side is over a hundred miles, and the spherical excess is 64″.

The more ordinary method of triangulation is, however, that of chains of triangles, in the direction of the meridian and perpendicular thereto. The principal triangulations of France, Spain, Austria, and India are so arranged. Oblique chains of triangles are formed in Italy, Sweden, and Norway, also in Germany and Russia, and in the United States. Chains are composed sometimes merely of consecutive plain triangles; sometimes, and more frequently in India, of combinations of triangles forming consecutive polygonal figures. In this method of triangulating, the sides of the triangles are generally from 20 to 30 miles in length—seldom exceeding 40.

The inevitable errors of observation, which are inseparable from all angular as well as other measurements, introduce a great difficulty into the calculation of the sides of a triangulation. Starting from a given base in order to get a required distance, it may generally be obtained in several different ways—that is, by using different sets of triangles. The results will certainly differ one from another, and probably no two will agree. The experience of the computer will then come to his aid, and enable him to say which is the most trustworthy result; but no experience or ability will carry him through a large network of triangles with anything like assurance. The only way to obtain trustworthy results is to employ the method of least squares, an explanation of which will be found in FIGURE OF THE EARTH (vol. vii. p. 605). We cannot here give any illustration of this method as applied to general triangulation, for it is most laborious, even for the simplest cases. We may, however, take the case of a simple chain—commencing with the consideration of a single triangle in which all three angles have been observed.

Suppose that the sum of the observed angles exceeds the proper amount by a small quantity ϵ: it is required to assign proper corrections to the angles, so as to cause this error to disappear. To do this we must be guided by the *weight* of the determinations of each angle. When a series of direct and independent observations is made, under similar circumstances, of any measurable magnitude—as an angle—the weight of the result is equal to half the square of the number of observations divided by the sum of the squares of the differences of the individual measures from the mean of all. Now let h, k, l be the weights of the three measured angles, and let x, y, z be the corrections which should be applied to them. We know that $x+y+z+\epsilon=0$; and the theory of probabilities teaches us that the most probable values are those which make $hx^2+ky^2+lz^2$ a minimum. Here we arrive at a simple definite problem, the result of which is $hx=ky=lz$, showing that ϵ has to be divided into three parts which shall be proportional to the reciprocals of the weights of the corresponding angles. In what follows we shall, for simplicity, suppose the weights of the observed angles to be all equal.

Suppose now that A, B, C are the three angles of a triangle, and that the observed values are $A+e_1$, $B+e_2$, $C+e_3$; then, although e_1, e_2, e_3, the errors of observation, are unknown, yet by adding up the observed angles and finding that the sum is in excess of the truth by a small quantity e, we get $e_1+e_2+e_3=e$. Now, according to the last proposition, if we suppose the angles to be equally well observed, we have to subtract $\frac{1}{3}e$ from each of the observed values, which thus become $A+\frac{2}{3}e_1-\frac{1}{3}e_2-\frac{1}{3}e_3$, $B-\frac{1}{3}e_1+\frac{2}{3}e_2-\frac{1}{3}e_3$, $C-\frac{1}{3}e_1-\frac{1}{3}e_2+\frac{2}{3}e_3$. Then to obtain a and b by calculation from the known side c, we have

$$a \sin(C-\tfrac{1}{3}e_1-\tfrac{1}{3}e_2+\tfrac{2}{3}e_3)=c\sin(A+\tfrac{2}{3}e_1-\tfrac{1}{3}e_2-\tfrac{1}{3}e_3),$$

with a similar expression for the relation between b and c. Put α, β, γ for the cotangents of A, B, C, then the errors of the computed values of a and b are expressed thus—

$$\delta a=\tfrac{1}{3}a\{e_1(2\alpha+\gamma)+e_2(-\alpha+\gamma)+e_3(-\alpha-2\gamma)\}$$

$$\delta b=\tfrac{1}{3}b\{e_1(-\beta+\gamma)+e_2(2\beta+\gamma)+e_3(-\beta-2\gamma)\}$$

Now these actual errors must remain unknown; but we here make use of the following theorem, proved in the doctrine of probabilities. The probable error of a quantity which is a function of several independently observed elements is equal to the square root of the sum of the squares of the probable errors that would arise from each of the observed elements taken singly. Now suppose that each angle in a triangle has a probable error ϵ, then we replace e_1, e_2, e_3 by ϵ, and adding up the squares of the coefficients find for the probable error of a, $\pm\frac{1}{3}a\epsilon\sqrt{6}\sqrt{(\alpha^2+\alpha\gamma+\gamma^2)}$, and for that of b, $\pm\frac{1}{3}b\epsilon\sqrt{6}\sqrt{(\beta^2+\beta\gamma+\gamma^2)}$. Suppose the triangle equilateral, each side eight miles, and the probable error of an observed angle 0″·3; then the probable error of either of the computed sides will be found to be 0·60 inches.

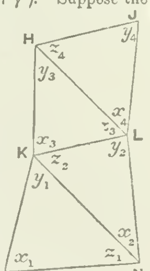

Fig. 5.

Take a chain of triangles as indicated in the diagram (fig. 5); suppose all the angles measured, and that the sides MN, HJ are measured bases; it is required to investigate the necessary corrections to the observed angles in order not only that the sum of the three angles of each triangle fulfil the necessary condition, but that the length of HJ, calculated from that of MN, shall agree with the measured length.

Let X_1, Y_1, Z_1, &c., be the angles as observed, x_1, y_1, z_1, &c., the required corrections; then each triangle on adding up the angles gives an equation $x_1+y_1+z_1+\epsilon_1=0$. Let the corrected angles be $X^1=X+x$, $Y^1=Y+y$, &c., then

$$\frac{HJ}{MN}=\frac{\sin X_1^1 \sin X_2^1 \sin X_3^1 \sin X_4^1}{\sin Y_1^1 \sin Y_2^1 \sin Y_3^1 \sin Y_4^1}$$

$$=\frac{\sin X_1 \sin X_2 \sin X_3 \sin X_4}{\sin Y_1 \sin Y_2 \sin Y_3 \sin Y_4}(1+u).$$

Let $\alpha_1, \beta_1, \gamma_1, \ldots$ be the cotangents of the angles, so that $\sin X^1=\sin X(1+\alpha x)$, then u in this last equation is easily seen to be the right hand member of the equation

$$f=\alpha_1x_1-\beta_1y_1+\alpha_2x_2-\beta_2y_2+\ \ldots\ .$$

Here f is known numerically, for the ratio of the measured bases is known, and the product of the ratios of the sines of the observed angles is known by computation. The most probable values of $x_1, y_1, z_1, \ldots$ are those which make the sum $\Sigma(x^2+y^2+z^2)$ a minimum, or, as we may write it,

$$\phi=\Sigma(x^2+y^2+(e+x+y)^2)$$

a minimum. This, and the previous equation in f, determine all the corrections. Differentiate both and multiply the former by a multiplier P, then

$$2x_i+y_i+e_i+P\alpha_i=0\,,$$
$$2y_i+x_i+e_i-P\beta_i=0\,,$$
$$3x_i=-P(2\alpha_i+\beta_i)-e_i\,,$$
$$3y'=\ \ P(\alpha_i+2\beta_i)-e_i\,.$$

Now, substitute these values in the f equation, and P becomes known; then follow at once all the corrections from the two last-written equations. These corrections being applied to the observed angles, every side in the triangulation has a definite value, which is obtained by the ordinary method of calculation.

A spheroidal triangle differs from a spherical triangle, not only in that the curvatures of the sides are different one from another, but more especially in this that, while in the spherical triangle the normals to the surface at the angular points meet at the centre of the sphere, in the spheroidal triangle the normals at the angles A, B, C meet the axis of revolution of the spheroid in three different points, which we may designate α, β, γ respectively. Now the angle A of the triangle as measured by a theodolite is the inclination of the planes BAα and CAα, and the angle at B is that contained by the planes ABβ and CBβ. But the planes ABα and ABβ containing the line AB in common cut the surface in two distinct plane curves. In order, therefore, that a spheroidal triangle may be exactly defined, it is necessary that the nature of the lines joining the three vertices be stated. In a mathematical point of view the most natural definition is that the sides be geodesic or shortest lines. Gauss, in his most elegant treatise entitled *Disquisitiones generales circa superficies curvas*, has entered fully into the subject of geodesic triangles, and has investigated expressions for the angles of a geodesic triangle whose sides are given, not certainly finite expressions, but approximations inclusive of small quantities of the fourth order, the side of the triangle or its ratio to the radius of the nearly spherical surface being a small quantity of the first order. The terms of the fourth order, as given by Gauss for any surface in general, are very complicated even when the surface is a spheroid. If we retain small quantities of the second order only, and put $\mathfrak{A}$, $\mathfrak{B}$, $\mathfrak{C}$ for the angles of the geodesic triangle, while A, B, C are those of a plane triangle having sides equal respectively to those of the geodesic triangle, then, σ being the area of the triangle and $\mathfrak{a}, \mathfrak{b}, \mathfrak{c}$ the measures of curvature at the angular points,

$$\mathfrak{A}=A+\frac{\sigma}{12}(2\mathfrak{a}+\mathfrak{b}+\mathfrak{c})\,,$$

$$\mathfrak{B}=B+\frac{\sigma}{12}(\mathfrak{a}+2\mathfrak{b}+\mathfrak{c})\,,$$

$$\mathfrak{C}=C+\frac{\sigma}{12}(\mathfrak{a}+\mathfrak{b}+2\mathfrak{c})\,.$$

The geodesic line being the shortest that can be drawn on any surface between two given points, we may be conducted to its most important characteristics by the following considerations: let p, q be adjacent points on a curved surface; through s the middle point of the chord pq imagine a plane drawn perpendicular to pq, and let S be any point in the intersection of this plane with the surface; then pS + Sq is evidently least when sS is a minimum, which is when sS is a normal to the surface; hence it follows that of all plane curves on the surface joining p, q, when those points are indefinitely near to one another, that is the shortest which is made by the normal plane. That is to say, the osculating plane at any point of a geodesic line contains the normal to the surface at that point. Imagine now three points in space, A, B, C, such that AB = BC = c; let the direction cosines of AB be l, m, n, those of BC l', m', n', then x, y, z being the coordinates of B, those of A and C will be respectively—

$$x-cl\ :\ y-cm\ :\ z-cn$$
$$x+cl'\ :\ y+cm'\ :\ z+cn'.$$

Hence the coordinates of the middle point M of AC are $x+\frac{1}{2}c(l'-l)$, $y+\frac{1}{2}c(m'-m)$, $z+\frac{1}{2}c(n'-n)$, and the direction cosines of BM are therefore proportional to $l'-l : m'-m : n'-n$. If the angle made by BC with AB be indefinitely small, the direction cosines of BM are as $\delta l : \delta m : \delta n$. Now if AB, BC be two contiguous elements of a geodesic, then BM must be a normal to the surface, and since δl, δm, δn are in this case represented by $\delta\frac{dx}{ds}$, $\delta\frac{dy}{ds}$, $\delta\frac{dz}{ds}$, we have

$$\frac{\frac{d^2x}{ds^2}}{\frac{du}{dx}} = \frac{\frac{d^2y}{ds^2}}{\frac{du}{dy}} = \frac{\frac{d^2z}{ds^2}}{\frac{du}{dz}},$$

which, however, are equivalent to only one equation. In the case of the spheroid this equation becomes

$$y\frac{d^2x}{ds^2} - x\frac{d^2y}{ds^2} = 0$$

which integrated gives $ydx - xdy = Cds$. This again may be put in the form $r \sin \alpha = C$, where α is the azimuth of the geodesic at any point—the angle between its direction and that of the meridian—and r the distance of the point from the axis of revolution.

From this it may be shown that the azimuth at A of the geodesic joining AB is not the same as the astronomical azimuth at A of B or that determined by the vertical plane AaB. Generally speaking, the geodesic lies between the two plane section curves joining A and B which are formed by the two vertical planes, supposing these points not far apart. If, however, A and B are nearly in the same latitude, the geodesic may cross (between A and B) that plane curve which lies nearest the adjacent pole of the spheroid. The condition of crossing is this. Suppose that for a moment we drop the consideration of the earth's non-sphericity, and draw a perpendicular from the pole C on AB, meeting it in S between A and B. Then A being that point which is nearest the pole, the geodesic will cross the plane curve if AS be between $\frac{1}{4}$AB and $\frac{3}{8}$AB. If AS lie between this last value and $\frac{1}{2}$AB, the geodesic will lie wholly to the north of both plane curves, that is, supposing both points to be in the northern hemisphere.

The circumstance that the angles of the geodesic triangle do not coincide with the true angles as observed renders it inconvenient to regard the geodesic lines as sides of the triangle. A more convenient curve to regard as the side of the spheroidal triangle is this: let L be a point on the curve surface between A and B, λ the point in which the normal at L intersects the axis of revolution, then if L be subject to the condition that the planes ALλ, BLλ coincide, it traces out a curve which touches at A and B the two plane curves before specified. Joining A, B, C by three such lines, the angles of the triangle so formed coincide with the true angles.

Let the azimuths (at the middle point, say) of the sides BC, CA, AB of a spheroidal triangle be α, β, γ, these being measured from 0° to 360° continuously, and the angles of the triangle lettered in the same cyclical direction, and let a, b, c be the lengths of the sides. Let there be a sphere of radius r, such that r is a mean proportional between the principal radii of curvature at the mean latitude ϕ of the spheroidal triangle, and on this sphere a triangle having sides equal respectively to a, b, c. If A′, B′, C′ be the angles of the spheroidal triangle, A, B, C those of the spherical triangle, then

$$A' - A = \frac{e^2}{12r^2}\cos^2\phi(b^2\sin 2\beta - c^2\sin 2\gamma),$$

$$B' - B = \frac{e^2}{12r^2}\cos^2\phi(c^2\sin 2\gamma - a^2\sin 2\alpha),$$

$$C' - C = \frac{e^2}{12r^2}\cos^2\phi(a^2\sin 2\alpha - b^2\sin 2\beta).$$

By adding these together, it appears that, to the order of terms here retained, the sum of the angles of the spheroidal triangle is equal to the sum of the angles of the spherical triangle. The spherical excess of a spheroidal triangle is therefore obtained by multiplying its area by $\frac{1}{\rho\rho'}$, Gauss's measure of curvature.

Further, let A_1, B_1, C_1 be the angles of a plane triangle having still the same sides a, b, c, then it may be shown by spherical trigonometry that, r being the radius of the sphere as before,

$$A - A_1 = \frac{\Delta}{3r^2}\left(1 + \frac{a^2 + 7b^2 + 7c^2}{120r^2}\right),$$

$$B - B_1 = \frac{\Delta}{3r^2}\left(1 + \frac{7a^2 + b^2 + 7c^2}{120r^2}\right),$$

$$C - C_1 = \frac{\Delta}{3r^2}\left(1 + \frac{7a^2 + 7b^2 + c^2}{120r^2}\right).$$

It is but seldom that the terms of the fourth order are required. Omitting them, we have Legendre's theorem, viz., "If from each of the angles of a spherical triangle, the sides of which are small in comparison with the radius, one-third of the spherical excess be deducted, the sines of the angles thus diminished will be proportional to the length of the opposite sides, so that the triangle may be computed as a plane triangle." By this means the spherical triangles which present themselves in geodesy are computed with very nearly the same ease as plane triangles. And from the expressions given above for the spheroidal angles A′, B′, C′ it may be proved that no error of any consequence can arise from treating a spheroidal triangle as a spherical, the radius of the sphere being as stated above.

When the angles of a triangulation have been adjusted by the method of least squares, the next process is to calculate the latitudes and longitudes of all the stations starting from one given point. The calculated latitudes, longitudes, and azimuths, which are designated geodetic latitudes, longitudes, and azimuths, are not to be confounded with the observed latitudes, longitudes, and azimuths, for these last are subject to somewhat large errors. Supposing the latitudes of a number of stations in the triangulation to be observed, practically the mean of these determines the position in latitude of the network, taken as a whole. So the orientation or general azimuth of the whole is inferred from all the azimuth observations. The triangulation is then supposed to be projected on a spheroid of given elements, representing as nearly as one knows the real figure of the earth. Then, taking the latitude of one point and the direction of the meridian there as given—obtained, namely, from the astronomical observations there—one can compute the latitudes of all the other points with any degree of precision that may be considered desirable. It is necessary to employ for this purpose formulæ which will give results true even for the longest distances to the second place of decimals of seconds, otherwise there will arise an accumulation of errors from imperfect calculation which should always be avoided. For very long distances, eight places of decimals should be employed in logarithmic calculations; if seven places only are available very great care will be required to keep the last place true. Now let ϕ, ϕ' be the latitudes of two stations A and B; α, α' their mutual azimuths counted from north by east continuously from 0° to 360°; ω their difference of longitude measured from west to east; and s the distance AB.

First compute a latitude ϕ_1 by means of the formula $\phi_1 = \phi + \frac{s}{\rho}\cos\alpha$, where ρ is the radius of curvature of the meridian at the latitude ϕ; this will require but four places of logarithms. Then, in the first two of the following, five places are sufficient—

$$\epsilon = \frac{s^2}{2\rho n}\sin\alpha\cos\alpha,$$

$$\eta = \frac{s^2}{2\rho n}\sin^2\alpha\tan\phi_1,$$

$$\phi - \phi = \frac{s}{\rho_\circ}\cos(\alpha - \tfrac{2}{3}\epsilon) - \eta,$$

$$\omega = \frac{s}{n}\,\frac{\sin(\alpha - \frac{1}{3}\epsilon)}{\cos(\phi' + \frac{1}{3}\eta)},$$

$$\alpha' - \alpha = \omega\sin(\phi' + \tfrac{2}{3}\eta) - \epsilon + 180°.$$

Here n is the normal or radius of curvature perpendicular to the meridian; both n and ρ correspond to latitude ϕ_1, and ρ_0 to latitude $\frac{1}{2}(\phi+\phi')$. For calculations of latitude and longitude, tables of the logarithmic values of $\rho \sin 1''$, $n \sin 1''$, and $2n\rho \sin 1''$ are necessary. The following table contains these logarithms for every ten minutes of latitude from 52° to 53° computed with the elements $a=20926060$ and $a:c=295:294$:—

Lat.	Log. $\frac{1}{\rho \sin 1''}$.	Log. $\frac{1}{n \sin 1''}$.	Log. $\frac{1}{2\rho n \sin 1''}$.
° ′			
52 0	7·9939434	7·9928231	0·37131
10	9309	8190	29
20	9185	81	28
30	9060	810,	26
₄0	8936	8065	24
50	8812	8024	23
53 0	8688	7982	22

The logarithm in the last column is that required also for the calculation of spherical excesses, the spherical excess of a triangle being expressed by $\frac{ab \sin C}{2\rho n \sin 1''}$.

It is frequently necessary to obtain the coordinates of one point with reference to another point; that is, let a perpendicular arc be drawn from B to the meridian of A meeting it in P, then, a being the azimuth of B at A, the coordinates of B with reference to A are

$$AP = s\cos(\alpha - \tfrac{2}{3}\epsilon),$$
$$BP = s\sin(\alpha - \tfrac{1}{3}\epsilon),$$

where ϵ is the spherical excess of APB, viz., $s^2 \sin a \cos a$ multiplied by the quantity whose logarithm is in the fourth column of the above table.

Irregularities of the Earth's Surface.

In considering the effect of unequal distribution of matter in the earth's crust on the form of the surface, we may simplify the matter by disregarding the considerations of rotation and excentricity. In the first place, supposing the earth a sphere covered with a film of water, let the density ρ be a function of the distance from the centre so that surfaces of equal density are concentric spheres. Let now a disturbance of the arrangement of matter take place, so that the density is no longer to be expressed by ρ, a function of r only, but is expressed by $\rho+\rho'$, where ρ' is a function of three coordinates θ, ϕ, r. Then ρ' is the density of what may be designated disturbing matter; it is positive in some places and negative in others, and the whole quantity of matter whose density is ρ' is zero. The previously spherical surface of the sea of radius a now takes a new form. Let P be a point on the disturbed surface, P′ the corresponding point vertically below it on the undisturbed surface, $PP'=u$. The knowledge of u over the whole surface gives us the form of the disturbed or actual surface of the sea; it is an equipotential surface, and if V be the potential at P of the disturbing matter ρ', M the mass of the earth,

$$\frac{M}{a+u} + V = C = \frac{M}{a} - \frac{M}{a^2}u + V.$$

As far as we know, u is always a very small quantity, and we have with sufficient approximation $u = \frac{3V}{4\pi\delta a}$, where δ is the mean density of the earth. Thus we have the disturbance in elevation of the sea-level expressed in terms of the potential of the disturbing matter. If at any point P the value of u remain constant when we pass to any adjacent point, then the actual surface is there parallel to the ideal spherical surface; as a rule, however, the normal at P is inclined to that at P′, and astronomical observations have shown that this inclination, amounting ordinarily to one or two seconds, may in some cases exceed 10, or, as at the foot of the Himalayas, even 30 seconds. By the expression "mathematical figure of the earth" we mean the surface of the sea produced in imagination so as to percolate the continents. We see then that the effect of the uneven distribution of matter in the crust of the earth is to produce small elevations and depressions on the mathematical surface which would be otherwise spheroidal. No geodesist can proceed far in his work without encountering the irregularities of the mathematical surface, and it is necessary that he know how they affect his astronomical observations. The whole of this subject is dealt with in his usual elegant manner by Bessel in the *Astronomische Nachrichten*, Nos. 329, 330, 331, in a paper entitled "Ueber den Einfluss der Unregelmässigkeiten der Figur der Erde auf geodätische Arbeiten, &c." But without entering into further details it is not difficult to see how local attraction at any station affects the determinations of latitude, longitude, and azimuth there.

Let there be at the station an attraction to the north-east throwing the zenith to the south-west, so that it takes in the celestial sphere a position Z′, its undisturbed position being Z. Let the rectangular components of the displacement ZZ′ be ξ measured southwards and η measured westwards. Now the great circle joining Z′ with the pole of the heavens P makes there an angle with the meridian $PZ = \eta \operatorname{cosec} PZ' = \eta \sec \phi$, where ϕ is the latitude of the station. Also this great circle meets the horizon in a point whose distance from the great circle PZ is $\eta \sec\phi \sin\phi = \eta \tan\phi$. That is, a meridian mark, fixed by observations of the pole star, will be placed that amount to the east of north. Hence the observed latitude requires the correction ξ; the observed longitude a correction $\eta \sec\phi$; and any observed azimuth a correction $\eta \tan\phi$. Here it is supposed that azimuths are measured from north by east, and longitudes eastwards.

The expression given for u enables one to form an approximate estimate of the effect of a compact mountain in raising the sea-level. Take, for instance, Ben Nevis, which contains about a couple of cubic miles; a simple calculation shows that the elevation produced would only amount to about 3 inches. In the case of a mountain mass like the Himalayas, stretching over some 1500 miles of country with a breadth of 300 and an average height of 3 miles, although it is difficult or impossible to find an expression for V, yet we may ascertain that an elevation amounting to several hundred feet may exist near their base. The geodetical operations, however, rather negative this idea, for it is shown in a paper in the *Philosophical Magazine* for August 1878 by Colonel Clarke that the form of the sea-level along the Indian arc departs but slightly from that of the mean figure of the earth. If this be so, the action of the Himalayas must be counteracted by subterranean tenuity.

Suppose now that A, B, C, ... are the stations of a network of triangulation projected on or lying on a spheroid of semiaxis major and excentricity a, e, this spheroid having its axis parallel to the axis of rotation of the earth, and its surface coinciding with the mathematical surface of the earth at A. Then basing the calculations on the observed elements at A, the calculated latitudes, longitudes, and directions of the meridian at the other points will be the true latitudes, &c., of the points as projected on the spheroid. On comparing these geodetic elements with the corresponding astronomical determinations, there will appear a system of differences which represent the inclinations, at the various points, of the actual irregular surface to the surface of the spheroid of reference. These differences will suggest two things,—first, that we may improve the agreement of the two surfaces, by not restricting the spheroid of reference by the condition of making its surface coincide with the mathematical surface of the earth at A; and secondly, by altering the form and dimensions of the spheroid. With respect to the first circumstance, we may allow the spheroid two degrees of freedom, that is, the normals of the surfaces at A may be allowed to separate a small quantity, compounded of a meridional difference and a difference perpendicular to the same. Let the spheroid be so placed that its normal at A lies to the north of the normal to the earth's surface by the small quantity ξ and to the east by the quantity η. Then in starting the calculation of geodetic latitudes, longitudes, and azimuths from A, we must take, not the observed elements ϕ, a, but for ϕ, $\phi+\xi$, and for a, $a+\eta\tan\phi$, and zero longitude must be replaced by $\eta\sec\phi$. At the same time suppose the elements of the spheroid to be altered from a, e to $a+da$, $e+de$. Confining our attention at first to the two points A, B, let (ϕ'), (a'), (ω) be the numerical elements at B as obtained in the first calculation, viz., before the shifting and alteration of the spheroid; they will now take the form

$$\begin{aligned}&(\phi')+f\xi+g\eta+hda+kde,\\&(a')+f'\xi+g'\eta+h'da+k'de,\\&(\omega)+f''\xi+g''\eta+h''da+k''de,\end{aligned}$$

where the coefficients $f, g, \ldots$ &c. can be numerically calculated. Now these elements, corresponding to the projection of B on the spheroid of reference, must be equal severally to the astronomically determined elements at B, corrected for the inclination of the surfaces there. If ξ', η' be the components of the inclination at that point, then we have

$$\begin{aligned}\xi'&=(\phi')-\phi'+f\xi+g\eta+hda+kde,\\\eta'\tan\phi'&=(a')-a'+f'\xi+g'\eta+h'da+k'de,\\\eta'\sec\phi'&=(\omega)-\omega+f''\xi+g''\eta+h''da+k''de,\end{aligned}$$

where ϕ', a', ω are the observed elements at B. Here it appears that the observation of longitude gives no additional information, but is available as a check upon the azimuthal observations.

If now there be a number of astronomical stations in the triangulation, and we form equations such as the above for each point, then we can from them determine those values of ξ, η, da, de, which make the quantity $\xi^2+\eta^2+\xi'^2+\eta'^2+\ldots$ a minimum. Thus we obtain that spheroid which best represents the surface covered by the triangulation.

In the *Account of the Principal Triangulation of Great Britain and Ireland* will be found the determination, from 75 equations, of the spheroid best representing the surface of the British Isles. Its elements are $a=20927005\pm295$ feet, $b:a-b=280\pm8$; and it is so placed that at Greenwich Observatory $\xi=1''{\cdot}864$, $\eta=-0''{\cdot}546$.

Taking Durham Observatory as the origin, and the tangent plane to the surface (determined by $\xi=-0''{\cdot}664$, $\eta=-4''{\cdot}117$) as the plane of x and y, the former measured northwards, and z measured vertically downwards, the equation to the surface is

$$\begin{aligned}&{\cdot}99524953x^2+{\cdot}99288005y^2+{\cdot}99763052z^2\\&-0{\cdot}00671003xz-41655070z=0.\end{aligned}$$

Altitudes.

The precise determination of the altitude of his station is a matter of secondary importance to the geodesist; nevertheless it is usual to observe the zenith distances of all trigonometrical points. The height of a station does indeed influence the observation of terrestrial angles, for a vertical line at B does not lie generally in the vertical plane of A, but the error (which is very easily investigated) involved in the neglect of this consideration is much smaller than the errors of observation. Again, in rising to the height h above the surface, the centrifugal force is increased and the magnitude and direction of the attraction of the earth are altered, and the effect upon the observation of latitude is a very small error expressed by the formula $\frac{h}{a}\cdot\frac{g'-g}{g}\sin 2\phi$, where g, g' are the values of gravity at the equator and at the pole. This is also a quantity which may be neglected, since for ordinary mountain heights it amounts to only a few hundreths of a second.

The uncertainties of terrestrial refraction render it impossible to determine accurately by vertical angles the heights of distant points. Generally speaking, refraction is greatest at about daybreak; from that time it diminishes, being at a minimum for a couple of hours before and after mid-day; later in the afternoon it again increases. This at least is the general march of the phenomenon, but it is by no means regular. The vertical angles measured at the station on Hart Fell showed on one occasion in the month of September a refraction of double the average amount, lasting from 1 P.M. to 5 P.M. The mean value of the coefficient of refraction k determined from a very large number of observations of terrestrial zenith distances in Great Britain is ${\cdot}0792\pm{\cdot}0047$; and if we separate those rays which for a considerable portion of their length cross the sea from those which do not, the former give $k={\cdot}0813$ and the latter $k={\cdot}0753$. These values are determined from high stations and long distances; when the distance is short, and the rays graze the ground, the amount of refraction is extremely uncertain and variable. A case is noted in the Indian Survey where the zenith distance of a station 10·5 miles off varied from a depression of 4′ 52″·6 at 4.30 P.M. to an elevation of 2′ 24″·0 at 10.50 P.M.

If h, h' be the heights above the level of the sea of two stations, $90°+\delta$, $90°+\delta'$ their mutual zenith distances (δ being that observed at h), s their distance apart, the earth being regarded as a sphere of radius $=a$, then, with sufficient precision,

$$h'-h=s\tan\left(s\frac{1-2k}{2a}-\delta\right),$$

$$h-h'=s\tan\left(s\frac{1-2k}{2a}-\delta'\right)$$

If from a station whose height is h the horizon of the sea be observed to have a zenith distance $90°+\delta$, then the above formula gives for h the value

$$h=\frac{a}{2}\cdot\frac{\tan^2\delta}{1-2k}.$$

Suppose the depression δ to be n minutes, then $h=1{\cdot}054n^2$ if the ray be for the greater part of its length crossing the sea; if otherwise, $h=1{\cdot}040n^2$. To take an example: the mean of eight observations of the zenith distance of the sea horizon at the top of Ben Nevis is 91° 4′ 48″, or $\delta=64{\cdot}8$; the ray is pretty equally disposed over land and water, and hence $h=1{\cdot}047n^2=4396$ feet. The actual height of the hill by spirit-levelling is 4406 feet, so that the error of the height thus obtained is only 10 feet.

Longitude.

The determination of the difference of longitude between two stations A and B resolves itself into the determination of the local time at each of the stations, and the comparison by signals of the clocks at A and B. Whenever telegraphic lines are available these comparisons are made by electro-telegraphy. A small and delicately-made apparatus introduced into the mechanism of an astronomical clock or chronometer breaks or closes by the action of the clock a galvanic circuit every second. In order to record the minutes as well as seconds, one second in each minute, namely that numbered 0 or 60, is omitted. The seconds are recorded on a chronograph, which consists of a cylinder revolving uniformly at the rate of one revolution per minute covered with white paper, on which a pen having a slow movement in the direction of the axis of the cylinder describes a continuous spiral. This pen is deflected through the agency of an electromagnet every second, and thus the seconds of the clock are recorded on the chronograph by offsets from the spiral curve. An observer having his hand on a contact key in the same circuit can record in the same manner his observed times of transits of stars. The method of determination of difference of longitude is, therefore, virtually as follows. After the necessary observations for instrumental corrections, which are recorded only at the station of observation, the clock at A is put in connexion with the circuit so as to write on both chronographs, namely, that at A and that at B. Then the clock at B is made to write on both chronographs. It is clear that by this double operation one can eliminate the effect of the small interval of time consumed in the transmission of signals, for the difference of longitude obtained from the one chronograph will be in excess by as much as that obtained from the other will be in defect. The determination of the personal errors of the observers in this delicate operation is a matter of the greatest importance, as therein lies probably the chief source of residual error.

Since the article FIGURE OF THE EARTH was written, considerable additions to the data for the determination of the semiaxes of the earth have been obtained from India, viz., a new meridian arc of 20°, the southern point of which is at Mangalore, together with several arcs of longitude, the longest of which, between Bombay and Nizagapatam, extends over 10° 30′. The effect of the accession of these new measures is to alter the figure previously given to the following: the semiaxes of the spheroid best representing the large arcs now available are

$$a=20926202;\quad c=20854895;\quad c:a=292\cdot465:293\cdot465.$$

This value of the major semiaxis exceeds that previously given by 140 feet, whereas the new polar semiaxis is less than the old by 226 feet. If we admit that the figure may possibly be an ellipsoid (not of revolution), then the investigation leads us, through the solution of 51 equations, to these values of the semiaxes—

$$a=20926629,$$
$$b=20925105,$$
$$c=20854407.$$

The greater axis of the equator lies in longitude 8° 15′ west of Greenwich, a meridian which passing through Ireland and Portugal cuts off a portion of the north-west corner of Africa, and in the opposite hemisphere cuts off the north-east corner of Asia. The apparent ellipticity of the equator is much reduced by the addition of the new data, and it would not be right to put too much confidence in the ellipsoidal figure until many more arcs of longitude shall have furnished the means of testing the theory more decisively than can be done at present. (See *Philosophical Magazine*, August 1878.) (A. R. C.)

GEOFFREY OF MONMOUTH (1110?-1154), one of the most famous of the Latin chroniclers, was born at Monmouth early in the 12th century. Very little is known of his life. He became archdeacon of the church in Monmouth, and in 1152 was elected bishop of St Asaph. He died in 1154. Three works have been attributed to him—the *Chronicon sive Historia Britonum*; a metrical *Life and Prophecies of Merlin*; and the *Compendium Gaufredi de Corpore Christi et Sacramento Eucharistiæ*. Of these the first only is genuine; internal evidence is fatal to the claims of the second; and the *Compendium* is known to be written by Geoffrey of Auxerre. The *Historia Britonum* appeared in 1147, and created a great sensation. Geoffrey professed that the work was a translation of a Breton work he had got from his friend Walter Calenius, archdeacon of Oxford. It is highly probable that the Breton work never existed. The plea of translation was a literary fiction extremely common among writers in the Middle Ages, and was adopted to give a mysterious importance to the communications of the author and to deepen the interest of his readers. We may compare with this Sir Walter Scott's professed quotations from "Old Plays," which he wrote as headings for chapters in his novels. If Geoffrey consulted a Breton book at all, it would probably be one of the Arthurian romances then popular in Armorica. His history is a work of genius and imagination, in which the story is told with a Defoe-like minuteness of detail very likely to impose on a credulous age. It is founded largely on the previous histories of Gildas and the so-called Nennius; and many of the legends are taken direct from Virgil. The history of Merlin, as embodied in the *Historia*, is found in Persian and Indian books. Geoffrey's imagination may have been greatly stimulated by local English legends, especially in the numerous stories he gives in support of his fanciful derivations of names of places. Whatever hints Geoffrey may have got from popular tales, and whatever materials he may have accumulated in the course of his reading, the *Historia* is to be thought of as largely his own creation and as forming a splendid poetical whole. Geoffrey, at all events, gave these stories their permanent place in literature. We have sufficient evidence to prove that in Wales the work was considered purely fabulous. (See *Giraldus Cambrensis*, *Itinerarium Cambriæ*, lib. i., c. 5, and *Cambriæ Descriptio*, c. vii.) And William of Newbury says "that fabler (Geoffrey) with his fables shall be straightway spat out by us all." Geoffrey's *Historia* was the basis of a host of other works. It was abridged by Alfred of Beverley (1150), and translated into Anglo-Norman verse, first by Geoffrey Gaimar (1154), and then by Wace (1180), whose work, *Li Romans de Brut*, contained a good deal of new matter Early in the 13th century was published Layamon's *Brut*; and in 1278 appeared Robert of Gloucester's rhymed *Chronicle of England*. These two works, being written in English, would make the legends popular with the common people. The same influence continued to show itself in the works of Roger of Wendover (1237), Matthew Paris (1259), Bartholomew Cotton (1300?), Matthew of Westminster (1310), Peter Langtoft, Robert de Brunne, Ralph Higden, John Harding, Robert Fabyan (1512), Richard Grafton (1569), and Raphael Holinshed (1580), who is especially important as the immediate source of some of Shakespeare's dramas. A large part of the introduction of Milton's *History of England* consists of Geoffrey's legends, which are not accepted by him as historical. The stories, thus preserved and handed down, have had an enormous influence on literature generally, but especially on English literature. They became familiar to the Continental nations; and they even appeared in Greek, and were known to the Arabs. With the exception of the translation of the Bible, probably no book has furnished so large an amount of literary material to English writers. The germ of the popular nursery tale, *Jack the Giant-Killer*, is to be found in the adventures of his Corineus, the companion of Brutus, who settled in Cornwall, and had a desperate fight with giants there. Goëmagot, one of these giants, is said to be the origin of Gog and Magog—two effigies formerly exhibited on the Lord Mayor's day in London, which are referred to in several of the English dramatists, and still have their well-known representatives in the Guildhall of the city. Chaucer gives Geoffrey a place in his "House of Fame," where he mentions "Englyssh Gaunfride" (Geoffrey) as being "besye for to bere up Troye."

Meanwhile the Arthurian romances had assumed a unique place in literature. The Arthur of later poetry is a grand ideal personage, seemingly unconnected with either space or time, and performing feats of extraordinary and superhuman valour. The real Arthur—if his historical existence is to be conceded—was most probably a Cumbrian or

Strathclyde Briton; and Geoffrey is responsible for the blunder of transferring him to South Wales. So intimately is Geoffrey connected with Arthur's celebrity, that he is often called Galfridus Arturus. Although the wondrous cycle of Arthurian romances scarcely originated with Geoffrey, he made the existing legends radiant with poetic colouring. They thus became the common property of Europe; and, after being modified by the trouvères in France, the minnesingers in Germany, and by such writers as Gaimar, Wace, Mapes, Robert de Borron, Luces de Gast, and Hélie de Borron, they were converted into a magnificent prose poem by Sir Thomas Malory, in 1461. Malory's *Morte Darthur*, printed by Caxton in 1485, is as truly *the* epic of the English mind as the *Iliad* is the epic of the Greek mind.

The first English tragedy, *Gorboduc, or Ferrex and Porrex* (1565), which was written mainly by Sackville, is founded on the *Historia Britonum.* John Higgins, in *The Mirror for Magistrates* (1587), borrows largely from the old legends. This work was extremely popular in the Elizabethan period, and furnished dramatists with plots for their plays. Spenser's *Faërie Queene* is saturated with the ancient myths; and, in his *Arthur*, the poet gives us a noble spiritual conception of the character. In the tenth canto of Book ii. there is—

> "A chronicle of Briton kings,
> From Brut to Uther's rayne.

Warner's lengthy poem entitled *Albion's England* (1586) is full of legendary British history. Drayton's *Polyolbion* (1613) is largely made up of stories from Geoffrey, beginning with *Britain-founding Brute.* Geoffrey's good faith and historic accuracy are warmly contended for by Drayton, in Song x. of his work.

In Shakespeare's time Geoffrey's legends were still implicitly believed by the great mass of the people, and were appealed to as historical documents by so great a lawyer as Sir Edward Coke. They had also figured largely in the disputes between the Edwards and Scotland. William Camden was the first to prove satisfactorily that the *Historia* was a romance. Shakespeare's *King Lear* was preceded by an earlier play entitled *The Chronicle History of King Lear and his Three Daughters, Gonorill, Ragan, and Cordelia, as it hath been divers and sundry times lately acted.* Shakespeare's immediate authority was Holinshed; but the later chronicles, in so far as they were legendary, were derived from Geoffrey. The story of *Cymbeline* is another illustration of the fascination these legends exercised over Shakespeare. An early play, ascribed by some to Shakespeare, on *Locrine*, Brutus's eldest son, is a further example of how the dramatists ransacked Geoffrey's stores. The *Historia* was a favourite book with Milton; and he once thought of writing a long poem on King Arthur, whose qualities he would probably have idealized, as Spenser has done, but with still greater moral grandeur. In addition to the evidence afforded by the introduction to his *History of England*, Milton shows in many ways that he was profoundly indebted to early legendary history. His exquisite conception of Sabrina, in *Comus*, is an instance of how the original legends were not only appropriated but ennobled by many of our writers. In his Latin poems, too, there are some interesting passages pertinent to the subject.

Dryden once intended to write an epic on Arthur's exploits; and Pope planned an epic on Brutus. Mason's *Caractacus* bears witness to Geoffrey's charm for poetic minds. Wordsworth has embalmed the beautiful legend of *Pious Elidure* in his own magic verse. In chapter xxxvi. of the *Pickwick Papers* Dickens gives what he calls "The True Legend of Prince Bladud," which is stamped throughout with the impress of the author's peculiar genius, and lit up with his sunny humour. Alexander Smith has a poem treating of *Edwin of Deira*, who figures towards the close of Geoffrey's history. And Tennyson's *Idylls of the King* furnish the most illustrious example of Geoffrey's influence; although the poet takes his stories, in the first instance, from Malory's *Morte Darthur.* The influence the legends have had in causing other legends to spring up, and in creating a love for narrative, is simply incalculable. In this way Geoffrey was really, for Englishmen, the inventor of a new literary form, which is represented by the romances and novels of later times.

There are several MSS. of Geoffrey's work in the old Royal Library of the British Museum, of which one formerly belonging to Margan Abbey is considered the best. The titles of the various editions of Geoffrey are given in Wright's *Biog. Brit. Lit.*, in the volume devoted to the Anglo-Norman period, which also contains an excellent notice of Geoffrey. The work compiled by Bale and Pits gives a mythical literary history, corresponding to Geoffrey's mythical political history. Of the *Life and Prophecies of Merlin*, falsely attributed to Geoffrey, 42 copies were printed for the Roxburghe Club in 1830. The *Historia* was translated into English by Aaron Thompson (London, 1718); and a revised edition was issued by Dr Giles (London, 1842), which is to be found in the volume entitled *Six Old English Chronicles* in Bohn's Antiquarian Library. A discussion of Geoffrey's literary influence is given in "Legends of Pre-Roman Britain," an article in the *Dublin University Magazine* for April 1876. The latest instance of the interest in Geoffrey is the publication of the following work:—*Der Münchener Brut Gottfried von Monmouth in französ. Versen des zwölften Jahrhunderts*, herausgeg. von R. Hofmann und K. Vollmöller, Halle, 1877.

For further information about Geoffrey, consult Warton's *English Poetry*; Morley's *English Writers*; Skene's *Four Ancient Books of Wales*; and a valuable paper on "Geoffrey of Monmouth's History of the Britons," in the 1st vol. of Mr Thomas Wright's *Essays on Archæological Subjects* (London, 1861). (T. GI.)

GEOFFROY SAINT-HILAIRE, ÉTIENNE (1772-1844), a celebrated French naturalist, was the son of Jean Gérard Geoffroy, procurator and magistrate of Étampes, Seine-et-Oise, where he was born, April 15, 1772. His early education was carefully superintended by his mother and paternal grandmother, and when still a boy he had already become acquainted with the masterpieces of the literature of the ancients, and of the age of Louis XIV. Destined by his friends for the church, he entered, as an exhibitioner, the college of Navarre, in Paris, where he studied natural philosophy under Brisson; and in 1788 he obtained one of the canonicates of the chapter of Sainte Croix at Étampes, and also a benefice. Science, however, offered to him a career more congenial to his tastes than that of an ecclesiastic, and, after some persuasion, he gained from his father permission to remain in Paris, and to attend the lectures at the Collége de France and the Jardin des Plantes, on the condition that he should likewise read law. He accordingly took up his residence at Cardinal Lemoine's college, and there became the pupil and soon the esteemed associate of Brisson's friend, Haüy, the eminent mineralogist, under whose guiding influence his passion for the natural sciences daily deepened. Having, before the close of the year 1790, taken the degree of bachelor in law, he became a student of medicine, but the lectures of Fourcroy at the Jardin des Plantes, and of Daubenton at the Collége de France, and his favourite scientific pursuits gradually came to occupy his almost exclusive attention. His studies at Paris were at length suddenly interrupted, for, on the 12th or 13th of August 1792, Haüy and the other professors of Lemoine's college, as also those of the college of Navarre, were arrested by the revolutionists as priests, and confined in the prison of St Firmin. Through Daubenton and other persons of distinction with whom he was acquainted, Geoffroy on the 14th August obtained an order for the release of Haüy in the name of the Academy; still the other professors of the two colleges, save Lhomond, who had been rescued by his pupil Tallien, remained in confinement. Geoffroy, foreseeing their certain destruction if they remained in the hands of the revolutionists, determined if possible to secure their liberty by stratagem. By bribing one of the officials at St Firmin, and disguising himself as a commissioner of prisons, he gained admission to his friends, and entreated them to effect their escape by following him. All, however, dreading lest their deliverance should render the doom of their fellow-captives the more certain, refused the offer, and one priest only, who was unknown to Geoffroy, left the prison. Already on the night of the 2d of September the massacre of the proscribed had begun, when Geoffroy, yet intent on saving the life of his friends and teachers, repaired to St Firmin. At 4 o'clock on the morning of the 3d Sept., after 8 hours' waiting, he by means of a ladder assisted the escape of twelve ecclesiastics, not of the number of his acquaintance, and then the approach of dawn and the discharge of a gun directed at him warned him, his chief purpose unaccomplished, to return to his lodgings. Leaving Paris he retired to Étampes, where, in consequence of the anxieties of which he had lately been the prey, and the horrors which he had witnessed, he was for some time seriously ill. At the beginning of the winter of 1792 he returned to his studies in Paris, and in March of the following year Daubenton, through the interest of Bernardin de Saint Pierre, procured him the office of sub-keeper and assistant demonstrator of the cabinet of natural history, vacant by the resignation of Lacépède. By a law passed June 10th, 1793, Geoffroy was appointed one of the twelve professors of the newly constituted museum of natural history, being assigned the chair of zoology. In the same year he busied himself with the formation of a menagerie at that institution. On the 6th May 1794 commenced his opening course of lectures, and on December 1st he read to the society of natural history his first paper, on the subject of the Aye-aye. It was in 1794, also, that through the introduction of Tessier he entered into correspondence with Georges Cuvier, to whom, after the perusal of some of his manuscripts, he wrote: "Venez jouer parmi nous le rôle de Linné, d'un autre législateur de l'histoire naturelle." Shortly after the appointment of Cuvier as Mertrud's assistant (see vol. vi. p. 740), Geoffroy received him into his house. The two friends wrote together five memoirs on natural history, one of which, on the classification of mammals, puts forward the idea of the subordination of characters upon which Cuvier based his zoological system. It was in a paper entitled "Histoire des Makis, ou singes de Madagascar," written in 1795, that Geoffroy first gave expression to his views on "the unity of organic composition," the influence of which is perceptible in all his subsequent writings: nature, he observes, presents us with only one plan of construction, the same in principle, but varied in its accessory parts.

In 1798 Geoffroy was chosen a member of the great scientific expedition to Egypt. With Delile and Larrey, on the capitulation of Alexandria in August 1801, he resisted the claim made by the British general Hutchinson to the collections of the expedition, sending him word that, were his demand persisted in, history would have to record of him that he also had burnt a library in Alexandria. Early in January 1802 Geoffroy returned to his accustomed labours in Paris. He was elected a member of the academy of sciences of that city in September 1807. In March of the following year the emperor, who had already recognized his national services by the award of the cross of the legion of honour, selected him to visit the museums of Portugal, for the purpose of procuring from them collections, and these, though in the face of considerable opposition from the British, he eventually was successful in retaining as a permanent possession for his country. In 1809, the year after his return to France, he was made professor of zoology of the faculty of sciences at Paris, and from that period he devoted himself more exclusively than before to the study of anatomical philosophy. In 1815 he was elected political representative for his native town. Three years later he gave to the world the first part of his celebrated *Philosophie Anatomique*, the second volume of which, published in 1822, and memoirs subsequently written account for the formation of monstrosities on the principle of arrest of development, and of the attraction of similar parts. When, in 1830, Geoffroy proceeded to apply to the invertebrata his views as to the unity of animal composition, he found a vigorous opponent in Georges Cuvier, and the discussion between them, continued up to the time of the death of the latter, soon attracted the attention of the scientific throughout Europe. Geoffroy, a synthesist, contended, in accordance with his theory of unity of plan in organic composition, that all animals are formed of the same elements, in the same number, and with the same connexions: homologous parts, however they differ in form and size, must remain associated in the same invariable order. With Goethe he held that there is in nature a law of compensation or balancing of growth, so that if one organ take on an excess of development, it is at the expense of some other part (*cf.* Darwin, *Origin of Species*, 5th ed., p. 182); and he maintained that, since nature takes no sudden leaps, even organs which are superfluous in any given species, if they have played an important part in other species of the same family, are retained as rudiments, which testify to the permanence of the general plan of creation. It was his conviction that, owing to the conditions of life, the same forms had not been perpetuated since the origin of all things, although it was not his belief that existing species are becoming modified (see Darwin, *op. cit.*, p. xvi.). Cuvier, who was an analytical observer of facts, admitted only the prevalence of "laws of coexistence" or "harmony" in animal organs, and maintained the absolute invariability of species, which he declared had been created with a regard to the circumstances in which they were placed, each organ contrived with a view to the function it had to fulfil, thus putting, in Geoffroy's consideration, the effect for the cause. In July 1840 Geoffroy became blind, and some months later he had a paralytic attack. From that time his strength gradually failed him. He resigned his chair at the museum in 1841, and on the 19th June 1844, at the age of 72, he died.

Geoffroy wrote—*Catalogue des Mammifères du Muséum national d'Histoire naturelle*, 1813, not quite completed; *Philosophie anatomique*,—t. i., *Des organes respiratoires*, 1818, & t. ii., *Des Monstruosités humaines*, 1822; *Système dentaire des Mammifères et des Oiseaux*, 1st pt., 1824; *Sur le Principe de l'Unité de Composition organique*, 1828; *Cours de l'Histoire naturelle des Mammifères*, 1829; *Principes de Philosophie zoologique*, 1830; *Études progressives d'un Naturaliste*, 1835; *Fragments biographiques*, 1832; *Notions synthétiques, historiques, et physiologiques de Philosophie naturelle*, 1838; and other works; also part of the *Description de l'Égypte par la Commission des Sciences*, 1821-30; and, with F. Cuvier, *Histoire naturelle des Mammifères*, 4 vols., 1820–42; besides very numerous papers published in the *Annales du Muséum*, the *Ann. des Sci. nat.*, the *Bulletin philomatique*, *La Décade égyptienne*, *La Décade philosophique*, the *Rev. encyclopédique*, *Mém. de l'Acad. des Sciences*, and elsewhere, among the subjects of which are the anatomy of marsupials, ruminants, and electrical fishes, the vertebrate theory of the skull, the opercula of fishes, teratology, palæontology, and the influence of surrounding conditions in modifying animal forms.

See *Vie, Travaux, et Doctrine Scientifique d'Étienne Geoffroy Saint-Hilaire, par son fils M. Isidore Geoffroy Saint-Hilaire*, Paris and Strasburg, 1847, to which is appended a list of Geoffroy's works: and Joly, in *Biog. Universelle*, t. xvi., 1856. (F. H. B.)

GEOFFROY SAINT-HILAIRE, ISIDORE (1805–61), a French zoologist, son of the preceding, was born at the Jardin des Plantes, Paris, December 16, 1805. In his earlier years he showed an aptitude for mathematics, but eventually he devoted himself to the study of natural history and of medicine, and in 1824 he was appointed assistant naturalist to his father. On the occasion of his taking the degree of doctor of medicine, September 8, 1829, he read a thesis entitled *Propositions sur la monstruosité, considérée chez l'homme et les animaux*; and in 1832–37 was published his great teratological work, *Histoire générale et particulière des anomalies de l'organisation chez l'homme et les animaux*, 3 vols. 8vo, with 20 plates. In 1829 he delivered for his father the second part of a course of lectures on ornithology, and during the three following years he taught zoology at the Athénée, and teratology at the École pratique. He was elected a member of the academy of sciences at Paris on April 15, 1833, was in 1837 appointed to act as deputy for his father at the faculty of sciences in Paris, and in the following year was sent to Bordeaux to organize a similar faculty there. He became successively inspector of the academy of Paris (1840), professor of the museum on the retirement of his father, inspector general of the university (1844), a member of the royal council for public instruction (1845), and, on the death of Blainville, professor of zoology at the faculty of sciences (1850). In 1854 he founded the Acclimatization Society of Paris, of which he was president. He died at Paris, November 10, 1861.

Besides the above-mentioned works, he wrote—*Essais de Zoologie générale*, 1841; *Vie . . . . d'Étienne Geoffroy Saint-Hilaire*, 1847; *Acclimatation et Domestication des Animaux utiles*, 1849, 4th ed., 1861; *Lettres sur les substances alimentaires et particulièrement sur la viande de cheval*, 1856; and *Histoire naturelle générale des règnes organiques*, 3 vols., 1854–62, which was not completed, chap. xx. of tome iii. being unfinished He was the author also of various papers on zoology, comparative anatomy, and palæontology, published for the most part in the *Annales du Muséum*, the *Mémoires des Savants étrangers*, the *Comptes rendus*, and the *Dict. des Sciences naturelles*.

GEOGRAPHY

Introduction.

GEOGRAPHY is the science which describes the earth, the term being derived from two Greek words γῆ, the earth, and γράφω, to write. By means of geography the surface of the earth is delineated and described, boundaries are defined, areas are exactly measured, and the relative positions of places are determined. Geography thus embraces a wide range of subjects, and it has been found necessary to divide its study into several distinct sections.

I. Comparative Geography traces the history of discovery, and records the changes which have taken place in land and sea in historic times.

II. Mathematical Geography explains the figure, magnitude, and motion of the earth, teaches how to determine the positions of places on its surface, and shows how the whole or any portion of the earth may, on the principles of projection, be delineated on a map or chart.

III. Physical Geography is the description of the actual state of the earth's surface in its three great divisions—land, sea, and air.

IV. Political Geography describes the earth as divided into countries, occupied by various nations, and improved by human art and industry.

The following article is limited to a view of the progress of geographical discovery, an explanation of the principles of mathematical geography, and a synopsis of physical geography. For details relating to political geography the reader must consult the descriptive articles under their particular headings.

I. View of the Progress of Geographical Discovery.

Four main causes have led to geographical discovery and exploration, namely, commercial intercourse between different countries, the operations of war, pilgrimages and missionary zeal, and in later times the pursuit of knowledge for its own sake, which is the highest of all motives.

The Phœnicians are the earliest commercial people of whose discoveries we have any correct accounts. They first explored the shores of the Mediterranean, and eventually extended their voyages through the Straits of Gibraltar, and visited the western shores of Spain and Africa, planting colonies and opening wider fields for their commerce by instructing the natives in their arts and improvements. They also monopolized the trade with India; and their chief emporium, the rich city of Tyre, was the centre whence the products of the East and West were distributed. The trade of the West was brought from the port called Tarshish in Scripture, which is probably identical with Carthage, where the ships arrived from Spain, Africa, and distant Britain. Concerning the far eastern land reached by the Phœnicians, called Ophir in Scripture, there has been much dispute. The voyage to Ophir, we are told, occupied three years thither and homeward, and the cargo consisted of gold, ivory, apes, peacocks, and "algum" wood (1 Kings ix. 26, and x. 11). The following reasons lead to the conclusion that Ophir was the Malabar coast of India. In the Hebrew the word for apes is *kopk* (without any etymology in Semitic tongues), in Sanskrit *kafi*. Ivory in Hebrew is *shen-habbim*; in Sanskrit *ibha* is an elephant. Peacocks is in Hebrew *tokki-im* from *togei*, the name still used on the Malabar coast, derived from the Sanskrit. Algum wood, or almug, is corrupted from *valgu* (ka), sandal wood from Malabar. Thus the Phœnicians were the first great carriers of the ancient world, extending their commercial operations from their central mart of Tyre on the Syrian coast to the tin-yielding isles of the Cassiterides in the far west, and to the ports of India in the east.

The great Phœnician colony of Carthage retained in full vigour the commercial spirit of the parent state. The Carthaginians traded on the coasts of Spain and Gaul, and extended their discoveries southwards along the coast of Africa, and to the Fortunate Islands, now known as the Canaries. Herodotus relates how the Phœnicians, setting sail from the Red Sea, made their way to the south, and when autumn approached they drew their vessels to land, sowed a crop, and waited till it was grown, when they reaped it and again put to sea. Having spent two years in this manner, in the third year they reached the pillars of Hercules and returned to Egypt. But the most celebrated voyage of antiquity, undertaken for the purpose of discovery, was the expedition under Hanno, fitted out by the senate of Carthage with the view of attempting the complete survey of the western coast of Africa. Hanno is said, in the *Periplus Hannonis*, to have set sail with a fleet of 60 vessels, and the extent of his voyage has been variously estimated as reaching to the river Nun, to a little beyond Sierra Leone, and even as far as the Gulf of Benin. Another famous navigator, who sailed from the Carthaginian colony of Massilia (Marseilles) in about 320 B.C., was Pytheas. He steered northwards along the coasts of Spain and Gaul, sailed round the island of Albion, and stretching still further to the north, he discovered an island known to the ancients as *Ultima Thule*, which may possibly have been the Shetland Isles.

Carthag

The conquests of Alexander the Great, by making known the vast empire of Persia, materially enlarged the bounds of geographical knowledge. Although the course of his expedition was mainly by land, the mind of the conqueror was also intent on commerce and maritime discovery. In 327 B.C. Alexander led an army of Greeks down the valley of the Cabul river into the Punjab, and his expedition resulted in a voyage of discovery from the mouth of the Indus to that of the Tigris, and in opening direct intercourse between Grecian and Hindu civilization. The Greeks who accompanied Alexander were accurate observers, and described the towns and villages, the products and the aspect of the country, with care. The conqueror resolved to return through Gedrosia (the modern Baluchistan), but he also intended to open the trade by sea between Europe and India, and his general Nearchus, a native of Crete, volunteered to lead this famous voyage of discovery. His fleet consisted of 30 galleys containing 2000 men. On October 2, 326 B.C., the fleet of Nearchus left the Indus, and the anchorages each night are carefully recorded. On the 17th of December Cape Jask was doubled and the fleet entered the Persian Gulf, and on the 9th of February it was at the mouth of the Karún. Nearchus rejoined Alexander at Susa; and the conqueror himself embarked in the fleet and ascended the Tigris to Opis, above Baghdad. He then ordered his successful admiral to prepare another expedition for the circumnavigation of Arabia; but unfortunately the great conqueror died at Babylon in 324 B.C., and the fleet was dispersed.

The dynasties founded by Alexander's generals, Seleucus, Antiochus, and Ptolemy, encouraged the same spirit of enterprise which their master had so carefully fostered, and extended geographical knowledge in several directions. Seleucus Nicator established the Greco-Bactrian empire, and continued the intercourse with India. The most authentic information respecting the Gangetic valley was supplied by Megasthenes, an ambassador sent by Seleucus, who reached the remote city of Patali-putra, the modern Patna, on the Ganges.

The Ptolemies of Egypt showed equal anxiety to extend the bounds of geographical knowledge. Ptolemy Euergetes sent an expedition which discovered Abyssinia, and fitted out a fleet under Eudoxus to explore the Arabian Sea. After two successful voyages, Eudoxus left the Egyptian service, and proceeded to Cadiz with the object of fitting out an expedition for the purpose of African discovery; and we learn from Strabo that the veteran explorer made at least two voyages southward along the coast of Africa. The Ptolemies sent fleets annually from their Red Sea ports of Berenice and Myos Hormus to Arabia, as well as to ports on the coasts of Africa and India.

Romans. The Romans did not encourage navigation and commerce with the same ardour as their predecessors; still the luxury of Rome, which gave rise to demands for the varied products of all the countries of the known world, led to an active trade both by ships and caravans. But it was the military genius of Rome, and the ambition for universal empire, which led not only to the discovery but also to the survey of nearly all Europe, and of large tracts in Asia and Africa. Every new war produced a new survey and itinerary of the countries which were conquered. In the height of their power the Romans had surveyed and explored all the coasts of the Mediterranean, Italy, Greece, the Balkan peninsula, Spain, Gaul, western Germany, and Britain; but the eastern parts of Germany, Denmark, Sweden, and Russia were still unknown regions. In Africa their empire included Egypt, Carthage, Numidia, and Mauritania. In Asia they held Asia Minor and Syria, had sent expeditions into Arabia, and were acquainted with the more distant countries formerly overrun by Alexander, namely, Persia, Scythia, Bactria, and India. Roman intercourse with India especially led to the extension of geographical knowledge.

The first Roman who undertook a journey to India was solely influenced by the desire to acquire a knowledge of the people and their doctrines. This was Apollonius, a resident at Antioch, who set out towards the close of the first half century of our era. He and his attendants, Damis and Philostratus, reached the Indus, and journeying across the Punjab, came to a bronze pillar with the inscription "Here Alexander halted"; but it is doubtful whether the party advanced as far the Ganges. It was, however, in the reigns of Severus and his immediate successors that Roman intercourse with India was at its height.

In all time, while warriors and explorers extended the area of geographical knowledge, there have been students who have striven to systematize and put into due form the accumulated information. From the first it was perceived that a knowledge of localities could not be attained without some notion of their relative positions, and their distances from each other. Consequently the attempts to establish fixed principles on which the surface of the earth, or any portion of it, could be delineated, were almost coeval with the earliest voyages of discovery.

The first attempt made to determine the position of places appears to have depended on the division of the earth into "climates," distinguished by the species of animals and plants produced in each. This method, however, was soon abandoned for another, which consisted in observing at places the length of the longest and shortest days by means of a "gnomon." An upright pillar of a known height being erected on a level pavement, by observing the lengths of the meridian shadows the progress of the sun from tropic to tropic was traced. The most ancient observation with the gnomon is that of Pytheas, in the days of Alexander the Great, who observed at the summer solstice at Massilia that the length of the meridian shadow was to the height of the gnomon as 213⅕ to 600, an observation which makes the meridian altitude of the sun at Marseilles on that day 70° 27′. The merit of the invention of the gnomon in Greece is ascribed to the astronomical school of Miletus; but there is reason to believe that this method of observation was invented in Egypt, and that Thales carried the knowledge of it into Greece. This was the first step towards connecting geography with astronomy; and little further advance was made until the establishment of the famous astronomical school of Alexandria.

Eratosthenes (276–196 B.C.) was the first who reduced geography to a regular system, and laid its foundations on clear and solid principles. Under the patronage of the Ptolemies he had access to all the materials collected by Alexander and his generals. The doctrine of the sphericity of the earth had by this time been adopted, and the aim of his labours was to delineate, in conformity with this principle, the known parts of the earth's surface. Founding his system on the use of the gnomon, he supposed a line to be traced through certain places, in all of which the longest day was known to be exactly of the same length. Such a line would evidently be a parallel to the equator. This first parallel passed through Rhodes, and was ever afterwards adopted as the basis of ancient maps. Eratosthenes continued his work by tracing other parallels at certain intervals from the first, one through Alexandria, another through Syene, a third through Meroe. He also traced, at right angles to these, a meridian passing through Rhodes and Alexandria, southwards to Syene and Meroe. As the progress which he thus made towards the completion of what he had so skilfully conceived naturally tended to enlarge his ideas concerning geographical science, he attempted next to determine the circumference of the globe by the actual measurement of a segment of one of its great circles. Posidonius made another measurement of an arc of the meridian between Rhodes and Alexandria about 170 years afterwards; but the amount of error in the calculations of Eratosthenes and Posidonius is uncertain, for want of a knowledge of the true length of the stadium in which their results are expressed. The ancients made their first meri-

dian at the sacred promontory of Iberia, and their longitudinal error increased rapidly as they advanced eastwards. This is no doubt due to their longitudes being based entirely on distances calculated in the itineraries of travellers. Such data of course produced very great distortions in the representations given of the countries on the surface of the globe.

The improvements introduced by Eratosthenes were perfected in principle by Hipparchus, who flourished from 160 to 135 B.C. He was the first astronomer who undertook the arduous task of making a catalogue of the stars and fixing their relative positions. His object was to transmit to posterity a knowledge of the state of the heavens at the period of his observations. The extremities of the imaginary axis round which the heavens perform their diurnal revolutions suggest two fixed points by which the position of the great circle of the celestial sphere, called the celestial equator, is determined. If a great circle be supposed to pass through these points and any star, the position of the star will be ascertained if we measure in degrees and parts of a degree the arc of the meridian circle intercepted between the star and the equator, and also the arc of the equator intercepted between a given point in it and the meridian circle passing through the star. Upon this principle Hipparchus arranged the stars according to their places in the heavens; and the great improvement which he introduced into geography consisted in this, that he applied to the determining of the position of any point on the surface of the earth the same rule which he had introduced in the arrangement of the constellations. Thus he furnished the means of ascertaining the relative positions of places with far greater accuracy than could be obtained from itinerary measurements. He made a considerable number of observations for latitude, and pointed out how longitudes might be determined by observing the eclipses of the sun and moon.

The most ancient maps that have reached modern times are those which illustrate Ptolemy's geography, but an earlier map made for Aristagoras, king of Miletus (500 B.C.), is minutely described by Herodotus. Ptolemy composed his system of geography in the reign of Antoninus Pius, about 150 A.D. His materials consisted of all the itineraries prepared by the Romans, proportions of the height of the gnomon and its shadow at the time of the equinoxes and solstices taken by different astronomers, calculations founded on the length of the longest days, and various reports of travellers and navigators. Ptolemy undertook the task of comparing and reducing this mass of crude material into one system, following the principles laid down by Hipparchus, but which had been neglected during the two centuries and a half since his time, even by such men as Strabo and Pliny. In Ptolemy's work we find for the first time the mathematical principle of the construction of maps, as well as of several projections of the sphere.

The errors of Ptolemy arose from defective information, and the want, in many instances, and especially as regards the remote parts of the then known world, of astronomical observations. He adopted the measure of a degree at 500 stadia; and the latitudes along the chief parallel of Rhodes, as first laid down by Eratosthenes, are tolerably correct. But the elements for determining the longitudes were still derived from itineraries, and errors in latitude accumulated to the north and south of the central parallel.

ebo. Although Ptolemy was the first scientific geographer whose work has come down to us in a complete form, the earlier labours of Strabo, who lived in the reigns of Augustus and Tiberius, are of equal value, and we fortunately possess the whole of his 17 books. Pliny also devoted two books of his extensive work to geography; and the scattered geographical notices of other ancient writers were collected into one work of four volumes by Hudson, and published between 1698 and 1712, with notes by Dodwell. From the days of Ptolemy to the revival of letters in Europe, little was done towards the scientific improvement of geographical science, though military and commercial enterprise led to a great extension of knowlege of the earth's surface.

After the dissolution of the Roman empire, Constantinople became the last refuge of arts, taste, and elegance; while Alexandria continued to be the emporium whence were imported the commodities of the East. The emperor Justinian sent two Nestorian monks to China, who returned with eggs of the silkworm concealed in a hollow cane, and thus silk manufactures were established in the Peloponnesus and the Greek Islands. It was also in the reign of Justinian that Cosmas Indicopleustes, an Egyptian merchant, made several voyages, and afterwards composed his *Topographia Christiana*, containing a particular description of India. The great outburst of Mahometan conquest was followed by an Arabian civilization, having its centres at Cordova and Baghdad, in connexion with which geography again received a share of attention.

From the 9th to the 13th century intelligent Mahometan travellers wrote accounts of what they had seen and heard in distant lands, which have been handed down to us; while the caliphs of Baghdad encouraged the study of geographical science.

The caliph Al-Mamûn, the worthy son and successor of Hârûn er-Rashîd, caused an Arabic version of Ptolemy's great astronomical work (Σύνταξις μεγίστη) to be made, which is known as the *Almagest*, the word being nothing more than the Greek μεγίστη with the Arabic article *al* prefixed. The geography of Ptolemy is also constantly referred to by Arab writers. The learned men under Al-Mamûn began to apply themselves to astronomy in 813 A.D., following the system of Ptolemy; and the first observations that are properly their own were made by El-Bâthany in Mesopotamia, of the vernal and autumnal equinoxes, in 882 A.D. The Arab astronomers also measured a degree on the plains of Mesopotamia, and Ibn Yûnus observed three eclipses at Cairo. The caliph's librarian, Abu Jaïer Muhammad Ben Musa, wrote a geographical work, now unfortunately lost, entitled *Rasm el Arsi* ("A Description of the World"), which is often referred to by subsequent writers as having been composed on the model of that of Ptolemy.

The earliest Arabian traveller whose observations have come down to us is the merchant Sulaiman, who embarked in the Persian Gulf and made several voyages to India and China, in the middle of the 9th century. Sulaiman's information was supplemented by that collected by another writer named Abu Zaid; and, so far as India is concerned, this work is the most important that we possess before the grand epoch of the discoveries of Marco Polo. Next to Sulaiman followed the voyages of Sindbad the Sailor, whose narrative, though inserted in the *Arabian Nights*, also forms a distinct and separate work, which was translated into French by M. Langlès in 1814. Baron Walckenaer ascribes to the voyages of Sindbad a date about coincident with those of Sulaiman. Ibn Khurdadra, a fire-worshipper converted to Islam, who died in 912 A.D., also wrote an account of India. Al Masudi, a great traveller who knew all the countries between Spain and China, described the plains, mountains, and seas, the dynasties and peoples, in his *Murûju-l Zahab* ("Meadows of Gold"). He died in 956. His contemporaries were Al Istakhri, who travelled through all the Mahometan countries, and wrote his *Book of Climates* in 950, and Ibn Haukal, whose *Book of Roads and Kingdoms* was written in 976. Al Idrisi was born at Ceuta, and after travelling far and wide, settled in Sicily, where he was induced by Roger II., the Norman king, to write his book on geography, the full title of which is *The Delight of those who seek to wander through the Regions of the World.* Finally Al Kazwíní, who was a compiler from the works of Istakhri and Ibn Haukal in about 1263, brings us down to the times when the Italian explorers began to make known the vast realms of Asia to the people of Europe.

The Mongol and Turkish dynasties, which succeeded each other after the fall of the Arabian caliphs, also produced rulers who encouraged geographical science. Philosophers assembled at the court of Hulaku Khan (1253–1264) at Maraghah in the north of Persia; and his friend Nâsiru-'d-Din was the most famous astronomer of the age. He constructed the tables known as the Tables of the Ilkhany, which corrected some important errors in the former mode of adjusting the commencement of the new year. Nearly two centuries later, in 1446, Ulugh Begh, of the house of Timur, succeeded to the throne of Samarkand, and under his auspices the famous tables called "Zij Ulugh Begh" were composed. They continued to be authorities for long afterwards, and even Kinneir, in determining the latitudes of places in Persia, often quotes the tables of Ulugh Begh.

Northmen

The Northmen of Denmark and Norway, who were the terror of all the coasts of Europe, and who established themselves in England and Ireland, in France and Sicily, were also great promoters of geographical discovery during the darkest period of the Middle Ages. The Northmen were far from being always vikings, bent only on rapine and plunder. They were very often peaceful merchants. King Alfred sent Ulfsten and the Norwegian Ottar on voyages of discovery towards the White Sea; and the Scandinavian merchants brought the products of India to England and Ireland. From the 8th to the 11th century a commercial route from India passed through Kharism and Novgorod to the Baltic, and immense quantities of Arabian coins have been found in Sweden, and particularly in the island of Gothland, which are preserved at Stockholm. Five-sixths of them were from the mints of the Samanian dynasty, which reigned in Khorasan and Transoxiana from about 900 to 1000 A.D. It was the trade with the East that originally give importance to the city of Visby in Gothland.

In the end of the 9th century Iceland was colonized from Norway; and in 985 the intrepid viking Erik, surnamed the Red, discovered Greenland, and induced some of his Icelandic countrymen to settle on its inhospitable shores. In 986 young Bjorni, son of one of Erik's comrades, sailed from Iceland to join his father in Greenland, but shaped his course too far to the south, and was the discoverer of America. He sailed along the coasts of Connecticut, Massachusetts, and Nova Scotia, before he eventually found the fjord on the Greenland coast where his father dwelt. Then Leif, the son of Erik, bought the ship from young Bjorni and made another voyage of discovery, and once more the coast of America was visited. Other expeditions were undertaken by his two brothers, intercourse was kept up between Greenland and Norway, and the saga of Thorfinn tells us of other voyages to America. The last that was heard of the Norwegian colonies in Greenland was in a brief of Pope Nicolas V. in 1448, where it is stated that, 30 years before, the settlements had been destroyed by the attacks of savages. Two noble Venetians, Nicolo and Antonio Zeno, who were in the service of the prince of the Faroe Islands in the end of the 13th century, recorded their observations respecting the Norse colonies. Antonio actually went to Greenland, and heard of the visits of fishermen to two parts of North America called Estotiland and Drogeo.

At length the long period of barbarism which accompanied and followed the fall of the Roman empire drew to a close in Europe. The crusades had a very favourable influence on the intellectual state of the Western nations. Interesting regions, known only by the scant reports of pilgrims, were made the objects of attention and research; while religous zeal, and the hope of gain, combined with motives of mere curiosity, induced several persons to travel by land into remote regions of the East, far beyond the countries to which the operations of the crusaders extended. Among these was Benjamin of Tudela, who set out from Spain in 1160, travelled by land to Constantinople, and having visited India and some of the eastern islands, returned to Europe by way of Egypt after an absence of 13 years.

Christian missionary zeal was another motive for exploration. John of Plano Carpini in Perugia, a Franciscan monk, was the head of one of the missions despatched by Pope Innocent to call the chief and people of the Tatars to a better mind. He reached the headquarters of Batu, on the Volga, in February 1246; and, after some stay, went on to the camp of the great khan near Karakorum, and returned safely in the autumn of 1247. A few years afterwards, a Fleming named Rubruquis was sent by St Louis on a mission to the Tatar chiefs, and wrote a very interesting narrative. He entered the Black Sea in May 1253, visited Batu and the court of the great khan Mangu near Karakorum, and got back to Antioch about the end of June 1255. Rubruquis had the merit of being the first modern traveller who gave a correct account of the Caspian Sea. He ascertained that it had no outlet. At nearly the same time Hayton, king of Armenia, made a journey to Karakorum in 1254, by a route far to the north of that followed by Carpini and Rubruquis. He was treated with honour and hospitality, and returned by way of Otrar, Samarkand, and Tabriz, to his own territory. The curious narrative of King Hayton was translated by Klaproth.

Marco Polo

While the republics of Italy, and above all the state of Venice, were engaged in distributing the jewels, the spices, and the fine cloths of India over the Western world, it was impossible that motives of curiosity, as well as a desire of commercial advantage, should not be awakened to such a degree as to impel some to brave all the obstacles and dangers to be encountered in visiting those remote countries. Among these were Nicolo and Maffeo Polo, two brothers who traded with the East and visited Tatary. The recital of their travels fired the youthful imagination of young Marco Polo, the son of Nicolo, and he set out for the court of Kublai Khan, with his father and uncle, in 1265. After a journey of three years and a half they reached Yeu-king, near the spot where Peking now stands, and young Marco was enrolled among the attendants of honour of the Grand Khan. During the seventeen years that he remained in this service, Marco Polo was employed on important missions; and besides what he learnt from his own observation, he collected from others much information concerning countries which he did not visit. He returned to Europe possessed of a vast store of knowledge respecting the eastern parts of the world, and, being afterwards made a prisoner by the Genoese, he dictated the narrative of his travels during his captivity. The work of Marco Polo is the most valuable narrative of travels that appeared during the Middle Ages, and its latest and ablest editor truly says, "All other travellers of that time are but stars of a low magnitude beside the full orb of Marco Polo."

Still these minor orbs continued to do useful geographical work, while striving to spread the truths of the Gospel. Among them were John of Monte Corvino, a Franciscan monk, Andrew of Perugia, John Marignioli, and Friar Jordanus, who visited the west coast of India, and above all Friar Odoric of Pordenone. Odoric set out on his travels in about 1318, and was in western India and northern China between 1321 and 1328, dying in 1331. He went by Constantinople to Trebizond, thence through

Persia to Ormuz, where he embarked for Tana in Salsette. He then went to Malabar, Sumatra, and Java, and by the ports of China to Cambaluc or Peking, where he remained for three years. Turning westward he journeyed by Shensi into Tibet, and was the first European to visit Lassa. His homeward journey led him by Cabul and Khorasan to Tabriz, and thence to Venice. His companion was an Irishman named Friar James.[1]

Ibn Batuta, the great Arab traveller, is separated by a wide space of time from his countrymen already mentioned, and he finds his proper place in a chronological notice after the days of Marco Polo—for he was not born at Tangier until 1304. He began his wanderings in 1325, his career thus coinciding in time with that of Sir John Mandeville (1322-1356), but the Moor was more trustworthy than the Englishman. Ibn Batuta went by land from Tangier to Cairo, then visiting Syria, and performing the pilgrimages to Medina and Mecca. After exploring Persia, and again residing for some time at Mecca, he made a voyage down the Red Sea to Yemen, and travelled through that country to Aden, which remarkable place he correctly describes. Thence he visited the African coast, touching at Mombo'as and Quiloa, and then sailed across to Ormuz and the Persian Gulf. He crossed Arabia from Bahreyn to Jiddah, traversed the Red Sea and the desert to Syene, and descended the Nile to Cairo. After this he revisited Syria and Asia Minor, crossed the Black Sea to Caffa, and proceeded to the camp of the khan of Kipchak at the foot of the Caucasus. Ibn Batuta crossed the desert from Astrakhan to Bokhara, and went over the Hindu Kush to Cabul, reaching the Indus somewhere below Larkhana, in 1333. He gives an interesting account of Muhammad Tughluk, then ruler of Delhi, in whose service the great traveller remained for about eight years. He was sent on an embassy to China in 1342, travelling by land from Delhi to the seaport; whence the ambassadors sailed down the west coast of India to Calicut, and then visited the Maldive Islands and Ceylon. He made a voyage through the Islands to China, and on his return he proceeded from Malabar to Baghdad and Damascus, where he got his first news from home and heard of his father's death. Finally he reached Fez, the capital of his native country, in November 1349, after an absence of twenty-four years, and came to the conclusion that there was no place like home. After a journey into Spain, he set out for Central Africa in 1352, and reached Timbuctoo and the Niger, returning to Fez in 1353. He had travelled over a length of at least 75,000 English miles. His narrative was committed to writing from his dictation, by order of the sultan of Fez, and the work was completed in December 1355. Ibn Batuta died at the age of seventy-three, in the year 1377. His whole work was carefully edited in the original, with a translation into French under the auspices of the Asiatic Society of Paris, and published in 1858. Colonel Yule has given us an English version of the portion relating to China.

Ibn Batuta was certainly the greatest of Arab travellers, and soon after his death in the kingdom of Fez, the opposite realm of Spain began to send forth explorers to distant lands. The peaceful reign of Henry III. of Castile is famous for the attempts of that prince to extend the diplomatic relations of Spain to the remotest parts of the earth. Mariana tells us that he sent embassies to the princes of Christendom and to the Moors. In 1403 the Spanish king sent a knight of Madrid, named Ruy Gonzalez de Clavijo, to the court of the mighty Timur, at Samarkand. He returned in 1406, and died soon after, but not before he had written a most valuable and interesting narrative of his travels from Constantinople through Persia and Khorasan to the Oxus, and thence by the Iron Gates to Samarkand.

Several Italians continued to make important journeys in the East during the 15th century. Among them was Nicolo Conti, who passed through Persia, sailed along the coast of Malabar, visited Sumatra, Java, and the south of China, returned by the Red Sea, and got home to Venice in 1444, after an absence of twenty-five years. He related his adventures to Poggio Bracciolini, secretary to Pope Eugenius IV.; and the narrative contains much interesting information. Towards the end of the same century, the Venetians sent several embassies to Uzun Hassan, the ruler of Persia, and to Shah Ismail, his successor; and the narratives of the envoys furnish some new geographical information. The first of these was Caterino Zeno, who induced Uzun Hassan to make war on the Turks in 1472; and he was followed by Josafat Barbaro and Ambrogio Contarini. Another Venetian traveller of this period, whose narrative has been preserved, was Giovan Maria Angiolello. He was in the service of the Turks, and was present in their campaign against the Persians. One of the most remarkable of the Italian travellers was Ludovico di Varthema, whose insatiable desire to see foreign countries induced him to leave his native land in the year 1502. He went to Egypt and Syria, and for the sake of visiting the holy cities became a Mahometan. After many extraordinary adventures he got on board a ship at Aden. Varthema is the first European who gave an account of the interior of Yemen. He afterwards visited and described many places in Persia, India, and the Eastern Archipelago, returning to Europe in a Portuguese ship after an absence of five years.

In mentioning Varthema we have anticipated events; but in the 15th century the time was approaching when the discovery of the Cape of Good Hope was almost indefinitely to widen the scope of geographical enterprise. The great event was preceded by the discovery of the polarity of the magnetic needle, and the consequent construction of the mariner's compass. This most important discovery appears to have been made in China, and it is uncertain when the compass was first used by Western nations. Its introduction has been attributed to Flavio Gioia, a citizen of Amalfi, in the kingdom of Naples, about the year 1307. Encouraged by the possession of this sure guide, by which at all times and in all places he could with certainty steer his course, the navigator gradually abandoned the method of sailing along the shore, and boldly committed his bark to the open sea. Navigation was then destined to make rapid progress. The growing spirit of enterprise, combined with the increasing light of science, prepared the states of Europe for entering upon that great career of discovery, of which the details constitute the materials for the history of modern geography. Portugal took the lead in this new and brilliant path, and foremost in the front rank of the worthies of this little hero-nation stands the figure of Prince Henry the Navigator.

The work of Prince Henry is well defined by his biographer, Mr Major. Until his day the pathways of the human race had been the mountain, the river, and the plain, the strait, the lake, and the inland sea. It was he who first conceived the thought of opening a road through the unexplored ocean,—a road replete with danger but abundant in promise. Born on March 4, 1394, Prince Henry was a younger son of King João of Portugal and of Philippa of Lancaster, the grandchild of Edward III.; so that he was half an Englishman. Prince Henry relinquished the pleasures of the court, and took up his abode on the inhospitable promontory of Sagres, at the extreme south-western

[1] Sir John Mandeville copied largely from Odoric, and the substance of his travels to the Indies and Cathay is entirely stolen from the Italian traveller, though amplified with fables from Pliny and other ancients, as well as from his own imagination. See Colonel Yule in his account of Odoric (*Cathay, and the Way Thither*, i. p. 27).

angle of Europe. To find the sea-path to the "thesauris Arabum et divitis Indiæ" was the object to which he devoted his life. He collected the information supplied by ancient geographers, unweariedly devoted himself to the study of navigation and cartography, and invited, with princely liberality of reward, the co-operation of the boldest and most skilful navigators of every country. The prince's motto was "Talent de bien faire,"—the word "talent," in those days, conveying not the idea of power or faculty, but of desire. Having acquired military renown by the capture of Ceuta in 1415, he set his mind upon the conquest of Guinea, and sent every year two or three vessels to examine the coasts beyond Cape Nun, which was then the limit of exploration. Yet none of his ships for many years had the hardihood to round Cape Bojador.

The first fruit of Prince Henry's explorations was the rediscovery of Madeira and Porto Santo, in 1418 and 1420. The truth of the romantic story of the first discovery of Madeira by two English lovers named Robert Machim and Anna d'Arfet, in the time of Edward III., has been demonstrated by Mr Major. Madeira and Porto Santo were granted to Prince Henry by his brother, King Duarte, in 1433. In the same year one of the prince's ships, commanded by Gil Eannes, at length doubled Cape Bojador. In 1435 Affonso Gonsalves Baldaya, the prince's cup-bearer, passed 50 leagues beyond the cape; and eight years afterwards Nuño Tristam got to a point 25 miles beyond Cape Blanco. But it was not until 1445 that the mouth of the Senegal was reached by Diniz Dias; and in those days the Portuguese gave the name of Guinea to the country commencing at Cape Nun. In 1481 the king of Portugal assumed the title of lord of Guinea. Up to 1446 there had been 51 caravels to the Guinea coast, and almost every year some new advance was made. Meanwhile the Canaries and Azores were brought within the realms of Spain and Portugal. In 1402 a Norman named Jean de Bethencourt, accompanied by Gadifer de la Salle, had landed on the island of Lançarote, and with reinforcements from Spain he subjugated Forteventura and Ferro, and received the sovereignty of the Canaries from the king of Castile. But he returned to his lands in Normandy in 1406, and died there in 1425. Gomera, Palma, Teneriffe, and the Great Canary were still unconquered. Prince Henry made several attempts to establish Portuguese rule on these islands; the right was long disputed with Spain; and it was not until 1479 that the treaty of Alcaçora provided for the concession of the sovereignty of the Canaries to Spain. Prince Henry, however, successfully colonized the Azores, and in 1444 St Michael's was discovered, the settlement of the other islands following soon afterwards.

In 1455 an important expedition was despatched by Prince Henry, under the command of a young Venetian adventurer named Alvise Cadamosto. Touching at Madeira and the Canaries, Cadamosto made his way to Cape Blanco on the African coast, and thence to Senegal and the Gambia. He returned with a full report of all he had seen, and in the following year he again sailed from Lagos direct for Cape Blanco, with three ships, and discovered the mouth of a river which he named the Rio Grande (Jeba *i*). In 1457 Diogo Gomez sailed with orders to proceed as far as he could, and made his way to the Gambia. The Cape Verd Islands were discovered and colonized about 1462.

Prince Henry the Navigator died on the 13th of November 1460, and was buried near his father and mother in the monastery of Batalha. In 1839 a monument to his memory was erected at Sagres. During the long period in which the prince was continuing his maritime explorations, he did not cease to cultivate the science of cartography. The geographer Jayme of Majorca superintended his school of navigation at Sagres, and at the prince's instance the finest specimen of mediæval map-making that has been preserved was prepared at Venice under the superintendence of Fra Mauro of the Camaldolese convent of San Miguel de Marano. The geographical knowledge of the 15th century is also shown by the famous Borgia map (see Plate II.), a bronze planisphere which came into the possession of Cardinal Borgia about 1794, and was published in 1797 by the cardinal's nephew. The Borgia map, however, is of the very beginning of the 15th century.

The progress of discovery for a time received a check from the death of Prince Henry, but only for a time. In 1462 Pedro de Cintra extended Portuguese exploration 600 miles beyond the furthest point reached by Cadamosto, and discovered Sierra Leone. Fernau Gomez followed in 1469, and opened the trade with the Gold Coast; and in 1484 Diogo Cam discovered the mouth of the Congo. The king of Portugal next despatched two vessels of 50 tons in August 1486, under the command of Bartholomeu Dias, to continue discoveries southwards; while, in the following year, he sent Pedro de Covilham and Affonso de Payva to discover the country of Prester John. Dias succeeded in rounding the southern point of Africa, which he named Cabo Tormentoso; but king João II., foreseeing the realization of the long-sought passage to India, gave it the enduring name of the Cape of Good Hope. Dias returned to Lisbon in December 1487; meanwhile Payva had died at Cairo; but Covilham, having heard that a Christian ruler reigned in the mountains of Ethiopia, penetrated into Abyssinia in 1490. He delivered the letter which João II. had addressed to Prester John to the negûs Alexander of Abyssinia, but he was detained by that prince and never allowed to leave the country.

The results westward and eastward of the exertions of Prince Henry were the discovery of America by Columbus and of the Cape route to India by Vasco da Gama.

Christopher Columbus was born at Genoa about 1435. His name in Italian was Colombo, and in Spain he is known as Cristoval Colon. The fame of the Portuguese discoveries attracted strangers from all parts of the world, and in 1470 Columbus arrived at Lisbon. He was in Portugal from 1470 to 1484, during which time he made several voyages to the coast of Guinea in the Portuguese service. He married a daughter of Bartholomeu Perestrello, to whom Prince Henry had granted the commandership of Porto Santo, and lived for some time on that island. He learned, from many pilots experienced in the western voyages to the Azores, facts and signs which convinced him that there was an unknown land towards the west. Columbus also studied the *Imago Mundi* of Cardinal Pierre d'Ailly, whence he culled all he knew of Aristotle and Strabo; and he read the narrative of Marco Polo. By 1474 his grand project of discovery was established in his mind, and nothing afterwards could divert him from the pursuit of it. On the refusal of the king of Portugal to entertain his proposal, Columbus left Lisbon with his son in 1484, and he spent the interval until 1492 in appeals to the Spanish court At length, having overcome all obstacles, he set sail with a fleet of three ships from Palos, on the 3d of August 1492, on his unprecedented and perilous voyage. On the 12th of October, having crossed the Atlantic, Columbus sighted land, which was named San Salvador. Mr Major has recently proved that this island is one of the Bahamas, now known as Watling Island. After discovering Cuba, Hispaniola, and many small islands, Columbus set sail on his return voyage on January 16, 1493, and arrived at Palos on the 15th of March. His reception in Spain was enthusiastic, and commensurate with the grandeur of his achievement and on the 25th of September 1493 he sailed from Cadiz on his second voyage, with a fleet of three large ships and fourteen caravels. On the 3d of November he discovered the

Columbus

island of Dominica, and during the voyage his discoveries included the Windward Islands and Jamaica. He returned to Cadiz on June 11, 1496; and it was not until May 30, 1498, that he set sail on his third voyage. The first land he came to formed a new discovery, which he named the island of Trinidad, and it was in this voyage that he reached the mainland of South America, and discovered the islands of Cubagua and Margarita. A colony had been formed on Hispaniola, and soon afterwards a judge named Francisco de Bobadilla arrived from Spain, having been sent, at the instigation of the great discoverer's enemies, to inquire into his conduct. Bobadilla seized upon the government, and sent Columbus home in chains. Ferdinand and Isabella were overwhelmed with shame, and the people with astonishment, on his arrival. He was at once released, and false promises of restitution and reward were profusely made. But Bobadilla was superseded, not by Columbus, but by Nicolas de Ovando. On the 9th of May 1502, however, Columbus was allowed to sail on a fourth and last voyage of discovery. He reached the island of Martinique on the 13th of June, and touched at Dominica and Hispaniola. Thence he sailed westward, discovering the coast of Veragua and the harbour of Porto Bello. After a stay in Jamaica, he set sail for Spain on the 12th of September 1504, and arrived at San Lucar on the 7th of November. He lived for two years longer, experiencing the blackest ingratitude from the Spanish court. At length, in debt and poverty, and bowed down by disappointment, this great man died May 20, 1506. His body was buried at Valladolid, and removed in 1513 to Cartuja de las Cuevas near Seville. A monument was erected over his grave, with the inscription—

A Castilla y Leon,
Nuevo Mundo dió Colon.

In 1536 the bodies of Columbus and his son Diego were transported to St Domingo; and thence they were removed to Havana in 1795. The ashes of the immortal discoverer now repose in the cathedral of Havana.

While Columbus was discovering a new world, the Portuguese continued their persevering efforts to reach India by sea. Vasco da Gama sailed from Lisbon on the 8th of July 1497 with four vessels built expressly for the voyage, the largest not exceeding 120 tons, and called the "Sam Gabriel." His brother Paolo commanded the "Sam Raphael," and the "Berrio" was under Nicolas Coelho. On November 22, with a fair wind, Da Gama rounded the Cape of Good Hope, and anchored in the bay named San Bras by Bartholomeu Dias, on the 25th. On Christmas Day he sighted land, which, on that account, he named Natal. He reached Mombas on the 7th of April, and on the 20th of May 1498 he anchored before Calicut. Da Gama returned to Lisbon in August 1499; and at his recommendation another fleet was fitted out, consisting of thirteen well-armed ships, under Pedro Alvarez Cabral, with Bartholomeu Dias and Nicolas Coelho under his orders. The expedition sailed on the 9th of March 1500; and on the 22d of April Cabral discovered the coast of Brazil, and took formal possession for the king of Portugal. Resuming his voyage to the East, he reached Calicut in September, and obtained permission to build a factory, establishing friendly relations also at Cananor and Cochin. He returned to Lisbon in July 1501. Vasco da Gama set sail, with a much larger fleet, on his second voyage in 1502. He visited several ports on the west coast of India, engaged in war as well as in commerce, and returned in September 1503. In 1503 Antonio da Saldanha and Affonso de Albuquerque sailed for India, and made terms of friendship with the chief of Quilon. Dom Francisco de Almeida, the first viceroy of the Indies, was sent out in 1505. He founded the ports of the Angediva and Cananor, and his son Laurenço discovered Ceylon. Tristam da Cunha, with Affonso de Albuquerque under his orders, was sent to occupy Socotra; and in 1506 Albuquerque came to India as second viceroy. He explored the coasts of Arabia and Persia, made the king of Ormus tributary to Portugal, and sent embassies to Abyssinia. In 1509 (?) a factory was established at Malacca; and on November 25, 1510, the great Albuquerque conquered Goa, and established the seat of his government there. In 1512 the Moluccas were discovered; and in 1517 Fernam Peres de Andrade reached China, and entered into commercial relations with the governor of Canton. In 1524 Vasco da Gama arrived in India for a third time, as viceroy, and landed at Goa on the 11th of September. He died at Cochin on the 24th of December 1524, and in 1538 his body was transported to Portugal, and buried in his tomb at Vidigueira, of which town he was count.

The voyages of Vasco da Gama revolutionized the commerce of the East. Until then the Venetians held the carrying trade of India, which was brought by the Persian Gulf and Red Sea into Syria and Egypt, the Venetians receiving the rich products of the East at Alexandria and Beyrout, and distributing them over Europe. This commerce was a great source of wealth to Venice; but after the discovery of the new passage round the Cape, and the conquests of the Portuguese, the trade of the East passed into other hands.

The achievements of Columbus and Da Gama are immeasurably enhanced when we consider the inadequate means at their disposal, their small and ill-formed ships, and their defective knowledge of navigation. The mariner's compass had been in use for nearly two centuries, and it was Columbus himself who first observed the phenomena of variation. But the compass and rough sea-card were the only appliances, until the learned Nuremberger, Martin Behaim, invented the application of the astrolabe to purposes of navigation, which enabled mariners to ascertain their latitude. This was in the year 1480. The astrolabe was used by Vasco da Gama on his first voyage round the Cape of Good Hope; but the movement of a ship rendered accuracy impossible, and the liability to error was increased by the necessity for three observers. One held the astrolabe by a ring passed over the thumb, the second measured the altitude, and the third read off. The astrolabe was a metal circle graduated round the edge, with a limb called the *alhidada* fixed to a pin in the centre, and working round the graduated circle. The instrument had two sights fitted upon it, one at each end, and was suspended by a ring so as to hang vertically on one hand, while the *alhidada* was worked up and down until the sun could be seen through both the sights. It then gave the zenith distance. The *Ordenanzas* of the Spanish council of the Indies record the course of instruction prescribed for pilots, which included the *De Sphæra Mundi* of Sacrobosco, the spherical triangles of Regiomontanus, the *Almagest* of Ptolemy, the use of the astrolabe and its mechanism, the adjustments of instruments, cartography, and the methods of observing the movements of heavenly bodies. The only observations employed by the ancients for finding the longitude were those of the eclipses of the moon, and it was not until 1610 that Galileo discovered another method by observation of Jupiter's satellites.

The astro

The discoveries of Columbus awakened a spirit of enterprise in Spain which continued in full force for a century; adventurers flocked eagerly across the Atlantic, and discovery followed discovery in rapid succession. Many of the companions of Columbus continued his work. Pinzon in 1499 reached the mouth of the Amazon; and in the same year Alonzo de Ojeda, accompanied by a Florentine named Amerigo Vespucci, touched the coast of South America somewhere near Surinam, following the shore as far as the Gulf of Maracaibo. Vespucci afterwards made three voyages to the Brazilian coast; and in 1504 he wrote an account of his four voyages, which was widely circulated, and became the means of procuring for its author the high honour of giving his name to the whole continent. Mr Major has discussed the hitherto obscure question of the way in which the name "America" originated, in a paper distinguished for great learning and very able criticism. He has shown that the word "America" first appeared on the *Mappe Monde* drawn by Leonardo da Vinci, and he explains the chain of circumstances which led to its adoption. The first map known to exist with America delineated upon it is that drawn by Juan de la Cosa, the pilot of Columbus in his second voyage, which is dated 1500. Juan de la Cosa was with Ojeda and Vespucci, and afterwards with Ojeda in his last ill-fated expedition. In May 1507, just a year after the death of Columbus, one Martin Waldseemüller (Hylacomulus) wrote a work called *Cosmographiæ Introductio*, to which was appended a Latin edition of the four voyages of Vespucci. In this book, which was printed at St Dié in Lorraine, he proposed that the name of America should be given to the New World. In 1508 the first engraved map containing the New World appeared, in an edition of Ptolemy printed at Rome, but it does not bear the name of America. But in 1509 the name "America," proposed by Hylacomulus in 1507, appears, as if it was already accepted as a well-known denomination, in an anonymous work entitled *Globus Mundi*, published at Strasburg. This was three years before the death of Vespucci. The *Mappe Monde* of Leonardo da Vinci, to which Major assigns the date of 1514, has the name of America across the South American continent.

In 1508 Ojeda obtained the government of the coast of South America from Cabo de la Vela to the Gulf of Darien; and at the same time Diego Nicuesa was appointed governor of Veragua from the Gulf of Darien to Cape Gracias a Dios. The two adventurers arrived at Hispaniola together; but Ojeda set out first for his government, landed at Carthagena in 1510, and sustained a bloody defeat from the natives, in which his lieutenant, Juan de la Cosa, was killed. Ojeda then embarked, and eventually selected a site on the east side of the Gulf of Darien for his seat of government. Here he was again defeated by the natives, and, returning to Hispaniola for aid, he died there in extreme poverty. Nicuesa was still more unfortunate, and died at sea. The Spaniards in the Gulf of Darien were left by Ojeda under the command of Francisco Pizarro, the future conqueror of Peru. After suffering from famine and disease, Pizarro embarked the survivors in small vessels, but outside the harbour they met a ship which proved to be that of the bachiller Martin Fernandez Enciso, Ojeda's partner, coming with provisions and reinforcements. They all returned to their settlement called San Sebastian, but found that the Indians had destroyed the fort, and Enciso determined to abandon it. One of the crew of Enciso's ship, Vasco Nuñez de Balboa, the future discoverer of the Pacific Ocean, induced his commander to form a settlement on the other side of the Gulf of Darien. The soldiers became discontented and deposed Enciso, when Vasco Nuñez, a clever and courageous adventurer, took command of the Darien settlement in March 1511. Enciso was a man of learning, and an accomplished cosmographer. His work *Suma de Geografia*, which was printed in 1519, is the first Spanish book which gives an account of America. Vasco Nuñez, the new commander, entered upon a career of conquest in the neighbourhood of Darien, which ended in the discovery of the Pacific Ocean on the 25th of September 1513. In 1514 Pedrarias de Avila, an old man of rank and some reputation, but with no ability, and of a malicious disposition, was appointed to supersede Vasco Nuñez as governor of Darien, and the bachiller Enciso came out in his fleet. Pedrarias, on a false pretext, beheaded Vasco Nuñez in 1517, which was one of the greatest calamities that could have happened to South America at that time; for the discoverer of the South Sea was on the point of sailing with a little fleet into his unknown ocean, and a humane and judicious man would have been the conqueror of Peru, instead of the cruel and ignorant Pizarro. In the year 1519 Panama was founded by Pedrarias; and the conquest of Peru by Pizarro followed a few years afterwards. Hernan Cortes overran and conquered Mexico from 1518 to 1521, and the discovery and conquest of Guatemala by Alvarado, of Florida by Hernando de Soto, and of Nueva Granada by Quesada, followed in rapid succession. The first detailed account of the west coast of South America was written by that keenly observant old soldier, Pedro de Cieza de Leon, who was travelling in South America from 1533 to 1550, and published his story at Seville in 1553.

But the great anxiety of the Spanish Government at that time was to find a westward route to the Moluccas. For this purpose Juan Diaz de Solis was despatched in October 1515, and in January 1516 he discovered the mouth of the Rio de la Plata. He was, however, killed by the natives, and his ships returned. In the following year Magellan laid before Charles V., at Valladolid, a scheme for reaching the Spice Islands by sailing westward. He had already served with his own countrymen, the Portuguese, on the coast of India and at the taking of Malacca, and he was an accomplished and resolute seaman. With a fleet of five ships, and the rank of captain-general, Magellan sailed from San Lucar on the 21st of September 1519. After touching on the coast of Brazil, at the Rio de la Plata, and at the ports on the east coast of Patagonia, Magellan entered the straits which bear his name in October 1520. In consequence of many fires being seen on the southern shores of the strait, he named that country Tierra del Fuego. The fleet, now consisting of the "Trinidad," "Vittoria," and "Concepcion," emerged from the strait and entered the Pacific Ocean on the 27th of November 1520. They then steered north-west, crossed the line on the 13th of February 1521, and on the 6th of March reached the Ladrone Islands. Thence Magellan proceeded to the Philippines. He was killed in an attack on the island of Matan, which he made in order to bring it under subjection to his ally the king of Zebu, on the 26th of April 1521. Thus fell this great navigator, who was second only to Columbus in the history of nautical exploration. His brother-in-law, Duarte Barbosa, was selected to succeed Magellan in command of the fleet, with João Serrao as his colleague. They were both killed in battles with the natives, and eventually a Biscayan named Sebastian del Cano, sailing home by way of the Cape of Good Hope, reached San Lucar in command of the "Vittoria" on the 6th of September 1522, with eighteen survivors. Del Cano was received with great distinction by the emperor, who granted him a globe for his crest, and the motto "Primus circumdedisti me."

While the Spaniards were circumnavigating the world and completing their knowledge of the coasts of Central and South America, the Portuguese were actively engaged on similar work as regards Africa and the East Indies.

In Abyssinia the mission of Covilham led to further intercourse. In April 1520 the Portuguese viceroy of the Indies took a fleet into the Red Sea, and landed an embassy consisting of Dom Rodriguez de Lima and Father Francisco Alvarez, a priest whose detailed narrative is the earliest and not the least interesting account we possess of Abyssinia. It was not until 1526 that the embassy was dismissed; and not many years afterwards the negûs entreated the help of the Portuguese against Mahometan invaders, and the viceroy sent an expeditionary force, commanded by his brother Cristoforo da Gama, with 450 musketeers. Da Gama was taken prisoner and killed, but his Portuguese enabled the Christians of Abyssinia to regain their power, and a Jesuit mission remained in the country. While Abyssinia was thus opened to the enterprise of the Portuguese on the east side of Africa, they also established a close connexion with the kingdom of Congo on the west side, and obtained much information respecting the interior of the continent. Duarte Lopes, a Portuguese settled in the country, was sent on a mission to Rome by the king of Congo, and Pope Sixtus V. caused him to recount to his chamberlain, Felipe Pigafetta, all he had learned during the nine years he had been in Africa, from 1578 to 1587. This narrative, under the title of *Description of the Kingdom of Congo*, was published at Rome by Pigafetta in 1591. A map was attached on which the two equatorial lakes, Victoria and Albert Nyanza, and Lake Tanganyika are shown, and the empire of Monomoezi or Uniamuezi is laid down. The most valuable work on Africa during the 16th century is, however, that written by Leo Africanus. This famous traveller was born at Granada, and retired into Africa when his native town was captured by the Spaniards. He travelled extensively in the north and west of Africa, and was eventually taken by pirates and sold to a master who presented him to Pope Leo X. At the pope's desire he translated his work on Africa into Italian, and died in about the year 1526.

In the East Indies the Portuguese acquired predominating influence at sea, establishing factories on the Malabar coast, in the Persian Gulf, at Malacca, and in the Spice Islands, and extending their commercial enterprises from the Red Sea to China. Their missionaries were received at the court of Akbar, and Benedict Goes, a native of the Azores, was despatched on a journey overland from Agra to China. He started in 1603, and, after traversing the least known parts of Central Asia, he reached the confines of China. He appears to have ascended from Cabul to the plateau of the Pamir, and thence onwards by Yarkand, Khotan, and Aksu. He died at a place called Socieu in March 1607; and thus, as one of the brethren pronounced his epitaph, "seeking Cathay he found heaven."

The activity and love of adventure, which became a passion for two or three generations in Spain and Portugal, spread to other countries. It was the spirit of the age; and England, Holland, and France soon began to enter upon the same glorious career. English enterprise was first aroused by John and Sebastian Cabot, father and son, who came from Venice and settled at Bristol in the time of Henry VII. The Cabots received a patent, dated March 5, 1496, empowering them to seek unknown lands; and John Cabot discovered Newfoundland and part of the coast of America. Sebastian afterwards made a voyage to Rio de la Plata in the service of Spain, but he returned to England in 1548, and received a pension from Edward VI. "in consideration of the good and acceptable services done and to be done." He was placed at the head of the Society of Merchant Adventurers, and, by his knowledge and experience, he was the means of keeping alive the spirit of enterprise in England, and of extending her foreign commerce. At his suggestion a voyage was undertaken for the discovery of a north-east passage to Cathay, with Sir Hugh Willoughby as captain-general of the fleet, and Richard Chancellor as pilot-major. They sailed in May 1553, but Willoughby and all his crew perished in a harbour on the Lapland coast. Chancellor, however, was more fortunate. He reached the White Sea, performed the journey overland to Moscow, where he was well received, and may be said to have been the founder of the trade between Russia and England. He returned to Archangel and brought his ship back in safety to England. On a second voyage, in 1556, Chancellor was drowned; and three subsequent voyages, led by Stephen Burrough, Pet, and Jackman, effected an examination of the straits which lead into the Sea of Kara.

English enterprise.

The Cabots.

The French followed closely on the track of John Cabot, and the hardy Norman and Breton seamen frequented the banks of Newfoundland at the commencement of the 16th century. In 1524 Francis I. sent Giovanni da Verazzano of Florence on an expedition of discovery to the coast of North America; and the details of his voyage were embodied in a letter addressed by him to the king of France from Dieppe, in July 1524. On April 20, 1534, Jacques Cartier sailed from St Malo with two vessels of 60 tons each, for the purpose of continuing the discoveries of Verazzano, and he visited Newfoundland and the Gulf of St Lawrence. In the following year he made another voyage, discovered the island of Anticosti, and ascended the St Lawrence to a place called Hochelaga, now Montreal. He returned, after passing two winters in Canada; and on another occasion he also failed to establish a colony. Admiral de Coligny made several unsuccessful endeavours to form a colony in Florida under Jean Ribault of Dieppe, René de Laudonnière, and others, but the settlers were furiously assailed by the Spaniards and the attempt was abandoned.

Age of Elizabeth.

The reign of Elizabeth is famous for the gallant enterprises that were undertaken by sea and land to discover and bring to light the unknown parts of the earth. The great promoter and father of English geographical discovery was Richard Hakluyt, who was born near London in 1553. He was at Westminster School, and when quite a boy he imbibed a love for cosmography and maritime discovery. At Oxford he read all the narratives of voyages and travels that came within his reach, and delivered lectures on cartography. In 1585 he was at Paris, as chaplain to the English embassy, and in 1605 he became a prebendary of Westminster. He was the chief promoter in the formation of the two companies for colonizing Virginia in 1606; and he devoted his life to the encouragement of similar undertakings, and to their record. Hakluyt died in 1616, and was buried in Westminster Abbey. He was incessantly employed in the collection, examination, and translation of accounts of voyages and travels, and of charters, letters, and other documents bearing on the subject, and in correspondence with men eager either to impart or receive information. Sir Philip Sidney, Sir Francis Walsingham, Lord Thomas Howard, and Sir Francis Drake were among those who supported and encouraged him, and Ortelius and Mercator were his correspondents. His first work was the *Divers Voyages touching the Discoverie of America*; and the second was brought out while he was in Paris in 1586, entitled *A Notable Historie containing Foure Voyages made by French Captaynes unto Florida*. In 1587 he published at Paris a revised edition of the *De Orbe Novo* of Peter Martyr Anghiera. His *Principal Navigations* was published in folio in 1589, and dedicated to Sir Francis Walsingham; and the new edition, in three volumes, appeared in 1598. Hakluyt also got translations made of Leo Africanus, of Mendoza's *History of China*, and of Galvano's *Discoveries of the World*, which were published. His last publication was a translation of Hernando de Soto's discoveries in Florida. He left many valuable papers at his death, most of which, together with a vast number of other narratives, were published in 1622 in the great work of the Rev. Samuel Purchas, entitled "Hakluytus Posthumus, or Purchas his Pilgrimes."

Hakluyt.

It is from the rich treasure-house of Hakluyt and Purchas that our knowledge of the gallant deeds of the English and other explorers of the Elizabethan age is mainly derived. The great collections of voyages and travels of De Bry and Hulsius served a similar useful purpose on the continent of Europe. One important object of English maritime adventurers of those days was to discover a route to Cathay by the north-west, a second was to settle Virginia, and a third was to beat up the Spanish settlements in the Indies. Nor was the trade to Muscovy and Turkey neglected; while latterly a resolute and successful attempt was made to establish commercial relations with East India.

Martin Frobisher led the way in the direction of the north-west, sailing from the Thames in 1576, and sighting the southern part of Greenland on the 11th of July. In this voyage he discovered a part of the coast of Labrador, and the strait (now known to be a deep bay) which bears his name. He brought home some stones which were believed to be gold, and the consequence was that there arose an eager desire to obtain more. Many speculators subscribed, and Frobisher was sent out on a second voyage, "more for the searching of this gold ore than for the searching any further discovery of the passage." He left Gravesend on May 27, 1577, wasted his time in picking up stones on the shores of Frobisher's Strait, and returned on the 22d of August. The excitement about the gold ore still continued. The queen gave the name of *Meta Incognita* to the newly discovered country; and on May 21, 1578, Frobisher set out on a third voyage with a fleet of fifteen ships. After touching at Greenland, they made for the opposite shore through an ice-encumbered sea, and the fleet was separated during a heavy gale. They reached various ports in England during October, and by that time the bubble about the gold ore had burst, and the enterprise was considered a failure. The first of the three voyages alone was a voyage of discovery.

In 1585 John Davis, an admirable seaman and most resolute explorer, was employed by some merchants, chief among whom was Mr William Sanderson of London, to take up the glorious work where Frobisher had left off. He sailed from Dartmouth on the 7th of June 1585, and, reaching the south-west coast of Greenland, he called it the "Land of Desolation." He then stood over to the opposite coast, which he examined in the neighbourhood of Cape Walsingham, returning to Dartmouth on September 30. In 1588 he sailed on the 7th of June and coasted along Greenland, having friendly intercourse with the Eskimo. He also examined part of the Labrador coast. In his third voyage he sailed from Dartmouth on the 17th of May, and sighted Greenland on the 14th of June. On this occasion he went as far north as 72° 12′, naming the great island bluff—which is now so well known to voyagers up Baffin's Bay—"Sanderson his Hope of a North-West Passage." Crossing over Davis Strait, the bold explorer discovered the strait which now bears the name of Hudson. Davis was followed in his northern voyages by Waymouth, Hall, and Knight; and in 1607 Henry Hudson was despatched on a voyage of discovery in a small vessel of 80 tons. He sighted the east coast of Greenland in 73° N., examined the north-west end of Spitzbergen, as far as a point which he named Hakluyt Headland, and reached 80° 23′ N. In 1608 he made a second voyage, during which he examined the edge of the ice between Spitzbergen and Greenland. In his third voyage, in 1609, he was employed by the Dutch, and discovered the Hudson River. In 1610 he was again employed by English merchants, and entered Hudson's Bay, but was infamously abandoned in an open boat by his crew. In 1612 Sir Thomas Button continued the exploration of Hudson's Bay, which was completed by Thomas James and Luke Fox in 1631.

In 1616 the little bark "Discovery," of 35 tons, was fitted out by those persevering adventurers Sir Thomas Smith, Sir Dudley Digges, John Wolstenholme, and Alderman Jones, for another attempt in the icy seas. This was the most successful Arctic voyage of the 17th century. Robert Bylot was appointed master of the "Discovery," and William Baffin was pilot. They sailed from Gravesend, with 17 souls on board, on the 26th of March, and were off Hope Sanderson, the extreme point of Davis, on the 30th of May. The "Discovery" reached what is now called "the north water" of Baffin's Bay on the 1st of July, and, after discovering the head of the great bay which bears his name, the pilot Baffin returned by sailing down the west side of it. On August 30 the "Discovery" was again safely anchored in Dover roads. It was exactly 200 years before any other vessel followed in her track, and reached "the north water." Both Davis and Baffin afterwards served and were killed in the East Indies.

The Dutch emulated the English in the Arctic seas during this period. Their merchants opened a trade with Kola and Archangel as early as 1578, but the difficulty of penetrating into the Sea of Kara led them to try the possibility of finding a passage round the northern end of Novaya Zemlya. The credit of the conception of this voyage is due to the great cosmographer Peter Plancius, and the merchants of Amsterdam adopted the idea, and despatched a vessel of 100 tons called the "Mercurius," under the command of William Barents. He sailed from the Texel on June 4, 1594, and sighted Novaya Zemlya on the 4th of July. Sailing northwards along the coast he rounded Cape Nassau and reached the edge of the ice. For many days he perseveringly sought for a passage through it. In his second voyage he merely went to the entrance of the Sea of Kara. But his third voyage was the most important. Heemskerk was the commander, Barents was pilot, and the mate, Gerrit de Veer, was the historian of the voyage. They sailed from Amsterdam on May 13, 1596. On June 19, Spitzbergen was discovered, and the whole western coast and part of the northern examined. The record of the subsequent proceedings of Barents and his crew, of their famous voyage round the north-western end of Novaya Zemlya, and of their terrible sufferings in the first Arctic winter ever faced by Europeans, is deeply interesting as it is told in the simple narrative of Gerrit de Veer. Barents had long been ill, and when they set sail from their dismal winter harbour on June 14, 1597, in open boats, he was too weak to stand, and was carried from the house. He died on the 19th, and found a grave in the midst of his discoveries.

English circumnavigators. The maritime enterprise of England, in the days of Elizabeth, was mainly directed towards the discovery of a north-west passage; but many voyages were also made to Guinea and the West Indies, and twice English vessels followed in the track of Magellan, and circumnavigated the globe.

Drake. In 1577 Francis Drake, who had previously served with Hawkins in the West Indies, undertook his celebrated voyage round the world. His fleet consisted of three ships and two pinnaces, which were broken up during the voyage. The ships were the "Pelican" of 100 tons, on board of which Drake himself embarked, the "Elizabeth" of 80, and the "Marigold" of 30 tons. After some stay at Port San Julian on the coast of Patagonia, the fleet entered the Straits of Magellan on the 20th of August 1578, when Drake changed the name of his ship to the "Golden Hind." They reached the western entrance on the 6th of September, and soon afterwards the "Marigold" parted company in a gale of wind, and was never heard of again, while the "Elizabeth" basely deserted her consort and returned to England. Drake, in the "Golden Hind," continued the voyage alone. At first he was driven to the southernmost point of Tierra del Fuego, and thus discovered that there was a passage, though he did not round Cape Horn. He then proceeded northward along the west coast of America, touching at the island of Mocha off the Chilian coast, at Valparaiso, Coquimbo, Tarapaca, Arica, Callao, and Payta. Off Cape

San Francisco, nearly on the equator, he captured a very rich Spanish treasure-ship called the "Cacafuego"; and it is right to observe that England was then at peace with Spain. Drake resolved to attempt the discovery of a passage from the Pacific to the Atlantic, and with this object he continued to shape a course northwards along the American continent. On the 5th of June 1579 the "Golden Hind" reached her most northern point in 48°, when the attempt was abandoned, and Drake put into a harbour to refit, named Port Drake, which appears to have been the modern harbour of San Francisco, on the coast of California. The coast from the southern extremity of the Californian peninsula to Cape Mendocino was discovered by Juan Rodriguez Cabrillo and Francisco de Ulloa in 1539. Drake's discoveries extend from Cape Mendocino to 48° N.

Leaving California, Drake sailed across the Pacific and reached the Philippine Islands in October. He touched at Ternate and Java, and rounded the Cape of Good Hope on June 15, 1580. The "Golden Hind" anchored safely at Plymouth on the 26th of the following September. Drake was graciously received and knighted by the queen, and the "Golden Hind," the first English ship that circumnavigated the globe, was preserved for many years at Deptford. When at last she was broken up, a chair was made from one of her planks and presented to the university of Oxford.

Mr Thomas Cavendish, a gentleman of Suffolk, emulous of Drake's example, fitted out three vessels for an expedition to the South Sea, and sailed from Plymouth on July 21, 1586. Cavendish passed through Magellan's Straits in January 1587, and, taking the same route as Drake along the west coast of America, he reached Mazatlan in September. A rich Spanish treasure-ship was captured off Cape San Lucas, the southern extremity of California, on the 4th of November, and Cavendish then steered across the Pacific, seeing no land until he reached the Ladrone Islands. He arrived safely at Plymouth on the 9th of September 1588. The third English voyage into the Pacific was not
kins. so fortunate. Sir Richard Hawkins sailed from Plymouth on the 12th of June 1593 in the good ship "Dainty," passed through Magellan's Straits, and all went well until they reached the bay of Atacames, 57 miles north of the equator, in June 1594. Here the English were attacked by a Spanish fleet, and, after a desperate naval engagement, Hawkins was forced to surrender. Hawkins declared his object to be discovery and the survey of unknown lands, and his voyage, though terminating in disaster, bore good fruit. *The Observations of Sir Richard Hawkins in his Voyage into the South Sea*, published in 1622, are very valuable, and form the most charming work of the kind which was written during that period. It was long before another English ship entered the Pacific Ocean. Sir John Narborough took two ships through the Straits of Magellan in 1670 and touched on the coast of Chili; but it was not until 1685 that Cook and Dampier sailed over the part of the Pacific where, nearly a century before, the "Dainty" had to strike her flag to the Spaniard.

The exploring enterprise of the Spanish nation did not wane after the conquest of Peru and Mexico, and the acquisition of the vast empire of the Indies. It was rather spurred into renewed activity by the audacity of Sir John Hawkins in the West Indies, and by the appearance of Drake, Cavendish, and Richard Hawkins in the Pacific.

In the interior of South America the Spanish conquerors had explored the region of the Andes from the isthmus of Panama to Chili; and in 1541 Francisco de Orellana discovered the whole course of the Amazon from its source in the Quitenian Andes to the Atlantic. A second voyage down the great river was made in 1561 by the mad pirate Lope de Aguirre; but it was not until 1639 that a full account was written of the mighty stream by Father Cristoval de Acuña, who ascended it from its mouth to the city of Quito. The voyage of Drake across the Pacific was preceded by that of Alvaro de Mendaña, who was despatched from Peru in 1567 to discover the Australian land which was believed to exist in the South Sea. After a voyage of eighty days across the Pacific, Mendaña discovered the Salomon Islands; and the expedition returned in safety to Callao. The appearance of Drake on the Peruvian coast led to an expedition being fitted out at Callao, to go in chase of him, under the command of Pedro Sarmiento. He sailed from Callao in October 1579, and made a careful survey of the Straits of Magellan, with the object of fortifying that entrance to the South Sea. The colony which he afterwards took out from Spain was a complete failure, and is only remembered now from the name of "Port Famine" which Cavendish gave to the site at which he found the starving remnant of Sarmiento's settlers. In June 1595 Mendaña sailed from the coast of Peru in command of a second expedition to colonize the Salomon Islands. After discovering the Marquesas, he reached the island of Santa Cruz of evil memory, where he and many of the settlers died. His young widow took command of the survivors and brought them safely to Manila. The viceroys of Peru still persevered in their attempts to plant a colony in Australia. Pedro Fernandez de Quiros, who was pilot under Mendaña and Luis Vaez de Torres were sent in command of two ships to continue the work of exploration. They sailed from Callao on December 21, 1605, and discovered several islands of the New Hebrides group. They anchored in a bay of a large island which Quiros named "Australia del Espiritu Santo." From this place Quiros returned to America, but Torres continued the voyage, passed through the strait between Australia and New Guinea which bears his name, and explored and mapped the southern and (as has recently been proved) also the eastern coast of New Guinea.

The Portuguese, in the early part of the 17th century (1578–1640), were under the dominion of Spain, and their enterprise was to some extent damped; but their missionaries extended geographical knowledge in Africa. Father Francisco Paez acquired great influence in Abyssinia, and explored its highlands from 1600 to 1622. Fathers Mendez and Lobo traversed the deserts between the coast of the Red Sea and the mountains, became acquainted with the shores of Lake Tsana, and discovered the sources of the Abai or Blue Nile in 1624–1633.

But the attention of the Portuguese was mainly devoted to vain attempts to maintain their monopoly of the trade of India against the powerful rivalry of the English and Dutch. The English enterprises were persevering, continuous, and successful. James Lancaster made a voyage to the Indian Ocean from 1591 to 1594; and in 1599 the merchants and adventurers of London resolved to form a company, with the object of establishing a trade with the East Indies. On the 31st of December 1599 Queen Elizabeth granted the charter of incorporation to the East India Company, and Sir James Lancaster, one of the directors, was appointed general of their first fleet. He was accompanied by John Davis, the great Arctic navigator, as pilot-major. This voyage was eminently successful. The ships touched at Achin in Sumatra and at Java, returning with full ladings of pepper in 1603. The second voyage was commanded by Sir Henry Middleton; but it was in the third voyage, under Keelinge and Hawkins, that the mainland of India was first reached in 1607. Captain Hawkins landed at Surat and travelled overland to Agra, passing some time at the court of the Great Mogul. In the voyage of Sir Edward Michelborne, John Davis of Arctic fame lost his life in a fight with a Japanese junk on December 27, 1605. The eighth voyage, led by Captain Saris, extended the operations of the company to Japan; and in 1613 the Japanese Government granted privileges to the Company: but the English retired in 1623, giving up their factory. The chief result of this early intercourse between England and Japan was the interesting series of letters written by William Adams from 1611 to 1617. Adams, however, though an Englishman, went to Japan in a Dutch ship. From the tenth voyage of the East India Company, commanded by Captain Best, who left England in 1612, dates the establishment of permanent English factories on the coast of India. It was Captain Best who secured a regular firman for trade from the Great Mogul. From that time a fleet was despatched every year, and the Company's operations greatly increased geographical knowledge of India and the Eastern Archipelago.

The visits of Englishmen to Eastern countries, at this time, were not confined to the voyages of the Company. Journeys were also made by land, and, among others, Thomas Coryat, of Odcombe in Somersetshire, walked from France to India, and died in the Company's factory at Surat. In 1561 Mr Anthony Jenkinson arrived in Persia with a letter from Queen Elizabeth to the shah. He travelled through Russia to Bokhara, and returned by the Caspian and Volga. In 1579 Christopher Burroughs built a ship at Nijni Novgorod and traded across the Caspian to Baku; and in 1598 Sir Anthony and Robert Shirley arrived in Persia, and Robert was afterwards sent by the shah to Europe as his ambassador. He was followed by a Spanish mission under Garcia de Silva, who wrote an interesting account of his travels; and to Sir Dormer Cotton's mission, in 1628, we are indebted for Sir Thomas Herbert's charming narrative. In like manner, Sir Thomas Roe's mission to India resulted not only in a large collection of valuable reports and letters of his own, but also in the detailed account of his chaplain Mr Terry. But the most learned and intelligent traveller in the East, during the 17th century, was the German Kœmpfer, who accompanied an embassy to Persia in 1684, and was afterwards a surgeon in the service of the Dutch East India Company. He was in the Persian Gulf, India, and Java, and resided for more than two years in Japan, from 1690 to 1692. His *History of Japan* was published in England in 1727, Kœmpfer himself having died in 1716. From these various sources a considerable increase was made in the knowledge of India, Persia, and the further East.

Dutch enterprise.

The Dutch nation, as soon as it was emancipated from Spanish tyranny, displayed an amount of enterprise which, for a long time, was fully equal to that of England. The memorable Arctic voyages of Barents were quickly followed by the establishment of a Dutch East India Company; and Holland, ousting the Portuguese, not only established factories on the mainland of India and in Japan, but acquired a preponderating influence throughout the Eastern Archipelago. In 1583 Jan Hugen van Linschoten made a voyage to India with a Portuguese fleet, and his full and graphic descriptions of India, Africa, China, and the Eastern Archipelago must have been of no small use to his countrymen in the commencement of their distant voyages. The first of their Indian voyages was performed by ships which sailed from Holland in April 1595, and rounded the Cape of Good Hope. A second large Dutch fleet sailed in 1598; and, so eager was the young republic to extend her commerce over the world that another fleet, consisting of five ships of Rotterdam, was sent in the same year by way of Magellan's Straits, under Jacob Mahu as admiral, with William Adams as pilot. Mahu died on the passage out, and was succeeded by Simon de Cordes, who was killed on the coast of Chili. In September 1599 the fleet had entered the Pacific. The ships were then steered direct for Japan, and anchored off Bungo in April 1600. In the very same year, 1598, a third expedition was despatched under Oliver van Noort, a native of Utrecht. The fleet left Holland in September 1598, and entered the South Sea, through the Straits of Magellan, in February 1600, after a tedious, and in truth unskilful, navigation of nearly a year and a half from the time of leaving Holland. After keeping along the west coast of America nearly as far as the line, Van Noort shaped a course for the Ladrone Islands, and arrived off Manila. In August 1601 he anchored in front of Rotterdam, after an absence of three years, but the voyage contributed nothing to geography. The Dutch Company in 1614 again resolved to send a fleet to the Moluccas by the westward route, and Joris Spilbergen was appointed to the command as admiral, with a commission from the States-General. He was furnished with 4 ships of Amsterdam, 2 of Rotterdam, and 1 from Zeeland. On May 6, 1615, Spilbergen entered the Pacific Ocean, and touched at several places on the coast of Chili and Peru, defeating the Spanish fleet in a naval engagement off Chilca. After plundering Payta and making requisitions at Acapulco, the Dutch fleet crossed the Pacific and reached the Moluccas in March 1616. At that time the Dutch Company had 37 sail of European shipping and 3000 troops in the East Indies.

Horn rounded.

The Dutch now resolved to discover a passage into the Pacific to the south of Tierra del Fuego, the existence of which was ascertained by Sir Francis Drake. The vessels fitted out for this purpose were the "Eendracht," of 360 tons, commanded by Jacob le Maire, and the "Horn," of 110 tons, under Jan Schouten. They sailed from the Texel on June 14, 1615, and by the 20th of January 1616 they were south of the entrance of Magellan's Straits. Passing through the strait of Le Maire they came to the southern extremity of Tierra del Fuego, which was named Cape Horn, in honour of the town of Horn in West Friesland, of which Schouten was a native. They passed the cape on the 31st of January, encountering the usual westerly winds. The great merit of this discovery of a second passage into the South Sea lies in the fact that it was not accidental or unforeseen, but was due to the sagacity of those who designed the voyage. On March 1 the Dutch fleet sighted the island of Juan Fernandez; and, having crossed the Pacific, the explorers sailed along the north coast of New Guinea, and arrived at the Moluccas on September 17, 1616. In 1623 the Dutch sent expeditions against Brazil and Peru, which, however, did little to advance geographical knowledge, except that the Brazilian invasion resulted in the valuable work of Nieuhof.

There were several early indications of the existence of the great Australian continent, which have been very ably discussed by Mr Major; and the Hollanders endeavoured to obtain further knowledge concerning the country and its extent; but only its northern and western coasts had been visited before the time of Governor Van Diemen. Dirk Hartog had been on the west coast in latitude 26° 30′ S. in 1616. Pelsert struck on a reef called "Houtman's Abrolhos" on June 4, 1629. In 1697 the Dutch captain Vlamingh landed on the west coast of Australia in 31° 43′ S., and named the Swan River, where he saw some black swans. In 1642 the governor and council of Batavia fitted out two ships to prosecute the discovery of the south land, and entrusted the command to Captain Abel Jansen Tasman. This voyage proved to be the most important to geography that had been undertaken since the first circumnavigation of the globe. Tasman sailed from Batavia in the yacht "Heemskirk" on the 14th of August 1642, and from Mauritius on the 8th of October. On November 24 high land was sighted in 42° 30′ S., which was named Van Diemen's Land, and, after landing there, sail was again made, and New Zealand (at first called Staten Land) was discovered on the 14th of December. Tasman communicated with the natives and anchored in what he called Murderer's Bay. From New Zealand it was resolved to steer eastward to longitude 220°, and then north. On this course the ships arrived at Tongatabu, one of the Friendly Islands of Cook; in April 1643 they were off the north coast of New Guinea; and on June 15 Tasman returned to Batavia. In 1644 Tasman made a second voyage to effect a more full discovery of New Guinea.

The French directed their enterprise more in the direction of North America than of the Indies. One of their most distinguished naval worthies was Samuel Champlain, a native of Brouage in Saintonge, whose friend and patron was Aymar de Chastes, governor of Dieppe, a devoted follower of Henry IV. Champlain after the close of the war with the League in Brittany, in which he served, made a remarkable journey through Mexico and the West India Islands from 1599 to 1602, and on his return he found that M. de Chastes was, undeterred by previous failures, resolved to undertake the establishment of a colony in Canada. Champlain was sent on a voyage of reconnaissance, and on his return he found that the Sieur de Chastes was dead. In 1603 the Sieur de Monts was named vice-admiral of the coasts of Acadia, and Champlain sailed with him from Dieppe. He was for some years engaged in surveying all the coasts of Acadia and Cape Breton, and in 1607 he returned to France with De Monts. In the following year another attempt was made. Champlain, with a colleague named Du Pont Gravé, sailed to the St Lawrence, and on July 3, 1608, they first arrived at Quebec. In 1609 Champlain ascended the Iroquois to the lake which still bears his name. By 1611 a regular colony was established at Quebec; and in 1620 Champlain was installed as governor. He died towards the end of the year 1635. Champlain was an able navigator and a resolute explorer, and he made a very large addition to the knowledge of Canada and Acadia (Novia Scotia).

alley.

The last expedition of the 17th century was purely scientific. In 1699 Edmund Halley, the astronomer-royal, in command of the "Paramour Pink," undertook a voyage to improve the knowledge of longitude, and of the variation of the compass. The results of his voyage were the construction of a variation chart, and proposals for finding the longitude by occultations of fixed stars.

rogress navi- tion.

During the 17th century very considerable progress was made in the art of navigation, and in systematizing and delineating the vast mass of material that was accumulated by the ceaseless activity of explorers. The Dutch took the lead as map-makers. Mercator invented the useful projection which bears his name; and Ortelius, Hondius, and Hulsius compiled a series of valuable maps. In finding the latitude at sea, the astrolabe very generally gave place to the cross-staff, because the graduation of the latter was larger and more easily read off. The cross-staff was a very simple instrument, consisting of a graduated pole with cross pieces, called transversaries (of which there were four used according to the altitude), also graduated, which were fitted to work on it. The bearings of the sun were taken by compass, to ascertain when it was near the meridian; then the end of the long staff was placed close to the observer's eye, and the transversary moved until one end exactly touched the horizon, and the other the sun's centre. This was continued until the sun dipped, when the meridian altitude was obtained. The back-staff was an improvement on the cross-staff, invented by the great Arctic navigator John Davis. It was fitted with a reflector, and it was thus the first rough idea of the principle of the quadrant and sextant. The cross-staff was used for low altitudes, because both ends of the transversary could easily be seen at the same time, and the astrolabe for high altitudes. With the invention of these instruments came instructions for their use, and for working out observations. In England the first of these was *The Old Rutter of the Sea*, printed in 1490. Then followed the *Seaman's Secrets* of John Davis, and *A Regiment of the Sea, containing very necessary Matters, with a perfect Sea Card*, by Thomas Hood, published in 1596. Hood also sold compasses constructed on Mr Norman's principle, near the Minories. These manuals contained definitions, treatises on the use of the sea card and compass, tables of declination and rules for applying it, rules for dead reckonings and longitude, and instructions in the use of instruments. Latitude was obtained by observation, but longitude had usually to be reckoned on the chart from the meridian of Grand Canary, which in those days was used by all civilized countries. The differences of time between the eclipses of the moon at the place of the observer and the place for which it was calculated in the *ephemerides* for that day was another method in use of finding the difference of longitude. Mariners were also provided with tables giving the number of miles in a degree of longitude for every degree of latitude. Much attention was bestowed upon the phenomena of the variation and dip of the magnetic needle. Robert Norman, the hydrographer, discovered the dip or inclination of the needle in 1576, and in 1581 he observed the variation of the compass at London, and found it to be 11° 15′ E. In the same year his *Discourse of the Magnet or Loadstone* was published by Ballard. In 1580 Mr Borough, comptroller of the navy, found the variation of the compass at Limehouse to be 11° 19′ E. It may be observed here that in 1657 there was no variation at London, and that it moved westerly until 1815, when it was 24° 27′ W. It is now returning eastwards.

ross- aff.

By means of these rough instruments and calculations our Elizabethan navigators and their contemporaries succeeded in delineating the vast regions that were discovered. Thus the sum of human knowledge was augmented, while men's minds were enlarged, and the wealth and prosperity of nations were increased, through the provision of safe guides by which lands and seas could be traversed, and distant countries visited.

In the 18th century, to a far greater extent than had ever been the case before, geography began to be cultivated for its own sake, and expeditions were fitted out with the objects of discovery and of acquiring knowledge. The same objects also generally formed part of those enterprises which were avowedly undertaken for conquest, in the search of wealth, or from motives of religious zeal.

The improvement of scientific apparatus naturally went hand in hand with the progress of discovery. The great desideratum was the means of finding the longitude; and it was the creation of a commission for the discovery of longitude in 1713 which, so far as England is concerned, gave the greatest stimulus to inventions connected with geographical research. To the Board of Longitude is due the conception of the *Nautical Almanac*, and the establishment of a surveying branch of the naval service. The *Nautical Almanac* first appeared in 1767, under the auspices of Dr Maskelyne, the astronomer-royal, who, by furnishing tables of lunar distances, supplied another means of finding the longitude. The invention by Hadley, in 1731, of the quadrant for use at sea, which entirely superseded the astrolabe and cross-staff, was a still greater improvement; and it was soon followed by better instruments on the same principle—the sextants of Dollond and Troughton. The work of travellers on land also became more accurate in proportion as instruments and maps were improved. Early explorers by land were content with itineraries and maps which only indicated distances. The introduction of observations by compass bearings was an important improvement; and after the invention of Hadley's quadrant, these rough route surveys began to be checked and verified by astronomical observations.

The most remarkable example of the early application of these improvements is to be found in the survey of China by the Jesuit missionaries. They first prepared a map of the country round Peking, which was submitted to the emperor Kang-hi, and, being satisfied with the accuracy of the European method of surveying, he resolved to have a survey made of the whole empire on the same principles. This great work was commenced in July 1708, and the completed maps were presented to the emperor in 1718. The records preserved in each city were examined, topographical information was diligently collected, and the Jesuit fathers checked their triangulation by meridian altitudes of the sun and pole star, and by a system of remeasurements. The result was a more accurate map of China than existed, at that time, of any country in Europe. Kang-hi next ordered a similar map to be made of Tibet, the survey being executed by two lamas who were carefully trained as surveyors by the Jesuits at Peking. From these surveys were constructed the well-known maps which were forwarded to Duhalde, and from which D'Anville constructed his atlas.

Several European missionaries had previously found their way from India to Tibet. Antonio Andrada, in 1624, was the first European to enter Tibet since the visit of Friar Odoric in 1325. The next journey was that of Fathers Grueber and Dorville about 1660, who succeeded in passing from China, through Tibet, into India. In 1715 Fathers Desideri and Freyre made their way from Agra, across the Himálayas, to Lassa, the capital of Tibet; and the Capuchin Friar Orazio della Penna resided at Lassa from 1735 until 1747. But the most remarkable journey in this direction was performed by a Dutch traveller named Samuel Van de Putte. He is the only European who has ever completed the journey from India, through Lassa, to China, and returned to India by the same route. He left Holland in 1718, went by land through Persia to India, and eventually made his way to Lassa, where he resided for a long time. He went thence to China, returned to Lassa, and was in India in time to be an eye-witness of the sack of Delhi by Nadir Shah in 1737. In 1743 he left India, and died at Batavia on the 27th of September 1745. The premature death of this illustrious traveller is the more to be lamented because his vast knowledge died with him. Two English missions sent by Warren Hastings to Tibet, one led by Mr George Bogle in 1774, and the other by Captain Turner in 1783, completes the list of Tibetan explorers in the 18th century. From Persia much new information was supplied by Chardin, Tavernier, Hamilton, Thevenot, and Krusinski, and by English traders on the Caspian. In 1738 John Elton traded between Astrakhan and the Persian port of Enzelî on the Caspian, and undertook to build a fleet for Nadir Shah. Another English merchant, named Jonas Hanway, arrived at Astrabad from Russia, and travelled to the camp of Nadir at Kazvîn. One lasting and valuable result of Hanway's wanderings was a most charming book of travels. The extension of the dominions of the Company largely increased the knowledge of India. In 1700 Guillaume Delisle, the principal creator of the modern system of geography, published his map of the continents of the Old World; and his successor D'Anville produced his map of India in 1752. D'Anville's map contained all that was then known, but ten years afterwards Major Rennell commenced his surveying labours, which extended over a period from 1763 to 1782. His survey covered an area 900 miles long by 300 wide, from the eastern confines of Bengal to Agra, and from the Himálayas to Calpi. Rennell was indefatigable in collecting geographical information; his Bengal atlas appeared in 1781, his famous map of India in 1788, and the memoir in 1792. Surveys were also made along the Indian coasts, and the charts of Huddert, Ritchie, and M'Cluer were the forerunners of the more accurate and elaborate productions of the succeeding century.

Arabia received very careful attention, in the 18th century, from the Danish scientific mission, which included Carsten Niebuhr among its members. Niebuhr landed at Loheia, on the coast of Yemen, in December 1762, and went by land to Sana. All the other members of the mission died, and he proceeded from Mocha to Bombay. He then made a journey through Persia and Syria to Constantinople, returning to Copenhagen in 1767. His invaluable work, the *Description of Arabia*, was published in 1772, and was followed in 1774–78 by two volumes of travels in Asia. The great traveller survived until 1815, when he died at the age of eighty-two. James Bruce of Kinnaird, the contemporary of Niebuhr, was equally devoted to Eastern travel. After studying Arabic and Geez for some years, he went out as consul to Algiers, and resided there from 1762 to 1765, exploring and sketching the Roman ruins in Algiers and Tunis. In 1765 he travelled by land from Tunis to Tripoli, and then took a passage for Candia, but was shipwrecked near Bengazi, and had to swim on shore. He eventually reached Candia, and, sailing thence to Sidon, travelled through Syria. In June 1768 he landed at Alexandria in the dress of an Arab, and soon afterwards we hear of him at Jiddah, the port of Mecca, in the dress of a Turkish sailor. He had resolved to attempt the discovery of the source of the Nile; and in 1769 he landed at Massowah, on the Abyssinian coast. He then penetrated to Axum and Gondar, and in November 1770 he reached the source of the Abai, then supposed to be the main stream of the Nile. He thus attained the great object of his ambition. Returning by the desert into Egypt, Bruce reached England in 1774, and settled once more at his old home at Kinnaird after an absence of ten years. Urged by his old friend, Mr Daines Barrington, the great traveller at length published his *Travels to Discover the Source of the Nile in the Years* 1768–73 (5 vols. 4to) in 1790. Bruce, like many other conscientious and deserving explorers, was assailed by calumny and detraction. But every succeeding year has added to the high estimation in which his labours are held, and to the reverence with which his memory is cherished. He died at Kinnaird House, Stirlingshire in 1794.

Before the death of Bruce an African Association was formed, in 1788, for collecting information respecting the interior of that continent, with Major Rennell and Sir Joseph Banks as leading members, and Bryan Edwards as secretary. The association first employed a Mr Ledyard to cross Africa from east to west on the parallel of the Niger, and Mr Lucas to cross the Sahara to Fezzan. Ledyard, who had previously made a most extraordinary journey into Siberia, died at Cairo in 1788. Lucas went from Tripoli to Mesurata, obtained some information respecting Fezzan, and returned in 1789. One of the chief problems the Association wished to solve was that of the existence and course of the river Niger, which Maxwell believed to be identical with the Congo. Mungo Park, then an assistant surgeon of an Indiaman, volunteered his services, which were accepted by the Association, and in 1795 he arrived at the English factory of Pisania, 200 miles up the Gambia. Leaving this station in December he reached Ludamar, where a Moorish chief imprisoned him until the following July. He then crossed a mountainous tract to a Mandingo town called Kamalia. Quite destitute, and suffering from fever, he remained there for several months, but finally found his way back to Pisania, and returned to England. The interesting narrative of his adventures, with a goographical memoir by Rennell, was published in 1799. Five years afterwards he accepted an offer from the Government to command an expedition into the interior of Africa, the plan being to cross from the Gambia to the Niger, and descend the latter river to the sea. Park left the factory of Pisania, on the Gambia, on the 4th of May 1805, accompanied by Lieutenant Martyn and 35 soldiers, besides guides. All died but four during the rainy season, and the rest, including Mungo Park, perished in a rapid on the Niger, having been attacked from the shore by order of a chief who thought he had not received suitable presents. Park was only thirty-five at the time of his death. The details respecting the fate of the ill-fated explorer and his party were obtained from the guide.

While the English were at work in the direction of the Niger, the Portuguese were not unmindful of their old exploring fame. In 1798 Dr Lacerda, an accomplished astronomer, was appointed to command a scientific expedition of discovery to the north of the Zambesi. He started in July, crossed the Muchenja Mountains, and reached the capital of the Cazembe, where he died of fever. Dr Lacerda left a valuable record of his adventurous journey; but with Mungo Park and Lacerda the history of African exploration in the 18th century closes.

In South America scientific exploration was busily at work during this period. The great event of the century, as regards that continent, was the measurement of an arc of the meridian. The undertaking was proposed by the French Academy, and a commission left Paris in 1735, consisting of La Condamine, Bouguer, and Godin. Spain appointed two accomplished naval officers, the brothers Ulloa, as coadjutors. The operations were carried on during eight years on a plain to the south of Quito; and, in addition to his memoir on this memorable and most important measurement, La Condamine collected much valuable geographical information during a voyage down the Amazon. The arc measured was 3° 7′ 3″ in length; and the work consisted of two measured bases connected by a series of triangles, one north and the other south of the equator, on the meridian of Quito. Contemporaneously, in 1738, M. Maupertuis of St Malo measured an arc of the meridian in Lapland. Another result of this expedition was the publication of a valuable work by the brothers Ulloa.

The English and French Governments despatched several expeditions of discovery into the Pacific and round the world during the 18th century. They were preceded by those wonderful and romantic voyages of the buccaneers, of such men as Woodes Rogers, Davis, Shelvocke, Clapperton, and Dampier, which can never fail to interest, while they are not without geographical value. The works of Dampier are especially valuable, and the narratives of William Funnell and Lionel Wafer furnished the best accounts then extant of the isthmus of Darien. Dampier's literary ability eventually secured for him a commission in the king's service; and he was sent on a voyage of discovery, during which he explored part of the coasts of Australia and New Guinea, and discovered the strait which bears his name between New Guinea and New Britain, returning in 1701. In 1721 Jacob Roggewein was despatched on a voyage of some importance across the Pacific by the Dutch West India Company, during which he discovered Easter Island on April 6, 1722.

The voyage of Lord Anson to the Pacific in 1740–44 was of a predatory character, and he lost more than half his men from scurvy; while it is not pleasant to reflect that at the very time when the French and Spaniards were measuring an arc of the meridian at Quito, the English under Anson were pillaging along the coast of the Pacific, and burning the town of Payta. But a romantic interest attaches to the wreck of the "Wager," one of Anson's fleet, on a desert island near Chiloe, for it bore fruit in the charming narrative of Byron, which will endure for all time. In 1764 Captain Byron himself was sent on a voyage of discovery round the world, which led immediately after his return, to the despatch of another to complete his work, under the command of Captain Wallis.

The expedition, consisting of the "Dolphin" commanded by Captain Wallis, and the "Swallow" under Captain Carteret, sailed in September 1766, but the ships were separated on entering the Pacific from the Straits of Magellan. Wallis discovered Tahiti on June 19, 1767, of which island he gave a detailed account, and Sir Charles Saunders's Island; he returned to England on May 17, 1768. Carteret discovered the Charlotte and Gloucester Islands, and Pitcairn Island on July 2, 1767; revisited the Santa Cruz group, which was discovered by Mendaña and Quiros; and discovered the strait separating New Britain from New Ireland. He reached Spithead again on February 20, 1769. Wallis and Carteret were followed very closely by the French expedition of Bougainville, which sailed from Nantes in November 1766. Bougainville had first to perform to him the unpleasant task of delivering up the Falkland Islands (Malouines), where he had encouraged the formation of a French settlement, to the Spaniards. He then entered the Pacific, and reached Tahiti on April 2, 1768. Passing through the New Hebrides group he touched at Batavia, and arrived at St Malo after an absence of two years and four months.

The three voyages of Cook form an era in the history of geographical discovery. All his work was thoroughly and completely done. He systematically surveyed every land he discovered, collecting information touching every branch of inquiry, so that his labours form a very large addition to geographical knowledge. James Cook was born near Whitby, Yorkshire, in 1728, and had been marine surveyor of Newfoundland and Labrador from 1763 to 1767. In the latter year he commissioned the "Endeavour" and sailed for Tahiti, with the object of observing the transit of Venus, accompanied by Sir Joseph Banks and Dr Solander, a pupil of Linnæus. The transit was observed at Tahiti on June 3, 1769. After exploring Tahiti and the Society group, Cook was six months surveying the two islands of New Zealand, and the coast of New South Wales from latitude 38° S. to the northern extremity. Passing through Torres Strait, he touched at Batavia, and arrived in England on June 12, 1771.

Cook's second voyage was mainly intended to explore the region round the Antarctic Circle; and it may be mentioned that meanwhile a French ship, commanded by M. Kerguelen, had sailed southwards in 1771, and discovered the island which bears his name. Captain Cook was provided with two vessels built at Whitby, the "Resolution," which he himself commanded, and the "Adventure" under Captain Furneaux, who had been with Wallis. After rounding the Cape the two vessels reached a south latitude of 57° 15′ On March 26, 1773, Captain Cook arrived at New Zealand and proceeded to the Society Islands, whence he made another voyage southwards between the meridians of 170° E. and 106° 54′ W. On this occasion he was stopped by ice in 71° 10′ S. During the second voyage Cook visited Easter Island, discovered several islands of the New Hebrides and New Caledonia; and on his way home by Cape Horn, in March 1774, he discovered the Sandwich Island group. Arrived at Spithead on July 30, 1774. The account of the second voyage was written by the young naturalist George Forster, whose subsequent work was so justly eulogized by Humboldt. The third voyage was intended to attempt the passage from the Pacific to the Atlantic by the north-east. The "Resolution" and "Discovery" sailed in 1776, and Cook again took the route by the Cape of Good Hope. In 1777 he was at the Friendly group, and on January 18, 1778, he discovered the Sandwich Islands. He then proceeded to the North American coast, and, after a stay of a month in Nootka Sound, he proceeded northwards, fixed the position of the western extremity of America, and surveyed Behring Strait. On August 17, 1778, he was stopped by the ice in 70° 41′ N., and named the farthest visible point on the American shore Icy Cape. He then visited the Asiatic shore and discovered Cape North, bearing up on August 29 when he was in the 180th degree of longitude. Returning to the Sandwich Islands, Captain Cook was murdered by the natives of Hawaii. On February 14, 1779, his second, Captain Clerke, took the command, and proceeding to Petropaulowski in the following summer, he again examined the edge of the ice, but only got to 70° 33′ N. The ships returned to England in October 1780.

In 1785 the French Government fitted out a very carefully-prepared expedition of discovery at Brest, which was placed under the command of La Perouse, an accomplished and experienced officer. After touching at Concepcion in Chili, and at Easter Island, La Perouse proceeded to the Sandwich Islands, and thence to the coast of California, of which he has given a very interesting account. He then went across the Pacific to Macao, and in July 1787 he proceeded to explore the Gulf of Tartary and the shores of Saghalien, remaining some time at Castries Bay, so named after the French minister of marine. Thence he went to the Kurile Islands and Kamchatka, and sailed from the far north down a meridian to the Navigator and Friendly Islands. He was in Botany Bay in January 1788; and sailing thence, the explorer, his ship, and crew were never seen again. Their fate was long uncertain. In September 1791 Captain D'Entrecasteaux sailed from Brest with two vessels, to seek for tidings. He visited the New Hebrides, Santa Cruz, New Caledonia, and Salomon Islands, and made careful though rough surveys of the Louisiade Archipelago, islands north of New Britain, and part of New Guinea. D'Entrecasteaux died on board his ship on July 20, 1793, without ascertaining the fate of La Perouse. It was Captain Peter Dillon who at length ascertained, in 1828, that the ships of La Perouse were wrecked on the island of Vanikoro during a hurricane.

The work of Captain Cook bore fruit in many ways. His master, Captain Bligh, was sent in the "Bounty" to convey breadfruit plants from Tahiti to the West Indies. He reached Tahiti in October 1788, and in April 1789 a mutiny broke out, and he, with several officers and men, was thrust into an open boat in mid-ocean. During the remarkable voyage he then made to Timor, Captain Bligh passed amongst the northern islands of the New Hebrides, which he named the Banks Group, and made several running surveys. He reached England in March 1790. The "Pandora," under Captain Edwards, was sent out in search of the "Bounty," and discovered the islands of Cherry and Mitre, east of the Santa Cruz group, but she was eventually lost on a reef in Torres Strait. In 1796–97 Captain Wilson, in the missionary ship "Duff," discovered the Gambier and other islands, and rediscovered the islands known to and seen by Quiros, but since called the Duff Group. Another result of Captain Cook's work was the colonization of Australia. On January 18, 1788, Admiral Phillip and Captain Hunter arrived in Botany Bay in the "Supply" and "Sirius," followed by six transports, and established a colony at Port Jackson. Surveys were then undertaken in several directions. In 1795 and 1796 M. Flinders and G. Bass were engaged on exploring work in a small boat called the "Tom Thumb." In 1797 Bass, who had been a surgeon, made an expedition southwards, continued the work of Cook from Ram Head, and explored the strait which bears his name, and in 1798 he and Flinders were surveying the east coast of Van Diemen's Land. The planting of a colony at Port Jackson led to the despatch of an expedition to complete the exploration of the Australian coasts. The command was given to Captain Matthew Flinders. He was furnished with a vessel called the "Investigator," and sailed from England on July 18, 1801. Commencing from King George's Sound, Captain Flinders discovered and made a preliminary survey of all the south coast of Australia to Bass Strait, and the east coast from the barrier reef to Torres Strait, as well as the east coast of the Gulf of Carpentaria. Flinders met the French expedition under Baudin and Freycinet with the two ships "Géographe" and "Naturaliste," which was engaged upon the same work. He was taken prisoner by the French in 1804 and detained until 1810, so that his work did not appear before 1814.

Yet another out-come of Captain Cook's work was the voyage of George Vancouver, who had served as a midshipman in Cook's second and third voyages. The Spaniards under Quadra had commenced a survey of north-western America and occupied Nootka Sound, which their Government eventually agreed to surrender. Captain Vancouver was sent out to receive the cession, and to survey the coast from Cape Mendocino northwards. He commanded the old "Discovery," and was at work during the seasons of 1792, 1793, and 1794, wintering at the Sandwich Islands. Returning home in 1795, he completed his narrative and very valuable series of charts, and died in 1798.

Vancouver.

The 18th century saw the Arctic coast of North America reached at two points, as well as the first scientific attempt to reach the North Pole. The Hudson's Bay Company had been incorporated in 1670, and its servants soon extended their operations over a wide area to the north and west of Canada. In 1741 Captain Christopher Middleton was ordered to solve the question of a passage from Hudson's Bay to the westward. Leaving Fort Churchill in July 1742 he stood northwards and discovered the Wager River and Repulse Bay, bearing up again on August 9. He was followed by Captain W. Moor in 1746, and Captain Coats in 1751, who examined the Wager Inlet up to the end. On November 6, 1769, Samuel Hearne was sent by the Hudson's Bay Company to discover the sea on the north side of America, but was obliged to return. On February 23, 1770, he set out again from Fort Prince of Wales; but, after great hardships, he was again forced to return to the fort. He started once more on December 7,1771, and at length reached the Coppermine River, which he surveyed to its mouth, but his observations are very unreliable. With the same object of reaching the sea, Alexander Mackenzie, with a party of Canadians, set out from Fort Chepewyan on June 3, 1789, and descended a river which bears the explorer's name. His account of the journey is even more unsatisfactory than that of Hearne.

Hudson's Bay Company.

In February 1773 the Royal Society submitted a proposal to the king for an expedition to try how far navigation was possible towards the Pole. The "Racehorse" and "Carcass" bombs were selected as best adapted for the service, and Captains Phipps and Lutwidge were appointed to command them. The expedition sailed on June 2, 1773, and sighted the coast of Spitzbergen on the 28th. Captain Phipps stood into every opening he could find in the ice, but was invariably stopped by a solid barrier. He examined a line extending over twenty degrees of longitude, and found no opening in the heavy polar pack in any direction. After a very careful and persevering examination of the ice, the expedition returned to England in September. The highest latitude reached was 80° 48′ N. But the most important Arctic work in the 18th century was performed by the Russians, for they succeeded in delineating the whole of the northern coast of Siberia. Some of this work, indeed, was done at a still earlier date. The Cossack Deschneff made an extraordinary voyage, in the summer of 1648, from the river Kolyma, through Behring Strait to Anadyr, a performance which has never since been equalled. Between 1738 and 1750 the mates Manin and Sterlegoff made their way in small sloops from the mouth of the Yenisei as far north as 75° 15′ N. The land from Taimyr to Cape Chelyuskin, the most northern extremity of Siberia, was mapped by the mate Chelyuskin, who discovered the extreme point in May 1742. To the east of Cape Chelyuskin the Russians encountered greater difficulties. They built small vessels at Yakutsk on the Lena, 900 miles from its mouth, whence the first expedition was despatched under Lieutenant Prontschicbeff in 1735. He sailed from the mouth of the Lena to the mouth of the Olonek; where he wintered, and on September 1, 1736, he got as far as 77° 29′ N., within five miles of Cape Chelyuskin, which is in 77° 34′ N. Both he and his young wife died of scurvy, and the vessel returned. A second expedition, under Lieutenant Laptieff, started from the Lena in 1739, but encountered masses of drift ice in Chatanga bay, and with this ended the voyages to the westward of the Lena. Several attempts were also made to navigate the sea from the Lena to the Kolyma. In 1736 Lieutenant Laptieff sailed, but was stopped by the drift ice in August, and in 1739, during another trial, he reached the mouth of the Indigirka, where he wintered. In the season of 1740 he continued his voyage to beyond the Kolyma, wintering at Nijni Kolymsk. In 1725 Vitus Behring, a Dane in the Russian service, received his instructions from Peter the Great a few days before the czar's death. Two vessels were built for Behring at Okhotsk, and sailing in July 1728, he ascertained the existence of the strait between Asia and America which bears his name. In September 1740 Behring again sailed from Okhotsk, with Steller on board as naturalist. In June 1741 Commodore Behring named the magnificent peak on the coast of North America Mount St Elias, and explored the Aleutian Islands. In November the ship was wrecked on Behring Island; and the gallant Dane, worn out with scurvy, died there on the 8th of December 1741. In March 1770 a merchant named Liakhoff saw a large herd of reindeer coming from the north to the Siberian coast, which induced him to start in a sledge in the direction whence they came. Thus the New Siberian Islands were discovered, and for years afterwards the seekers for fossil ivory resorted to them. The Russian Captain Vassili Tchitschakoff in 1765 and 1766 made two persevering attempts to penetrate the ice north of Spitzbergen, and reached to 80° 30′ N., and Russian parties twice wintered at Bell Sound. But the result was the same as all others have obtained before and since; the Spitzbergen route is evidently not the way to the Pole.

The 18th century saw great progress in the collection and arrangement of geographical material, and in the work of surveying and map-making. Collections of voyages and travels were brought together in the four quarto volumes of Astley (1745) and the two folios of Harris (1764); while Dr Hawkesworth edited the Government voyages to the Pacific in 1773. Sir Joseph Banks was the great patron of geography in England, aided by the indefatigable labours of such critical geographers as Rennell, Dalrymple, and Barrington; while in France the great cartographer D'Anville introduced a habit of critical accuracy, and caused a complete revolution in the art of map-making.

Towards the close of the century it was recognized that geography served more extensive and important uses than had ever before been supposed. The route survey was sufficient for the traveller or soldier, while accurate charts guided the mariner across the ocean. But surveys are also the basis of statistics and of administration, and rigorous accuracy became necessary. Surveys on a trigonometrical basis, which have been proceeding in all the countries in Europe (except Turkey) and in India during the present, were commenced in the last century. In Great Britain the Ordnance Survey was begun in April 1784, when General Roy measured a base line on Hounslow Heath. The triangulation of the British Isles was commenced in 1784 and completed in 1852. Maps based on trigonometrical surveys may eventually explain and illustrate the physical aspect of the whole globe, but at present they are necessarily confined to those nations which are in the front rank of civilization. Countries which are not so advanced are still obliged to be content with such maps as sufficed for all the world in the last century, before the results of trigonometrical surveys were available. These secondary maps are adapted for the requirements of the countries which use them, being based on positions fixed by astronomical observations, on cross bearings, and often on chained distances. The third class of maps includes the work of explorers of unknown or little known regions, and of geographers who delineate the features of such regions by compilation and by intelligent collation of the work of travellers. There are thus three grand divisions in the character and uses of maps. There are first those which aim at minute accuracy, and which are intended as documents for administrative purposes, and in pursuing exact statistical investigations. Secondly, there are maps which are based on less accurate surveys of countries less populous or less advanced in civilization; these are useful for political, geographical, and military purposes, but are not to be relied on to the same extent or in the same way as is the case with those based on trigonometrical surveys. Thirdly, there are the roughly compiled maps of little known regions, which are constantly in course of improvement, and which do the work of pioneers.

In treating here of the progress of geographical discovery in the present century, it is to those who prepare the last class of maps, to the pioneers—the discoverers—that we must mainly, though not exclusively, confine our attention. We propose to review the work of discoverers and explorers of the 19th century in two sections as regards time,—first during the first thirty, and secondly during the last forty-eight years. The Royal Geographical Society was founded in 1830, and forms a landmark. In each period we shall take first the work done in Asia, then Africa, then America, then Australia, then Polynesia, and finally the Arctic and Antarctic regions.

At the beginning of the century British rule in India was extended over the plains of the Ganges almost to the Sutlej, and the attention of explorers was drawn to the mighty mass of the Himálayas. Captain Herbert, in 1818, attempted to give a general view of the physical character of this great range, and Moorcroft reached the Mansarowa lake, and the upper courses of the Indus and Sutlej; while Mr Manning, in 1811, was the only Englishman who ever visited Lassa, the capital of Tibet. The mission of Sir John Malcolm to Persia in 1808 led to much geographical work being achieved. On his staff was Macdonald Kinneir, who wrote a valuable memoir on the geography of Persia; while at the same time Lieutenant J. Macartney, under Mountstuart Elphinstone, was collecting materials for a map of Afghanistan. In 1810 Pottinger and Christie made an important journey through Baluchistan by different routes, Christie afterwards visiting Herat and Yezd; and in 1827 Mr Stirling of the Bengal Civil Service crossed the Hazárah mountains.

The close of the war in 1815 led to numerous efforts for the furtherance of geographical discovery, especially in Africa and the far north. In 1818 to 1820 Captain Lyon, R.N., and Mr Ritchie landed at Tripoli, and penetrated as far as Mourzouk; and this led to the more important expedition of Major Denham and Captain Clapperton, R.N., which was despatched by the Government. They landed at Tripoli in 1823, and advanced into the interior as far as the east coast of Lake Tchad, of which they gave a most interesting account, obtaining latitudes by meridian altitudes and longitudes by lunar observations. Clapperton's furthest point was at Saccatoo, westward of the lake, and here he was forced to turn back. But in 1825 he was again employed to explore the interior of Africa, and this time he started from the Atlantic side with his faithful servant Richard Lander. Landing in the Bight of Benin, he succeeded in reaching Saccatoo from the west side, thus completing a route from Tripoli on the Mediterranean to the coast of Guinea. But at Saccatoo the gallant sailor succumbed at last, dying on the 13th of April 1827. His faithful servant Lander returned to the coast; and in 1830 he and his brother were employed to explore the course of the Niger or Quorra. They embarked on the river near Boossa, passed through the Yorriba country, and came out at the mouth of the Nun.

The Admiralty also considered that a river of such magnitude as the Zaire or Congo ought to be explored. Captain Tuckey, R.N., was selected to conduct the Congo expedition, and received command of a steamer called the "Congo," with a crew of 49 officers and men. The expedition reached the mouth of the great river on July 5, 1816, and proceeded up to the foot of the falls of Yellala, the farthest point hitherto reached. Captain Tuckey, with 15 of his party, landed on the north shore on the 14th of August; and, after travelling for about 40 miles over a hilly country, he reached the head of the falls and the banks of the upper river. He had explored the river for a distance of 280 miles from the sea. But death overtook the commander of the expedition and several officers, and the "Congo" returned in command of the master, Mr Fitzmaurice, after executing the survey from the foot of the falls to Embomma.

South America had produced two eminent physical geographers, namely, Caldas of Bogota and Unanue of Lima, before the scenery of the Orinoco and the Andes became familiar to Europe through the charming narratives of Humboldt. It was in 1799 that the great Prussian naturalist embarked at Coruña, and landed at Cumana on the coast of Venezuela. His observant eye and bright imagination, combined with habits of scientific thought, produced pictures of the physical aspects of the regions he explored which are quite unequalled. What he said of George Forster is even more true of himself: "He depicted in pleasing colours the changing stages of vegetation, the relations of climate and articles of food in their influence on the civilization of mankind. All that can give truth, individuality, and distinctiveness to the delineation of exotic nature is united in his work." The Orinoco and Cassiquiari, the falls of Tequendama, the mountains of Quindiu, Chimborazo, and Quito, Cajamarca, and the upper Amazon, and the varied scenery of Mexico, are imprinted on the imagination with life-like form and colouring by this great master of description. His service to geography was far greater than that of any mere discoverer. Humboldt left the New World in 1804.

The greatest and most important enterprise, after the peace of 1815, was the renewal of Arctic exploration under the auspices of Sir John Barrow. To the great work of Scoresby, and to the careful observations of himself and his father, we are indebted for the most exhaustive account of the Spitzbergen seas, and of the ice which encumbers them. When the Government expeditions were undertaken, the volumes of Scoresby formed a storehouse of useful and well-digested information. The true object of modern Arctic enterprise has been the advancement of science, a noble and sufficient reason for incurring expenditure and facing dangers and hardships. In consequence of Sir John Barrow's representations, orders were given in 1818 for the preparation of four vessels for Arctic service,—two to attempt the passage from the Atlantic to the Pacific, and two to attempt an approach to the North Pole. But, as Sir John Barrow himself explained, the main objects were not the accomplishment of voyages by these routes, but the acquisition of useful knowledge. Sir John Ross, who commanded one of the two expeditions, circumnavigated Baffin's Bay on the track of that great navigator, and re-established his fame. Captain Buchan, who led the other, battled with the impenetrable pack to the north of Spitzbergen, like Phipps before him, and then returned. There can be no great success without continuity of effort and perseverance, and the early voyages of this century achieved lasting results, because those who sent them out were endowed with tenacity of purpose. No sooner had Ross returned than Parry was appointed to command two strongly built vessels, the "Hecla" and "Griper," and to proceed on the same service. On the 11th of May 1819 Parry sailed, and on the 1st of August he entered the portals of Lancaster Sound, and commenced the discovery of a new region. He succeeded in sailing for 300 miles along the southern shores of the islands which now bear his name, among ice floes of moderate thickness, until he reached the edge of the impenetrable polar pack at the western extreme of Melville Island. He went as far as it will ever be possible for any vessel to go in this direction, and then wintered in a harbour of Melville Island. In 1820 he returned with a rich harvest of scientific observations, and of valuable information in all branches of inquiry. This first expedition was most successful. Parry's second voyage was into Hudson's Bay in search of a passage westward in that direction. He discovered a strait (that of "Fury and Hecla"), and passed two winters 1821–23 on the coast of Melville Peninsula. The third voyage (1824–25) was again up Baffin's Bay; but it was unsuccessful, and one of his vessels, the "Fury," was lost. Still every voyage, whether successful or not in its main object, brought back valuable results. Meanwhile the "Griper," commanded by Captain Clavering, had, in 1823, penetrated through the ice to the east coast of Greenland in 76° N., to enable Captain Sabine to take pendulum observations in that position. The Russian Captain Lutke had also surveyed the west coast of Novaya Zemlya from 1821 to 1824. Parry, after his return from the third voyage, proposed an attempt to reach the Pole by travelling over the ice during the summer, on the Spitzbergen meridians. He sailed on this service in the "Hecla" on the 3d of April 1827, and, after placing her in a secure harbour in Spitzbergen, he began his bold and interesting attempt with two boats, fitted with runners for being dragged over the ice. But the whole mass of ice was drifting south faster than Parry's men, with all their efforts, could advance north. However, on July 23, 1827, he attained the latitude of 82° 45′ N., which continued to be the highest parallel ever reached by man until Captain Markham went beyond it in 1875. Parry returned to England in October. Another expedition of a private character left England in June 1829 under the command of Sir John Ross, who was accompanied by his distinguished nephew James C. Ross. In August they reached Lancaster Sound, and then proceeded southwards down Regent's Inlet, wintering on the most northern peninsula of America, to which Ross gave the name of Boothia. Here they passed three winters, while, during the intervening summers, some exploring work was accomplished, and James Ross planted the Union Jack on the North Magnetic Pole on the 1st of June 1831. At last they were forced to abandon their little vessel the "Victory," and make their way to the whalers in Baffin's Bay in open boats. They were picked up and arrived in England after an absence of four years.

While these bold and perilous voyages were being conducted in the Arctic seas, a series of land journeys completed the delineation of the northern coast of America, which had just been touched at two points in the last century, by Hearne and Mackenzie. From 1819 to 1823 the gallant Sir John Franklin, with Dr Richardson and George Back, were struggling to explore the Arctic coast eastward from the mouth of the Coppermine River. After great sufferings they embarked on the river on June 30, 1820, reaching the mouth on July 18, and exploring 550 miles of coast line to the eastward, as far as Point Turnagain. On the return journey across the barren lands, the party escaped death from starvation almost by a miracle. Undaunted by this terrible experience, Franklin, Richardson, and Back started on another expedition in 1825, this time by descending the Mackenzie River. Reaching its mouth on July 7, Franklin and Back discovered 374 miles of coast to the westward, as far as Return Reef; while Richardson explored the space between the mouths of the Mackenzie and Coppermine. In 1833 Back undertook a third journey with the object of succouring the Rosses, who had long been missing. He discovered and explored the Back or Great Fish River for 530 miles, and in July 1834 reached its mouth in the Arctic Ocean. The gaps on the north coast, which were left by Franklin and Back, were subsequently filled in by servants of the Hudson's Bay Company. In 1837 Messrs Simpson and Dease, in a boat, connected Return Reef with Cape Barrow. In 1839 the same explorers went from Cape Turnagain to the mouth of Back's River, and still further eastward to Castor and Pollux River. On August 26, 1839, Simpson built a cairn at Cape Herschel, on King William Island, separated by a strait ten miles wide from the mainland. Dr Rae was sent in 1846 to winter in Repulse Bay, and in 1847 he travelled round the Gulf of Akkoolee and connected the work of Ross in Boothia with that of Parry during his second voyage. In 1854 he united the work of Ross with that of Simpson, and ascertained that Boothia was connected with the mainland of America by an isthmus. Thus the whole northern coast of America was explored and delineated without a break.

The Russians were engaged on daring Arctic exploration at the same time. In 1809 to 1812 a Russian officer named Hedenstrom surveyed the New Siberia Islands; and in 1821 Lieutenant Anjou made further investigations respecting the state of the ice to the northward. Baron Wrangell prosecuted similar researches from his headquarters at Nijni Kolymsk, near the mouth of the Kolyma. He made four sledge journeys over the Polar Sea from 1820 to 1823, exploring the coast from the Kolyma to Cape Chelagskoi, and making several attempts to advance northwards, but always encountering weak ice. Wrangell's interesting narrative is an important addition to Arctic literature.

The Russians, as well as the French, sent several voyages into the Pacific during the first half of the 19th century. In 1804 Admiral Krusenstern made a voyage round the world, and his pupil, Otto von Kotzebue, son of the dramatist, commanded the "Rurick" from 1815 to 1818 on a voyage of discovery. He discovered the great bay known as Kotzebue Sound, sounded in Behring Strait, and made careful observations of the currents. Wintering in California he returned to the Aleutian Islands in the following spring; and during the voyage homewards he discovered several new islands in the Pacific, especially Romanzoff and Krusenstern in the Dangerous Archipelago. During another Russian voyage, commanded by Billinghausen, Lazareff and other coral islands in the Dangerous Archipelago were discovered, and in 1828 Captain Lutke, in the "Seniavine," surveyed the Caroline group. Captain Freycinet, the officer who served with Baudin and edited his work, also examined the Caroline Islands in the "Uranie" in 1819, but his voyage was mainly in the interests of natural history. Duperry in 1822–23 did some surveying work on the coast of New Ireland. But the most important French voyage was that of Dumont D'Urville, who was sent out to seek for traces of La Perouse in 1828. He visited Tecopia and other islands in the "Astrolabe," and was nearly a month at Vanikoro collecting relics of the ill-fated expedition. The voyage of D'Urville contributed largely to the advancement of science, and resulted in the publication of a magnificent work in 1830.

The only English scientific voyage to the Pacific in this period was sent out mainly to co-operate with Parry in his third voyage, and Franklin in his second journey. It was commanded by Captain Beechey, who had been first lieutenant with Parry during his first Arctic voyage, and on May 19, 1825, he sailed from Spithead in H.M.S. "Blossom." After visiting Easter, Gambier, Pitcairn, and other islands, the "Blossom" arrived at Honolulu on May 20, 1826, and in July she was in Behring Strait, entering Kotzebue Sound on the 22d. Proceeding along the north coast of America, the ship's barge got as far as 156° 21′ W. to a low cape called Point Barrow, at the very time when Franklin and Back were at Return Reef. The accurate examination of the coast was made under circumstances which demanded great fortitude and perseverance, and reflects credit on the officers and crew. The "Blossom" returned to Honolulu in January 1827, and arrived at Macao on the 12th of April. Captain Beechey next proceeded to survey the Loo Choo and Bonin Islands, and, after another visit to the far north, and the coasts of California and Mexico, he returned home by Cape Horn and arrived at Woolwich on October 12, 1828. His valuable and interesting narrative, in two volumes, was published in 1831. Mr James Weddell, a master in the navy, made a voyage to the Antarctic Ocean in 1822–24, and went as far south as 74°.

The Royal Geographical Society was founded in 1830, and forms a landmark in the history of discovery. The men who initiated the idea and gave it shape were Sir John Barrow, Sir John Cam Hobhouse, Sir Roderick Murchison, Mr Robert Brown (*Princeps Botanicorum*), and Mr Bartle Frere. They formed the Foundation Committee. The first president was Lord Goderich, and the vice-presidents Sir John Barrow, Colonel Leake, Sir John Franklin, and Mr Greenough. Through this organization explorers and students were encouraged and assisted, information was systematically collected and arranged, and the work of discovery was advanced. A similar society in Paris preceded that of London in point of time, and now every civilized country has established a Geographical Society.

Our rapid review of the progress of discovery since the foundation of the Geographical Society will commence with the continent of Asia, where there were and still are vast and most interesting unexplored regions. In British India the Trigonometrical Survey has been proceeded with, and is now approaching completion. During its progress the Himálayan peaks were measured, and in 1848 Sir Andrew Waugh fixed the height of the loftiest, which he named Mount Everest, at 29,002 feet above the sea. In 1831 Humboldt published his *Asie Centrale*, which, with the *Erdkunde von Asien* of Carl Ritter, gave new and clearer ideas of the orography of Central Asia. Many travellers explored the remoter parts of the Himálayan chain; while, in 1848, Dr Hooker in Sikkim, and Dr Thomson in Ladak, reached the summits of the passes leading to Tibet and Yarkand. Our relations with Afghanistan led to further exploration. In 1840 Lieutenants Abbott, Conolly, and Shakespear visited Khiva, and in 1841 Colonels Stoddart and Conolly were murdered at Bokhara, while Eldred Pottinger gallantly defended Herat. Sir Alexander Burnes had previously made his remarkable journey from Cabul to Bokhara and back through Persia, and in 1838 Lieutenant Wood of the Indian Navy discovered the source of the Oxus. Butakoff and other Russian officers, in 1848 and subsequent years, surveyed the sea of Aral, and Middendorf made extensive explorations and discoveries in Siberia. After the Afghan war it was long before any progress was made in the exploration of Central Asia, but through the opening of the treaty ports in China and the navigation of the Yangtsze a considerable increase was made in our knowledge of the Celestial Empire. In 1869 Mr R. B. Shaw and Mr Haywood reached the cities of Yarkand and Kashgar, and Mr Shaw published a most graphic account of the physical aspects of Eastern Turkestan. In the previous year Mr Ney Elias surveyed the Yellow River of China, and afterwards made a journey through a previously unknown portion of western Mongolia; and during 1866–68 the distinguished French geographer Lieutenant Garnier surveyed the course of the great Cambodian river. The Russians, meanwhile, in their advance into Central Asia, had enabled scientific travellers like Fedchenko and others to explore Khokand and the northern part of the Pamir, and the more adventurous Prjewalski made important journeys through Mongolia and to the frontiers of Tibet. Colonels Walker and Montgomerie, of the great Trigonometrical Survey of India, organized a system of training native explorers, who made journeys across the Pamir and to the upper waters of the Oxus, as well as through the previously unknown parts of Tibet. In the last mission of Sir Douglas Forsyth to Kashgar, Captain Trotter of the Trigonometrical Survey of India formed one of the staff. He did much valuable exploring work on the Pamir table-land, and verified the work of Lieutenant Wood at the source of the Oxus. In 1845 MM. Huc and Gabet travelled through Tibet; and in western China the French missionaries have since done useful geographical work. English diplomatic officers have found their way from the south-western provinces of China into Burmah, and Baron Richthofen has made very extensive exploring journeys through the Chinese empire. The most important journey across Arabia in the present century was made by Mr W. Gifford Palgrave in 1863.

frica Geographical discoverers of the 19th century have had a great work to do in Africa. D'Anville and his successors cleared off all that was uncertain on the map, all that had come from the information given by Duarte Lopez to Pigafetta, and from Leo Africanus, and left a great blank. James Bruce and Mungo Park, Clapperton and Tuckey, merely touched the edges or penetrated in single lines across the vast unknown area. But they have been followed by many others, and now great progress has been made. In 1831 Monteiro and Gamitta were sent by the Portuguese Government, in the footsteps of La Cerda, to the capital of Cazembe; while, in 1849 and 1843–47, Ladislaus Magyar and Graça explored some of the southern affluents of the Congo. Rüppell (1838), Harris (1843), and Dr Beke (1840), Lefebvre and Dillon (1839–43), Ferret and Galinier (1847) improved the existing knowledge of Abyssinia, to which a further important contribution was made by the expeditionary field force sent in 1867–68 to enforce the release of English captives; and progress was made, under the auspices of the Egyptian Government, in exploring the White Nile above Khartoum. In 1849 the discoveries of Denham and Clapperton were followed up by Richardson, Overweg, and Barth, who, like their predecessors, went from Tripoli to Mourzouk, the capital of Fezzan. The two first died in Africa, but Dr Barth returned home with a rich harvest of results. He reached Kouka the capital of Bornou, on Lake Tchad, and in 1851 he visited the south side of that lake, and advanced some distance to the eastward. In 1852 he was at Saccatoo, where Clapperton died, whence he crossed the Niger and eventually reached Timbuctoo. After a stay of some months Dr Barth left Timbuctoo in March 1854, and got back to Tripoli in the end of 1855, being the sole survivor of his party. Dr Vogel, in 1853–57, followed up the discoveries in the direction of Lake Tchad, and fell a victim to science; and the researches of Dr Baikie in 1854 supplemented the work of the Landers in the lower part of the course of the Niger. Dr Baikie also explored 250 miles of the river Chadda or Benue.

On the eastern coast of Africa, the missionaries Rebmann and Krapf ascertained the existence of the snowy peaks of Kenia and Kilimanjaro near the equator, and collected reports touching the equatorial lakes in the interior. This led to the expedition of Captain Burton in 1857, who, accompanied by Captain Speke, landed opposite to Zanzibar, and, advancing westward, discovered Lake Tanganyika. Captain Burton's admirable description of the region between the coast and the great lake he had discovered is one of the most valuable contributions to African descriptive geography. His companion, Captain Speke, made an excursion northwards to the southern coast of a lake which he judged to be a main source of the Nile. In this belief he again set out in 1860 to attempt the achievement of a journey from Bagamoyo, opposite Zanzibar, to the Nile. This great enterprise was crowned with success. Speke traced out the western shore, and visited the northern outlet, of the Victoria Nyanza, the main reservoir of the White Nile. He then marched northwards to Gondokoro and descended the Nile. He had heard of a second great Nile reservoir, which Sir Samuel Baker discovered in 1864, and named the Albert Nyanza. The Bahr el Ghazal and other western feeders of the Nile were visited by Consul Petherick, and explored in 1868–71 by Dr Schweinfurth, whose work ranks with that of Burton as a record of African discovery.

The travels of Dr Livingstone in Southern Africa also added considerably to our knowledge of the geography of that continent. In 1848 he started from Cape Colony, visited Lake Ngami in 1849, and eventually reached the Portuguese town of St Paul Loanda in 1855. Thence he marched across the continent, discovering the great falls and a considerable part of the course of the Zambesi. In his second expedition he proceeded up the Zambesi and its tributary the Shire, and discovered the Lake Nyassa. On his third and last expedition he landed on the east coast at the mouth of the Rovuma, and made his way thence to Lake Nyassa. The great traveller then followed in the footsteps of Dr Lacerda and Monteiro to the Cazembe's capital, and thence to Lake Tanganyika. From Ujiji, on that lake, he made his way westward to the river Lualaba (the upper course of the Congo), and returning in a destitute condition to Ujiji, he was there succoured by Mr Stanley. Finally he once more started, and died in the midst of his discoveries among the remoter sources of the Congo. Lieutenant Cameron's expedition in 1873 had for its main object the succour of Livingstone, but the news of the great traveller's death was received at Unyanyembe. Cameron then continued his march by a new route to Ujiji, and completed the survey of the southern half of Lake Tanganyika, discovering the Lukuga outlet. Thence he advanced westward across the Manyuema country to Livingstone's furthest point at Nyangwe, crossed the Lualaba, and traversed the whole width of the African continent

Livin stone

reaching St Paul Loanda on the west coast. Mr Stanley followed in 1874. He circumnavigated and fixed the outline of the Victoria Nyanza, followed Cameron across Lake Tanganyika to Nyangwe, and then descended the great River Congo, discovering its course, and connecting the work of Livingstone with that of Tuckey. Mr Young has since completed the survey of Lake Nyassa; Nachtigal has supplemented the work of Barth and Vogel in the Tchad region; while Duveyrier and other French explorers have examined the region of the Sahara. In the far south the Limpopo basin, and the country intervening between the Limpopo and Zambesi, have been made known to us by St Vincent Erskine and Elton, Carl Mauch and Baines. Thus the extent of the unknown parts of Africa has been rapidly curtailed, while our knowledge has been widened during the last half century.

eri- reys. th erica.

On the American continent scientific progress has been made in the United States and the dominion of Canada, where, within the last half century, boundary commissions and surveys have fixed positions and described previously unknown regions of great extent. In South America there are vast unexplored regions to the eastward of the Andes, and in the basins of the great rivers. Sir Robert Schomburgk did much valuable work in Guiana, and explored the delta of the Orinoco in 1841; while Spix and Martius, Poeppig and Castelnau, Maw and Smyth, Herndon and Gibbon, Spruce and Bates, Wallace and Chandless, and others, explored the basin of the Amazon. The labours of Pissis in Chili, of Raimondi and Werthermann in Peru, of Codazzi in Colombia and Venezuela, and of Morales and others in the Argentine Republic, have been most valuable to geographical science. In Patagonia, Fitz Roy and King explored the Santa Cruz river, Cox and Morales have since added to our knowledge, and Commander Musters, R.N., was the first traveller who traversed the whole of Patagonia from south to north, 960 miles of latitude, of which 780 were previously unknown to Europeans.

. a.

The difficulty of exploring the interior of the Australian continent was caused by the scarcity of water, and the immense distances it was necessary to cross without supplies of any kind. Hence the work of exploration has required and called forth high and noble qualities in a degree quite equal to any that have been recorded in any other part of the world. The names of Sturt and Leichhardt, of Eyre and Grey, of Macdouall Stewart and Burke, of Gregory, of Forrest and Warburton, will be handed down as those of intrepid and courageous explorers who laid open the secrets of the interior of Australia.

The Pacific Ocean was explored by numerous expeditions during the 18th and early part of the 19th centuries. Still much remained to be done in the way of verification and more complete survey. From 1826 to 1836 Captain Fitzroy, with the naturalist Darwin, surveyed Magellan's Strait and the west coast of South America; and further important surveys in the Pacific were afterwards executed by Captain Wilkes of the United States Navy, and by Belcher, Kellett, and Denham.

But the great geographical work of the present century must be the extension of discovery in the Arctic and Antarctic regions. Progress has been made in both directions, and in both much remains to be done. It is this polar work which calls forth the highest qualities of an explorer; it is here that the greatest difficulties must be overcome; and it is here that the most valuable scientific results are to be obtained.

Between the years 1830 and 1843 much was done in the Antarctic regions. In 1830–32 Mr John Biscoe, R.N., made a voyage in a brig belonging to Messrs Enderby, and discovered "Enderby Land" and "Graham Land" in 67° S.; and from 1837 to 1840 Dumont d'Urville discovered "La Terre Adèle" and "Coté Clarie," going as far south as 66° 30′. Auckland Island was discovered by Bristow in 1806. In 1839 Balleny, in another vessel belonging to Messrs Enderby, discovered the Balleny Islands in 66° 44′ S., and Sabrina Island in 65° 10′ S. The Antarctic expedition of Sir James Ross sailed from England in 1839. In 1840 Sir James explored Kerguelen Island, and wintered at Hobart Town. He then visited the Auckland Islands, and, crossing the Antarctic Circle, reached the great icy barrier, and discovered Victoria Land, with its lofty volcanoes, in January 1841. He gained the latitude of 78° 4′ S. in 187° E., and established the continuity of the southern continent from 70° to 79° S. In 1841 Ross again wintered at Van Diemen's Land, and in January 1842 crossed the Antarctic circle in 156° 28′ W. He was once more stopped by the great icy barrier in 78° 10′ S., after having penetrated through ice floes of more than 1000 miles in width. Extraordinary dangers were encountered in the ice, many valuable observations were taken, and in 1842 the expedition wintered at the Falkland Islands. In the following season another exploring voyage was made beyond the Antarctic Circle, and in September 1843 this most important expedition returned to England.

On the return of Sir James Ross attention was once more turned to the Arctic regions; and in the spring of 1845 Sir John Franklin's Arctic expedition, consisting of the "Erebus" and "Terror," sailed from Woolwich. His instructions were to make the North-West Passage, but the main object of the expedition was the advancement of science, and to secure it the most accomplished officers in the navy were appointed, as well as the eminent naturalist Dr Goodsir. It is now known that, in the first and second seasons, the expedition was very successful. In 1845 Sir John Franklin made a remarkable run up Wellington Channel to 77° N.; in 1846, proceeding south, he had almost achieved the North-West Passage when his ships were permanently beset to the north of King William Island in 70° 5′ N. and 98° 23′ W. Here the veteran explorer died on June 11, 1847; and all his companions perished in the attempt to reach one of the Hudson's Bay Company's settlements in the summer of 1848. Those among them who reached Cape Herschel, and it is certain that some did reach that point, undoubtedly discovered the North-West Passage.

Franklin.

The expeditions which were sent out in search of Sir John Franklin's ships did much important geographical work; but their principal use was the establishment, through their means, of the true method of extensive Arctic exploration. The grand object of the officers and men employed on this service was the relief of their missing countrymen, and their utmost efforts were devoted to the examination of the largest possible extent of coast-line. Hence the discovery of the modern system of Arctic sledge travelling, the only efficient means of exploring the icy regions around the North Pole. In 1848–49 Sir James Ross discovered the western side of North Somerset, and Sir Leopold M'Clintock served his first apprenticeship in the ice under that veteran explorer. Austin's expedition sailed in 1850, and wintered nearly in the centre of the region discovered by Parry during his first voyage. It was then that M'Clintock developed and put in practice the system of Arctic sledge-travelling which has since achieved such grand results; and Captain Ommanney, M'Clintock, and his colleagues Sherard Osborn, Frederick Mecham, Robert Aldrich, and Vesey Hamilton made what were then unparalleled journeys in various directions. In December 1849, also, Captains Collinson and M'Clure went out to conduct further search by way of Behring Strait. The former made the most remarkable voyage on record along the north coast of America, while M'Clure took his ship between the west coast of Banks Island and the tremendous polar pack, until he was within sight of the position attained by Parry in his first voyage from Baffin's Bay. Here M'Clure's ship was finally iced up in the Bay of God's Mercy. On the return of Austin's expedition, the same ships were again sent out under Captains Belcher and Kellett by Baffin's Bay; and M'Clintock, Osborn, Mecham, and Hamilton, who were once more in the front rank of searchers, surpassed even their former efforts. Mecham discovered a record left by M'Clure on Melville Island which revealed his position, and thus he and his officers and crew, by marching from their abandoned ship to the "Resolute" and returning to England with the expedition of Belcher and Kellett, were enabled to make the North-West Passage partly by ship and partly sledging over the ice. They all returned in 1854. But the concluding search was made by Sir Leopold M'Clintock in the "Fox" from 1857 to 1859, when he found the record on King William Island, and thus discovered the fate of Franklin. These search expeditions added immensely to our knowledge of the Arctic regions, and established the true method of exploration. Sea voyages in the summer season are useful for reconnaissances, but efficient polar work can only be achieved by wintering at a point beyond any previously reached, and sending out extended sledge parties in the spring.

After the return of M'Clintock, England neglected the great work of Arctic exploration for fifteen years; but a deep interest was taken in the discovery of the unknown polar regions by other nations, and numerous efforts to explore them were made in the interval. In 1853–55 Dr Kane, with the American brig "Advance," wintered just within the entrance of Smith Sound, and sent an exploring party for some distance up the east side of the channel; and in 1860–61 Dr Hayes wintered near the same spot, and made a sledge journey up the west side. Ten years afterwards Captain Hall, accompanied by Dr Bessels, a German scientific explorer, sailed in the "Polaris" in August 1871, and succeeded in making his way up the channels leading north from Smith Sound for 250 miles, wintering in 81° 38′ N. Captain Hall unfortunately died in the autumn of 1871, and his comrades returned after suffering great hardships. The "Polaris" was abandoned, but she had attained the highest latitude ever reached by any vessel up to that date. In the direction of Spitzbergen and Novaya Zemlya the Norwegian walrus hunters made many daring voyages. They circumnavigated both those masses of Arctic land, and yearly frequented the hitherto closed Sea of Kara. The Swedes, under the lead of the accomplished and indefatigable Nordenskiöld, have made voyage after voyage to

Spitzbergen explored.

Spitzbergen, and afterwards to the north-east. The first Swedish expedition to Spitzbergen was in 1857, the second in 1861, the third in 1864, the fourth in 1868, consisting of the steamer "Sophia," which reached the highest latitude ever attained by a vessel trying the Spitzbergen route, namely, 81° 42′ N. In 1872 a fifth expedition started, and Nordenskiöld then passed his first winter in the Arctic regions, and gained experience of sledge-travelling in the spring, exploring a large area of North-East Land. Experience also proved that the Spitzbergen route was not one by which large results could be secured, although the scientific researches of the Swedes in Spitzbergen itself were most valuable. In 1875 therefore Professor Nordenskiöld made his first attempt towards the north-east, reaching the mouth of the Yenisei; and in 1876 he made an equally successful voyage in the same direction. The Germans also entered the field of Arctic enterprise. In 1868 Captain Koldewey made a summer voyage to Spitzbergen, and in 1869–70 he went in the "Germania" to the east coast of Greenland, accompanied by Lieutenant Payer, wintered at Pendulum Island, discovered by Clavering in 1823, whence they made a sledge journey to the northward as far as 77°, and explored a deep fjord in about 73° 15′ N. during the navigable season. English yachtsmen, notably Lamont and Leigh Smith, were also in the field; and the latter made important corrections of the charts of North-East Land. But by far the most important and successful voyage in this period was that of Lieutenants Weyprecht and Payer in the Austrian steamer "Tegethoff." Sailing in 1872, they were beset in the ice to the north of Novaya Zemlya during the winter of 1872–73, and were drifted northwards until, on August 31, 1873, they sighted a previously unknown country. It proved to be very extensive, and was named Franz Josef Land. In March 1874 Lieutenant Payer started on an extended sledge journey, in the equipment of which he closely followed M'Clintock's system. He discovered a great extent of coast-line, and attained a latitude of 82° 5′ N. at Cape Fligely. The Austrian explorers were eventually obliged to abandon the "Tegethoff," reaching Norway in September 1874; but their expedition was a great success, and they added an extensive region to the map of the known world.

Austi expe tion.

In England the very important branch of geographical research relating to the Arctic regions was neglected by the Government during this interval of fifteen years, while Americans, Swedes, Norwegians, Germans, Austrians, and English yachtsmen were making praiseworthy efforts with more or less success. The resumption of English Arctic research on an adequate scale is due to the exertions and arguments of Admiral Sherard Osborn from 1865 until 1875. He set forth the valuable results to be obtained, and the means of success. Basing his arguments on long experience, he showed that it was necessary for success that an expedition should follow a coast-line, that it should pass beyond any point previously reached and there winter, and that the work should be completed by extended sledge parties in the spring. At length an expedition was fitted out on these principles, the Smith Sound route was selected, and in May 1875 the "Alert" and "Discovery" sailed from Portsmouth under the command of Captain Nares. As regards the ice navigation the success of the expedition was complete. Captain Nares, in the face of unparalleled difficulties, brought the ships to a point farther north than any vessel of any nation had ever reached before, wintered the "Alert" in 82° 27′ N., and, in the face of still greater difficulties, brought both vessels safely home again. The extended sledge-travelling called forth an amount of heroic devotion to duty, and of resolute perseverance in spite of greater obstacles than had ever been encountered before, which add a proud page to the history of English naval enterprise. The exploring parties were led by Commander Markham and Lieutenants Aldrich and Beaumont. Advancing over the great frozen Polar Sea, Markham reached 83° 20′ 26″ N., the highest latitude ever attained by any human being. He thus won the blue ribbon of Arctic discovery. Aldrich discovered 200 miles of coast to the westward, while Beaumont added to our knowledge of the north coast of Greenland. The results of the Arctic expedition of 1875–76 were the creation of a young generation of experienced Arctic officers, the discovery of 300 miles of new coast-line and of a large section of the Polar Ocean, the attainment of the highest latitude ever reached by man, a year's magnetic and meteorological observations at two stations both further north than any before taken, tidal observations, the examination of the geology of a vast region and the discovery of a fossil forest in 82° N., and large natural history collections representing the fauna and flora of a new region.

Engli Arcti exped tion.

Mark ham's highe

The return of this memorable expedition again incited our neighbours to further efforts. In the summer of 1878 the Dutch entered the field, and the schooner "William

Barents," under Lieutenants de Bruyne and Koolemans Beynen, made a useful reconnaissance of the Barent's Sea; while Professor Nordenskiöld left Sweden in July 1878, in the well-equipped steamer "Vega," to achieve the North-East Passage. In August he rounded Cape Chelyuskin, the most northern point of the Old World, and reached the mouth of the Lena. But much work remains to be done in the polar regions, in order to complete the connexion between Aldrich's furthest in 1876 and M'Clintock's in 1854, to complete the discovery of the north side of Greenland, to explore the northern bounds of Franz Josef Land, and to discover lands north of Siberia.

There is one great branch of physical geography which has only been effectively studied within the last thirty years, namely, the physical geography of the sea. Mathew Fontaine Maury, by his wind and current charts, by his trade wind, storm, rain, and whale charts, and above all by his charming work *The Physical Geography of the Sea*, gave the first impulse to this study. It was Captain Maury who organized the first deep-sea soundings in the North Atlantic, which up to that time was deemed to be unfathomable; and when his work was published, the illustrious Humboldt declared Maury to be the founder of a new and important science—the meteorology of the sea. He first took charge of the Washington Observatory in 1842; he resigned that post under a deep sense of duty in April 1861, after a career of great usefulness; and he ended a noble and well-spent life in 1872. The investigations into the physical geography of the sea, which were combined into a system by Maury, have since been ably and zealously continued by others, among whom the names of Dr Carpenter, Sir Wyville Thomson, and Professor Mohn of Christiania are pre-eminent. The voyage of the "Challenger" from 1873–1876, under Captains Nares and Thomson, with Sir Wyville Thomson as chief of the scientific staff, was organized with the object of examining and mapping the bottom of the ocean, of describing the fauna of the great depths, of ascertaining the temperatures at various depths, and of solving questions relating to oceanic circulation. The area thus explored in the Atlantic, Antarctic, Pacific, and Indian Oceans is of vast extent, and the researches, ably and zealously conducted, have resulted in an important addition to geographical knowledge.

In this rapid sketch of the history of geographical discovery, the labours of numerous explorers during many generations have been enumerated; but its perusal will show that, notwithstanding all this work, there is much remaining to be done. Vast areas round both poles, and in the interior of Asia, Africa, South America, and New Guinea, are still unknown, even more extensive regions have only been partially explored, and millions of square miles remain to be surveyed, before the work of geographers is complete. (C. R. M.)

II. Mathematical Geography.

All our knowledge of the planet on which we live, whether obtained from the explorations of travellers, the voyages of navigators, or the discoveries of astronomy in modern times, goes to confirm the doctrine held and taught by philosophers in a remote antiquity that the earth is spherical. What is spherical, however, is not the actual surface of the earth, but rather that of the sea produced in imagination to pass through the continents. That the surface of the sea is convex any one may—at a seaside station where there is a high cliff—convince himself, by noting with a telescope at the top of the cliff the exact appearance of a ship in, or slightly beyond, the horizon, and then, immediately after, repeating at the foot of the cliff the same observation on the same ship. By a more precise observation of the sea horizon from a known altitude one may even calculate the radius of the earth.

Let m (fig. 1) be a point on the top of a mountain; hnk a portion of the earth's surface; mnv a line drawn from m towards the centre of the earth; mh a tangent from m to the spherical surface; and ml a horizontal line through m, that is, ml is perpendicular to mv. Then by the mere measure of the angle lmh, or the depression of the sea horizon, one can, knowing mn, calculate very simply the radius of the earth.

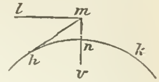

Fig. 1.

Let the height $mn = h$, the angle $lmh = \delta$, and the radius of the earth $= r$; then since the angle subtended at the earth's centre by hn is δ, it is clear that $(h + r) \cos\delta = r$, which gives r in terms of h and δ, known quantities. In fact, since h and δ are both small, $r = \frac{1}{2}h \div \sin^2\frac{1}{2}\delta$. But here we have assumed that the ray of light proceeding from h to m takes a rectilinear course; this is not true however, for the path is curved, its concavity being turned towards the earth—a consequence of terrestrial refraction. From the laws of terrestrial refraction, which have been very minutely studied, we know that the formula last written down should be $r = \cdot 422h \div \sin^2\frac{1}{2}\delta$. Now to take an actual case—the depression of the sea horizon at the top of Ben Nevis is 64′ 48″ (this is the mean of several observations, taken with special precautions for the express purpose of this experimental calculation), and the height of the hill is 4406 feet, or ·8345 of a mile. The formula gives at once $r = 3965$ miles, which is remarkably near the truth. But this method is not capable of precision on account of the variableness of terrestrial refraction. In connexion with the appearance of the sea horizon from a height the following formulæ are useful:—h being the height in feet, δ the depression or *dip* of the horizon in minutes, s the distance of the horizon in miles, then

$$\delta = \left(1 - \frac{1}{40}\right)\sqrt{h}\,; \qquad s = \frac{4}{3}\sqrt{h}.$$

Thus, for instance, to a spectator on the top of Snowdon, which is 3590 feet in height, the distance of the sea horizon is about 80 miles.

The first great fact in the description of the earth being that it is spherical (or at any rate so nearly so that, were a perfect model of it constructed, no one could, by unaided vision, discover that it is not spherical), the next points to be noted are,—secondly, that the earth rotates uniformly round an axis passing through its centre, and fixed, or very nearly fixed as to direction, in space; and thirdly, that its figure is not spherical but spheroidal, the surface being that found by the revolution of an ellipse round its minor axis, the axis of figure corresponding with the axis of diurnal rotation. The spheroidal figure is a necessary consequence of the rotation. The rotation of the earth once in 24 hours, although made evident by the rising and setting of the heavenly bodies, is rendered perhaps more distinctly visible by Foucault's pendulum experiment. Let a heavy ball be suspended by a fine thread, free from tension, from a fixed point. Let it be drawn aside from the position of equilibrium and then dropped so that it commences to oscillate in a vertical plane passing through the point of suspension. Then a careful observation of the pendulum will show that its plane of oscillation is not fixed, but has a uniform rotation in a direction opposite to that of the earth's rotation. Suppose, for instance, that the pendulum were suspended at the north pole and that it were set oscillating in a plane passing through any one fixed star, then it will continue to oscillate in that same plane notwithstanding the earth's rotation. Consequently, to the observer there the plane of the pendulum's oscillation will appear to rotate through 360° in 24 hours. At the equator, since there is no component of rotation there, the pendulum would continue to move in one and the same plane. At intermediate stations the rate of rotation is easily calculated; and observations confirm the calculations, and have made the earth's rotation actually visible.

The poles of the earth are the points in which the axis of rotation, or of figure, meet the surface; and the equator is the circle in which the surface is intersected by a plane through the earth's centre, perpendicular to the axis of rotation Every point of the equator is therefore equidistant from the poles.

To determine the position of a point in space three co-ordinates or measurements are necessary; they may be three lines, or two lines and one angle, or two angles and one line. Thus, to define the precise position of a point on the earth's surface, we express it by latitude, longitude, and altitude; the first two are angular measures, the third a linear magnitude, namely the height above the surface of the sea.

The line in which the surface of the earth is intersected by a plane through the axis of rotation is called a meridian, and all meridians are evidently similar curves. A line perpendicular to the surface at any point is called a vertical line; it corresponds with the direction of gravity there; being produced outwards, that is, away from the earth's centre it meets the heavens in the *zenith*; and produced downwards it intersects the axis of revolution; it would of course pass through the earth's centre were it a sphere; as it is, it passes *near* the earth's centre.

The angle between the meridian planes of two stations as A and B is called the difference of longitude of A and B, or the longitude of B with reference to A. In British maps the longitudes of all places are expressed with reference to the Royal Observatory of Greenwich.

The latitude of any point is the angle made by the vertical line there with the plane of the equator, or the co-latitude is the angle between the vertical line and the axis of rotation. The surface of the earth being one of revolution, any intersecting plane parallel to the equator cuts it in a circle. If we imagine the vertical lines drawn at any two points, as P and Q, in such a circle it is evident from the symmetry of the surface that these verticals make the same angle with the equator; in other words, the latitudes of all points on this circle are equal. Such circles are called parallels; they intersect meridians at right angles.

If we suppose that at any point Q of the surface the meridian, or a small bit of it, is actually traced on the surface, and also a portion of the parallel through the same point, then these lines, crossing at right angles in Q, mark there the directions which we call north and south, east and west—the meridian lying north and south, the parallel east and west. Planes containing the vertical line at Q are vertical planes there. A vertical plane is defined by its azimuth, which is the angle it makes with the meridian plane; the azimuth at Q of any object (or point) celestial or terrestrial is the angle which the vertical plane passing through the object makes with the meridian. The south meridian is generally taken as the zero of azimuth. The plane touching the surface at Q is the visible horizon there—a plane parallel to this through the centre of the earth being called the rational horizon. The altitude at Q of a heavenly body, as a star, is the angle which the line drawn from Q to the star makes with the plane of the horizon,—the zenith distance of the same star being the angle between its direction and the vertical at Q.

By a degree of the meridian is meant this: if E, F are points on the same meridian such that the directions of their verticals make with each other an angle of one degree—a ninetieth part of a right angle—then the distance between E and F measured along the meridian is a degree of the meridian. As the radius of curvature of an ellipse is variable, increasing from the extremity of the major axis to the extremity of the minor axis, so on the earth's surface a degree of the meridian is found by geodetic measurement to increase from the equator to the poles.

The actual length of a degree of the meridian at the equator is 362746·4 feet; at either pole it is 366479·8 feet. The length of one degree of the equatorial circle is 365231·1 feet.

With regard to the figure of the earth as a whole, the polar radius is 3949·79 miles, and the radius of the equator 3963·30 miles; the difference of these, called the ellipticity, is $\frac{1}{293}$ of the mean radius. A spheroid with these semiaxes is equivalent in volume to a sphere having a radius of 3958·79 miles. Without referring further here to the spheroidal figure, we shall now, having given the precise dimensions, regard the earth as a sphere whose radius is 3959 miles. On such a sphere one degree is 69·09 miles. From the definitions given above it appears that the radius of the parallel which corresponds to all points whose latitude is ϕ is $3959 \cos\phi$; and that one degree of this circle, *i.e.*, one degree of longitude in the latitude ϕ is $69{\cdot}09 \cos\phi$ expressed in miles.

In the representation of the spherical earth (fig. 2) P is the pole, QQ the equator, E, F any two points on the surface, PE*e*, PF*f* the meridians of those points intersecting the equator in *e* and *f* Join EF by a great circle; then in the spherical triangle PEF the angle at P is the difference of longitude of E and F, PE is the co-latitude of E, and PF the co-latitude of F, the latitudes being *e*E and *f*F respectively. The angle at E, being that contained between the meridian there and a vertical plane passing through F, is the azimuth of F (measured in this case from the north), while the angle at F is the azimuth of E. If, then, there be given the latitudes and longitudes of two places, to find their distance apart, and their relative bearings, it becomes necessary to calculate a spherical triangle (PEF) in which two sides and the included angle are given,—the calculation bringing out the third side, which is the required distance, with the adjacent azimuthal angles.

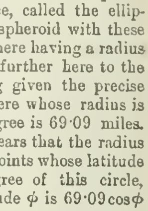

Fig. 2.

The latitudes and longitudes of places on the earth's surface are determined by observations of the stars, of the sun, and of the moon. As the earth rotates, the zenith of any place (not being on the equator) traces out among the stars a small circle having for centre that point in which the axis of rotation meets the heavens. If there were a star at this last point it would be apparently motionless, having always the same altitude and azimuth. The pole star, though very conveniently near the north pole of the heavens, and without perceptible motion to the unaided eye, is in reality moving in a very small circle. The zenith of a point on the equator traces out in the heavens a great circle, namely, the celestial equator.

As the positions of points on the earth are defined with reference to the equator and a certain fixed meridian, so the positions of stars are defined by their angular distance from the celestial equator, called in this case declination, and by their right ascension, which corresponds to terrestrial longitude. Stars which are on the same meridian plane (extended to the heavens) have the same right ascension. Right ascension is expressed in time from 0^h to 24^h. A sidereal clock, going truly, indicates 24^h for every revolution of the earth: at every observatory, the sidereal clock there shows, at each moment, the right ascension of the stars which at that moment are on the meridian. Thus the right ascension of the zenith is the sidereal time.

In the left hand circle of the diagram (fig. 3) two concentric small circles are drawn such that the sum of their radii is a right angle or 90°. Let the inner circle be that traced among the stars by the zenith of any given place, say Q, then the outer circle encloses all those stars

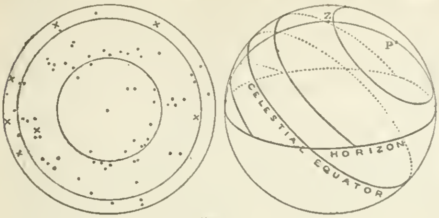

Fig. 3.

which are circumpolar at Q, that is, whose entire course is performed above that horizon; for clearly the zenith distance of none of these can exceed 90° at Q. Or if the outer circle be that described by the zenith of Q, then the inner circle encloses all those stars which are circumpolar at Q. The second circle in the diagram shows the diurnal paths of stars with reference to the horizon.

If we consider in the first circle the changes of distance between any one star and the zenith of Q as the latter traces out its path in the heavens, we see that the distance becomes alternately a maximum and a minimum every twelve hours, namely, when the meridian of Q passes through the star. This is called the star's culmination or meridian transit. It will be clear from an inspection of the figure that, if for instance the star culminate to the south of the zenith, the star's declination plus its zenith distance at culmination is equal to the latitude of the zenith, that is, of Q. A corresponding rule is easily made for a northern transit. Thus the simplest manner of determining the latitude is to measure the zenith distance of a known star at its meridian transit.

The position of the zenith at any moment may be determined by simultaneous observation of the zenith distance of two known stars. For these distances clearly determine a point in the heavens (two points rather, which however need not be confounded) whose declination and right ascension can be computed by spherical trigonometry. Thus, at the same time, are obtained both the time and the latitude. For the success of this method, which is suitable for travellers exploring an unknown country, it is desirable that the stars should differ in azimuth by about a right angle.

If the path of the zenith, that is, the latitude, be known, then clearly a single observation of the zenith distance of a known star, which should be towards the east or west, not towards the north or south, will fix the place or right ascension of the zenith, that is, the sidereal time, at the moment of observation. Here the pole, the zenith, and the star are the angular points of a spherical triangle, of which the three sides are known: the angle at the pole, being computed, is the difference of right ascension of the star and the zenith. Thus the sidereal time is found.

The determination of the difference of longitude of the two stations AB on the earth's surface requires that the true time be kept at each. All that is necessary is a comparison of these times at any instant. For instance, the time at B may, by the transport of chronometers, be brought to A, and thus the difference of the local times be ascertained, or the indications of the clock at A may be conducted by electro-telegraphy to B. The difference of the local times at A and B is the time a star takes to pass from the meridian of the one to that of the other; and this is the difference of longitude which may be converted into angle at the rate of 360° to 24^h.

But the traveller in unknown lands, who seeks to fix astronomically his position, has no telegraph to count on and his expectations for longitude depend chiefly on observations of the moon. In the *Nautical Almanac* are published the angular distances of the moon from certain stars in its path for every three hours of Greenwich time. Therefore, by actually observing the distance of the moon from one of these stars, one can infer the corresponding Greenwich time at the moment of observation. The comparison of this with the local time gives the longitude.

Observations on the sun have shown that it traces out amongst the stars in the course of a year a great circle, inclined to the equator at an angle of $23\frac{1}{2}$°; at midsummer it attains a maximum northern declination of $23\frac{1}{2}$°, and at midwinter a maximum southern declination of the same amount. Hence it is inferred that the earth moves round the sun in a plane, completing one orbital revolution yearly, the axis of the earth's diurnal rotation being inclined to this plane at an angle of $66\frac{1}{2}$°. Upon this angle of inclination depend the seasons, and in great measure the climates of the different portions of the earth's surface.

It is usual to draw on globes and in maps a circle or parallel at the distance of $23\frac{1}{2}$° from the equator on either side; of these circles the northern is called the Tropic of Cancer, the southern is the Tropic of Capricorn. A circle drawn with a radius of $23\frac{1}{2}$° from the North Pole as centre is the Arctic Circle; a similar and equal circle round the South Pole is the Antarctic Circle.

When the sun is in the equator—which it crosses from north to south in September, and from south to north in March—it is in the horizon of either pole. When the sun has northern declination, the North Pole is in constant daylight and the South Pole in darkness. When the sun has southern declination the North Pole on the contrary is in constant darkness while the South Pole is illuminated by sunshine. At midsummer in the northern hemisphere the whole region within the Arctic Circle is in constant daylight, and that within the Antarctic Circle is in darkness; at midwinter this state of things is exactly reversed. The portion of the globe lying between the Tropic of Cancer and the Arctic Circle is called the North Temperate Zone; that between the Tropic of Capricorn and the Antarctic Circle is the South Temperate Zone. In the former the sun is always to the south of the zenith; in the latter it is always to the north.

In the Torrid Zone, which lies between the Tropics, the sun, at any given place, passes the meridian to the north of the zenith for part of the year, and to the south for the remainder.

When the sun is to the north of the equator the days are longer than the nights in the northern hemisphere, while in the southern hemisphere the nights are longer than the days; when the sun has southern declination this condition is reversed. As the sun increases his north declination from 0° to $23\frac{1}{2}$°, not only do the days increase in length in the northern hemisphere, but the rays of the sun—in the Temperate and Arctic regions—impinge more perpendicularly on the surface; hence the warmth of summer. Even in summer the rays of the sun in the Arctic regions strike the surface very obliquely; this, combined with the protracted season of darkness, produces excessive cold. Summer in the northern hemisphere is thus contemporaneous with winter in the southern; while winter in the northern hemisphere is simultaneous with summer in the southern.

The length of the day at any place at any season of the year is easily ascertained from the following considerations. Let *ns* (fig. 4) be the axis of rotation, *eq* the equator orthographically projected on a meridian plane, *ab* the parallel of the given place; draw the diameter *fg* making the angle *nog* equal to the sun's declination, which we suppose to be north, then the hemisphere *gnaef* is in sunshine, while the hemisphere *gbqsf* is in darkness. As the earth rotates, a point which is at a at midday is carried from a towards b, which it reaches at midnight; h is reached at 6 o'clock P.M. and k at sunset. Now if ϕ be the latitude of the place and δ the sun's declination $hk = \sin\phi \tan\delta$; this in the parallel whose radius is $\cos\phi$ corresponds to an angle whose sine is $\tan\phi \tan\delta$. Call this angle η; the time taken to rotate through it is $\frac{1}{15}\eta$; hence the length of the daylight is $12^h + \frac{2}{15}\eta$, and the length of night $12^h - \frac{2}{15}\eta$.

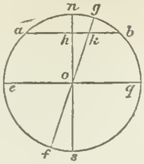

Fig. 4.

Now η vanishes when either ϕ or δ is zero; that is, at the equator the nights and days are equal in length throughout the year; and again when the sun is in the equator, that is, at the equinox, the nights and days are equal in all latitudes. When the sun's declination is equal to the co-latitude, η is a right angle, and the sun does not actually set; this can only happen at places within the polar circle. The longest day at Gibraltar is $14^h\ 27^m$, at Falmouth $16^h\ 11^m$, and in Shetland $18^h\ 14^m$; while in Iceland it is 20^h on the south coast and 24^h on the north. At Washington the longest day is $14^h\ 44^m$, and at Quebec $15^h\ 40^m$.

All this, however, is on the supposition that day ends with sunset; but the length of apparent day is increased by atmospheric refraction and reflection. When the disk of the setting sun first seems to touch the horizon it is in reality wholly below it and is only seen by refraction. After the sun has wholly set at any given place his light still continues to illuminate the upper portion of the atmosphere there, so that, instead of ending abruptly, daylight gradually fades away until the sun is 18° below the horizon.

In a diagram (fig. 5) similar to the last draw *mi* parallel to *gf*, and at a distance from it equal to the sine of 18°; then *gbf* being the hemisphere unenlightened by the direct rays of the sun, *gmif* will represent the twilight zone. A point in the latitude of a describing the parallel *ab* loses sight of the sun at k, and is in twilight until it reaches the small circle *mi*, when the sun's zenith distance is 108°. The duration of twilight corresponds then to the portion *kl* of *ab*, the angle rotated through being

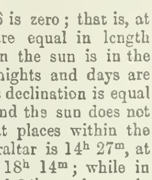

Fig. 5.

$$\sin^{-1}(hl : hb) - \sin^{-1}(hk : hb);$$

this converted into time gives the duration of twilight. Here

$$hk = \sin\phi \tan\delta\ ;\ kl = \sin 18^\circ \sec\delta.$$

At any given latitude the twilight is shortest when the great circle passing through k and l passes also through the sun. Expressed algebraically, if τ be the duration of the shortest twilight in angular measure and δ the sun's declination at the time, then

$$-\sin\delta = \sin\phi \tan 9^\circ$$
$$\sin\tfrac{1}{2}\tau = \sec\phi \sin 9^\circ.$$

Suppose in the last diagram the sun to be at his greatest northern declination, then $ng = 23\tfrac{1}{2}^\circ$, $gm = 18^\circ$, and $mq = 48\tfrac{1}{2}^\circ$. Hence a place whose latitude is $48\tfrac{1}{2}^\circ$ N. has, at midsummer, twilight lasting from sunset to midnight and continuing from midnight to sunrise, that is, for a few days there is no absolute darkness. A little further south this twilight is interrupted by a short period of darkness. Since $is = 23\tfrac{1}{2}^\circ - 18^\circ = 5\tfrac{1}{2}^\circ$, we see from the diagram that the South Pole is at this time in total darkness, which extends to all places within $5\tfrac{1}{2}^\circ$ of it. When the sun's declination is 9° south, the North Pole is in the centre of the twilight belt; thus all places whose latitude is greater than 81° then move in continual twilight, alternating between clearness and dimness, never attaining either daylight or total darkness. The actual period during which either pole is in total darkness is about two and a half months.

At the equator, the shortest twilight occurs at the equinox, when it is $1^h\ 12^m$; the longest when the sun is in the tropics, being $1^h\ 18^m$. At London, in latitude $51\tfrac{1}{2}^\circ$, twilight continues all night from May 22 to July 21; it is shortest about three weeks after the autumnal and three weeks before the vernal equinox, when its duration is $1^h\ 50^m$. At Washington the shortest twilight (being $1^h\ 33^m$) occurs on the 6th of March and 7th October; at Quebec the shortest is $1^h\ 46^m$, falling on the 3d March and 10th October.

At page 205, fig. 19 is a perspective representation of the earth—of more than a hemisphere, in fact—namely, the segment *mgnafi* in fig. 5. It exhibits all those regions of the earth which at Greenwich apparent noon at midsummer are in sunshine *and* twilight. It is very remarkable how Asia and America, but especially the former, just escape going into darkness.

Construction of Maps.

In the construction of maps, one has to consider how a portion of spherical surface, or a configuration traced on a sphere, can be represented on a plane. If the area to be represented bear a very small ratio to the whole surface of the sphere, the matter is easy: thus, for instance, there is no difficulty in making a map of a parish, for in such cases the curvature of the surface does not make itself evident. If the district is larger and reaches the size of a county, as Yorkshire for instance, then the curvature begins to be sensible, and one requires to consider how it is to be dealt with. The sphere not being a developable surface cannot be opened out into a plane like the cone or cylinder, consequently in a plane representation of configurations on a sphere it is impossible to retain the desired proportions of lines or areas or equality of angles. But though one cannot fulfil all the requirements of the case, we may fulfil some by sacrificing others; that is to say, we may, for instance, have in the representation exact similarity to all very small portions of the original, but at the expense of the areas, which will be quite misrepresented. Or we may retain equality of areas if we give up the idea of similarity. It is therefore usual, excepting in special cases, to steer a middle course, and, by making compromises, endeavour to obtain a representation which shall not offend the eye.

A globe gives a perfect representation of the surface of the earth; but practically, the necessary limits to its size make it impossible to represent in this manner the details of countries. A globe of the ordinary dimensions serves scarcely any other purpose than to convey a clear conception of the earth's surface as a whole, exhibiting the figure, extent, position, and general features of the continents and islands, with the intervening oceans and seas; and for this purpose it is indeed absolutely essential and cannot be replaced by any kind of map.

The construction of a map virtually resolves itself into the drawing of two sets of lines, one set to represent meridians, the other to represent parallels. These being drawn, the filling in of the outlines of countries presents no difficulty. The first and most natural idea that occurs to one as to the manner of drawing the circles of latitude and longitude is to draw them according to the laws of perspective. But, as Lagrange has remarked, one may regard geographical maps from a more general point of view as representations of the surface of the globe, for which purpose we have but to draw meridians and parallels according to any given law; then any place we have to fix must take that position with reference to these lines that it has on the sphere with reference to the circles of latitude and longitude. Let the law which connects latitude and longitude, ϕ and ω, with the rectangular coordinates x and y in the representation be such that $dx = md\phi + nd\omega$, and $dy = m'd\phi + n'd\omega$. In fig. 6 let the lines intersecting in the parallelogram PQRS be the representations of the meridians rp, sq and parallels rs, pq intersecting in the indefinitely small rectangle $pqrs$ on the surface of the sphere. The coordinates of P being x and y, while those of p are ϕ and ω the coordinates of the other points will stand thus

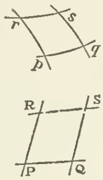

Fig. 6.

q	ϕ	$\omega+d\omega$
r	$\phi+d\phi$	ω
s	$\phi+d\phi$	$\omega+d\omega$
Q	$x+nd\omega$	$y+n'd\omega$
R	$x+md\phi$	$y+m'd\phi$
S	$x+md\phi+nd\omega$	$y+m'd\phi+n'd\omega$.

Thus we easily see that $PR=(m^2+m'^2)^{\frac{1}{2}}d\phi$; and $PQ=(n^2+n'^2)^{\frac{1}{2}}d\omega$; also the area of the parallelogram PQRS is equal to $(m'n-mn')d\phi d\omega$. If $90^\circ \pm \psi$ are the angles of the parallelogram, then

$$\tan\psi=\frac{mn+m'n'}{m'n-mn'}.$$

If the lines of latitude and of longitude intersect at right angles, then $mn+m'n'=0$. Since the length of pr is $=d\phi$, its representation PR is too great in the proportion of $(m^2+m'^2)^{\frac{1}{2}}:1$; and pq being in length $\cos\phi d\omega$, its representation PQ is too great in the ratio of $(n^2+n'^2)^{\frac{1}{2}}:\cos\phi$. Hence the condition that the rectangle PQRS is similar to the rectangle $pqrs$ is $(m^2+m'^2)\cos^2\phi=n^2+n'^2$, together with $mn+m'n'=0$; or, which is the same, the condition of similarity is expressed by

$$-n'=m\cos\phi\,;\ n=m'\cos\phi.$$

Since the area of the rectangle $pqrs$ is $\cos\phi d\phi d\omega$, the exaggeration of area in the representation will be expressed by $m'n-mn':\cos\phi$. Thus when the nature of the lines representing the circles of latitude and longitude is defined we can at once calculate the error or exaggeration of scale at any part of the map, whether measured in the direction of a meridian or of a parallel: and also the misrepresentation of angles.

The lines representing in a map the meridians and parallels on the sphere are constructed either on the principles of true perspective or by artificial systems of developments. The perspective drawings are indeed included as a particular case of development in which, with reference to a certain point selected as the centre of the portion of spherical surface to be represented, all the other points are represented in their true azimuths,—the rectilinear distances from the centre of the drawing being a certain function of the corresponding true distances on the spherical surface. For simplicity we shall first apply this method to the projection or development of parallels and meridians when the pole is the centre. According to what has been said above, the meridians are now straight lines diverging from the pole, dividing the 360° into equal angles; and the parallels are represented by circles having the pole as centre, the radius of the parallel whose co-latitude is u being ρ, a certain function of u. The particular function selected determines the nature of the development.

Let Ppq, Prs (fig. 7) be two contiguous meridians crossed by parallels rp, sq, and O$p'q'$, O$r's'$ the straight lines representing these meridians. If the angle at P is $d\mu$, this also is the value of the angle at O. Let the co-latitude

$$Pp=u,\ Pq=u+du\,;\ Op'=\rho,\ Oq'=\rho+d\rho,$$

the circular arcs $p'r'$, $q's'$ representing the parallels pr, qs. If the radius of the sphere be unity,

$$p'q'=d\rho\,;\quad p'r'=\rho d\mu,$$
$$pq\ =du\,;\quad vr\ =\sin u d\mu.$$

Put

$$\sigma=\frac{d\rho}{du}\,;\quad \sigma'=\frac{\rho}{\sin u}\,,$$

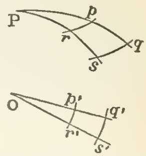

Fig. 7.

then $p'q'=\sigma pq$ and $p'r'=\sigma' pr$. That is to say, σ, σ' may be regarded as the relative scales, at co-latitude u, of the representation, σ applying to meridional measurements, σ' to measurements perpendicular to the meridian. A small square situated in co-latitude u, having one side in the direction of the meridian—the length of its side being i—is represented by a rectangle whose sides are $i\sigma$ and $i\sigma'$; its area consequently is $i^2\sigma\sigma'$.

If it were possible to make a perfect representation, then we should have $\sigma=1$, $\sigma'=1$ throughout. This, however, is impossible. We may make $\sigma=1$ throughout by taking $\rho=u$. This is known as the *Equidistant Projection*, a very simple and effective method of representation.

Or we may make $\sigma'=1$ throughout. This gives $\rho=\sin u$, a perspective projection, namely, the *Orthographic*. Or we may require that areas be strictly represented in the development. This will be effected by making $\sigma\sigma'=1$, or $\rho d\rho=\sin u du$, the integral of which is $\rho=2\sin\frac{1}{2}u$, which is the *Equivalent Projection* of Lambert, sometimes referred to as *Lorgna's Projection*. In this system there is misrepresentation of form, but no misrepresentation of areas. Or we may require a projection in which all small parts are to be represented in their true forms. For instance, a small square on the spherical surface is to be represented as a small square in the development. This condition will be attained by making $\sigma=\sigma'$, or $\frac{d\rho}{\rho}=\frac{du}{\sin u}$, the integral of which is, c being an arbitrary constant, $\rho=c\tan\frac{1}{2}u$. This, again, is a perspective projection, namely, the *Stereographic*. In this, though all small parts of the surface are represented in their correct shapes, yet, the scale varying from one part of the map to another, the *whole* is not a similar representation of the original. The scale $\sigma=\frac{1}{2}c\sec^2\frac{1}{2}u$, at any point, applies to all directions round that point.

These two last projections are, as it were, at the extremes of the scale; each, perfect in its own way, is in other respects very objectionable. We may avoid both extremes by the following considerations. Although we cannot make $\sigma=1$ and $\sigma'=1$, so as to have a perfect picture of the spherical surface, yet considering $\sigma-1$ and $\sigma'-1$ as the local errors of the representation, we may make $(\sigma-1)^2+(\sigma'-1)^2$ a minimum over the whole surface to be represented. To effect this we must multiply this expression by the element of surface to which it applies, viz., $\sin u du d\mu$, and then integrate from the centre to the (circular) limits of the map. Let β be the spherical radius of the segment to be represented, then the total misrepresentation is to be taken as

$$\int_0^\beta\left\{\left(\frac{d\rho}{du}-1\right)^2+\left(\frac{\rho}{\sin u}-1\right)^2\right\}\sin u du,$$

which is to be made a minimum. Putting $\rho=u+y$, and giving to y only a variation subject to the condition $\delta y=0$ when $u=0$, the equations of solution—using the ordinary notation of the calculus of variations—are

$$N-\frac{d(P)}{du}=0\,;\ P_\beta=0,$$

P_β being the value of $2p\sin u$ when $u=\beta$. This gives

$$\sin^2 u\frac{d^2y}{du^2} + \sin u\cos u\frac{dy}{du} - y = u - \sin u,$$

$$\left(\frac{dy}{du}\right)_\beta = 0.$$

This method of development is due to Sir George Airy, whose original paper—the investigation is different in form from the above—will be found in the *Philosophical Magazine* for December 1861. The solution of the differential equation leads to this result—

$$\rho = 2\cot\frac{u}{2}\log_e\sec\frac{u}{2} + C\tan\frac{u}{2},$$

$$C = 2\cot^2\frac{\beta}{2}\log_e\sec\frac{\beta}{2}$$

The limiting radius of the map is $R = 2C\tan\frac{1}{2}\beta$. In this system, called by the Astronomer-Royal the "*Projection by balance of errors*," the total misrepresentation is an absolute minimum.

Returning to the general case where ρ is any function of u, let us consider the local misrepresentation of direction. Take any indefinitely small line, length $= i$, making an angle α with the meridian in co-latitude u. Its projections on a meridian and parallel are $i\cos\alpha$, $i\sin\alpha$, which in the map are represented by $i\sigma\cos\alpha$, $i\sigma'\sin\alpha$. If then α' be the angle in the map corresponding to α,

$$\tan\alpha' = \frac{\sigma'}{\sigma}\tan\alpha.$$

Put

$$\frac{\sigma'}{\sigma} = \frac{\rho du}{\sin u d\rho} = \Sigma,$$

and the error $\alpha' - \alpha$ of representation $= \epsilon$, then

$$\tan\epsilon = \frac{(\Sigma - 1)\tan\alpha}{1 + \Sigma\tan^2\alpha}.$$

Put $\Sigma = \cot^2\zeta$, then ϵ is a maximum when $\alpha = \zeta$, and the corresponding value of ϵ is

$$\epsilon = \frac{\pi}{2} - 2\zeta$$

For simplicity of explanation we have supposed this method of development so applied as to have the pole in the centre. There is, however, no necessity for this, and any point on the surface of the sphere may be taken as the centre. All that is necessary is to calculate by spherical trigonometry the azimuth and distance, with reference to the assumed centre, of all the points of intersection of meridians and parallels within the space which is to be represented in a plane. Then the azimuth is represented unaltered, and any spherical distance u is represented by ρ. Thus we get all the points of intersection transferred to the representation, and it remains merely to draw continuous lines through these points, which lines will be the meridians and parallels in the representation.

The exaggeration in such systems, it is important to remember, whether of linear scale, area, or angle, is the same for a given distance from the centre, whatever be the azimuth; that is, the exaggeration is a function of the distance from the centre only.

We shall now examine and exemplify some of the most important systems of projection and development, commencing with

Perspective Projections.

In perspective drawings of the sphere, the plane on which the representation is actually made may generally be any plane perpendicular to the line joining the centre of the sphere and the point of vision. If V be the point of vision, P any point on the spherical surface, then p, the point in which the straight line VP intersects the plane of the representation, is the projection of P.

In the orthographic projection, the point of vision is at an infinite distance and the rays consequently parallel; in this case the plane of the drawing may be supposed to pass through the centre of the sphere. Let the circle (fig. 8) represent the plane of the equator on which we propose to make an orthographic representation of meridians and parallels. The centre of this circle is clearly the projection of the pole, and the parallels are projected into circles having the pole for a common centre. The diameters aa', bb' being at right angles, let the semicircle bab' be divided into the required number of equal parts; the diameters drawn through these points are the projections of meridians. The distances of c, of d, and of e from the diameter aa' are the radii of the successive circles representing the parallels. It is clear that, when the points of division are very close, the parallels will be very much crowded towards the outside of the map: so much so, that this projection is not much used.

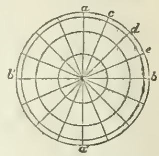

Fig. 8.

For an orthographic projection of the globe on a meridian plane, let $qnrs$ (fig. 9) be the meridian, ns the axis of rotation, then qr is the projection of the equator. The parallels will be represented by straight lines passing through the points of equal division; these lines are, like the equator, perpendicular to ns. The meridians will in this case be ellipses described on ns as a common major axis, the distances of c, of d, and of e from ns being the minor semiaxes.

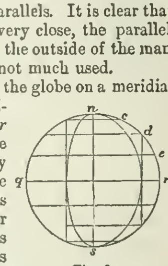

Fig. 9.

Let us next construct an orthographic projection of the sphere on the horizon of any place. Set off the angle aop (fig. 10) from the radius oa, equal to the latitude. Drop the perpendicular pP on oa, then P is the projection of the pole. On ao produced take $ob = p$P, then ob is the minor semi-axis of the ellipse representing the equator, its major axis being qr at right angles to ao. The points in which the meridians meet this elliptic equator are determined by lines drawn parallel to aob through the points of equal subdivision $cdefgh$. Take two points, as d and g, which are 90° apart, and let ik be their projections on the equator; then i is the pole of the meridian which passes through k. This meridian is of course an ellipse, and is described with reference to i exactly as the equator was described with reference to P. Produce io to l, and make lo equal to half the shortest chord that can be drawn through i; then lo is the semi-axis of the elliptic meridian, and the major axis is the diameter perpendicular to iol.

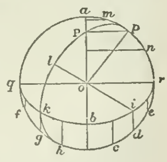

Fig. 10.

For the parallels: let it be required to describe the parallel whose co-latitude is u: take $pm = pn = u$, and let $m'n'$ be the projections of m and n on oPa; then $m'n'$ is the minor axis of the ellipse representing the parallel. Its centre is of course midway between m' and n', and the greater axis is equal to mn. Thus the construction is obvious. When pm is less than pa, the whole of the ellipse

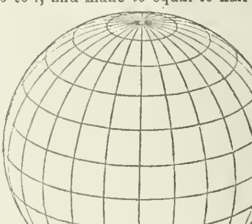

Fig. 11.—Orthographic Projection.

is to be drawn. When pm is greater than pa, the ellipse touches the circle in two points; these points divide the ellipse into two parts, one of which, being on the other side of the meridian plane aqr, is invisible.

Stereographic Projection.—In this case the point of vision is on the surface, and the projection is made on the plane of the great circle whose pole is V. Let kplV (fig. 12) be a great circle through the point of vision, and ors the trace of the plane of projection. Let c be the centre of a small circle whose radius is $cp = cl$; the straight line pl represents this small circle in orthographic projection.

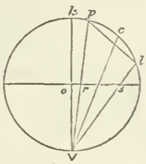

Fig. 12.

We have first to show that the stereographic projection of the small circle pl is itself a circle; that is to say, a straight line through V, moving along the circumference of pl, traces a circle on the plane of projection ors. This line generates an oblique cone standing on a circular base, its axis being cV (since the angle pVc = angle cVl); this cone is divided symmetrically by the plane of the great circle kpl, and also by the plane which passes through the axis Vc, perpendicular to the plane kpl. Now Vr·Vp, being = Vo sec kVp·Vk cos kVp = Vo·Vk, is equal to Vs·Vl; therefore the triangles Vrs, Vlp are similar, and it follows that the section of the cone by the plane rs is similar to the section by the plane pl. But the latter is a circle, hence also the projection is a circle; and since the representation of every infinitely small circle on the surface is itself a circle, it follows that in this projection the representation of small parts is (as we have before shown) strictly similar. Another inference is that the angle in which two lines on the sphere intersect is represented by the same angle in the projection. This may otherwise be proved by means of fig. 13, where Vok is the diameter of the sphere passing through the point of vision, fgh the plane of projection, kt a great circle, passing of course through V, and ouv the line of intersection of these two planes. A tangent plane to the surface at t cuts the plane of projection in the line rvs perpendicular to ov; tv is a tangent to the circle kt at t, tr and ts are any two tangents to the surface at t.

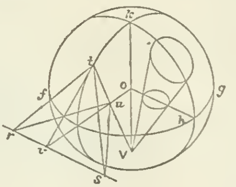

Fig. 13.

Now the angle vtu (u being the projection of t) is $90° - ot$V $= 90° - o$V$t = ou$V $= tuv$, therefore tv is equal to uv; and since tvs and uvs are right angles, it follows that the angles vts and vus are equal. Hence the angle rts also is equal to its projection rus; that is, any angle formed by two intersecting lines on the surface is truly represented in the stereographic projection.

We have seen that the projection of any circle of the sphere is itself a circle. But in the case in which the circle to be projected passes through V, the projection becomes, for a great circle, a line through the centre of the sphere; otherwise, a line anywhere. It follows that meridians and parallels are represented in a projection on the horizon of any place by two systems of orthogonally cutting circles, one system passing through two fixed points, namely, the poles; and the projected meridians as they pass through the poles show the proper differences of longitude.

To construct a stereographic projection of the sphere on the horizon of a given place. Draw the circle $vlkr$ (fig. 14) with the diameters kv, lr at right angles; the latter is to represent the central meridian. Take koP equal to the co-latitude of the given place, say u: draw the diameter PoP′, and vP, vP′ cutting lr in pp': these are the projections of the poles, through which all the circles representing meridians have to pass. All their centres then will be in a line smn which crosses pp' at right angles through its middle point m. Now to describe the meridian whose west longitude is ω, draw pn making the angle $opn = 90° - \omega$, then n is the centre of the required circle, whose direction as it passes through p will make an angle $opg = \omega$ with pp'.

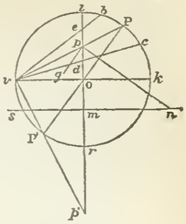

Fig. 14.

The lengths of the several lines are

$$op = \tan\tfrac{1}{2}u\,; \quad op' = \cot\tfrac{1}{2}u\,;$$
$$om = \cot u\,; \quad mn = \operatorname{cosec} u \cot\omega.$$

Again, for the parallels, take Pb = Pc equal to the co-latitude, say c, of the parallel to be projected; join vb, vc cutting lr in e, d. Then ed is the diameter of the circle which is the required projection; its centre is of course the middle point of ed, and the lengths of the lines are

$$od = \tan\tfrac{1}{2}(u - c); \quad oe = \tan\tfrac{1}{2}(u + c).$$

The line sn itself is the projection of a parallel, namely, that of which the co-latitude $c = 180° - u$, a parallel which passes through the point of vision.

A very interesting connexion, noted by Professor Cayley, exists between the stereographic projection of the sphere on a meridian plane (*i.e.*, when a point on the equator occupies the centre of the drawing) and the projection on the horizon of any place whatever. The very same circles that represent parallels and meridians in the one case represent them in the other case also. In fig. 15, abs being a projection in which an equatorial point is in the centre, draw any chord ab perpendicular to the centre meridian cos, and on ab as diameter describe a circle, when the property referred to will be observed. This smaller circle is now the stereographic projection of the sphere on the horizon of some place whose co-latitude we may call u.

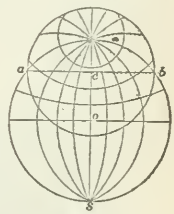

Fig. 15.

The radius of the first circle being unity, let $ac = \sin x$, then by what has been proved above $co = \sin x \cot u = \cos x$; therefore $u = x$, and $ac = \sin u$. Although the meridian circles dividing the 360° at the pole into equal angles must be actually the same in both systems, yet a parallel circle whose co-latitude is c in the direct projection abs belongs in the oblique system to some other co-latitude as c'. To determine the connexion between c and c', consider the point t (not marked), in which one of the parallel circles crosses the line soc. In the direct system, p being the pole,

$$pt = 1 - \tan\tfrac{1}{2}(90° - c) = \frac{2}{1 + \cot\tfrac{1}{2}c}$$

and in the oblique,

$$pt = ac\left(\tan\tfrac{1}{2}u - \tan\tfrac{1}{2}(u - c')\right),$$

which, replacing ac by its value $\sin u$, becomes

$$\frac{2\sin\tfrac{1}{2}u \sin\tfrac{1}{2}c'}{\cos\tfrac{1}{2}(u - c')} = \frac{2}{1 + \cot\tfrac{1}{2}u \cot\tfrac{1}{2}c'}\,,$$

therefore $\tan\tfrac{1}{2}c = \tan\tfrac{1}{2}c' \tan\tfrac{1}{2}u$ is the required relation.

Notwithstanding the facility of construction, the stereographic projection is not much used in map-making. But it may be made very useful as a means of graphical interpolation for drawing other projections in which points are represented in their true azimuths, but with an arbitrary law of distance, as $\rho = f(u)$. We may thus avoid the calculation of all the distances and azimuths (with reference to the selected centre point) of the intersections of meridians and parallels. Construct a stereographic projection of the globe on the horizon of the given place; then on this projection draw concentric circles (according to the stereographic law) representing the loci of points whose distances from the centre are consecutively 5°, 10°, 15°, 20°, &c., up to the required limit, and a system of radial lines at intervals of 5°. Then to construct any other projection,—commence by drawing concentric circles, of which the radii are

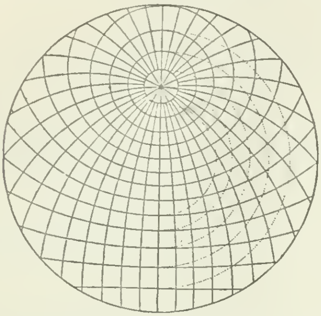

FIG. 16.—Stereographic Projection.

previously calculated by the law $\rho = f(u)$, for the successive values of u, 5°, 10°, 15°, 20°, &c., up to the limits as before, and a system of radial lines at intervals of 5°. This being completed, it remains to transfer the points of intersection from the stereographic to the new projection by graphic interpolation.

We now come to the general case in which the point of vision has any position outside the sphere. Let *abcd* (fig. 17) be the great circle section of the sphere by a plane passing through *c*, the central point of the portion of surface to be represented, and V the point of vision. Let *pj* perpendicular to V*c* be the plane of representation, join *m*V cutting *pj* in *f*, then *f* is the projection of any point *m* in the circle *abc*, and *ef* is the representation of *cm*. Let the angle $com = u$, $Ve = k$, $Vo = h$, $ef = \rho$; then, since $ef : eV = mg : gV$,

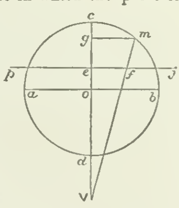

Fig.

$$\rho = \frac{k \sin u}{h + \cos u},$$

which gives the law connecting a spherical distance u with its rectilinear representation ρ. The relative scale at any point in this system of projection is given (keeping to our previously adopted notation) by

$$\sigma = k\frac{1 + h\cos u}{(h + \cos u)^2}\,;\quad \sigma' = \frac{k}{h + \cos u},$$

the former applying to measurements made in a direction which passes through the centre of the map, the latter to the transverse direction. The product $\sigma\sigma'$ gives the exaggeration of areas. With respect to the alteration of angles we have

$$\Sigma = \frac{h + \cos u}{1 + h\cos u},$$

and the greatest alteration of angle is

$$= \sin^{-1}\left(\frac{h-1}{h+1}\tan^2\frac{u}{2}\right).$$

This vanishes when $h = 1$, that is, if the projection be stereographic; or for $u = 0$, that is, at the centre of the map. At a distance of 90° from the centre, the greatest alteration is $90° - 2\cot^{-1}\sqrt{h}$. (See *Philosoph. Mag.*, April 1862.)

The constants h and k can be determined, so that the total misrepresentation, viz.,

$$M = \int_0^\beta \left\{(\sigma - 1)^2 + (\sigma' - 1)^2\right\}\sin u\,du,$$

shall be a minimum, β being the greatest value of u, or the spherical radius of the map. On substituting the expressions for σ and σ' the integration is effected without difficulty. Put

$$\lambda = \frac{1 - \cos\beta}{h + \cos\beta}\,;\quad \nu = (h-1)\lambda,$$

$$H = \nu - (h+1)\log_e(\lambda + 1),$$

$$H' = \frac{\lambda}{h+1}(2 - \nu + \tfrac{1}{3}\nu^2).$$

Then the value of M is

$$M = 4\sin^2\tfrac{1}{2}\beta + 2kH + k^2H',$$

When this is a minimum

$$\frac{dM}{dh} = 0;\quad \frac{dM}{dk} = 0.$$

$$\therefore\ kH' + H = 0;\quad 2\frac{dH}{dh} + k\frac{dH'}{dh} = 0.$$

Therefore $M = 4\sin^2\frac{1}{2}\beta - \frac{H^2}{H'}$, and h must be determined so as to make $H^2 : H'$ a maximum. In any particular case this maximum can only be ascertained by trial, that is to say, $\log H^2 - \log H'$ must be calculated for certain equidistant values of h, and then the particular value of h which corresponds to the required maximum can be obtained by interpolation. Thus we find that if it be required to make the best possible perspective representation of a hemisphere, the values of h and k are $h = 1{\cdot}47$ and $k = 2{\cdot}034$; so that in this case

$$\rho = \frac{2{\cdot}034\sin u}{1{\cdot}47 + \cos u}.$$

For a map of Africa or South America, the limiting radius β we may take as 40°; then in this case

$$\rho = \frac{2{\cdot}543\sin u}{1{\cdot}625 + \cos u}.$$

For Asia, $\beta = 54°$, and the distance h of the point of sight

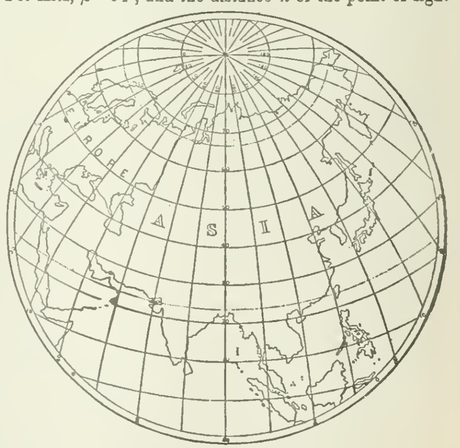

Fig. 18.

in this case is 1·61. Fig. 18 is a map of Asia having the meridians and parallels laid down on this system.

Figure 19 is a perspective representation of more than a hemisphere, the radius β being 108°, and the distance h of the point of vision, 1·40.

The co-ordinates xy of any point in this perspective may be expressed in terms of the latitude and longitude of the corresponding point on the sphere in the following manner. The co-ordinates originating at the centre, take the central meridian for the axis of y and a line perpendicular to it for the axis of x. Let the latitude of the point G, which is to occupy the centre of the map, be γ; if ϕ, ω be the latitude and longitude of any point P (the longitude being reckoned from the meridian of G), u the distance PG, and μ the

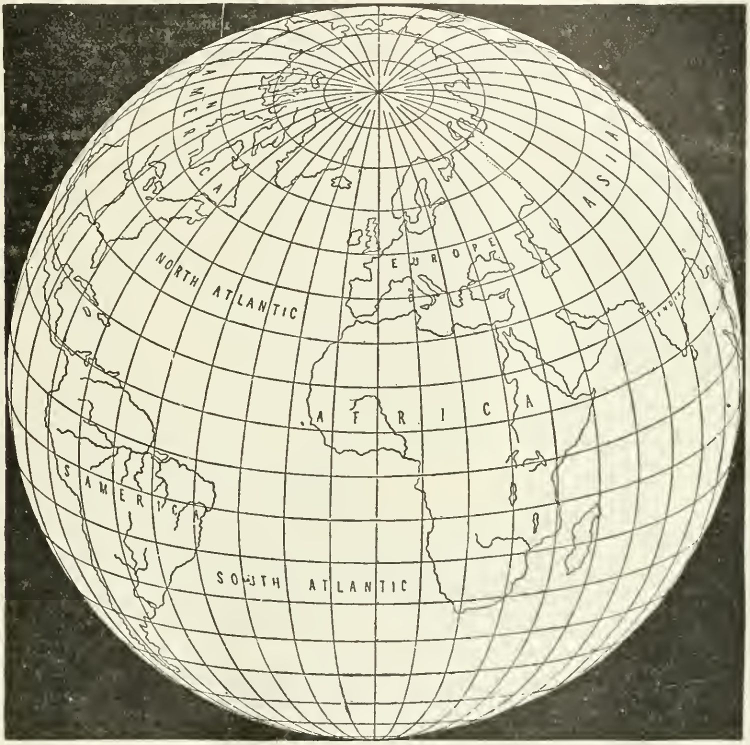

FIG. 19.—Twilight Projection.

azimuth of P at G, then the spherical triangle whose sides are $90° - \gamma$, $90° - \phi$, and u gives these relations—

$$\sin u \sin \mu = \cos \phi \sin \omega,$$
$$\sin u \cos \mu = \cos \gamma \sin \phi - \sin \gamma \cos \phi \cos \omega,$$
$$\cos u = \sin \gamma \sin \phi + \cos \gamma \cos \phi \cos \omega.$$

Now $x = \rho \sin \mu$, $y = \rho \cos \mu$, that is,

$$\frac{x}{k} = \frac{\cos \phi \sin \omega}{h + \sin \gamma \sin \phi + \cos \gamma \cos \phi \cos \omega},$$
$$\frac{y}{k} = \frac{\cos \gamma \sin \phi - \sin \gamma \cos \phi \cos \omega}{h + \sin \gamma \sin \phi + \cos \gamma \cos \phi \cos \omega},$$

by which x and y can be computed for any point of the sphere. If from these equations we eliminate ω, we get the equation to the parallel whose latitude is ϕ; it is an ellipse whose centre is in the central meridian, and its greater axis perpendicular to the same. The radius of curvature of this ellipse at its intersection with the centre meridian is

$$\frac{k \cos \phi}{h \sin \gamma + \sin \phi}.$$

The elimination of ϕ between x and y gives the equation of the meridian whose longitude is ω, which also is an ellipse whose centre and axes may be determined.

The following table contains the computed co-ordinates for a map of Africa, which is included between latitudes 40° north and 40° south, and 40° of longitude east and west of a central meridian.

ϕ	Values of x and y.				
	$\omega=0°$	$\omega=10°$	$\omega=20°$	$\omega=30°$	$\omega=40°$
0°	$x=$ 0·00	9·69	19·43	29·25	39·17
	$y=$ 0·00	0·00	0·00	0·00	0·00
10°	$x=$ 0·00	9·60	19·24	28·95	38·76
	$y=$ 9·69	·9·75	9·92	10·21	10·63

Conical Development.

The conical development is adapted to the construction of maps of tracts of country of no great extent in latitude but any extent in the direction of a parallel. Selecting the mean parallel, or that which most nearly divides the area to be represented, we have to consider the cone which touches the sphere along that parallel. In fig. 20, which is an orthographic projection of the sphere on a meridian plane, let Pp be the parallel of contact with the cone. ON being the axis of revolution, the tangents at P and p will intersect ON produced in V. Let Qq be a parallel to the north of Pp, Rr another parallel the same distance to the south, that is, $PQ = PR$. Take on the tangent PV two points H, K such that $PH = PK$, each being made equal to the arc PQ. It is clear, then, that the surface generated by HK is very nearly coincident with the surface generated by RQ when the figure rotates round ON through any angle, great or small. The approximation of the surfaces will, however, be very close only if QR is very small. Suppose, now, that the paths of H and K, as described in the revolution round ON, are actually marked on the surface of the cone, as well as the line of contact with the sphere. And further, mark the surface of the cone by the intersections with it of the meridian planes through OV at the required equal intervals. Then let the cone be cut along a generating line and opened out into a plane, and we shall have a representation as in fig. 21 of the spherical surface contained between the latitudes of Q and R. The parallels here are represented by concentric circles, the meridians by lines drawn through the common centre of the circles at equal angular intervals. Taking the radius of the sphere as unity, and ϕ being the latitude of P, we see that $VP = \cot\phi$, and if ω be the difference of longitude between two meridians, the corresponding length of the arc Pp is $\omega\cos\phi$. The angle between these meridians themselves is $\omega\sin\phi$.

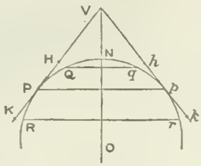

Fig. 20.

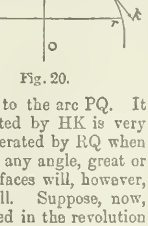

Fig. 21.

Suppose, now, we require to construct a map on this principle for a tract of country extending from latitude $\phi - m$ to $\phi + m$, and covering a breadth of longitude of $2n$, m and n being expressed in degrees. In fig. 21 let $HKkh$ be the quadrilateral formed by the extreme lines, so that $HK = hk = 2m$; then the angle HVh is $2n\sin\phi$ expressed in degrees. Now, taking the length of a degree as the unit, $VP = 57{\cdot}296\cot\phi$, and $VH = 57{\cdot}296\cot\phi - m$. It may be convenient in the first instance to calculate the chords Hh, Kk, and thus construct the rectilinear quadrilateral $HKkh$. The lengths of these chords are

$$Hh = 2(57{\cdot}296\cot\phi - m)\sin(n\sin\phi),$$
$$Kk = 2(57{\cdot}296\cot\phi + m)\sin(n\sin\phi),$$

and the distance between them is $2m\cos(n\sin\phi)$. The inclined sides of this trapezoid will then meet in a point at V, whose distance from P and p must correspond with the calculated length of VP. Now with this centre V describe the circular arcs representing the parallels through H, K, P. Also if the parallels are to be drawn at every degree of latitude, divide HK into $2m$ equal parts, and through each point of division describe a circular arc from the centre V. Then divide Pp into $2n$ equal parts, and draw the meridian lines through each of these points of division and the centre V.

If the centre V be inconveniently far off, it may be necessary to construct the centre parallel by points, that is, by calculating the coordinates of the various points of division. For this purpose, draw through the intersection of the centre meridian and centre parallel a line perpendicular to the meridian and therefore touching the parallel. Let the coordinate x be measured from the centre along this line, and y perpendicular to it. Then the coordinates of a point whose longitude measured from the centre meridian is ω are

$$x = \cot\phi\sin(\omega\sin\phi),$$
$$y = 2\cot\phi\sin^2\tfrac{1}{2}(\omega\sin\phi) = x\tan\tfrac{1}{2}(\omega\sin\phi),$$

the radius of the sphere being the unit; if a degree be the unit, these must be multiplied by $57{\cdot}296$.

The great defect of this projection is the exaggeration of the lengths of parallels towards either the northern or southern limits of the map. Various have been the devices to remedy this defect, and amongst these the following is a system very much adopted. Having subdivided the central meridian and drawn through the points of division the parallels precisely as described above, then the true lengths of degrees are set off along *each* parallel; the meridians, which in this case become curved lines, are drawn through the corresponding points of the parallels (fig. 22).

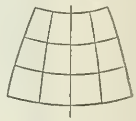

Fig. 22.

This system is that which was adopted in 1803 by the "Dépôt de la Guerre" for the map of France, and is there known by the title "*Projection de Bonne.*" It is that on which the Ordnance Survey map of Scotland on the scale of one inch to a mile is constructed, and it is frequently met with in ordinary atlases. It is ill-adapted for countries having great extent in longitude, as the intersections of the meridians and parallels become very oblique—as will be seen on examining the map of Asia in most atlases. If ϕ_0 be taken as the latitude of the centre parallel, and co-ordinates be measured from the intersection of this parallel with the central meridian, as in the case of the conical projection, then, if ρ be the radius of the parallel of latitude ϕ, we have $\rho = \cot\phi_0 + \phi_0 - \phi$. Also, if S be a point on this parallel whose co-ordinates are x, y, so that $VS = \rho$, and θ be the angle VS makes with the central meridian, then $\rho\theta = \omega\cos\phi$; and

$$x = \rho\sin\theta,\quad y = \cot\phi_0 - \rho\cos\theta.$$

Now, if we form the differential coefficients of x and y with respect to ϕ and ω, the latitude and longitude of S, we get

$$m'n - mn' = \cos\phi,$$
$$mn + m'n' = \frac{\omega}{\rho}\cos\phi(\cos\phi - \rho\sin\phi);$$

the first of which equations proves that the areas are truly represented. Moreover, if $90° \pm \psi$ be the angles of intersections of meridians and parallels,

$$\tan\psi = \theta - \omega\sin\phi,$$

which indeed might have been more easily obtained. In the case of Asia, the middle latitude $\phi_0 = 40°$, and the extreme northern latitude is 70°. Also the map extends 90° of longitude from the central meridian; hence, at the north-west and north-east corners of the map the angles of intersection of meridians and parallels are $90° \pm 33°{\cdot}54'$. But for comparatively small tracts of country, as France or Scotland, this projection is very suitable.

Another modification of the conical projection consists in taking, not a tangent cone, but a cone which, having its vertex in the axis of revolution produced, intersects the sphere in two parallels,—these parallels being approximately midway between the centre parallel of the country and the extreme parallels. By this means part of the error is thrown on the centre parallel which is no longer represented by its true length, but is made too small, while the parallels forming the intersections of the cone are truly represented in length.

The exact position of these particular parallels may be determined so as to give, upon the whole, the least amount of exaggeration for the entire map. This idea of a cutting cone seems to have originated[1] with the celebrated Gerard Mercator, who in 1554 made a map of Europe on this principle, selecting for the parallels of intersection those of 40° and 60°. The same system was adopted in 1745 by De-lisle for the construction of a map of Russia. Euler in the *Acta Acad. Imp. Petrop.*, 1778, has discussed this projection and determined the conditions under which the errors at the northern extremity, at the centre, and at the southern extremity of a map so constructed shall be severally equal. Let c, c' be the co-latitudes of the extreme northern and southern parallels, γ, γ' those of two intermediate parallels, which are to be truly represented in the projection. Let OC′, Om' (fig. 23) be two consecutive meridians, as represented in the developed cone; the difference of longitude being ω, let the angle at O be $h\omega$. The degrees along the meridian being represented by their proper lengths, $CC' = c' - c$; and P corresponding to the pole, let $OP = z$, then $OC = z + c$; and so for G, G′, C′. The true lengths of G′n' and Gn, namely, $\omega \sin \gamma'$ and $\omega \sin \gamma$, are equal to the represented lengths, namely, $h\omega(z+\gamma')$ and $h\omega(z+\gamma)$ respectively, whence γ and γ' are known when h and z are known. Comparing now the represented with the true lengths of parallel at the extremities and at the centre, if e be the common error that is to be allowed, then

Fig. 23.

$$e = h\omega(z+c) - \omega \sin c,$$
$$e = -h\omega(z + \tfrac{1}{2}c + \tfrac{1}{2}c') + \omega \sin \tfrac{1}{2}(c+c'),$$
$$e = h\omega(z+c') - \omega \sin c'.$$

The difference of the first and third gives h, and then subtracting the second from the mean of the first and third, we get

$$z + \tfrac{1}{2}(c+c') = \tfrac{1}{2}(c'-c) \cot \tfrac{1}{2}(c'-c) \tan \tfrac{1}{2}(c'+c).$$

Thus z being known, the common centre of the circles representing the parallels is given. The value of h is given by the equation $h(c'-c) = \sin c' - \sin c$, and γ and γ' can be easily computed. But there is no necessity for doing this as we may construct the angles at O, which representing a difference of longitude ω are in reality equal to $h\omega$.

For instance, to construct a map of Asia on this system, having divided the central meridian into equal spaces for degrees, z must be calculated. Here we have $c = 20°$, $c' = 80°$, whence $z + 50° = 15° \tan 50° \cot 15° = 66°{\cdot}7$. Hence in this case the centre of the circles is 16°·7 beyond the north pole; also $h = {\cdot}6138$, so that a difference of longitude of 5° is represented at O by an angle of 3° 4′ 9″. The degrees of longitude in the parallel of 70° are in this map represented too large in the ratio of 1·150 : 1; those in the mid-latitude of 40° are too small in the ratio of 0·933 : 1; and those in 10° latitude are too large in the ratio of 1·05 to 1.

Gauss's Projection

may be considered as another variation of the conical system of development. Meridians are represented by lines drawn through a point, and a difference of longitude ω is represented by an angle $h\omega$, as in the preceding case. The parallels of latitude are circular arcs, all having as centre the point of divergence of the meridian lines, and the law of their formation is such that the representations of all small parts of the surface shall be precisely similar to the parts so represented. Let u be the co-latitude of a parallel, and ρ, a function of u, the radius of the circle representing this parallel. Consider the infinitely small space on the sphere contained by two consecutive meridians the difference of longitude of which is $d\mu$, and two consecutive parallels whose co-latitudes are u and $u+du$. The sides of this rectangle (fig. 24) are $pq = du$, $pr = \sin u d\mu$, whereas in the representation $p'q'r's'$, $p'q' = d\rho$, $p'r' = \rho h d\mu$, the angle at O being $= h d\mu$. Now, as the representation is to be similar to the original,

$$\frac{p'q'}{p'r'} = \frac{d\rho}{h\rho d\mu} = \frac{pq}{pr} = \frac{du}{\sin u d\mu},$$

whence $\dfrac{d\rho}{\rho} = h \dfrac{du}{\sin u}$, and integrating,

$$\rho = k\left(\tan \frac{u}{2}\right)^h,$$

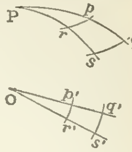

Fig. 24.

where the constant h is to be determined according to the requirements of each individual case. This investigation was first made in 1772 by the German mathematician J. H. Lambert,[2] but in 1825 it was again brought forward by Gauss in an essay written in answer to a prize question proposed by the Royal Society of Sciences at Copenhagen. A translation of this essay is to be found in the *Philosophical Magazine* for 1828 (see page 112), where Lambert's projection comes out as a particular solution of the general problem. Again, in a general investigation of the problem of "similar representation," Sir John Herschel, in the 30th volume of the *Journal of the Royal Geographical Society* (1860), deduced as a particular case this same projection. A large map of Russia was constructed and published on this system by the Geographical Society of St Petersburg in 1862.

The relative scale in this development is—

$$\frac{d\rho}{du} = \frac{hk}{a} \cdot \frac{\left(\tan \frac{u}{2}\right)^h}{\sin u},$$

where a is the radius of the sphere. It is a minimum when $u = \cos^{-1} h$. This minimum should occur in the vicinity of the central parallel of the map; if u_0 be the co-latitude of this parallel, we may put

$$\rho = k\left(\tan \frac{u}{2}\right)^{\cos u_0}.$$

Or if we agree that the scale of the representation shall be the *same* at the extreme co-latitudes c, c', then

$$h = \frac{\log \sin c' - \log \sin c}{\log \tan \frac{1}{2}c' - \log \tan \frac{1}{2}c}.$$

To construct a map of North America extending from 10° latitude to 70°, we may take $h = \frac{2}{3}$, and k such as shall make the difference of radii of the extreme parallels $= 60$, namely $k = 104{\cdot}315$. The scales of the representation at the northern and southern limits are 1·116 and 1·096 respectively. The radii of the parallels are these—

70° . . .	32·801	30° . . .	72·328
60° . . .	43·356	20° . . .	82·255
50° . . .	53·177	10° . . .	92·801
40° . . .	62·728	0° . . .	104·315

Having drawn a line representing the central meridian, and selected a point on it as the centre of the concentric circles, let arcs be described with the above radii as parallels. For meridians, in this system a difference of longitude of 10° is represented by an angle of two-thirds that amount, or 6° 40′. The chord of this angle on the parallel of 10°, whose radius is 92·801, is easily found to be 10·792. Now stepping this quantity with a pair of compasses along the parallel, we have merely to draw lines through each of the points so found and the common centre of circles. The points of division of the parallel may be checked by taking the chord of 20°, or rather of 13° 20′,

[1] See page 178 of *Traité des Projections des Cartes Géographiques*, by A. Germain, Paris, an admirable and exhaustive essay. See also the work entitled *Coup d'œil historique sur la Projection des Cartes de Géographie*, by M. d'Avezac, Paris, 1863.

[2] *Beiträge zum Gebrauche der Mathematik und deren Anwendung*, vol. iii. p. 55, Berlin, 1772.

which is 21·547. The map of North America so found (fig. 25) shows small portions of country in strictly correct forms; but the areas are slightly too great at the extreme latitudes and too small in the centre. At any part of the map a degree of latitude may be used as the true scale in any direction.

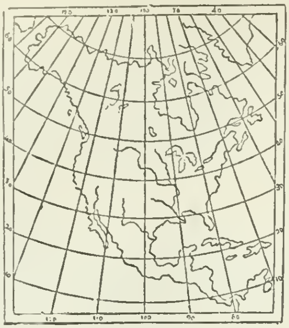

Fig. 25.

The value $h=\frac{1}{3}$, as suggested by Sir John Herschel, is admirably suited for a map of the world. The representation is fan-shaped, with remarkably little distortion (fig. 26).

It follows from what has been said above that the condition that the scale is true at the equator is $hk=a$, which determines k when h is given. The radius of the parallel whose co-latitude is u being ρ, let r be the distance of that parallel from the equator; then, keeping to the condition that the scale is true at the equator,

$$\rho=\frac{a}{h}\tan^h\frac{u}{2},$$

$$r=\frac{a}{h}\left(1-\tan^h\frac{u}{2}\right).$$

When h is very small, the angles between the meridian lines in the representation are very small; and proceeding to the limit, when h is zero the meridians are parallel, that is, the vertex of the cone has removed to infinity. And at the limit when h is zero we have

$$r=a\log_e\cot\frac{u}{2},$$

which is the characteristic equation of

Mercator's Projection.

From the manner in which we have arrived at this projection it is clear that it retains the characteristic property of Gauss's projection,—namely, similarity of representation of small parts of the surface. In Mercator's chart the equator is represented by a straight line, which is crossed at right angles by a system of parallel and equidistant straight lines representing the meridians. The parallels are straight lines parallel to the equator, and the distance of the parallel of latitude ϕ from the equator is, as we have seen above, $r=a\log_e\tan(45°+\frac{1}{2}\phi)$. In the vicinity of the equator, or indeed within 30° of latitude of the equator, the representation is very accurate, but as we proceed northwards or southwards the exaggeration of area becomes larger, and eventually excessive,—the poles being at infinity. This distance of the parallels may be expressed in the form $r=a(\sin\phi+\frac{1}{3}\sin^3\phi+\frac{1}{5}\sin^5\phi+\ldots.)$, showing that near the equator r is nearly proportional to the latitude. As a consequence of the similar representation of small parts, a curve drawn on the sphere cutting all meridians at the same angle—the loxodromic curve—is projected into a straight line, and it is this property which renders Mercator's chart so valuable to seamen. For instance: join by a straight line on the chart Land's End and Bermuda, and measure the angle of intersection of this line with the meridian. We get thus the bearing which a ship has to retain during its course between these ports. This is not great-circle sailing, and the ship so navigated does not take the shortest path. The projection of a great circle (being neither a meridian nor the equator) is a curve which cannot be represented by a simple algebraic equation.

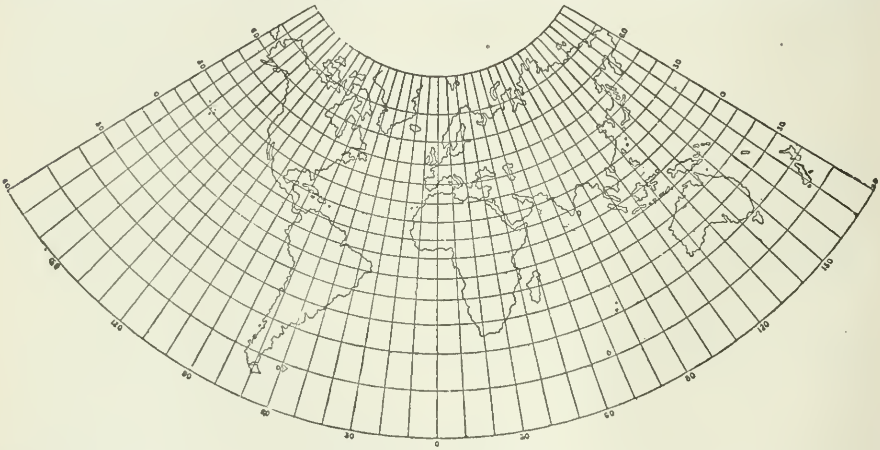

Fig. 26.—Fan-shaped Map of the World.

If we apply Mercator's system of projection *along a meridian*, as proposed by Lambert, we have the representation of all possible great circles. The diagram (fig. 27) gives the projection. The two vertical bounding lines are the equator—crossed at right angles by the initial meridian passing through one of the poles. From the form of the representations of parallels round the pole it is clear that the distortion up to a distance of 30° or 40° from the initial meridian is not at all great. The representation extends to infinity upwards and downwards, and the left and right half are interchangeable; if interchanged the representation is on a meridian extending from pole to pole.

The meridian Mercator drawn as described in the last paragraph—with the meridians and parallels rather close—

may be made to serve the important purpose of enabling one to trace on the ordinary Mercator's chart the track of a great circle joining any two places, and of indicating at the same time the distance of the two places. For this

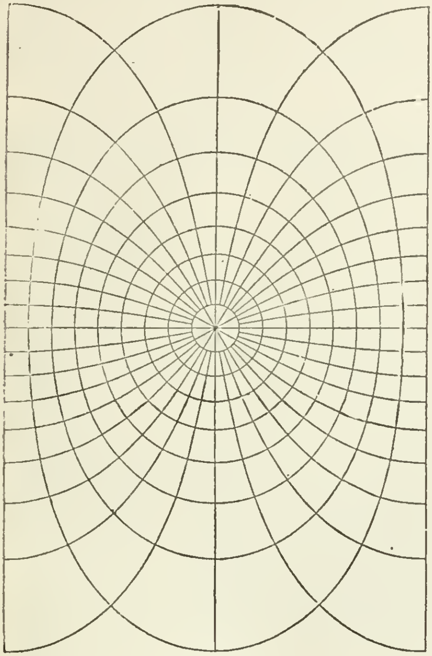

Fig. 27.

purpose the two charts must be on the same scale, one of them being on tracing paper or tracing linen. The transparent chart being placed over the other, the equator in the ordinary chart must coincide with the initial meridian in the meridian Mercator. Retaining this relative position, let the upper chart be moved until the two points (the projection of the great circle joining which is required) on the ordinary Mercator are found to lie on a great circle of the meridian Mercator.

The curvatures of the meridians and parallels in the meridian Mercator are expressed by very simple formulæ. Let x, y be the coordinates, measured from the pole along and perpendicular to the initial meridian, of any point S of the representation,—x corresponding to an arc of the sphere $= x$, and y to an arc η which is on the sphere the distance of S from the initial meridian. Then if x', y' be the centre of curvature of the parallel at S, x'', y'' the centre of curvature of the meridian at S,

$$x' = x - \tan x\ , \quad x'' = x + \frac{1}{\tan x}\ ,$$

$$y' = y - \sin \eta\ , \quad y'' = y - \frac{1}{\sin \eta}\ .$$

The corresponding radii of curvature are $\sin\beta \div \cos x$, where β is the spherical radius of the small circle, and $1 \div \sin x \sin \gamma$, where γ is the longitude of the great circle, counted from the initial meridian.

Polyconic Development.

Imagine a hollow globe formed of a mere surface of paper, to be cut by a system of parallel planes along equidistant parallels of latitude; let also one meridian be cut through, from north pole to south pole, 180°. In this state let the whole be opened out into a plane from the meridian exactly opposite to the one cut through, and the previously spherical surface is converted into a number of strips of paper, each of which is part of a circular belt, with the exception of the equator, which will be straight. All points which lay on the parallel whose co-latitude is u now lie on an arc of a circle whose radius is $\tan u$ and length $2\pi \sin u$; moreover, the centres of these arcs lie in the same straight line, which is the central meridian produced. The parallels being now defined, we must define meridians. These may be formed by laying off on each parallel the degrees of longitude according to their true lengths, which is the system adopted in the maps of the United States Coast Survey. Or we may take for meridians that system of lines which cuts the parallels at right angles, forming the rectangular polyconic system.

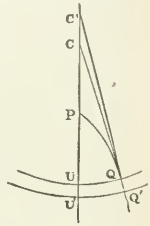

Fig. 28.

In this case, let P (fig. 28) be the north pole, CPU the central meridian, U, U′ points in that meridian whose co-latitudes are u and $u+du$, so that $UU' = du$. Make $PU = u$, $UC = \tan u$, $U'C' = \tan(u+du)$; and with CC′ as centres describe the arcs UQ, U′Q′, which represent the parallels of co-latitude u and $u+du$. Let PQQ′ be part of a meridian curve cutting the parallels at right angles. Join CQ, C′Q′; these being perpendicular to the circles will be tangents to the curve. Let $UCQ = 2\phi$, $UC'Q' = 2(\phi + d\phi)$, then the small angle CQC′, or the angle between the tangents at QQ′, will $= 2d\phi$. Now

$$CC' = C'U' - CU - UU' = \tan(u + du) - \tan u - du = \tan^2 u\, du\ ;$$

and in the triangle CC′Q the perpendicular from C on C′Q′ is equal to either side of the equation

$$\tan^2 u\, du \sin 2\phi = -\tan u\, d\phi.$$

$$-\tan u\, du = \frac{2d\phi}{\sin 2\phi}\ ,$$

which is the differential equation of the meridian: the integral is $\tan\phi = \omega \cos u$, where ω, a constant, determines a particular meridian curve. The distance of Q from the central meridian, $\tan u \sin 2\phi$, is equal to

$$\frac{2 \tan u \tan \phi}{1 + \tan^2\phi} = \frac{2\omega \sin u}{1 + \omega^2 \cos^2 u}$$

At the equator this becomes simply 2ω. Let any equatorial point whose actual longitude is 2ω be represented by a point on the developed equator at the distance 2ω from the central meridian, then we have the following very simple construction (due to Mr O'Farrell of the Ordnance Survey Office) Let P (fig. 29) be the pole, U any point in the central meridian, QUQ′ the represented parallel whose radius $CU = \tan u$. Draw SUS′ perpendicular to the meridian through U; then to determine the point Q, whose longitude is, say, 3°, lay off US equal to half the true length of the arc of parallel on the sphere, *i.e.*, 1° 30′ to radius sin u, and with the centre S and radius SU describe a circular arc, which will intersect the parallel in the required point Q. For if we suppose 2ω to be the longitude of the required point Q, US is by construction $= \omega \sin u$, and the angle subtended by SU at C is

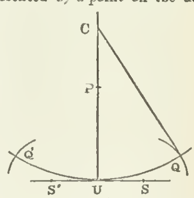

Fig. 29.

$$\tan^{-1}\left(\frac{\omega \sin u}{\tan u}\right) = \tan^{-1}(\omega \cos u) = \phi\ ,$$

and therefore $UCQ = 2\phi$, as it should be. The advantages of this method are that with a remarkably simple and convenient mode of construction we have a map in which the parallels and meridians intersect at right angles.

The following table contains the lengths of the radii for describing parallels, and also the lengths of degrees of longitude for every 5° of latitude,—the radius of the sphere being 57·296.

Lat.	Radius for Parallel.	Degree of Longitude.	Lat.	Radius for Parallel.	Degree of Longitude.
0°	∞	1·0000	45°	57·30	·7071
5	654·89	·9962	50	48·08	·6428
10	324·94	·9848	55	40·12	·5736
15	213·83	·9659	60	33·08	·5000
20	157·42	·9397	65	26·72	·4226
25	122·87	·9063	70	20·85	·3420
30	99·24	·8660	75	15·35	·2588
35	81·83	·8191	80	10·10	·1736
40	68·28	·7660	85	5·01	·0872

With regard to the distortion involved in this system of development, consider a small square described on the surface of the sphere, its sides being parallel to and perpendicular to the meridian. Let u and 2ω define its position, and let i be the length of its side. If we differentiate the equation $\tan\phi = \omega\cos u$, u being constant, $\sec^2\phi\, d\phi = \cos u\, d\omega$. But the representation of $2d\omega$ is $2\tan u d\phi$, which is equal to $\sin u \cos^2\phi\, d.2\omega$; hence that side of the square which is parallel to the equator is represented by $i\cos^2\phi$. And similarly the meridional side is represented by

$$i\cos^2\phi(1+\omega^2+\omega^2\sin^2 u).$$

Therefore the square is represented by a rectangle whose sides are in the proportion of

$$1 : 1+\omega^2+\omega^2\sin^2 u,$$

and its area is increased in the proportion of

$$1+\omega^2+\omega^2\sin^2 u : (1+\omega^2\cos^2 u)^2.$$

Fig. 30 is a representation on this system of the continents of Europe and Africa, for which it is well suited. For Asia this system would not do, as in the northern latitudes, say along the parallel of 70°, the representation is much cramped.

Fig. 30.

With regard to the distortion in the map of Africa as thus constructed, consider a small square in latitude 40° and in 40° longitude east or west of the central meridian, the square being so placed as to be transformed into a rectangle. The sides, originally unity, become 0·95 and 1·13, and the area 1·08, the diagonals intersecting at 90° ± 9° 56′. In the perspective projection a square of unit side occupying the same position, when transformed to a rectangle, has its sides 1·02 and 1·15, its area 1·17, and its diagonals intersect at 90° ± 7° 6′. The latter projection is therefore the best in point of "similarity," but the former represents areas best This applies, however, only to a particular part of the map; along the equator tow ds 30° or 40° longitude, the polyconic is certainly in rior, while along the meridian it is better than the perspective—except, of course, near the centre. Upon the whole, the more even distribution of distortion gives the advantage to the perspective system. The system of lines ordinarily used for the map of Africa is objectionable, and has scarcely the excuse of facility of construction, since the perspective coordinates given above are so easily computed.

Ordnance Survey Maps.

The method of development used in the Ordnance Survey maps of England on the scale of one inch to a mile, as also in the county maps of England, Scotland, and Ireland, on the 6-inch scale is this. A central meridian having been selected, let a perpendicular arc be drawn from any trigonometrical station p to the meridian, meeting it in q. S being a point of reference selected in the central meridian, make $Sq = y$, $pq = x$. Then in the development, a straight line drawn to represent the central meridian is the axis of y, and a line at right angles to this is the axis of x. The point whose coordinates are $x = pq$, $y = Sq$ is the representation of p. Supposing the earth spherical, if ϕ, ω be the latitude and longitude of p, then, ω being small, that is, only a few degrees,

$$dx = \quad -y\tan\phi\, d\phi + \cos\phi(1-\tfrac{1}{2}x^3\tan^2\phi)d\omega,$$
$$dy = (1+\tfrac{1}{2}x^2-\tfrac{1}{2}x^2\tan^2\phi)d\phi \quad + \quad x\sin\phi\, d\omega,$$

from which the distortion can be computed. It principally consists in the exaggeration of the scale in a north-and-south direction at the extreme longitudes, where $\sigma = \sec x$.

Contours.

In maps of a large scale, it is usual to show the relief of the ground by contour lines, which are the intersections with the actual surface of a system of equidistant horizontal planes. Contours indicate not only the height of the ground but its slope. Fig. 31 shows a piece of contoured country, including two summits and a "col" between them.

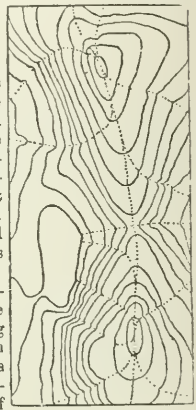

Fig. 31.

The dotted lines, which, however, are not shown in maps, are lines of greatest slope, cutting contours at right angles. At each summit, supposing the contours there to be ellipses (Dupin's indicatrices), there is an infinity of steepest lines having a common tangent there. At the col, where the indicatrix is an hyperbola, there are two steepest lines intersecting at right angles, of which one is the "water-shed" joining the summits. (A. R. C.)

III. Physical Geography.

This term in its ordinary acceptation means a description of the physical features of the earth. It includes an account of the phenomena of the atmosphere; of the composition, distribution, and movements of the sea; of the forms of the land, with its water circulation, earthquakes, and volcanoes; of the distribution of plant and animal life. Its object, however, is not to present a mere bald enumeration of facts, but to group the facts together in such a way as to bring before the mind a luminous picture of the whole structure and working of the earth as a habitable planet. Physical geography is not so much a science or branch of science as a collection of the data ascertained, and probable conclusions arrived at, by different sciences, in so far as these bear upon its own subject. Accordingly, it culls from all departments of inquiry whatever helps to give additional distinctness and vividness to that broad conception of the daily economy of the globe which it is its aim to form and develop.

So vast a subject, if treated in its entirety, would demand a very large allotment of space for its adequate discussion. Some of its branches have, during the last few years, received so much development that in the present edition of this work it has been considered more expedient to make them the subject of special articles; and here, therefore, to avoid the repetition which a general article on physical geography would involve, there will be given, instead of a formal essay, a mere outline or synopsis of the branches of knowledge embraced in the subject, with references to the other parts of the work where detailed information may be looked for. In the first three parts of the article GEOLOGY, a large section of what is usually included under physical geography will be found.

1. *The Earth in its Cosmical Relations.*—From astronomy we learn the shape and size of the earth, its motions of rotation round its axis and of revolution in an elliptical orbit round the sun, the origin of day and night, and of the seasons. Speculating on the original condition of the whole solar system, we may regard it as having been in the condition of a nebula, gradually contracting, condensing, and leaving behind successive rings, which on disruption and reaggregation formed planets. Hence the primitive condition of our globe as a separate mass must have been gaseous or fluid. Since that time the earth has been cooling and contracting, but still retains a high residual temperature in its interior. This original condition, and the internal heat of the earth, must be constantly kept in view as an explanation of many of the features of its outer surface. See GEOLOGY, part i.; ASTRONOMY, chapter i.; GEOGRAPHY (MATHEMATICAL); GEODESY.

2. *The Atmosphere or Gaseous Envelope of the Earth.*—The solid planet is covered by two envelopes, one of gas which completely surrounds it, and one of water, which occupies about three-fourths of its surface. In studying the atmosphere we have to consider its height, its composition, its temperature, its moisture, and its pressure (see ATMOSPHERE, METEOROLOGY). Its height must be at least 40 or 50 miles. This deep gaseous ocean consists of a mixture of the two gases, oxygen (21 parts by weight) and nitrogen (79 parts), with a minute proportion of carbonic acid (·004) and of aqueous vapour. The physical geographer takes note of the manifold importance of oxygen, not only in supporting animal life, but in the general oxidation of the earth's outer crust. He recognizes the atmospheric carbonic acid as the source of the carbon built up into the structure of plants. He cannot contemplate without ever-increasing wonder and delight the coming and going of the water-vapour in the air, as it rises incessantly from every sea and land, and after condensation into visible form courses over the land as rain, brooks, rivers, and glaciers (see GEOLOGY, part iii.). The consideration of the temperature of the atmosphere elicits the facts that temperature falls as we rise above the sea-level, and as we recede from the equator to the poles, and that it is profoundly affected by the relative positions of sea and land. The want of strict dependence upon latitude in this distribution of temperature is strikingly brought out by the contrast between the mean temperature of Labrador and Ireland on the same parallels (see CLIMATE, ISOTHERMS). In dealing with the moisture of the air we have to consider the phenomena of evaporation and condensation, the formation of dew, clouds, rain, snow, and hail, the distribution of rain, the position of the snow-line, the occurrence of deserts, &c. (see METEOROLOGY). The study of the pressure of the atmosphere, which appears to vary with variations in temperature and amount of vapour, brings before us the cause of the constant aerial movements. The law has now been well established that air always flows out from tracts where the barometric pressure is high into those where it is low. A knowledge of the distribution of pressure over the globe furnishes the key to the great movements of the atmospheric circulation. The trade winds, for example, blow constantly from a belt of high pressure towards the equator, where the pressure remains low. Periodic winds, like the monsoons and land and sea breezes, shift with the changes in atmospheric pressure. Thus Asia during winter is a vast region of high pressure; the winds round its margin therefore flow out towards the sea. In summer, on the other hand, it becomes a region of low pressure, and the winds consequently blow inland from the sea. Sudden and violent atmospheric movements, such as tempests and hurricanes, are illustrations of the same law, the force of the wind being always proportional to the shortness of the space between great extremes of pressure (see ATMOSPHERE).

3. *The Ocean or Water-Envelope of the Earth,* from the point of view of physical geography, presents for consideration the form of the basins in which it is contained, the shape and nature of their bottom, their submarine ridges and islands, the density and composition of the water, the distribution of marine temperature, the ice of the sea, and the movements of the ocean due to cosmical causes as in the tides, to the effects of winds as in surface drifts, currents, and waves, and to differences of temperature. The largest additions in recent years to our knowledge of the earth have been made in the ocean, notably by the different expeditions and cruises equipped for the purpose by the British Government. The climates of the sea have been systematically determined, and the extraordinary fact has been brought to light that the great mass of the ocean water is cold, or below 40° Fahr. Even in the equatorial parts of the ATLANTIC and PACIFIC OCEANS (*q.v.*), though the upper layers of water partake in the heat of the intertropical latitudes, a temperature of 40° is found within 300 fathoms of the surface, while at the bottom, at depths of 2500 or 3000 fathoms, the temperature (32°·4 to 33° Fahr.) is very little above that of the freezing-point of fresh water. It has been proved that the bottom temperature of every ocean in free communication with the poles has a temperature little different from that of the water in polar latitudes. Between Scotland and the Faroe Islands a sounding was obtained giving even a temperature of 29°·6, or 2·4 degrees below the freezing-point of fresh water, and very little above that of salt water. These observations warrant the conclusion that a vast system of circulation takes place in the ocean. The cold heavy polar water creeps slowly towards the equator under the upper lighter water, which moves away towards the poles.

4. *The Land.*—We have to consider the distribution of the land over the face of the globe, the grouping of the continents, the forms and trend of the great terrestrial ridges, the relation of coast-line to superficial area, the contours of the land, as mountains, table-lands, valleys, and plains, the relation of the continents to each other as regards general mass (see GEOLOGY, part ii.; AFRICA, AMERICA, ASIA, EUROPE). Over this framework of land there is a ceaseless circulation of water. The vapour raised by the sun's heat from every ocean and surface of water on the land, after being condensed into clouds and rain, falls in large measure upon the land, and courses over its surface from mountain to shore in brooks and rivers, which again have their own distinguishing phenomena, such as the formation of terraces, deltas, &c. Part of the water performs an underground circulation and returns to the surface in springs. Another portion falls as snow upon the mountains and descends into valleys in the form of glaciers. In this ceaseless flow of water from the summits to the sea we must recognize one of the great agencies by which the present contour of the land has been moulded (see GEOLOGY, part iii., section ii.).

The physical geographer collects, moreover, data which show the reaction of the earth's interior upon its surface,—proofs from bores and mines of a progressive increase of temperature downwards, the evidence of hot springs, and of earthquakes and volcanoes. He finds proofs of oscillations in the level of the land, some regions having been raised and others depressed within the times of human history. From the geologist he learns that such instability has characterized the outer crust of the planet from very ancient times, and that indeed it is to the results of terrestrial movements that we owe the existence of mountain ranges and even the dry land itself (see GEOLOGY, part iii., section i., and part vii.). He perceives that the present area of land on the earth's surface is the result of the balance of two antagonistic processes—the destruction caused by superficial agents on every portion of land exposed to their influence, and the periodic elevation, by subterranean action, of the land so wasted, or of new land from beneath the sea.

5. *Distribution of Animal and Vegetable Life.*—It is usual to include in treatises on physical geography an outline of the distribution of plants and animals, with an account of the great regions or provinces into which zoologists and botanists have divided the continents. The question naturally arises why the distribution should be as it is. Two answers obviously suggest themselves—1st, climate, and 2d, the power possessed by plants and animals of diffusing themselves. Yet climate only explains a part of this problem, and it is evident that migration cannot possibly account for the diffusion of innumerable organisms. There is a large residuum of unexplained phenomena on which much light is thrown by geological inquiry. Thus, for example, the presence of living Arctic forms of vegetation on the mountains of central Europe can be connected with the occurrence of the remains of Arctic animals in the superficial deposits of that region, and with other facts which make it clear that at no very distant date an Arctic climate prevailed over most of Europe, that at that time a northern vegetation spread southwards and covered the plains and heights of Europe even as far south as the Alps and Pyrenees, and that as the climate gradually ameliorated the northern vegetation was extirpated from the low grounds by the advance of plants better suited to the milder temperature, but continued to maintain its ground amid the congenial frosts and snows of the mountains, where to this day it still flourishes (see DISTRIBUTION). (A. GE.)

GEOLOGY

GEOLOGY is the science which investigates the history of the earth. Its object is to trace the progress of our planet from the earliest beginnings of its separate existence, through its various stages of growth, down to the present condition of things. It seeks to determine the manner in which the evolution of the earth's great surface features has been effected. It unravels the complicated processes by which each continent has been built up. It follows, even into detail, the varied sculpture of mountain and valley, crag and ravine. Nor does it confine itself merely to changes in the inorganic world. Geology shows that the present races of plants and animals are the descendants of other and very different races which once peopled the earth. It teaches that there has been a progress of the inhabitants, as well as one of the globe on which they dwelt; that each successive period in the earth's history, since the introduction of living things, has been marked by characteristic types of the animal and vegetable kingdoms; and that, however imperfectly they have been preserved or may be deciphered, materials exist for a history of life upon the planet. The geographical distribution of existing faunas and floras is often made clear and intelligible by geological evidence; and in the same way light is thrown upon some of the remoter phases in the history of man himself. A subject so comprehensive as this must require a wide and varied basis of evidence. It is one of the characteristics of geology to gather evidence from sources which at first sight seem far removed from its scope, and to seek aid from almost every other leading branch of science. Thus, in dealing with the earliest conditions of the planet, the geologist must fully avail himself of the labours of the astronomer. Whatever is ascertainable by telescope, spectroscope, or chemical analysis, regarding the constitution of other heavenly bodies, has a geological bearing. The experiments of the physicist, undertaken to determine conditions of matter and of energy, may sometimes be taken as the starting-points of geological investigation. The work of the chemical laboratory forms the foundation of a vast and increasing mass of geological inquiry. To the botanist, the zoologist, even to the unscientific, if observant, traveller by land or sea, the geologist turns for information and assistance.

But while thus culling freely from the dominions of other sciences, geology claims as its peculiar territory the rocky framework of the globe. In the materials composing that framework, their composition and arrangement, the processes of their formation, the changes which they have undergone, and the terrestrial revolutions to which they bear witness, lie the main data of geological history. It is the task of the geologist to group these elements in such a way that they may be made to yield up their evidence as to the march of events in the evolution of the planet. He finds that they have in large measure arranged themselves in chronological sequence,—the oldest lying at the bottom and the newest at the top. Relics of an ancient sea-floor are overlaid by traces of a vanished land-surface; these are in turn covered by the deposits of a former lake, above which once more appear proofs of the return of the sea. Among these rocky records lie the lavas and ashes of long-extinct volcanoes. The ripple left upon the shore, the cracks formed by the sun's heat upon the muddy bottom of a dried-up pool, the very imprint of the drops of a passing rain-shower, have all been accurately preserved, and yield their evidence as to geographical conditions widely different from those which exist where such markings are now found.

But it is mainly by the remains of plants and animals imbedded in the rocks that the geologist is guided in unravelling the chronological succession of geological changes. He has found that a certain order of appearance characterizes these organic remains, that each great group of rocks is marked by its own special types of life, and that these types can be recognized, and the rocks in which they occur can be correlated even in distant countries, and where no other means of comparison would be possible. At one moment he has to deal with the bones of some large mammal scattered through a deposit of superficial gravel, at another time with the minute foraminifers and ostracods of an upraised sea-bottom. Corals and crinoids crowded and crushed into a massive limestone where they lived and died, ferns and terrestrial plants matted together into a bed of coal where they originally grew, the scattered shells of a submarine sand-bank, the snails and lizards which lived and died within a hollow tree, the insects which have been imprisoned within the exuding resin of old forests, the footprints of birds and quadrupeds, the trails of worms left upon former shores—these, and innumerable other pieces of evidence, enable the geologist to realize in some measure what the faunas and floras of successive periods have been, and what geographical changes the site of every land has undergone.

It is evident that to deal successfully with these varied materials, a considerable acquaintance with different branches of science is needful. Especially necessary is a tolerably wide knowledge of the processes now at work in changing the surface of the earth, and of at least those forms of plant and animal life whose remains are apt to be preserved in geological deposits, or which in their structure and habitat enable us to realize what their forerunners were. It has often been insisted upon that the present is the key to the past; and in a wide sense this assertion is eminently true. Only in proportion as we understand the present, where everything is open on all sides to the fullest investigation, can we expect to decipher the past, where so much is obscure, imperfectly preserved, or not preserved at all. A study of the existing economy of nature ought thus to be the foundation of the geologist's training.

While, however, the present condition of things is thus employed, we must obviously be on our guard against the danger of unconsciously assuming that the phase of nature's operations which we now witness has been the same in all past time, that geological changes have taken place in former ages in the manner and on the scale which we behold to-day, and that at the present time all the great geological processes, which have produced changes in the past eras of the earth's history, are still existent and active. Of course we may assume this uniformity of action, and use the assumption as a working hypothesis. But it ought not to be allowed any firmer footing, nor on any account be suffered to blind us to the obvious truth that the few centuries wherein man has been observing nature form much too brief an interval, by which to measure the intensity of geological action in all past time. For aught we can tell the present is an era of quietude and slow change, compared with some of the eras which have preceded it. Nor can we be sure that, when we have explored every geological process now in progress, we have exhausted all the causes of change which, even in comparatively recent times, have been at work.

In dealing with the Geological Record, as the accessible solid part of the globe is called, we cannot too vividly realize that at the best it forms but an imperfect chronicle. Geological history cannot be compiled from a full and continuous series of documents. From the very nature of its origin the record is necessarily fragmentary, and it has been further mutilated and obscured by the revolutions of successive ages. And even where the chronicle of events is continuous, it is of very unequal value in different places. In one case, for example, it may present us with an unbroken succession of deposits many thousands of feet in thickness, from which, however, only a few meagre facts as to geological history can be gleaned. In another instance it brings before us, within the compass of a few yards, the evidence of a most varied and complicated series of changes in physical geography, as well as an abundant and interesting suite of organic remains. These and other characteristics of the geological record will become more apparent and intelligible as we proceed in the study of the science.

In the systematic treatment of the subject the following arrangement will here be followed:—

1. *The Cosmical Aspects of Geology.*—Under this head we may consider the evidence supplied by astronomy and physics regarding the form and motions of the earth, the composition of the sun and planets, and the probable history of the solar system.

2. *Geognosy,—an Inquiry into the Materials of the Earth's Substance.*—In this division we deal with the parts of the earth, its envelopes of air and water, its solid crust, and the probable condition of its interior. Especially, we have to study the more important minerals of the crust, and the chief rocks of which that crust is built up. In this way we lay a foundation of knowledge regarding the nature of the materials constituting the mass of the globe, and may next proceed to investigate the processes by which these materials are produced and altered.

3. *Dynamical Geology* embraces an investigation of the various agencies whereby the rocks of the earth's crust are formed and metamorphosed, and by which changes are effected upon the distribution of sea and land, and upon the forms of terrestrial surfaces. Such an inquiry necessitates a careful study of the existing geological economy of nature, and forms a fitting introduction to the investigation of the geological changes of former periods. This and the previous section include most of what is embraced under Physical Geography; and for the reason stated under that heading the subject will here be treated more in detail than is usual in geological treatises.

4. *Structural Geology, or the Architecture of the Earth.*—We now advance to consider how the various materials composing the crust of the earth have been arranged. We learn that some have been formed in beds or strata on the floor of the sea, that others have been built up by the slow aggregation of organic forms, that others have been poured out in a molten condition or in showers of loose dust from subterranean sources. We further find that, though originally laid down in almost horizontal beds, the rocks have subsequently been crumpled, contorted, and dislocated, that they have been incessantly worn down, and have often been depressed and buried beneath later accumulations.

5. *Palæontological Geology.*—This branch of the subject deals with the organic forms which are found preserved in the crust of the earth. It includes such questions as the relations between extinct and living types, the laws which appear to have governed the distribution of life in time and in space, the relative importance of different genera of animals in geological inquiry, the nature and use of the evidence from organic remains regarding former conditions of physical geography. This subject will be more properly discussed in the article PALÆONTOLOGY, and will therefore be only cursorily treated in the following pages.

6. *Stratigraphical Geology.*—This section might be called geological history. It works out the chronological succession of the great formations of the earth's crust, and endeavours to trace the sequence of events of which they contain the record. More particularly it determines the order of succession of the various plants and animals which in past time have peopled the earth, and thus ascertains what has been the grand march of life upon the planet.

7. *Physiographical Geology*, starting from the basis of fact laid down by stratigraphical geology regarding former geographical changes, embraces an inquiry into the origin and history of the features of the earth's surface—continental ridges and ocean basins, plains, valleys, and mountains. It explains the causes on which local differences of scenery depend, and shows under what very different circumstances, and at what widely separated intervals, the hills and mountains, even of a single country, have been produced.

PART I.—COSMICAL ASPECTS OF GEOLOGY.

Before geology had attained to the position of an inductive science, it was customary to begin all investigations into the history of the earth by propounding or adopting some more or less fanciful hypothesis in explanation of the origin of our planet, or even of the universe. Such preliminary notions were looked upon as essential to a right understanding of the manner in which the materials of the globe had been put together. To the illustrious James Hutton (1785) geologists are indebted for strenuously upholding the doctrine that it is no part of the province of geology to discuss the origin of things. He taught them that in the materials from which geological evidence is to be compiled there can be found "no traces of a beginning, no prospect of an end." In England, mainly to the influence of the school which he founded, and to the subsequent rise of the Geological Society (1807), which resolved to collect facts instead of fighting over hypotheses, is due the disappearance of the crude and unscientific cosmologies by which the writings of the earlier geologists were distinguished.

But there can now be little doubt that in the reaction against those visionary and often grotesque speculations, geologists were carried too far in an opposite direction. In allowing themselves to believe that geology had nothing to do with questions of cosmogony, they gradually grew up in the conviction that such questions could never be other than mere speculation, interesting or amusing as a theme for the employment of the fancy, but hardly coming within the domain of sober and inductive science. Nor would they soon have been awakened out of this belief by anything in their own science. It is still true that in the data with which they are accustomed to deal, as comprising the sum of geological evidence, there can be found no trace of a beginning. The oldest rocks which have been discovered on any part of the globe have probably been derived from other rocks older than themselves. Geology by itself has not yet revealed, and is little likely ever to reveal, a trace of the first solid crust of our globe. If then geological history is to be compiled from direct evidence furnished by the rocks of the earth, it cannot begin at the beginning of things, but must be content to date its first chapter from the earliest period of which any record has been preserved among the rocks.

Nevertheless, though geology in its usual restricted sense has been, and must ever be, unable to reveal the earliest history of our planet, it no longer ignores, as mere speculation, what is attempted in this subject by its sister sciences. Astronomy, physics, and chemistry have in late years all contributed to cast much light on the earlier stages of the earth's existence, previous to the beginning of what is commonly regarded as geological history. But whatever extends our knowledge of the former conditions of our globe may be legitimately claimed as part of the domain of geology. If this branch of inquiry therefore is to continue worthy of its name as the science of the earth, it must take cognizance of these recent contributions from other sciences. It must no longer be content to begin its annals with the records of the oldest rocks, but must endeavour to grope its way through the ages which preceded the formation of any rocks. Thanks to the results achieved with the telescope, the spectroscope, and the chemical laboratory, the story of these earliest ages of our earth is every year becoming more definite and intelligible.

Relations of the Earth in the Solar System.

Before entering upon the study of the structure and history of the earth, we may with advantage consider the general relations of our planet to the solar system, especially in view of its origin and history. It is now regarded as in the highest degree probable that all the members of that system have had a common origin. The investigations of recent years have revived and given a new form and meaning to the well-known nebular hypothesis, in which Laplace sketched the progress of the system from the state of an original nebula to its existing condition of a central incandescent sun with surrounding cool planetary bodies. He supposed that the nebula, originally diffused at least as far as the furthest member of the system, began to condense towards the centre, and that in so doing it threw off or left behind successive rings which on disruption and further condensation assumed the form of planets, sometimes with a further formation of rings, which in the case of Saturn remain, though in other planets they have broken up and united into satellites.

According to this view we should expect that the matter composing the various members of the solar system should be everywhere nearly the same. The fact of condensation round centres, however, indicates at least differences of density throughout the nebula. Mr Lockyer has, indeed, suggested that the materials composing the nebula arranged themselves according to their respective densities, the lightest occupying the exterior and the heaviest the interior of the mass. And if we compare the densities of the various planets, they certainly seem to support this suggestion. These densities are shown in the following table, that of the earth being taken as the unit:—

Density of the Sun		0·25
,,	Mercury	1·12
,,	Venus	1·03
,,	Earth	1·00
,,	Mars	0·70
,,	Jupiter	0·24
,,	Saturn	0·13
,,	Uranus	0·17
,,	Neptune	0·16

There is not indeed a strict progression in the diminution of density, but the fact remains that, while the planets near the sun are about twice as heavy as they would be if they consisted of such a substance as granite, towards the outer limits of the system they are composed of matter as light as cork. Again, in some cases, a similar relation has been observed between the densities of the satellites and their primaries. The moon, for example, has a density little more than half that of the earth. The first satellite of Jupiter is less dense, though the other three are found to be more dense than the planet. Further, in the condition of the earth itself, a very light gaseous atmosphere forms the outer portion, beneath which lies a heavier layer of water, while within these two envelopes the materials forming the solid substance of the planet are so arranged that the outer layer or crust has only about half the density of the whole globe. Mr Lockyer finds in the sun itself evidence of the same tendency towards a stratified arrangement in accordance with relative densities, as will be immediately further alluded to.

There seems therefore to be much probability in the hypothesis that, in the gradual condensation of the original nebula, each successive mass left behind represented the density of its parent layer, and consisted of progressively heavier matter. The remoter planets, with their low density and vast absorbing atmospheres, may be supposed to consist of metalloids like the outer parts of the sun's atmosphere, while the interior planets are no doubt mainly metallic. The rupture of each planetary ring would, it is conceived, raise the temperature of the resultant nebulous planet to such a height as to allow the vapours to rearrange themselves by degrees in successive layers, or rather shells, according to density. And when the planet gave off a satellite, that body would, it might be expected, have the composition and density of the outer layers of its primary.[1]

For many years the only evidence available as to the actual composition of other heavenly bodies than our own earth was furnished by the *aerolites, meteorites,* or falling stars, which from time to time have entered our atmosphere from planetary space, and have descended upon the surface of the globe. Subjected to chemical analysis these foreign bodies show considerable diversities of composition; but in no case have they yet yielded a trace of any element not already recognized among terrestrial materials. Upwards of twenty of our elements have been detected in aerolites, sometimes in the free state, sometimes combined with each other. More than half of them are metals, including iron, nickel, manganese, calcium, sodium, and potas-

[1] Mr Lockyer communicated some of his views to Professor Prestwich, who gave them in his interesting *Inaugural Lecture* at Oxford, in 1875. He has further stated them in his Manchester Lectures, *Why the Earth's Chemistry is as it is.*

sium. There occur also carbon, silicon, phosphorus, sulphur, oxygen, nitrogen, and hydrogen. In some of their combinations these elements, as found in the meteoric stones, differ from their mode of occurrence in the accessible parts of the earth. Iron, for example, occurs as native metal, alloyed with a variable proportion (6 to 10 per cent.) of metallic nickel. But in other respects they closely resemble some of the familiar materials of the earth's rocky crust. Thus we have such minerals as pyrite, apatite, olivine, augite, hornblende, and labradorite. No more reliable proof could be desired that some at least of the other members of the solar system are formed of the same materials as compose the earth.

But in recent years a far more precise and generally applicable method of research into the composition of the heavenly bodies has been found in the spectroscope. By means of this instrument, the light emitted from self-luminous bodies can be analysed in such a way as to show what elements are present in their intensely hot luminous vapour. When the light of a burning metal is examined with a properly-arranged prism, it is seen to give a dark band or *spectrum* which is traversed by certain vertical bright lines. This is termed a *radiation-spectrum*. Each element appears to have its own characteristic arrangement of lines, which retain the same relative position, intensity, and colours. Moreover, gases and the vapours of solid bodies are found to intercept those rays of light which they themselves emit. The spectrum of burning sodium, for example, shows two bright yellow lines. If therefore white light from some other source passes through the vapour of sodium, these two bright lines become dark lines, that portion of the light being exactly cut off which would have been given out by the sodium itself. This is called an *absorption-spectrum*.

By this method of examination it has been ascertained that many of the elements of which our earth is composed exist in the state of incandescent vapour in the atmosphere of the sun. Among these are some of our most familiar metals—iron, zinc, copper, nickel, with sodium, magnesium, barium, calcium, and vast quantities of free hydrogen. Moreover, as Mr Lockyer has pointed out, these elements appear to succeed each other in relation to their respective densities. Thus the coronal atmosphere which, as seen in total eclipses, extends to so prodigious a distance beyond the orb of the sun, consists mainly of sub-incandescent hydrogen and another element which may be new. Beneath this external vaporous envelope lies the chromosphere where the vapours of incandescent hydrogen, calcium, and magnesium can be detected. Further inward the spot-zone shows the presence of sodium, titanium, &c.; while still lower, a layer (the *reversing* layer) of intensely hot vapours, lying probably next to the inner brilliant photosphere gives spectroscopic evidence of the existence of incandescent iron, manganese, cobalt, nickel, copper, and other well-known terrestrial metals.[1]

The spectrosope has likewise been successfully applied by Mr Huggins and others to the observation of the fixed stars and nebulæ, with the result of establishing a similarity of elements between our own system and other bodies in sidereal space. In the radiation spectra of nebulæ Mr Huggins finds the hydrogen lines very prominent; and he conceives that they may be glowing masses of that element. Sir William Thomson and Professor Tait have suggested, on the other hand, that they are more probably clouds of stones in rapid motion, perhaps in an atmosphere of hydrogen. Among the fixed stars absorption spectra have been recognized, pointing to a structure resembling that of our sun, viz., a solid or liquid incandescent nucleus, surrounded with an atmosphere of glowing vapour.[2] According to Mr Lockyer, those stars or nebulæ which have the highest temperature have the simplest spectra, and in proportion as they cool their materials become more and more differentiated into what we call elements. He remarks that the most brilliant or hottest stars show in their spectra only the lines of gases, as hydrogen. Cooler stars, like our sun give indications of the presence, in addition, of the more stable metals—magnesium, sodium, calcium, iron. A still lower temperature he regards as marked by the appearance of the other metals, metalloids, and compounds, so that the older a star or planet is the more will it lose free hydrogen till, when it comes to the condition of our earth, all its free hydrogen will have disappeared.[3] According to this view the atoms of all the elements existed originally in the nebula dissociated from each other by reason of the intense heat. As the nebula gravitated towards its nucleus and cooled, the atoms came together, and the elements appeared in a certain order, beginning with hydrogen, and passing on through the metals and metalloids into compounds such as we find on our globe. The sun would thus be a star considerably advanced in the process of differentiation or association of its atoms. It contains, so far as we know, no metalloids or compounds, while stars like Sirius show the presence only of hydrogen, with but a feeble proportion of metallic vapours; and on the other hand, the red stars indicate by their spectra that their metallic vapours have entered into combination, whence it is inferred that their temperature is lower than that of our sun.

Further confirmation of these views as to the order of planetary evolution is furnished by the form and structure of the earth. Reference has already been made to the fact that the outer crust of our planet possesses only about half the density of the whole mass. It consists largely of metalloids—oxygen, silicon, carbon, sulphur, chlorine. On the other hand, lavas and mineral veins, which are believed to have been supplied from some considerable depth, contain abundance of metallic ingredients.

The form of the globe likewise points to a former fluid condition. As the result of computations from ten measured arcs of the meridian made by different observers between the latitudes of Sweden and the Cape of Good Hope, Bessel obtained the following data for the dimensions of the earth:—

Equatorial diameter.........	41,847,192 feet, or	7925·604 miles.
Polar diameter....	41,707,314 ,,	7899·114 ,,
Amount of polar flattening,	139,768 ,,	26·471 ,,

The equatorial circumference is thus a little less than 25,000 miles, and the difference between the polar and equatorial diameters (nearly $26\frac{1}{2}$ miles) amounts to about $\frac{1}{300}$th of the equatorial diameter.[4] More recently, however, it has been shown that the oblate spheroid indicated by these measurements is not a symmetrical body, the equatorial circumference being an ellipse instead of a circle, The diameter of which the vertices touch the surface of the globe in longitudes 14° 23′ E. and 194° 23′ E. of Greenwich is nearly two miles longer than that at right angles to it.[5]

In obedience to the influence of rotation on its axis, our planet would tend to assume exactly such a flattening at the poles as it has been proved to possess. This was discovered and demonstrated by Newton, and the amount o

the ellipticity was actually calculated by him, long before any measurement had confirmed such a conclusion.

The tendency of modern research is thus to give probability to the conception that not only in our own solar system, but throughout the regions of space, there has been a common plan of evolution, and that the matter diffused through space in stars, nebulæ, and systems is substantially the same as that with which we are familiar. Hence the study of the structure and probable history of the sun and the other heavenly bodies comes to possess an evident geological interest, seeing that it may yet enable us to carry back the story of our planet far beyond the domain of ordinary geological evidence, and upon data not less reliable than those furnished by the rocks of the earth's crust.

II. The Movements of the Earth in their Geological Relations.

We are here concerned only with those aspects of the earth's motions which materially influence the progress of geological phenomena.

1. *Rotation.*—In obedience to the impulse communicated to it at its original separation, the earth rotates on its axis. This movement is completed in about 24 hours, and to it is due the succession of day and night. So far as observation has yet gone, this movement is uniform, though recent calculations of the influence of the tides in retarding rotation tend to show that a very slow diminution of the angular velocity is in progress. This velocity varies relatively in different places, according to their position on the surface of the planet. At each pole there can be no velocity, but from these two points towards the equator there is a continually increasing rapidity of motion, till at the equator it is equal to a rate of 507 yards in a second.

To the rotation of the earth are due certain remarkable influences upon currents of air, which circulate either towards the equator or towards the poles. Currents which move from polar latitudes travel from parts of the earth's surface where the velocity of rotation is small to others where it is great. Hence they lag behind, and their course is bent more and more westward. An air current quitting the north polar or north temperate regions as a north wind is deflected out of its course and becomes a north-east wind. On the opposite side of the globe a similar current setting out straight for the equator is changed into a south-east wind. This is the reason why the well-known trade-winds have their characteristic westward deflexion. On the other hand, a current setting out northwards or southwards from the equator passes into regions having a less velocity of rotation than it possesses itself, and hence it travels on in advance and is gradually deflected eastward. The aerial currents blowing steadily across the surface of the ocean produce currents in its waters which have a westward tendency communicated to them indirectly from the effect of rotation. A certain deflexion is said to be experienced by such rivers as flow in a meridional direction, like the Volga. Those which flow polewards are asserted to press upon their eastern rather than their western banks, while those which run in the opposite direction are stated to be thrown more against the western than the eastern. The reality of this action may be doubted.

2. *Revolution.*—Besides turning on its axis the globe performs a movement round the sun, termed revolution. This movement is accomplished in rather more than 365 days. It determines for us the length of our year, which is, in fact, merely the time required for one complete revolution. The path or orbit followed by the earth round the sun is not a perfect circle but an ellipse, with the sun in one of the foci, the mean distance of the earth from the sun being 92,400,000 miles. By slow secular variations the form of the orbit alternately approaches and recedes from that of a circle. At the nearest possible approach between the two bodies, owing to change in the ellipticity of the orbit, the earth is 14,368,200 miles nearer the sun than when at its greatest possible distance. These maxima and minima of distance occur at vast intervals of time. The last considerable eccentricity took place about 200,000 years ago, and the previous one more than half a million of years earlier. Since the amount of heat received by the earth from the sun is inversely as the square of the distance, eccentricity must have had in past time much effect upon the climate of the earth, as will be pointed out further on (section 7, p. 218).

3. *Precession of the Equinoxes.*—If the axis of the earth were perpendicular to the plane of its orbit, there would be equal day and night all the year round. But it is really inclined to that plane at an angle of 23½°. Hence our hemisphere is alternately presented to and turned away from the sun, and in this way brings us the familiar alternation of the seasons—the long days of summer and the short days of winter. Again, were the earth a perfect sphere of uniform density throughout, the position of its axis of rotation would not change. But owing to the protuberance along the equatorial regions, the attraction chiefly of the sun and moon tends to pull the axis aside, or to make it describe a conical movement like that of the axis of a top round the vertical. Hence each pole points successively to different stars. This movement, called the precession of the equinoxes, in combination with other planetary movements, completes its cycle in 21,000 years. At present the winter in our northern hemisphere coincides with the earth's approach to the sun, or *perihelion.* In 10,500 years hence it will take place when the earth is at the farthest part of its orbit from the sun, or in *aphelion.* This movement acquires great importance when considered in connexion with the secular variations in the eccentricity of the orbit (see section 7).

4. *Change in the Obliquity of the Ecliptic.*—The angle at which the axis of the earth is inclined to the plane of its orbit does not remain strictly constant. It oscillates through long periods of time to the extent of about a degree and a half, or perhaps a little more, on either side of the mean. According to Dr Croll,[1] this oscillation must have considerably affected former conditions of climate on the earth, since, when the obliquity is at its maximum, the polar regions receive about eight and a half days more of heat than they do at present—that is, about as much heat as lat. 76° enjoys at this day. This movement must have augmented the geological effects of precession, to which reference has just been made, and which are described in section 7.

5. *Stability of the Earth's Axis.*—That the axis of the earth's rotation has successively shifted, and consequently that the poles have wandered to different points on the surface of the globe, has been maintained by geologists as the only possible explanation of certain remarkable conditions of climate, which can be proved to have formerly obtained within the Arctic Circle. Even as far north as lat. 81° 45′ abundant remains of a vegetation indicative of a warm climate, and including a bed of coal 25 to 30 feet thick, have been found *in situ.* It is contended that where these plants lived the ground could not have been permanently frozen or covered for most of the year with thick snow. In explanation of the difficulty, it has been suggested that the north pole did not occupy its present position, and that the locality where the plants occur lay in more southerly latitudes. Without at present entering on

[1] Croll, *Trans. Geol. Soc. Glasgow*, ii. 177.

the discussion of the question whether the geological evidence requires necessarily so important a geographical change, let us consider how far a shifting of the axis of rotation has been a possible cause of change during that section of geological time for which there are records among the stratified rocks.

From the time of Laplace[1] astronomers have strenuously denied the possibility of any sensible change in the position of the axis of rotation. It has been urged that, since the planet acquired its present oblate spheroidal form, nothing but an utterly incredible amount of deformation could overcome the greater centrifugal force of the equatorial protuberance. It is certain, however, that the axis of rotation does not strictly coincide with the principal axis of inertia. Though the angular difference between them must always have been small, we can, without having recourse to any extra-mundane influence, recognize two causes which, whether or not they may suffice to produce any change in the position of the main axis of inertia, undoubtedly tend to do so. In the first place a widespread upheaval or depression of certain portions of the surface to a considerable vertical amount might shift that axis. In the second place an analogous result might arise from the denudation of continental masses of land and the consequent filling up of sea-basins. Sir William Thomson freely concedes the physical possibility of such changes. "We may not merely admit," he says, "but assert as highly probable, that the axis of maximum inertia and axis of rotation, always very near one another, may have been in ancient times very far from their present geographical position, and may have gradually shifted through 10, 20, 30, 40, or more degrees, without at any time any perceptible sudden disturbance of either land or water."[2] But though, in the earlier ages of the planet's history, stupendous deformations may have occurred, and the axis of rotation may have often shifted, it is only the alterations which can possibly have occurred during the accumulation of the stratified rocks that need to be taken into account in connexion with former changes of climate. If it can be shown therefore that the geographical revolutions necessary to shift the axis are incredibly stupendous in amount, improbable in their distribution, and completely at variance with geological evidence, we may reasonably withhold our belief from this alleged cause of the changes of climate during geological history.

It has been estimated by Sir William Thomson "that an elevation of 600 feet, over a tract of the earth's surface 1000 miles square and 10 miles in thickness, would only alter the position of the principal axis by one-third of a second, or 34 feet."[3] Mr George Darwin has shown that on the supposition of the earth's complete rigidity no redistribution of matter in new continents could ever shift the pole from its primitive position more than 3°, but that, if its degree of rigidity is consistent with a periodical readjustment to a new form of equilibrium, the pole may have wandered some 10° or 15° from its primitive position, or have made a smaller excursion and returned to near its old place. In order, however, that these maximum effects should be produced, it would be necessary that each elevated area should have an area of depression corresponding in size and diametrically opposite to it, that they should lie on the same complete meridian, and that they should both be situated in lat. 45°. With all those coincident favourable circumstances, an effective elevation of $\frac{1}{300}$ of the earth's surface to the extent of 10,000 feet would shift the pole $11\frac{1}{3}'$; a similar elevation of $\frac{1}{20}$ would move it $1° 46\frac{1}{2}'$; of $\frac{1}{10}$, 3° 17′; and of $\frac{1}{2}$, $8° 4\frac{1}{2}'$. Mr Darwin admits these to be superior limits to what is possible, and that, on the supposition of intumescence or contraction under the regions in question, the deflexion of the pole might be reduced to a quite insignificant amount.[4]

Under the most favourable conditions, therefore, the possible amount of deviation of the pole from its first position would appear to have been too small to have seriously influenced the climates of the globe within geological history. If we grant that these changes were cumulative, and that the superior limit of deflexion was reached only after a long series of concurrent elevations and depressions, we must suppose that no movements took place elsewhere to counteract the effect of those about lat. 45° in the two hemispheres. But this is hardly credible. A glance at a geographical globe suffices to show how large a mass of land exists now both to the north and south of that latitude, especially in the northern hemisphere, and that the deepest parts of the ocean are not antipodal to the greatest heights of the land. These features of the earth's surface are of old standing. There seems, indeed, to be no geological evidence in favour of any such geographical changes as could have produced even the comparatively small displacement of the axis considered possible by Mr Darwin.

In an ingenious suggestion Dr John Evans contended that, even without any sensible change in the position of the axis of rotation of the nucleus of the globe, there might be very considerable changes of latitude due to disturbance of the equilibrium of the shell by the upheaval or removal of masses of land between the equator and the poles, and to the consequent sliding of the shell over the nucleus until the equilibrium was restored. This hypothesis starts on the assumption of a thin crust enclosing a liquid or viscous interior—an assumption which, as will be shown in subsequent pages, is negatived by considerations in physics. The Rev. O. Fisher has suggested that the almost universal traces of present or former volcanic action, the evidence from the compressed strata in mountain regions that the crust of the earth must have a capacity for slipping towards certain lines, the great amount of horizontal compression of strata which can be proved to have been accomplished, and the secular changes of climate—notably the former warm climate near the north pole—furnish grounds for inquiry "whether a fluid substratum over a rigid nucleus would not be compatible with mechanical considerations, and whether, under those circumstances, changes in latitude would not result from unequal thickening of the crust."[5]

6. *Changes of the Earth's Centre of Gravity.*—Though no known geological operation seems to have been capable of producing an effective change in the position of the axis of rotation of the earth, there may have been variations in the position of its centre of gravity. Any change of that kind must affect the ocean, which of course adjusts itself in relation to the earth's centre of gravity. The enormous accumulation of ice at one pole during the maximum of eccentricity will displace the centre of gravity, and, as the result of this change will raise the level of the ocean in the glacial hemisphere,[6] Dr Croll has estimated that, if the present mass of ice in the southern hemisphere is taken at 1000 feet thick extending down to lat. 60°, the transference of this mass to the northern hemisphere would raise the level of the sea 80 feet at the north pole. Other methods of calculation give different results. Mr Heath puts the rise at 128 feet; Archdeacon Pratt makes it more; while the Rev. O. Fisher gives it at

409 feet.[1] More recently, in returning to this question, Dr Croll remarks "that the removal of two miles of ice from the Antarctic continent [and at present the mass of ice there is probably thicker than that] would displace the centre of gravity 190 feet, and the formation of a mass of ice equal to the one-half of this, on the Arctic regions, would carry the centre of gravity 95 feet farther, giving in all a total displacement of 285 feet, thus producing a rise of level at the north pole of 285 feet, and in the latitude of Edinburgh of 234 feet." A very considerable additional displacement would arise from the increment of water to the mass of the ocean by the melting of the ice. Supposing half of the two miles of Antarctic ice to be replaced by an ice-cap of similar extent and one mile thick in the northern hemisphere, the other half being melted into water and increasing the mass of the ocean, Dr Croll estimates that from this source an extra 200 feet of rise would take place in the general ocean level, so that there would be a rise of 485 feet at the north pole, and 434 feet in the latitude of Edinburgh.[2] There must thus have been an alternate submergence and emergence of the low polar lands due to the alternate shifting of the centre of gravity.

7. *Influence of the Earth's Movements upon Climate.*—Although the treatment of this subject involves a reference to questions which must be discussed in their poper place in subsequent parts of this article, it will be most appropriately inserted here as a distinct and most important branch of the astronomical relations of geology. In later pages it will be shown that the climate of the earth has undergone many great vicissitudes during geological history,—for example, that a warm and genial temperature has once prevailed in arctic latitudes, while at another time snow and ice extended far down into the heart of Europe. Of this latter change, which took place within a comparatively recent geological period, the traces still remain remarkably fresh, and have excited great interest and discussion. It is known as the Glacial Period or Ice Age. But we now know that other similar periods of great cold probably preceded it at widely separated intervals.

Various theories have been proposed in explanation of such striking variations in climate. Some of these have appealed to a change in the position of the earth's axis relatively to the mass of the planet (p. 216). Others have been based on the notion that the earth may have passed through hot and cold regions of space. Others, again, have called in the effects of terrestrial changes, such as the distribution of land and sea, on the assumption that elevation of land about the poles must cool the temperature of the globe, while elevation round the equator would raise it. But as the changes of temperature have affected vast areas of the earth's surface, while there is a total absence of all proof of any such enormous vicissitudes in physical geography as would be required, and since there is accumulating proof in favour of periodic alternations of climate, there is a growing conviction that no mere local changes could have sufficed, but that secular variations in climate must be assigned to some general and probably recurring cause.[3]

By degrees geologists accustomed themselves to the belief that the cold of the glacial period was not due to mere terrestrial changes, but was to be explained somehow as the result of cosmical causes. Among the various suggestions, one deserves careful consideration—change in the eccentricity of the earth's orbit. Sir John Herschel[4] pointed out many years ago that the direct effect of a high condition of eccentricity is to produce an unusually cold winter followed by a correspondingly hot summer on the hemisphere whose winter occurs in aphelion, while an equable condition of climate will at the same time prevail on the opposite hemisphere. But both hemispheres must receive precisely the same amount of solar heat, because the deficiency of heat resulting from the sun's greater distance during one part of the year is exactly compensated by the greater length of that season. Sir John Herschel even considered that the direct effects of eccentricity must thus be nearly neutralized.[5] As a like verdict was afterwards given by Arago, Humboldt, and others, geologists were satisfied that no important change of climate could be attributed to change of eccentricity.

It is to the luminous memoirs of Dr James Croll that geology is indebted for the first fruitful suggestion in this matter, and for the subsequent elaborate development of the whole subject of the physical causes on which climate depends. He has been so good as to draw up for this article the following summary of his views (taken chiefly from his paper in the *Phil. Mag.* for February 1870). The reader will find the subject fully worked out in Dr Croll's work, *Climate and Time*, 1875.

"Assuming the mean distance of the sun to be 92,400,000 miles, then when the eccentricity is at its superior limit, ·07775, the distance of the sun from the earth, when the latter is in the aphelion of its orbit, is no less than 99,584,100 miles, and when in the perihelion it is only 85,215,900 miles. The earth is, therefore, 14,368,200 miles farther from the sun in the former than in the latter position. The direct heat of the sun being inversely as the square of the distance, it follows that the amount of heat received by the earth in these two positions will be as 19 to 26. The present eccentricity being ·0168, the earth's distance during our northern winter is 90,847,680 miles. Suppose now that, from the precession of the equinoxes, winter in our northern hemisphere should happen when the earth is in the aphelion of its orbit, at the time that the orbit is at its greatest eccentricity; the earth would then be 8,736,420 miles farther from the sun in winter than it is at present. The direct heat of the sun would therefore, during winter, be one-fifth less and during summer one-fifth greater than now. This enormous difference would necessarily affect the climate to a very great extent. Were the winters under these circumstances to occur when the earth was in the perihelion of its orbit, the earth would then be 14,368,200 miles nearer the sun in winter than in summer. In this case the difference between winter and summer in our latitudes would be almost annihilated. But as the winters in the one hemisphere correspond with the summers in the other, it follows that while the one hemisphere would be enduring the greatest extremes of summer heat and winter cold, the other would be enjoying perpetual summer.

"It is quite true that whatever may be the eccentricity of the earth's orbit, the two hemispheres must receive equal quantities of heat per annum; for proximity to the sun is exactly compensated by the effect of swifter motion. The total amount of heat received from the sun between the two equinoxes is therefore the same in both halves of the year, whatever the eccentricity of the earth's orbit may be. For example, whatever extra heat the southern hemisphere may at present receive per day from the sun during its summer months, owing to greater proximity to the sun, is exactly compensated by a corresponding loss arising from the shortness of the season; and, on the other hand, whatever deficiency of heat we in the northern hemisphere may at present have per day during our summer half-year, in consequence of the earth's distance from the sun, is also exactly compensated by a corresponding length of season.

"It is well known, however, that those simple changes in the sun's summer and winter distances would not alone produce a glacial epoch, and that physicists, confining their attention to the purely astronomical effects, were perfectly correct in affirming that no increase of eccentricity of the earth's orbit could account for that epoch. But the important fact was overlooked that, although the glacial epoch could not result directly from an increase of eccentricity, it might nevertheless do so indirectly from physical agents that were brought into operation as a result of an increase of eccentricity. The following is an outline of what these physical agents were, how they were brought into operation, and the way in which they may have led to the glacial epoch.

"With the eccentricity at its superior limit and the winter occurring in the aphelion, the earth would, as we have seen, be 8,736,420 miles farther from the sun during that season than at present. The reduction in the amount of heat received from the sun, owing to his increased distance, would lower the midwinter temperature to an enormous extent. In temperate regions the greater portion of the moisture of the air is at present precipitated in the form of rain, and the very small portion which falls as snow disappears in the course of a few weeks at most. But in the circumstances under consideration, the mean winter temperature would be lowered so much below the freezing-point that what now falls as rain during that season would then fall as snow. This is not all; the winters would then not only be colder than now, but they would also be much longer. At present the winters are nearly eight days shorter than the summers; but with the eccentricity at its superior limit and the winter solstice in aphelion, the length of the winters would exceed that of the summers by no fewer than thirty-six days. The lowering of the temperature and the lengthening of the winter would both tend to the same effect, viz., to increase the amount of snow accumulated during the winter; for, other things being equal, the larger the snow-accumulating period the greater the accumulation. It may be remarked, however, that the absolute quantity of heat received during winter is not affected by the decrease in the sun's heat,[1] for the additional length of the season compensates for this decrease. As regards the absolute amount of heat received, increase of the sun's distance and lengthening of the winter are compensatory, but not so in regard to the amount of snow accumulated. The consequence of this state of things would be that, at the commencement of the short summer, the ground would be covered with the winter's accumulation of snow. Again, the presence of so much snow would lower the summer temperature, and prevent to a great extent the melting of the snow.

"There are three separate ways whereby accumulated masses of snow and ice tend to lower the summer temperature, viz.:—

"*First*, By means of direct radiation. No matter what the intensity of the sun's rays may be, the temperature of snow and ice can never rise above 32°. Hence the presence of snow and ice tends by direct radiation to lower the temperature of all surrounding bodies to 32°. In Greenland, a country covered with snow and ice, the pitch has been seen to melt on the side of a ship exposed to the direct rays of the sun, while at the same time the surrounding air was far below the freezing-point; a thermometer exposed to the direct radiation of the sun has been observed to stand above 100°, while the air surrounding the instrument was actually 12° below the freezing-point. A similar experience has been recorded by travellers on the snow-fields of the Alps. These results, surprising as they no doubt appear, are what we ought to expect under the circumstances. Perfectly dry air seems to be nearly incapable of absorbing radiant heat. The entire radiation passes through it almost without any sensible absorption. Consequently the pitch on the side of the ship may be melted or the bulb of the thermometer raised to a high temperature by the direct rays of the sun, while the surrounding air remains intensely cold. The air is cooled by *contact* with the snow-covered ground, but is not heated by the radiation from the sun.

"When the air is charged with aqueous vapour, a similar cooling effect also takes place, but in a slightly different way. Air charged with aqueous vapour is a good absorber of radiant heat, but it can only absorb those rays which agree with it in *period*. It so happens that rays from snow and ice are, of all others, those which it absorbs best. The humid air will absorb the total radiation from the snow and ice, but it will allow the greater part of, if not nearly all, the sun's rays to pass unabsorbed. But during the day, when the sun is shining, the radiation from the snow and ice to the air is negative; that is, the snow and ice cool the air by radiation. The result is, the air is cooled by radiation from the snow and ice (or rather, we should say, *to* the snow and ice) more rapidly than it is heated by the sun; and, as a consequence, in a country like Greenland, covered with an icy mantle, the temperature of the air, even during summer, seldom rises above the freezing-point. Snow is a good reflector, but as simple reflection does not change the character of the rays they would not be absorbed by the air, but would pass into stellar space. Were it not for the ice, the summers of North Greenland, owing to the continuance of the sun above the horizon, would be as warm as those of England; but, instead of this, the Greenland summers are colder than our winters. Cover India with an ice sheet, and its summers would be colder than those of England.

"*Second*, Another cause of the cooling effect is that the rays which fall on snow and ice are to a great extent reflected back into space. But those that are not reflected, but absorbed, do not raise the temperature, for they disappear in the mechanical work of melting the ice. For whatsoever may be the intensity of the sun's heat the surface of the ground will be kept at 32° so long as the snow and ice remain unmelted.

"*Third*, Snow and ice lower the temperature by chilling the air and condensing the vapour into thick fogs. The great strength of the sun's rays during summer, due to his nearness at that season, would, in the first place, tend to produce an increased amount of evaporation. But the presence of snow-clad mountains and an icy sea would chill the atmosphere and condense the vapour into thick fogs. The thick fogs and cloudy sky would effectually prevent the sun's rays from reaching the earth, and the snow, in consequence, would remain unmelted during the entire summer. In fact, we have this very condition of things exemplified in some of the islands of the Southern Ocean at the present day. Sandwich Land, which is in the same parallel of latitude as the north of Scotland, is covered with ice and snow the entire summer; and in the island of South Georgia, which is in the same parallel as the centre of England, the perpetual snow descends to the very sea-beach. Captain Sir James Ross found the perpetual snow at the sea-level at Admiralty Inlet, South Shetland, in lat. 64°; and while near this place the thermometer in the very middle of summer fell at night to 23° F. The reduction of the sun's heat and lengthening of the winter, which would take place when the eccentricity is near to its superior limit and the winter in aphelion, would in this country produce a state of things perhaps as bad as, if not worse than, that which at present exists in South Georgia and South Shetland.

"The cause which above all others must tend to produce great changes of climate, is the deflexion of great ocean currents. A high condition of eccentricity tends, we have seen, to produce an accumulation of snow and ice on the hemisphere whose winters occur in aphelion. The accumulation of snow in turn tends to lower the summer temperature, cut off the sun's rays, and retard the melting of the snow. In short, it tends to produce on that hemisphere a state of glaciation. Exactly opposite effects take place on the other hemisphere, which has its winter in perihelion. There the shortness of the winters, combined with the high temperature arising from the nearness of the sun, tends to prevent the accumulation of snow. The general result is that the one hemisphere is cooled and the other heated. This state of things now brings into play the agencies which lead to the deflexion of the Gulf-stream and other great ocean currents.

"Owing to the great difference between the temperature of the equator and the poles, there is a constant flow of air from the poles to the equator. It is to this that the trade-winds owe their existence. Now, as the strength of these winds will, as a general rule, depend upon the difference of temperature that may exist between the equator and higher latitudes, it follows that the trades on the cold hemisphere will be stronger than those on the warm. When the polar and temperate regions of the one hemisphere are covered to a large extent with snow and ice, the air, as we have just seen, is kept almost at the freezing-point during both summer and winter. The trades on that hemisphere will, of necessity, be exceedingly powerful; while on the other hemisphere, where there is comparatively little snow or ice, and the air is warm, the trades will consequently be weak. Suppose now the northern hemisphere to be the cold one. The north-east trade winds of this hemisphere will far exceed in strength the south-east trade winds of the southern hemisphere. The *median line* between the trades will consequently lie to a very considerable distance to the south of the equator. We have a good example of this at the present day. The difference of temperature between the two hemispheres at present is but trifling to what it would be in the case under consideration; yet we find that the south-east trades of the Atlantic blow with greater force than the north-east trades, sometimes extending to 10° or 15° N. lat., whereas the north-east trades seldom blow south of the equator. The effect of the northern trades blowing across the equator to a great distance will be to impel the warm water of the tropics over into the Southern Ocean. But this is not all; not only would the median line of the trades be shifted southwards, but the great equatorial currents of the globe would also be shifted southwards.

"Let us now consider how this would affect the Gulf-stream. The South American continent is shaped somewhat in the form of a triangle, with one of its angular corners, called Cape St Roque, pointing eastwards. The equatorial current of the Atlantic impinges against this corner; but as the greater portion of the current lies a little to the north of the corner, it flows westwards into the Gulf of Mexico and forms the Gulf-stream. A considerable portion of the water, however, strikes the land to the south of the cape, and is deflected along the shore of Brazil into the Southern Ocean, forming what is known as the Brazilian current. Now, it is obvious that the shifting of the equatorial current of the Atlantic only a few degrees to the south of its present position—a thing which would certainly take place under the conditions which we have been detailing—would turn the entire current into the Brazilian branch, and instead of flowing chiefly into the Gulf of Mexico, as at present, it would all flow into the Southern Ocean, and the Gulf-stream would consequently be stopped. The stoppage of the Gulf-stream, combined

[1] When the eccentricity is at its superior limit, the absolute quantity of heat received by the earth during the year is, however, about one three-hundredth part greater than at present. But this does not affect the question at issue.

with all those causes which we have just been considering, would place Europe under a glacial condition, while at the same time the temperature of the Southern Ocean would, in consequence of the enormous quantity of warm water received, have its temperature (already high from other causes) raised enormously. And what holds true in regard to the currents of the Atlantic holds also true, though perhaps not to the same extent, of the currents of the Pacific.

"If the breadth of the Gulf-stream be taken at 50 miles, its depth at 1000 feet, its mean velocity at 2 statute miles an hour, the temperature of the water when it leaves the Gulf at 65°, and the return current at 40° F.,[1] then, as has been shown in *Climate and Time*, chapter ii., the quantity of heat conveyed into the Atlantic by this stream is equal to one-fourth of all the heat received from the sun by that ocean from the Tropic of Cancer to the Arctic Circle.[2] From principles discussed at considerable length in the chapter referred to, it is shown that, but for the Gulf-stream and other currents, London would have a mean annual temperature 40° lower than at present.

"But there is still another cause which must be noticed:—a strong undercurrent of air *from* the north implies an equally strong upper current *to* the north. Now if the effect of the undercurrent would be to impel the warm water at the equator to the south, the effect of the upper current would be to carry the aqueous vapour formed at the equator to the north; the upper current, on reaching the snow and ice of temperate regions, would deposit its moisture in the form of snow; so that it is probable that, nowithstanding the great cold of the glacial epoch, the quantity of snow falling in the northern region would be enormous. This would be particularly the case during summer, when the earth would be in the perihelion and the heat at the equator great. The equator would be the furnace where evaporation would take place, and the snow and ice of temperate regions would act as a condenser.

"The foregoing considerations, as well as many others which might be stated, lead to the conclusion that, in order to raise the mean temperature of the globe, *water* should be placed along the equator, and not *land*, as was contended by Sir Charles Lyell and others. For if land be placed at the equator, the possibility of conveying the sun's heat from the equatorial regions by means of ocean currents is prevented."

Inter-Glacial Periods.—Allusion has already been made to the fact that there is accumulating evidence to show that changes of climate have been recurrent, and that this alternation or periodicity goes far to prove them to be due to some general or cosmical cause. Dr Croll has ingeniously shown that every long cold period in each hemisphere must have been interrupted by several shorter warm periods, and "when the one hemisphere," he says, "is under glaciation, the other is enjoying a warm and equable climate. But, owing to the precession of the equinoxes, the condition of things on the two hemispheres must be reversed every 10,000 years or so. When the solstice passes the aphelion, a contrary process commences; the snow and ice gradually begin to diminish on the cold hemisphere and to make their appearance on the other hemisphere. The glaciated hemisphere turns by degrees warmer, and the warm hemisphere colder, and this continues to go on for a period of ten or twelve thousand years, until the winter solstice reaches the perihelion. By this time the conditions of the two hemispheres have been reversed; the formerly glaciated hemisphere has now become the warm one, and the warm hemisphere the glaciated. The transference of the ice from the one hemisphere to the other continues as long as the eccentricity remains at a high value. It is probable that, during the warm inter-glacial periods, Greenland and the Arctic regions would be comparatively free from snow and ice, and enjoying a temperate and equable climate."

[1] Sir Wyville Thomson states that in May 1873 the *Challenger* expedition found the Gulf-stream, at the point where it was crossed, to be about 60 miles in width, 100 fathoms deep, and flowing at the rate of 3 knots per hour. This makes the volume of the stream one-fifth greater than the above estimate.

[2] The quantity of heat conveyed by the Gulf-stream for distribution is equal to 77,479,650,000,000,000,000 foot-pounds per day. The quantity received from the sun by the North Atlantic is 310,923,000,000,000,000,000 foot-pounds.

PART II.—GEOGNOSY:

AN INVESTIGATION OF THE MATERIALS OF THE EARTH'S SUBSTANCE.

Before we enter upon any discussion of the geological changes which our planet has undergone, it is needful first of all to study the materials of which the planet consists. It is from the evidence furnished by the nature and arrangement of these materials that geological history must be compiled.

Viewed in a broad way then, the earth may be considered as consisting of (1) two envelopes,—an outer one of gas completely surrounding the planet, and an inner one of water covering about three-fourths of the globe; and (2) a globe cool and solid on its surface but possessing a high internal temperature.

I. The Envelopes.

1. *The Atmosphere.*—The gaseous envelope to which the name of atmosphere is given extends at least to a distance of 40 or 45 miles from the earth's surface, perhaps in a state of extreme tenuity to a much greater height. But its thickness must necessarily vary with latitude and changes in atmospheric pressure; the layer of air lying over the poles is not so deep as that which surrounds the equator.

Geologically considered, the atmosphere presents itself as an agent of change by virtue of its composition and the chemical reactions which it effects, its varying temperature and consequent influence in expanding and contracting rocks, and its movements.

Many speculations have been made regarding the chemical composition of the atmosphere during former geological periods. There can indeed be no doubt that it must originally have differed very greatly from its present condition. The oxygen which now forms fully a half of the outer crust of the earth was originally doubtless part of the atmosphere. So, too, the vast beds of coal found all over the world, in geological formations of many different ages, represent so much carbonic acid once present in the air. The chlorides in the sea likewise were probably carried down out of the atmosphere in the primitive condensation of the aqueous vapour. It has often been suggested that during the Carboniferous period the atmosphere must have been warmer and with more aqueous vapour and carbonic acid in its composition than at the present day, to admit of so luxuriant a flora as that from which the coal seams were formed. There seems, however, to be at present no method of arriving at any certainty on this subject.

As now existing, the atmosphere is considered to be normally a mechanical mixture of nearly 4 volumes of nitrogen and 1 of oxygen, with a minute proportion of carbonic acid, and still smaller quantities of other substances. Expressed in a tabular form this composition is as follows:—

Nitrogen	79·00
Oxygen	20·96
Carbonic acid	0·04

These quantities are liable to some variation according to locality. On the sea, for example, the proportion of carbonic acid is said to average about 0·03. In the air of streets and houses the proportion of oxygen diminishes, while that of carbonic acid increases. According to the minute researches of Dr Angus Smith, very pure air should contain not less than 20·99 of oxygen, with 0·030 of carbonic acid; but he found impure air in Manchester to have only 20·21 of oxygen, while the proportion of carbonic acid in that city during fog was ascertained to rise sometimes to 0·0679, and in the pit of the theatre to the very large amount of 0·2734. Small as the percentage of carbonic acid in ordinary air may seem, yet the total amount of this gas in the whole atmosphere probably exceeds what would be disengaged if all the vegetable and animal matter on the earth's surface were burnt.

The other substances present in much more minute quantities are gases, vapours, and solid particles. Of these by much the most important is the vapour of water, which is always present, but in very variable amount according to temperature, ranging from about 4 to a maximum of 16 grains in 1000 grains of air.[1] It is this vapour which condenses into dew, rain, hail, and snow. In assuming a visible form, and descending through the atmosphere, it takes up a minute quantity of air, and of the different substances which the air may contain. Being caught by the rain, and held in solution or suspension, these substances can be best examined by analysing rain-water. In this way ammonia, nitric, sulphurous, and sulphuric acids, chlorides, various salts, solid carbon, inorganic dust, and organic matter have been detected. M. J. J. Pierre found as the result of his analysis that in the neighbourhood of Caen, in France, a hectare of land receives annually from the atmosphere, by means of rain—

Chloride of	sodium	37·5	kilogrammes.
,,	potassium	8·2	,,
,,	magnesium	2·5	,,
,,	calcium	1·8	,,
Sulphate of	soda	8·4	,,
,,	potash	8·0	,,
,,	lime	6·2	,,
,,	magnesia	5·9	,,

To these ingredients must be added traces of ammonia, various salts, and organic substances, besides others still undetermined.[2] The powerful oxidizing agent ozone is present in variable but always minute quantities in the air.

The comparatively small but by no means unimportant proportions of these various components of the atmosphere are much more liable than the more essential gases to great variations. Chloride of sodium, for instance, is, as might be expected, particularly abundant in the air bordering the sea. Nitric acid, ammonia, and sulphuric acid appear in the air of towns most conspicuously. The organic substances present in the air are sometimes living germs, such as probably often lead to the propagation of disease, and sometimes mere fine particles of dust derived from the bodies of living or dead organisms.[3]

2. *The Oceans.*—About three-fourths of the surface of the globe (or about 144,712,000 square miles) is covered by the irregular sheet of water known as the sea. Within the last ten years much new light has been thrown upon the depths, temperatures, and biological conditions of the ocean-basins, more particularly by the "Lightning," "Porcupine," and "Challenger" expeditions fitted out by the British Government. It has been ascertained that few parts of the Atlantic Ocean exceed 3000 fathoms, the deepest sounding obtained there being one taken about 100 miles north from the island of St Thomas, which gave 3875 fathoms, or rather less than $4\frac{1}{2}$ miles. The Atlantic appears to have an average depth in its more open parts of from 2000 to 3000 fathoms or from about 2 to $3\frac{1}{2}$ miles. In the Pacific Ocean the "Challenger" got soundings of 3950 and 4475 fathoms, or about $4\frac{1}{2}$ and rather more than 5 miles. But these appear to mark exceptionally abyssal depressions, the average depth being, as in the Atlantic, between 2000 and 3000 fathoms. We may therefore assume, as probably not far from the truth, that the average depth of the ocean is about 2500 fathoms, or nearly 3 miles.

The water of the oceans is distinguished from the ordinary terrestrial waters by a higher specific gravity, and the presence of so large a proportion of saline ingredients as to impart a strongly salt taste. The average density of sea-water is about 1·026, but it varies slightly in different parts even of the same ocean. According to the recent observations of Mr J. Y. Buchanan during the "Challenger" expedition, some of the heaviest sea-water occurs in the pathway of the trade-winds of the North Atlantic, where evaporation must be comparatively rapid, a density of 1·02781 being registered. Where, however, large rivers enter the sea, or where there is much melting ice, the density diminishes; Mr Buchanan found among the broken ice of the Antarctic Ocean that it had sunk to 1·02418.[4]

The greater density of sea-water depends of course upon the salts which it contains in solution. There seems no reason to doubt that these salts are, in the main, parts of the original constitution of the sea, and thus that the sea has always been salt. It is also probable that, as in the case of the atmosphere, the composition of the ocean water has in former geological periods been very different from what it is now, and that it has acquired its present character only after many ages of slow change, and the abstraction of much mineral matter originally contained in it. There is evidence indeed among the geological formations that large quantities of lime, silica, chlorides, and sulphates have in the course of time been removed from the sea.[5]

But it is evident also that, whatever may have been the original composition of the oceans, they have for a vast section of geological time been constantly receiving mineral matter in solution from the land. Every spring, brook, and river removes various salts from the rocks over which it moves, and these substances, thus dissolved, eventually find their way into the sea. Consequently sea-water ought to contain more or less traceable proportions of every substance which the terrestrial waters can remove from the land, in short, of probably every element present in the outer shell of the globe, for there seems to be no constituent of this earth which may not, under certain circumstances, be held in solution in water. Moreover, unless there be some counteracting process to remove these mineral ingredients, the ocean water ought to be growing, insensibly perhaps, but still assuredly, salter, for the supply of saline matter from the land is incessant. It has been ascertained indeed, with some approach to certainty, that the salinity of the Baltic and Mediterranean is gradually increasing.[6]

The average proportion of saline constituents in the water of the great oceans far from land is about three and a half parts in every hundred of water. But in enclosed seas, receiving much fresh water, it is greatly reduced, while in those where evaporation predominates it is correspondingly augmented. Thus the Baltic water contains from one-seventh to nearly a half of the ordinary proportion in ocean water, while the Mediterranean contains sometimes one-sixth more than that proportion. The mineral constituents include the following average ratios of salts[7]:—

[1] The quantity of aqueous vapour depends upon the temperature, warm air being able to retain more than cold air. Air at a temperature of 10° C. is saturated when it contains 9·362 grammes of vapour in a cubic metre of air.

[2] *Chimie Agricole*, quoted by Dr Angus Smith, *Air and Rain*, p. 232.

[3] The air of towns is peculiarly rich in impurities, especially in manufacturing districts, where much coal is used. These impurities, however, though of serious consequence to the towns in a sanitary point of view, do not sensibly affect the general atmosphere, seeing that they are probably in great measure taken out of the air by rain, even in the districts which produce them. They possess, however, a special geological significance, and in this respect, too, have important economic bearings. See on this whole subject Dr Angus Smith's work already cited.

[4] Buchanan, *Proc. Roy. Soc.* (1876), vol. xxiv.

[5] Dr Sterry Hunt even supposes that the saline waters of Canada and the northern States derive their mineral ingredients from the salts still retained among the sediments and precipitates of the ancient sea in which the earlier Palæozoic rocks were deposited.—*Geological and Chemical Essays*, p. 104.

	Percentage.
Chloride of sodium (common salt)	75·786
Chloride of magnesium	9·159
Chloride of potassium	3·657
Sulphate of lime (gypsum)	4·617
Sulphate of magnesia (Epsom salts)	5·597
Bromide of sodium	1·184
	100·000
Total percentage of salts in sea-water	3·527

Besides these chief ingredients, sea-water has yielded minute traces of iodine, fluorine, silica, phosphoric acid, carbonate of lime and magnesia, silver, lead, copper, arsenic. Doubtless more perfect analysis will greatly increase this list.

In addition to its salts sea-water always contains dissolved atmospheric gases. From the researches conducted during the voyage of the "Bonité" in the Atlantic and Indian Oceans it was estimated that the gases in 100 volumes of sea-water ranged from 1·85 to 3·04, or from two to three per cent. From observations made during the "Porcupine" cruise of 1868 it was inferred that the proportion of oxygen was greatest (25·1 per cent.) in the surface water, and least (19·5) in the bottom water, while that of carbonic acid was least at the top (20·7) and greatest (27·9) at the bottom, and that the action of the waves was partially to eliminate the latter gas and to increase the amount of oxygen. More recently, however, during the voyage of the "Challenger," Mr J. Y. Buchanan ascertained that the proportion of carbonic acid was always nearly the same for similar temperatures, the amount in the Atlantic surface water, between 20° and 25° C., being 0·0466 gramme per litre, and in the surface Pacific water 0·0268. He points out the curious fact that, according to his analyses, sea-water contains sometimes at least thirty times as much carbonic acid as an equal bulk of fresh water would do, and he traces the greater power of absorption to the presence of the sulphates.

II. The Solid Globe.

1. *General Considerations.*—Within the atmospheric and oceanic envelopes lies the inner solid globe. Reference has already been made to the comparative density of the planet among the other members of the solar system. In all speculation about the history of the earth, the density of the whole mass of the planet as compared with water—the standard to which the specific gravities of terrestrial bodies are referred—is a question of prime importance. Various methods have been employed for determining the earth's density. The deflexion of the plumb-line on either side of a mountain of known structure and density, the time of oscillation of the pendulum at great heights, at the sea-level, and in deep mines, the comparative force of gravitation as measured by the torsion balance—each of these processes has been tried with the following various results:—

Plumb-line experiments on Schiehallien (Maskelyne and Playfair) gave as the mean density of the earth	4·713
Do. on Arthur's Seat, Edinburgh, (James)	5·316
Pendulum experiments on Mont Cenis (Carlini and Giulio)	4·950
Do. in Harton coal-pit, Newcastle (Airy)	6·565
Torsion balance experiments (Cavendish)	5·480
Do. do. (Baily)	5·660

Though these observations are somewhat discrepant, we may feel satisfied that the globe has a mean density neither much more nor much less than 5·5; that is to say, it is five and a half times heavier than one of the same dimensions formed of pure water. Now the average density of the materials which compose the accessible portions of the earth is between 2·5 and 3; so that the mean density of the whole globe is about twice as much as that of its outer part. We might therefore infer that the inside consists of much heavier materials than the outside, and consequently that the mass of the planet must contain at least two dissimilar portions—an exterior lighter crust or rind, and an interior heavier nucleus. But the effect of pressure must necessarily increase the specific gravity of the interior as will be alluded to further on.

2. *The Crust.*—It was formerly a prevalent belief that the exterior and interior of the globe differed from each other to such an extent that, while the outer parts were cool and solid, the vastly more enormous inner part being intensely hot was more or less completely fluid. Hence the term "crust" was applied to the external rind in the usual sense of that word. This crust was variously computed to be 10, 15, 20 or more miles in thickness. For reasons which will be afterwards given, the idea of internal liquidity has been opposed by eminent physicists and is now abandoned by most geologists. The term "crust," however, continues to be used as a convenient word to denote the cool, upper, or outer layer of the earth's mass, accessible to human observation. It is in the structure and history of this crust that the main subjects of geological investigation are contained. It will therefore be fully treated of in the following parts of this article.

There are, however, some general views as to its composition and the arrangement of its materials, which may appropriately find a place in this preliminary section. Evidently our direct acquaintance with the chemical constitution of the globe must be limited to that of the crust, though by inference we may eventually reach highly probable conclusions regarding the constitution of the interior. Chemical research has discovered that sixty-four simple or as yet indecomposable bodies, called elements, in various proportions and compounds, constitute the accessible part of the crust. Of these, however, the great majority are comparatively of rare occurrence. The crust, so far as we can examine it, is mainly built up of about sixteen elements, which may be arranged in the two following groups, the most abundant bodies being placed first in each list:—

Metalloids.	Atomic Weight	*Metals.*	Atomic Weight
Oxygen	15·96	Aluminium	27·30
Silicon	28·00	Calcium	39·90
Carbon	11·97	Magnesium	23·94
Sulphur	31·98	Potassium	39·04
Hydrogen (really a metal)	1·00	Sodium	22·99
Chlorine	35·37	Iron	55·90
Phosphorus	30·96	Manganese	54·80
Fluorine	19·10	Barium	136·80

By far the most abundant and important of these elements is oxygen. It forms about 23 per cent. by weight of air, 88·88 per cent. of water, and about a half of all the rocks which compose the visible portion or "crust" of the globe. Another metalloid, silicon, comes next in abundance. It is always united with oxygen, forming the mineral silica which, either alone or in combination with various metallic bases as silicates, constitutes a half of all the known mass of the globe. Of the remaining metalloids carbon and sulphur sometimes occur in the free state, but usually in combination with oxygen or some base or metal. Chlorine and fluorine are found associated with metallic bases. Hydrogen is properly a metal, and occurs chiefly in combination with oxygen as the oxide, water. Phosphorus occurs with oxygen principally in phosphate of lime.

Of the metals by far the most important in the architecture of the exterior of the earth is aluminium. In conjunction with oxygen and silicon it forms the basis of most crystalline rocks. Calcium, magnesium, potassium, and sodium, combined with oxygen, enter largely into the composition of rocks. Iron is the great colouring material in nature, most of the yellow, brown, red, and green hues of rocks being due to some of its combinations. The sixteen elements mentioned in the foregoing lists form about ninety-nine parts of the earth's crust; the other elements constitute only about a hundredth part, though they include gold, silver, copper, tin, lead, and the other useful metals, iron excepted.

It is clear then that, so far as accessible to our observation, the outer portion of our planet consists mainly of metalloids, and its metallic constituents have in great part entered into combination with oxygen, so that the atmosphere contains the residue of that gas which has not yet united itself to terrestrial compounds. In a broad view of the arrangement of the chemical elements in the external crust, the suggestive speculation of Durocher deserves attention.[1] He regarded all rocks as referable to two layers or magmas co-existing in the earth's crust the one beneath the other, according to their specific gravities. The upper or outer layer, which he termed the acid or siliceous magma, contains an excess of silica, and has a mean density of 2·65. The lower or inner layer, which he called the basic magma, has from six to eight times more of the earthy bases and iron oxides, with a mean density of 2·96. To the former he assigned the early plutonic rocks, granite, felsite, &c., with the more recent trachytes; to the latter he relegated all the heavy lavas, basalts, diorites, &c. The ratio of silica is 7 in the acid magma to 5 in the basic. Though the proportion of this acid or of the earthy and metallic bases cannot be regarded as any certain evidence of the geological date of rocks, nor of their probable depth of origin, it is nevertheless a fact that (with many important exceptions) the eruptive rocks of the older geological periods are very generally super-silicated and of lower specific gravity, while those of later time are very frequently poor in silica but rich in the earthy bases and in iron and manganese, with a consequent higher specific gravity. The latter, according to Durocher, have been forced up from a lower zone through the lighter siliceous crust.

3. *The Interior or Nucleus.*—Though we cannot hope ever to have direct acquaintance with more than the mere outside skin of our planet, we may be led to infer the irregular distribution of materials within the crust from the present distribution of land and water, and the observed differences in the amount of deflexion of the plumb-line near the sea and near mountain-chains. The fact that the southern hemisphere is almost wholly covered with water appears explicable only on the assumption of an excess of density in the mass of that portion of the planet. The existence of such a vast sheet of water as that of the Pacific Ocean is to be accounted for, says Archdeacon Pratt, by the presence of "some excess of matter in the solid parts of the earth between the Pacific Ocean and the earth's centre, which retains the water in its place, otherwise the ocean would flow away to the other parts of the earth."[2] The same writer points out that a deflexion of the plumb-line towards the sea, which has in a number of cases been observed, indicates that "the density of the crust beneath the mountains must be less than that below the plains, and still less than that below the ocean-bed."[3] Apart therefore from the depressions of the earth's surface in which the oceans lie, we must regard the internal density, whether of crust or nucleus, to be somewhat irregularly arranged,—there being an excess of heavy materials in the water hemisphere and beneath the ocean-beds as compared with the continental masses.

In our ignorance regarding the chemical constitution of the nucleus of our planet, an argument has sometimes been based upon the known fact that the specific gravity of that nucleus is about double that of the crust. This has been held by some writers to prove that the interior must consist of much heavier material, and is therefore probably metallic. But in so reasoning they forget that the effect of pressure ought to make the density of the nucleus much higher, even if the interior consisted of matter no heavier than the crust. In fact, we might argue for the probable comparative lightness of the substance composing the nucleus. That the total density of the planet does not greatly exceed its observed amount seems only explicable on the supposition that some antagonistic force counteracts the effects of pressure. The only force we can suppose capable of so acting is heat. But how and to what extent this counterbalancing takes place is still unknown.

If we regard the question from another point of view, however, the idea of a metallic nucleus seems not improbable. When the materials of the globe existed in a fluid condition, as they are usually supposed to have done, they would doubtless arrange themselves in accordance with their relative specific gravities. The denser elements would sink towards the centre, the lighter would remain outside. That this distribution has certainly taken place to some extent is evident from the structure of the envelopes and crust. It is what might be expected if the constitution of the globe resembles on a small scale the larger planetary system of which it forms a part. The existence of a metallic interior has always been inferred from the metalliferous veins which traverse the crust, and which are commonly supposed to have been filled from below.

Admitting the possibility or even probability of a metallic nucleus, in spite of the comparatively low density of the globe as a whole, we might speculate further as to the arrangement of the denser internal materials. The late Mr David Forbes suggested that the planet might be supposed to consist of three layers of uniform densities, enclosed one within the other, the density increasing towards the centre in arithmetical progression. Allowing 2·5 as the specific gravity of the crust or outer layer, he assigned 12·0 or thereabouts as that of the middle layer, and supposed that the inner nucleus might possess one averaging 20·0.[4] Materials do not yet exist for any satisfactory conclusions on his subject.

In the evidence obtainable as to the former history of the earth, no fact is of more importance than the existence of a high temperature beneath the crust, which has now been placed beyond all doubt. This feature of the planet's organization is made clear by the following proofs:—

(1.) *Volcanoes.*—In many regions of the earth's surface openings exist from which steam and hot vapours, ashes and streams of molten rock are from time to time emitted. The abundance of these openings seems inexplicable by any mere local causes, but must be regarded as indicative of a very high internal temperature. If to the still active vents of eruption we add those which have formerly been the channels of communication between the interior and the surface, there are probably few large regions of the globe where proofs of volcanic action cannot be found. Everywhere we meet with masses of molten rock which have risen from below as if from some general reservoir.

(2.) *Hot Springs.*—Where volcanic eruptions have ceased, evidence of a high internal temperature is still often to be found in springs of hot water which continue for centuries to maintain their heat. Thermal springs, however, are not confined to volcanic districts. They sometimes rise even in regions many hundreds of miles distant from any active volcanic vent. The hot springs of Bath (temp. 120° Fahr.) and Buxton (temp. 82° Fahr.) in England are

fully 900 miles from the Icelandic volcanoes on the one side, and 1100 miles from those of Italy and Sicily on the other.

(3.) *Borings, Wells, and Mines.*—The influence of the seasonal changes of temperature extends downward from the surface to a depth which varies according to latitude, to the thermal conductivity of the soils and rocks, and perhaps to other causes. The cold of winter and the heat of summer may be regarded as following each other in successive waves downward, until they disappear along a limit at which the temperature remains constant. This zone of invariable temperature is commonly believed to lie somewhere between 60 and 80 feet down in temperate regions. At Yakutsk in eastern Siberia (lat. 62° N.), however, the soil is permanently frozen to a depth of about 700 feet.[1] In Java, on the other hand, a constant temperature is said to be met with at a depth of only 2 or 3 feet.[2]

It is a remarkable fact, now verified by observation all over the world, that below the limit of the influence of ordinary seasonal changes the temperature, so far as we yet know, is nowhere found to diminish downwards. It always rises; and its rate of increment never falls much below the average. The only exceptional cases occur under circumstances not difficult of explanation. On the one hand, the neighbourhood of hot-springs, of large masses of lava, or of other manifestations of volcanic activity, may raise the subterranean temperature much above its normal condition; and this augmentation may not disappear for many thousand years after the volcanic activity has wholly ceased, since the coolingdown of a subterranean mass of lava would necessarily be a very slow process. On the other hand, the spread of a thick mass of snow and ice over any considerable area of the earth's surface, and its continuance there for several thousand years, would so depress the subterranean isothermals that for many centuries afterwards there might be a fall of temperature for a certain distance downwards. At the present day, in at least the more northerly parts of the northern hemisphere, there are such evidences of a former more rigorous climate, as in the well sinking at Yakutsk already referred to.[3] Sir William Thomson[4] has calculated that any considerable area of the earth's surface covered for several thousand years by snow or ice, and retaining, after the disappearance of that frozen covering, an average surface temperature of 13° C., "would during 900 years show a decreasing temperature for some depth down from the surface, and 3600 years after the clearing away of the ice would still show residual effect of the ancient cold, in a half rate of augmentation of temperature downwards in the upper strata, gradually increasing to the whole normal rate, which would be sensibly reached at a depth of 600 metres." But beneath the limit to which the influence of the changes of the seasons extends, observations in most parts of the globe show that the temperature invariably rises as we penetrate towards the interior of the earth. According to present knowledge the average rate of increase amounts to 1° Fahr. for every 50 or 60 feet of descent, and this rise is found whether the boring be made at the sea-level or on elevated ground. The subjoined table gives the results of temperature observations at widely separated localities[5]:—

(4.) *Irregularities in the Downward Increment of Heat.*—While these examples prove a progressive increase of temperature, they show also that this rate of increase is not strictly uniform. The more detailed observations which have been made in recent years have brought to light the important fact that considerable variations in the rate of increase take place even in the same bore. If, for instance, we examine the temperatures obtained at different depths in the Rose Bridge colliery shaft cited in the foregoing list, we find them to read as in the following columns:—

Depth in Yards.	Temperature (Fahr.).	Depth in Yards.	Temperature (Fahr.).
558	78	745	89
605	80	761	90½
630	83	775	91½
663	85	783	92
671	86	800	93
679	87	806	93½
734	88½	815	94

At La Chapelle, in an important well made for the water-supply of Paris, observations have been taken of the temperature at different depths, as shown in the subjoined table[6]:—

Depth in Metres.	Temperature (Fahr.).	Depth in Metres.	Temperature (Fahr.)
100	59·5	500	72·6
200	61·8	600	75·0
300	65·5	660	76·0
400	69·0		

In drawing attention to the temperature-observations at the Rose Bridge colliery—the deepest mine in Great Britain—Professor Everett points out that, assuming the surface temperature to be 49° Fahr., in the first 558 yards the rate of rise of temperature is 1° for 57·7 feet; in the next 257 yards it is 1° in 48·2 feet; in the portion between 605 and 671 yards—a distance of only 198 feet—it is 1° in 33 feet; in the lowest portion of 432 feet it is 1° in 54 feet.[7] When such irregularities occur in the same vertical shaft, it is not surprising that the average should vary so much in different places.

There can be little doubt that one main cause of these variations is to be sought in the different thermal conductivities of the rocks of the earth's crust. The first accurate measurements of the conducting powers of rocks were made by the late Professor J. D. Forbes at Edinburgh (1837–1845). He selected three sites for his thermometers, one in "trap-rock" (a porphyrite of Lower Carboniferous age), one in loose sand, and one in sandstone, each instrument being sunk to a depth of 24 French feet from the surface. He found that the wave of summer heat reached the first instrument on 4th January, the second on 25th December, and the third on 3d November, the trap-rock being by far the worst conductor, and the solid sandstone by far the best.[8]

The British Association has recently appointed a committee to investigate this subject in greater detail. Already some important determinations have been made by it regarding the absolute conductivity of various rocks. As a rule the lighter and more porous rocks offer the greatest

resistance to the passage of heat, while the more dense and crystalline offer the least resistance. The resistance of opaque white quartz is expressed by the number 114, that of basalt by 273, while that of cannel coal stands very much higher at 1538, or more than thirteen times that of quartz.[1]

It is evident also that, from the texture and structure of most rocks, the conductivity must vary in different directions through the same mass, heat being more easily conducted along than across the "grain," the bedding, and the other numerous divisional surfaces. Experiments have been made to determine these variations in a number of rocks. Thus, the conductivity in a direction transverse to the divisional planes being taken as unity, the conductivity parallel with these planes was found in a variety of magnesian schist to be 4·028. In certain slates and schistose rocks from central France the ratio varied from 1 : 2·56 to 1 : 3·952. Hence in such fissile rocks as slate and mica-schist heat may travel four times more easily along the lines of cleavage or foliation than across them.[2]

In reasoning upon the discrepancies in the rate of increase of subterranean temperatures, we must also bear in mind that certain kinds of rock are more liable than others to be charged with water, and that, in almost every boring or shaft, one or more horizons of such water-bearing rocks are met with. The effect of this interstitial water is to diminish thermal resistance. Dry red brick has its resistance lowered from 680 to 405 by being thoroughly soaked in water, its conductivity being thus increased 68 per cent. A piece of sandstone has its conductivity heightened to the extent of 8 per cent. by being wetted.[3]

Mr Mallet has contended that the variations in the amount of increase in subterranean temperature are too great to permit us to believe them to be due merely to differences in the transmission of the general internal heat, and that they point to local accessions of heat arising from transformation of the mechanical work of compression, which is due to the constant cooling and contraction of the globe.[4] But it may be replied that these variations are not greater than, from the known divergences in the conductivities of rocks, they might fairly be expected to be.

(5.) *Probable Condition of the Earth's Interior.*—Various theories (mostly fanciful) have been propounded on this subject. There are only three which merit serious consideration. (1.) One of these supposes the planet to consist of a solid crust and a molten interior. (2.) The second holds that, with the exception of local vesicular spaces, the globe is solid and rigid to the centre. (3.) The third contends that, while the mass of the globe is solid, there lies a liquid substratum beneath the crust.

1. The arguments in favour of internal liquidity may be summed up as follows. (*a.*) The ascertained rise of temperature inwards from the surface is such that, at a very moderate depth, the ordinary melting point of even the most refractory substances would be reached. At 20 miles the temperature, if it increases progressively, as it does in the depths accessible to observation, must be about 1760° Fahr.; at 50 miles it must be 4600°, or far higher than the fusing-point even of so stubborn a metal as platinum, which melts at 3080° Fahr. (*b.*) All over the world volcanoes exist from which steam and torrents of molten lava are from time to time erupted. Abundant as are the active volcanic vents, they form but a small proportion of the whole which have been in operation since early geological time. It has been inferred therefore that these numerous funnels of communication with the heated interior could not have existed and poured forth such a vast amount of molten rock, unless they drew their supplies from an immense internal molten nucleus. (*c.*) When the products of volcanic action from different and widely-separated regions are compared and analysed, they are found to exhibit a remarkable uniformity of character. Lavas from Vesuvius, from Hecla, from the Andes, from Japan, and from New Zealand present such an agreement in essential particulars as, it is contended, can only be accounted for on the supposition that they have all emanated from one vast common source.[5] (*d.*) The abundant earthquake shocks which affect large areas of the globe are maintained to be inexplicable unless on the supposition of the existence of a thin and somewhat flexible crust. These arguments, it will be observed, are only of the nature of inferences drawn from observations of the present constitution of the globe. They are based on geological data, and have been frequently urged by geologists as supporting the only view of the nature of the earth's interior compatible with geological evidence.

2. The arguments against the internal fluidity of the earth are based on physical and astronomical considerations of the greatest importance. They may be arranged as follows:—

(*a.*) Argument from precession and nutation.—The problem of the internal condition of the globe was attacked as far back as the year 1839 by the late Mr Hopkins of Cambridge, who endeavoured to calculate how far the planetary motions of precession and nutation would be influenced by the solidity or liquidity of the earth's interior. He found that the precessional and nutational movements could not possibly be as they are if the planet consisted of a central ocean of molten rock surrounded with a crust of 20 or 30 miles in thickness, that the least possible thickness of crust consistent with the existing movements was from 800 to 1000 miles, and that the whole might even be solid to the centre, with the exception of comparatively small vesicular spaces filled with melted rock.[6]

M. Delaunay, in a paper on *The Hypothesis of the Interior Fluidity of the Globe*,[7] threw doubt on Hopkins's views, and suggested that, if the interior were a mass of sufficient viscosity, it might behave as if it were a solid, and thus the phenomenon of precession and nutation might not be affected. Sir William Thomson, who had already arrived at the conclusion that the interior of the globe must be solid, and acquiesced generally in Hopkins's conclusions, pointed out that M. Delaunay had not worked out the problem mathematically, otherwise he could not have failed to see that the hypothesis of a viscous and quasi-rigid interior "breaks down when tested by a simple calculation of the amount of tangential force required to give to any globular portion of the interior mass the precessional and nutational motions which, with other physical astronomers, he attributes to the earth as a whole."[8] Sir William, in making this calculation, holds that it demonstrates the earth's crust down to depths of hundreds of kilometres to be capable of resisting such a tangential stress (amounting to nearly $\frac{1}{10}$th of a gramme weight per square centimetre) as would with great rapidity draw out of shape any plastic substance which could properly be termed a viscous fluid. "An angular distortion of 8″ is produced in a cube of glass by a distorting stress of about ten grammes weight per square centimetre. We may therefore safely conclude that the rigidity of the earth's interior substance could not be less than a millionth of the rigidity of glass without very sensibly augmenting the lunar nineteen-yearly nutation."[9]

In Hopkins's hypothesis he assumed the crust to be infinitely rigid and unyielding, which is not true of any material substance. Sir William Thomson has recently returned to the problem, in the light of his own researches in vortex-motion. He now finds that, while the argument against a thin crust and vast liquid interior is still invincible, the phenomena of precession and nutation do not decisively settle the question of internal fluidity, though the solar semi-annual and lunar fortnightly nutations absolutely disprove the existence of a thin rigid shell full of liquid. If the inner surface of the crust or shell were rigorously spherical, the interior mass of supposed liquid could experience no precessional or nutational influence, except in so far as, if heterogeneous in composition, it might suffer from external attraction due to non-sphericity of its surfaces of equal density. But "a very slight deviation of the inner surface of the shell from perfect sphericity would suffice, in virtue of the quasi-rigidity due to vortex-motion, to hold back the shell from taking sensibly more precession than it would give to the liquid, and to cause the liquid (homogeneous or heterogeneous) and the shell to have sensibly the same precessional motion as if the whole constituted one rigid body."[1]

The assumption of a comparatively thin crust requires that the crust shall have such perfect rigidity as is possessed by no known substance. The tide-producing force of the moon and sun exerts such a strain upon the substance of the globe that it seems in the highest degree improbable that the planet could maintain its shape as it does unless the supposed crust were at least 2000 or 2500 miles in thickness.[2] That the solid mass of the earth must yield to this strain is certain, though the amount of deformation is so slight as to have hitherto escaped all attempts to detect it. Had the rigidity been even that of glass or of steel, the deformation would probably have been by this time detected, and the actual phenomena of precession and nutation, as well as of the tides, would then have been very sensibly diminished.[3] The conclusion is thus reached that the mass of the earth "is on the whole more rigid certainly than a continuous solid globe of glass of the same diameter."[4]

(*b*.) Argument from the tides.—The phenomena of the oceanic tides are only explicable on the theory that the earth is either solid to the centre, or possesses so thick a crust (2500 miles or more) as to give to the planet practical solidity. Sir William Thomson remarks that, "were the crust of continuous steel, and 500 kilometres thick, it would yield very nearly as much as if it were india-rubber to the deforming influences of centrifugal force, and of the sun's and moon's attractions." It would yield, indeed, so freely to these attractions "that it would simply carry the waters of the ocean up and down with it, and there would be no sensible tidal rise and fall of water relatively to land."[5] Mr George H. Darwin has recently investigated mathematically the bodily tides of viscous and semi-elastic spheroids, and the character of the ocean tides on a yielding nucleus.[6] His results tend to increase the force of Sir William Thomson's argument, since they show that "no very considerable portion of the interior of the earth can even distantly approach the fluid condition," the effective rigidity of the whole globe being very great.

(*c*.) Argument from relative densities of melted and solid rock.—The two preceding arguments must be considered decisive against the hypothesis of a thin shell or crust covering a nucleus of molten matter. It has been further urged, however, as an objection to this hypothesis, that cold solid rock is necessarily more dense than hot melted rock, and that even if a thin crust were formed over the central molten globe it would immediately break up and the fragments would sink towards the centre.[7] Undoubtedly this would happen were the material of the earth's mass of the same density throughout. But, as has been already pointed out, the specific gravity of the interior is at least twice as much as that of the visible parts of the crust. If this difference be due, not merely to the effect of pressure, but to the presence in the interior of intensely heated metallic substances, we cannot suppose that solidified portions of such rocks as granite and the various lavas could ever have sunk into the centre of the earth, so as to build up there the honey-combed cavernous mass which might have served as a nucleus in the ultimate solidification of the whole planet. From the considerations above advanced we have seen that the earth's central mass may be plausibly conjectured to be metallic. Into this dense central mass the comparatively light crust could not sink, though its earliest formed portions would no doubt descend until they reached a stratum with specific gravity agreeing with their own, or until they were again melted.[8]

3. The ingenious suggestion of Mr Fisher, already cited (*ante*, p. 217), in favour of the existence of a possible fluid or viscous substratum between the flexible outer shell and an inner rigid nucleus, is made with the view of reconciling the requirements of physics with those facts in geology which seem to demand the existence of a mobile mass of intensely hot matter at no great depth beneath the surface. Whether it does so must be left for physicists to decide. But, on geological grounds, it may be questioned whether such a fluid substratum is needed. We must bear in mind that the land of the globe, regarding the geological structure of which alone we know anything, covers but a small part of the whole surface of the planet; that the existing continents seem from earliest times to have specially suffered from the reaction between the heated interior and the cooled exterior, forming, as it were, lines of relief from the strain of compression; and that along such lines, if the substance of the interior be everywhere just about the melting point, relief from pressure by corrugation would cause liquefaction of the matter so relieved, and its ascent towards the surface; so that evidences of volcanic action on the terrestrial ridges might be expected to occur, and to be referable to all ages. Mr Fisher assumes the contraction of rock in cooling to be ·000007 linear for one degree Fahr.; and he argues that, as this amount would not account for the observed contraction in the crust, we must have recourse to some additional explanation, such as the escape of steam and vapours from volcanic orifices. The validity of the assertion that the amount of horizontal compression of the superficial strata is greater than the cooling of a solid earth can account for may be questioned. The violently contorted rocks indicative of great horizontal compression occur chiefly along the crests of the great terrestrial ridges where the maximum effects of corrugation were to be looked for. To the argument from climate it may be replied on the other hand, with great plausibility, that secular changes may be accounted for by the effect of the variations in the eccentricity of the earth's orbit combined with the precession of the equinoxes, as already described.

(6.) *Age of the Earth and Measures of Geological Time.*—The age of our planet is a problem which may be attacked either from the geological or physical side.

1. The geological argument rests chiefly upon the observed rates at which geological changes are being effected at the

[1] Sir W. Thomson, *Brit. Assoc. Rep.*, 1876, Sections, p. 5.

[7] This objection has been repeatedly urged by Sir William Thomson See *Trans. Roy. Soc. Edin.*, xxiii. 157; and *Brit. Assoc. Rep.*, 1876, Sections, p. 7.
[8] See D. Forbes, *Geol. Mag.*, vol. iv. p. 435.

present time, and is open to the obvious preliminary objection that it assumes the existing rate of change as the measure of past revolutions,—an assumption which may be entirely erroneous, for the present may be a period when all geological events march forward more slowly than they used to do. The argument proceeds on data partly of a physical and partly of an organic kind. (*a*) The physical evidence is derived from such facts as the observed rates at which the surface of a country is being lowered by rain and streams, and new sedimentary deposits are formed. These facts will be more particularly dwelt upon in later portions of this article. If we assume that the land has been worn away, and that stratified deposits have been laid down nearly at the same rate as at present, then we must admit that the stratified portion of the crust of the earth must represent a very vast period of time. Dr Croll puts this period at not less, but possibly much more, than 60 million years. (*b*) On the other hand, human experience, so far as it goes, warrants the belief that changes in the organic world proceed with extreme slowness. Yet in the stratified rocks of the earth's crust we have abundant proof that the whole fauna and flora of the earth's surface have passed through numerous cycles of revolution,—species, genera, families, appearing and disappearing many times in succession. On any supposition it must be admitted that these vicissitudes in the organic world can only have been effected with the lapse of vast periods of time, though no reliable standard seems to be available whereby these periods are to be measured. The argument from geological evidence is strongly in favour of an interval of probably not much less than 100 million years since the earliest form of life appeared upon the earth, and the oldest stratified rocks began to be laid down.

2. The argument from physics as to the age of our planet is based by Sir William Thomson upon three kinds of evidence:—(1) the internal heat and rate of cooling of the earth; (2) the tidal retardation of the earth's rotation; and (3) the origin and age of the sun's heat.

(1.) Sir William Thomson, applying Fourier's theory of thermal conductivity, pointed out some years ago (1862) that in the known rate of increase of temperature downward and beneath the surface, and the rate of loss of heat from the earth, we have a limit to the antiquity of the planet. He showed, from the data available at the time, that the superficial consolidation of the globe could not have occurred less than 20 million years ago, or the underground heat would have been greater than it is; nor more than 400 million years ago, otherwise the underground temperature would have shown no sensible increase downwards. He admitted that very wide limits were necessary. In more recently discussing the subject, he inclines rather towards the lower than the higher antiquity, but concludes that the limit, from a consideration of all the evidence, must be placed within some such period of past time as 100 millions of years.[1]

(2.) The argument from tidal retardation proceeds on the admitted fact that, owing to the friction of the tide-wave, the rotation of the earth is retarded, and is therefore much slower now than it must have been at one time. Sir William Thomson contends that had the globe become solid some ten thousand million years ago, or indeed any high antiquity beyond 100 million years, the centrifugal force due to the more rapid rotation must have given the planet a very much greater polar flattening than it actually possesses. He admits, however, that, though 100 million years ago that force must have been about 3 per cent. greater than now, yet "nothing we know regarding the figure of the earth and the disposition of land and water would justify us in saying that a body consolidated when there was more centrifugal force by 3 per cent. than now might not now be in all respects like the earth, so far as we know it at present."[2] Professor Tait, in repeating this argument, concludes that, taken in connexion with the previous one, "it probably reduces the possible period which can be allowed to geologists to something less than ten millions of years."[3] He does not state, however, on what grounds he so reduces the available period, nor does he notice the objection urged by Dr Croll that, granting the gradual submergence of the polar lands owing to the slackened speed of rotation, the subaerial denudation of the rising equatorial land might well keep pace with the effects of the oceanic subsidence, so that we cannot infer from the present form of the earth what may have been its precise amount of polar compression at the time of solidification.[4]

(3.) The third argument, based upon the age of the sun's heat, is confessedly less reliable than the two previous ones. It proceeds upon calculations as to the amount of heat which would be available by the falling together of masses from space, which gave rise by their impact to our sun. The vagueness of the data on which this argument rests may be inferred from the fact that in one passage Professor Tait places the limit of time during which the sun has been illuminating the earth as, "on the very highest computation, not more than about 15 or 20 millions of years," while, in another sentence of the same volume, he admits that, "by calculations in which there is no possibility of large error, this hypothesis [of the origin of the sun's heat by the falling together of masses of matter] is thoroughly competent to explain 100 millions of years solar radiation at the present rate, perhaps more."[5] One hundred millions of years is probably amply sufficient for all the requirements of geology.

III. Composition of the Earth's Crust.

MINERALS AND ROCKS.

The visible and accessible portion of the earth is formed of minerals and rocks. A mineral may be classified as an inorganic body distinguished by a more or less definite chemical composition, and usually a characteristic geometrical form. A rock is an aggregate mass, sometimes of one, more commonly of two or more minerals. Upwards of 800 species of minerals and a vast number of varieties have been described. A very large proportion of these occur but rarely, and, though interesting and important to the mineralogist, do not demand the special attention of the geologist. While almost every mineral may be made to yield data of more or less geological significance, only those which enter into the composition of rock masses, or which are of frequent occurrence as accessories there, require to be familiarly known by the student of geology.

1. Rock-Forming Minerals.

The following are the more important minerals which enter into the composition of rocks:—

Quartz (SiO_2) occurs either crystallized as rock-crystal, or non-crystalline as calcedony. In the former condition it is an essential constituent of granite, felsite, and many other igneous rocks, as well as of sandstone and numerous aqueous rocks. The non-crystallized or colloid quartz is chiefly met with in cavities and fissures of rock where it has been slowly deposited from aqueous solution. Numerous varieties of calcedony occur, as agate, carnelian, jasper, flint, chert, Lydian-stone, &c.

Felspars (silicates of alumina, with potash, soda, or lime) constitute the most abundant group of rock-forming minerals. For the purposes of the petrographer they are conveniently divided into two series—(1) the Monoclinic or Orthoclase felspars (with cleavage angles of 90°), containing from 4 to 16 per cent. of potash and

[4] *Quart. Jour. Science*, July 1877.

[5] *Op. cit.*, pp. 153, 175.

usually more or less soda, sometimes as much as 10 per cent., and (2) the Triclinic or Plagioclase felspars (with oblique cleavage angles, or less than 90°), including a soda group with 8 to 12 per cent. of soda, and a lime group with 6 to 20 per cent. of lime. The felspars form a large part of most igneous rocks. By their decay they form clay, and in that condition enter largely into the composition of the argillaceous stratified rocks, such as shale, mudstone, slate, &c.

Hornblende is a meta-silicate of magnesium, with lime, iron, or manganese, and frequently alumina. The white non-aluminous varieties (tremolite, actinolite, anthophyllite, asbestos) chiefly occur as constituents of such metamorphic rocks as crystalline limestone, gneiss, &c. The black or dark green aluminous varieties enter as essential constituents into the composition of many rocks, as diorite and hornblende slate.

Augite (resembling hornblende in composition) is divisible into two groups. The pale non-aluminous varieties (diopside, sahlite, coccolite, &c.) occur under conditions like those of the pale hornblendes. The dark aluminous or common augite is abundant as an ingredient of some igneous rocks, as basalt. Allied to augite are diallage (important as a constituent of diallage-rock or gabbro), hypersthene, and bronzite. Uralite is the name of a mineral of frequent occurrence among Palæozoic rocks, having the external form of augite and the cleavage of hornblende.

Olivine (an ortho-silicate of magnesium, with part of the magnesium replaced by iron or manganese) is a conspicuous ingredient among the basalt rocks. It appears also to have been the original magnesian constituent of many rocks now altered into serpentine.

Nepheline (a silicate of alumina and soda with a little potash) takes the place of felspar in some lavas. It likewise occurs among the ejected blocks of Somma, and, in the form of elæolite, among the ancient crystalline rocks of Norway.

Leucite ($K_2Al_2Si_4O_{12}$) is a characteristic ingredient of many Tertiary and recent lavas. It has not been met with among any of the Palæozoic or Secondary igneous rocks, nor ever in association with quartz.

Haüyne and *Noscan* are two minerals allied to garnet, found in some Tertiary lavas.

Mica.—Under this general term are included several species of minerals distinguished by their basal cleavage into thin laminæ and by their splendent or silvery lustre. The non-magnesian micas include muscovite or potash-mica, the most abundant of all, and lepidolite or lithia-mica; of the magnesian micas the most important is biotite. Muscovite enters into the composition of granite, gneiss, mica-schist, micaceous sandstone, and many other rocks. Biotite is likewise abundantly distributed among the older crystalline rocks. Lepidomelane is a black mica often found in fine-grained granites. Other species are margarodite—an abundant constituent of many unctuous schists formerly called talc-schists, and haughtonite—which, according to Heddle, is the common mica of the granites in the Scottish Highlands.

Garnet (an aluminous ortho-silicate with lime, magnesia, iron, or manganese) occurs in rhombic dodecahedrons or allied forms, and also massive in many metamorphic rocks, as mica-schist, eclogite, &c.

Epidote (a variable silicate of lime, alumina, iron, or manganese) occurs in yellow or greenish translucent crystals or crystalline masses in many of the older crystalline rocks, though seldom as an abundant constituent. It is probably always an alteration-product.

Tourmaline, in its common black variety, *schorl*, forms with quartz the rock known as schorl-rock, and occurs in some granites, gneisses, schists, and other crystalline rocks.

Zircon (silicate of zirconium) is found as a constituent of zircon-syenite, and more sparingly in other crystalline rocks.

The hydrous silicates have resulted from the alteration of the anhydrous forms. As constituents of rocks they may be grouped into two series:—(1) the aluminous, including the zeolites, and (2) the magnesian, embracing talc, chlorite, serpentine, and their allies.

Zeolites form a numerous genus of minerals distinguished usually by their boiling up before the blowpipe, owing to the escape of their water of crystallization, by their frequent pearly lustre, inferior hardness, and their occurrence in cavities and veins where they have been deposited from solution. They are found as abundant secondary products in many amygdaloids, also in altered limestones and other metamorphic rocks.

Serpentine (SiO_2,44·14; MgO,42·97; H_2O,12·89) is a dull impure, usually green, granular to compact, more rarely foliated, mineral, with a hardness of 3 to 4 or even sometimes 5. Like the other hydrous magnesian silicates it has a soapy or greasy feel. It occurs abundantly in many altered rocks as a pseudomorph after some of the anhydrous magnesian silicates, also as a massive rock forming huge beds often associated with metamorphosed limestones.

Chlorite is a general term including several minerals which agree in possessing a greenish colour, soapy feel, hardness of only 2 to 2·5, and specific gravity of 2·65 to 2·85. It occurs in chlorite slate and in many rocks as an alteration-product.

Talc (SiO_2,59 to 63; MgO,30 to 33; H_2O, from a trace up to 7 per cent.) occurs in hexagonal plates or scales, cleaving readily into flexible non-elastic laminæ, but most commonly granular and massive, white to pale leek or apple-green, with marked pearly lustre on cleavage-planes. It is met with in talc-slate, also frequently in crystalline rocks as a result of the alteration of hornblende, augite, or other anhydrous magnesian silicate.

Delessite and *Saponite* are soft green hydrous magnesian silicates found as products of alteration in basalt-rocks.

Carbon occurs chiefly as beds in the form of coal, lignite, peat, &c. Graphite, however, is often met with in black or steel-grey splendent scales and granular masses in metamorphosed rocks. Anthracite also takes sometimes the form of black glancing grains or of a diffused fine black dust through certain palæozoic formations.

Carbonates play an important part both as individual minerals and as rock-masses. The three most important are calcite, dolomite, and siderite.

Calcite (carbonate of lime) is one of the most abundant minerals. It occurs crystallized as a secondary product in most rocks which have undergone decomposition, especially where they contain silicates into the composition of which lime enters. It is also found massive as limestone, forming beds having sometimes an aggregate thickness of many hundred feet and an extent of thousands of square miles.

Dolomite (carbonate of lime and magnesia) is likewise both a product of alteration and an original formation. In the former condition it is met with crystallized as bitter-spar in many metamorphic rocks as well as in veins and cavities of unaltered formations. It occurs also as an amorphous granular substance, sometimes replacing calcite, and sometimes in vast beds or masses of original deposit.

Siderite, *Chalybite*, or *Spathic Iron* (carbonate of iron) occurs both crystallized and massive. In the crystallized form it is comparatively unimportant as a constituent of rocks, being then found chiefly in veins and cavities where other alteration-products have been deposited. But in its massive condition it is found mixed with clay and other impurities, and forming beds and nodules which are among the most important ores of iron.

Sulphur, though seldom occurring in large masses, is widely diffused as an accessory ingredient of rocks. It occurs crystallized or finely granular in mineral veins, in nodules of limestone, and other concretions, and in beds of limestone and marl. It also takes the form of a crust in the sublimations of volcanic vents. Its frequent association in Tertiary strata with the remains of lacustrine shells, insects, and plants shows that it has in these cases been formed at ordinary temperatures from aqueous solutions.

Sulphides, combinations of sulphur with the metals, iron, copper, lead, zinc, and a few others, have a wide distribution among rocks. Where aggregated into masses they form mineral veins. It is the iron sulphides which deserve chiefly the attention of the petrographer. They occur in two varieties—*pyrite*, crystallizing in isometric forms, and *marcasite*, in rhombic forms. The former has a remarkably extensive diffusion throughout rocks of all ages, usually as minute crystals and thin streaks, but often in concretions and more massive veins. Marcasite also is abundantly distributed though less so than pyrite. From its greater liability to oxidation the strata through which it is diffused are apt to yield rapidly to the action of the weather, sulphuric acid and different alum compounds being produced.

Sulphates.—The most generally occurring sulphates in rocks are gypsum and barytes. *Gypsum* (hydrous sulphate of lime) in minute monoclinic prisms and macles may be obtained by the evaporation of sea-water, and in larger crystals of the same form it is found in many stratified formations. It likewise occurs as a secondary product in laminar or fibrous veins through rocks of igneous origin. Beds of gypsum, resulting from aqueous deposition, frequently appear interstratified with rock-salt and the associated products of evaporation. The anhydrous sulphate, anhydrite, likewise occurs among rock-salt deposits, but has a much more limited diffusion than gypsum. *Barytes* (sulphate of baryta) almost always occurs in veins or threads running through rocks. It is a common vein-stone in association with metallic ores.

Halite or *Rock-salt* (chloride of sodium) is more widely diffused than was formerly supposed. Microscopic research has shown its presence in the form of cubes in the minute cavities in the quartz of granite and other rocks. It occurs as scattered crystals, generally replaced by clay or some other substance, in many stratified formations. Its chief habitat, however, is in the various saliferous deposits where it takes the form of solid beds of salt.

Fluorite or *Fluor-spar* (fluoride of lime) is essentially a vein-stone, associated with metallic ores, especially with sulphides of lead and zinc. It occurs also in scattered cubes through various crystalline rocks, such as granite, gneiss, porphyrite.

Apatite (phosphate of lime, with fluorine and often chlorine) has been shown by microscopic investigation to have a very wide distribution among crystalline rocks. It occurs in fine needles or stouter hexagonal prisms in a large number of crystalline rocks, as granite, quartz-trachyte, syenite, diorite, basalt, and many others. It also occurs massive as beds among the more ancient geological formations.

Iron oxides.—These are abundantly distributed through rocks of all ages. Hæmatite (peroxide of iron) occurs crystallized in veins through crystalline rocks, also massive and earthy in beds, and sometimes in minute scales (rubin-glimmer) disseminated through the minerals of many crystalline rocks. Magnetite (Fe_3O_4) has an extensive diffusion in the form of minute octohedra or grains through crystalline rocks. In some of these rocks indeed, as in basalt, it plays the part of a chief constituent. It also occurs in many metamorphic rocks both scattered in detached crystals and segregated into veins or beds. Titanoferrite or titaniferous iron is likewise found as a plentiful ingredient in many crystalline rocks, particularly among the older basalts and dolerites. Hydrous iron oxide or limonite is diffused through almost all rocks. It is the usual brown or yellow colouring substance of minerals, and may be looked for wherever rocks containing iron have been exposed to the weather. It occurs also mixed with clay and other impurities in beds, as in the bog-iron-ore of lakes and marshes.

2. Rocks.

I. General Characters.

A rock may be defined as a mass of mineral matter, composed of one, more usually of several, kinds of minerals,—having, as a rule, no definite external form, and liable to vary considerably in chemical composition. The crust of the earth is built up of rocks, including under this term, not only hard solid masses like granite and limestone, but even all loose incoherent deposits such as mud, soil, peat, and blown sand.

Rocks may be distinguished by external and internal characters.

i. *External Characters.*

1. *Structure*, or the manner in which the component particles have been built up into the mineral masses called rocks, is the fundamental character. Viewed broadly, there are two leading types of structure among rocks—crystalline or massive, and fragmental.

(*a*.) Crystalline—consisting of a network of interlaced crystals and crystalline particles. Sometimes those crystals are large (half an inch or more in length), as in many granites, when the texture is called coarse or macro-crystalline; in other cases they are so minute as not to be discernible with the naked eye, when the texture is micro-crystalline or compact. While the crystalline structure is particularly characteristic of rocks which have crystallized from igneous fusion, it is not altogether peculiar to them. It may be produced by chemical deposit from aqueous solutions, or it may be developed in rocks previously granular by chemical infiltration and metamorphism.

Under the head of crystalline it is usual to include the *glassy* or *vitreous* structure. Rocks possessing this character are natural glasses produced by igneous fusion, such as obsidian and pitchstone. In most of these rocks, however, the process of devitrification may be observed; the glass has evidently become more and more stony as it cooled, by the appearance in it of small spherules, or hairs, or crystals, until in some cases it has become entirely lithoid. These stages are best studied with the microscope, and belong to the internal rather than the external characters.

When larger crystals than those of the compact base are scattered through a rock, the texture is said to be *porphyritic*. Many rocks, when in a melted condition, have had a cellular texture given to them by their imprisoned steam, like the open, cavernous texture of ill-baked bread. Several varieties of this texture are distinguished,—as *vesicular*, when there are comparatively few and small holes; *scoriaceous*, when the cavities occupy about as much space as the solid part, and are of very unequal sizes and forms; *pumiceous*, when the cells are much more numerous than the solid portion, and when, consequently, a piece of the rock may even float in water; *amygdaloidal*, when by subsequent infiltration the cells have been filled up with concretions of calcite, calcedony, zeolite, &c., which, from the elongated flattened form of the cells, are frequently almond-shaped.

Foliated rocks have their crystalline ingredients arranged in more or less defined layers, which usually inosculate. *Schistose* rocks are those where the foliated arrangement has been so produced that the rock splits into rude rough laminæ or plates.

Most of the crystalline rocks have resulted from igneous fusion. Some, like limestone, have been formed as deposits in water. The foliated rocks are generally believed to have acquired their peculiar character from the re-crystallization of their ingredients along original divisional planes, such as the lines of deposit.

(*b*.) Fragmental or Clastic.—These are all derivative from previously formed masses. They vary in texture from coarse masses consisting of accumulated blocks, several feet or even yards in length, to such fine aggregates as only show their secondary origin by microscopic investigation. They are said to be *conglomeratic* when they consist of beds of rounded water-worn pebbles like compacted gravel; *agglomeratic*, when the blocks are large, rounded, or sub-angular, and tumultuously thrown together; *brecciated*, when the fragments are angular and not water-worn. Most clastic rocks are *bedded*, that is, arranged in beds or layers. Each bed may consist of many thin layers or laminæ, which, when they enable the rock to split up into thin leaves, give what is called a *shaly* or *fissile* structure. Many fragmental rocks show a *concretionary* structure. When the concretions are like the roe of a fish, and of a calcareous nature, they form the *oolitic* structure; when of larger size, like peas, they give the *pisolitic* structure. There is often also a crystalline structure developed in rocks originally quite fragmental; many limestones, for example, made up originally of water-worn fragments of shells, corals, &c., slowly acquire a crystalline character from the action of percolating and slightly acidulous water. The action of rain on the exposed parts of a recent coral reef produces this change in the dead coral.

2. *Colour.*—This character varies so much even in the same rock, according to the freshness of the surface examined, that it possesses but a subordinate value as a means of discriminating rocks. Nevertheless, when cautiously used, it may be made to afford valuable indications as to the probable nature and composition of rocks. It is in this respect always desirable to compare a freshly-broken with a weathered piece of the rock. *White* indicates usually the absence or comparatively small amount of the metallic oxides, especially iron. It may either be the original colour of the rock, as in chalk and calc-sinter, or may be developed by weathering, as the white crust on flints and on many porphyries. *Black* seldom occurs on a weathered surface of rock. Its existence may be due either to the presence of carbon, when weathering will not change it much, or to some iron-oxide (magnetite chiefly), or some silicate rich in iron (as hornblende and augite). Many rocks (basalts and dolerites particularly) which look quite black on a fresh surface, become red, brown, or yellow on exposure. *Yellow*, as a dull earthy colouring matter, almost always indicates the presence of hydrated peroxide of iron. Bright, metallic, gold-like yellow is usually that of iron-sulphide. *Brown* occurs as the original colour in some carbonaceous rocks (lignite), and ferruginous beds (bog-iron-ore, clay-ironstone, &c.). It very generally, on weathered surfaces, points to the oxidation and hydration of minerals containing iron. *Red*, in the vast majority of cases, is due to the presence of granular peroxide of iron. This mineral gives dark blood-red to pale flesh-red tints. As it is liable, however, to hydration, these hues are often mixed with brown and yellow. *Green*, as the prevailing tint of rocks, occurs among metamorphic schists, when its presence is usually due to some of the hydrous magnesian silicates (chlorite, talc, serpentine). It occurs also among the igneous rocks, especially those of older

geological formations, where some of the hornblende, olivine, or other similar silicates have been altered. Among the sedimentary rocks it is principally due to the proto-silicate of iron in glauconite. Carbonate of copper colours some rocks a bright emerald or verdigris green. The mottled character so common among many stratified rocks is frequently traceable to unequal weathering, some portions being more oxidized than others; while some, on the other hand, become deoxidized from the reducing action of decaying organic matter. To the latter cause may be attributed the circular green spots so often found among red strata.

3. *Lustre*, as an external character of rocks, does not possess the value which it has among minerals. In most rocks the granular texture prevents the appearance of any distinct lustre. Where a rock shows a completely vitreous lustre it will usually be found to consist of a volcanic glass. A splendent semi-metallic lustre may often be observed upon the foliation planes of schistose rocks and upon the laminæ of micaceous sandstones. As this silvery lustre is almost invariably due to the presence of mica, it is commonly called distinctively micaceous. A metallic lustre is met with sometimes in beds of anthracite; more usually its occurrence among rocks indicates the presence of metallic oxides or sulphides.

4. *Hardness and Frangibility.*—A rock which can easily be scratched with the nail is almost always much decomposed, though some chloritic and talcose schists are soft enough to be thus affected. Compact rocks which can easily be scratched with the knife, and are apparently not decomposed, may be limestones, or other fragmental masses. Crystalline rocks, as a rule, cannot be scratched with the knife unless considerable force be used. The ease with which a rock may be broken is the measure of its frangibility. Most rocks break most easily in one direction; attention to this point will sometimes throw light upon their internal structure.

5. *Fracture* is the surface produced when a rock is split or broken, and depends for its character upon the texture of the mass. Finely granular compact rocks are apt to break with a *splintery* fracture where wedge-shaped plates adhere by their thicker ends to, and lie parallel with, the general surface. When the rock breaks off into concave and convex rounded shell-like surfaces, the fracture is said to be conchoidal, as may be seen in obsidian and other vitreous rocks, and in exceedingly compact limestones. The fracture may also be *foliated*, *slaty*, or *shaly*, according to the structure of the rock. Many black, opaque, compact rocks are translucent on the thin edges of fracture, and afford there, with the aid of a lens, a glimpse of their internal composition.

6. *Feel.*—Practice enables a geologist to discriminate some rocks by the feel of their weathered or fresh surfaces. The hydrous magnesian silicates, as already mentioned, have a marked soapy or greasy feeling under the fingers. Some micaceous schists, with margarodite or an allied mica, likewise exhibit the same character.

7. *Smell.*—Many rocks when freshly broken emit distinctive odours. Those containing volatile hydrocarbons give sometimes an appreciable *bituminous* odour, as is the case with some of the dolerites, which in central Scotland have been intruded through coal-seams and carbonaceous shales. Limestones have often a *fetid* odour; rocks full of decomposing sulphides are apt to give a *sulphurous* odour; those which are highly siliceous yield, on being struck, an *empyreumatic* odour. It is very characteristic of argillaceous rocks to emit a strong earthy smell when breathed upon.

8. *Specific gravity* is an important character among rocks as among minerals. It varies from 0·6 among the hydrocarbon compounds to 3·1 among the basalts. As already stated, the average specific gravity of the rocks of the earth's crust may be taken to be about 2·5, or from that to 3·0.

9. *Magnetism* is a distinguishing feature of many igneous and some metamorphic rocks. In some cases it exists in such development as powerfully to affect the magnetic needle, so that observations with that instrument among rocks of this character are deceptive. But even when much more sparingly present, the existence of magnetic iron in a rock may be shown by reducing the rock to powder in an agate mortar, washing carefully the triturated powder, and drying the heavy residue, from which grains of magnetite may be extracted with a magnet. This may be done with any basalt

ii. *Internal Characters.*

These are revealed chiefly by the microscope and chemical analysis. By the former we learn what are the component minerals of a rock, how they are built up into its mass, and what changes they have undergone. By the latter we are taught the chemical constitution of rocks, and are enabled to bring into close relations rocks which have externally no resemblance to each other, or, on the other hand, to show that rocks externally similar are chemically very distinct.

1. *Microscopic Examination.*—This method of inquiry has made great advances during the last 20 years, especially from the labours of German petrographers. Slices are cut from the rocks to be examined, and after being polished on one side with great care, are cemented by that side with Canada balsam to glass, and are then ground down until they attain the requisite transparency. In this way the minutest features in the structure of a rock can be leisurely studied. By the application of polarized light to these thin slices a marvellously delicate method of petrographical analysis is afforded.

Among the igneous rocks three leading types of microscopic structure have been established, chiefly through the researches of Professor Zirkel of Leipsic:—(1.) Purely-crystalline.—Granite (fig. 1) is a good example, consisting, as it does, entirely of crystals interlaced with each other. (2.) Half-crystalline.—In this division, which embraces most of the eruptive masses, the rocks consist of a non-crystalline amorphous matrix with crystals scattered through it. This matrix may be either (*a*) entirely glassy (figs. 2 and 3); (*b*) partly devitrified through separation of peculiar little granules and needles which are not "microlites" of the component parts of the rock; (*c*) an aggregation of such little granules, needles, and hairs, between which no glass, or almost none, appears (microcrystallitic); or (*d*) microfelsitic, nearly related to the two previous groups, and consisting of an amorphous mass marked usually with indefinite or half-effaced granules and filaments. (3.) Non-crystalline.—Rocks of this class are much less common than those of the other two. In their most typical condition they consist entirely of a non-

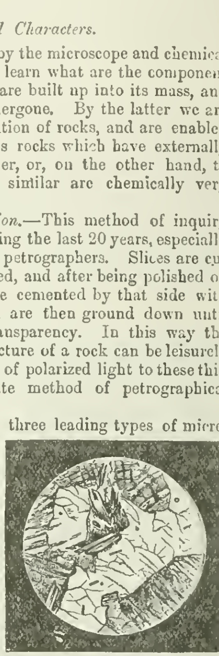

Fig. 1.—Microscopic Structure of Rocks—Purely crystalline—Section of Granite (× 18 diameter). The white mineral is quartz; that with shading, orthoclase. Some flakes of mica are shown as striated forms.

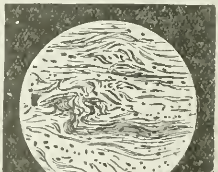

Fig. 2.—Microscopic Structure of Obsidian. A volcanic glass, with numerous microlites, which have been drawn out in a general direction during the flow of the melted rock (fluid-structure). (× 18 diameter.)

crystallized or amorphous (*nicht individualisirten*) substance, sometimes glassy and sometimes microfelsitic.

Rocks really formed of compacted sediment become sometimes so close-grained that their origin may not be apparent to the naked eye. Their truly derivative character is well brought out by the microscope. In fig. 4, for example, the structure of a piece of fine greywacke is shown. It will be observed that the component particles are not crystals, but broken and more or less rounded fragments of different minerals. The larger white pieces are quartz, the darker portions consist of granules of slate, felspar, and other substances, with a little siliceous ferruginous cement. Many exceedingly compact and even flinty argillaceous rocks are in this way shown by microscopic examination to be formed of water-worn particles.

FIG. ..—Microscopic Structure of Pitchstone. A glassy base, with numerous feathered and needle-shaped microlites, and a sanidine crystal.

Rocks which have been so affected by subsequent changes as to acquire a new crystalline character, and to receive the name Metamorphic, exhibit many characteristic features of structure under the microscope. Limestones, for example, which have been altered into saccharoid marble are found to consist of crystalline grains of calcite, showing the characteristic cleavage of that mineral (fig. 5). The foliated rocks (schists) show a curious blending of the characters of igneous and sedimentary rocks. Thus they have often a distinctly granular structure, resembling that of sedimentary deposits, with, at the same time, an arrangement of the micaceous folia reminding us of the fluid structure of igneous rocks. In fig. 6, for instance, the quartz-grains are to be observed in layers separated by folia of mica which curve and twist like the microlites in an obsidian (compare fig. 2).

FIG. 4.—Microscopic Structure of a fragmental rock. Greywacke.

FIG. 5.—Microscopic Structure of Saccharoid white Marble (Carrara).

Much light has been cast on the origin and history of igneous rocks by microscopic investigation. It is easy, for example, to see in what order the several mineral components have crystallized out of the original glass. Thus in basalt the magnetite has appeared before the augite, in which it has been abundantly enclosed. Again, the movement of the still liquid or viscid rock, when many of its crystals had already been produced, is beautifully shown by the "fluid structure" (fig. 2), where minor crystals and particles are drawn into curving lines which bend round the large crystals, and also by the frequent fracture of the larger crystals and the insertion of portions of the general ground-mass of the rock between the separated pieces. That intensely saline water was present during the formation of many crystalline rocks is proved by the presence in their crystals of minute cavities filled with fluid and containing cubes of halite (common salt). Liquid carbonic acid has been observed in such cavities.

FIG. 6.—Microscopic Structure of Mica-schist.

Most interesting and important information is likewise afforded by the microscope regarding the subsequent changes which rocks have undergone through the influence chiefly of percolating water. Every gradation of alteration from the fresh mineral to its complete pseudomorph may be observed. In this way many serpentines have been shown to have been originally olivine rocks. It can be seen, too, how certain minerals decay, and to what products their alteration gives rise, even when the general mass of the rock looks to the eye still tolerably fresh. There can be little doubt that the application of microscopic analysis is destined to throw much light upon both the formation and the subsequent history of the sedimentary rocks. These have not yet been so sedulously explored as the igneous groups. The obscure subject of metamorphism is especially open to elucidation by the microscopic method.[1]

2. *Chemical Analysis.*—This method of investigation must supplement the work of the microscope. A mere chemical analysis gives the ultimate chemical constitution of a rock, but may afford little clue to its mineral structure, which can only be thoroughly examined by means of the microscopic method. On the other hand, many rocks do not allow of satisfactory determination of their constitution by means of the microscope. For these chemical analysis is, of course, indispensable. But our knowledge of no rock can be considered complete until the rock has been subjected to both processes of investigation.

II. Classification and Description.

A precise yet convenient classification of rocks is still required. We may adopt chemical characters as the basis of arrangement, and group rocks according as they may be sulphates, carbonates, silicates, &c.; but in so doing we place together rocks which, from a geological point of view, have no real affinity. Again, we may select mineralogical composition as the groundwork of the classification; but in this case also great violence may be done in the geological relationships of the rocks. In many respects the long established geological arrangement according to manner of production is a useful one—igneous, aqueous, and metamorphic rocks. There is, of course, the obvious objection to it that it starts upon a preconceived theory of the origin of the rocks, and this objection must be admitted to be serious. Every year, however, is diminishing its force by making us more certain of the mode of formation of different rocks; and, probably, some modification of it will in the end be very generally adopted. In the meantime the most eligible course seems to be to choose a scheme of arrangement which, confessedly imperfect and temporary, shall recognize at once the mineralogical, chemical, and geological relations of the rocks. With this object the following classification will be adopted here.

I. *Crystalline and Glassy Non-Fragmental Rocks.*

1. Simple Rocks (composed of one mineral substance),—chiefly of aqueous rocks formed from chemical precipitates.

---

[1] The reader will find this subject fully treated in Zirkel's *Mikroskopische Beschaffenheit der Mineralien und Gesteine* (1873), Rosenbusch's *Mikroskopische Physiographe der Mineralien und Gesteine* (1873-7), Vogelsang's *Krystalliten* (1874), and De la Vallée and Renard, *Sur les roches plutoniennes de la Belgique* (Acad. Royale de Belgique, 1876).

2. Compound Rocks (composed of two or more minerals), including (*a*) Massive series, embracing the various igneous rocks, as granite and lava, and (*b*) Schistose series, including all the crystalline schists and most of the so-called metamorphic rocks.

II. *Fragmental or Clastic Rocks*, including (*a*) Gravel and Sand Rocks, (*b*) Clay Rocks, (*c*) Plant-formed Rocks, (*d*) Rocks formed from animal remains, (*e*) Volcanic Agglomerates and Tuffs.

I. *Crystalline and Glassy or Non-Fragmental Rocks.*

The great majority of these rocks are original formations; that is, they have not been palpably derived from the destruction of pre-existing rocks, as in the case of the fragmental series. They include all chemical precipitates, whether these possess a distinctly crystalline or a dull granular texture, all rocks which have consolidated from igneous fusion, and all the schistose and metamorphic rocks which, whatever may have been their original character, now possess a crystalline or foliated structure.

1. *Simple Rocks.*

Limestone is a mass of carbonate of lime, either nearly pure or mixed with clay or other impurity. Few rocks vary more in texture and composition. It may be a hard flinty close-grained mass, breaking with a splintery or conchoidal fracture; or a crystalline rock built up of fine crystals of calcite and resembling loaf sugar in colour and texture (fig. 5); or a dull earthy friable chalk-like deposit; or a compact massive finely-granular rock resembling a close-grained sandstone or freestone. The colours, too, vary extensively, the most common being shades of blue-grey and cream-colour passing into white. Some limestones are highly siliceous, the calcareous matter having been accompanied with silica in the act of deposition; others are argillaceous, sandy, ferruginous, dolomitic, or bituminous. To some of these varieties particular names have been assigned:—*Oolite*, a granular limestone built up of small roe-like grains, each of which consists of concentric coats of lime; *Pisolite*, an oolitic or pisolitic limestone where the grains are as large as peas; *Travertine* (*calcareous tufa*), the material deposited by calcareous springs, usually white or yellowish, varying in texture from a soft chalk-like substance or marl to a compact building-stone; *Stalactite*, the calcareous pendant deposit formed on the roofs of caverns, vaults, bridges, &c. The water from which the hanging lime-icicles are derived drips to the floor, and on further evaporation there gives rise to the crust-like deposit known as *stalagmite*. *Hydraulic limestone* contains sufficient silica (and usually alumina) that, when it is burnt and subsequently mixed with water, a compound containing silicate of calcium is formed, which has the property of "setting" or hardening under water. Limestones containing perhaps as much as 25 per cent. of silica, alumina, iron, &c., which in themselves would be unsuitable for many of the ordinary purposes for which limestones are used, can be used for making hydraulic mortar. These limestones occur sometimes in beds like those in the Lias of Lyme Regis, sometimes in nodules like those of Sheppey, from which Roman cement is made. *Cement-stone* is the name given to many pale dull ferruginous limestones, which contain an admixture of clay, and some of which can be profitably used for making hydraulic mortar or cement. *Fetid limestone* (*stinkstein*, *swinestone*) gives off a fetid smell, like that of sulphuretted hydrogen gas, when struck with a hammer. In some cases, as in that at North Berwick, the rock seems to have been deposited by volcanic springs containing decomposable sulphides as well as lime. In other instances the odour may be connected with the decomposition of organic matter. In some quarries in the Carboniferous Limestone of Ireland, as mentioned by Mr Jukes, the freshly broken rock may be smelt at a distance of a hundred yards when the men are at work, and occasionally the stench becomes so strong that the workmen are sickened by it and require to leave off work for a time. *Cornstone* is an arenaceous or siliceous limestone particularly characteristic of some of the Palæozoic red sandstone formations. *Rottenstone* is a decomposed siliceous limestone from which most or all of the lime has been removed, leaving a siliceous skeleton of the rock. A similar decomposition takes place in some ferruginous limestone with the result of leaving a yellow skeleton of ochre.

Marble is limestone which has acquired a granular crystalline structure. Ordinary statuary marble is a familiar example of this rock. It is white, fine-grained, composed of minute crystalline granules of calcite, and resembles loaf-sugar, whence the term "saccharoid" often applied to it (fig. 5). Fine silvery scales of mica or talc may often be noticed even in the purest marble. Some limestones associated with gneiss and schist are peculiarly rich in minerals,—tremolite, actinolite, anthophyllite, zoisite, and many other species occurring there, often in great abundance. Many varieties of colour and texture occur among these limestones, as may be seen in the numerous kinds of ornamental marble.

Dolomite (*Magnesian Limestone*) is a massive formation of the carbonates of lime and magnesia, commonly associated with gypsum, rock-salt, and other results of the evaporation of saturated saline waters. It is dull granular to finely crystalline in texture, sometimes full of cavities lined with crystals of dolomite, sometimes aggregated into botryoidal, mammillated, and other concretionary forms. Dolomite also occurs as the result of a chemical transformation of ordinary limestone, carbonate of magnesia replacing carbonate of lime. This process, known as *dolomitization*, was largely insisted on by Von Buch and has been discussed by Bischof. The metamorphic variety of the rock is generally quite crystalline, resembling saccharoid marble in texture, and sometimes even in colour, though yellowish tints are apt to predominate. As a proof of the dolomitization or conversion of limestone into dolomite the fact may be noticed that fossil shells, and other organisms consisting originally of calcite, have been altered into dolomite. On a small scale a similar change may be observed in a limestone where it is traversed by some igneous dyke. Even along the vertical joints of limestone where no igneous matter has penetrated, and where percolating water has probably been the only agent of change, the limestone is changed for some distance on either side into a dull yellow dolomite, locally termed "dunstone."

Gypsum occurs as a rock in the form of beds and concretions as well as in strings and veins. It is associated with red strata, often with dolomite, rock-salt, and anhydrite.

Rock-salt, massive chloride of sodium, occurs in beds sometimes 60 to 90 feet in thickness, rudely crystalline, usually stained red from an admixture of red sediment, like that of the red clays and sandstones among which the salt-beds occur.

Ironstone.—Besides the iron ores met with in veins associated with other accompaniments of metalliferous lodes, there are many which were doubtless formed as chemical precipitates on the floors of lakes and other sheets of water. Some of these deposits (either peroxide or carbonate of the protoxide of iron) arise from precipitation in water or on moist ground where organic matter, especially of vegetable origin, has decomposed. The hard crust of hydrous peroxide of iron which forms under wet or boggy soil (*moor-band pan*, *bog-iron-ore*) is an example of such a deposit now in course of formation. Where the peroxide has been reduced and become carbonate, it occurs in beds or nodules usually mixed with a variable proportion of clay (*clay ironstone*), and sometimes with a good deal of carbonaceous matter from associated vegetation (*black-band ironstone*). Clay iron-ore is one of the most valuable ores of the metal, and occurs largely in beds and nodules in the Carboniferous system, as well as in parts of the Jurassic series in Britain. In some of the oldest geological formations extensive beds occur of hæmatite and magnetite.

Serpentine.—This mineral occurs massive, forming large bands of rock. In some places it may have been an original deposit from oceanic water, comparable to the glauconite found filling the chambers of *Foraminifera*, and occurring extensively both in old geological formations and on the present ocean-floor. The serpentines associated with the gneisses and other crystalline rocks have had this origin assigned to them by Sterry Hunt. There can be no doubt, however, that many, probably most, serpentines are the results of the alteration of pre-existing rocks. Tschermak pointed out that much serpentine has been produced by the hydration and alteration of olivine, and this view has been confirmed by illustrations from all parts of the world. In many serpentines the forms of the original crystals of olivine may still be detected. Hence the difficulty in understanding how there could be intrusive masses of serpentine—a hydrated magnesian silicate—is now removed, for we see that the original olivine-rocks may have been intruded as molten masses which would preserve their external characters as eruptive rocks though undergoing an internal conversion into serpentine. With many Palæozoic limestones, and more particularly with the crystalline beds which occur among the schistose rocks, serpentine is frequently associated. Some of this may represent the result of an alteration of dolomite, though, as above stated, it may with more probability be connected with some original oceanic deposit of a magnesian silicate.

2. *Compound Rocks.*

Nearly the whole of the rocks in this division consist of two or more minerals. A few examples occur, however, where, at least in some parts of their mass, the rocks are formed of only one mineral. Strictly speaking, these exceptions should be placed among the simple rocks. But they are so closely linked with the compound masses that to separate them would do much more violence to geological continuity than any harm likely to arise from the present arrangement. Besides, a rock which, like obsidian, may appear quite simple at one place may, at a short distance, show the presence of other minerals entitling it to a place among the compound rocks.

(*a*.) *Massive Rocks.*—This important division consists almost entirely of rocks which have resulted from igneous fusion. Considered from a chemical point of view, these rocks may be described as mixtures in different proportions of silicates of alumina, magnesia, lime, potash, and soda, usually with magnetic iron and phosphate of lime, and, in a great group of rocks, with an excess of silicic acid, existing as free quartz. Taking this last feature as a basis of arrangement, some petrographers have proposed to divide the igneous rocks into an acid group, including such rocks as granite, quartz-porphyry, and quartz-trachyte, where the percentage of silica ranges from 60 to 75, and a basic group, typified by such rocks as leucite-lava and basalt, where the proportion of silica is only about 50 per cent.

In the vast majority of igneous rocks the chief silicate is a felspar,—the number of rocks where the felspar is represented by another silicate (as leucite or nepheline) being comparatively few and unimportant. As the felspars group themselves into two great series, the monoclinic or orthoclase, and the triclinic or plagioclase, the former with, on the whole, a preponderance of silica, and as the minerals occur under tolerably distinct and definite conditions, it has been proposed to divide the felspar-bearing massive rocks into two series,—(1) the orthoclase rocks, having orthoclase as their chief silicate, and often with free silica in excess, and (2) the plagioclase rocks, where the chief silicate is some species of triclinic felspar. The former series corresponds generally to the acid group above mentioned, while the plagioclase rocks are on the whole decidedly basic. It has been objected to this arrangement that the so-called plagioclase felspars are in reality very distinct minerals, with proportions of silica, ranging from 43 to 69 per cent.; soda from 0 to 12; and lime from 0 to 20. But in the state of minute subdivision in which the minerals occur in many igneous rocks, it is often scarcely possible to determine the species of felspar.

Without attempting here any formal classification, according either to relative proportion of silica or to the distinguishing felspar, it may be sufficient to arrange the following description of the massive rocks in a continuous series, with the most typical acid or orthoclase rocks at the beginning, and the basic felsparless rocks at the end.

Granite is a thoroughly crystalline-granular admixture of felspar, mica, and quartz. The felspar is chiefly orthoclase, but striated triclinic felspars (as oligoclase and albite) may often be observed in smaller quantity. The mica in most granites seems to be the potash or muscovite variety, usually of a white silvery aspect; sometimes it is dark brown or black, and belongs to biotite (magnesian mica) or lepidomelane. Dr Heddle finds the common mica of the granites in the Scottish Highlands to be a new variety, which he has called haughtonite. The quartz may be observed to form a kind of paste or magma wrapping round the other ingredients (see fig. 1). It is only in cavities of the granite that the component minerals occur as independent well-formed crystals, and there too the accessory minerals are chiefly found, such as beryl, topaz, tourmaline, &c.

Microscopic examination of granite by Sorby and other later observers has shown that the quartz is full of cavities containing liquid, sometimes in such numbers as to amount to a thousand millions in a cubic inch. The liquid in these cavities appears usually to be water containing chlorides of soda and potash, with sulphates of potash, soda, and lime.

Granites vary in texture from extremely coarse crystalline masses, with crystals an inch or more in length, to fine granular rocks which pass into elvanite or felsite. They are sometimes porphyritic, with large scattered orthoclase crystals. The variety known as graphic granite is distinguished by the way in which the quartz is crystallized through the felspar in imperfect or hemihedral shells arranged with their longer axes generally parallel, so as to produce on cross fracture the appearance of Hebrew characters.

The mean of eleven analyses of granites made by Dr Haughton gave the following average composition:—Silica, 72·07; alumina, 14·81; peroxide of iron, 2·22; potash, 5·11; soda, 2·79; lime, 1·63; magnesia, 0·33; loss by ignition, 1·09; total, 100·05,—with a mean specific gravity of 2·66.

Granite occurs (1) as an eruptive rock, forming huge bosses, which rise through other formations both stratified and unstratified, and sending out veins into the surrounding and overlying rocks, which usually show evidence of much alteration as they approach the granite; (2) connected with true volcanic rocks, and forming probably the lower portions of masses which flowed out at the surface as lavas; and (3) in the heart of mountain chains and elsewhere, so intimately connected with metamorphic rocks as to suggest that it is itself a final stage of the metamorphism of rocks. Granite is thus a decidedly *plutonic* rock; that is, it has consolidated at some depth beneath the surface, and in this respect differs from the superficial *volcanic* rocks, such as lavas, which have flowed out above ground from volcanic orifices.

Quartz-porphyry, Felsite-porphyry, Felstone, Felsite.—These names are given to different conditions under which orthoclase and quartz unite to form a massive eruptive rock. When the quartz forms well-marked grains, blebs, or crystals, the rock is a quartz-porphyry; when the felspar and quartz are so intimately mixed as to appear to the eye as a homogeneous matrix, the rock is called by one of the other epithets.

The base of the rock, whether in the form of quartz-porphyry or felstone, is usually exceedingly compact or even flinty in texture. Under the microscope it shows the microfelsitic character, the true nature and origin of which is still the subject of much discussion among petrographers. When the quartz occurs in forms visible to the naked eye it usually appears as round or irregular grains, varying in size from mere specks up to pieces as large as a pea or larger. Less frequently it occurs definitely crystallized, and sometimes in perfect doubly terminated pyramids.

Besides the othoclase of the diffused matrix, this mineral occurs in crystalline fragments and crystals, which sometimes reach to the length of an inch or more, so as to give a markedly porphyritic character to the rock. Triclinic felspars usually occur, though perhaps not so commonly as in granite. Mica and hornblende are among the most frequent of the minerals which accompany the two essential constituents, while apatite, magnetite, and pyrite are not infrequent accessories.

The colours of quartz-porphyry and felstone depend chiefly upon those of the felspar,—flesh-red, reddish-brown, purple, yellow, bluish or slate-grey, and even white, being in different places characteristic. The presence of much mica or hornblende gives dark grey, brown, or greenish tints. It will be observed in this, as in other rocks containing much felspar, that the colour, besides depending on the hue of that mineral, is greatly regulated by the nature and stage of decomposition. A rock weathering externally with a pale yellow or white crust may be found to be quite dark in the central undecayed portion.

The flesh-red quartz-porphyry of Dobritz, near Meissen, in Saxony, was found by Rentzsch to have the following chemical composition:—Silica, 76·92; alumina, 12·89; potash, 4·27; soda, 0·68; lime, 0·68; magnesia, 0·98; oxide of iron, 1·15; water, 1·97; total, 99·54,—specific gravity, 2·49.

Besides the differences of colour already referred to, minor varieties in composition are produced by the relative abundance and size of the felspar crystals, and by the presence of mica (*micaceous quartz-porphyry, micaceous felstone*, or *felsite*), hornblende (*hornblendic quartz-porphyry* or *felstone*), or other accessory ingredient. The variety called minette consists of a felsite base with crystals of orthoclase and dark mica, and may be regarded as a micaceous felstone, bearing the same relation to the acid felspar-rocks (felstones) that mica-porphyrite does to the more basic forms (porphyrites). When the base is very compact, and the felspar-crystals well defined and of a different colour from the base, the rock sometimes takes a good polish, and may be used with effect as an ornamental stone. In ordinary language such a stone is classed with the "marbles," under the name of "porphyry."

Closely related to the quartz-porphyries and felstones, of which, indeed, it can be regarded only as a variety, comes the rock known as *elvan* or *elvanite*. This is a Cornish term for a crystalline-granular mixture of quartz and orthoclase, forming veins which proceed from granite, or occur only in its neighbourhood and are evidently associated with it. It forms an immediate stage between granite and quartz-porphyry.

Quartz-porphyry and the other varieties included under this species occur (1) with plutonic rocks, as eruptive bosses or veins, often associated with granite, from which, indeed, the elvanite, as just stated, may be seen to proceed directly; of frequent occurrence also as veins and irregularly intruded masses among highly convoluted rocks, especially when these have been more or less metamorphosed; (2) in the chimneys of old volcanic orifices, forming there the "neck" or plug by which the vent is filled up; and (3) as truly volcanic rocks which have been erupted at the surface in the form of flows of lava, either (*a*) submarine, as in the felstones of

Wales, associated with the marine Lower Silurian rocks, or (*b*) subaerial, as probably in the quartz-porphyry of Arran, and perhaps in the series of the "green-slates and porphyries" of the Silurian system in Cumberland, which Professor Ramsay has conjectured to be the products of a subaerial volcano.

Pitchstone (*Retinite*) is a glassy rock, having a pitch-like or resinous lustre, and a black or dark-green colour ranging through shades of green, brown, and yellow to nearly white. It is essentially an orthoclase rock, and may be regarded as the natural glass of many of the more granular or crystalline orthoclase rocks, such as the quartz-porphyries or felsites. Examined microscopically, it is found to consist of glass in which are diffused, in greater or less abundance, hair-like microlites, angular or irregular grains, or more definitely formed crystals. The pitchstone of Corriegills, in the island of Arran, presents abundant green, feathery, and dendritic microlites of a pyroxenic character (see fig. 3).

According to Durocher the mean composition of pitchstone is—silica, 70·6; alumina, 15·0; potash, 1·6; soda, 2·4; lime, 1·2; magnesia, 0·6; oxides of iron and manganese, 2·6; loss by ignition, 6·0. The mean specific gravity is given as 2·34.

Pitchstone is found either as intrusive dykes, veins, or bosses, probably in close connexion with former volcanic activity, or in sheets which, like the porphyritic pitchstone of the Isle of Eigg, flowed out at the surface as lava-streams.

Liparite (*Rhyolite*, *Quartz-trachyte*) is an orthoclase rock containing an excess of silica which usually appears in distinct grains or in doubly terminated pyramids. The orthoclase, which is of the variety termed sanidine, is sparingly accompanied with triclinic felspar. Other frequent ingredients are magnesia-mica, hornblende, augite, apatite, and magnatite. Considerable diversity exists in the texture of this rock. Some varieties are coarse and granitoid in character, and are regarded by some petrographers as the equivalents in Tertiary times of the granite of older geological periods. From this crystalline aspect intermediate varieties may be obtained like the quartz-porphyries, passing by degrees into more or less distinctly vitreous rocks. Throughout all these gradations, however, a characteristic ground mass can be seen under the microscope having a glassy, enamel-like, or porcellanous character. An analysis by Vom Rath of a rhyolite from the Euganean Hills gave—silica, 76·03; alumina, 13·32; soda, 5·29; potash, 3·83; protoxide of iron, 1·74; magnesia, 0·30; lime, 0·85; loss, 0·32; total, 101·68,—specific gravity, 2·553. Liparite is a volcanic rock of late geological date occurring in the form of erupted lavas.

Obsidian is a volcanic glass representing the vitreous condition of a highly silicated sanidine-rock, such as liparite. It resembles bottle glass, having a perfect conchoidal fracture, and breaking into sharp splinters, semi-transparent or translucent at the edges. The colours of the rock are black, brown, or greyish-green, rarely yellow, blue, or red, but not infrequently streaked or banded with paler and darker lines. When a thin slice of obsidian is prepared for the microscope it is found to be very pale yellow, grey, or nearly colourless. On being magnified it shows that the usual dark colours are almost always produced by the presence of minute crystals, needles, and black hair-like bodies. In rare examples the obsidian appears as a perfect glass without any foreign admixture. The minute crystals and hair-like bodies sometimes so increase in abundance as to make the rock lose the aspect of a glass and assume that of a dull flint-like or enamel-like stone. This devitrification can only be properly studied with the microscope. Again little granules (*spherulites*) of a dull grey enamel (pearlstone) appear, and in some parts of the rock so abundantly as to alter its character and convert it from obsidian into pearlstone. The average chemical composition of the rock is—silica, 71·0; alumina, 13·8; potash, 4·0; soda, 5·2; lime, 1·1; magnesia, 0·6; oxides of iron and manganese, 3·7; loss, 0·6; total, 100·0,—mean specific gravity, 2·40. Obsidian occurs as a product of the volcanoes of late geological periods.

Pearlstone (*Perlite*) is another vitreous condition of sanidine lava. As its name denotes, it consists of vitreous or enamel-like globules, occasionally assuming polygonal forms by mutual pressure. These globules sometimes constitute the entire rock, their outer portions shading off into each other so as to form a compact mass; in other cases they are separated by and cemented in a compact glass or enamel. They consist of successive very thin shells, which, in a transverse section, are seen as concentric rings, usually full of the same kind of hair-like crystallites and crystals as in obsidian. Occasionally there are found among them true spherulites where the internal structure is radiating fibrous. When such spherulites occupy the main mass they give rise to *spherulite-rock*.

Pumice is a general term for the cellular and filamentous or froth-like parts of lavas. In the great majority of cases it is a form of the obsidians, showing under the microscope the usually vitreous characters, and possessing a specific gravity of 2·0 to 2·53, though, owing to its porous nature, it possesses great buoyancy and readily floats on water. At Hawaii, however, some of the pyroxenic or olivine lavas give rise to a pumiceous froth which has the usual outward characters of ordinary pumice.

The rocks enumerated up to this point are all orthoclase-rocks, and markedly siliceous, frequently showing their excess of silica in the form of quartz grains or crystals. In the succeeding group free quartz is not found as a marked constituent, although occasionally it occurs in some quantity. In this series syenite may be regarded as the equivalent of granite in the quartzose series, orthoclase-porphyry of quartz-porphyry and felstone, and trachyte of liparite.

Syenite.—According to the modern nomenclature, this name, which was formerly given in England to a granite with hornblende replacing mica, is now restricted to a rock consisting essentially of a mixture of orthoclase and hornblende, to which plagioclase, quartz, and mica are occasionally added. The name syenite, first used by Pliny in reference to the rock of Syene, was introduced by Werner as a scientific designation, and applied to the rock of the Plauenscher-Grund, Dresden. Werner afterwards, however, made that rock a greenstone. The base of all syenites like that of granites is crystalline, without a trace of any amorphous substance between the crystals, such as most igneous rocks contain. Hence the texture is of that crystalline kind commonly known as granitic.

The typical syenite of the Plauenscher-Grund, formerly described as a coarse-grained mixture of flesh-coloured orthoclase and black hornblende, containing no quartz, and with no indication of plagioclase, was regarded as a normal orthoclase-hornblende rock. Microscopical research has, however, shown that well-striated triclinic felspar, as well as quartz, occurs in it. Its composition is shown by the following analysis:—silica, 59·83; alumina, 16·85; protoxide of iron, 7·01; lime, 4·43; magnesia, 2·61; potash, 6·57; soda, 2·44; water, &c., 1·29; total, 101·03. The average specific gravity of syenite is from 2·75 to 2·90.

Syenite occurs under conditions similar to those in which granite is found; it has been erupted in large irregular masses, especially among metamorphic rocks, as well as in smaller bosses and veins.

Orthoclase Porphyry (*Quartzless Porphyry*) is an orthoclase rock containing no quartz, or a very sparing admixture of that mineral, but with a little plagioclase, and not unfrequently with some hornblende and dark biotite. It contains from 55 to 65 per cent. of silica. It differs thus from quartz-porphyry and felstone in its smaller proportion of silica, but the distinction is one which, except by chemical or microscopical analyses, must often be difficult to establish between the fine compact felstones and the orthoclase porphyries, especially when the latter contain free quartz. This rock is sometimes termed syenite-porphyry, since it is associated with syenite much in the same way that elvanite is with granite. It is like syenite a plutonic rock, and occurs in veins, dykes, and intrusive sheets. Probably, however, many of the so-called "felstones" which occur as lavas, contemporaneously ejected with the older Palæozoic formations, are really orthoclase-porphyries.

Trachyte, a term originally applied to a large series of modern volcanic rocks possessing a characteristic roughness (τραχύς) under the finger, is now restricted to rocks consisting essentially of sanidine, with more or less triclinic felspar, usually with hornblende, biotite, or augite, and sometimes with magnetite and apatite. In microscopic structure the rock is distinguishable from the quartz-trachytes or liparites by the absence or feeble development of any microfelsitic ground-mass, and in general by the presence of a porphyritic base, consisting either of a pure glass or of one with devitrification products. The average composition of trachyte may be stated thus:—silica, 60·0; alumina, 17·0; protoxide of iron, 8·0; magnesia, 1·0; lime, 3·5; soda, 4·0; potash, 5·0; loss by ignition, 1·5. Average specific gravity, 2·65. Trachyte is a volcanic rock of Tertiary and post-Tertiary date.

Phonolite (*Clinkstone*), a term suggested by the metallic ringing sound emitted by the compact varieties when struck, is applied to a mixture of sanidine felspar and nepheline with hornblende and usually nosean. An average specimen contained silica, 57·7; alumina, 20·6; potash, 6·0; soda, 7·0; lime, 1·5; magnesia, 0·5; oxides of iron and manganese, 3·5; loss by ignition, 3·2 per cent. The specific gravity may be taken as about 2·58. Phonolite is sometimes found splitting into thin slabs which can be used for roofing purposes. Occasionally it assumes a porphyritic texture from the presence of large crystals of sanidine or of hornblende. When the rock is partly decomposed and takes a somewhat porous texture, it resembles trachyte in appearance.

Like trachyte, phonolite is a thoroughly volcanic rock and of late geological date. It occurs sometimes filling the pipes of volcanic orifices, sometimes as sheets which have been poured out in the form of lava-streams, and sometimes as dykes and veins.

In the rocks enumerated up to this point the essential felspar constituent is orthoclase; in the felspar rocks now to be described the corresponding ingredient is nearly always some triclinic form. In the volcanic rocks of this series there is usually some mineral of the hornblende or augite family present in such quantity as to give a green or even black colour to the mass.

Porphyrite may be used as the designation of rocks which consist essentially of some triclinic felspar, and show a glassy or partially devitrified ground-mass containing abundant crystals of plagioclase with magnetite or titaniferous iron, and sometimes hornblende, augite, or mica. These rocks include many varieties which have not yet been thoroughly examined. The texture varies from coarse crystalline-granular to exceedingly close-grained, and passes occasionally even into vitreous. Porphyrite is a volcanic rock very characteristic of the later palæozoic formations, occurring there as interstratified lava-beds, and in eruptive sheets, dykes, veins, and irregular bosses.

Diorite (*Greenstone* in part) is a crystalline mixture of oligoclase or some allied felspar and hornblende with magnetic iron and apatite. Where free quartz occurs the rock is called *quartz-diorite*. The more compact dark varieties have been termed *aphanite*. The average chemical composition of this rock may be taken to be—silica, 53·2; alumina, 16·0; potash, 1·3; soda, 2·2; lime, 6·3; magnesia, 6·0; oxides of iron and manganese, 14·0; loss by ignition, 1·0. The mean specific gravity is about 2·95. Diorite occurs as an eruptive rock under conditions similar to those of quartz-porphyry and syenite. It is found in palæozoic volcanic regions, as in North Wales, in "neck"-like masses which may mark the position of some of the volcanic orifices of eruption.

Propylite is a name given to certain Tertiary volcanic rocks consisting of a plagioclase felspar and hornblende in a fine-grained ground-mass. They are subject to considerable alteration, the hornblende being converted into epidote. Some quartziferous propylites have been described by Zirkel from Clarence King's *Survey of the 40th Parallel*, wherein the quartz abounds in liquid cavities containing briskly moving bubbles, and sometimes double enclosures with an interior of liquid carbonic acid.

Hornblende-Andesite is a rock of late geological date consisting of a plagioclase felspar and hornblende often with a little sanidine. The ground-mass is frequently quite crystalline, or shows a small proportion of a felsitic nature, with microlites and granules. When the rock contains free quartz it is called *Dacite*.

In the next series of rocks augite plays a similar part to that taken by hornblende in the foregoing species.

Diabase.—This name has been given to certain dark green or black eruptive rocks found in the older geological formations and consisting essentially of a triclinic or plagioclase felspar, augite, magnetic or titaniferous iron, sometimes olivine, and usually with more or less of a diffused greenish substance which has resulted from the alteration of the augite or olivine. The texture is sometimes quite crystalline; in other cases it shows a felsitic ground-mass. Except that the so-called diabases are confined to Palæozoic rocks and the basalts to Tertiary and post-Tertiary formations, there seems no essential distinction between these two groups, though, of course, as the diabases are much older and have been far longer exposed to metamorphic processes, they are in general less fresh than the basalts.

Melaphyre is a term which has been so variously used that the sense in which it is taken must always be explained. Thus Senft described it as a rock having an indistinctly mixed character, with colours ranging from dirty greenish-brown, or reddish-grey, or greenish black-brown, to a complete black; hard and tough when fresh, and then showing crystals of reddish-grey labradorite, with magnetic titaniferous iron, and usually with carbonates of lime and iron, and ferruginous chlorite (delessite), in crystalline grains; compact or earthy, or sometimes porphyritic or amygdaloidal. Naumann defines melaphyre as a close-grained rock, very often amygdaloidal, composed essentially of labradorite, with an undetermined silicate, some titaniferous iron, carbonates of lime and of iron, and sometimes crystals of augite, rubellan, and mica. Zirkel called it generally crypto-crystalline, sometimes porphyritic, very often amygdaloidal rock, consisting of a mixture of oligoclase and augite with magnetic iron. Lastly, Rosenbusch proposes to restrict it to those plagioclase-augite rocks which contain olivine, and possess a distinct porphyry ground-mass. There can be little doubt that, like the so-called diabases, the melaphyres are merely older forms of the great basalt-family

Augite-Andesite is the name given to certain dark eruptive rocks of Tertiary and post-Tertiary date which consist of a triclinic felspar (oligoclase, or some species rather richer in silica than labradorite) and augite, with sometimes sanidine, hornblende, biotite, magnetite, or apatite, and in some varieties quartz. The composition of an example from Santorin, erupted in the year 1866, was found to be as follows:—silica, 67·35; alumina, 15·72; magnesia, 1·16; lime, 3·60; soda, 5·04; potash, 1·86; oxides of iron, 1·94; loss by ignition, 0·36; total, 101·06. Mean specific gravity, 2·75.

Basalt.—Under this term are included those widespread and important volcanic rocks which consist of a triclinic felspar, probably always labradorite, augite, olivine, and magnetic or titaniferous iron, with apatite, and sometimes sanidine or nepheline. The more coarsely crystalline varieties are known as *dolerite*, while those of intermediate texture have been termed *anamesite*, the more close-grained black heavy kinds being distinctively *basalts*. The chemical composition of an average variety may be set down as silica, 45·0; alumina, 15·0; magnesia, 6·5; lime, 10·5; soda, 3·5; potash, 1·5; oxides of iron and manganese, 15·0; loss by ignition, 3·0. Mean specific gravity, 2·95.

Zirkel has described under the name of basalt certain rocks in which the part of the felspar is played by another mineral, in some cases nepheline, in others leucite.

Basalt occurs as dykes and veins, intrusive bosses and sheets, and successive contemporaneous flows. It often presents a columnar structure, as at Staffa and the Giant's Causeway, whence the structure has been popularly termed basaltic.

Tachylite is a black volcanic glass often found in association with basalt, of which indeed it is merely the vitreous condition. Thus a basalt-dyke sometimes shows a thin crust of this pitch-like substance on its walls, where the molten rock was first suddenly cooled.

Palagonite is a volcanic glass related to basalt, and found in fragments in some tuffs.

Gabbro (*Diallage-rock*) is a compound of a triclinic felspar and diallage often with olivine, and also very generally with magnetic or titaniferous iron and apatite, more rarely with hornblende, biotite, or quartz. An average chemical composition is silica, 50·0; alumina 15·0; magnesia, 7·0; lime, 10·0; soda, 2·5; potash, 0·5; oxides of iron and manganese, 12·5; loss by ignition, 2·5. Mean specific gravity, 2·95.

A very few crystalline massive rocks occur without felspar as an essential constituent; but they are of comparatively little importance as rock-masses, though interesting in themselves and sometimes of considerable beauty.

Pikrite is a rock rich in olivine, usually more or less serpentinized, with augite, magnetite, or ilmenite, and a little brown biotite, hornblende, or apatite.

Eulysite is a mixture of olivine, augite, and red garnet.

Garnet-olivine-rock is composed of olivine, diallage, and garnet.

Enstatite-olivine-rock consists of olivine and enstatite (bronzite or hypersthene) with magnetite or chromite.

Lherzolite is a mixture of olivine, pyroxene, picotite, and usually some magnetite.

Eclogite is a compound of garnet and omphacite, or smaragdite (hornblende).

Dunite is a mixture of olivine and chromite, found with serpentine.

Limburgite is composed of crystals of olivine, augite, and magnetite, in a base more or less vitreous.

(*b*.) *Schistose or Foliated Rocks*.—These form an exceedingly well-defined characteristic series. They are distinguished from the massive rocks by the possession of an internal arrangement into more or less closely parallel layers or folia, consisting of materials which have assumed a crystalline character along these layers. The layers may be composed of only one mineral, but are usually of two or more, which occur either in distinct, often alternate, laminæ or intermingled in the same layer. Moreover, the layers are not usually continuous for more than a short space. As a rule they are strikingly lenticular, thickening out and then dying away, and reappearing after an interval on the same or a different plane. They are likewise characteristically welded, as it were, into each other, the crystalline particles of one lamina being so intermingled with those of the layers above and below it that the whole coheres as a tough not easily fissile mass. Though arranged in distinct layers, a schistose rock is usually distinguished from an ordinary sedimentary one by the irregularity of its lamination, and by a remarkable and eminently distinctive puckering or crumpling of the folia. The vast plications which can be seen from a distance running up the face of a mountain are repeated on a smaller scale in hand specimens, and even down to such proportions as can only be seen with a microscope. As already stated, the origin of these rocks has been the subject of much discussion. That they are metamorphosed sediments, and not original chemical precipitates, is the general opinion of geologists. See part iv.

A foliated rock showing this characteristic irregular fissility in a marked degree is termed a "schist." This word, placed after the distinguishing mineral of the rock, is used as the name of the rock, as mica schist, chlorite-schist, hornblende-schist. If the mass loses its fissile tendency owing to the felting together of the component mineral into a tough coherent whole, the word rock is usually substituted for schist, as in hornblende-rock, actinolite-rock, and so on. There are thus three kinds of fissility among rocks:—(1) that of original deposit, as in shale,—this is termed lamination; (2) that of cleavage, as in clay slate; (3) that of foliation, as in the schists. There is a fourth kind of divisional planes, that of joints, sometimes so closely placed together as almost to rival the others, as will be pointed out in part iv.

Mica-schist (*Mica-slate*) is a schistose aggregate of quartz and mica. The relative proportions of the two minerals vary widely even in the same mass of rock. Each is arranged in lenticular wavy laminæ. The quartz shows greater inconstancy in the number and thickness of its folia. Frequently a layer of this mineral may often be seen to swell out to a thickness of an inch or more, and, dwindling rapidly down to a mere thread, disappear. The quartz may often be observed to retain a granular character like that of quartz-rock, no doubt indicative of its originally sedimentary origin (see fig. 6). The mica lies in thin plates, sometimes so dovetailed into each other as to form long continuous irregular crumpled folia, separating the quartz layers, and often in the form of thin spangles and membranes running in the quartz. Among the accessory minerals, garnet, felspar, and hornblende are not infrequent. Mica-schist forms extensive regions in Norway, Scotland, the Alps, and other parts of Europe, in connexion with other members of the schistose family of rocks. It is also found encircling granite masses in Scotland and Ireland as a metamorphic zone a mile or so broad, which shades away into the unaltered strata of greywacke or slate outside.

Though the possession of a fissile structure, showing abundant divisional surfaces covered with glistening mica, is characteristic of mica-schist, we must distinguish between this structure and that of many micaceous sandstones which can be split into thin seams each splendent with the sheen of its mica-flakes. A little examination will show that in the latter case the mica has not crystallized *in situ*, but exists merely in the form of detached worn scales, which, though lying on the same general plain, are not welded into each other as in a schist; also that the quartz does not exist in folia but in rounded separate grains.

Gneiss is a crystalline schistose aggregate of the same minerals as in granite—felspar, quartz, and mica. The relative proportions of these minerals, and the manner in which they are grouped with each other, give rise to numerous varieties of the rock. As a rule the folia are coarser and the schistose character less perfect than in mica-schist. Sometimes the quartz lies in tolerably pure bands a foot or even more in thickness with plates of mica scattered through it. These quartz layers may be replaced by a crystalline mixture of quartz and felspar, or the felspar will take the form of independent lenticular folia, while the mica runs abundantly through the rock, and by its own ready cleavage imparts a fissile structure to the whole. Sometimes the mica is mostly or wholly replaced by hornblende, in other cases by talc (*protogine-gneiss*). Like mica-schist, gneiss occupies a large space in regions where the older geological formations come to the surface. Varieties of it are also found in the metamorphic zone encircling some masses of granite. So coarse is the texture of many gneisses that they cannot, in hand-specimens nor even in large blocks, be certainly discriminated from granite. In such cases it is only by examination in the field and the detection of clear evidence of foliated structure that their true character can be determined.

An interesting and important variety is met with in some regions of gneiss and schist, viz., conglomerate bands in which pebbles of quartz and other materials from less than an inch to more than a foot in diameter are imbedded in a foliated matrix. Examples of this kind are found in the pass of the Tête Noir between Martigny and Chamouni, in N. W. Ireland, in the islands of Bute and Islay, and in different parts of Argyllshire. These enclosures are not to be distinguished from the ordinary water-worn blocks of true conglomerates; but the original matrix which encloses them has been so altered as to acquire a micaceous foliated structure, and to wrap the pebbles round as with a kind of glaze. These facts are of considerable value in regard to the theory of the origin of the crystalline schists.

Granulite (*Leptynite*) is a crystalline schistose aggregate of orthoclase and quartz, with some garnet and kyanite.

Chlorite-schist (or *Chlorite-slate*) is a schistose aggregate of green chlorite, often with some quartz, felspar, mica, or talc. The more massive forms (*lapis ollaris*, potstone) can be cut as building stone, or for the manufacture of articles for domestic use.

Talc-schist is a schistose aggregate of whitish-green or yellowish talc often combined with felspar or quartz. Dr Heddle has recently shown that many so-called talc-schists contain no talc, but owe their unctuous character to a variety of mica (margarodite).

Hornblende-schist is a schistose mass of black or dark-green hornblende, but often interleaved with felspar, quartz, or mica. When the schistose character disappears, the mass becomes a *hornblende rock* (amphibolite). When the variety actinolite occurs instead of common hornblende it forms actinolite-schist.

Numerous other varieties of schists have been described, but they occupy very subordinate places among the foliated rocks. The following analyses show the chemical composition of the more important of those which have been enumerated:—

	Silica.	Alumina.	Oxides of Iron.	Protoxide of Manganese.	Magnesia.	Lime.	Soda.	Potash.	Water.			Specific Gravity.
Mica-schist	65·13	18·16	5·27	0·51	2·70	0·32	0·53	2·99	3·73	TiO_2 1·54	=100·88	2·773
Mica gneiss	70·20	14·04	6·84	...	0·80	2·03	0·91	2·98	1·67	,, 0·72	=100·19	...
Hornblende gneiss	56·83	19·68	8·64	trace	3·28	1·89	3·14	2·34	2·69	,, 0·47 CuO 0·09	= 99·05	2·80
Granulite	73·47	14·86	3·28	...	0·67	1·62	1·80	3·95	0·57	...	=100·22	...
Chlorite-schist	42·08	3·51	26·85	0·59	17·10	1·04	...	...	11·24	...	=102·41	2·75
Talc-schist	50·81	4·53	7·58	...	31·55	...	...	...	4·42	...	= 98·89	...
Hornblende-rock	49·42	18·12	15·01	...	3·16	8·65	2·57	1·27	1·80 loss	...	=100·00	...

As the disappearance of the schistose structure produces a crystalline amorphous compound like that of a massive or ordinary igneous rock, we are brought at last round again to rocks which we cannot distinguish from those to which elsewhere an igneous origin is assigned. In gneiss, for example, the same minerals occur which form granite, and possess a crystalline character. Any process, such as irregular internal motion of the mass, which could destroy the schistose structure and produce a thoroughly granite-like texture, would give rise to a rock which, whatever its previous history might have been, could not be distinguished from granite. That such internal transformations have taken place among the crystalline gneissose masses can hardly be doubted. And thus, at the one end of the schistose series, we may have ordinary unaltered sediment; at the other, after many intermediate stages, a thoroughly crystalline amorphous rock like granite or syenite.

II. Fragmental (Clastic) Rocks.

This great series embraces all rocks of a secondary or derivative origin; in other words, all formed of particles which had previously existed on the surface of the earth in another form, and the accumulation and consolidation of which gave rise to new compounds. Some of these rocks have been produced by the mechanical action of running water, such as gravel, sand, and mud; others have arisen from the gathering together of the remains of once living plants or animals; others have been formed by the consolidation of the loose debris thrown out by volcanoes.

(*a*.) *Gravel and Sand Rocks.*—Ordinary *gravel* and *sand* are produced by the action of running water on every sea-coast and river-course. These sedimentary materials, being mere mechanical formations, vary indefinitely in composition, according to the nature of the source from which they are derived. As a rule they consist of the detritus of siliceous rocks, these being among the most durable materials. Quartz, in particular, enters largely into the composition of sandy and gravelly detritus. Fragmentary materials tend to group themselves according to their size and relative density. Hence they are apt to occur in layers, and to show the characteristic *stratified* arrangement of *sedimentary* rocks. They may enclose the remains of any plants or animals entombed on the same sea-floor, river-bed, or lake-bottom.

Blown sand is sand which has been produced by previous wave-action, and is blown into long ridges or dunes by prevailing winds. It varies in composition as ordinary sandstones do, being sometimes entirely siliceous, sometimes calcareous where derived from triturated shells or other calcareous organisms. Layers of finer and coarser particles often alternate as in water-formed sandstone. Grasses and other plants bind the surface of the shifting sand, but are apt to be covered by fresh encroachments of the loose material, and then by their decay they give rise to dark peaty layers in the sand. Calcareous blown sand is compacted into hard stone by the action of rain-water which alternately dissolves a little of the lime and re-deposits it on evaporation as a thin crust cementing the grains of sand together.

Cliff-debris consists of angular rubbish disengaged by frost and ordinary atmospheric waste from the face of cliffs, crags, and steep slopes. It slides down the declivities of hilly regions, and accumulates at the base of slopes and precipices, until washed away by rain or by brooks. It naturally depends for its composition upon the nature of the solid rocks from which it is derived. The material constituting glacier moraines is of this kind.

Rain-wash is a loam or earth which accumulates on the lower parts of slopes or at their base, and is due to the gradual descent of the finest particles of disintegrated rocks by the transporting action of rain. *Brick-earth* is the name given in the south-east of England to thick masses of such loam which are extensively used for making bricks.

Subsoil is the broken-up part of the rocks immediately under the soil. Its character of course is determined by that of the rock out of which it is formed by subaerial disintegration.

Soil is the product of the subaerial decomposition of rocks and of the decay of plants and animals. Primarily the character of the soil is determined by that of the subsoil, of which indeed it is merely a further disintegration. The formation of soil is treated in part iii., pages 265, 269.

Conglomerate (*Puddingstone*) is a name given to any rock formed of consolidated gravel or shingle. The component pebbles are rounded and water-worn. They may consist of any kind of rock, though usually of some hard and durable sort, such as quartz or quartz-rock. A special name may be given according to the nature of the pebbles, as quartz-conglomerate, limestone-conglomerate, granite-conglomerate, &c. The paste or cementing matrix may consist of a hardened sand or clay, and may be siliceous, calcareous, argillaceous, or ferruginous. In the coarser conglomerates, where the blocks may exceed 6 feet in length, there is often very little indication of stratification. Except where the flatter stones show by their general parallelism the rude lines of deposit, it may be only when the mass of conglomerate is taken as a whole, in its relation to the rocks below and above it. that its claim to be considered a stratified rock will be conceded.

Breccia is a rock in which the stones are angular and not rounded, and usually with less trace of stratification than in conglomerate. Intermediate stages between this rock and the preceding, where the stones are partly angular and partly subangular and rounded, are known as *brecciated conglomerate*.

Sandstone is a rock formed of consolidated sand. The component grains are for the most part of quartz—a most durable mineral, which must here be regarded as the residue left after all the more decomposable minerals of the original rocks have been carried away in solution or in suspension as fine mud. The colours of sandstones arise, not so much from that of the quartz, which is commonly white or grey, as from the film or crust which often coats the grains and holds them together as a cement. As already stated iron is the great colouring ingredient of rocks. In sandstones it gives rise to red, brown, yellow, and green hues, according to its degree of oxidation and hydration. In ordinary red sandstones, for example, each grain of sand is coated with red earthy hæmatite. In yellow sandstone the oxide has become hydrous in the form of limonite.

There is as much variety of composition among sandstones as among conglomerates. Though they consist for the most part of siliceous grains, they include others of clay, felspar, mica, or other mineral; and these may increase in number so as to give a special character to the rock. Thus sandstones may be argillaceous, felspathic, micaceous, calcareous, &c. By an increase in the argillaceous constituents, a sandstone may pass into one of the clay-rocks, just as modern sand on the sea-floor shades imperceptibly into mud. On the other hand, by an augmentation in the size of the grains a sandstone may become a grit, or a pebbly or conglomeratic sandstone, and pass into a fine conglomerate. A piece of fine-grained sandstone seen under the microscope looks like a coarse conglomerate, so that the difference between the two rocks is little more than one of relative size.

Among the varieties of sandstones may be mentioned *Flagstone*, a thin-bedded sandstone capable of being split into slabs or flags; *Freestone*, a sandstone which can be cut freely in any direction (the term is popularly applied to some limestones and other rocks); and *Buhrstone*, a highly siliceous, exceedingly compact. though cellular, rock (with *Chara* seeds, &c.), found alternating with unaltered Tertiary strata in the Paris basin, and forming from its hardness and roughness an excellent material for the grindstones of flour-mills.

Greywacke is a compact aggregate of rounded or subangular grains of quartz, slate, felspar, or other minerals or rocks cemented by a paste which is usually siliceous but may be argillaceous, felspathic, or calcareous. Grey, as its name denotes, is the prevailing colour; but it passes into brown, brownish-purple, and sometimes, where anthracite occurs, into black. The rock is distinguished from ordinary sandstone by its darker hue, its hardness, the variety of its component grains, and above all by the compact cement in which the grains are imbedded. In many varieties so pervaded is the rock by the siliceous paste that it possesses great toughness, and its grains seem to graduate into each other as well as into the surrounding matrix. Such rocks when fine-grained can hardly, at first sight or with the unaided eye, be distinguished from some compact igneous rocks, though a microscopic examination at once reveals their fragmental character. In other cases, where the greywacke has been formed mainly out of the debris of granite, quartz-porphyry, or other felspathic masses, the grains consist so largely of felspar, and the paste also is so felspathic, that the rock might be mistaken for some close-grained granular porphyry. Greywacke occurs extensively among the Palæozoic formations in beds alternating with shales and conglomerates. It represents the sand of the Palæozoic sea-floor, retaining often its ripple-marks and sun-cracks. The metamorphism it has undergone has generally not been great, and for the most part is limited to induration, partly by pressure and partly by permeation of a siliceous cement.

Quartz-rock (*Quartzite*) is a close-grained granular aggregate of quartz cemented by a highly siliceous matrix. Originally it consisted of a tolerably pure quartz-sand, which has been metamorphosed by pressure and the transfusion of a siliceous cement into an exceedingly hard mass. This cement was probably produced by the solvent action of heated water upon the quartz grains, which very generally seem to shade off into each other, or into the intervening silica. It is owing no doubt to the purely siliceous character of the grains that the blending of these with the surrounding cement is more intimate than in greywacke, so much so that the rock often assumes an almost flinty homogeneous texture. That quartz-rock as here described is an original sedimentary rock and not a chemical deposit is shown, not only by its granular texture, but by the exact resemblance of all its leading features to ordinary sandstone—false-bedding, alternation of coarser and finer layers, worm-burrows, and fucoid-casts. It occurs in the form of large masses interstratified with limestones, slates, and schists. It is also met with locally as an altered form of sandstone, where this rock is traversed by igneous dykes and indurated into quartz-rock for a distance of a few inches or feet from the intrusive mass. Bands of highly silicated sandstones, having the lustrous aspect, fine grain, and great hardness of quartz-rock, occur among the unaltered shales and other strata of the Carboniferous system. In such cases, the supposition of any general metamorphism being inadmissible, we must suppose either that these quartzose bands have been indurated, for example, by the passage through them of thermal silicated water, or that the quartz-rock is there an original formation.

(*b.*) *Clay-rocks.*—These are composed of the finer argillaceous sediments or muds derived from the waste of previously formed rocks. Perfectly pure clay, hydrated silicate of alumina, may be seen where some granites and other felspar-bearing rocks decompose. But, as a rule, the clay is mixed with various impurities.

Pipe-clay is white, nearly pure, and free from iron. *Fire-clay* is a deposit largely found in connexion with coal-seams, contains little iron, and is nearly free from lime and alkalies. Some of the most typical fire-clays are those long used at Stourbridge, Worcestershire, for the manufacture of pottery. The best glass-house pot-clay, that is, the most refractory, and therefore used for the construction of pots which have to stand the intense heat of a glass-house, has the following composition:—silica, 73·82; alumina, 15·88; protoxide of iron, 2·95; lime, trace; magnesia, trace; alkalies, ·90; sulphuric acid, trace; chlorine, trace; water, 6·45; specific gravity, 2·51. A very siliceous close-grained or flinty variety, termed *Gannister*, occurs in the Lower Coal-measures of the north of England, and is now largely ground down as a material for the hearths of iron furnaces. *Brick-clay* is properly rather an industrial than a geological term, since it is applied to any clay, loam, or earth, from which bricks or coarse pottery are made. It is an impure clay, containing a good deal of iron, with other ingredients. An analysis gave the following composition of a brick-clay:—silica, 49·44; alumina, 34·26; sesquioxide of iron, 7·74; lime, 1·48; magnesia, 5·14; water, 1·94.

Mudstone is a fine, usually more or less sandy, argillaceous rock, having no fissile character, and of somewhat greater hardness than any form of clay. The term *Clay-rock* has been applied by some writers to an indurated clay requiring to be ground and mixed with water before it acquires plasticity.

When clay has been deposited intermittently so as to assume a thinly stratified or fissile structure, it receives the general name of *Shale*. Under this term are included all laminated and indurated clays which are capable of being split along the lines of deposit into hard leaves. They present almost endless varieties of texture and composition, passing on the one hand into clays, on the other into flagstones and sandstones, or again, through calcareous gradations into limestone, or through ferruginous varieties into clay-ironstone, and through bituminous kinds into coal. An important variety, known as *Oil-shale*, and containing so much bituminous matter that it is now extensively used as a source for the manufacture of solid paraffin and mineral oils is described in the next section.

Flinty-slate (*Lydian-stone, Hornstone*) is siliceous shale or mudstone which has been indurated into an exceedingly compact flinty mass, breaking with a conchoidal or splintery fracture, and usually of dark colours, black, brown, and red, more rarely white.

Clay-slate is a compact close-grained, very hard, fissile argillaceous rock, dull lead-blue, grey, green, red, purple, or black in colour, splitting into thin leaves which are not those of original deposit but those produced by a superinduced cleavage. In this case the rock has been affected by great lateral pressure, whereby its particles have been forced to adjust themselves with their longer axes perpendicular to the direction of pressure. This rearrangement has imparted to the rock a fissility wholly independent of original lamination. The possession of this cleavage is the distinctive character of a true slate.

(*c.*) *Rocks formed of the Debris of Plants.*—These have sometimes been produced by the decay and entombment of vegetation on the spot where it grew, sometimes by the drifting of the plants to a distance and their consolidation there. In the latter case, they may be mingled with inorganic sediment, so as to pass into carbonaceous shale.

Peat is vegetable matter, more or less decomposed and chemically altered, found in boggy places and elsewhere where marshy plants grow and decay. It varies from a pale yellow or brown fibrous substance, like turf or compressed hay, in which the plant remains are abundant and conspicuous, to a compact dark-brown or black material, resembling black clay when wet and some varieties of lignite when dried. The nature and proportions of the constituent elements of peat, after being dried at 100° C., are illustrated by the analysis of an Irish example which gave—carbon, 60·48; hydrogen, 6·10; oxygen, 32·55; nitrogen, 0·88; while the ash was 3·30.

There is always a large proportion of water which cannot be driven off even by drying the peat. In the manufacture of compressed peat for fuel this constituent, which of course greatly lessens the value of the peat as compared with an equal weight of coal, is driven off to a great extent by chopping the peat into fine pieces, and thereby exposing a large surface to evaporation. The ash varies in amount from less than 1·00 to more than 65 per cent., and consists of sand, clay, ferric oxide, sulphuric acid, and minute proportions of lime, soda, potash, and magnesia.

Lignite is compressed and chemically altered vegetable matter, often retaining a lamellar or ligneous texture, and stems with woody fibre crossing each other in all directions. It varies from pale brown or yellow to deep brown or black. Some shade of brown is the usual colour, whence the name *brown coal*, by which it is often known. It occurs in beds chiefly among the Tertiary strata, under conditions similar to those in which coal is found in older formations. It may be regarded as a stage in the alteration and mineralization of vegetable matter intermediate between peat and true coal.

Coal, the most completely mineralized form of vegetable matter, occurs as a black (sometimes dark-brown), brittle, usually lustrous substance, intercalated in beds between strata of sandstone, shale, fireclay, &c., in geological formations of Palæozoic, Secondary, and Tertiary age. The word coal is rather a popular than a scienific term, as it is indiscriminately applied to any mineral substance capable of being used as fuel. Strictly employed it ought only to be used with reference to beds of fossilized vegetation, the result either of the growth of plants on the spot or of the drifting of them thither.

The following analyses show the chemical constituents in some of the principal varieties of coal :—

	Caking Coal.	Splint Coal.	Cannel Coal.	Anthracite.
Carbon	86·75	79·58	66·4	91·44
Hydrogen	5·24	5·50	7·54	3·46
Oxygen	6·61	8·33	10·84	2·58
Nitrogen		1·13	1·36	0·21
Earthy substances	1·40	6·46	13·82	2·31
Specific gravity	1·28	1·31	1·27	1·39

Diatom-earth is a siliceous deposit formed chiefly of the frustules of diatoms. It is laid down both in salt and in fresh water. Wide tracts of it are now being deposited on the bed of the South Pacific. In Virginia, United States, an extensive tract occurs covered with diatom-earth to a depth of 40 feet. It is used as a polishing or tripoli powder.

Oil shale (*Brandschiefer*) is shale containing such a proportion of hydrocarbons as to be capable of yielding mineral oil on slow distillation. This substance occurs as ordinary shales do, in layers or beds, interstratified with other aqueous deposits, as in the Scottish coal-fields. It is in a geological sense true shale, and owes its peculiarity to the quantity of vegetable (or animal) matter which has been preserved among its inorganic constituents. It consists of fissile argillaceous layers, highly impregnated with bituminous matter, passing on one side into common shale, on the other into cannel or parrot coal. The richer varieties yield from 30 to 40 gallons of crude oil to the ton of shale. They may be distinguished from non-bituminous or feebly bituminous shales (throughout the shale districts of Scotland) by the peculiarity that a thin paring curls up in front of the knife, and shows a brown lustrous streak. Some of the shales in the Lothians are crowded with the valves of ostracod crustaceans, besides scales, corprolites, &c., of ganoid fishes (*Palæoniscus, Amblypterus, Megalichthys*, &c.); and it is possible that the bituminous matter may in some cases have resulted from animal organisms, though the abundance of plant remains indicates that it is probably in most cases of vegetable origin. Under the name "pyroschists" Sterry Hunt classes the clays or shales (of all geological ages) which are hydrocarbonaceous, and yield by distillation volatile hydrocarbons, inflammable gas, &c.

(*d.*) *Rocks formed of Animal Remains.*—These may be formed on land, as in bone caves, but most abundantly under water, as on the bottom of lakes and of the sea. They may be calcareous, siliceous, or phosphatic.

Limestone.—Besides the limestones resulting from the deposition of chemical precipitates of carbonate of lime, there is another important series derived from the remains of organisms, either by growth on the spot, or by accumulation as mechanical sediment. Limestone so originating has often been so altered that it cannot always be distinguished from that which has been chemically produced, especially when it has been exposed to the action of percolating acidulated water, for in that case a crystalline texture is gradually superinduced, by which the original organic structures in the mass are wholly or in great part obliterated. Limestone composed of the remains of living organisms forms thin layers and massive beds. In some instances, as in that of the English and Irish Mountain Limestone, it occurs in masses several thousand feet thick, which extend for hundreds of square miles, and form the rock out of which picturesque valleys, gorges, hills, and table-lands have been excavated. Limestone may be either of fresh water or of marine origin. Some of the more common and important varieties may be here enumerated :—

Coral-rock is limestone formed by the continuous growth of coral-building polyps. This substance affords an excellent illustration of the way in which organic structure may be effaced from a limestone entirely formed from the remains of once living animals. Though the skeletons of the reef-building corals remain distinct on the upper surface, those of their predecessors beneath them are gradually obliterated by the passage through them of percolating water dissolving and redepositing carbonate of lime. This same action may be observed among the stalactites of a damp vault, in which, though the successive rings of growth are preserved, a crystalline divergent structure is superinduced, which traverses these rings from the centre outward. We can thus understand how a mass of crystalline limestone may have been produced from one formed out of organic remains without the action of any subterranean heat, but merely by the permeation of water from the surface. *Crinoidal* (*Encrinite*) *Limestone* is a rock composed in great part of joints of encrinites, with *Foraminifera*, corals, and mollusks. It varies in colour from white or pale grey, through shades of bluish-grey (sometimes yellow or brown, less commonly red) to a dark-grey or even black colour. It is abundant among Palæozoic formations, being especially characteristic of the lower part of the Carboniferous system. *Chalk* as a lithological term is applied to a white soft rock, meagre to the touch, soiling the fingers, formed of a fine calcareous flour derived from the remains of *Foraminifera*, echinoderms, mollusks, and other marine organisms. It occurs in massive beds, and covers a great part of the south-east and east of England. In Ireland and elsewhere it assumes a firmer grain and various colours, so as to pass into some of the numerous varieties of compact white limestone. *Shell-Marl*, a soft white, earthy, or crumbly deposit, is formed in lakes and ponds by the accumulation of the remains of shells and *Entomostraca* on the bottom. When such calcareous deposits become solid compact stone they are known as *fresh-water* (*lacustrine*) *limestone*. These are generally of a smooth texture, and either dull white or pale grey, their fracture only slightly conchoidal, rarely splintery. *Ooze* is a mud of organic origin found covering vast areas of the floor of the Atlantic and other oceans. Some of it is calcareous and formed wholly or mostly of the remains of *Foraminifera*, particularly of forms of the genus *Globigerina*; hence this deposit has been termed foraminiferal or globigerina ooze. Sometimes it is mainly siliceous, consisting of the remains of *Radiolaria* (Radiolarian ooze) or of diatoms (Diatom ooze). These deposits are further referred to in the section of this article which treats of the geological aspects of the ocean. *Shell-sand* is a sand composed in great measure or wholly of comminuted shells, found commonly on a low shelving coast exposed to prevalent on-shore winds. This deposit when thrown above the reach of the waves and often wetted by rain, or by trickling runnels of water, is apt to become consolidated into a mass, owing to the solution and redeposit of lime round the grains of shell.

Flint and *Chert* are siliceous rocks (which, though not strictly fragmental, may be conveniently placed here) found in nodules and layers in limestones of many different geological ages. Flint is a dark horny substance, breaking with a splintery to conchoidal fracture. It is particularly abundant in the chalk formation. Chert is an impure flint, containing more clay or lime with the silica. These substances seem in some cases to have had a directly organic origin, having been secreted from sea-water by the living organisms; in other cases, where for example we find a calcareous shell, or echinus, or coral, converted into silica, it would seem that the substitution of silica for lime has been effected by a process of chemical pseudomorphism either after or during the formation of the limestone.[1]

(*e*.) *Volcanic Fragmental Rocks* form an interesting group composed of the loose materials ejected from volcanic vents. In their typical condition they consist merely of consolidated volcanic debris, including bombs, scoriæ, ejected blocks, sand, lapilli, and dust. It is evident, however, that, when these materials were deposited in water, there would necessarily be a limit beyond which they would not extend, and where they would be mingled with and would insensibly pass into ordinary non-volcanic sediment. Hence we may expect to find transitional varieties between rocks formed directly from the results of volcanic explosion and ordinary sedimentary deposits Moreover, as these fragmental volcanic masses usually consist almost wholly of the detritus of different lavas, which have been blown into fragments in the volcanic chimneys, we may expect to find, on the other hand, a passage from them into rocks derived from consolidated lava-beds by ordinary aqueous erosion. (See part iv.)

Volcanic Conglomerate is a rock composed mainly or wholly of rounded or subangular fragments of any volcanic rocks in a paste derived chiefly or wholly from the same materials, usually exhibiting a stratified arrangement, and often found intercalated between successive sheets of lava. In most cases conglomerates of this kind have been formed by the accumulation of materials ejected from volcanic vents; occasionally, as just remarked, they may have resulted from the aqueous erosion of previously solidified lavas, or from a combination of both these processes. There does not appear at present to be any satisfactory method of always determining the exact mode of formation, except that well-rounded and smoothed stones will almost certainly indicate long-continued water-action rather than trituration in a volcanic vent.

The volcanic conglomerates may receive different names according to the nature of the component fragments: thus we have *basalt-conglomerates*, where these fragments are wholly or mainly of basalt, *trachyte-conglomerates*, *porphyrite-conglomerates*, *phonolite-conglomerates*, &c.

Volcanic Breccia resembles volcanic conglomerates, except that the stones are angular. This angularity indicates an absence of aqueous erosion, and, under the circumstances in which it is found, usually points to volcanic explosions. There is a great variety of breccias, as *basalt-breccia*, *diabase-breccia*, &c.

Volcanic Agglomerate is the name given to a tumultuous assemblage of blocks of all sizes up to masses several yards in diameter. It is met with in the "necks" or pipes of old volcanic orifices. The stones and paste are commonly of one or more volcanic rocks, such as basalt or porphyrite, but they include also fragments of the surrounding rocks, whatever these may be, through which the volcanic orifice has been drilled. As a rule agglomerate is devoid of stratification; but sometimes it includes portions which have a more or less distinct arrangement in beds of coarser and finer detritus, often placed on end or inclined in different directions at high angles.

[1] Hull and Hardman on Chert, *Trans. Roy. Dub. Soc.*, new ser., vol. i. 71, 1878.

Volcanic Tuff.—This general term may be made to include all the finer kinds of volcanic detritus, ranging on the one hand through coarse gravelly deposits into conglomerates, and on the other into exceedingly compact fine-grained rocks formed of the finest and most impalpable kind of volcanic dust. Some tuffs are full of microlites or imperfect forms of crystallization derived from the lava which has blown into dust. Others are formed of small rounded or angular grains of different lavas with fragments of various rocks through which the volcanic funnels have been drilled. Minutely cellular grains, as if derived from the ebullition of very fluid glassy lava like palagonite, constitute much of the tuff in some of the volcanic necks of Carboniferous age in central Scotland. Some tuffs have consolidated under water, others on dry land. As a rule they are distinctly stratified. Near the original vents of eruption they commonly present rapid alternations of finer and coarser detritus indicative of successive phases of volcanic activity.

The tuffs may be subdivided according to the nature of the lava from the disintegration of which they have been formed. Thus we have *felsite-tuffs*, *trachyte-tuffs*, *basalt-tuffs*, *pumice-tuffs*, *porphyrite-tuffs*, *palagonite-tuffs*. Some varieties have received special names. *Trass* (*Duckstein*, *Tuffstein*) is a compact yellow pumiceous tuff which has filled up some of the valleys of the Eifel region and is largely quarried as an hydraulic mortar. *Peperino* is an Italian tuff of late geological date. full of separate crystals of augite and other minerals.

PART III.—DYNAMICAL GEOLOGY.

Under this section is included the investigation of those processes of change which are at present in progress upon the earth, whereby modifications are made on the structure and composition of the crust, on the relations between the interior and the surface, as shown by volcanoes, earthquakes, and other terrestrial disturbances, on the distribution of oceans and continents, on the outlines of the land, on the form and depth of the sea-bottom, on climate, and on the races of plants and animals by which the earth is tenanted. It brings before us, in short, the whole range of activities which it is the province of geology to study, and leads us to precise notions regarding their relations to each other, and the results which they achieve. A knowledge of this branch of the subject is thus the essential groundwork of a true and fruitful acquaintance with the principles of geology, seeing that it necessitates a study of the present order of nature, and thus provides a key for the interpretation of the past.

The whole range of operations included within the scope of inquiry in this branch of the science may be regarded as a vast cycle of change, into which we may break at any point, and round which we may travel, only to find ourselves brought back to our starting-point. It is a matter of comparatively small moment at what part of the cycle we begin our inquiries. We shall always find that the changes we see in action have resulted from some that preceded, and give place to others which follow them.

At an early time in the earth's history, anterior to any of the periods of which a record remains in the visible rocks, the chief sources of geological action probably lay within the earth itself. The planet still retained a great store of its initial heat, and in all likelihood was the theatre of great chemical changes, giving rise, perhaps, to manifestations of volcanic energy somewhat like those which have so marvellously roughened the surface of the moon. As the outer layers of the globe cooled, and the disturbances due to internal heat and chemical action became less marked, the influence of the sun, which must always have operated, would then stand out more clearly, giving rise to that wide circle of superficial changes wherein variations of temperature and the circulation of air and water over the surface of the earth come into play.

In the pursuit of his inquiries into the past history and into the present *régime* of the earth, the geologist must needs keep his mind ever open to the reception of evidence for kinds and especially for degrees of action which he had not before imagined. Human experience has been too short to allow him to assume that all the causes and modes of geological change have been definitively ascertained. On the earth itself there may remain for future discovery evidence of former operations by heat, magnetism, chemical change, or otherwise, which may explain many of the phenomena with which geology has to deal. Of the influences, so many and profound, which the sun exerts upon our planet, we can as yet only dimly perceive a little. Nor can we tell what other cosmical influences may have lent their aid in the evolution of geological changes.

In the present state of our knowledge, all the geological energy upon and within the earth must ultimately be traced back to our parent sun. There is, however, a certain propriety and convenience in distinguishing between that part of it which is due to the survival of some of the original energy of the planet, and that part which arises from the present supply of energy received day by day from the sun. In the former case we have to deal with the interior of the earth and its reaction upon the surface; in the latter we deal with the surface of the earth, and to some extent with its reaction on the interior. This distinction allows of a broad treatment of the subject under two divisions:—

I. *Hypogene or Plutonic Action*—the changes within the earth caused by original internal heat and by chemical action.

II. *Epigene or Surface Action*—the changes produced on the superficial parts of the earth, chiefly by the circulation of air and water set in motion by the sun's heat.

DIVISION I.—HYPOGENE ACTION.

An Inquiry into the Geological Changes in Progress beneath the Surface of the Earth.

In the discussion of this branch of the subject we must carry in our minds the conception of a globe still intensely hot in its interior, radiating heat into space, and consequently contracting in bulk. Portions of molten rocks from inside are from time to time poured out at the surface. Sudden shocks are generated by which destructive earthquakes are propagated to and along the surface. Wide geographical areas are pushed up or allowed to sink down. In the midst of these movements very remarkable changes are produced upon the rocks of the crust; they are shattered, fractured, squeezed, crumpled, rendered crystalline, and even fused.

Section I.—Volcanoes and Volcanic Action.

The term volcanic action (vulcanism or vulcanicity) embraces all the phenomena connected with the expulsion of heated materials from the interior of the earth to the surface. Among these phenomena there are some of an evanescent character, while others leave permanent proofs of their existence. It is naturally to the latter that the geologist gives the chief attention, for it is by their means that he can trace the former phases of volcanic activity in regions where, for many ages, there have been no volcanic eruptions. In the operations of existing volcanoes he can observe only the superficial manifestations of volcanic action. But, examining the rocks of the earth's crust, he discovers that in the lapse of ages, amid the many terrestrial revolutions which geology reveals, the very roots of former volcanoes have been laid bare, displaying subterranean phases of vulcanism which could not be studied in any modern volcano. Hence an acquaintance only with active volcanoes will not give us a complete knowledge of volcanic action. It must be supplemented and enlarged by an investigation of the traces of former volcanoes preserved in the crust of the earth.

The openings by which the heated materials from the interior reach the surface include volcanoes (with their accompanying orifices), hot-springs, and gas-springs. A volcano may be defined as a conical eminence, composed wholly or mainly of materials which have been ejected from below, and which have accumulated at the surface round the vent of eruption. As a rule it presents at its summit a cup-shaped cavity termed the crater, at the bottom of which is the top of the main funnel or pipe whereby the communication is maintained with the heated interior. A volcano, when of small size, may consist merely of one diminutive cone; when of the largest dimensions, it forms a huge mountain, with many subsidiary cones and many lateral fissures or pipes, from which the heated volcanic products are given out.

Volcanoes may break through any kind of geological formation. In Auvergne, in the Miocene period, they burst through the granitic and gneissose plateau of central France. In Lower Old Red Sandstone times they pierced contorted Silurian rocks in central Scotland. In late Tertiary and post-Tertiary ages they found their way through soft marine strata, and formed the huge piles of Etna, Somma, and Vesuvius. On the banks of the Rhine, at Bonn and elsewhere they have penetrated some of the older alluvia of that river. In many instances, also, newer volcanoes have appeared on the sites of older ones. In Scotland the Carboniferous volcanoes have risen on the sites of those of the Old Red Sandstone, those of the Permian period have broken out among the earlier Carboniferous eruptions, while the Miocene lavas have been injected into all these older volcanic masses. Again, the newer *puys* of Auvergne were sometimes erupted through much older and already greatly denuded basalt-streams. Somma and Vesuvius have arisen out of the great Neapolitan plain of marine tuff. In central Italy, also, newer cones have been thrown up upon the great Roman plain of more ancient volcanic debris.

It is usual to class volcanoes as *active*, *dormant*, and *extinct*. This arrangement, however, often presents considerable difficulty in its application. An active volcano cannot of course be mistaken, for even when not in actual eruption it shows, by its abundant evolution of steam and hot vapours, that it might break out into activity at any moment. But it is in many cases impossible to decide whether a volcano should be called extinct or only dormant. The volcanoes of Silurian age in Wales, of Carboniferous age in Ireland, of Permian age in the Hartz, of Miocene age in the Hebrides, are certainly all extinct. But the Miocene volcanoes of Iceland are still represented there by Skaptar-Jökull, Hecla, and their neighbours. Somma, in the first century of the Christian era, would have been naturally regarded as an extinct volcano. Its fires had never been known to have been kindled within human tradition; its vast crater was a wilderness of wild vines and brushwood, haunted, no doubt, by wolf and wild-boar. Yet in a few days, in the autumn of the year 79 the half of the crater walls was blown out by a terrific series of explosions, the present Vesuvius was then formed within the limits of the earlier crater, and since that time volcanic action has been intermittently exhibited up to the present day. Some of the intervals of quietude, however, have been so considerable that the mountain might then again have been claimed as an extinct volcano. Thus, in the 131 years between 1500 and 1631, so completely had eruptions ceased that the crater had once more become choked with copsewood. A few pools and springs of very salt and hot water remained as memorials of the former condition of the mountain. But this period of quiescence closed with the eruption of 1631,—the most powerful of all the known explosions of Vesuvius, except the great one of 79.

In the island of Ischia, Mont Epomeo was last in eruption in the year 1302, its previous outburst having taken place, it is believed, about 17 centuries before that date. From the craters of the Eifel, Auvergne, the Vivarais, and central Italy, though many of them look as if they had only recently been formed, no eruption has been known to come during the times of human history or tradition. From these examples it is clear that no real distinction can be drawn between dormant and extinct volcanoes. Also, from the fact above mentioned, that volcanoes have often appeared on areas occupied by those of previous geological periods, it is equally evident that volcanic action is apt to show itself again and again even at vast intervals within the same regions and over the same sites.

§ 1. *Volcanic Products.*

The materials erupted from volcanic vents may be classed as (1) gases and vapours, (2) lavas, (3) fragmentary substances. A brief summary under each of these heads may be given here; the mode and order of appearance of the several products will be stated in § 2.

1. *Gases and Vapours.*—These play an important part in volcanic activity; they show themselves in the earliest stages of a volcano's history, and continue to appear for centuries after all the other evidences of subterranean action have ceased to be manifested. By much the most abundant of them all is *steam.* It has been estimated to form $\frac{999}{1000}$ths of the whole cloud which hangs over an active volcano. In great eruptions it rises in prodigious quantities, and is rapidly condensed into a heavy rainfall. M. Fouqué calculated that during 100 days Etna had ejected vapour enough to form, if condensed, 2,100,000 cubic metres of water. But even from volcanoes which, like the Solfatara near Naples, have been dormant for many centuries it sometimes still rises without intermission and in considerable volume. Jets of vapour rush out from clefts in the sides and bottom of a crater with a noise like that made by the steam blown off by a locomotive. The number of these funnels is often so large, and the amount of vapour so abundant, that only now and then, when the wind blows the dense cloud aside, can a momentary glimpse be had of a part of the bottom of the crater; while at the same time the rush and roar of the escaping steam remind one of the din of some vast factory. Aqueous vapour rises likewise from rents on the outside of the volcanic cone. It issues so copiously from the molten lava which pours down the slopes of the cone that the stream of rock is almost concealed from view by the cloud; and it continues to escape from fissures of the lava, far below the point from which the molten matter proceeded, for a long time after the rock has solidified and come to rest. So saturated, as it were, are many crystalline lavas with the vapour of water that Mr Scrope even suggested that they derive their mobility from this cause.

Probably in no case is the steam mere pure vapour of water. It is associated with other vapours and gases disengaged from the potent chemical laboratory underneath. Of these probably the most abundant is *sulphuretted-hydrogen,* readily traceable by its characteristic odour. Its liability to decomposition leads to the deposition of a yellow crust of sulphur about the orifices from which it rises; perhaps, also, in great part to the alteration of this gas must we attribute the *sulphuric acid* so frequently observed at volcanic vents. Another gas especially abundant at Vesuvius, but not detected in all volcanoes, is *hydrochloric acid,* which comes away with the steam, and gives it its pungent suffocating fumes. *Carbonic acid* appears in most volcanoes, partly as one of their usual products, but chiefly given off during the feebler conditions of activity and in the last stages of vulcanism. After an eruption of Vesuvius this gas has sometimes been discharged so copiously that hundreds of hares, pheasants, and partridges have been suffocated by it. In the ancient volcanic regions of the Eifel and Auvergne, it still rises in prodigious quantities. Bischof estimates that the quantity of carbonic acid evolved in the Brohl Thal amounts to five millions of cubic feet, or 300 tons of gas in one day. *Nitrogen,* derived doubtless from the decomposition of atmospheric air dissolved in the water which penetrates into the volcanic foci, has been frequently detected among the gaseous emanations.

With these gases and vapours are associated many substances which, sublimed by the volcanic heat, appear as deposits along crevices and surfaces wherein they reach the air and are cooled. Besides sulphur, which has been already mentioned, there are several chlorides (particularly that of sodium, and less abundantly those of iron, copper, and lead), sal-ammoniac, specular iron, oxide of copper (tenorite), boracic acid, and other substances. Sodium chloride sometimes appears so abundantly that wide spaces of a volcanic cone, as well as of the newly erupted lava, are crusted with salt, which can even be profitably removed by the inhabitants of the district. Considerable quantities of these chlorides may thus be buried between successive sheets of lava; and in long subsequent times may give rise to mineral springs, as has been suggested with reference to the saline waters which issue from volcanic rocks of Old Red Sandstone and Carboniferous age in Scotland. The iron-chloride forms a bright yellow and reddish crust on the crater walls, as well as on loose stones on the slopes of the cone. Specular iron forms abundantly as thin lamellæ in the fissures of Vesuvian lavas. Tenorite may be seen at the edge of the crater of Vesuvius, condensing into fine filaments which are blown away by the wind. An order of succession has been observed to take place in the appearance of the different volcanic gaseous discharges.

In connexion with the aqueous vapour of volcanoes, reference may be made here to the abundant discharges of water which accompany volcanic explosions. Three sources of this water may be assigned;—(1) from the melting of snow by a rapid accession of temperature previous to or during an eruption,—this takes place from time to time on Etna, and still more markedly in Iceland and among the snowy ranges of the Andes; (2) from the condensation of the vast clouds of steam which are discharged during an eruption,—this undoubtedly is the chief source of the destructive torrents so frequently observed to form part of the phenomena of a great volcanic explosion; and (3) from the disruption of reservoirs of water filling subterranean cavities, or of lakes occupying crater-basins,—this has several times been observed among the South American volcanoes, where immense quantities of dead fish, which inhabited the water, have been swept down with the escaping torrents. The volcano of Agua, in Guatemala, has never been known to discharge anything but water. In the large crater of Idjèn, one of the volcanoes of Java, lay a hot steaming lake of acid water. In the beginning of the year 1817 an eruption took place, by which the water was discharged with frightful destruction down the slopes of the mountain. After the explosion the basin filled again with water, but its temperature was no longer high.

In many cases the water rapidly collects volcanic dust as it rushes down, and soon becomes a pasty mud, or it issues at first in this condition from the volcanic reservoirs, from which, after violent detonations, it is discharged. Hence arise what are termed mud-lavas or aqueous lavas, which in many respects behave like true igneous lavas. This mud eventually consolidates into one of the numerous forms of tuff,—a rock which, as has been already stated (p. 239), varies greatly in the amount of its coherence, in its composition, and in its internal arrangement. Obviously, unless where subsequently altered, it can possess none of the crystalline structure of true lavas. As a rule it betrays its aqueous origin by more or less distinct evidence of stratification, by the multifarious pebbles, stones, blocks of rock, tree-trunks, branches, shells, bones, skeletons, which it has swept along in its course and preserved within its mass. Sections of this compacted tuff may be seen at Herculaneum. The *trass* of the Brohl Thal and other valleys in the Eifel district, referred to on p. 239, is another example of an ancient volcanic mud.

2. *Lavas.*—The term lava is applied generally to all the molten rocks which flow out from volcanoes.[1] The behaviour of the lava as it issues and flows down the volcanic cones will be described in the next sub-section. It will be sufficient to refer here to some of the leading peculiarities of the lavas viewed as volcanic products. (1.) Their specific gravity ranges between 2·37 and 3·22. (2.) The heavier varieties contain much magnetic or titaniferous iron, with augite and olivine, their composition being basic, and their proportion of silica averaging about 45 or 50 per cent. In this group come the basalts, dolerites, nepheline-lavas, and leucite-lavas. The lighter varieties contain commonly a minor proportion of metallic bases, but are rich in silica, their percentage of that acid ranging between 60 and 80. They are thus not basic but acid rocks. Among their more important species, trachyte, rhyolite, obsidian, pitchstone, and pumice may be enumerated. (3.) They differ much in texture. (*a*) Some are entirely crystalline, consisting of nothing but an interlaced mass of crystals and crystalline particles, as in some dolerites. (*b*) Some show more or less of a half-glassy or stony matrix, in which the constituent crystals are imbedded; this is the most common arrangement. (*c*) Others are entirely vitreous, such crystals or crystalline particles as occur in them being quite subordinate, and, so to speak, accidental enclosures in the main glassy mass. Obsidian or volcanic glass is the type of this group. (*d*) They further differ in the extent to which their mass has been affected by the interstitial steam at the time of their eruption. Some show no outward signs of any influence from that cause; in others, however, the expansion of the imprisoned steam has been such as to expand the still molten stone into an open cellular texture, somewhat like that of open ill-baked bread. Such a vesicular arrangement very commonly appears on the upper surface of a lava current. (4.) They vary greatly in colour and general external aspect. The heavy basic lavas are usually dark-grey, or almost black, though, on exposure to the weather, they usually acquire a brown tint from the oxidation and hydration of their iron. Their surface is commonly rough and rugged, until it has been sufficiently decomposed by the atmosphere to crumble into excellent soil which, under favourable circumstances, supports a luxuriant vegetation. The less dense lavas, such as phonolites and trachytes, are frequently paler in colour, sometimes pale yellow or buff, and decompose into light soils; but the obsidians present rugged black sheets of rock roughened with ridges and heaps of froth-like pumice.

3. *Fragmentary Materials.*—Under this title we include all the substances which, driven up into the air by volcanic explosions, fall in solid form to the ground—the dust, ashes, sand, cinders, and blocks of every kind which are projected from a volcanic orifice. These materials must obviously differ greatly in composition, texture, and appearance, even during a single eruption, and still more in successive explosions of the same volcano. For the sake of convenience separate names are applied to some of the more distinct varieties. Of these the more important are the following. (1.) *Ashes and Sand.*—In many eruptions vast quantities of an exceedingly fine light grey powder are ejected. As this substance greatly resembles what is left after a piece of wood or coal is burnt in an open fire, it has been popularly termed *ash*, and this name has been adopted by geologists. If, however, by the word ash the result of combustion is implied, its employment to denote any product of volcanic action must be regretted as apt to convey a wrong impression. The fine ashlike dust ejected by a volcano is merely lava in an extremely fine state of comminution. So minute are the particles that they find their way readily through the finest chinks of a closed room, and settle down upon floor and furniture as ordinary dust does when a house is shut up for a short time. From this finest form of material gradations may be traced through what is termed volcanic sand into the coarse varieties of ejected matter. In composition the ash and sand vary necessarily with the nature of the lava from which they are derived. (2.) When the fragments range from the size of a pea to that of a walnut they are called *lapilli*. These are pieces of lava, round, subangular, or angular in shape, and having the same indefinite range of composition as the finer dust. As a rule, the coarse fragments fall nearest the focus of eruption. Sometimes they are solid fragments of lava, but more usually they have a cellular texture, while sometimes they are so light and porous as to float readily on water, and, when ejected near the sea, to cover its surface over a large area. (3.) *Volcanic Blocks* are large pieces of stone, often angular in shape. In some cases they appear to be fragments loosened from already solidified rocks in the chimney of the volcano. Hence we find among them pieces of older tuffs, and of lavas recognizably belonging to early eruptions. But in other and numerous instances they are not volcanic rocks at all, but belong to earlier formations through which the volcanic chimney has been drilled. Blocks of a coarsely crystalline granitoid lava have been particularly observed both on Etna and Vesuvius. In the year 1870 a mass of that kind weighing several tons was to be seen lying at the foot of Vesuvius, within the entrance to the Atrio del Cavallo. Similar blocks occur among the Carboniferous volcanic pipes of central Scotland. In the older tuffs of Somma, blocks of altered limestone form the chief repositories of the Vesuvian minerals. (4.) *Volcanic Bombs and Slags.*—These have originally formed portions of the column of lava ascending the pipe of the volcano, and have been detached and hurled into the air by the successive explosions of steam. In the case of a bomb, we have a round, elliptical, or pear-shaped and often discoidal mass of lava, from a few inches to several feet in diameter. Sometimes it is tolerably solid throughout, more usually vesicular. Not unfrequently it consists of a hollow interior, with a shell which is vesicular towards the centre and becomes more close-grained towards the outside. There can be no doubt that, when torn by eructations of steam from the surface of the boiling lava, the material of these bombs was in as thoroughly molten a condition as the rest of the mass. From the rotatory motion imparted by its ejection, it took a circular form, and in proportion to its rapidity of rotation and fluidity would be the amount of its "flattening at the poles." The centrifugal force within would allow the expansion of the interstitial vapour, while the outer surface would rapidly cool and solidify; hence the solid crust, and the porous or even cavernous interior. Such bombs, varying from the size of an apple to that of a man's body, were found by Mr Darwin abundantly strewed over the ground in the island of Ascension.[2] They have been found likewise in the tuff of

[1] "Alles ist lava was im Vulkane fliesst und durch seine Flüssigkeit neue Lagerstätter einnimmt" is Leopold Von Buch's comprehensive definition.

[2] *Geological Observations on Volcanic Islands*, 2d edit., p. 42.

Lower Carboniferous date at Dunbar, in Scotland. When the ejected fragment of lava has a rough irregular form, and a porous structure like the clinker of an iron-furnace, it is known as a *slag*.

The fragmentary materials erupted by a volcano and deposited around it acquire by degrees more or less consolidation, partly from the mere pressure of the higher upon the lower strata, partly from the influence of infiltrating water. It has been already stated (part ii., p. 239) that different names are applied to the rocks thus formed. The coarse, tumultuous, unstratified accumulation of volcanic debris within a crater or funnel is called agglomerate. When the debris, though still coarse, is more rounded, and is arranged in a stratified form, it is a volcanic conglomerate. The finer-grained varieties, formed of dust and lapilli, are included in the general designation of tuffs. These are usually pale-yellowish, greyish, or brownish, sometimes black rocks, granular, porous, and often incoherent in texture. Organic remains sometimes occur in tuff. Where the volcanic debris has accumulated over the floor of a lake, or of the sea, the entombing and preserving of shells and other organic objects must continually take place. But even in the tuffs of a volcanic cone traces of animals and plants may be preserved. Professor Guiscardi of Naples has found about 100 species of marine shells of living species in the old tuffs of Vesuvius. Marine shells have been picked up within the crater of Monte Nuovo, and have been frequently observed in the old or marine tuff of that district. The showers of ash which fall on the outer slopes of a volcano, or the sheets of mud which sometimes are spread out there, cover over and often preserve the land-shells, insects, and vegetation living on the area at the time. The older tuffs of Vesuvius have yielded many remains of the shrubs and trees which at successive periods have clothed the flanks of the mountain.

§ 2. *Volcanic Action.*

We have now to consider the circumstances under which the various solid, liquid, and gaseous products of a volcano are emitted. Volcanic action may be either constant or periodic. Stromboli, in the Mediterranean, so far as we know, has been uninterruptedly emitting hot stones, steam, and lava, from the earliest period of history. Among the Moluccas the volcano Sioa, and in the Friendly Islands that of Tofua, have never ceased to be in eruption since their first discovery. The lofty cone of Sangay, among the Andes of Quito, is always giving off hot vapours; Cotopaxi, too, is ever constantly active. But, though examples of unceasing action may thus be cited from widely different quarters of the globe, they are nevertheless exceptional. The general rule is that a volcano breaks out from time to time with greater or less fury, and after longer or shorter intervals of quiescence.

To what particular cause or series of causes any special eruption may be due is a question to which at present no definite answer can be given. An attempt has been made to show that the explosions of a volcano are to some extent regulated by the conditions of atmospheric pressure over the area at the time. In the case of a volcanic funnel like Stromboli, where, as Mr Scrope pointed out, the expansive subterranean force within, and the repressive effect of atmospheric pressure without, just balance each other, any serious disturbance of that pressure might be expected to make itself evident by a change in the condition of the volcano. Accordingly, it has long been remarked by the fishermen of the Lipari Islands that in stormy weather there is at Stromboli a more copious discharge of steam and stones than in fine weather. They make use of the cone as a weather-glass, the increase of its activity indicating a falling, and the diminution a rising barometer. In like manner Etna, according to S. von Waltershausen, is most active in the winter months. When we remember the connexion now indubitably established between a more copious discharge of fire-damp in mines and a lowering of atmospheric pressure, we may be prepared to find a similar influence affecting the escape of vapours from the upper surface of the lava column of a volcano; for it must not be forgotten that it is not so much to the lava itself as to the expansive vapours accompanying it that the manifestations of volcanic activity are due. Among the Vesuvian eruptions since the middle of the 17th century, the number which took place in winter and spring was to that of those which broke out in summer and autumn as 7 to 4. But there may be other causes besides atmospheric pressure concerned in these differences; the preponderance of rain during the winter and spring may be one of these. At present we must wait for further data.

Kluge has sought to trace a connexion between the years of maximum and minimum sun-spots and those of greatest and feeblest volcanic activity, and has constructed lists to show that years which have been specially characterized by terrestrial eruptions have coincided with those marked by few sun-spots and diminished magnetic disturbance.[1] Such a connexion cannot be regarded as having yet been satisfactorily established. Again, the same author has called attention to the frequency and vigour of volcanic explosions about the middle of August, at or near the time of the yearly meteoric shower. But in this case, likewise, the cited examples can hardly yet be looked upon as more than coincidences.

The case of Kilauea, in Hawaii, seems to show a regular system of eruptive periods. Dana has pointed out that outbreaks of lava have taken place from that volcano at intervals of from eight to nine years, this being the time required to fill the crater up to the point of outbreak, or to a depth of 400 or 500 feet. But the great eruption of 1868 did not occur until after an interval of 18 years. The same author suggests that the missing eruption may have been submarine.

The approach of an eruption is not always indicated by any premonitory symptoms, for many tremendous explosions are recorded to have taken place in different parts of the world without any perceptible warning. Much in this respect would appear to depend upon the condition of liquidity of the lava, and the amount of resistance offered by it to the passage of the escaping vapours through its mass. In Hawaii, where the lavas are remarkably liquid, vast outpourings of lava have taken place quietly without earthquakes during the present century. But even there the great eruption of 1868 was accompanied by tremendous earthquakes.

The eruptions of Vesuvius are often preceded by a failure or diminution of the wells and springs in the district. But more frequent indications of an approaching outburst are conveyed by sympathetic movements of the ground beneath. Rumblings and groanings from a subterranean source are heard; slight tremors succeed, increasing in frequency and violence till they become distinct earthquake shocks. The vapours from the crater rise more abundantly into the air. All this time the lava column in the pipe or funnel of the volcano has been slowly ascending, forced upward and kept in perpetual agitation by the passage of the elastic vapours through its mass. If a long previous interval of quiescence has elapsed, there may be much solidified lava towards the top of the vent which will restrain the ascent of the still molten portion underneath. A vast pressure is thus exercised on the sides of the cone. Should these be too weak to resist, they will open in one or more rents, and the

[1] *Ueber Synchronismus und Antagonismus*, p. 72.

liquid lava will issue from the outer slope of the mountain; or the energies of the volcano will be directed towards clearing the obstruction in the chief throat, until, with tremendous explosions, and the rise of a vast cloud of dust and fragments, the bottom and sides of the crater are finally blown out, and the top of the cone disappears. The lava may now escape from the lowest part of the lip of the crater, while, at the same time, immense numbers of red-hot bombs, scoriæ, and stones are shot up into the air, most of them falling back into the crater, but many descending upon the outer slopes of the cone, and some even upon the country beyond the base of the mountain. The lava rushes down at first like one or more rivers of melted iron, but, as it cools, its rate of motion lessens. Clouds of steam rise from its surface, as well as from the central crater. Indeed, every successive paroxysmal convulsion of the mountain is marked, even at a distance, by the rise of huge ball-like wreaths or clouds of steam, mixed with dust and stones, forming a vast column which towers sometimes a couple of miles above the summit of the cone. By degrees these diminish in frequency and intensity. The lava ceases to flow, the showers of stones and dust dwindle down, and after a time, which may vary from hours to days or months, even in the *régime* of the same mountain, the volcano becomes once more tranquil.

Let us now consider some of the aspects of this action which have more particular geological interest from the permanent changes with which they are connected, or from the way in which they enable us to detect and realize conditions of volcanic energy in former periods.

Fissures.—During the convulsions which culminate in the formation of a volcano, as well as in the subsequent progress of the mountain so formed, the ground at and around the focus of action is liable to be rent open by fissures. These tend to diverge from the focus; but around the vent where the rocks have been most exposed to concussion the fissures sometimes intersect each other in all directions. In the great eruption of Etna, in the year 1669, a series of six parallel fissures opened on the side of the mountain. One of these, with a breadth of two yards, ran for a distance of 12 miles, in a somewhat winding course, to within a mile of the top of the cone. Similar fissures, but on a smaller scale, have often been observed on Vesuvius; and they are recorded from many other volcanoes.

Two obvious causes may be assigned for the production of fissures:—(1) the enormous expansive force of the imprisoned vapours acting upon the walls of the funnel and convulsing the cone by successive explosions; and (2) the hydrostatic pressure of the lava-column in the funnel, amounting to about 125 lb per square inch, or 8 tons on the square foot, for each 100 feet of depth. Both of these causes may act simultaneously.

Into the rents thus formed the molten lava naturally finds its way. It is indeed forced into them, and solidifies there like iron in a mould. The cliffs of many an old crater show how marvellously they have been injected by such *veins* or *dykes* of lava. Those of Somma, and the Val del Bue on Etna, have long been known. The dykes project now from the softer tuffs like great walls of masonry. Such wedges of solid rock driven into the cone must widen its dimensions, and at the same time from their length and ramifications must bind the substance of the cone together, and thus strengthen it against the effects of future convulsions. We can understand, therefore, how there should be for a time an alternation in the character of the eruptions of a volcano, depending in great measure upon the relation between the height of the cone on the one hand and the strength of its sides on the other. When the sides have been well braced together by interlacing dykes, and further thickened by the spread of volcanic materials all over their slopes, they may resist the effects of explosion and of the pressure of the ascending lava-column. In this case the volcano may find relief only from its summit, and if the lava flows forth it will do so from the top of the cone. As the cone increases in elevation, however, the pressure from within upon its sides augments. Eventually egress is once more established on the flanks by means of fissures, and a new series of lava-streams is poured out over the lower slopes.

Though lava very commonly issues from the lateral fissures on a volcanic cone, it may sometimes approach the surface without actually flowing out. The great fissure on Etna in 1669, for example, was visible even from a distance by the long line of vivid light which rose from the incandescent lava within. Again, it frequently happens that minor volcanic cones are thrown up on the line of a fissure. This may arise either from the congelation of the lava round the point of emission, or from the accumulation of ejected scoriæ round the fissure-vent. Of the former structure examples occur in Hawaii, where the lava is remarkably liquid, and rapidly hardens into tears or drops, like wax down the sides of a candle. Where in viscid lavas the steam tears off and throws up many scoriæ and bombs, a cone of such loose materials will naturally form round the orifice by which the lava escapes from the flank of the mountain.

Explosions.—Although volcanic materials may be erupted to a large extent without the appearance of visible fissures, they cannot in such cases reach the surface without some explosive action, and the consequent displacement and removal of previously existing rock. Vents are thus blown out of the solid crust, the volcanic energy being, as it were, concentrated on a given point, which we may suppose must usually be the weakest in the structure of that part of the crust. The operation has often been observed in volcanoes already formed, and has even been witnessed on ground previously unoccupied by a volcanic vent. The history of the cone of Vesuvius brings before us a long series of such explosions, beginning with that of 79—the greatest which has occurred within the times of human history—and coming down to the present day. Even now, in spite of all the lava and ashes poured out during the last eighteen centuries, it is easy to see how stupendous must have been that earliest explosion, by which the southern half of the ancient crater was blown out. At every successive important eruption, a similar but minor operation takes place within the present cone. The hardened cake of lava forming the floor is burst open, and with it there usually disappears much of the upper part of the cone, and sometimes, as in 1872, a large segment of the crater-wall. In the year 1538 a new volcano, Monte Nuovo, was formed in 24 hours on the margin of the Bay of Naples. A cavity was drilled by successive explosions, and such quantities of stones, scoriæ, and ashes were thrown out from it as to form a hill 440 English feet above the sea-level, and more than a mile and a half in circumference. Most of the fragments now to be seen on the slopes of the cone and inside its beautifully perfect crater are of various volcanic rocks, many of them being black scoriæ; but pieces of Roman pottery, together with fragments of the older underlying tuff, and some marine shells, have been obtained; and these doubtless formed part of the soil and subsoil dislocated and ejected during the explosions.

It is not necessary, and it does not always happen, that any actual solid or liquid volcanic rock is ejected even when explosions of considerable violence take place, whereby the rocks through which the funnel rises are much shattered. Thus among the cones of the extinct volcanic tract of the Eifel, some occur consisting entirely, or nearly so, of comminuted debris of the Devonian greywacke and slate which form the prevailing rocks there, and through which the various volcanic vents have been opened. Evidently in these cases elastic vapours only forced their way to the surface; and we see what probably often takes place in the early stages of a volcano's history, though the fragments of the underlying disrupted rocks are in most instances buried and lost under the far more abundant subsequent volcanic materials. Sections of ancient volcanic necks or pipes sometimes afford an excellent opportunity of observing that these orifices were originally opened by the blowing out of the solid crust and not by the formation of fissures. Many examples occur in Scotland among volcanic rocks of Old Red Sandstone, Carboniferous, and Permian age. The orifices are there filled with fragmentary materials wherein portions of the surrounding and underlying rocks form a noticeable proportion.

Showers of Dust and Stones.—A communication having been opened, either by fissuring or explosion, between the heated interior and the surface, fragmentary materials seldom fail to be ejected from it. These may consist at first mainly of the rocks through which the orifice has been opened, as has just been explained. But if eruptive energy continues, they soon appear in larger quantities, and consist of thoroughly volcanic substances. In a great eruption vast numbers of red-hot stones are shot up into the air, and fall back partly into the crater and partly on the outer slopes of the cone. But instances are known where large stones, ejected obliquely, have described huge parabolic curves in the air, and fallen at a great distance. Stones 8 ℔ in weight occur among the ashes which buried Pompeii. The volcano of Antuco in Chili is said to send stones flying to a distance of 36 miles, and Cotopaxi is reported to have hurled a 200-ton block 9 miles.

But in many great eruptions, besides a constant shower of stones and scoriæ, a vast column of exceedingly fine dust rises out of the crater, sometimes to a height of more than a mile, and then spreads outwards like a sheet of cloud. So dense sometimes is this dust-cloud that the sun is obscured, and for days together the darkness of night reigns for miles around the volcano. In 1822 this was the case at Vesuvius, the ashes not only falling thickly on the villages round the base of the mountain, but travelling as far as Ascoli, which is 56 Italian miles distant from the volcano on one side, and as Casano, 105 miles on the other. But probably the most stupendous outpouring of volcanic ashes on record was that which took place, after a quiescence of 26 years, from the volcano Coseguina, in Nicaragua, during the early part of the year 1835. On that occasion utter darkness prevailed over a circle of 35 miles radius, the ashes falling so thickly that, even 8 leagues from the mountain, they covered the ground to a depth of about 10 feet. It was estimated that the rain of dust and sand fell over an area at least 270 geographical miles in diameter. Some of the finer materials, thrown so high as to come within the influence of an upper air-current, were borne away eastward, and fell four days afterwards at Kingston, in Jamaica—a distance of 700 miles.

An inquiry into the origin of these showers of fragmentary materials brings vividly before us some of the essential features of volcanic action. We find that bombs, slags, and lapilli may be thrown up in comparatively tranquil states of a volcano, but that the showers of fine dust are discharged with violence, and only appear when the volcano becomes more energetic. Thus, at the constantly, but quietly, active volcano of Stromboli, the column of lava in the pipe may be watched slowly rising and falling with a slow rhythmical movement. At every rise the surface of the lava swells up into blisters several feet in diameter, which by and by burst with a sharp explosion that makes the walls of the crater vibrate. A cloud of steam rushes out, carrying with it hundreds of fragments of the glowing lava, sometimes to a height of 1200 feet. It is by the ascent of steam through its mass that a column of lava is kept boiling at the bottom of a crater, and by the explosion of successive larger bubbles of steam that the various bombs, slags, and fragments of lava are torn off and tossed into the air. It has often been noticed at Vesuvius that, after each great concussion, a huge ball-like cloud of steam rushes up from the crater. Doubtless it is the sudden escape of that steam which causes the explosion. The violence of the explosion will depend greatly upon the viscidity of the lava, and the consequent resistance offered to the upward passage of the steam. Explosions and accompanying scoriæ are abundant at Vesuvius, where the lavas are comparatively viscid; they are almost unknown at Kilauea, where the lava is remarkably liquid.

The steam, collecting into larger or smaller vesicles, works its way upward through the substance of the molten lava. As the elasticity of this compressed vapour overcomes the pressure of the overlying lava, it escapes at the surface, and there the lava is thus kept in ebullition. But this comparatively quiet operation, which may be watched within the craters of many active volcanoes, does not produce clouds of fine dust. The friction of the millions of stones ascending and descending through the air in the dark column above the crater, though it must doubtless cause much dust and sand, can give rise to but an insignificant proportion of what is actually reduced to the condition of extreme subdivision necessary to produce widespread darkness and a thick far-reaching deposit of ashes. The explanation now accepted calls in the explosive action of steam as the immediate cause of the trituration. A sudden and powerful explosion of steam, it is maintained, will blow the top of the lava column into dust, like water shot out of a gun. We must remember that the aqueous vapour by which many lavas are so largely impregnated must exist interstitially far down in the lava-column, under an enormous pressure, and at a white heat. The sudden ascent of lava so constituted will relieve the pressure rapidly without sensibly affecting the temperature of the mass. Consequently the white-hot steam will at length explode, and reduce the molten mass containing it to the finest powder.

Evidently no part of the operations of a volcano has greater geological significance than the ejection of such enormous quantities of fragmentary matter. In the first place, the fall of these loose materials round the orifice of discharge is one main cause of the growth of the volcanic cone. The heavier fragments gather around the vent, and there too the thickest accumulation of finer dust takes place. Hence, though successive explosions may blow out the upper part of the crater-walls, and prevent the mountain from growing so rapidly in height, every eruption must add to the diameter of the cone. In the second place, as every shower of dust and sand adds to the height of the ground on which it falls, thick volcanic accumulations may be formed far beyond the base of the mountain. In these are entombed trees and other kinds of vegetation, together with the bodies of many animals, as well as the works of man. Hence new geological formations arise which, in their component materials, not only bear witness to the volcanic eruptions which produced them, but preserve a record of the land-surfaces over which they spread. In the third place, besides the distance to which the fragments may be hurled by volcanic explosions, or to which they may be diffused by the ordinary aerial movements, we have to take into account the vast spaces across which the finer dust is sometimes borne by upper currents in the atmosphere. An instance has already been cited where ashes from Coseguina fell 700 miles away, having been carried all that long distance by a high counter-current of air, moving apparently at the rate of about 7 miles an hour in an opposite direction to that of the wind which blew at the surface. On several occasions ashes from one of the Icelandic volcanoes have fallen so thickly between the Orkney and Shetland Islands that vessels passing there have had the unwonted deposit shovelled off their decks in the morning. In the year 1783, during an eruption of Skaptar-Jökull, so vast an amount of fine dust was ejected that the atmosphere over Iceland continued loaded with it for months afterwards. It fell in such quantity over parts of Caithness—a distance of 600 miles—as to destroy the crops; that year is still spoken of by the inhabitants as the year of "the ashie." Traces of the same deposit were observed even as far as Holland. Hence it is evident that volcanic deposits may be formed in regions many hundreds of miles distant from any active volcano. A single thin layer of volcanic detritus in a group of sedimentary strata would thus not of itself prove the existence of contemporaneous volcanic action in its neighbourhood. It might be held to have been wind-borne from a volcano in a distant and separate region.

Lava-streams.—A microscopic examination of their intimate structure shows that lavas have been truly molten rocks. They usually consist fundamentally of a glass through which are diffused, in greater or less abundance, various microlites and crystals. Their degree of liquidity, at the time of emission, seems to depend on the extent to which the rock remains in the condition of glass, viscidity increasing with the development of the microlites and crystals out of the glassy menstruum in which, no doubt, originally their component molecules were diffused. The fluidity may also be governed in no small degree by the amount of vapour existing interstitially in the molten mass. Mr Scrope indeed contended that aqueous vapour was the main cause of the mobility of such crystalline lavas as those of Vesuvius. But even where the lava pours forth with a liquidity like that of melted iron, it speedily assumes a more viscid motion, as the process of devitrification advances and the rock is exposed to the chilling effects of radiation and of contact with air and soil. An interesting fact, admirably shown by the microscope, but often easily observable with the naked eye, is that in lava still liquid and mobile well-defined crystals make their appearance. These sometimes are broken during the continued movement of the surrounding mass, the separated fragments becoming involved in the general glassy base or portions of that base, are injected into the fractures of the crystals. Well-defined crystals of leucite may be seen in specimens of Vesuvian lava, which has been ladled out from a white-hot stream, impressed with a stamp, and thus suddenly congealed. On the other hand, the obsidians have solidified in the condition of complete glass, often without any trace of devitrification. The green pyroxenic lava of Hawaii exhibits so extreme a degree of fluidity that, during its ebullition in pools of the crater, jets not more than a quarter of an inch in diameter are tossed up, and, falling back on one another, make "a column of hardened tears of lava," while, in other places, the jets thrown up and blown aside by the wind give rise to long threads of glass which lie thickly together like mown grass, and are known by the natives under the name of Pele's Hair, after one of their divinities.[1]

It would be of the highest interest and importance to know accurately the temperature with which a lava stream issues. The difficulty of making any direct observation at the point of outflow has hitherto been insuperable. Measurements have been taken at various distances below the point where the moving lava could be safely approached; but these are not satisfactory, seeing that the outer crust of the lava cools rapidly, and gives no measure of the temperature even a short way underneath. Experiments made by Scacchi and Sainte-Claire Deville on the Vesuvian lava erupted in 1855, by thrusting thin wires of silver, iron, and copper into the lava, indicated a temperature of scarcely 700° C. Earlier observations of a similar kind, made in 1819, when a silver wire $\frac{1}{30}$th inch in diameter at once melted in the Vesuvian lava of that year, gave a greatly higher temperature. Evidence of the high temperature of lava has been adduced from the alteration it has effected upon refractory substances in its progress, as where, at Torre del Greco, it overflowed the houses, and was afterwards found to have fused the fine edges of flints, to have decomposed brass into its component metals, the copper actually crystallizing, and to have melted silver, and even sublimed it into small octohedral crystals. But such facts, though full of interest and importance, give us no clue to the absolute initial temperature of the lava, which must be greatly higher than that of the stream after several miles of descent on the mountain slopes, and after some hours or days of cooling.

In spite of this very high temperature, however, the lava issues abundantly charged with aqueous vapour, to the expansion of which, as we have seen, its ebullition and expulsion are mainly due. As this vapour at once begins to escape when the lava issues into the air, it shows itself by a dense white cloud hanging over the moving mass. The lava streams of Vesuvius sometimes appear with as large and dense a steam cloud at their lower ends as that which escapes at the same time from the main crater. Even after the molten mass has flowed several miles, steam continues to rise abundantly both from its end and from numerous points along its surface.

From the wide extent of basalt dykes, such as those of Britain, some of which rise to the surface at a distance of 200 miles and upwards from the main volcanic regions of their time, it is evident that the molten lava may sometimes occupy a far greater superficial area underneath than the mere circumference of the actual pipe or of the volcanic cone. We must conceive of a vast reservoir of melted rock impregnated with superheated steam, and impelled upwards by the elastic force of the vapour. The lava may be regarded rather as the sign than as the cause of volcanic action. It is the pressure of the imprisoned vapour, and its struggles to get free, which produce the subterranean earthquakes, the explosions, and the outpouring of lava. As soon as the vapour finds relief, the terrestrial commotion calms down again, and the quiescence continues until another accumulation of vapour demands a repetition of the same phenomena.

It is evident that the vapour may succeed in effecting its escape without driving molten rock up to the surface. There may be tremendous explosions without an actual outcome of lava. But, in most cases, so intimately are vapours and lava commingled in the subterranean reservoirs that they rise together, and the explosions of the one lead to the outflow of the other. The first point at which the lava makes its appearance at the surface will largely depend upon the structure of the ground. Two causes have been assigned in a foregoing section (p. 244) for the fissuring of a volcanic cone. As the molten mass rises within the chimney of the volcano, continued explosions of vapour take place from its upper surface, the violence of which may be inferred from the vast clouds of steam, of ashes, and of stones which are hurled to so great a height into the air. These explosions must at the same time powerfully affect the sides of the funnel, exposed as these are to the enormous pressure exerted by the imprisoned vapour. We cannot therefore be surprised that, when a volcano experiences shocks of such intensity as to be felt over a radius 100

[1] Dana, *Geol. U.S. Explor. Exped.*, p. 179.

miles or more, its sides should at last give way, and large divergent fissures should be opened down its cone. Again, the hydrostatic pressure of the column of lava must have a potent influence. At a depth of 1000 feet below the top of the column the pressure exerted on each square foot of the surrounding walls must amount to more than 80 tons. We may well believe that such a force, acting upon the walls of a funnel already shattered by a succession of terrific explosions, will be apt to prove too great for their resistance. When this happens, the lava pours forth from the outside of the cone. So fissured is the cone sometimes that the lava issues freely from many points. A volcano so affected has been graphically described as "sweating fire." More usually the lava issues only from one or two points. Should these lie well down on the cone, far below the summit of the lava-column, the lava, on its first escape, driven by hydrostatic pressure, will sometimes spout up high into the air—a fountain of molten rock. This was observed in 1794 on Vesuvius, and in 1832 on Etna. In the eruption of 1852 at Mauna Loa, an unbroken fountain of lava, from 200 to 700 feet in height and 1000 feet broad, burst out at the base of the cone. Similar "geysers" of molten rock have subsequently been noticed in the same region. Thus, in March and April 1868, four fiery fountains, throwing the lava to heights varying from 500 to 1000 feet, continued to play for several weeks.

In a lofty volcano, therefore, the chances are always rather against the lava rising to the lip of the crater and flowing out there. It does so now and then; but more frequently it escapes from some fissure or orifice in a weak part of the cone. In minor volcanoes, on the other hand, where the explosions are less violent, and where the thickness of the cone in proportion to the diameter of the funnel is often greater, the lava very commonly rises in the crater. Should the crater walls be too weak to resist the pressure of the molten mass, they will give way, and the lava will rush out from the breach. This is seen to have happened in several of the puys of Auvergne, so well figured and described by Mr Scrope. But if the crater be massive enough to withstand the pressure, the lava, if still impelled upward by the struggling vapour, will at last flow out from the lowest part of the rim.

It was at one time supposed that lava beds could not consolidate on such steep slopes as those of most volcanoes, and that their present inclined position was to be attributed to a central upheaval of each mountain. This idea formed the subject of the famous theory of elevation-craters (*Erhebungskratere*) of L. von Buch, E. de Beaumont, and other geologists. It was a matter of prime importance in the interpretation of volcanic action to have this question settled. To Constant Prevost belongs the merit of having completely exposed the fallacy of this theory. He pointed out that there was no more reason why lavas should not consolidate on steep slopes than that tears or drops of wax should not do so. Mr Poulett Scrope also showed conclusively that the steep slope of the lava-beds of a volcanic cone was original. Sir Charles Lyell and Mr Hartung subsequently obtained abundant additional evidence from the Canary Islands, Etna, and other volcanic districts, to disprove the elevation theory. Geologists are now agreed that thick sheets of lava, with all their characteristic features, can consolidate on slopes of even 35° and 40°. The lava in the Hawaii Islands has cooled rapidly on slopes of 25°, that from Vesuvius, in 1855, is here and there as steep as 30°. On the east side of Etna, a cascade of lava, which poured, in 1689, into the vast hollow of the Cava Grande, has an inclination varying from 18° to 48°, with an average thickness of 16 feet. On Mauna Loa some lava-flows are said to have congealed on slopes of 49°, 60°, and even 80°, though in these cases it could only be a layer of rock stiffening and adhering to the surface of the steep slope. Even when it consolidates on a steep slope, a stream of lava forms a sheet with parallel, upper, and under surfaces, a general uniformity of thickness, and often greater evenness of surface than where the angle of descent is low.

At its first appearance, where it issues from the mountain, the lava glows with a white heat, and flows with a motion which has been compared to that of honey or of melted iron. It soon becomes red, and, like a coal fallen from a hot fireplace, rapidly grows dull as it moves along, until it assumes a black, cindery aspect. At the same time the surface congeals, and soon becomes solid enough to support a heavy block of stone. Its aspect depends, not merely on the composition and fluidity of the lava, but on the point of egress, whether from the crater or from a fissure, on the form of the ground, the angle of slope, and the rapidity of flow. Lavas which have been kept in ebullition within the central chimney are apt to acquire a rough cellular texture. The surface of the moving stream breaks up into rough brown or black cinder-like slags, and irregular rugged cakes, which, with the onward motion, grind and grate against each other with a harsh metallic sound, sometimes rising into rugged mounds or getting seamed with rents and gashes, at the bottom of which the red-hot glowing lava may be seen. When lava escapes from a lateral fissure it may have no scoriæ, but its surface will present froth-like, curving lines, as in the scum of a slowly flowing river, or will be arranged in curious ropy folds, as the layers have successively flowed over each other and congealed. These and many other fantastic coiled shapes were exhibited by the lava which flowed from the side of Vesuvius in 1858. A large area which has been flooded with lava is perhaps the most hideous and appalling scene of desolation anywhere to be found on the surface of the globe.

A lava stream at its point of escape from the side of a volcanic cone occupies a comparatively narrow breadth; but it usually spreads out as it descends, and moves more slowly. The sides of the moving mass look like huge embankments, or like some of the long mounds of "clinkers" one sees in a great manufacturing district. The advancing end of the mass is often much steeper, creeping onward like a great wall or rampart, down the face of which the rough blocks of hardened lava are ever rattling.

The rate of movement is regulated by the fluidity of the lava, by its volume, and by the form and inclination of the ground. Hence, as a rule, a lava-stream moves faster at first than afterwards, because it has not had time to stiffen, and its slope of descent is considerably steeper than further down the mountain. One of the most fluid and swiftly flowing lava-streams ever observed on Vesuvius was that erupted on 12th August 1805. It is said to have rushed down a space of 3 Italian ($3\frac{3}{5}$ English) miles in the first four minutes, but to have widened out and moved more slowly as it descended, yet finally to have reached Torre del Greco in three hours. A lava erupted by Mauna Loa in 1852 went as fast as an ordinary stage-coach, or 15 miles in two hours. Long after a current has been deeply crusted over with slags and rough slabs of lava it continues to creep slowly forward for weeks or even months.

It happens sometimes that, as the lava moves along, the pressure of the still molten mass inside bursts through the outer hardened and deeply seamed crust, and rushes out with, at first, a motion much more rapid than that of the main stream; but such an offshoot rapidly congeals and comes to rest, though sometimes not before doing much damage to vineyards, gardens, houses, or other property in its course. Any sudden change in the form or slope of the ground, too, will affect the flow of the lava. Thus, should the stream reach the edge of a steep defile or cliff, it will pour over it in a cataract of glowing molten rock, with clouds of steam, showers of fragments, and a noise utterly indescribable. Or if, on the other hand, the current should encounter a ridge or hill across its path, it will accumulate in front of it until it either finds egress round the side or actually overrides and entombs the obstacle. The hardened crust or shell within which the still fluid lava moves serves to keep the mass from spreading. We often find, however, that the lava has subsided here and there inside its crust, and has left curious cavernous spaces and tunnels. Into these, when the whole is cold, we may creep, and may find them sometimes festooned and hung with stalactites of lava.

As a rule a lava-stream shows three component layers. At its bottom lies a rough, slaggy mass, produced by the rapid cooling of the lava, and the breaking up and continued onward motion of the scoriform layer. The central and main portion of the stream consists of solid lava, often, however, with a more or less carious and vesicular texture. The upper part, as we have seen, is a mass of rough broken-up slags, scoriæ, or clinkers. The proportions borne by these respective layers to each other vary continually. Some of the more fluid ropy lavas of Vesuvius have an inconstant and thin slaggy crust; others may be said to consist of little else than scoriæ from top to bottom. These divergences in texture seem to depend largely upon the amount of interstitial steam imprisoned within the lava, and the conditions under which it can effect its escape. Throughout the whole mass, but more especially along its upper surface, the steam under its diminished pressure expands, and pushing the molten rock aside, segregates into small bubbles or irregular cavities. Hence, when the lava solidifies, these steam-holes are seen to be sometimes so abundant that a detached portion of the rock containing them will float in water. They are often elongated in the direction of the motion of the lava-stream.

But, besides producing a general vesicular texture in the upper parts of the lava-stream, the aqueous vapour gives rise to much more striking features on the surface of the lava. If the outburst takes place from an orifice or fissure on the exterior of the volcanic cone, so vast an amount of steam will rush out there, with such boiling and explosion of the lava, that a cone of bombs, and slags, and irregular lumps of lava, will probably form round the spot—in fact a miniature or parasitic volcano, which will remain as a marked cone on its parent mountain long after the eruption which gave it birth has ceased. Moreover, even after such abundant discharge of steam, the lava-stream continues to exhale it, as it were, from every pore. Here and there on the surface of the moving mass a fissure opens, and a column of roaring hissing vapours rushes out from it, accompanied as before by an abundant discharge of lava-fragments, or even by the rise and outflow of the lava from beneath. Some lava-streams are thus dotted over with small cones a few feet or yards in height. Besides the steam which, in condensing, makes its presence so conspicuous, many other vapours entangled in the pores of the lava escape from its fissures. The points at which vapours are copiously disengaged are termed *fumarole*. Among the exhalations, chlorides may be mentioned as particularly prominent; chloride of sodium frequently shows itself, not only in fissures, but even over the cooled crust of the lava, in small crystals, in tufts, or as a granular and even glassy incrustation. Chloride of iron is deposited as a yellow coating at the *fumarole*, where also bright emerald green films and scales of chloride of copper may be more rarely observed. Many chemical changes take place in the escape of the vapours through the lava. Thus specular-iron, probably the result of the mutual decomposition of steam and iron chloride, forms abundant scales, plates, and small crystals in the *fumarole* and vesicles of the lava. Sal-ammoniac also appears in large quantity on many lavas, not merely in the fissures, but also on the upper surface of the current. This salt is not directly a volcanic product, but results from some decomposition, probably from that of the aqueous vapour, whereby a combination is formed with atmospheric nitrogen.

The hardened crust of a lava-stream is a bad conductor of heat. Consequently, when the surface of the mass has become cool enough to be walked upon, the red hot mass may be observed through the rents to lie only a few inches below. Many years therefore may elapse before the temperature of the whole mass has fallen to that of the surrounding soil. Eleven months after an eruption of Etna, Spallanzani could see that the lava was still red hot at the bottom of the fissures, and a stick thrust into one of them instantly took fire. The Vesuvian lava of 1785 was found by Breislak seven years afterwards to be still hot and steaming internally, though lichens had already taken root on its surface. The ropy lava erupted by Vesuvius in 1858 was observed in 1870 to be still so hot, even near its termination, that steam issued abundantly from its rents, many of which were too hot to allow the hand to be held in them. Hoffmann records that the lava which flowed from Etna in 1787 was still steaming in 1830. But still more remarkable is the case of Jorullo, in Mexico, which sent out lava in 1759. Twenty-one years later a cigar could still be lighted at its fissures; after 44 years it was still visibly steaming; and even in 1846, that is. after 87 years of cooling, two vapour columns were still rising from it.[1]

This extremely slow rate of cooling has justly been regarded as a point of high geological significance in regard to the secular cooling and probable internal temperature of our globe. Some geologists have argued indeed that, if so comparatively small a portion of molten matter as a lava stream can maintain a high temperature under a thin, cold crust for so many years, we may, from analogy, feel little hesitation in believing that the enormously vaster mass of the globe may, beneath its relatively thin crust, still continue in a molten condition within. More legitimate deductions, however, might be drawn, if we knew more accurately and precisely in each case the rate of loss of heat, and how it varies in different lava-streams. Sir William Thomson, for instance, has suggested that, by measuring the temperature of intrusive masses of igneous rock in coal-workings and elsewhere, and comparing it with that of other non-volcanic rocks in the same regions, we might obtain data for calculating the time which has elapsed since these igneous sheets were erupted.

In its descent a stream of lava may reach a water-course, and, by throwing itself as a great embankment across the stream, may pond back the water and form a lake. Such is the origin of the picturesque Lake Aidat in Auvergne. Or the molten current may usurp the channel of the stream, and completely bury the whole valley, as has happened again and again among the vast lava-fields of Iceland. No change in physiography is so rapid and so permanent as this. The channel which has required, doubtless, many thousands of years for the water laboriously to excavate, is sealed up in a few hours under 100 feet or more of stone, and a still longer interval may elapse before this newer pile is similarly eroded.

By suddenly overflowing a brook or pool of water, molten lava sometimes has its outer crust shattered to fragments by a sharp explosion of the generated steam, while the fluid mass within rushes out on all sides. Numerous instances have occurred where the lavas of Etna and Vesuvius have protruded into the sea. Thus a current from the latter mountain entered the Mediterranean at Torre del Greco in 1794, and pushed its way for 360 feet outwards, with a breadth of

[1] E. Schleiden, quoted by Naumann, *Geol.*, i. p. 160.

1100 and a height of 15 feet. So quietly did it advance that Breislak could sail round it in a boat and observe its progress.

In passing from a fluid to a solid condition, and thus contracting, lava acquires different structures. Lines of divisional planes or joints traverse it, especially perpendicular to the upper and under surfaces of the sheet. These lines at various irregular distances cross each other so as to divide the rock into rude prisms. Occasionally another series of joints at a right angle to these traverses the mass parallel with its bounding surfaces, and thus the rock acquires a kind of fissile or bedded appearance. The most characteristic structure, however, among volcanic rocks is the prismatic, or, as it is incorrectly termed, "basaltic." Where this arrangement occurs, as it does so commonly in basalt, the mass is divided into tolerably regular pentagonal, hexagonal, or irregularly polygonal prisms or columns, set close together at a right angle to the main cooling surfaces. These prisms vary from 2 or 3 to 18 or more inches in diameter, and range up to 100 or even 150 feet in length.

Considerable discussion has arisen as to the mode in which this columnar structure has been produced. The experiments of Mr Gregory Watt were supposed to explain it by the production of a number of spherical concretions in the cooling mass, and the gradual pressure of those soft balls into hexagonal columns, as the mass contracted in cooling. He melted a mass of basalt, and on allowing it to cool observed that, when a small portion was quickly chilled, it took the form of a kind of slag-like glass, not differing much in appearance from obsidian; a larger mass, more slowly cooled, returned to a stony state. He remarked that during this process small globules make their appearance, which increase in size by the successive formation of external concentric coats, like those of an onion. And he supposed, as each spheroid must be touched by six others, the whole, if exposed to the same pressure acting in every direction, must be squeezed into a series of hexagons. To account, however, for a long column of basalt, we should have to imagine a pile of balls standing exactly centrically one upon the other, an arrangement which seems hardly possible. The prismatic structure is a species of jointing, due to the contraction of the rock as a whole, and not to the production of any internal peculiarities of texture. The concretionary structure associated with the columnar arises from a common tendency to weather out into nodular forms, and may be observed even where the rock is not columnar. Prismatic forms have been superinduced upon rocks by a high temperature and subsequent cooling, as where coal and sandstone have been invaded by basalt. They may likewise be observed to arise during the consolidation of a substance, as in the case of starch. In that substance the columnar structure is apt to radiate from certain centres, as may also be seen sometimes in basalt and other igneous rocks.

Mr Mallet has recently investigated this subject, and concludes that "all the salient phenomena of the prismatic and jointed structure of basalt can be accounted for upon the admitted laws of cooling, and contraction thereby, of melted rock possessing the known properties of basalt, the essential conditions being a very general homogeneity in the mass cooling, and that the cooling shall take place slowly, principally from one or more of its surfaces."[1]

In the more perfectly columnar basalts the columns are sometimes articulated, each prism being separable into vertebræ, with a cup and ball socket at each articulation. This peculiarity is traced by Mr Mallet to the contraction of each prism in its length and in its diameter, and to the consequent production of transverse joints, which, as the resultant of the two contracting strains, are oblique to the sides of the prism, but, as the obliquity lessens towards the centre, assume necessarily, when perfect, a cup-shape, the convex surface pointing in the same direction as that in which the prism has grown. This explanation, however, will hardly account for cases, which are not uncommon, where the convexity points the other way, or where it is sometimes in one direction, sometimes in the other.[2] The remarkable spheroids which appear in many weathered igneous rocks besides basalts may probably be due to some of the conditions under which the original contractions took place. They are quite untraceable on a fresh fracture of the rock. It is only after some exposure to the weather that they begin to appear, and then they gradually crumble away by the successive formation and disappearance of external weathered crusts or coats, which fall off into sand and clay. Almost all augitic or hornblendic rocks, even granite, exhibit the tendency to decompose into rounded spheroidal blocks.

By the outpouring of lava two important kinds of geological change are produced. In the first place, the surface of a country is thereby materially changed. Stream-courses, lakes, ravines, valleys, in short all the minor features of a landscape, may be completely overwhelmed under a sheet of lava, 100 feet or more in thickness. The drainage of the district is thus effectually altered, and all the numerous changes which flow from the operations of running water over the land are arrested and made to begin again in new channels. In the second place, considerable alterations may likewise be caused by the effects of the heat and vapours of the lava upon the subjacent or contiguous ground. Instances have been observed in which the lava has actually melted down opposing rocks, or masses of slags, on its own surface. Interesting observations, already referred to, have been made at Torre del Greco under the lava stream which overflowed part of that town in 1794. It was found that the window-panes of the houses had been devitrified into a white, translucent, stony substance, that pieces of limestone had acquired an open, sandy, granular texture, without loss of carbonic acid, and that iron, brass, lead, copper, and silver objects had been greatly altered, some of the metals being actually sublimed. We can understand therefore that, retaining its heat for so long a time, a mass of lava may induce many crystalline structures, rearrangements, or decompositions in the rocks over which it comes to rest, and proceeds slowly to cool. This is a question of considerable importance in relation to the behaviour of ancient lavas which have been intruded among rocks beneath the surface, and have subsequently been exposed, as will be referred to in the sequel.

But, on the other hand, the exceedingly trifling change produced even by a massive sheet of lava has often been remarked with astonishment. On the flank of Vesuvius we may see vines and trees still flourishing on little islets of the older land-surface completely surrounded by a flood of lava. Professor Dana has given an instructive account of the descent of a lava-stream from Kilauea in June 1840. Islet-like spaces of forest were left in the midst of the lava, many of the trees being still alive. Where the lava flowed round the trees the stumps were usually consumed, and cylindrical holes or casts remained in the lava, either empty or filled with charcoal. In many cases the fallen crown of the tree lay near, and so little damaged that the epiphytic plants on it began to grow again. Yet so fluid was the

[1] See an abstract of his paper, *Proc. Roy. Soc.*, January 1875.

[2] Mr Scrope pointed this out (*Geol. Mag.*, September 1875), though Mr Mallet (*Ibid.*, November 1875) replied that in such cases the articulations must be formed just about the dividing surface between the part of the rock which cooled from above, and that which cooled from below.

lava that it hung in pendent stalactites from the branches, which nevertheless, though clasped round by the molten rock, had barely their bark scorched. Again, for nearly 100 years there has lain on the flank of Etna a large sheet of ice which, originally in the form of a thick mass of snow, was overflowed by the molten flood, and has thereby been protected from the evaporation and thaw which would certainly have dissipated it long ago, had it been exposed to the air. The heat of the lava has not sufficed to melt it. There seems reason to suspect, however, that in other cases snow and ice have been melted in large quantities by overflowing lava. The great floods of water which rushed down the flank of Etna, after an eruption of the mountain in the spring of 1755, have been thus explained.

One further aspect of a lava-stream may be noticed here—the effect of time upon its surface. While all kinds of lava must, in the end, crumble down under the influence of atmospheric waste and, where other conditions permit, become coated with soil and support some kind of vegetation, yet extraordinary differences may be observed in the facility with which different lava-streams yield to this change, even on the flank of the same mountain. Every one who ascends the slopes of Vesuvius remarks this fact. After a little practice it is not difficult there to trace the limits of certain lavas even from a distance, in some cases by their verdure, in others by their barrenness. Five hundred years have not sufficed to clothe with green the still naked surface of the Catanian lava of 1381; while some of the lavas of the present century have long given footing to bushes of furze. Some of the younger lavas of Auvergne, which certainly flowed in times anterior to those of history, are still singularly bare and rugged. Yet, on the whole, where lava is directly exposed to the atmosphere, without receiving protection from occasional showers of volcanic ash, or being liable to be washed bare by heavy torrents of rain, its surface decays in a few years sufficiently to afford soil for a few plants in the crevices. When these have taken root they help to increase the disintegration. At last, as a more or less continuous covering of vegetation spreads over the rock, the traces of its volcanic origin one by one fade away from its surface. Some of the Vesuvian lavas of the present century already support vineyards.

Torrents of Water and Mud.—We have seen that large quantities of water accompany many volcanic eruptions. In some cases, where ancient crater-lakes or internal reservoirs have been shaken by repeated detonations, and finally disrupted, the mud which has thus been produced issues at once from the mountain. Such "mud-lavas," on account of their liquidity and swiftness of motion, are more dreaded for their destructiveness than even the true melted lavas. On the other hand, rain or melted snow, rushing down the cone and taking up loose volcanic dust, is converted into a kind of mud that grows more and more pasty as it descends. The mere sudden rush of such large bodies of water down the steep declivity of a volcanic cone cannot fail to effect much geological change. Deep trenches are cut out of the loose volcanic slopes, and sometimes large areas of woodland are swept away, the debris being strewn over the plains below.

During the great Vesuvian eruption of 1622 a torrent of this kind poured down upon the villages of Ottajano and Massa, overthrowing walls, filling up streets, and even burying houses with their inhabitants. It was by similar streams from the same volcano that some of the Roman cities on its flanks were overwhelmed in the first century. Many of the volcanoes of Central and South America discharge large quantities of mud directly from their craters. Thus in the year 1691 Imbaburu, one of the Andes of Quito, emitted floods of mud, so largely charged with dead fish that pestilential fevers arose from the subsequent effluvia. Seven years later (1698), during an explosion of another of the same range of lofty mountains, Carguairazo (14,706 feet), the summit of the cone is said to have fallen in, while torrents of mud, containing immense numbers of the fish *Pymelodus Cyclopum*, poured forth and covered the ground over a space of four square leagues. The carbonaceous mud (locally called *moya*) emitted by the Quito volcanoes sometimes escapes from lateral fissures, sometimes from the craters. Its organic contents, and notably its siluroid fish, which are the same as those found living in the streams above ground, prove that the water is derived from the surface, and accumulates in craters or underground cavities until discharged by volcanic action. Similar but even more stupendous and destructive outpourings have taken place from the volcanoes of Java, where wide tracts of luxuriant vegetation have at different times been buried under masses of dark grey mud, sometimes 100 feet thick, with a rough hillocky surface from which the top of a submerged palm-tree might have been seen protruding.

Between the destructive effects of mere water-torrents and that of these mud-floods there is, of course, the notable difference that, whereas in the former case a portion of the surface is swept away, in the latter, while sometimes considerable demolition of the surface takes place at first, the main result is the burying of the ground under a new tumultuous deposit by which the surface is greatly changed, not only as regards its temporary aspect, but in its more permanent features, such as the position and form of its water-courses.
